

MINUTES OF THE 42nd GENERAL ASSEMBLY OF THE EUROPEAN ASSOCIATION FOR THE STUDY OF DIABETES

held in Copenhagen, Denmark, on 16 September 2006 at 18.15

Present:	Drs.	E.	Ferrannini	(President)
		J.	Škrha	(Honorary Treasurer)
		D. L.	Eizirik	(Honorary Secretary)
		E.	Gale	(Editor-in-Chief, Diabetologia)
		V.	Jørgens	(Executive Director)

The President welcomed everyone to the 42nd General Assembly.

1. MINUTES, 41st GENERAL ASSEMBLY 2005

Since there were no comments, the minutes were approved unanimously and officially signed as a correct record.

2. REPORTS

a) President

Dr. Ferrannini reported that a teleconference had taken place with the European Medicines Agency (EMA) to discuss the format of the meeting in London at the EMA offices on 22 September 2006. The EASD committee for this meeting includes Drs. C. Bailey, A. Barnett, B. Charbonnel, S. Del Prato, E. Ferrannini, R. Heine and R. Holman, U. Smith and E. Standl.

The President reported on the meeting held in Vienna, Austria on 15–16 February 2006 organised by the Austrian Ministry of Health (OBIG) which had been attended by representatives from EASD, WHO and patient organisations. As a result of the meeting the recommendation had been made to set up a working group to take initiatives to increase the awareness of diabetes.

The President reported that ‘The case for a UN resolution’ had been prepared by the IDF to highlight the need for a United Nations Resolution on diabetes in order to focus attention on the need to stop the growing diabetes epidemic.

Dr. Ferrannini reported that ISPAD was a small, but enthusiastic organisation which had recently held a very well-attended meeting in Cambridge, UK. Following information that pediatricians are not attending the EASD Annual Meetings, discussions to organise a pediatric track in the programme of the Annual Meeting have been put forward. Dr. Dahl-Jørgensen has also suggested organising a joint EASD/ISPAD Postgraduate Course on Pediatric Diabetes in Europe in 2008.

The President reported that a joint statement with ADA on guidelines on the treatment of type 2 diabetes was simultaneously published in August in both *Diabetologia* and *Diabetes Care*. Drs. R.J. Heine and R. Holman lead an ad-hoc committee from the EASD which also included Dr. S. del Prato and Dr. U. Smith.

More details on EASD and EFSD activities were reported in the President’s Address given before the Minkowski Lecture, which is available on the internet under: <http://www.easd-lectures.org/copenhagen/index.php?menu=lectures&id=66> and in his speech before the 38th Claude Bernard Lecture, available under: <http://www.easd-lectures.org/copenhagen/index.php?menu=lectures&id=72>

b) Honorary Treasurer

Dr. Škrha reported that the income of the Association had increased in 2005 due to the registration fees for the Annual Meeting 2005 being collected directly by the EASD office. Expenses increased due to an increase in the costs paid for the Annual Meetings, with costs for the Munich Meeting in 2004 being paid in 2005. Regarding expenditure there are no significant differences between the years 2004 and 2005. The Honorary Treasurer said that after having personally checked the accounts of EASD, he was satisfied with the accounting. He summarised by saying the accounts of EASD were secure and correctly kept in accordance with non-profit legislation.

Dr. Škrha thanked the EASD staff for their friendly assistance and the members of the Executive Committee for the fruitful collaboration.

The President thanked Dr. Škrha for his diligence.

c) Honorary Auditors

The President asked the Honorary Auditors to formally discharge the accounts. Drs. Tiedge and Katsilambros confirmed that the accounts had been checked carefully and were in perfect order. Dr. Ferrannini asked for the vote to accept the accounts.

The accounts were accepted unanimously.

d) Honorary Secretary

Dr. Eizirik reported that 1931 abstracts had been received, with the highest number coming from USA and UK, closely followed by Germany and Italy.

For the Annual Meeting in 2006, 97 (70%) of the 138 applications for Travel Grants received were accepted (total value Euro 60.280). From the 34 received, 15 Stayment Grants were awarded.

Dr. Eizirik closed his report by thanking all members of the EASD staff for their outstanding help and support with the organisation of the EASD Annual Meetings.

e) Editor-in-Chief, Diabetologia

Dr. Gale reported that the submission rate had doubled from 900 to 1800 per year, resulting in a doubling of the number of pages. Acceptance rate is 20%, with the Impact Factor remaining steady at 5.4. Dr. Gale said there had been an improvement in the processing of the papers, with 33 days being needed for the first decision and 65 days from acceptance to online publication. Dr. Gale pointed out that the journal was being sent to members on time i.e. on 20th of the month preceding the month of the journal.

f) Chair, Postgraduate Education Sub-committee

Dr. Ferrannini announced that due to a family emergency Dr. Pieber had had to return home earlier than expected. Dr. Pieber has also stepped down from his position as Chair of the Postgraduate Education Sub-Committee.

3. ELECTIONS**a) President extension until 2008**

The extension of the President's term of office until 2008 was unanimously approved with one abstention.

b) Editor-in-Chief extension until 2008

The extension of the Editor-in-Chief's term of office until 2008 was unanimously approved with one abstention.

c) Vice President 2006–2009

The Council's election of Dr. C. Boitard (F) was unanimously approved with one abstention.

d) Honorary Treasurer 2006–2009

The Council's election of Dr. G. Spinass (CH) was unanimously approved.

e) Honorary Secretary Adjunct 2006–2007

The Council's election of Dr. M. Stumvoll (D) was unanimously approved.

f) Chair, Postgraduate Education Sub-committee 2006–2009

The Council's election of Dr. J. Nolan (IRE) was unanimously approved with one abstention.

g) Council Members 2007–2010

The following Council Members were unanimously elected by the General Assembly:

Drs. F. Ashcroft (UK)

F. Bosch (E)

V. Petrenko (L)

A. Siebenhofer (A).

4. STUDY GROUPS

Dr. Eizirik announced that Dr. A. Cuesta and colleagues had proposed creating a new Study Group: European Group for the Study of Genetics of Diabetes. The Council unanimously agreed with the creation of the Study Group. The Honorary Secretary announced that Dr. A. Ceriello and colleagues had proposed creating a new Study Group: EASD Study group on Diabetes and Cardiovascular Disease. The Council unanimously agreed with the creation of the Study Group. The General Assembly unanimously approved the creation of the two new Study Groups.

5. HONORARY MEMBERSHIP

Drs. E. Cerasi and J. Roth were unanimously elected by the General Assembly.

6. ANY OTHER BUSINESS

There was no other business.

Dr. Ferrannini thanked the outgoing members of the Executive for their dedication and friendly cooperation. He presented Drs. Škrha and Standl with the Albert Renold Medal.

Dr. Ferrannini also thanked the outgoing members of the Council: Drs. I. Gourieva, S. Lenzen, C. Sanjeevi and J.-L. Selam.

Dr. Ferrannini thanked the industry for their support. He also expressed his sincere gratitude to Dr. J Nerup for his outstanding contribution to the organisation of the 42nd EASD Annual Meeting. He again thanked Dr. D. L. Eizirik and the members of the Programme Committee for their hard work with regard to the scientific programme. The President warmly thanked the ladies working in the EASD secretariat for their kind and efficient help.

Dr. Ferrannini brought the General Assembly to a close at 19:15.

Agenda for the 43rd General Assembly of the European Association for the Study of Diabetes

to be held in Amsterdam, The Netherlands on 20 September 2007 at 18:15 hours

43rd EASD Annual Meeting of the European Association for the Study of Diabetes

Amsterdam, The Netherlands, 18 – 21 September 2007

Abstracts

Index of Oral Sessions

- OP 1 Prediction of diabetes
- OP 2 Lipoproteins and vascular disease
- OP 3 Brain metabolism
- OP 4 Molecular regulation of beta cell function and survival
- OP 5 Endothelial biology in diabetes
- OP 6 Predictors and markers of cardiovascular disease and mortality
- OP 7 Body weight regulation
- OP 8 Insulin therapy: physiology and pharmacokinetics
- OP 9 Insulin secretion in vivo
- OP 10 Immunopathogenesis of type 1 diabetes: from mice to men
- OP 11 Nephropathy: mechanisms
- OP 12 Prevalence of childhood diabetes and mortality in type 2 diabetes
- OP 13 Thiazolidinediones
- OP 14 Genome-wide association scans
- OP 15 Signal transduction and metabolism in liver
- OP 16 Mechanisms of beta cell dysfunction and death
- OP 17 Cardiovascular disease: role of glycaemia and other factors
- OP 18 Models of care
- OP 19 GLP-1 based therapies
- OP 20 Pregnancy: screening, epidemiology and outcomes
- OP 21 Adipocyte derived peptides
- OP 22 Signal transduction in metabolism
- OP 23 Peripheral neuropathy: novel therapies
- OP 24 Zinc transporter SLC30A8: candidate gene for beta cell function
- OP 25 Lifestyle
- OP 26 Inflammation in metabolism
- OP 27 Psychological aspects of diabetes
- OP 28 Imaging beta cell signal transduction
- OP 29 Genetics of type 2 diabetes
- OP 30 Mitochondrial function
- OP 31 Hypoglycaemia
- OP 32 Diabetes in children and adolescents in all its forms
- OP 33 Adipocytes
- OP 34 Regulation of insulin exocytosis
- OP 35 Mechanisms of cardiovascular complications: animal models
- OP 36 Nephropathy: treatment
- OP 37 Novel therapies
- OP 38 Insulin therapy: clinical studies
- OP 39 Retinopathy: clinical observations
- OP 40 Islet cell differentiation and neogenesis

- OP 41 Novel biomarkers for coronary vascular disease
- OP 42 Metabolism in vasculature
- OP 43 Metformin and sulfonylureas
- OP 44 Treatment of type 1 diabetes in pregnancy
- OP 45 Incretin effects: clinical
- OP 46 Genetics of type 1 diabetes mellitus
- OP 47 Adiponectin and diabetic complications
- OP 48 Making the best use of diabetes technology

Index of Poster Sessions

- PS 1 Obesity as a predictor of type 2 diabetes
- PS 2 The spectrum of diabetic disorders
- PS 3 Genetics and epidemiology of metabolic syndrome, stroke and hypertension
- PS 4 Genome-wide association scans and bioinformatic tools for identifying candidate pathways
- PS 5 Genetics and epidemiology of type 1 diabetes and LADA
- PS 6 Type 2 diabetes genes
- PS 7 Updates on the type 2 diabetes genes TCF7L2 and PPARgamma
- PS 8 Epidemiology: treatment
- PS 9 Diabetes mortality and hospitalisation in different populations
- PS 10 Cardiovascular risk factors
- PS 11 Gender, intrauterine environment and risk of diabetes
- PS 12 Social and economic complications of diabetes
- PS 13 Environmental factors in diabetes aetiology
- PS 14 Genetics and epidemiology of diabetic nephropathy
- PS 15 Classification of IGT, type 2 diabetes and metabolic syndrome
- PS 16 Diabetes prevalence and incidence
- PS 17 Circulating risk factors
- PS 18 Genetics of beta cell function and insulin resistance
- PS 19 Gluco- and lipotoxicity as mediators of beta cell degeneration
- PS 20 ER stress, ROS and FFA-induced beta cell degeneration
- PS 21 Putative mediators of beta cell damage in type 2 diabetes
- PS 22 Beta cells – a choice of death
- PS 23 Beta cell dysfunction and death following different insults
- PS 24 The role of cytokines and chemokines on pancreatic islet physiology and pathology

- PS 25 Immunoregulation and novel interventions in diabetes secondary to beta cell loss
- PS 26 Immunopathogenesis of animal and human diabetes
- PS 27 Immunology and prediction of type 1 diabetes
- PS 28 Pancreas and islet transplantation
- PS 29 Regulation of glucagon synthesis and release
- PS 30 Transcriptional regulation in beta cells
- PS 31 Beta cell neogenesis and replication
- PS 32 Mediators of insulin secretion
- PS 33 Intracellular signaling for insulin secretion

OP 1 Prediction of diabetes

0001

Predicting diabetes: performance of six diabetes risk questionnaires in the Hoorn Study

M. Alsema¹, G. Nijpels¹, L. M. Bouter¹, C. D. A. Stehouwer², R. J. Heine³, J. M. Dekker¹;

¹EMGO Institute, VU University Medical Center, Amsterdam,

²Department of Internal Medicine, Academic Hospital Maastricht,

³Department of Endocrinology / Diabetes Center, VU University Medical Center, Amsterdam, The Netherlands.

Background and Aims: Several investigators have developed simple risk questionnaires not requiring blood testing to detect undiagnosed prevalent type 2 diabetes (DM2) or to predict incident DM2. Until now, no extensive external validation of available risk questionnaires with oral glucose tolerance test (OGTT) defined incidence of DM2 has been made. We evaluated the performance of existing diabetes risk questionnaires in detection of undiagnosed DM2 and in prediction of incident DM2.

Materials and Methods: Four risk questionnaires for prevalent DM2 using routinely available data were found: the Danish diabetes risk score, the Cambridge risk score, the Rotterdam risk score and a symptom-risk questionnaire (SR-Q) from the Hoorn Study. Two risk questionnaires for incident DM2 were found; the ARIC and the Finnish diabetes risk score. These risk scores were evaluated in the Hoorn Study, which is a population-based prospective cohort study with repeated OGTT measurements. OGTT-data were used for definition of prevalent (150 cases out of 2379) and 6.4-year incident DM2 (134 cases out of 1353).

Results: The area under the ROC curve was generally higher for prevalent DM2 (range from 0.69 to 0.76) than it was for incident DM2 (range from 0.63 to 0.69). Although the performance of the risk scores was very similar, the ARIC risk score performed best for both prevalent (0.76 [0.73–0.80]) and incident DM2 (0.69 [0.64–0.73]) (Figure).

Conclusion: Available risk questionnaires developed in Caucasian populations are less accurate in prediction of incident DM2 as compared to detection of prevalent undiagnosed DM2. The slightly better performance of the ARIC risk questionnaire might be due to the fact that it was developed on incident DM2, defined by the OGTT. Because of the high cardiovascular risk constituted by post-load OGTT levels, for primary prevention, it is probably important to develop a diabetes risk questionnaire based on OGTT data.

Additive effects of adiponectin and C-reactive protein in predicting the risk of type 2 diabetes: a 10-year prospective study

K. S. L. Lam^{1,2}, N. M. S. Wat¹, A. W. K. Tso¹, C. H. Y. Fong¹, A. Xu^{1,2};

¹Department of Medicine, ²Research Centre of Heart, Brain, Hormone, and Healthy Aging, The University of Hong Kong, Hong Kong, China.

Background and Aims: Both serum adiponectin, an adipokine with insulin-sensitizing and anti-inflammatory action, and high sensitivity C-reactive protein (hsCRP), a marker of chronic low-grade systemic inflammation, have been reported to predict the development of type 2 diabetes. Here we

examined, in a 10-year prospective study, whether these two biomarkers had an additive effect on predicting the long-term risk of type 2 diabetes.

Materials and Methods: Serum adiponectin and hsCRP were measured in 417 non-diabetic Chinese subjects from the Hong Kong Cardiovascular Risk Factor Prevalence Study, who had returned for their 10-year follow-up in 2005/06. Of these, 76 had developed DM, according to the 1998 WHO diagnostic criteria. Adiponectin was measured using an in-house ELISA assay and hsCRP was measured using a particle-enhanced immunoturbidimetric assay. The association of adiponectin and hsCRP, alone or in combination, with the 10-year risk of diabetes was investigated.

Results: Compared to the 341 subjects who remained non-diabetic at year-10, subjects who had developed diabetes consisted of more men ($p < 0.003$). They had higher baseline BMI, waist circumference, mean arterial blood pressure, plasma glucose (fasting and 2-hour post-OGTT), fasting insulin, HOMA-insulin resistance index (HOMA-IR), triglycerides, LDL-cholesterol and hsCRP levels (all $p < 0.001$ except for LDL-cholesterol with $p < 0.05$). They also had lower baseline serum adiponectin and HDL-cholesterol levels (both $p < 0.001$). In a stepwise multiple logistic regression analysis model including sex, age, BMI, fasting insulin, presence of metabolic syndrome according to NCEP criteria, adiponectin and hsCRP, only baseline adiponectin (adjusted OR 0.44; 95% CI 0.27–0.74; $p = 0.002$), hsCRP (adjusted OR 1.43; 95% CI 1.10–1.84; $p = 0.007$) and metabolic syndrome (adjusted OR 2.72; 95% CI 1.55–4.78; $p = 0.001$) were independently predictive of diabetes at 10 years. The addition of baseline adiponectin or hsCRP to a model consisting of sex, age and BMI significantly improved the prediction of diabetes risk, as reflected by the likelihood ratios in logistic regression analysis ($p = 0.001$ for adiponectin and $p = 0.019$ for hsCRP). Furthermore, the combined addition of adiponectin and hsCRP to the model provided significantly greater improvement than the addition of adiponectin alone ($p = 0.048$) or the addition of hsCRP alone ($p = 0.003$).

Conclusion: Serum adiponectin and hsCRP were both independent predictors of the 10-year risk of diabetes in this Chinese cohort. Their usefulness as biomarkers for predicting the development of type 2 diabetes were over and above those of conventional risk factors including sex, age and BMI, and appeared to be additive when these two new biomarkers were used together.

0003

Comparison of a risk score based on non-invasive measurements and fasting glucose for prediction of type 2 diabetes risk in the EPIC-Potsdam Study

M. B. Schulze¹, K. Hoffmann¹, H. Boeing¹, C. Thamer², H.-U. Häring², A. Fritsche², H. Al-Hasani³, H.-G. Joost³;

¹Department of Epidemiology, German Institute of Human Nutrition Potsdam-Rehbruecke, Nuthetal, ²Department of Internal Medicine IV, University of Tübingen, ³Department of Pharmacology, German Institute of Human Nutrition Potsdam-Rehbruecke, Nuthetal, Germany.

Background and Aims: The German Diabetes Risk Score (DRS) is a tool for screening of large populations for individuals at high risk of developing type 2 diabetes based on non-invasive measurements. However, it remains unclear whether its prediction is comparable to or could be enhanced by other screening methods, in particular fasting plasma glucose (FPG).

Materials and Methods: In the prospective EPIC-Potsdam Study, 9,711 men and 15,402 women aged 35–65 years and free of diabetes were followed for incident type 2 diabetes with 849 detected incident cases of physician confirmed type 2 diabetes over an average of 7 years of follow-up. Among the 7588 participants with fasting blood samples at baseline, there were 200 incident cases, and we randomly selected 647 fasting participants as sub-cohort for a case-cohort with all participants having FPG < 126 mg/dl at baseline. We evaluated the predictive power of the German Diabetes Risk Score, FPG, and the combination of both to identify individuals at high risk to develop type 2 diabetes through receiver operator characteristic (ROC) curve analysis based on logistic regression models with the area under the curve (AUC) being a measure of the discriminatory power.

Results: The German Diabetes Risk Score, consisting of information on age, waist circumference, height, history of hypertension, physical activity, smoking, and consumption of red meat, whole-grain bread, coffee, and alcohol, performed similarly to fasting glucose (ROC AUC: 0.845 and 0.852,

respectively). A model consisting of the German Diabetes Risk Score plus FPG performed better (ROC AUC: 0.905). Sensitivity and specificity were 85.0% and 68.2% for Score Points ≥ 500 , 93.0% and 23.7% for FPG ≥ 80 mg/dl, 81.5% and 67.7% for FPG ≥ 90 mg/dl and 50.0% and 93.0% for FPG ≥ 100 mg/dl. The corresponding sensitivity and specificity for ≥ 500 Score Points plus FPG ≥ 80 mg/dl were 81.0% and 73.2%, and for ≥ 500 Score Points plus FPG ≥ 90 mg/dl 73.0% and 83.9%, respectively.

Conclusion: The German Diabetes Risk Score (<http://drs.dife.de/en>) predicts incident type 2 diabetes similarly well as FPG. In addition, FPG as a second screening step in addition to the German Diabetes Risk Score enhances the discriminatory power.

Atrial natriuretic peptide correlates with insulin resistance/impaired glucose tolerance in cardiopathic patients affected by valvulopathy

P. C. G. Lucotti, L. D. Monti, E. Setola, E. Galluccio, M. G. Pala, A. Rossodivita, S. Costa, M. Oldani, G. La Canna, A. Castiglioni, E. Bosi, O. Alfieri, P. Piatti;

Medicine Division, Diabetology, Endocrinology and Metabolic Disease Unit, Scientific Institute San Raffaele, Milan, Italy.

Background and Aims: Few data are available concerning insulin resistance and glucose tolerance in patients affected by cardiac valvulopathy. The pathogenetic aspects involved in such alterations could be linked with the metabolic effects of myocardial-secreted peptides in condition of myocardial damage or dysfunction, as atrial natriuretic peptide (ANP) that has been shown to exert a potent lipolytic effect. The aim of the present study was to correlate ANP levels with glucose tolerance, insulin resistance, NEFA and inflammation markers.

Materials and Methods: Thirty patients (Group 1) with aortic/mitral valve disease before valve replacement and 58 patients (Group 2) submitted to aortic/mitral valve replacement were compared to 58 normal subjects (Group 3). A standard OGTT was performed in the three groups. None of the patients of group 1 and 2 had known diabetes while all the patients showed a normal ejection fraction and, at coronarography before intervention, the coronaries were free from atherosclerotic lesions.

Results: In group 1, according to glycemic levels after OGTT, 39% of the patients had IGT and 25% had a diabetic response. Similar results were found in group 2 where 43% of the patients had IGT and 19% with a diabetic response while the normal subjects were NGT. Mean HbA1c levels were significantly higher in Group 1 and 2 compared to normal subjects. Insulin sensitivity measured during OGTT (ISI index) showed a marked insulin resistance in Group 1 as in Group 2 compared to normal subjects, independently from the degree of glucose tolerance (diabetic response: 4.4 ± 1.1 and 2.1 ± 1.2 ; IGT: 5.8 ± 0.7 and 5.6 ± 0.7 ; NGT: 15.5 ± 2.2 and 12.4 ± 3.1 for group 1 and 2 vs group 3: $21.7 \pm 1.9 \cdot 10^{-4}$ dl kg⁻¹ min⁻¹/μUml⁻¹, $p < 0.0001$). Interestingly, ANP levels were significantly higher in group 1 and 2 (148.9 ± 22.4 and 67.9 ± 1.2 pg/ml) than in normal subjects (32.4 ± 1.4 pg/ml; $p < 0.001$). In accordance with a possible lipolytic effect of ANP, NEFA levels were significantly increased in group 1 and 2, in the fasting state (0.81 ± 0.04 and 0.50 ± 0.03 vs 0.38 ± 0.02 mmol/l, $p < 0.001$) and during OGTT (at 60 min: 0.36 ± 0.04 and 0.20 ± 0.01 vs 0.15 ± 0.01 mmol/l, $p < 0.002$). ANP levels significantly correlated with NEFA levels, HbA1c and ISI index.

Conclusion: In conclusion, chronic valvular disease, in the absence of atherosclerosis, seems to be characterized by high ANP levels which, in turn, determine a lipolytic effect, increasing NEFA levels. This mechanism could explain the pathogenesis of insulin resistance and impaired glucose tolerance in this class of patients. Furthermore, patients with chronic valvular disease represent a new class of patients at high risk for developing type 2 diabetes and they need to be inserted in programs for early diagnosis and treatment of this disease.

0005

Novel biomarkers identified by protein profiling: potential new diagnosis and therapeutics for type 2 diabetes

L. Liu¹, Z. Xie¹, S. Zangen², R. Manteiga¹, S. Hacoheh², W. W. Cheatham³, I. Raz², C. Gelber¹;

¹SCIENCE, ATCC, Manassas, United States, ²Diabetes Unit, Hadassah Hebrew University Medical Center, Jerusalem, Israel, ³Research, MedStar Research Institute, Washington, DC, United States.

Background and Aims: The pre-diabetic state can be present for 10 or more years prior to detection of glycemic disorders. Treatment of pre-diabetics can suspend or prevent Diabetes; yet few pre-diabetics are identified and treated since no simple laboratory test exists to determine the actual risk of an individual to develop Type 2 Diabetes (T2D). Due to the delay in diagnosis, diabetes complications have already advanced and thus, the future risk of further complication and derailment is severely increased.

Materials and Methods: We applied various proteomics approaches to identify disease-specific biomarkers in serum samples from Cohen Diabetic (CD) Rat Model, T2D patients and matched healthy individuals. The Cohen diabetic (CD) rat is comprised of 2 strains manifesting many features common to T2D in humans. The sensitive strain (CDs) develops diabetes within 30 days of a high sucrose/copper poor diet (HSD), while the resistant strain (CDr) retains normal blood glucose when fed with the same diet. Neither strain shows any signs of diabetes when provided regular rodent diet (RD). CD rat serum samples were profiled using Surface-Enhanced Laser Desorption/Ionization mass spectrometry, two-dimensional liquid chromatography and 2-dimensional gel electrophoresis. The protein markers were sequenced using liquid chromatography tandem mass spectrometry (LC/MS/MS).

Results: A constellation of differentially expressed proteins emerged when profiled proteins from normal serum were compared with diabetic samples. A panel of 27 differentially expressed biomarker {Apolipoproteins (C-III precursor, C2, A-1, E, and H) and liver regeneration-related protein}, inflammatory mediators (Complement component C9), protease inhibitors (Thrombin, Serpina 3M, LMW T-kininogen I precursor, inter- α -inhibitor H4 heavy chain and Serpinc 1), proteins associated with insulin signaling pathway (α -2-HS-glycoprotein, pregnancy-zone protein, Fetuin β and Spin 2a) and several novel and unknown proteins. A predicted protein of the Serpin family was found to be upregulated in CDr and share homology with the C-terminal fragment of Serpina 3M (D3). WB using a D3 specific polyclonal serum showed that the full length protein, ~50 kDa, is expressed in the liver and secreted into the serum of CDr and CDs rats, while the D3 polypeptide fragment was detected in the serum of CDr only. To investigate the relevance of this biomarker to human T2D, a Western Blot was performed on human serum samples reacted with D3 specific polyclonal serum. A doublet protein bands with MW of 60–80 kDa was shown to be differently expressed with a ~65kD band emphasized in T2D patients whereas the ~75kDa band is emphasized in healthy individuals. In addition, a smaller fragment (~20 kDa) reacting with D3-specific serum appears to be downregulated in diabetic patients as compared with healthy individuals.

Conclusions: In this study, we demonstrated that using proteomics profiling of normal and T2D serum samples we identified a constellation of differentially expressed protein/peptide markers, some of which were novel, associated with inflammation, insulin signaling, lipid metabolism, and several unknown. Their potential use for development of early diagnosis or therapeutics of T2D is investigated.

Quantification of a subset of 48 blood-borne protein biomarkers in a case controlled study can distinguish between converters to diabetes type 2 within 5 years and matched non-converters

M. P. McKenna¹, R. Gerwien¹, E. Moler¹, J. Kolberg¹, M. Urdea¹, V. Lyssenko², T. Tuomi³, B. Isomaa⁴, L. Groop²;

¹Research, Tethys Bioscience, Emeryville, United States, ²Clinical Science, Diabetes and Endocrinology, Lund University, Malmo, Sweden, ³Department of Medicine, Helsinki University Hospital, Finland, ⁴Folkhalsan Ostanlid, Malmska Municipal Health Care Center and Hospital, Jakobstad, Finland.

Background and Aims: The Botnia Study is a family based study initiated in 1990 to identify genes predisposing individuals to type 2 diabetes. From this

cohort we have compared individuals who did and did not convert to diabetes to determine whether or not a panel of serum protein biomarkers can be used to predict the future development of type 2 diabetes within 5 years.

Materials and Methods: Molecular Counting Technology (MCT), a new ultrasensitive protein detection method, was employed to quantify 42 proteins in small volumes (on average 1.3 μL / assay) of 444 blood samples from the Botnia cohort. The nested case/control study involved baseline blood samples collected from 148 subjects who developed diabetes during a 7 yr follow-up period and matched 2:1 (296 subjects) for BMI, family history, age, gender, and glucose tolerance status with non-converters. Baseline test results for the subjects (e.g. BMI, age, SBP, DBP, smoking history, fasting glucose, 2 hour glucose, total cholesterol, HDL cholesterol, triglycerides, free fatty acids (FFA), serum insulin (at -10, 0, 30, 60, 120 min of OGTT), etc.) were available and used in conjunction with the new protein information. A total of 48 molecular biomarkers and 5 clinical parameters were tested. Sixteen statistical predictive models and marker search algorithms were used for the analysis and were compared based upon Akaike Information Criterion (AIC) and the c-statistic.

Results: Seven of the 48 biomarkers quantifications (including both proteins and other blood borne markers) provided the majority of the statistical distinction noted for the two populations: seven biomarkers were selected in the majority of models. In this analysis only subjects who converted within 5 yrs ($n=60$) and non-converters with at least 8 years of follow-up ($n=177$) were included. Consistent with the initial matching of subjects, BMI, family history, age and glucose were not significant factors. The best models generated from repeated 10-fold cross-validations involved only protein markers (c statistic = 0.73–0.78). Although individual proteins had p-values as low as 10^{-4} individually, the concentration of no single biomarker of the 48 studied was capable of distinguishing the converter from non-converter populations as well as statistical models constructed from multiple proteins. Existing risk indices based upon age, gender, family history, SBP, HDL and FGT were also significantly less useful for segmenting the two closely matched groups (c statistic = 0.58–0.63). The seven protein biomarkers in the new panel are related to glucose and lipid metabolism, inflammation, and the coagulation and complement cascades.

Conclusion: A panel of biomarkers may provide a new tool for identifying individuals at future risk of developing T2D with a sensitivity and specificity of approximately 80%.

Parabolic relation between plasma triglycerides and LDL-cholesterol in the general population and patients with type 2 diabetes mellitus 6-year follow-up results from the Hoorn study

M. Brouwers¹, J. Dekker², A. Georgieva¹, M. van Greevenbroek¹, C. van der Kallen¹, R. Heine^{2,3}, T. de Bruin⁴, C. Stehouwer¹;

¹Internal Medicine, University Hospital Maastricht, The Netherlands,

²EMGO Institute, VU University Medical Center, Amsterdam,

The Netherlands, ³Endocrinology/Diabetes Center, VU University Medical Center, Amsterdam, The Netherlands, ⁴Translational Genetics and

Medicine, GlaxoSmithKline, Research Triangle Parc, United States.

Background and Aims: Patients with type 2 diabetes mellitus often present with moderately elevated plasma triglycerides and fairly normal LDL-cholesterol levels. Of interest, lowering of plasma triglycerides, e.g. by lifestyle intervention or fibrates, is often accompanied by an increase in LDL-cholesterol in these patients.

In the present study, we hypothesized that plasma triglycerides and LDL-cholesterol are related in a parabolic fashion, i.e. at low triglycerides (< 1.5 mmol/L) an increase in plasma triglycerides is accompanied by an increase in LDL-cholesterol, whereas a further increase in plasma triglycerides is followed by a decline in LDL-cholesterol levels. This hypothesis was based on the fact that triglycerides are mainly transported by VLDL2 particles at low plasma triglycerides, whereas VLDL1 particles are abundant at high triglycerides levels. The former particle is mainly degraded into buoyant LDL particles, the latter into small-dense LDL.

Materials and Methods: Data were obtained twice with an interval of six years in 1343 subjects derived from the general population (the Hoorn study). Three groups were defined: one with triglycerides < 1.5 mmol/L at both time-points (group A), one group with triglycerides < 1.5 mmol/L at one and > 1.5 mmol/L at the other measurement (group B), and one group with triglycerides > 1.5 mmol/L at both measurements (group C). The diabetic state was ascertained by an oral glucose tolerance test.

Results: In a mixed linear model for repeated measurements, a positive relation between triglycerides and LDL-cholesterol was observed for males in group A ($\beta=0.5$, $p<0.001$) and group B ($\beta=0.2$, $p<0.001$), whereas a negative relation was found for males in group C ($\beta=-0.2$, $p=0.003$) (Figure 1a). The regression slopes did not differ between subjects with and without type 2 diabetes mellitus. In the female subgroup, the relation was similar, but not significantly negative in group C ($\beta=-0.1$, $p=0.4$) (Figure 1b). Again, the results were not different for female diabetic patients.

Conclusion: The present parabolic relation between triglycerides and LDL-cholesterol provides more insight in the complex relation of clinically relevant cardiovascular risk markers and shows that one cannot interpret one without the other. (Fig. 1)

Hypertriglyceridaemic waist predicts coronary heart disease in the EPIC-Norfolk Prospective Population Study

B. J. Arsenault¹, I. Lemieux¹, J.-P. Després¹, N. J. Wareham², R. Luben³, J. J. P. Kastelein⁴, K.-T. Khaw³, S. M. Boekholdt⁵;

¹Québec Heart Institute, Hôpital Laval Research Centre, Canada, ²Medical Research Council Epidemiology Unit, University of Cambridge, United Kingdom, ³Department of Public Health and Primary Care, Institute of Public Health, Cambridge, United Kingdom, ⁴Department of Vascular Medicine, Academic Medical Center, Amsterdam, The Netherlands, ⁵Department of Cardiology, Academic Medical Center, Amsterdam, The Netherlands.

Background and Aims: The combination of an elevated waist circumference and triglyceride (TG) levels, the so-called hypertriglyceridemic waist (HTGW) phenotype, could represent an inexpensive and practical method that could be performed on a regular basis by health professionals in order to identify patients carrying features of the metabolic syndrome. The objective of the present study was to investigate whether the HTGW phenotype is associated with an increased risk of CHD in apparently healthy men and women.

Materials and Methods: A prospective case-control study nested in the EPIC-Norfolk cohort was performed. Cases were apparently healthy men and women aged 45 to 79 years who developed fatal or nonfatal CHD (n=927), and were matched by age, gender and enrollment time to 1642 controls who remained free of CHD. HTGW was defined as waist girth > 90 cm and TG levels > 2.0 mmol/L for men and as waist girth > 85 cm and TG levels > 1.5 mmol/L for women.

Results: Men with CHD had higher waist girths (98 ± 10 vs. 95 ± 9 cm, p<0.001) and TG levels [1.9 (1.4–2.7) vs. 1.7 (1.2–2.3) mmol/L, p<0.001] compared to CHD-free controls. Women with CHD also had higher waist girths (87 ± 11 vs. 83 ± 10 cm, p<0.001) and TG levels [1.8 (1.3–2.4) vs. 1.5 (1.1–2.1) mmol/L, p<0.001] compared to CHD-free controls. Men with the HTGW phenotype had unadjusted hazard ratio (HR) for future CHD of 1.66 (95% CI, 1.33 to 2.07; p<0.0001) whereas women had unadjusted HR for future CHD of 2.39 (95% CI, 1.76 to 3.24; p<0.0001). After adjustments for the Framingham Risk Score (FRS), men with an elevated waist girth and elevated TG had OR of 1.29 (95% CI, 1.01 to 1.64; p=0.04) compared to men with low waist and low TG levels. After adjustments for the FRS, women with an elevated waist girth and elevated TG had OR of 1.70 (95% CI, 1.25 to 2.28; p=0.002) compared to women with low waist and low TG levels.

Conclusion: The HTGW phenotype predicts the risk of CHD even after control for traditional risk factors in both men and women of in a European cohort representative of a contemporary Western population.

Postprandial changes in LDL composition, oxidisability and particle size and endothelial function following three consecutive meals in men with and without type 2 diabetes

P. G. Scheffer¹, M. E. Tushuizen², R. P. Vermue¹, C. Rustemeijer², R. J. Heine², M. Diamant²;

¹Metabolic Laboratory, Clinical Chemistry, ²Endocrinology and Diabetes Center, VU University Medical Center, Amsterdam, The Netherlands.

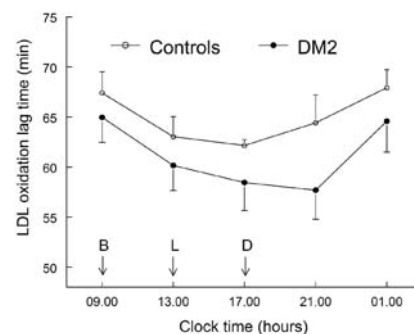

Background and Aims: Type 2 diabetes (DM2) is associated with low-grade inflammation and oxidative stress, leading to cardiovascular damage. We studied whether postprandial hyperglycaemia and hypertriglyceridaemia, both of which have been linked to oxidative stress and inflammation, affect the low-density lipoprotein (LDL) composition, size and susceptibility to oxidation in men with and without DM2.

Materials and Methods: Nine men with DM2 (mean±SD: age 55.7±4.2 yrs; HbA1c 7.5±1.3 %; BMI 32.7±2.8 kg/m²), and 7 age-matched healthy men were given 3 standardized high-fat mixed meals (900kcal; 50g fat, 50g carbohydrate, 35g protein) as breakfast (t=0, 09.00 a.m.), lunch (t=4h, 01.00 p.m.) and dinner (t=8h, 05.00 p.m.). Blood sampling was performed before the meals, and at 12h (09.00 p.m.), and 16h (01.00 a.m.) after breakfast. Flow-mediated dilation (FMD) of the brachial artery was measured by ultrasound

before each blood collection. LDL was isolated by ultracentrifugation and the mean LDL particle size was measured by high performance gel-filtration chromatography. The susceptibility of LDL to in vitro oxidation, expressed as lag time, was determined by monitoring the conjugated dienes formation.

Results: Area-under-the-curve for plasma glucose and triglycerides (TG) concentrations were higher in DM2 (P<0.05). DM2 had a most marked rise in plasma glucose and TG at t=12h after breakfast (P<0.01 and P<0.05, respectively). At baseline, DM2 relative to controls had smaller LDL particles (21.58±0.49 and 21.90±0.40 nm, respectively; P<0.05) and in agreement a lower cholesterol-to-protein content in their LDL (3.9±0.5 and 4.2±0.2 mmol/g, respectively; P<0.05). FMD at baseline was lower in DM2 compared to controls (4.0% and 7.5%, respectively; P<0.01), and decreased postprandially in both groups, reaching the lowest value at t=4h. Although not significant, the LDL TG/cholesterol ratio was 31% higher in DM2 at baseline. LDL was postprandially enriched in TG-to-cholesterol ratio in DM2 (18%; P<0.01) and controls (13%; P<0.05) reaching a maximum concentration 12h after breakfast. No postprandial changes were observed in LDL particle size, but LDL was more prone to oxidation in the postprandial state (Figure). In particular, LDL lag time was significantly decreased at t=4h and t=8h after breakfast (both P<0.05), and subsequently returned to baseline levels in healthy men, whereas LDL oxidisability increased further until t=12h in DM2.

Conclusion: In DM2, an increase in susceptibility of LDL particles to oxidation was found in the postprandial state, which was paralleled by endothelial dysfunction. The physiological exposure to 3 consecutive meals and the prolonged study-period allowed to uncover the full scope of alterations in LDL composition and function in DM2.

0010

Carotid intima-media thickness and apoB/apoA-I ratio in middle-aged patients with type 2 diabetes

E. M. Dahlén¹, T. Länne², J. Engvall³, T. Lindström⁴, E. Grodzinsky⁵, F. Nyström², C. J. Ostgren¹;

¹Linköpings universitet, Dept. of Health and Society, ²Linköpings universitet, Dept. of Medicine and Care, ³Dept. of Clinical Physiology, Linköping University Hospital, Linköping, Sweden, ⁴Dept. of Endocrinology, Linköping University Hospital, ⁵County Council of Östergötland, Research and Development dept. of Local Health, Linköping, Sweden.

Background and Aims: Hypercholesterolaemia, and elevated levels of LDL-cholesterol in particular, is a strong risk factor for atherosclerotic cardiovascular mortality. Recently, the balance between the proatherogenic apolipoprotein B (apoB) and the antiatherogenic apolipoprotein a-I (apoA-I), has been suggested to be more predictive in the evaluation of cardiovascular risk. Intima-media thickness (IMT) of the carotid arteries is used as a surrogate and intermediate endpoint of early atherosclerosis. The aim of this study was to explore the association between the IMT and the apoB/apoA-I ratio compared to serum triglycerides, total cholesterol, LDL- and HDL-cholesterol in middle aged patients with type 2 diabetes.

Material and Methods: We analysed data from 249 consecutive patients with type 2 diabetes (152 men and 97 women) aged 55–66 years (mean age 60.8 years) who participated in the ongoing observational CARDIPP (Cardiovascular Risk factors in Patients with Diabetes – a Prospective study in Primary care) study. Nurses in primary care measured blood pressure and anthropometric measurements. Blood samples were taken for analyses of serum lipids and HbA1c. Blood samples were also frozen for later analysis of apoB, apoA-I and C-Reactive Protein (CRP). The carotid ultrasonographic

investigations were performed at the University Hospital of Linköping and Länsjukhuset Ryhov, Jönköping, Sweden. The intima-media thickness of the carotid arteries, were evaluated by a Philips P700 ultrasound device (Philips Ultrasound, Santa Ana, California, United States) with either a 5 MHz or a 3.5 MHz transducer. A longitudinal image was frozen in diastole, and a section of 10 mm measured manually by tracing a cursor along the echo edges.

Results: In a bivariate correlation analysis, only apoB/apoA-I ratio ($r=0.203$, $p=0.002$), apoB ($r=0.156$, $p=0.018$), age ($r=0.139$, $p=0.034$) and treatment with statins ($r=-0.171$, $p=0.033$) correlated with IMT. Serum triglycerides, Total cholesterol, LDL-cholesterol, LDL-/HDL-cholesterol ratio, CRP, HbA1c and systolic blood pressure were not significantly correlated to IMT. When further exploring the strength of the association between IMT and apoB/apoA-I ratio in a multiple linear regression with IMT as dependent variable including apoB/apoA-I ratio, gender, age, smoking status, HbA1c, CRP, LDL- and HDL-cholesterol and LDL-/HDL-cholesterol ratio, serum triglycerides, treatment with statins and mean systolic blood pressure, only the apoB/apoA-I ratio remained significantly associated with IMT ($p=0.041$).

Conclusion: We conclude that there is a strong association between the apoB/apoA-I ratio and IMT, in middle aged patients with type 2 diabetes. The association is independent of conventional lipids and lipoproteins, inflammatory markers, glycaemic control and use of statins.

Matrix γ -carboxyglutamic acid protein (MGP) levels in type 2 diabetic patients with or without chronic kidney disease (CKD). Their correlation with insulin resistance and Lp(a) levels

S. Antonopoulos¹, M. Mylonopoulou², S. Mikros¹, E. Konstantellou³, G. Papadakis², A. Melidonis¹, N. Tentolouris⁴, N. Katsilambros⁴;

¹Diabetes Center, Tzanio General Hospital, Piraeus, ²Nephrology Dept, Tzanio General Hospital, Piraeus, ³Biochemistry Dept, General Hospital, Nikaia, ⁴1st Dept of Propaedeutic Medicine, University Medical School, Athens, Greece.

Background and Aims: Matrix GLA Protein (MGP) was the first in vivo inhibitor of vascular calcification discovered, expressed in abundance in atherosclerotic plaques. Results of the Framingham Study in 2006 correlated higher levels of MGP with low HDL-cholesterol and high triglycerides levels, age, systolic hypertension, smoking, obesity and high Framingham score. Homeostasis Model Assessment (HOMA) is an efficient and practical estimator of Insulin Resistance (IR). Lipoprotein (a) is a well established independent risk factor for Cardiovascular Disease (CVD). It is a strong promoter of atherogenesis and thrombogenesis and a strong predictor of advanced atherosclerosis, independent of LDL cholesterol. Our aim was to study the differences in MGP, HOMA and Lp(a), in type 2 diabetic patients with or without stage 4 Chronic Kidney Disease (CKD).

Materials and Methods: We studied 100 patients divided in 4 groups. Group 1: 25 patients (age 67 ± 9 years, 11 men) with T2 DM and stage 4 CKD, Group 2: 25 diabetic patients (67 ± 7 years, 10 men) without renal disease Group 3: 25 stage 4 CKD patients (65 ± 7 years, 14 men) without diabetes, and Group 4: 25 healthy individuals (65 ± 3 years, 10 men). Serum MGP was measured by enzyme-linked immunosorbent assay (ELISA, Biomedica, Vienna, Austria). We explored possible correlations among MGP, HOMA and Lp(a).

Results: MGP was significantly elevated in diabetic patients with stage 4 CKD compared to non-diabetics with kidney disease ($p=0.002$). Accordingly, HOMA-IR was significantly elevated in group 1 compared to all other patient groups ($p=0.003$). Lp(a) was found to be significantly elevated in group 1 patients compared to group 2 ($p=0.007$) and group 4 ($p<0.001$) patients. There was no significant difference in Lp(a) between uremic patients with (group 1) or without (group 3) diabetes. Moreover, after controlling for group differences, MGP was found to be independently and significantly correlated with Lp(a) ($p=0.09$) as well as with HOMA-IR ($p=0.003$).

Conclusion: The results indicate that the atherogenic process and the subsequent vascular calcification, as expressed by MGP and Lp(a) levels, play an important role as CVD risk factors in patients with CKD with or without diabetes. The patients with diabetes and concomitant pre-ESRD display an even greater danger for future cardiovascular complications compared to non-diabetics with CKD and diabetics without CKD. The high levels of the protective MGP in these patients might reflect the negative feedback process because of the intense calcification on their atheromatous vessel walls. MGP

was also independently correlated with serum levels of Lp(a) and HOMA-IR, suggesting the in vivo correlation of the vascular calcification process with atherogenesis and with the Insulin Resistance pathophysiological spectrum.

0012

Fibroblast cholesterol efflux to plasma from metabolic syndrome subjects is not impaired

R. P. F. Dullaart¹, A. K. Groen², G. M. Dallinga-Thie³, R. de Vries¹, W. J. Sluiter¹, A. van Tol¹;

¹Endocrinology, University Medical Center, Groningen, ²Laboratory of Experimental Hepatology, Academic Medical Center Amsterdam, ³Laboratory of Vascular Medicine, Erasmus University Medical Center, Rotterdam, The Netherlands.

Background and Aims: It is unknown whether the ability of plasma to stimulate cellular cholesterol efflux, an early step in the anti-atherogenic reverse cholesterol transport pathway, is abnormal in metabolic syndrome (MetS) subjects.

Materials and Methods: In 76 subjects with and 94 subjects without MetS (NCEP, ATP III criteria), we determined plasma (apo)lipoproteins, pre- β -HDL (formation), phospholipid transfer protein (PLTP) activity, cholesterol esterification (EST), cholesteryl ester transfer (CET), adiponectin, serum paraoxonase-1 (arylesterase) activity, and the ability of plasma from each subject to stimulate cholesterol efflux out of cultured fibroblasts obtained from a single donor.

Results: Apolipoprotein E, PLTP activity, EST and CET were higher ($p=0.04$ to <0.001), whereas adiponectin and paraoxonase-1 activity ($p<0.01$) were lower in MetS subjects. Pre- β -HDL and pre- β -HDL formation were not different between subjects with and without MetS. Cellular cholesterol efflux to plasma from MetS subjects was slightly higher vs. plasma from subjects without MetS (8.5 ± 0.90 vs. 8.8 ± 1.00 % per 4 h, $p=0.05$), but the difference was not significant after age, sex and diabetes adjustment. Cellular cholesterol efflux was positively related to pre- β -HDL formation, EST, PLTP activity and apolipoprotein E ($p<0.05$ for all by multiple linear regression analysis), without an independent association with MetS.

Conclusion: No defect in the ability of plasma from MetS subjects to promote fibroblast cholesterol efflux was found, despite low HDL cholesterol. Higher cholesterol esterification, PLTP activity and apolipoprotein E levels may contribute to maintenance of cholesterol efflux in MetS.

Localization and processing of the Amyloid Precursor Protein are regulated by the interaction with PED/PEA-15

A. P. M. Barbagallo, P. Iardino, G. Perruolo, A. Ilardi, I. Esposito, A. T. Alberobello, A. Perfetti, A. Cassese, F. Giacco, F. Beguinot, P. Formisano; DIP. Biologia e Patologia Cellulare e Molecolare & IEOS-CNR, University of Naples, Italy.

Background and Aims: Increasing evidence indicates that insulin plays a physiological role in brain, in particular in cognitive function and memory performance. Recent data suggest the association between insulin-resistance and cognitive decline. Alterations of genes involved in insulin signalling have also been found in patients with Alzheimer Disease (AD) and other neurodegenerative disorders. PED/PEA-15 (Phosphoprotein Enriched in Diabetes/Phosphoprotein enriched in astrocytes) is commonly overexpressed in individuals with type 2 diabetes and its overexpression induces insulin-resistance both in vitro and in vivo. PED/PEA-15 is physiologically expressed at high levels in brain, and in particular we now show that its expression is enhanced in the hippocampus, prefrontal and frontal cortex, brain structures with an important role in learning and memory. We hypothesize that PED/PEA-15 could represent a link between insulin-resistance and cognitive impairment.

Materials and Methods: To explore the function of PED/PEA-15 in brain, a yeast two-hybrid system has been used to search for proteins that specifically interact with PED/PEA-15 in brain. Further studies have been performed in the neuroblastoma cell line, N2a.

Results: By yeast two-hybrid system we identified the Amyloid Precursor Protein (APP), a protein involved in the pathogenesis of AD, as a PED/PEA-15 molecular interactor. We confirmed the interaction between PED/PEA-15 and APP in intact cells and in mouse brain by co-immunoprecipitation and pull down experiments. We then evaluated the effect of this interaction on APP proteolytic processing by measuring the amount of soluble APP fragment (sAPP) secreted in the culture medium. In cells transfected with APP, the simultaneous overexpression of PED/PEA-15 determined a 5-fold increase of sAPP secretion in the culture medium compared to control cells, without modifying precursor expression. APP plasma membrane expression is reduced in PED/PEA-15 overexpressing cells compared to control cells. Inhibition of conventional PKC isoforms (cPKCs) by Bisindolylmaleimide (100nM) caused a 50% decrease of PED/PEA-15-dependent sAPP secretion and reverses PED/PEA-15 effects on APP expression onto the plasma membrane, while the ERK1/2 inhibitor PD98059 (50 microM) did not alter these effects.

Conclusion: Our data show that PED/PEA-15 overexpression enhances sAPP secretion by increasing APP processing via a PKC-dependent mechanism. Modulation of APP processing in neurons may be involved in cognitive functions.

0014

Insulin signaling, glucose transporters and glycogen content in the cerebral cortex from undernourished suckling rats

F. Escrivá, E. Fernández, L. de Miguel, C. J. Martínez-Honduvilla, C. Álvarez; Bioquímica y Biología Molecular II, Facultad de Farmacia, Universidad Complutense, Madrid, Spain.

Background and Aims: The developing brain is vulnerable to nutrient insufficiency because of its high needs for both energy generation and synthetic purposes. Undernutrition during critical periods of brain growth increases the risk of neurological disorders. Malnourished children have low intellectual performance; however, most of them are economically disadvantaged, a condition that influences intellectual aptitudes and masks the direct effects of poor nutrition on developing brain metabolism. Animal models applied to search for definite effects of food restriction on brain metabolism could be useful to reveal possible relationships between undernutrition and long-term damage in this organ. The brain contains a small amount of glycogen, mainly in astrocytes; its precise role is not well understood. Some studies suggest that glycogen provides glucose when needed. Indeed, little is known

about the role of insulin in the regulation of brain glycogen metabolism. We have shown that circulating glucose and insulin are reduced in suckling undernourished rats, but they have improved insulin sensitivity in peripheral tissues. The manner in which insulin signalling in the brain is affected by early undernutrition has not been systematically studied. Since suckling constitutes a critical phase of rat brain growth, the purpose of this study was to investigate glucose transporters, glycogen content and insulin signalling in the cortex of undernourished 10-day-old rats.

Materials and Methods: Wistar rats were submitted to a 60% restriction of the commercial diet from 16th day of pregnancy and during lactation. Offspring from restricted dams and those from dams that received *ad libitum* the same diet were studied at age 10 day. Suckling rats, injected or not with i.p. insulin, were killed by decapitation. Cerebral cortices was rapidly removed. Glycogen was measured from glucose derived by amyloglucosidase hydrolysis. Microvessels of the blood-brain barrier were isolated by attachment to glass beads. Total membrane fraction and whole lysates were also obtained. Endothelial and astroglial GLUT-1, neuronal GLUT-3 and proteins associated with insulin signaling (receptor, Akt, GSK3) were analyzed by Western.

Results: Accumulated glycogen in the cortex from undernourished rats was 30 % higher than control values. Undernutrition led to an increase in glial GLUT-1; however, neither endothelial GLUT-1 nor neuronal GLUT-3 were altered. The content of insulin receptor did not differ between control and restricted rats. The degrees of insulin receptor, Akt and GSK3 α/β phosphorylation were not affected by i.p. exogenous insulin. Nevertheless, phospho-GSK3 α/β was markedly elevated in undernourished rats.

Conclusion: The increases in GSK3 phosphorylated and glycogen content observed in undernourished suckling rats raised the possibility that undernutrition enhances insulin sensitivity via enhancing some step of the signaling cascade in the cortex. It suggests that a fraction of the blood glucose taken up by astrocytes was directed to glycogen synthesis, perhaps depressing the amount of glucose utilized by energy generation or synthetic purposes. Further studies are needed to verify if these changes that coincide with the critical period of brain growth, when energy demand is high, can lead to deleterious consequences on brain development.

Brain insulin signaling regulation by leptin and serotonin. Potential impact on the development of metabolic diseases

K. Gerozissis¹, S. M. Banas¹, F. Berthou², V. Bailleux², C. Rouch¹, M. Taouis²; ¹Laboratoire de physiopathologie de la nutrition, Université Paris, France, ²Neuroendocrinologie Moléculaire de la Prise Alimentaire, Université Paris-Sud, Orsay, France.

Background and Aims: The central nervous system has a primary role in the control of energy and glucose homeostasis and insulin, in interaction with leptin and serotonin, is a major regulator of these processes. Disruption of physiological signaling leads, along with peripheral insulin resistance, to central insulin resistance that is directly involved in metabolic diseases (MD). This study focuses on the interaction of the above negative regulators with brain insulin signaling.

Materials and Methods: *In vivo* experiments. Adult male Wistar rats, received icv, 1 nmol of LY294002, a phosphatidylinositol 3 kinase (PI3K) inhibitor and one hour later, ip, 5 mg/kg of dexfenfluramine (dF), a stimulator of the serotonergic system. Food intake (FI) was measured during the dark phase, after four hours and overnight, starting 30 min following dF injection. **Cellular approach.** In differentiated human neuroblastoma (SH-SY5Y) cells expressing endogenous long isoform leptin receptor and insulin receptor (IR). We have previously shown that leptin or insulin activate STAT-3 (Signal Transducer and Transcription Factor 3) and MAPK (mitogen-activating protein kinase) phosphorylation, and PI3K activity. SH-SY5Y cells were incubated for 10 min, in presence of leptin (15 nM) or insulin (100 nM), and serotonin (10 microM). Phosphorylated STAT-3 and MAPK were detected using specific antibodies.

Results: FI was dramatically reduced by dF. Associated to dF, LY294002 largely restored FI, suggesting that PI3K is involved in the serotonergic-dependent FI inhibition, as it is involved in leptin- and insulin-dependent anorexic effect.

In SH-SY5Y cells, where leptin pre-treatment was shown to abolish insulin effect and vice versa, serotonin increased basal MAPK phosphorylation.

Furthermore, serotonin clearly increased MAPK phosphorylation in response to insulin and leptin. Preliminary results indicate that STAT-3 phosphorylation in response to insulin or leptin is also positively affected by the addition of serotonin.

Conclusion: The present studies indicate that serotonin, insulin and leptin at the neuronal and brain level, share several signaling pathways such as STAT-3, MAPK and IRS/PI3K. In addition to leptin and insulin, serotonin involves the PI3K pathway in its anorectic action. Whether this action is direct on IR, IRS or PI3K, or indirect by increasing extracellular brain insulin release, needs further investigation. These data suggest a complex interaction in the brain between serotonin, leptin and insulin signaling pathways. Thus modifications of leptin and/or serotonin levels in the brain, observed in situations favoring metabolic disturbances, may impair brain insulin efficiency and contribute to the central insulin resistance, a potential determinant step on the development of peripheral insulin resistance that leads to MD, including T2D.

Evidence of GLP-1 effects on human brain glucose delivery and metabolism

O. Schmitz¹, S. Lerche¹, B. Brock¹, J. Rungby¹, H. E. Boetker¹, N. Moeller², A. Rodell³, J. J. Holst⁴, A. Gjedde³;

¹Department of Pharmacology, Aarhus University, ²Medical Research Laboratory, Aarhus University Hospital, ³PET-center, Aarhus University Hospital, ⁴Department of Medical Physiology, Copenhagen University, Denmark.

Background and Aims: Glucagon-like-peptide-1 (GLP-1) has many effects regarding glucose homeostasis. GLP-1 receptors are broadly represented in the brain. Recent research in rodents has suggested a potentially protective effect of GLP-1 in the brain. The mechanism behind this effect is unknown. The possible role of GLP-1 in the human brain glucose metabolism is not well characterized. To gain more insight into changes of glucose delivery and/or metabolism, which may explain neuroprotective effects, we explored glucose transport and consumption in 10 healthy men in a randomized, double-blinded placebo-controlled cross-over experimental design.

Materials and Methods: The acute effect (independent of insulin) of GLP-1 on glucose uptake in the brain was visualized by Positron Emission Tomography (PET) during a pituitary-pancreatic normoglycaemic (plasma glucose \approx 4.5mM) clamp with 18-fluoro-deoxy-glucose (FDG) as a tracer of glucose.

Results: The insulin infusion rate was 0.12mU/kg/min, growth hormone and glucagon were replaced to baseline levels. Intact GLP-1 levels were 51 ± 3 (mean \pm SEM) vs. 0.95 ± 0.1 pmol/l (GLP-1 vs. placebo). In total cerebral grey matter, GLP-1 reduced cerebral glucose uptake by 30%, 0.99 micromol/cm³/min \pm 0.09 (placebo) vs. 0.70 ± 0.04 (GLP-1) (P=0.05). In the cerebral cortex, reduction was 29%, 0.98 ± 0.09 vs. 0.69 ± 0.04 (P=0.06), in white matter 26%, 0.50 ± 0.04 vs. 0.37 ± 0.02 (P=0.03), in thalamus 31%, 1.11 ± 0.12 vs. 0.77 ± 0.06 (P=0.05), in striatum 28%, 0.98 ± 0.09 vs. 0.70 ± 0.05 (P=0.06), in cerebellar cortex 30%, 1.12 ± 0.12 vs. 0.82 ± 0.06 (P=0.06) and in brainstem 33%, 0.76 ± 0.07 vs. 0.50 ± 0.03 (P=0.02). The same regions showed a uniform trend towards reduced cerebral glucose metabolism. As a result, the intra cerebral glucose concentration remained the same in all regions, with and without GLP-1.

Conclusion: For the first time, we demonstrate that a hormone involved in postprandial glucose regulation also limits glucose delivery to brain tissue and hence provides a possible explanation for the connection between plasma glucose and brain glucose regulation. As GLP-1 reduces glucose uptake across the intact blood brain barrier at normal glycaemia, GLP-1 may also protect the brain by limiting intra cerebral glucose fluctuation when plasma glucose is increased.

Insulin-stimulated brain glucose uptake is enhanced in subjects with impaired glucose tolerance (IGT)

K. A. Virtanen¹, J. Hirvonen¹, M. Bucci^{1,2}, M. Honka¹, S. Nesterov¹, P. Iozzo^{1,3}, J. O. Rinne¹, P. Nuutila^{1,4};

¹Turku PET Centre, University of Turku, Finland, ²Alma Mater Studiorum, University of Bologna, Italy, ³Institute of Clinical Physiology, CNR – National Research Council, Pisa, Italy, ⁴Department of Medicine, Turku University Hospital, Finland.

Background and Aims: Central nervous system regulates hepatic glucose metabolism. However, cerebral blood flow, cerebral glucose uptake and hepatic glucose uptake has not been studied earlier simultaneously in same subjects.

Materials and Methods: We studied 8 subjects with impaired glucose tolerance (IGT) and 10 normal subjects in random order twice, during the fasting state and euglycemic hyperinsulinemia (1 mU/min/kg clamp) in separate days. Cerebral and hepatic glucose uptake was measured using [¹⁸F]-fluoro-deoxyglucose ([¹⁸F]FDG) and PET, and cerebral blood flow was quantified using [¹⁵O]H₂O and PET. Hepatic glucose uptake rate was determined using graphical analysis, and cerebral blood flow and glucose uptake were determined using statistical parametric mapping (SPM).

Results: Insulin had no effect on global or regional perfusion either in healthy or IGT subjects. During the fasting state, cerebral glucose uptake was 8.5 % lower in IGT than in normal subjects (p = ns). Insulin stimulation did not change cerebral glucose uptake in normal subjects but enhanced glucose uptake by 13.5% in IGT subjects as compared to fasting values (p < 0.05). This increment was most prominent in amygdala, hippocampus, and orbitofrontal cortex.

In the same subjects, hepatic glucose uptake was stimulated (+25%) by insulin in normal subjects as compared with fasting values (p = 0.02) but not in IGT group.

Conclusion: Insulin-stimulated cerebral glucose uptake is up-regulated in IGT subjects. The liver of IGT subjects reflects insulin resistance.

Brain unsaturated fatty acid (FA) uptake is increased in obesity and reversed by weight reduction

P. Nuutila, A. Viljanen, J. Hirvonen, K. Virtanen, A. Karmi, V. Oikonen, J. Kemppainen, T. Viljanen, M. Haaparanta, K. Nägren, O. Solin, P. Iozzo, Turku PET Centre, University of Turku, Turku, Finland.

Background and Aims: Free fatty acids (FFA) are taken up by the brain, but their role in obesity and metabolic syndrome is poorly understood. The aim of this study was to test whether brain fatty acid uptake is enhanced in obese subjects having metabolic syndrome (MBO), and whether weight reduction modifies it.

Materials and Methods: A total of seven healthy subjects (age 42 ± 11 year, BMI 26.8 ± 2.5 kg/m²) and 22 MBO patients (age 43 ± 8 year, BMI 33.5 ± 4.1 kg/m²) were studied during fasting conditions using PET with [¹¹C]-palmitate and [¹⁸F]fluoro-6-thia-heptadecanoic acid (FTHA). In mitochondria, [¹⁸F]-FTHA is trapped after initial steps of oxidation. Sixteen MBO subjects were restudied after 6 weeks of very low calorie diet intervention. The fractional tracer uptake (FUR) was calculated voxel-wise, and an automated ROI-analysis was performed to derive regional FUR estimates. FUR was multiplied with serum FFA concentration to yield FFA uptake ([¹⁸F]-FTHA) and nonoxidised retention ([¹¹C]-palmitate). The results were analyzed using repeated-measures analysis of variance (rmANOVA).

Results: The cerebral global fatty acid uptake derived from [¹⁸F]-FTHA-PET was 50 % higher in MBO compared with controls (p=0.012). The mean percentual increment was +130% in the white matter and +47% in the gray matter and uniform across brain regions. In the MBO group, weight reduction (-11 ± 2.5 kg) decreased fatty acid uptake by 17% (p=0.01). In line with this, fatty acid retention measured using [¹¹C]-palmitate was + 86 % higher in the MBO group (p=0.017), but did not change following weight reduction.

Conclusions: Fatty acid uptake and accumulation in the brain appears to be increased in MBO; and decreases after weight reduction, which seems to primarily affect the oxidative fate of fatty acids. These results could contribute to altered brain white matter volume in obesity and may have consequences on the regulation of peripheral metabolism.

Epigenetic regulation of PGC-1 α in human type 2 diabetic islets and effect on insulin secretion

T. S. Rönn¹, C. Ling¹, S. del Guerra², R. Lupi², C. Granhall¹, H. Luthman¹, P. Masiello², P. Marchetti², L. Groop¹, S. del Prato²;

¹Clinical Sciences, Diabetes and Endocrinology, Lund University, Malmö, Sweden, ²Endocrinology and Metabolism, Metabolic Unit, University of Pisa, Italy.

Background and Aims: Insulin secretion in pancreatic islets is dependent upon mitochondrial function and production of ATP. The transcriptional co-activator peroxisome proliferator activated receptor- γ coactivator-1 α (PGC-1 α) is a master regulator of mitochondrial genes and its expression is decreased and related to impaired oxidative phosphorylation in muscle from patients with type 2 diabetes (T2D). Also, we recently showed that PGC-1 α mRNA was reduced by 90% ($p < 0.005$) in T2D human pancreatic islets and correlated with reduced insulin secretion. Furthermore, a polymorphism (Gly482Ser polymorphism) in the PGC-1 α gene was associated with markedly reduced PGC-1 α mRNA levels ($p < 0.0001$) and insulin secretion ($p < 0.05$) in T2D islets. In order to study potential mechanisms leading to impaired PGC-1 α expression and insulin secretion we measured DNA methylation of the PGC-1 α promoter in human islets and studied whether experimental (siRNA) down-regulation of PGC-1 α in human islets influences insulin secretion.

Materials and Methods: Human pancreatic islets from 10 T2D (age: 65.1 \pm 2.6 years, sex[M/F]: 5/5, BMI: 26.9 \pm 1.1 kg/m²) and 10 non-diabetic (ND; age: 54.3 \pm 4.0 years, sex[M/F]: 7/2, BMI: 25.6 \pm 1.2 kg/m²) multi-organ donors were analysed for DNA methylation at 4 target sites in the PGC-1 α promoter region using bisulfite sequencing. mRNA levels were quantified by Real-Time Quantitative RT-PCR. PGC-1 α silencing RNA (siRNA) was used for experimental down-regulation of PGC-1 α expression in human islets and insulin secretion studies were performed with 3.3 resp. 16.7 mmol/l glucose. Differences in PGC-1 α mRNA levels, percentage of DNA methylation and insulin-secretion between the different groups studied were analyzed using non-parametric Mann-Whitney exact test. Correlations were calculated using Spearman correlation coefficient.

Results: There was an approximately 2-fold increase in DNA methylation in the PGC-1 α promoter of T2D compared with ND human islets (10.5 \pm 2.7 % vs. 4.7 \pm 0.9 %; $p < 0.04$). The degree of DNA methylation showed a trend to an inverse correlation with the PGC-1 α mRNA level ($r = -0.48$; $p = 0.07$). Transfection with PGC-1 α siRNA resulted in a 45% reduction in PGC-1 α mRNA level, 32% reduction in insulin mRNA level, and a 41% reduction in insulin secretion (measured as insulin stimulation index, i.e. incremental folds above baseline insulin release), $p < 0.05$.

Conclusion: Expression of PGC-1 α in human islets is subject to DNA methylation which, in turn, could influence insulin secretion.

Nuclear cytosolic translocation of PTB1 in human islets of type 2 diabetic patients

K.-P. Knoch¹, F. Ehehalt², K. Erdmann¹, S. Kersting², H. Bergert², M. Jäger¹, D.-D. Dittert³, E. Kuhlisch⁴, S. Bornstein⁵, E. Bonifacio⁶, H. Saeger², M. Solimena¹;

¹Experimental Diabetology, Medical School, Dresden, ²Visceral, Thoracic and Vascular Surgery, Medical School, Dresden, ³Pathology, Medical School, Dresden, ⁴Institute for Medical Informatics and Biometrics, Medical School, Dresden, ⁵Clinic III, Medical School, Dresden, Germany, ⁶Immunology of Diabetes Unit, San Raffaele Scientific Institute, Milan, Italy.

Background and Aims: The rapid biosynthesis of insulin secretory granules (SG) is regulated by glucose. Previously we have shown that in rat islets and cultured insulinoma INS-1 cells glucose and glucagon-like peptide 1 (GLP-1) rapidly increase SG biogenesis through the activation of a posttranscriptional pathway involving the nucleocytoplasmic translocation of polypyrimidine tract-binding protein 1 (PTB1). In this study we compared the glucose-

stimulated insulin turnover and the translocation of PTB1 in human islets isolated from patients with or without type 2 diabetes (T2D) who underwent pancreatectomy because of pancreatic diseases.

Materials and Methods: Islets were isolated from the macroscopically healthy resection margins of pancreatic tissue from 5 patients with T2D and 6 matched non-diabetic (ND) patients. Insulin content and insulin secretion were measured before and after islet stimulation with 25 mM glucose for 2 hours. The subcellular localization of polypyrimidine tract-binding protein 1 (PTB1) was analyzed by western blotting and confocal microscopy.

Results: Glucose stimulated insulin secretion was decreased, albeit not significantly, in T2D islets compared to ND islets. Strikingly, stimulation increased the total amount of insulin (islet insulin content + secreted insulin) in each islet preparation from ND patients, but not from T2D subjects. Furthermore, stimulation decreased the nuclear levels of PTB1 in ND islets, but not in T2D islets. Confocal microscopy supported the retention of PTB1 in stimulated T2D islets.

Conclusion: These results point to impaired glucose-stimulated rapid turnover of insulin as a specific trait of T2D islets. Nuclear retention of PTB1 suggests that reduced insulin biosynthesis contributes to this impairment, and thus to deficient insulin secretion. Overall, these data highlight the importance of investigating the post-transcriptional mechanisms regulating insulin biosynthesis and degradation to gain insight into the pathogenesis of T2D.

The effects of E-cadherin engagement on human beta-cell survival and function

D. Bosco, P. Morel, D. Matthey-Doret, T. Berney; Surgery, University of Geneva, Switzerland.

Background and Aims: E-cadherin is a cell-to-cell adhesion molecule that has been shown to be involved in islet cell differentiation and aggregation, as well as in the maintenance of islet architecture. In this work, we aimed to assess whether E-cadherin plays a role in the function and survival of adult human beta-cells. This task is rendered difficult as it is challenging to distinguish between effects that are mediated directly by E-cadherin ligation versus the effects that are downstream of this ligation, such as cell-to-cell communication via gap junctions to the cell membrane. To overcome this problem we used a recombinant protein consisting of the ectodomain of human E-cadherin fused to the Fc region of IgG (E-cadh-Fc) as a model matrix for single cell adhesion to specifically study the effects mediated by E-cadherin ligation.

Materials and Methods: Human islets were isolated from pancreases harvested from multiorgan cadaveric donors. Islet cells were obtained by Accutase treatment and incubated in suspension for 24 h in CMRL medium at low density to limit cell-to-cell aggregation and to allow cell recovery. Cells were then seeded on microscopic slides coated with E-cadh-Fc. Controls include uncoated glass slides and glass slides coated with analogous fused proteins containing the ectodomains of human N-cadherin (N-cadh-Fc) or human P-cadherin (P-cadh-Fc). In every experiment, beta-cells were detected using immunofluorescence for insulin. Cells were attached on the different substrates for 24 h and apoptosis was assessed by TUNEL. To assess insulin secretion, cells were attached for 1 h and were submitted to a reverse hemolytic plaque assay (RHPA). Hemolytic plaques that developed around single beta-cells or beta-cell pairs were analysed after 1 h stimulation with 16.7 mM glucose. Data are expressed as means \pm SEM of 6 independent experiments and statistically analysed by Student's t test.

Results: When attached on uncoated glass slides, 14.6 \pm 3.9 % of single beta-cells were TUNEL positive. This percentage significantly ($p = 0.02$) decreased to 3.9 \pm 1.1 % ($p = 0.02$) for beta-cells aggregated into pairs and to 5.6 \pm 1.0 for single beta-cells attached on E-cadh-Fc ($p = 0.05$ vs control). Neither N-cadh-Fc nor P-cadh-Fc affected the percentage of apoptotic cells when compared to control. By RHPA, it was observed that 11.4 \pm 2.3 % of single beta-cells attached on control glass were surrounded by a hemolytic plaque with a total plaque development (for 100 beta-cells) of 14900 \pm 3700 μ m². These values were increased to 28.4 \pm 7.6 % ($p = 0.05$ vs control) and 73800 \pm 30400 μ m² ($p = 0.08$ vs control) for beta-cell pairs. When attached on E-cadh-Fc, 25.5 \pm 4.7 % ($p = 0.02$ vs control) of single beta-cells were surrounded by a hemolytic plaque and the total plaque development was 54400 \pm 12400 μ m² ($p = 0.01$ vs control).

Conclusion: These results indicate that cell-to-cell contact at least in part via E-cadherin engagement improves human beta-cell survival and secretion.

0022

Role of glucokinase in the regulation of β cell mass under insulin resistant conditions

Y. Terauchi¹, A. Nakamura¹, I. Takamoto², N. Kubota², T. Kadowaki²;

¹Department of Endocrinology and Metabolism, Yokohama City University,

²Department of Metabolic Diseases, University of Tokyo, Japan.

Background and Aims: Glucokinase (Gck) functions as a glucose sensor for insulin secretion, and in mice fed standard chow, haploinsufficiency of β cell-specific glucokinase (*Gck*^{+/-}) led to impaired insulin secretion to glucose, but the animals had a normal β cell mass. When fed a high-fat (HF) diet, wild-type mice showed marked β cell hyperplasia, whereas *Gck*^{+/-} mice showed insufficient β cell hyperplasia, decreased β cell replication and impaired up-regulation of insulin receptor substrate (*Irs*)-2 in islets, despite the presence of a similar degree of insulin resistance. Thus, Gck and *Irs*-2 are required for β cell hyperplasia to occur in response to HF diet-induced insulin resistance. In the present study, we investigated the role of Gck in the regulation of β cell mass under various insulin resistant conditions.

Materials and Methods: We generated an animal model with insulin resistance and impaired insulin secretion by crossing *Irs*-1^{-/-} and *Gck*^{+/-} mice, and investigated glucose tolerance and β -cell mass in the *Irs*-1^{-/-}*Gck*^{+/-} mice and *Irs*-1^{-/-} mice on the standard-chow diet or HF diet. To evaluate the role of Gck in pregnancy, we investigated glucose tolerance and β -cell mass in pregnant wild-type, *Gck*^{+/-} and *Irs*-2^{-/-} mice.

Results: On the standard-chow diet, *Irs*-1^{-/-} mice showed normal glucose tolerance and *Irs*-1^{-/-}*Gck*^{+/-} mice exhibited severe diabetes. After 20 weeks on the HF diet, *Irs*-1^{-/-} mice developed only mild diabetes as a result of compensatory hyperinsulinemia, whereas *Irs*-1^{-/-}*Gck*^{+/-} mice demonstrated the exacerbation of diabetes because of a lack of compensatory hyperinsulinemia, despite the similar degrees of obesity and insulin resistance shown by both HF diet-fed groups. On the standard-chow diet, the proportion of the area of β cell to the total area of the pancreas (β cell mass) was $1.19 \pm 0.06\%$ in *Irs*-1^{-/-} mice and $0.53 \pm 0.13\%$ in wild-type mice of the same genetic background. On the HF diet, β cell mass was $1.88 \pm 0.12\%$ in *Irs*-1^{-/-} mice, indicating β cell hyperplasia to compensate for HF diet-induced insulin resistance. By contrast, β cell mass was $1.17 \pm 0.21\%$ in *Irs*-1^{-/-}*Gck*^{+/-} mice on the standard-chow diet, but there was no significant difference between those on the standard-chow diet and those on the HF diet. There were significantly fewer insulin and PCNA double-positive cells in the *Irs*-1^{-/-}*Gck*^{+/-} mice on the HF diet than in the *Irs*-1^{-/-} mice on the HF diet. Body weight was significantly increased by 70 to 80% in both *Gck*^{+/-} and wild-type mice on day 17.5 of pregnancy, but fed glucose level was significantly lower in pregnant *Gck*^{+/-} mice than in non-pregnant *Gck*^{+/-} mice. β -cell mass was significantly increased by 70% and 67%, respectively, in pregnant wild-type and *Gck*^{+/-} mice, compared with non-pregnant ones. There was little difference in β cell size between the two pregnant groups. In *Irs*-2^{-/-} mice, marked aggravation of glucose intolerance and lack of compensatory β cell hyperplasia was seen on the HF diet, whereas fed glucose level was not increased and β cell mass was increased during pregnancy.

Conclusion: Haploinsufficiency of Gck led to insufficient β cell hyperplasia on the HF diet, but to the compensatory increase in β cell mass under *Irs*-1-deficient or pregnancy-associated insulin-resistant conditions. These results suggest the existence of Gck-dependent and Gck-independent pathway in the regulation of β cell hyperplasia to occur in response to insulin resistance.

0023

Glucose tolerance and insulin secretion in pancreatic beta cell specific Mn-SOD knockout mice

M. Tsuda¹, T. Adachi², T. Shimizu³, T. Shirasawa³, K. Tsuda¹;

¹Laboratory of Metabolism, Graduate School of Human and Environmental Studies, Kyoto, ²Department of Genomic Drug Discovery Science, Graduate School of Pharmaceutical Sciences, Kyoto, ³Research Team for Molecular Biomarkers, Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan.

Background and Aims: Oxidative stress is well known as the cause of aging, cancer, arteriosclerosis, and/or diabetic complications, but the detailed

mechanisms are not cleared. Manganese superoxide dismutase (Mn-SOD) reduces superoxide in mitochondrial matrix. We have generated the pancreatic beta-cell specific Mn-SOD knockout (beta-KO) mice. The aim of this study is to investigate glucose tolerance and insulin secretion in the beta-KO mice.

Materials and Methods: Twelve- and 24-week-old beta-KO or age-matched Mn-SOD flanked loxp (F/F) male mice were used. Body weights and non-fasting plasma glucose and insulin level were measured. For the intraperitoneal glucose tolerance test (ipGTT), the mice were fasted for over 14hr and blood was drawn from the tail vein at 0, 15, 30, 60, and 120 min after intraperitoneal injection of glucose (2g/kg body weight). Then, plasma glucose levels were measured. On the pancreatic perfusion, the insulin secretion level was measured. Perfusion flow with 3.3 mM glucose concentration was performed for 30 min. Then, perfusion flow with 11.1 mM glucose concentration was performed for 30 min, and thereafter, with 3.3 mM glucose concentration for 10 min. For check of viability, perfusion flow with 11.1 mM glucose and 10 mM arginine concentration was performed for 10 min. Then, beta-KO and F/F mouse islets were isolated, and stimulated with 5.5 mM or 11.1 mM glucose concentration for 30 min in 37°C. Moreover, protein contents of beta-KO and F/F mouse islets were measured, and the insulin secretion level of beta-KO and F/F mouse islets was corrected using each protein content. The morphological observation of pancreas was performed. Two types of stains were performed. Staining for succinate dehydrogenase (SDH) activity was performed for analysis of mitochondrial functions. Furthermore, immunostaining was performed using insulin and glucagon antibody for analysis of morphology of pancreatic islets.

Results: Body weights were significantly lower in beta-KO than F/F mice at both 12 and 24 weeks of age. Non-fasting plasma glucose and insulin levels were not significantly different between beta-KO and F/F mice. The plasma glucose level in ipGTT was significantly higher in beta-KO than F/F mice. On the pancreatic perfusion with 11.1 mM glucose concentration, the insulin secretion level was significantly lower in beta-KO than F/F mice. The insulin secretion level per islet was significantly higher in beta-KO than F/F mice, but the insulin secretion level per protein was significantly lower in beta-KO than F/F mice. Mitochondrial SDH activity was lower in beta-KO than F/F mice. Hyperplasia was observed in pancreatic islets of beta-KO mice.

Conclusion: Beta-KO mice exhibited glucose intolerance, suggesting that insulin secretion capacity of beta-KO mice was decreased. We surmise that mitochondrial Mn-SOD in beta-cells is one of the important enzymes for insulin secretion.

0024

Reduced sensitivity to oxidative stress in beta cells of K_{ATP} channel-deficient Sur1KO mice

M. Düfer¹, B. Gierl¹, P. Krippel-Drews¹, L. Aguilar-Bryan², J. Bryan², G. Drews¹;

¹Pharmazeutisches Institut, Universität Tübingen, Germany,

²Pacific Northwest Research Institute, University of Washington, Seattle, United States.

Background and Aims: In beta cells of wildtype (WT) mice the opening of K_{ATP} channels and subsequent membrane hyperpolarization contribute to the impairment of insulin secretion induced by oxidative stress. The aim of the present study was to investigate whether beta cells of K_{ATP} channel-deficient, Sur1KO mice are less sensitive to H₂O₂ than WT cells.

Materials and Methods: Membrane potential (V_m) recordings were performed in the perforated-patch configuration; [Ca²⁺]_c was determined using fluorescence techniques; insulin secretion was monitored by radioimmunoassay.

Results: In islets of WT mice stimulated with 15 mM glucose insulin secretion was dose-dependently reduced by H₂O₂ between 0.025 and 0.5 mM (n=7–10). By contrast, insulin release from Sur1KO islets was not affected by H₂O₂ concentrations up to 100 μ M (n=9), but was decreased by 0.25 and 0.5 mM H₂O₂ (n=9). The IC₅₀ for H₂O₂ was threefold higher in Sur1KO vs WT islets (0.46±0.10 mM vs 0.16±0.02 mM, respectively). As insulin secretion is critically determined by membrane potential-regulated changes of [Ca²⁺]_c we investigated whether [Ca²⁺]_c and membrane potential were less sensitive to H₂O₂ in Sur1KO vs WT beta cells. 10 μ M H₂O₂ stopped [Ca²⁺]_c oscillations in WT beta cells stimulated with 15 mM glucose and reduced [Ca²⁺]_c to basal values (n=9), while oscillations persisted in Sur1KO beta cells (n=8). In isolated WT beta cells 10 and 100 μ M H₂O₂ hyperpolarized V_m by 15.5±1.3

mV (n=11) or 17.8±1.9 mV (n=4), respectively, which drastically reduced or terminated action potentials within 5 min after H₂O₂ application; AP frequency = 112±8.1 APs/min in 15 mM glucose, n=13, vs 16.1±9.3 (n=9) or 23.0±23.0 (n=4) APs/min in 10 or 100 μM H₂O₂, respectively. 10 or 100 μM H₂O₂ did not change V_m or the action potential frequency in Sur1KO beta cells (n=6–10). Higher H₂O₂ concentrations (1 mM) produced a large, irreversible increase of [Ca²⁺]_c that was not blocked by L-type Ca²⁺-channel inhibitors in WT (n=5) or Sur1KO beta cells (n=4).

Conclusion: Elimination of K_{ATP} channels significantly reduced the H₂O₂-mediated impairment of insulin secretion. Electrical activity and Ca²⁺ influx, preconditions for normal exocytosis, persist in Sur1KO beta cells under conditions of oxidative stress, but are disrupted in WT cells. High H₂O₂ concentrations, >100 μM, that affect [Ca²⁺]_c in WT and Sur1KO beta cells inhibit insulin secretion independent of K_{ATP} channels. As the lower concentrations of H₂O₂ are more relevant in the immune response leading to beta cell failure during development of type 1 diabetes mellitus, modulation of K_{ATP} channels could be a promising target to protect beta cells against oxidative stress.

Exendin-4 rapidly increases nitric oxide production, promotes proliferation and protects against glucolipoapoptosis in human coronary artery endothelial cells

Ö. Tütüncü¹, D. Nathanson², Å. Sjöholm², T. Nyström², Q. Zhang¹;

¹Karolinska Institutet, Research Center, Stockholm South Hospital, ²Karolinska Institutet, Internal Medicine, Stockholm South Hospital, Sweden.

Background and Aims: Endothelial dysfunction plays an important role in macrovascular complications in diabetes. We recently showed that the glucagon-like peptide-1 receptor is expressed in human coronary artery endothelial cells (HCAEC) and that GLP-1 improves endothelial dysfunction in type 2 diabetic patients with coronary artery disease. Exendin-4 is a stable GLP-1 receptor agonist and has been approved for clinical use against type 2 diabetes in Europe and the U.S. The aim of the present study was to investigate the effects of exendin-4 on neogenesis and apoptosis under normal and hyperglucolipidemic conditions (simulating the diabetic milieu) in HCAEC cells *in vitro*.

Materials and Methods: HCAEC cells were cultured in the endothelial growth medium in the presence of 5 mM glucose. Phosphorylation and expression of endothelial nitric oxide synthase (eNOS) were examined by Western blotting using anti-phospho-eNOS and anti-eNOS antibodies, respectively. β-actin examined in same blots acted as loading control. Real-time production of NO in single living HCAECs was monitored by a highly sensitive non-fluorescent cell-permeable NO probe, DAF-2DA. In the cell, the product reacts rapidly with NO in the presence of O₂ to form a highly fluorescent compound. ³H-thymidine incorporation was assayed in 96-well plates as a measure of DNA synthesis, and caspase-3 activity was evaluated using ELISA kit as a measure of apoptosis. DNA synthesis and apoptosis were examined after 48 h-incubation with the reagents. Cell death was assessed using Trypan-blue inclusion.

Results: Incubation of HCAEC cells with exendin-4 from 1 to 10 nM for 10 min resulted in a dose-dependent increase of eNOS phosphorylation to an extent comparable with that of GLP-1 and acetylcholine. Continuous treatment of the cells with exendin-4 for 48 h resulted in increased expression of eNOS protein. Similar to the acute effects of the peptide, long-term treatment with exendin-4 also enhanced the phosphorylation state of the enzyme even when normalized for eNOS expression. In cells pre-loaded with the NO probe DAF-2DA, addition of exendin-4 (10 nM) resulted in a rapid increase in NO production in single living HCAECs. Additionally, exendin-4 promoted DNA synthesis in HCAEC after 48 h incubation in 5 mM glucose, evaluated by thymidine incorporation and neogenesis, confirmed by an increased cell number. Incubation of the cells with high glucose or palmitate provoked apoptosis and cell death, both of which were completely prevented by exendin-4.

Conclusions: Our study reveals salutary effects of exendin-4 on cell regeneration and protection from glucolipoapoptosis in human coronary artery endothelial cells, effects that are associated with increased eNOS activity and NO production. These novel findings add yet other beneficial properties of exendin-4, increasing its clinical utility in type 2 diabetic patients in whom endothelial dysfunction is a salient feature that adversely affects their survival. Elucidation of the mechanisms underlying these beneficial vascular effects of exendin-4 may be exploited when intervening pharmacologically against vascular dysfunction in diabetes and may form the basis of improved incretin enhancers that hold the potential to prevent vascular lesions in diabetic patients.

Interaction of C-reactive protein with leptin impairs its ability to stimulate eNOS through alpha1AMP activation in human aortic endothelial cells

F. Andreozzi, C. Procopio, E. Laratta, P. Iania, I. Laino, I. Presta, D. Scarpelli, G. Ruscio, M. L. Hribal, G. Sesti;
Department of Experimental and Clinical Medicine, University of Catanzaro-Magna Græcia, Italy.

Background and Aims: Obesity is associated with leptin-resistance, increased circulating C-reactive protein (CRP) levels and endothelial dysfunction. Recent evidence suggests that leptin can modulate vascular tone through local mechanisms involving NO release. Vasorelaxant responses to ACh are markedly attenuated in mesenteric microvessels from ob/ob mice while leptin replacement reverts this phenotype. Leptin selectively stimulates phosphorylation and activation of the alpha2 catalytic subunit of AMPK in skeletal muscle resulting in stimulation of fatty acid oxidation in muscle by inhibiting acetyl-CoA carboxylase (ACC) activity. In human endothelial cells, activation of AMPK induces eNOS phosphorylation at Ser¹¹⁷⁷ and NO production. We hypothesized that leptin may exert vasodilator action by stimulating phosphorylation and activation of eNOS in vascular endothelium increasing production of NO via a AMPK-dependent pathway.

Materials and Methods: Human Aortic Endothelial Cells (HAEC) were treated with leptin alone (10ng/ml for 20 min), or after stimulation with AICAR (2mM for 1h) or 5-Iodotubercidin (0.2 micro for 3h). Smart pool siRNAs were used to knockdown expression of human alpha1- or alpha2-AMPK in transient transfection assay. eNOS Activity Assay kit was used to measure eNOS activity by monitoring the conversion of [³H]Arginine to Citrulline after leptin stimulation.

Results: Exposure of cultured human aortic endothelial cells (HAECs) to leptin resulted in phosphorylation of both Thr¹⁷² AMPK and Ser⁷⁹ ACC. Similar results were observed with AICAR. Both leptin and AICAR stimulates Ser¹¹⁷⁷ eNOS phosphorylation. AMPK chemical inhibitor 5-Iodotubercidin was able to revert the stimulatory effect of leptin. To confirm the role of AMPK in mediating vasodilator action of leptin, we used siRNAs to specifically knockdown either the alpha1 or alpha2 isoform of AMPK catalytic subunit. In transient transfection assays, selective siRNAs reduced by 80% the abundance of both alpha1 and alpha2 AMPK isoforms. The stimulatory effect of leptin on Ser¹¹⁷⁷ eNOS was blocked by alpha1AMPK siRNA, but not alpha2AMPK siRNA, indicating that leptin stimulates eNOS through alpha1AMPK. To reproduce these results *in vivo*, we acutely treated C57BL/6J mice with human leptin. In aortas of mice, leptin stimulated both Thr¹⁷² AMPK and Ser¹¹⁷⁷ eNOS phosphorylation. Recent studies have suggested that a potential mechanism contributing to leptin resistance *in vivo* is the inhibitory action of CRP, which binds to leptin and attenuates its physiological functions. To test this phenomenon *in vitro*, we pre-incubated human leptin in the presence of human CRP for 30min before treating HAECs. We observed that leptin pre-incubated with CRP was unable to stimulate both Thr¹⁷² AMPK, Ser⁷⁹ACC and Ser¹¹⁷⁷ eNOS phosphorylation.

Conclusion: These data suggest that leptin has novel vascular actions, since it acutely activates eNOS in HAECs through a signaling pathway that involves alpha1AMPK. Moreover, the data confirm the cross-talk between leptin and the inflammatory protein CRP raising the possibility that disruption of leptin-CRP interaction may be a new therapeutic objective for the treatment of obesity-related vascular complications.

0027

Calreticulin induces dysfunctional vascular endothelial cell-extracellular matrix interactions under high glucose conditions

S. Sasson, Y. Riahi;
Department of Pharmacology, Hebrew University School of Medicine, Jerusalem, Israel.

Background and Aims: Recent studies show that hyperglycaemia increases the expression of the protein calreticulin in vascular cells *in vitro* and *in vivo*. Among other functions, calreticulin also controls cell-extracellular matrix (ECM) interactions by binding to and activating key proteins of the adhesion network to form focal ECM-contacts. We aimed at investigating whether overexpression of calreticulin contributes to dysfunctional VEC-ECM interactions in diabetes.

Materials and Methods: Primary cultures of bovine aortic endothelial cells were prepared and exposed to 2 or 25 mmol/l D-glucose in complete Dulbecco's modified Eagle's medium (DMEM). Adenovirus expressing calreticulin and siRNA constructs were used to augment or silence calreticulin expression, respectively. Calreticulin mRNA and protein content in VEC were determined by real-time PCR and Western blot analyses. VEC proliferation, adhesion to matrix proteins, *in vitro* re-endothelisation potential, expression levels and tyrosine phosphorylation of adhesion proteins and binding of calreticulin to adhesion molecules were determined by using established assays and immunoprecipitation protocols.

Results: Hyperglycaemic conditions slow the rate of proliferation, motility and the ability of VEC to fill in 'scratches' to restore confluent and uninterrupted VEC monolayers *in vitro*. Our results show that these effects reflect an enhanced adherence of VEC to ECM components (e.g., fibronectin) under high glucose conditions in comparison with cells exposed to low glucose. This effect was not due to the slight increase in the osmotic pressure of the high-glucose DMEM, since supplementation of the medium with high L-glucose level had no significant effects in these assays. When exposed to high D-glucose level, but not to L-glucose, VEC nearly doubled calreticulin mRNA and protein content in comparison with VEC at low glucose. A central role of calreticulin in modifying VEC-ECM interactions was established following an adenovirus-mediated overexpression of the protein in VEC that had been maintained at 2 mmol/l D-glucose. The proliferation and re-endothelisation behaviour of these cells were similar to that of VEC that were maintained at 25 mmol/l D-glucose. Moreover, VEC, which were exposed to 25 mmol/l D-glucose and in which calreticulin expression was silenced, acquired rates of proliferation and adherence capacity to ECM components characteristic of VEC incubated at 2 mmol/l D-glucose. Incubation of VEC at the high glucose level also increased the intracellular binding of calreticulin with the integrin-alpha receptor subunit. In parallel, it augmented the expression and tyrosine phosphorylation of paxillin and vinculin and of focal adhesion kinase (FAK). These proteins participate in the assembly of focal adhesion ECM-contacts. Similar interactions were observed in VEC overexpressing calreticulin. Conversely, silencing of calreticulin expression in these cells or transferring them to 2 mmol/l D-glucose significantly decreased the expression, tyrosine phosphorylation and association with calreticulin of these adhesion proteins.

Conclusions: We suggest that calreticulin recruits the adhesion machinery in VEC to form multiple and stronger focal contacts with the ECM. These interactions, which are enhanced under hyperglycaemic conditions, may impede the healing of lesions in the endothelial cell monolayer in blood vessels and contribute to diabetes-induced vasculopathy.

Telmisartan inhibits AGEs-induced asymmetric dimethylarginine accumulation by suppressing receptor for AGEs-mediated reactive oxygen species generation

A. Hayashida, S. Ueda, S.-I. Yamagishi, H. Miyazaki, Y. Matsumoto, K. Fukami, S. Okuda;
Department of Medicine, Kurume University School of Medicine, Japan.

Background and Aims: There is a growing body of evidence that asymmetric dimethylarginine (ADMA), an endogenous nitric oxide synthase inhibitor, could play an important role in endothelial dysfunction and atherosclerosis. Advanced glycation end products (AGEs), the senescent macroprotein derivatives which are formed in increased amounts in patients with diabetes and/or chronic kidney disease, have been also shown to contribute to atherosclerosis. However, a functional relationship between ADMA and AGE levels has not been fully understood.

Materials and Methods: Fifteen patients with end-stage diabetic nephropathy (ESRD) (24h Ccr < 10 ml/min, ranged 2.3–9.8 ml/min) who did not undergo hemodialysis treatment were enrolled in this study. Serum levels of ADMA and AGE were measured by HPLC and ELISA, respectively. Flow-mediated vasodilation (FMD) of the brachial artery was measured to assess endothelial function. *In vitro*, AGE were prepared by incubating BSA with 0.1 mol/l D-glyceraldehyde for 7 days. Reactive oxygen species (ROS) generation was measured by using the fluorescent probe CM-H₂DCFDA. RAGE expression was analyzed by western blotting.

Results: Plasma ADMA levels were inversely related to FMD (p<0.01) and were found to be significantly associated with plasma AGEs levels

($p < 0.05$). Therefore, we next performed the *in vitro*-experiments to clarify the molecular link between ADMA and AGEs using cultured human endothelial cells (ECs). AGEs significantly decreased enzymatic activity of dimethylarginine dimethylaminohydrolase (DDAH), a rate-limiting enzyme for ADMA degradation and subsequently increased ADMA production by cultured ECs, both of which were completely blocked by an antioxidant, *N*-acetylcysteine or telmisartan, an angiotensin II type-I receptor antagonist. Moreover, telmisartan was found to inhibit AGE-induced reactive oxygen species (ROS) generation by suppressing RAGE expression.

Conclusion: Our present study suggests that AGEs could inhibit DDAH activity and subsequently enhanced ADMA accumulation in ECs through RAGE-mediated ROS generation, thereby contributing to atherogenesis in patients with ESDN. Blockade by telmisartan of the AGE-RAGE interaction could play a protective role against endothelial dysfunction in ESDN by reducing ADMA.

Tumor necrosis factor modulates glycolysis, the glyoxalase system and induces the formation of specific methylglyoxal-modified proteins in aortic endothelial cells

M. Laga, F. Van Herreweghe, K. Vancompernelle;
VIB Dept. of Medical Protein Research, University of Ghent and VIB, Belgium.

Background and Aims: It is well established that the formation of intracellular methylglyoxal (MG)-derived Advanced Glycation End products (MG-AGEs) is one of the pathways that leads to hyperglycemic damage in endothelial cells. We have previously shown that Tumor Necrosis Factor (TNF) can induce the rapid formation of specific MG-derived AGEs in a tumor cell death model. Furthermore, these MG-AGEs are formed as a consequence of oxidative stress and involve the TNF-induced phosphorylation of glyoxalase I (GLO1). GLO1 is normally responsible for the detoxification of the cytotoxic glycolytic metabolite methylglyoxal. Because TNF can also contribute to the development of vascular complications in diabetes, the purpose of this study was to investigate whether TNF induces phosphorylation of GLO1, the formation of specific MG-derived AGEs and whether TNF modulates glycolysis and the glyoxalase system in aortic endothelial cells under normo- and hyperglycemic conditions.

Materials and Methods: Primary bovine aortic endothelial cells (bAEC) were incubated with TNF for different time points. The TNF-induced phosphorylation of GLO1 was investigated by 2-dimensional gelelectrophoresis combined with Western blotting using a polyclonal anti-glyoxalase antibody. The formation of specific MG-AGEs was investigated by two methods namely, by Western blotting using a monoclonal antibody (mAb6B) that recognizes a MG-derived argpyrimidine epitope and by *in vivo* cell labelling using ^{14}C -MG. The TNF-induced effect on glucose metabolism was examined by 2 parameters, namely by measuring the levels of fructose-2,6-bisphosphate (F2,6BP), an allosteric activator of PFK1, and by measuring glucose uptake using ^3H -labelled 2-deoxyglucose. The TNF-induced effect on the glyoxalase system was investigated by measuring the end product D-Lactate and GLO1 activities.

Results: TNF induces a rapid phosphorylation of GLO1 in primary bovine aortic endothelial cells (bAEC). This is not accompanied by a decrease in GLO1 activities in TNF-treated cells. Instead, TNF induces a rapid increase in the concentrations of D-lactate. These data indicate that TNF increases the intracellular concentrations of MG, which are not caused by inhibition of the detoxification of MG through the glyoxalase system, but are presumably derived from the TNF-induced stimulation of glycolysis. Indeed, TNF induces a considerable increase in glucose uptake in bAEC and strongly increase the F2,6BP levels, an allosteric activator of glycolysis. Furthermore, by using ^{14}C -MG, we could show that TNF induces the formation of specific MG-modified proteins in endothelial cells under normo- and hyperglycaemic conditions. It remains to be determined whether phosphorylated GLO1 mediates the formation of these specific MG-AGEs in endothelial cells.

Conclusion: Here we show for the first time that TNF induces increased intracellular levels of methylglyoxal and the formation of specific MG-modified proteins in aortic endothelial cells. This may be one of the underlying molecular mechanisms by which TNF contributes to the development of vascular complications in diabetes.

Reduction of both number and proliferative activity of human endothelial progenitor cells in obese patients

M. Artwohl¹, K. Tobler¹, M. Wolzt¹, C. Maier¹, B. Ludvik¹, A. Freudenthaler¹, D. Seidinger², S. Steiner-Böcker², E. Nansalma¹, A. Luger¹, S. M. Baumgartner-Parzer¹;

¹Medical University Vienna, Department of Internal Medicine III, Division of Endocrinology and Metabolism, ²Medical University Vienna, Department of Internal Medicine II, Division of Angiology, Austria.

Background and aims: Bone marrow-derived endothelial progenitor cells (EPCs) have only recently been described to circulate in human peripheral blood. Circulating EPCs are assumed to have a role in neoangiogenesis (new blood vessel formation) and vascular repair. Moreover, circulating numbers of EPCs have been shown to negatively correlate with risk factors for atherosclerosis and with disorders associated with vascular dysfunction. So far, it has been shown that the angiogenic activity of EPCs is reduced in obese, diabetic mice in comparison to lean, non-diabetic controls and that high concentrations of the adipose tissue-derived hormone leptin impair migration and tube formation of cultured human EPCs. On the basis of these findings the present study tested the hypothesis that number and proliferative activity of circulating human EPCs are different in obese versus lean control subjects.

Materials and Methods: Written informed consent was obtained from all subjects participating in this study. In brief, peripheral blood mononuclear cells (PBMCs) were isolated by density gradient centrifugation from whole blood obtained from obese- (BMI=46±1 [Range: 35–59], n=30) and lean subjects (BMI=22±1 [Range: 18–27], n=30). EPCs, expressing CD34⁺/CD133⁺/KDR⁺, were quantified using FACS-analyses. *In vitro*, EPCs grew out from colonies and, as a result of selective culture conditions, differentiated into mature endothelial cells, which were characterized by expression of CD31⁺ (PECAM), CD144⁺ (VE-Cadherin), and CD146⁺ (S-endo). Protein expression was determined by Western blot analyses.

Results: Blood glucose, triglycerides, cholesterol, LDL, apolipoprotein B, and lipoprotein (a) were not different in lean versus obese subjects. However, obese patients had higher ($p < 0.001$) HbA_{1c} (5.9±0.2% vs. 5.2±0.1%) and hsCRP (1±0.1mg/dl vs. 0.2±0.1mg/dl), but lower ($p < 0.001$) HDL (46.4±2.3mg/dl vs. 65.3±1.9mg/dl) and apolipoprotein A1 (121.4±3.4mg/dl vs. 152.3±4.5mg/dl) levels. Independent of the BMI, the number of CD34⁺/CD133⁺/KDR⁺-EPCs was positively associated with HDL (+1.8 EPCs / 10mg/dl HDL) and negatively with hsCRP (−3.2 EPCs / 1mg/dl CRP). Compared to their age and sex matched lean controls, obese patients had 38% ($p < 0.05$) less CD34⁺/CD133⁺/KDR⁺-EPCs, reflecting a reduction by 1.4 EPCs per 10kg/m². The proliferative capacity of cultured endothelial cells differentiated from the EPCs of lean control subjects was 20.3±3.3% per week, whereas it was only 9.6±2.2% in endothelial cells, differentiated from obese patients' EPCs. Reduced proliferative activity of obese patients' EPCs is reflected by decreased ($p < 0.05$) protein expression of cyclins (cyclin D3: −20±10%, cyclin E: −23±11%, cyclin A: −40±11%, cyclin B: −31±10%) and of the transcription factor E2F-1 (−17±6%) as well as by increased ($p < 0.05$) expression of the cell cycle inhibitor p21^{WAF-1/Cip1} (+41±17%) in these cells.

Conclusions: Reduction of both the number and the proliferative capacity (as shown in *in vitro* experiments) of circulating endothelial progenitor cells, could well contribute to development and progression of vascular dysfunction in obese patients.

OP 6 Predictors and markers of cardiovascular disease and mortality

HbA_{1c} in relation to 10-year fatal and non-fatal cardiovascular disease: The Hoorn Study

E. van 't Riet¹, J. M. Rijkkelijkhuizen¹, G. Nijpels¹, C. D. A. Stehouwer², L. M. Bouter¹, R. J. Heine³, J. M. Dekker¹;
¹EMGO-Institute, VU University Medical Centre, Amsterdam,
²Department of Internal Medicine, Academic Hospital Maastricht,
³Department of Endocrinology, VU University Medical Centre, Amsterdam, The Netherlands.

Background and Aims: Several large-scale studies have shown that in type 1 and type 2 diabetes patients HbA_{1c} is a strong predictor of cardiovascular disease. In the general non-diabetic population, the association between HbA_{1c} and both fatal and non-fatal cardiovascular disease are less clear. Therefore, we have investigated the associations between HbA_{1c} and 10-year fatal and non-fatal cardiovascular disease and with all-cause mortality in people without diabetes in a population based study.

Materials and Methods: The Hoorn Study is a population-based cohort study with 2484 participants at baseline in 1989 to 1990. The present study population comprised 1674 subjects without diabetes (known or newly-detected) at baseline and without missing data on HbA_{1c}, glucose levels and morbidity. Associations were analysed using Cox survival analysis, with HbA_{1c} as a continuous variable. Adjustments were made for age, sex, hypertension, LDL cholesterol, triglycerides, waist-to-hip ratio and smoking.

Results: The age- and sex-adjusted hazard ratios (with 95% confidence intervals) for all-cause mortality, CVD morbidity, CVD mortality and CVD morbidity and mortality combined were 1.37 (1.05–1.80), 2.00 (1.56–2.57), 1.62 (1.09–2.41) and 1.94 (1.54–2.43), respectively. After adjustment for traditional cardiovascular risk factors the association between HbA_{1c} and CVD morbidity remained significant, with a hazard ratio of 1.66 (1.28–2.13)

Conclusion: This is the first study in which the association of HbA_{1c} with cardiovascular disease in a population based study in people without diabetes was studied. Results showed that an increase of 1% of HbA_{1c} is associated with an approximate 66% increase in risk of developing non-fatal cardiovascular disease, independent of other known cardiovascular risk factors.

HbA_{1c} in relation to morbidity and mortality (hazard ratios with 95% CI)

	Model 1 (age and sex adjusted)	Model 2 (adjusted for age,sex, hypertension, smoking, LDL, triglycerides and waist-to-hip ratio)
All-cause mortality	1.37 (1.05–1.80)	1.20 (0.91–1.57)
Fatal CVD	1.62 (1.09–2.41)	1.26 (0.84–1.88)
Non-fatal CVD	2.00 (1.56–2.57)	1.66 (1.28–2.13)
Fatal and non-fatal CVD	1.94 (1.54–2.43)	1.60 (1.27–2.01)

0032

Fasting insulin and HOMA better predict cardiovascular events in non-diabetic women than in men

L. H. Oterdoom^{1,2}, A. P. de Vries^{1,2}, R. T. Gansevoort², P. E. de Jong², R. O. Gans¹, S. J. Bakker¹;

¹Department of Medicine, ²Department of Nephrology, University Medical Center Groningen, The Netherlands.

Background and Aims: Cardiovascular (CV) disease is the leading cause of death in diabetic and non-diabetic women. Almost all studies on fasting insulin as CV risk factor have been performed in non-diabetic men. Because diabetes mellitus is known to carry a greater CV risk in women than in men, we surmised that there may be a gender-difference in predictive properties of fasting insulin and Homeostasis Model Assessment (HOMA). We investigated prospectively whether fasting insulin and HOMA predict CV events in a non-diabetic general population, with an emphasis on a putative gender difference.

Materials and Methods: Fasting insulin was assessed in 7134 non-diabetic, fasting subjects of the PREVEND study. Major adverse cardiovascular events (MACE) were defined as the combination of CV morbidity and CV mortality. CV mortality was defined according to the cause of death as coded by the Dutch Central Bureau of Statistics. Events were recorded prospectively from baseline survey (1997-1998) until October 31st 2005. HOMA was calculated as: [glucose (mmol/L) x insulin (μU/ml) / 22.5]. Gender interaction was tested by entering an interaction term of insulin x gender and HOMA x gender in Cox-Regression analyses. Subsequent analyses were performed for women and men separately.

Results: Characteristics of the population are shown in table 1. During a median [interquartile range] follow-up of 7.4 [7.1–7.6] years, MACE occurred in 129 women and in 322 men. There was significant gender interaction for fasting insulin and HOMA as predictor of MACE (both P=0.002). The interaction indicated that with increasing insulin (fig 1) and HOMA, CV risk increased more in women than in men. After adjustment for smoking and BMI, the hazard ratio (HR [95%CI]) of the 4th vs the 1st quartile of insulin remained significant in women (1.9 [1.0–3.5], P<0.05), but not in men (1.2 [0.8–1.7], P=0.4). Results were not materially changed for HOMA (data not shown).

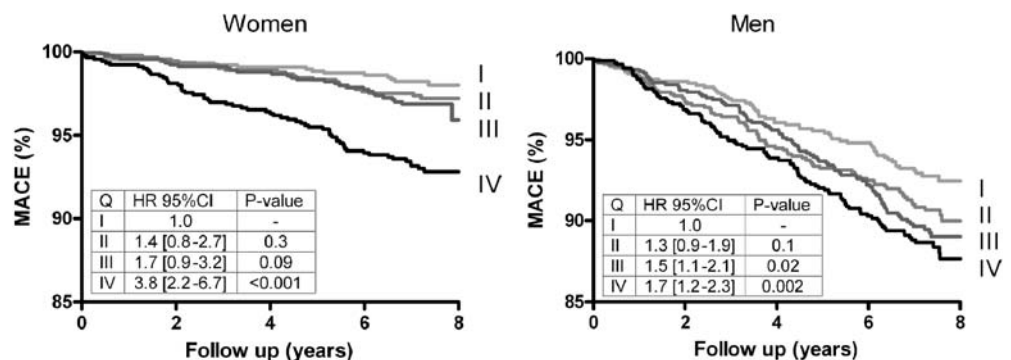

Conclusion: It has not been investigated before whether fasting insulin and HOMA bear a different CV risk in women and men. We found significant effect-modification by gender for both fasting insulin and HOMA, indicating that insulin resistance parallels diabetes with regard to an increased CV risk in women compared to men. Our results indicate that specific attention for interventions can potentially provide greater benefit in insulin resistant women than in insulin resistant men. (Fig. 1)

The NDR Risk Model – A novel tool for prediction of coronary risk in type 2 diabetic patients from the Swedish National Diabetes RegisterS. Gudbjornsdottir¹, J. Cederholm², K. Eeg-Olofsson¹, B. Eliasson¹, P. M. Nilsson³;¹Goteborg University, Department of Medicine, ²Department of Public Health and Caring Sciences, Family Medicine and Clinical Epidemiology Section, Uppsala, ³Department of Clinical Sciences Medicine, Division of Medicine, Lund, Sweden.

Background and Aims: There are a number of models for cardiovascular risk prediction in type 2 diabetes, most notably the UKPDS Risk Engine, which was constructed from baseline data in 4540 newly detected type 2 patients followed for 10 years (less than one-third were on antihypertensive treatment and only few used lipid-lowering agents at baseline). However, more patients than previously are now under long-term drug treatment for risk factors, which is not fully accounted for in current risk models.

Material and Methods: We used prospective data from the NDR of Sweden (1997–98), comprising 21 315 type 2 diabetic men and women (age 18–65 years, mean 57 years) followed for 6 years. Baseline risk factors included age, gender, diabetes duration, HbA_{1c}, use of antihypertensive and lipid-lowering drugs, smoking and microalbuminuria. Outcome measures in Cox regression analysis were incident fatal or non-fatal coronary heart disease (CHD) events (myocardial infarction, unstable angina, or PCI/CABG intervention; data from the Swedish hospital discharge register).

Results: Based on 120 603 person-years and 3162 CHD events, independent risk ratios (95% confidence intervals) for the included variables were in rank order: use of lipid-lowering drugs 1.520 (1.379–1.676), use of antihypertensive drugs 1.359 (1.260–1.466), smoking 1.279 (1.151–1.422), microalbuminuria 1.140 (1.054–1.234) and HbA_{1c} 1.087 (1.060–1.115). All variables were significant (P-values <0.001 except microalbuminuria, P=0.0011). Using these risk ratios and the ratios for age, sex and diabetes duration, an equation was created for estimation of the 10-year risk for fatal/non-fatal CHD.

This NDR Risk Model was applied in 20 879 type 2 diabetic patients aged 18–65 years with clinical data from 2005 (mean diabetes duration 6.4 years; 62% on antihypertensive and 50% on lipid-lowering treatment). The mean calculated 10-year risk for fatal/non-fatal CHD was 22±9%, compared to a calculated mean 10-year risk of 16±10% for fatal/nonfatal myocardial infarction when using the UKPDS Risk Model in the same cohort.

Conclusion: Using a model based on data from the NDR, the 10-year risk of CHD in a cross-sectional national sample of type 2 diabetic patients was about 40% higher than the comparable risk found when the UKPDS Risk Engine was applied. The NDR Risk Model for type 2 diabetic patients should be validated in independent cohorts.

0034

Do people with diabetes detected by a universal risk score have an increased risk of dying? The DETECT-2 studyD. Vistisen¹, C. Glümer¹, A. C. Jensen¹, S. Colagiuri², K. Borch-Johnsen¹;¹Department of Epidemiology, Steno Diabetes Center, Gentofte, Denmark,²Australian Centre for Diabetes Strategies, Prince of Wales Hospital, Randwick, Australia.

Background and Aims: Several risk scores for type 2 diabetes have been developed. Whether they identify individuals at highest risk of death or complications is still uncertain. The aim of this study was to examine whether a universal risk score for detecting undiagnosed diabetes also identifies individuals with the highest mortality risk.

Materials and Methods: Results are based on follow-up data in the DETECT-2 project. Five geographical regions were included, the age range was 30–74 years (N= 44,513) with a total of 5,477 deaths over 412,840 person-years. The universal risk score includes information on age, sex, BMI, and systolic blood pressure. All individuals had an OGTT performed. Screen detected diabetes (SDM) was defined according to the 1999 WHO diagnostic criteria. The universal risk score includes information on age, sex, BMI and systolic blood pressure. A score above a predefined threshold was considered screen positive. Individuals were classified as true positive (TP), false positive (FP), false negative (FN) and true negative (TN) accordingly. All-cause mortality was measured and Poisson regression analysis was used to calculate mortality rates. For the regions, mean follow up time was between 5 and 12 years.

Results: Screen positives were significantly older, more obese, with higher BP and cholesterol levels. The fraction of men was higher, but with less current smokers when comparing with the screen negative group. Crude mortality rates were higher in the screen positive group. However, when adjusting for age and sex this excess mortality disappeared in all regions except Europe. For all regions, excess mortality for screen positives was found in the population below 60 years of age.

Conclusion: The universal risk score predicts diabetes but only excess mortality in the population below 60 years of age.

Rate ratios (RR) for all cause mortality by screening category and region

Region		TP	FP	FN	TN
Europe	Crude RR	3.0 (2.6–3.4)	1.7 (1.6–1.8)	2.2 (1.8–2.6)	1

Type of preadmission antidiabetic treatment and mortality among patients hospitalized with myocardial infarction: a nationwide follow-up studyH. Thisted^{1,2}, F. Søndergaard¹, S. P. Johnsen^{1,3}, J. Rungby^{2,4};¹Department of Clinical Epidemiology, Aarhus University Hospital,²Department of Pharmacology, University of Aarhus,³Center of Cardiovascular Research, Aalborg Hospital, Aalborg,⁴Department of Endocrinology C, Aarhus University Hospital, Denmark.

Background and Aims: Improved glycaemic control may prevent cardiovascular complications in patients with type 2 diabetes mellitus. However, antidiabetic treatment may also be associated with adverse cardiovascular effects. Clinical studies have indicated an increased cardiovascular mortality among patients using some sulphonylureas as well as among patients using metformin. However, data are sparse and conflicting and we therefore sought to determine the impact of different types of antidiabetic treatment, including sulphonylureas, metformin and insulin, on mortality in patients with type 2 diabetes mellitus after hospitalization for myocardial infarction (MI).

Materials and Methods: We examined the mortality among users of the different antidiabetic therapies in a nationwide population-based follow-up study in Denmark. We identified 72,295 patients with a first-time hospitalization for MI in Denmark in the period 1996–2004 using data from the Danish National Patient Registry (DNPR). Among MI patients, data on diabetes and type of antidiabetic treatment were obtained from the DNPR and a national prescription database. Mortality was determined through the Civil Registration System. We estimated 30-day and 1-year hazard ratios (HRs) associated with the use of different antidiabetic treatments prior to MI adjusted for a range of prognostic factors including duration of diabetes, use of cardiovascular drugs and level of comorbidity using Cox regression analysis.

Results: We identified a total of 8,494 MI patients with type 2 diabetes mellitus. The overall 30-day and 1-year mortalities were 22.2% and 36.6%. We found no significant differences between the oral antidiabetic treatments, but the use of insulin was associated with an increased risk compared with the use of sulphonylureas (table). Adjusted HR for metformin was low, however non-significantly. Similar observations were evident during the 1-year follow-up period.

30-day HRs according to antidiabetic treatment

Antidiabetic treatments	N	Deaths	Mortality	Adjusted HRs (95% CI)
Sulphonylurea (mono)	2,635	605	23.0%	1.00 (reference)
Metformin (mono)	502	67	13.4%	0.90 (0.70–1.17)
Insulin (mono)	1,784	445	24.9%	1.16 (1.01–1.34)
Any combination	1,314	259	19.7%	1.09 (0.94–1.27)
No pharmacotherapy	2,098	475	22.6%	1.02 (0.89–1.16)

Conclusion: Mortality after MI remains high in patients with type 2 diabetes mellitus. Pre-MI antidiabetic treatments do not appear to be associated with substantial differences in mortality.

Human atrial natriuretic peptide (ANP) gene and metabolic risk factors in the French population

S. Maimaitiming^{1,2}, R. Roussel^{1,3}, F. Fumeron^{1,2}, K. Mohammedi^{1,3}, S. Hadjadj⁴, R. Aubert¹, B. Balkau⁵, M. Marre^{1,3},

¹INSERM, U 695, Paris, ²University Denis Diderot, Paris,

³AP-HP, Hôpital Bichat, Département d'Endocrinologie, Diabétologie, Paris,

⁴Diabetology, CHU, Poitiers, ⁵INSERM, U 258, Villejuif, France.

Background and Aims: The ANP plays an important role in blood pressure regulation, but also affects lipolysis in human adipocytes. This effect is reinforced by physical activity in overweight subjects. The gene coding for ANP (NPPA: natriuretic peptide precursor A) was thus considered as a candidate gene for susceptibility to hypertension and metabolic disorders. Our aim was to assess the effect of three NPPA polymorphisms, G664A (rs5063), 708C>T (rs5064) and 2238T>C (rs5065) on metabolic parameters levels and their interaction with overweight and physical activity in 5,212 French Caucasian subjects.

Materials and Methods: Subjects took part in DESIR (Epidemiologic Data on the Insulin Resistance Syndrome), a cohort of 2576 men and 2636 women from the middle-aged general population who were clinically and biologically evaluated at inclusion and at 3, 6 and 9-year visits. These SNPs were identified as tag SNPs in the Hapmap project and identified most of haplotypes at the NPPA locus. All quantitative tests are adjusted for sex, age and body mass index. The genotypes were determined by the Taqman process.

Results: In the whole population, there was a marginally significant effect of the 708C>T SNP on waist girth [CC: 83.5 ± 0.1cm, (n=4181), CT: 83.1 ± 0.2 (n=865) and TT: 81.2 ± 0.9 (n=51) *p*=0.04], HDL-C (CC: 1.63 ± 0.01 mM, CT: 1.63 ± 0.01 and TT: 1.77 ± 0.03, *p*=0.04) and ApoA1 levels (CC: 1.64 ± 0.01 g/l, CT: 1.65 ± 0.02 and TT: 1.72 ± 0.04, *p*=0.03). The 708C>T SNP interacted with overweight on triglycerides (TG), waist girth and serum glutamic pyruvic transaminase (SGPT) (*p*=0.002, *p*=0.03 and *p*=0.02 respectively for interaction) and in overweight subjects, was associated with TG [CC: 1.51 ± 0.03mM, (n=1834), CT: 1.37 ± 0.07 (n=389) and TT: 1.13 ± 0.31 (n=21), *p*=0.009], waist girth (CC: 93.1 ± 0.2cm, CT: 92.1 ± 0.4 and TT: 89.1 ± 1.8, *p*=0.009) and SGPT concentrations (CC: 31.8 ± 0.4, CT: 28.5 ± 0.9 and TT: 26.9 ± 4.2, *p*=0.006). 708C>T TT carriers had lower triglyceride concentrations in the physically active overweight subjects (*p*=0.01). The 2238T>C SNP interacted with overweight on waist girth and SGPT (*p*=0.08 and *p*=0.04 respectively for interaction) and in overweight subjects, was associated with waist girth [TT: 93.1 ± 0.2cm, (n=1521), TC: 92.4 ± 0.3 (n=574) and CC: 91.1 ± 0.9 (n=48), *p*=0.03] and SGPT concentrations (TT: 31.8 ± 0.5, TC: 29.5 ± 0.8 and CC: 26.1 ± 2.7, *p*=0.01). No association was found with 664G>A. Haplotype GTC, the only frequent haplotype with the minor allele of 708C>T and 2238T>C, was significantly associated with lower waist girth level (*p*=0.007), TG (*p*=0.02) and SGPT concentrations (*p*=0.008) in overweight subjects.

Conclusion: NPPA tag SNPs and haplotypes may be associated with cardiovascular risk in the general French population through association with lipid levels, in particular in overweight subjects.

Weight reduction modulates mRNA expression of pro-inflammatory molecules involved in NFκB activation and insulin signaling in subjects with the metabolic syndrome – the GENOBIN study

V. D. F. Mello^{1,2}, M. Kolehmainen¹, U. Schwab^{1,3}, U. Mager¹, D. E. Laaksonen³, L. Pulkkinen¹, L. Niskanen³, H. Gylling^{1,3}, R. Rauramaa^{4,5}, M. Uusitupa¹;

¹School of Public Health and Clinical Nutrition/Food and Health Research Centre, University of Kuopio, Finland, ²Internal Medicine, Federal University of Rio Grande do Sul, Porto Alegre, Brazil, ³Institute of Medicine, Internal Medicine, Kuopio University Hospital, Finland, ⁴Kuopio Research Institute of Exercise Medicine, University of Kuopio, Finland, ⁵Department of Clinical Physiology and Nuclear Medicine, Kuopio University Hospital, Finland.

Background and Aims: Circulating mononuclear cells have been implicated in the low-grade inflammatory state of obese individuals and in the pathogenesis of insulin resistance. Previously we showed that weight loss altered gene expression of selected cytokines in peripheral blood mononuclear cells (PBMCs), which was associated with an improvement of insulin and glucose metabolism in subjects with the metabolic syndrome (MS). We sought to evaluate how weight loss would affect mRNA expression of genes related to immunological and endothelial function and pro-inflammatory mediators, such as nuclear factor-κB (NFκB) inhibitor kinase beta (IKKβ) and suppressor of cytokine signalling-3 (SOCS3), all of which are related to NF-κB activation.

Materials and Methods: Altogether 34 overweight or obese (BMI: 32.6 ± 3.1 kg/m²) subjects with the MS were randomized to either a weight reduction (WR) or a control group for 33 weeks. Subjects in the WR group had an intensive 12-wk weight loss period followed by a 21-wk period where the minimum aim was weight maintenance. The mRNA expression was studied using real-time PCR and TaqMan[®] chemistry at baseline and wk 33. Measures of insulin and glucose metabolism (intravenous and oral glucose tolerance tests) and body composition were also assessed.

Results: WR decreased the mRNA expression of intercellular cell adhesion molecule-1 (ICAM1) [median -14.4% (interquartile range: -23 - 0), *p*<0.01], regulated on activation, normal T cell expressed and secreted (RANTES) [mean -7.8% (95% CI: -20.1 - 4.6), *p*<0.001], IKKβ [median -9.1% (interquartile range: -24.4 - 20.6), *p*<0.001] and SOCS3 [median -11.5% (interquartile range: -26.7 - 3.6), *p*<0.001]. The decrease in RANTES mRNA expression was correlated with an increase in the insulin sensitivity index (S_i), even after adjustment for changes in body weight (*r*=-0.50), body fat % (*r*=-0.53), or waist circumference (*r*=-0.46, *p*<0.05 for all). The change in RANTES mRNA expression also correlated with the change in ICAM1 (*r*=0.39, *p*<0.05) and IKKβ mRNA expression (*r*=0.63, *p*<0.01).

Conclusion: Weight loss decreased the mRNA expression of RANTES and SOCS3 in the PBMCs of subjects with the MS. The decrease in RANTES mRNA expression was associated with an improvement in S_i and a decrease in ICAM1 and IKKβ mRNA expression. These results suggest that weight loss decreases expression of pro-inflammatory mediators associated with the NFκB activation and insulin signaling in the PBMCs of obese subjects with the MS, which is associated with an improvement in insulin sensitivity and endothelial function.

Intravenous insulin affects hypothalamic insulin receptor substrates and inhibits appetite-stimulating neuropeptides at euglycaemia in normal rats

S. D. Bouman¹, L. Jessen¹, P. J. Larsen², J. Jelsing², U. Ribel¹, J. Sturis¹, C. L. Brand¹;

¹Insulin Pharmacology, Novo Nordisk A/S, Maaloev,

²Basic Research Facilities, Rheoscience A/S, Roedovre, Denmark.

Background and Aims: Insulin has a signaling role in energy balance, with central insulin suppressing food intake and body weight. It has been suggested that peripheral insulin enters the brain and influences energy

balance via direct impact on hypothalamic neurons involved in appetite regulation. The aim of our study was to investigate the effect of peripheral hyperinsulinemia on appetite-regulating neuropeptides at euglycemia in freely-moving rats.

Materials and Methods: Normal male Sprague-Dawley rats were implanted with permanent catheters via the jugular vein and carotid artery. A week later, the rats were fasted overnight and then placed in cages allowing free movement and stress-free infusions and blood sampling. The animals were divided into five groups, and received a continuous intravenous infusion with either vehicle for 5 hours, a low dose of insulin ($15 \text{ pmol} \times \text{kg}^{-1} \times \text{min}^{-1}$) for 5 or 8 hours, or a high dose of insulin ($120 \text{ pmol} \times \text{kg}^{-1} \times \text{min}^{-1}$) for 5 or 8 hours. Arterial blood samples were withdrawn at 10-minute intervals for plasma glucose determination, and glucose was infused as needed to maintain plasma glucose at basal levels. The control group (infused with insulin vehicle) received saline instead of glucose. At the end of the infusion period the rats were sacrificed and their brains were removed and frozen. For analysis of neuropeptide changes, *in situ* hybridization on coronal cryostat sections was employed to quantify hypothalamic contents of mRNAs encoding neuropeptide Y (NPY), agouti-related peptide (AgRP), proopiomelanocortin (POMC), cocaine- and amphetamine-regulated transcript (CART), melanin-concentrating hormone (MCH), and corticotropin-releasing hormone (CRH). Hypothalamic mRNAs for the insulin receptor substrates IRS-2 and IRS-4 were also analyzed, to verify that insulin was directly involved in possible changes.

Results: A total of 46 rats were studied. All animals stayed normoglycemic throughout the studies, while plasma corticosterone indicated low stress levels. Plasma C-peptide (reflecting endogenous insulin secretion) was suppressed completely in the insulin-infused groups. Compared to the control vehicle group, insulin receptor substrates in the hypothalamus were affected by the insulin infusions, with a significant downregulation of IRS-4 in the arcuate nucleus ($p < 0.05$), and a tendency to upregulation of IRS-2 in the ventromedial hypothalamus. Neuropeptides were also changed by insulin, which decreased mRNA contents for AgRP ($p < 0.05$) and for NPY ($p = 0.07$) in the arcuate hypothalamus, in agreement with the proposed body weight regulating role of insulin. CART showed a small tendency to upregulation in the arcuate nucleus. POMC, MCH and CRH were not different between groups. In general, effects were stronger after 8 hours of insulin infusion than after 5 hours.

Conclusion: This study shows that peripheral insulin changes hypothalamic insulin receptor substrates and decreases hypothalamic appetite-stimulating neuropeptides, under non-stressed and non-hypoglycemic conditions. Thereby our study provides the first experimental support on the neuropeptide level for the concept that peripheral insulin acts as an afferent signal in the regulation of energy balance. These data also suggest involvement of hypothalamic IRS-4 in insulin's effects, in addition to the known role of IRS-2.

0039

Centrally-injected oleoyl-estrone reduces feeding and body weight in rats

J. R. Vasselli¹, P. J. Currie¹, T. Lukic², A. G. Harris³;

¹Obesity Research Center, A University Hospital of Columbia University College of Physicians and Surgeons, New York, ²R & D, Manhattan Pharmaceuticals Inc., New York, United States.

Background and Aims: Oleoyl-estrone (O-E) is a synthetic form of oleoyl-estrone, a molecule that exists naturally in the body as an endogenous acyl-estrone expressed and released from adipose tissue in proportion to body fat mass. O-E is currently in Phase IIa clinical trials for the treatment of obesity and morbid obesity. Previous studies have shown that oral and intravenous administration of O-E to rodents reduces both food intake and body weight. While O-E has anti-lipogenic effects, its site of action to produce reductions in feeding and body weight are not known. This study tests the hypothesis that O-E acts centrally by determining the effects of intracerebroventricular administration of O-E on food intake (FI) and body weight (BW) in normal lean rats.

Materials and Methods: Young adult male and female Sprague-Dawley (S-D) rats were implanted unilaterally with a stainless steel guide cannula targeted to the lateral or 3rd ventricles, respectively. Following recovery from surgery, the groups were microinjected with ascending doses of O-E dissolved in DMSO and diluted for injection with aCSF to a concentration of 0.5% DMSO. Single microinjections (4.0 and 2.0 μl volumes, respectively) of O-E were given in ascending order, with FI and BW measured in the males at 24 and 48 hrs

post-microinjection, and in females at 5, 24 and 48 hrs post-microinjection. O-E doses tested were vehicle, 100, 250, and 500 ng. Microinjection tests were separated by a minimum of 3 days.

Results: In males, microinjection of O-E significantly and dose-dependently reduced BW at 24 hrs post-microinjection ($p < 0.05$), with a maximum reduction vs. pre-test BW baseline at 500 ng of -10.6 g (from a starting weight of 485 g). Slight but non significant reductions of FI by O-E were noted in males. In females, microinjection of O-E significantly reduced BW at 5 hrs post-microinjection at 250 and 500 ng ($p < 0.01$), and at 24hrs post-microinjection at 250 ng ($p < 0.01$). A maximum BW reduction of -5.1 g at 24 hrs at 250 ng was observed (starting weight of 295 g). Also in females O-E reduced first 24-hr post-microinjection FI at the 250 and 500 ng doses ($p < 0.05$), with a maximum reduction vs. pre-test FI baseline of -4.6 g at the 250 ng dose. FI remained reduced ($p < 0.01$) at this level in the females at the 250 ng dose during the second 24-hr post-microinjection interval.

Conclusion: Acute cerebroventricular microinjections of O-E significantly and dose-dependently reduced BW in normal lean female and male S-D rats. In addition, O-E significantly reduced 24-hr food intake in females on the first and second days following microinjection. Significant reductions of BW in females prior to reductions of FI indicate that O-E enhanced energy expenditure as well as inhibited feeding. Our data indicate that in addition to its demonstrated peripheral anti-lipogenic effects, O-E acts centrally to inhibit feeding and reduce body weight in rats.

A common variant in the FTO gene region is associated with BMI in the general population and predisposes to adult and childhood obesity

H. Lango¹, M. N. Weedon¹, N. J. Timpson², E. Zeggini², R. M. Freathy¹, C. M. Lindgren², J. R. B. Perry¹, K. S. Elliott², N. W. Rayner², C. J. Groves², G. Davey-Smith³, the UK Type 2 Diabetes Genetics Consortium,

T. M. Frayling¹, A. T. Hattersley¹, M. I. McCarthy²;

¹Genetics of Complex Traits & Diabetes Genetics, Peninsula Medical School, Exeter, ²Wellcome Trust Centre for Human Genetics & OCDEM, University of Oxford, ³Department of Social Medicine, University of Bristol, United Kingdom.

Background and Aims: Obesity is a major risk factor for type 2 diabetes, and has a strong genetic component. However, there are no known examples of common genetic variants for which there is widely-replicated evidence of an effect on obesity. Using a genome-wide association study we aimed to identify common gene variants predisposing to obesity.

Materials and Methods: We used data from ~394,000 SNPs in 1924 UK type 2 diabetes patients generated by The Wellcome Trust Case Control Consortium. We used data from 8 replication studies (mean age 28–74 years, mean BMI 22.7–27.2 kg/m^2) consisting of 28,165 adults with BMI available, including a further 3757 type 2 diabetic patients, and 7477 children with anthropometric measures at birth and ages 7 to 11 years.

Results: Variants in the *FTO* gene were most strongly associated ($P = 6 \times 10^{-6} - 2 \times 10^{-5}$) with BMI in the genome wide study. SNP rs9939609 in intron 1 of *FTO* increased the risk of diabetes (OR 1.23 [1.18–1.32], $p = 7 \times 10^{-14}$) but this effect was attenuated ($p = 0.44$) when correcting for BMI. In the combined dataset each additional copy of the A-allele of rs9939609 is associated with a weight increase of $\sim 1.4 \text{ kg}$ ($P = 3 \times 10^{-35}$). Sixteen percent of the population carrying two A-alleles has a 67% higher odds of being obese than the 35% of TT homozygote carriers ($P = 1 \times 10^{-14}$). In children from the ALSPAC study, the A-allele was associated with BMI and obesity from age 7 years onwards, and with a specific increase in fat mass, as assessed at age 9 by DXA measures ($P = 6 \times 10^{-10}$).

Conclusion: Common variation in the *FTO* gene represents the first confirmed example of a common genetic effect on BMI and obesity in the general population. The association reflects a specific increase in fat mass. The function of the *FTO* gene is not known. Understanding how variation in the *FTO* gene region alters adiposity will provide insights into novel pathways involved in the control of adiposity.

Regional neuronal activation following calorific nutrient ingestion identified using functional magnetic resonance imaging – the case for a feeding network

Y. P. Samarasinghe¹, S. Lee², F. Zelaya², L. J. Reed², M.-M. Teh¹, P. Choudhary¹, A. Pernet¹, B. Wilson¹, M. Brammer², S. C. R. Williams², S. A. Amiel¹;

¹Diabetes Research Unit, King's College London School of Medicine, ²Institute of Psychiatry, Centre for Neuroimaging Sciences, London, United Kingdom.

Background and Aims: Type 2 diabetes and obesity are lifestyle diseases resulting from disrupted energy homeostasis and appetite control. Although homeostatic control is maintained by the hypothalamus, the motivational and psychosocial aspects of eating are influenced by the higher cerebral centres. Studies of human brains using functional magnetic resonance imaging (fMRI) have identified low frequency fluctuations in baseline activity described as resting state networks (RSN), which are probably the brains anticipatory state. These distinct, interconnected areas coordinate a variety of functions including vision, language, auditory and motor processing. A RSN for feeding has not been described. To identify regional neuronal responses to feeding, we used fMRI to compare oral glucose with an isocaloric, non-carbohydrate fat.

Materials and Methods: Ten fasted, right handed, healthy volunteers (median(range)age: 22(20–55) yrs) underwent 2x40min continuous fMRI scans during which they drank 75g glucose in 388mls water or 68mls peanut oil (fat) followed by 320mls water. Arterialised blood samples were obtained throughout. MR signal changes were correlated with a previously published model for hypothalamic activation after glucose ingestion. Brain regions were identified according to the power of the correlation ($p=0.0005$) and size of voxels (>500). The average time series for the glucose and fat data for each of the regions identified was compared by ANOVA ($p<0.05$).

Results: We identified significant neuronal signal change at 10(+/-4)mins after glucose ingestion in bilateral retrosplenium, left prefrontal cortex, insula, amygdala, posterior cingulate and cerebella cortical networks which was not different after the peanut oil ingestion ($p=0.06-0.57$). A signal change in the orbitomedial frontal (OMF) cortex however, was significantly stronger after peanut oil vs glucose ($p=0.009$). Response amplitude increased over the experimental period to 10 minutes (paired t-test $p<0.001$).

Conclusion: We have demonstrated an early (5–15mins) change in brain activation in a network of regions throughout the brain in response to both carbohydrate and fat ingestion, in isocaloric quantities and identical volumes. Regions identified have known associations to food seeking behaviour and appetite: insula cortex is activated in response to visceral stimulation; the amygdala with decrease in fear or greater reward; the prefrontal cortex by primary reinforcers (food and drink). The OMF is involved in sensory perception of modalities related to eating (taste, smell, visceral stimulation) and connects with the limbic structures above as well as the hypothalamus and brainstem. Its greater activation with the fat meal may relate to increased satiation attributed to fat or differences in satisfaction related to taste. These techniques will be useful in the further investigation of the central control of food intake and its contribution to obesity.

Small changes in blood glucose in healthy subjects alter fMRI brain activation responses to appetising vs bland foods

A. Swamy¹, S. Hoashi¹, J. Shaw¹, P. R. Corlett², S. Sunram-Lea³, J. Foster⁴, P. Fletcher², M. L. Evans¹;

¹Dept of Medicine, University of Cambridge, United Kingdom,

²Dept of Psychiatry, University of Cambridge, United Kingdom,

³Dept of Psychology, University of Lancaster, United Kingdom,

⁴Dept of Medicine, University of Western Australia, Australia.

Blood glucose was first postulated as a physiological controller of appetite/feeding over 50 years ago. Most recent work has concentrated on neuropeptide rather than substrate influences on feeding. Subtle changes in feeding behaviour particularly when presented with appetising food may contribute to human obesity. We therefore examined the effects of a small oral glucose load on patterns of brain activation following exposure to foods of differing

palatabilities. We studied 7 healthy right handed volunteers (age 30 ± 3 , BMI 23.9 ± 0.67 , 5 males, 2 females) on 2 occasions in random order. Overnight fasted subjects had a venous cannula inserted in left hand and then underwent fMRI scanning (Siemens TIM TRIO 3 Tesla). Immediately prior to entering scanner, subjects drank 150 ml containing either (1) 25g glucose (GLU) or (2) 5 aspartame tabs (CON). Subjects were blinded to study conditions with studies performed at least 1 week apart. During scans, subjects were presented with pictures comprising foods [F] (either appetising [AP] or bland [BL]) or non-foods [NF]. Venous plasma glucose was monitored throughout (Analox GM9 analyser). Baseline glucose values were similar on both study days (5.2 ± 0.3 vs 5.2 ± 0.2 $p=NS$). On GLU days, there was a modest but significant rise in plasma glucose (30 min 7.0 ± 0.2 vs 5.0 ± 0.2 GLU vs CON $p < 0.01$). Comparing F vs NF, presentation of food pictures resulted in marked activation in insula, caudate and putamen during both GLU and CON conditions. However, there were marked differences between study days when comparing AP and BL foods. Specifically, on CON days, there were no differences in activation between AP and BL (fig 2). In contrast, on GLU days, there was a significantly greater activation in insula and putamen when presented with appetising foods (figure and table below).

* = effect size < 0.05

	AP vs BL Effect size (SE)	
	Insula	Putamen
CON	-0.05 (0.06)	-0.03 (0.07)
GLU	0.14(0.06) *	0.17 (0.08) *

In summary, our data show that in the fasting state (CON), brain activation in response to bland and appetising foods was indistinguishable but this was reversed by a small oral glucose load. Our current study does not distinguish a direct effect of glucose from indirect effects mediated by insulin. Nevertheless, our data suggest that small changes in blood glucose can alter patterns of brain activation in healthy subjects when presented with different food types.

OP 8 Insulin therapy: physiology and pharmacokinetics

0043

Change in plasma glucose following exercise in type 1 diabetes: a comparison of three basal insulins

V. Arutchelvam¹, T. Heise², S. Dellweg², B. Elbroend³, I. Minns³, P. D. Home¹;

¹The Medical School, Newcastle University, United Kingdom,

²Profil Institut fuer Stoffwechselforschung, Neuss, Germany,

³Novo Nordisk, Crawley, United Kingdom.

Background and Aims: Exercise has complex effects on glucose production and utilization in particular in people on insulin therapy; both hyperglycaemia and hypoglycaemia can be exacerbated. Because of its large plasma depot insulin detemir would be expected to show fewer fluctuations in its effect during exercise than non-albumin bound insulins. We have therefore assessed the impact of physical exercise on the plasma glucose (PG) control of people with Type 1 diabetes, comparing three basal insulins (detemir, glargine, NPH).

Materials and Methods: In a two-centre randomised open-label three-period crossover study, participants were actively managed on each of the three insulins plus insulin aspart for a period of 4 weeks. At the end of each treatment period the participants performed an exercise study 6 h after injection of their last meal-time and basal insulin. Exercise was for 30 min at a target heart rate of 120 beats/min, with glucose monitoring every 10 min for 3 h, and self-monitoring thereafter.

Results: Forty-seven out of 51 randomized subjects completed the study (age 39±10 yr, BMI 25 ± 3 kg/m², diabetes duration 28±10 yr). Following exercise the differences in minimum PG, time to minimum PG, and area under the PG curve (AUC-PG_{0-150min}) did not differ significantly (Table). However, patient-related outcomes did differ, including number experiencing minor hypoglycaemia in the period 0–150 min post-exercise and the number needing carbohydrate to prevent or treat hypoglycaemia. These were statistically significantly lower with both insulin detemir and NPH insulin compared to insulin glargine. Minimum post-exercise cortisol levels were significantly higher with glargine than with detemir, suggested this hypoglycaemia elicited a more pronounced counter-regulatory hormone.

Conclusion: Although decrements in PG post-exercise were similar between insulin detemir, NPH insulin, and insulin glargine, hypoglycaemia and carbohydrate snacking post-exercise was less frequent with insulin detemir and NPH insulin versus insulin glargine, confirmed by the counter-regulatory cortisol response. The findings suggest a more stable level of plasma free insulin with insulin detemir during and after exercise, consistent with the study hypothesis.

0–150 min post exercise

	detemir	NPH	glargine
PG nadir (change from baseline, mmol/l)	2.0±2.0	2.1±1.8	1.8±1.9

G. B. Bolli, C. G. Fanelli;

Internal Medicine, University of Perugia, Italy.

Background: Binding with the FFA myristic acid in B29 position, makes the long-acting insulin analog detemir more lipophilic than human insulin

(HI). In rat, and likely in humans detemir crosses the blood-to-brain barrier more, and concentrates in hypothalamus more than HI. Aim of the present studies was to assess the brain/hypothalamus responses to euglycemia and hypoglycemia in humans during detemir vs HI hyperinsulinemia.

Methods: Because data on i.v. detemir in humans are lacking, preliminary studies were devoted to finding equipotency between i.v. detemir and HI. The best approximation (based on total glucose infusion rate in euglycemia, GIR) was molar ratio detemir:HI 8:1. Ten normal, non-diabetic subjects (6 males, age 36±7 years, BMI 22.9±2.6 kg/m²) were studied on 4 occasions at random, during i.v. infusion for 5h of either detemir (48 µmol/kg/min) or HI (6 µmol/kg/min) in euglycemia (plasma glucose, PG, 90 mg/dl) or during stepped hypoglycemic clamps (PG 90, 78, 66, 54, and 42 mg/dl steps).

Results: Only data regarding euglycemic clamps are available. In euglycemia, GIR with detemir was lower than HI during the first 90 min (p=0.007) but later was no different until the end of studies (9±0.5 vs 9.5±0.3 mg/Kg/min, p>0.2). The score of autonomic (2.1±0.6 vs 1.8±0.3) and neuroglycopenic symptoms of hypoglycemia (0.7±0.2 vs 0.7±0.1), and glucagon suppression were similar with detemir and HI (44±5 vs 45±6 pg/ml) (p>0.2). Cognitive function, expressed as sum of Z-scores was also similar with detemir vs HI (-1.38±0.32 vs -1.55±0.41, p>0.2).

Conclusion: This is the first study establishing equipotency between i.v. detemir and HI. The more lipophilic insulin detemir does not affect brain/hypothalamus responses to hyperinsulinemia in euglycemia. However, responses to hypoglycemia with insulin detemir vs HI remain to be analyzed.

This is an investigator-initiated trial not supported by pharmaceutical companies.

0045

Is insulin detemir hepatoselective when compared to NPH insulin using stable isotope methodology at plasma glucose concentrations of less than 4 mmol/l?

E. J. Smeeton¹, F. Shojaee-Moradie², N. Jackson², R. H. Jones²,

A. M. Umpleby², D. Russell-Jones¹;

¹Department of Diabetes and Endocrinology, The Royal Surrey County

Hospital, ²The Wolfson Centre for Translational Research, The University of Surrey, Guildford, United Kingdom.

Insulin Detemir has shown a greater effect on suppression of endogenous glucose production (Ra) compared to NPH insulin in euglycaemic clamp studies in individuals without diabetes. There is also a lower incidence of hypoglycaemia when compared to NPH insulin in clinical studies when used to treat diabetes. Insulin Detemir is a basal insulin with the unique property of being bound to albumin. This may explain some of its observed effects by a more physiological action, with greater suppression of endogenous glucose production and lesser effect on peripheral glucose uptake.

Fourteen participants with type 1 diabetes were studied in a double blind, cross over trial after subcutaneous injection of Insulin Detemir compared to NPH insulin when fasted. A continuous infusion of [6, 6-³H₂]glucose

Fig: Glucose Ra at time zero before injection of subcutaneous injection of either Insulin Detemir or NPH Insulin and at decreasing plasma glucose levels:

enabled endogenous glucose production (Ra) and peripheral glucose uptake (Rd) to be calculated.

Table: Shows Glucose Ra when Ra NPH is compared to Ra Insulin Detemir:

Plasma Glucose (mmol/l)	Mean Glucose Ra NPH (umol/kg/min) ± SEM	Mean Glucose Ra Insulin Detemir (umol/Kg/min) ± SEM	p value
6.0	8.59 ± 0.57	7.35 ± 0.51	0.03
5.5	8.44 ± 0.59	7.24 ± 0.51	0.03
5.0	8.22 ± 0.48	7.21 ± 0.57	0.08
4.5	7.78 ± 0.4	6.94 ± 0.47	0.08
4.0	8.0 ± 0.47	6.75 ± 0.52	0.03
3.5	8.0 ± 0.66	6.34 ± 0.57	0.02
3.0	7.84 ± 0.85	5.88 ± 0.53	0.01
2.5	8.17 ± 2.11	6.37 ± 1.13	0.01

No significant difference was observed between starting plasma glucose or Ra before administration of NPH or Detemir (plotted separately in the figure). Detemir had a greater effect on suppression of endogenous glucose output when compared to NPH insulin at plasma glucose concentrations between 4 and 2.5 mmol/l. This provides further evidence that Insulin Detemir is hepatoselective.

Head-to-head comparison of the long-acting insulin analogs glargine and detemir: effects on glucose and lipid metabolism in T1DM

F. Porcellati, P. Rossetti, N. Busciantella Ricci, P. Lucidi, P. Candeloro, G. B. Bolli, C. G. Fanelli;
Internal Medicine, University of Perugia, Italy.

Aims: To compare head-to-head the effects of the long-acting insulin analogs glargine (GLA) and detemir (DET) on plasma glucose (PG) and lipid metabolism (plasma free fatty acids, FFA; β -OH-butyrate, β -OH-B), 24 subjects with T1DM (38±10 years, BMI 22±1.6 kg/m², HbA1C 7.2±0.7%, mean±SD) were studied.

Methods: All subjects underwent 24 h euglycemic clamp twice, after s.c. injection 0.35 U/kg GLA or DET, after 2 week treatment with either GLA or DET once/daily (randomized, double-blind, cross-over study). Primary endpoints were total AUC of G infusion rate (GIR), FFA and β -OH-B.

Results: Median time of end of action (time at which PG was >8.3 mmol/l) was 24 h and 17.5 h (GLA and DET, p<0.001).

	Detemir	Glargine	point estimate (%)	95% confidence interval	P value
GIR AUC _{0–24 h} [mg/kg]	915±225	1412±662	70.3	53.4; 92.7	0.015
GIR AUC _{0–12 h}	773±200	807±352	97.7	78.5; 121.6	0.832
GIR AUC _{12–end of inf.}	142±194	605±390	17.4	8.2; 36.7	0.000
FFA AUC _{0–24 h} [mmol/l]	11±1.7	8±2.8	131	117; 143	0.001
FFA AUC _{0–12 h}	4.6±1.1	34±1.6	133	115; 147	0.002
FFA AUC _{12–end of study}	6±1.6	4.4±1.3	129	111; 144	0.004
β-OH-B AUC _{0–24 h} [mmol/l]	22.9±8.9	16.5±11.6	139	110; 158	0.014
β-OH-B AUC _{0–12 h}	6.4±1.4	7.9±6.4	91	61; 134	0.608
β-OH-B AUC _{12–end of study}	15.6±78	8.1±5.1	152	128; 168	0.001

a Point estimates and 95% confidence intervals for the ratio of treatment means are based on adjusted means derived from ANOVA

Conclusions: During the initial 12 h after s.c. injection, glucose metabolism is similarly controlled by GLA and DET, but DET has ~30% lower antilipolytic activity. During following 12–24 h, DET has lower activity also on glucose metabolism, explaining earlier end of action and greater increase in β -OH-B by end of study.

This is an investigator-initiated trial not supported by pharmaceutical companies.

Pharmacokinetics and pharmacodynamics of insulin VIAject™, insulin lispro and regular human insulin when injected subcutaneously immediately before a meal in patients with type 1 diabetes

S. S. Steiner¹, L. Heinemann², R. Pohl¹, F. Flacke¹, A. Pfuetzner¹, P. Simms¹, M. Hompesch³;

¹Biodel Inc., Danbury, United States,

²Profil Institute for Metabolic Research, Neuss, Germany,

³Profil Institute for Clinical Research, Chula Vista, United States.

Background and Aims: The aim of this study was to determine the action of VIAject™ (a very rapid acting formulation of regular human insulin (RHI)), RHI, and insulin lispro (Lispro) on postprandial blood glucose (BG) excursions after a standard meal in patients with Type 1 diabetes.

Materials and Methods: BG of 9 patients (5 males and 4 females; age 40 ± 10 yrs, BMI 24.0 ± 2.0 kg/m²) were stabilized by means of a glucose clamp (target BG 120 mg/dL) prior to meal ingestion. The glucose infusion was turned off prior to the standard meal and insulin dosing. Using a cross-over study design with fixed treatment order, the same patient specific dose of VIAject™, Lispro or RHI was injected s.c. immediately before the meal. Subsequently, postprandial glucose excursions were continuously monitored for 8 hours and glucose infusion was re-initiated if BG <60 mg/dL. Plasma insulin levels were determined throughout the study.

Results: (mean±SD)

Pharmacokinetics	RHI	Lispro	VIAject™
Ins Tmax (min)	143±29*	62±37	43±36*

*p<0.001, paired t-test

Pharmacodynamics (0–180 min.)	RHI	Lispro	VIAject™
BG TMax (min.)	93±56*	47±28	41±26*
BG Max (mg/dL)	185±44	158±33	157±27
BG Min (mg/dL)	103±21	73±31	87±24
BG Max-BG Min (mg/dL)	82±30	84±11*	70±18*

*p<0.05, paired t-test

The total number of hypoglycemic events (hrs requiring glucose infusion) 3 to 8 hours post injection were 13 with RHI, 11 with Lispro and 4 with VJ. The mean total amount of glucose infused to prevent hypoglycemia during this time was six times higher for RHI and twice as much for Lispro than with VIAject™. The areas above and below the normal glycemic target zone (BG AUC above 140 and below 80 mg/dL) summed for all patients per group was 81,895 for RHI, 57,423 for Lispro and 38,740 mg/dL*min for VIAject™.

Conclusion: VIAject™ was the fastest in reversing the rise in blood glucose following the standard meal. Patients treated with VIAject™ experienced reduced post prandial glucose excursions. In contrast, RHI had the highest glucose excursion, which is consistent with its slower absorption rate. Variability of the glucose levels (mean difference between maximal and minimal values) was significantly less for VIAject™ than Lispro, demonstrating VIAject's better glycemic control in these patients with Type 1 diabetes.

0048

Revisiting short-acting insulin analogues. In obese subjects with type 2 diabetes, are they short? A pharmacokinetics study

M. Gagnon-Auger, J.-P. Baillargeon, J. Ménard, P. Brassard, E. Martin, J.-L. Ardilouze;
Endocrine division, University of Sherbrooke, Canada.

Background and Aims: 1) Pharmacokinetics of short acting insulin (SAI) were established following small (4–10 IU) subcutaneous injections in normal weight healthy subjects, in lean subjects with type 1 diabetes and, rarely, in lean or moderately overweight subjects with type 2 diabetes (T2D). However, most patients using insulin are overweight and insulin resistant and receive much larger dosages. 2) Insulin absorption depends mainly on blood flow in adipose tissue (ATBF). However, in obese and insulin resistant subjects, ATBF is 40–70% lower than in healthy subjects and we showed that after subcutaneous injection of saline, ATBF decreases for a period which correlates with injected volume. This study aims to show that pharmacokinetics of SAI are delayed in obese subjects with T2D.

Materials and Methods: Plasma SAI (lispro) was measured by radioimmunoassay (RIA) method (Linco Inc) using a standard curve limited between 17.8 and 1780 pmol/mL. In our hands, CV ranged between 2.5 and 8. We studied 6 healthy control subjects (age: 23.7±2.4 yrs, BMI 22.1±1.4 kg/m²) following subcutaneous injection of 10 IU and 8 subjects with T2D (age: 60±6.8 yrs, BMI: 37.6±6.6 kg/m², duration of diabetes 18.4±9.1 yrs, duration of insulin therapy 4.6±4 yrs, HbA1c 8.1±1.1%) following 10 IU and 30 IU (random order).

Results: (see Fig) In controls, the curve shows expected results: C_{max} (maximal concentration) = 552±55 pmol/L, T_{max} (time to reach maximal concentration) = 50.0±8.9 min, AUC (trapezoidal method) = 79794 ± 21420 pmol.min/L. In T2D subjects, following 10 IU lispro injection, T_{max} was similar (52.5±16.7 min) to control (p=0.75), but C_{max} was 42% lower (353±96 pmol/L, p<0.001). AUC was also lower in T2D subjects (63735 ± 12557 pmol.min/L, p=0.10). In T2D subjects, following 30 IU, lispro peaked at 86.3±23.3 min, 36 min later than in controls after 10 IU (p=0.004) and C_{max} was 879.5±281 pmol/L. AUC was 2.8 times larger after 30 IU (197155 ± 36552 pmol.min/L) than after 10 IU injection (p<0.001), but only 2.5 times larger than in controls (p<0.001).

Conclusion: In healthy normal weight control subjects, our results reproduced data accepted and used in daily practice for insulin prescriptions. However, in a population of obese subjects with T2D, we showed for the first time that plasma levels of SAI are blunted (at low dosage) and severely delayed (at average dosage) when compared to the results of low dosage in non-obese controls. These data command for in depth exploration of pharmacokinetic and glucodynamic of SAI in obese subjects with T2D, so commonly treated by family practitioners and endocrinologists. (Fig. 1)

Beta cell compensation for insulin resistance involves distinct mechanisms, which are differentially impaired in prediabetes

A. Mari¹, A. Tura¹, G. Pacini¹, J. Petrie², M. Laakso³, J. Nolan⁴, A. Mitrakou⁵, E. Ferrannini⁶, & RISC investigators⁶;

¹Institute of Biomedical Engineering, National Research Council, Padova, Italy, ²Medical School, Ninewells Hospital, Dundee, United Kingdom, ³Department of Medicine, Kuopio University Hospital, Finland, ⁴Department of Endocrinology, St James' Hospital, Dublin, Ireland, ⁵Diabetes Centre, Henry Dunant Charitable Foundation, Athens, Greece, ⁶Department of Internal Medicine, University of Pisa, Italy.

Background and Aims: In normal subjects, insulin secretion is upregulated in the presence of insulin resistance; however, the characteristics of this regulation are still debated.

Materials and Methods: In 1309 healthy subjects from the RISC study, we measured insulin sensitivity (IS, by euglycaemic clamp, as M/steady-state insulin) and β -cell function from a 2h OGTT (by C-peptide deconvolution and modelling). Subjects (55% women; age 44±8 years; BMI 25±4 kg/m²; mean±SD) had normal glucose tolerance (NGT) or impaired fasting or 2-h post-OGTT glucose (IGM, n=152, ADA 1997). Dynamic β -cell function was quantified by a dose-response relating insulin secretion rate (ISR) to glucose concentration (dose-response slope=glucose sensitivity) and by a potentiation factor expressing a relative potentiation of the dose-response during the OGTT (characteristic parameter: 2h-to-basal ratio).

Results: In NGT subjects, IS was inversely related to basal and total ISR and ISR at 5 mM glucose (centre-, sex- and age-partialled r 's of -0.35, -0.38 and -0.23, respectively, all p<0.0001), as expected. In contrast, IS was only weakly related to β -cell glucose sensitivity ($r=-0.04$, $p=0.04$) but positively related to the potentiation factor ratio (partial $r=0.14$, $p<0.0001$). In comparison with NGT, IGM subjects had higher basal ISR (91[57] vs 68[36] pmolmin⁻¹m⁻², median[interquartile range], $p<0.0001$), total ISR (48[22] vs 39[17] nmol m⁻², $p<0.0001$) and ISR at 5 mM glucose (75[64] vs 69[49] pmolmin⁻¹m⁻², $p<0.0001$). On the other hand, IS (93[73] vs 133[86] μ molmin⁻¹kg_{FFM}⁻¹pM⁻¹, $p<0.0001$), β -cell glucose sensitivity (69[48] vs 118[82] pmolmin⁻¹m⁻²mM⁻¹), $p<0.0001$) and potentiation (1.7±0.8 vs 2.1±1.5, $p<0.002$) were impaired. By multivariate analysis of the whole dataset, the strongest determinants of glucose tolerance – expressed as the mean OGTT glucose levels – were glucose sensitivity, insulin sensitivity, the potentiation ratio and ISR at 5 mM glucose, (partial r 's of -0.33, -0.27, -0.21 and -0.14, respectively; total explained variance 37%, $p<0.0001$).

Conclusion: We conclude that insulin resistance upregulates the basal secretory tone (eg, ISR at 5 mM glucose) but does not substantially

influence the dynamic secretion parameters (β -cell glucose sensitivity and potentiation). Furthermore, β -cell function impairment in IGM concerns the dynamic parameters, while the regulation of the basal secretory tone is essentially intact. This suggests the existence of distinct β -cell mechanisms, of which those responsible for the dynamic secretory responses are selectively impaired in prediabetes.

Potential signals for beta cell compensation for insulin resistance

D. Stefanovski, O. Woolcott, M. Lottati, D. Zheng, L. N. Harrison, V. Ionut, S. P. Kim, I. Hsu, J. Chiu, K. Catalano, C. Kolka, J. M. Richey, R. N. Bergman;
Physiology and Biophysics, Keck School of Medicine of USC, Los Angeles, United States.

Background and Aims: Increased insulin is the primary mechanism of compensation for changes in insulin resistance which may occur due to environmental causes. Yet, the mechanism which is responsible for the compensatory hyperinsulinemia is not clarified. One obvious candidate is elevated glucose which could arise from reduced glucose tolerance secondary to insulin resistance. We asked if even subtle hyperglycemia accompanies the compensatory hyperinsulinemia of high fat feeding.

Materials and Methods: Male mongrel dogs ($n=9$) were fed the hypercaloric high fat diet (~5400kcal/d, 53% kcal from fat) for 6 weeks. The Frequently Sampled Intravenous Glucose Tolerance (FSIGT) test was utilized to assess changes in glucose homeostasis at weeks 0 (pre-diet), 2, 4 and 6 (W:0; W:2; W:4; W:6, respectively). Basal glucose and FFAs were obtained at three time intervals during the day (8–8:30am, 6–8 pm, and 2–4 am) at W:0, and W:6.

Results: Due to the diet, body weight was significantly increased by W:2 (+2.5+/-0.33 kg, $P<.001$) and remained elevated throughout the entire study (W:6 + 1.79 kg, $P<.001$). Within two weeks of fat feeding, insulin sensitivity (S_i) dramatically decreased by 45% (5.6+/-0.9 vs. 3.1+/-1.2; W:0 vs. W:2 $P=.04$). At W:6, S_i decreased by 66% (1.9+/-1.3, $P=0.006$). AIRg rose modestly by W:2 (14%, $P=NS$), increasing by 46% ($P<.02$) and 59% ($P<.001$) at W:4 and W:6, respectively. Despite hyperinsulinemia, we observed constancy of the Disposition Index ($P>.13$) over 6 weeks. Importantly, there was no increase in fasting glucose at any of the three time periods between weeks 0 and 6 ($P>.68$, $P>.56$, $P>.18$). In contrast the fasting FFA levels were increased by 0.08+/-0.02 mM ($P<.001$) at week 2 and remained elevated by week 6 ($P<.001$). Also, we observed highly significant increase of FFA in the middle of the night by week 6 (0.42 +/- 0.7 to 0.75 +/- 0.04 mM, $P<.001$). There was no significant correlation between the change of fasting levels of FFA from week 0 and the increase in insulin secretion, AIRg ($R=0.1$, $P=NS$). There was significant correlation between the change from week 0 in AUC of glucose after a glucose bolus, and AIRg ($R=-0.6$, $P<.001$). In addition there was strong correlation between the change from week 0 in AUC of glucose and rise in fasting FFA ($R=0.7$, $P<.001$).

Conclusion: We propose that the change from week 0 in the AUC of glucose might be due to the elevated FFA in the portal, which impair insulin ability to suppress endogenous glucose production (EGP). Thus, postprandial glucose or 24-hour basal FFAs and not 24-hour basal glucose might be the signal for β -cell compensation induced by insulin resistance.

0051

Relative contribution of insulin resistance and pancreatic beta cell dysfunction in the pathogenesis of impaired glucose tolerance in Friedreich ataxia

M. Cnop^{1,2}, A. Begu³, C. Depondt⁴, M. Pandolfo⁴, F. Fery¹;
¹Division of Endocrinology, Erasmus Hospital, Universite Libre de Bruxelles, Belgium, ²Laboratory of Experimental Medicine, Universite Libre de Bruxelles, Belgium, ³Division of Nutrition, Metabolic Disorders and Endocrinology, CHU Timone, Marseille, France, ⁴Department of Neurology, Erasmus Hospital, Universite Libre de Bruxelles, Belgium.

Background and Aims: Friedreich ataxia (FA) is a rare neurodegenerative disease caused by a GAA trinucleotide repeat expansion in the frataxin gene. FA patients have an increased prevalence of diabetes, but the pathogenesis of

this monogenic diabetes is poorly understood. Our aim was to study insulin secretion and insulin sensitivity in these patients.

Patients and Methods: We studied 13 non-diabetic FA patients (6F/7M) and 14 controls (10F/4M) matched for age (patients 32±2 years vs controls 31±2 years) and BMI (22.8±1.2 vs 23.3±1.2 kg/m²). Glucose tolerance was assessed by oral glucose tolerance testing. Frequently-sampled intravenous glucose tolerance tests were used to measure insulin secretion (acute insulin response to glucose, AIRg) and determine insulin sensitivity (insulin sensitivity index, SI) using the minimal model. The disposition index, a measure of beta cell adaptation to the prevailing insulin sensitivity, was calculated as AIRg x SI. Body composition was measured by injection of ³H₂O and resting energy expenditure by indirect calorimetry. The size of the GAA expansion in the frataxin gene was determined by PCR.

Results: Fasting glucose levels were similar in the FA and control groups (90±3 vs 89±2 mg/dl). The 2-hour glucose level during the oral glucose tolerance test was 143±9 in patients vs 118±4 mg/dl in controls ($p=0.01$). The prevalence of impaired glucose tolerance and diabetes was 31% and 15%, respectively, in FA patients, compared to 0% in the controls. FA patients were insulin resistant compared to controls (SI 21±3 vs 36±3 x 10⁻⁵ min⁻¹/(μ U/ml), $p=0.001$). Body composition (fat-free mass 46±3 vs 49±3 kg) and basal energy expenditure (28.6±1.0 vs 28.3±0.9 kcal/kg lean mass/24 h) were similar in patients and controls. In the patients, SI correlated inversely with the number of GAA repeats ($r=-0.58$, $p<.05$). Insulin secretion was not different between the two groups (AIRg 70±10 vs 62±10 μ U/ml). Hence, the disposition index tended to be lower in FA patients (1488±231 vs 2071±328 x 10⁻⁵ min⁻¹).

Conclusion: While the FA patients we studied were young and lean, they had a high prevalence of impaired glucose tolerance. Compared to controls, the patients were insulin resistant, the severity of which correlated with the number of trinucleotide repeats. Their insulin secretion in response to glucose was not different from the control group. Thus, the expected compensatory increase in insulin secretion in response to insulin resistance did not occur. Our findings suggest that patients with FA have markedly impaired pancreatic beta cell function/adaptation.

0052

Macrophage migration inhibitory factor (MIF) plays an important role in the maintenance of glucose homeostasis

V. Serre-Beinier, C. Toso, P. Morel, C. Gonelle-Gispert, D. Bosco, L. Bühler, T. Berney;
Surgical Research Unit, University Hospital Geneva, Switzerland.

Background and Aims: Macrophage migration inhibitory factor (MIF) is thought to be a key effector molecule of both the innate and antigen-specific immune system. While macrophages are the major source of MIF, MIF is also produced in pancreatic beta cells, adipocytes, liver, Leydig and ovarian follicular cells. MIF exerts a variety of biological functions, including macrophage activation, enhancement of adherence, phagocytosis, tumoricidal activity, and induction of nitric oxide (NO) production. *in vitro* experiments, it has been shown that MIF localise within the secretory granules of pancreatic beta cells in islets and once released, regulates insulin secretion in an autocrine fashion. We aimed to examine whether MIF regulates glucose metabolism *in vivo* using MIF knockout (MIF-KO) mice.

Materials and Methods: Male MIF knockout (MIF-KO) mice in C57BL/6 background were studied at 1–2 months (Young mice), at 6 months and at 12 months of age (Old mice). Glucose stimulated insulin secretion was evaluated by an intra-peritoneal glucose tolerance test (IPGTT) and insulin secretion was measured by ELISA. In order to measure the peripheral insulin sensitivity of MIF-KO mice, an insulin tolerance test (ITT) was performed.

Results: The Area Under the Curve (AUC) glucose excursion to IPGTT was significantly lower in young male MIF-KO mice compared with controls C57BL/6 mice (WT) (549 ± 217 vs 1305 ± 305; $p<.001$; $n = 7$). Fasting plasma glucose and insulin were not significantly different between young male MIF-KO and WT mice. ITT showed that MIF-KO mice had insulin sensitivity similar to that of WT mice. Young male MIF-KO demonstrated a reduction in body weight (16.1 ± 2.9 g vs 20.5 ± 1.6 g; $n = 7$; $p<.01$) compared to WT. At 6 months, MIF-KO mice showed an insulin response to IPGTT comparable to WT mice (AUC 1701 ± 725 vs 1256 ± 186; $n = 3$). The weight of the MIF-KO mice was similar to that of the WT (30.4 ± 1.8 g vs 29.4 ± 0.8 g; $n = 4$). Finally, old male MIF-KO mice showed a glucose intolerance with a higher glucose excursion to IPGTT evaluated by higher AUC compared to WT mice (1950 ± 302 vs 954 ± 223; $p<.001$; $n = 5$). This was accompanied by a significant

reduction in insulin response to IPGTT in MIF-KO mice compared to WT mice ($p < 0.001$). These MIF-KO mice had also a significantly higher body weight (38 ± 4.0 g vs 30.8 ± 1.3 g; $p < 0.05$; $n = 5$) compared to WT mice.

Conclusion: Deletion of MIF contributed to an impairment in glucose homeostasis with differences in glucose tolerance, insulin secretion and body weight. These changes are age-dependant. Data obtained on MIF-KO mice aged 12 months suggest that in humans, a progressive decrease in MIF secretion and/or MIF action within the insulin-secreting cells may contribute to beta cell dysfunction and the diminished insulin release associated with Type 2 diabetes.

0053

Beta cell specific overexpression of glucagon receptors results in improved insulin secretion in response to glucose but impaired response to glucagon

M. S. Winzell¹, J. Ahrén¹, E. Renström², B. Ahrén¹;

¹Clinical Sciences, Medicine, Lund University, Lund, Sweden, ²Clinical Sciences, Endocrinology, Lund University, Malmö, Sweden.

Background and Aims: Glucagon is critical for blood glucose homeostasis. It is the major counter-regulatory hormone to insulin and it is released during hypoglycaemia, stimulating hepatic glucose output (HGO). Glucagon can stimulate insulin secretion but during hyperglycaemia, glucagon secretion is inhibited by factors secreted from the islet cells. In type 2 diabetes, the suppression of glucagon secretion is blunted resulting in increased HGO and elevated insulin secretion. It is possible that an impaired effect of glucagon on the beta-cells may be one mechanism behind the insulin secretory defect observed in type 2 diabetes. To investigate the effect of potentiated glucagon signalling for insulin secretion we examined mice with beta-cell targeted overexpression of glucagon receptors.

Materials and Methods: Mice with beta-cell specific overexpression of glucagon receptors (GR-tg) were generated on the C57BL/6J background. Insulin secretion was examined in male mice in intravenous glucose tolerance tests (IVGTT), as well as in isolated islets. The response to glucagon was examined both in vivo and in vitro. Exocytosis was examined in single beta-cells by capacitance measurements.

Results: Basal circulating glucose levels were reduced in GR-tg mice, while insulin and glucagon were similar to wild-type (wt) mice. After an IVGTT, the acute insulin response (AIR) was improved in GR-tg mice (AIR: 1045 ± 56 pM vs. 520 ± 85 pM in wt $P = 0.006$). This resulted in improved glucose tolerance (KG(1–20min): 3.6 ± 0.3 vs. 2.5 ± 0.2 %/min in wt, $P = 0.02$). However, when glucagon was added to the IVGTT, the insulin response was significantly reduced compared to wt mice (AUC(0–20min): 37 ± 5 vs. 67 ± 10 nM²min in wt, $P = 0.01$). Despite increased insulin secretion after glucagon administration, the glucose elimination was slightly impaired in both wt and GR-tg mice (KG(1–20min): 2.4 ± 0.5 vs. 3.5 ± 0.5 %/min in tg with or without glucagon, $P > 0.05$) due to increased HGO. In isolated islets the insulin response to glucose was decreased in GR-tg (324 ± 44 in GR-tg vs. 524 ± 54 pg/h/islet in wt ($P = 0.008$) at 11.1 mM glucose). Insulin secretion in response to glucagon was reduced by 40% in GR-tg compared to wt islets (437 ± 57 vs. 770 ± 100 pg/h/islet in wt, $P = 0.014$). Exocytosis was studied in perforated patch-clamp experiments where glucagon was demonstrated to increase capacitance in wt beta-cells (46 ± 3 vs. 19 ± 3 fF, $P = 0.001$) while there was no response to glucagon in GR-tg beta-cells (39 ± 4 vs. 31 ± 3 fF, $P > 0.05$).

Conclusion: We demonstrate that insulin secretion in vivo is improved when GR are overexpressed in beta-cells, while the response to glucagon is blunted. In vitro, the inhibitory effect of glucagon on insulin exocytosis and secretion was confirmed. This illustrates that glucose and glucagon, when simultaneously elevated, inhibit insulin secretion through glucagon signalling in the beta-cells. Since GR-tg mice have improved glycaemia this study suggests that glucagon signalling in beta-cells are important for whole body glucose homeostasis and that this may be impaired in type 2 diabetes.

Chromogranin-B deficient mice are diabetic despite normal insulin granule biosynthesis

S. Barg^{1,2}, S. Obermüller¹, F. Calegari³, A. Lindqvist¹, A. King⁴, I. Lundqvist¹, A. Salehi¹, J. Karanauskaine^{1,5}, P. Rorsman⁶, P. Rosa⁴, W. Huttner⁷;

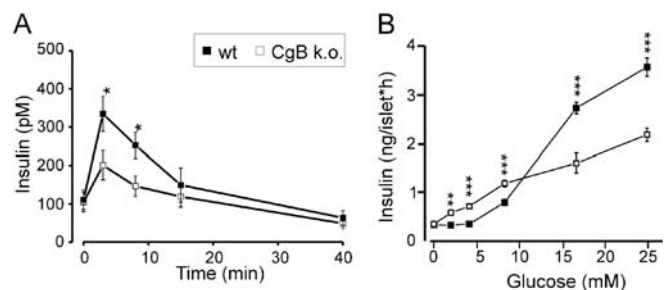

¹Islet Cell Physiology, Lund University, Malmö, Sweden, ²Vollum Institute, OHSU, Portland, United States, ³Neurogenesis/Cell Biology/Development, Center for Regenerative Therapies Dresden, Germany, ⁴Department of Medical Pharmacology, University of Milan, Italy, ⁵OCDEM, University of Oxford, United Kingdom, ⁶OCDEM, University of Oxford, United Kingdom, ⁷Max Planck Institute for Cell Biology and Genetics, Malmö, Germany.

Background and Aims: Granins form a family of highly acidic proteins that are primarily found in the lumen of dense-core secretory granules of neuroendocrine cells and neurons. The precise function of the granins is still debated, but evidence points into four main directions: 1) granulogenesis factor, 2) facilitation of the sorting of secretory peptides, 3) structural and storage function within the granule lumen, and 4) hormonal/paracrine activities. The ubiquitous chromogranin B (CgB) is expressed in insulin containing granules of pancreatic B-cells.

Materials and Methods: We have generated, by homologous recombination in ES cells, a mice line that lacks chromogranin (CgB k.o.) and then characterized the consequences of this mutation at the molecular, cellular and systemic levels, by *in vitro* and *in vivo* hormone release measurements, electron microscopy, electrophysiology/capacitance measurements, and live cell imaging in islets and other neuroendocrine tissues.

Results: CgB knockout animals exhibited a diabetic phenotype with impaired glucose tolerance, reduced stimulated secretion of insulin, glucagon and somatostatin, but elevated basal insulin and proinsulin release. Biogenesis, morphology and maturation of insulin granules was unaltered, while granule density was slightly reduced in adenocorticotrophic cells. No differences were found with regard to the exocytotic machinery, Ca²⁺-handling, and release kinetics of individual insulin granules.

Conclusion: We conclude that chromogranin B is not required for biogenesis and maintenance of functional granules, but may promote the processing of insulin into its mature form.

(A) Time course of insulin secretion in response to i.p. glucose (3g/kg body weight) injection at time 0; wt (black squares, $n = 12$) and k.o. (white squares, $n = 16$). ** $P < 0.01$; * $P < 0.05$. Mitochondrial substitution strains increase diabetes and glucose intolerance and change the morphology and function of the islets

L. Wester Rosenlöf¹, X. Yu¹, H. Weiss², A. Jörns³, M. Tiedge², S. Ibrahim¹; ¹Immunogenetics, University of Rostock, Germany, ²Medical Biochemistry and Molecular Biology, University of Rostock, Germany, ³Department of Clinical Biochemistry, Medical High school of Hannover, Germany.

Background and Aims: We have recently identified a mutation in the mitochondrial genome of the FVB/N mouse strain encoding for the ATP8 gene (a subunit of the ATP Synthase complex). The aim of our study was to characterize the impact of the ATP8 mutation on diabetes, glucose tolerance, islet morphology and insulin secretion. For that purpose Mitochondrial Substitution Strains (MSS) carrying the mutant FVB/N mitochondria were produced by repeated backcrossing (minimum 12 generations) to different inbred strains. Four strains were used; two C57BL/6 strains carrying the AKR/J or the FVB/N mitochondria (B6^{AKRmt} & B6^{FVBmt}) and two NOD/LtJ strains carrying the NOD/LtJ or FVB/N mitochondria (NOD & NOD^{FVBmt}). The B6^{AKRmt}/B6^{FVBmt} mice are polymorphic in the ATP8 gene only, but the NOD/NOD^{FVBmt} have an additional polymorphism in the COX III gene.

Materials and Methods: Animals from the NOD and the NOD^{FVBmt} strains (40–50 animals per group and sex) were monitored for body weight and blood glucose levels for 40 weeks. Intraperitoneal glucose tolerance test was performed on 12–13 weeks old NOD/ NOD^{FVBmt} and B6^{AKRmt}/B6^{FVBmt} mice. Pancreas sections of 12 and 16 weeks old NOD and NOD^{FVBmt} mice were analyzed for islet morphology, immune cell infiltration and beta cell mass. Islets from prediabetic NOD/ NOD^{FVBmt} mice were stimulated with KCl, 2.8 mM and 16.7 mM glucose and insulin secretion and content were analyzed by ELISA.

Results: Female NOD and NOD^{FVBmt} mice showed a diabetes incidence of 65–70% and 88% respectively. Interestingly, male NOD and NOD^{FVBmt} mice showed an incidence of 10–15% and 60% respectively. Diabetes onset was ~20 weeks for female NOD and NOD^{FVBmt} mice, 30–35 weeks for male NOD and 25 weeks for male NOD^{FVBmt} mice. Both NOD^{FVBmt} and B6^{FVBmt} mice showed higher blood glucose levels 60–120 minutes after glucose challenge ($p < 0.05$). In the pancreas of 12 week old mice a peri-insulinitis was observed in normal NOD but not in NOD^{FVBmt} mice. In 16 week old mice, both strains showed residual islets with very weak insulin staining. Glucose stimulated islets from NOD^{FVBmt} mice showed lower insulin secretion, while the insulin content was much higher. KCl stimulation revealed no obvious defect in exocytosis pathways.

Conclusion: The ATP8 mutation increases diabetes susceptibility in the NOD strain, particularly in male mice. Once an immune cell infiltration of beta cell has started, the mutation leads to a faster destruction. The mutation also negatively affects glucose-stimulated insulin secretion in beta cells resulting in impaired glucose tolerance in prediabetic animals.

Toll-like receptor 4: Regulator of beta cell-directed immune reactivity and development of body weight in the non-obese diabetic mouse

E. Gülden, S. Imamura, M. Ihira, H. Kolb, V. Burkart; Institute for Clinical Diabetes Research, German Diabetes-Center, Düsseldorf, Germany.

Background and Aims: Initiation and progression of beta cell-directed immune reactions underlying the pathogenesis of type 1 diabetes (T1D) are controlled by cells and mediators of the non-adaptive immune system. Recent findings have shown that the activities of non-adaptive immune cells, such as macrophages, strongly depend on the expression of toll-like receptors (TLR). Our previous studies demonstrated a critical role of TLR4 in the proinflammatory activation of macrophages. Based on these observations our present study was designed to investigate a potential regulatory effect of TLR4 on the development of beta cell-directed immunity and the pathogenesis of T1D.

Materials and Methods: Our studies were performed in mice with homozygous TLR4 expression (TLR4^{+/+}) or deficiency (TLR4^{-/-}) generated

from backcrosses (>12 generations) of TLR4 deficient C57BL10/ScCr mice on the background of the non-obese diabetic (NOD) mouse. In these mice the development of diabetes and body weight was monitored and potential immuno-regulatory effects of TLR4 were assessed by investigating the responses of spleen cell populations to concanavalin A (Con A), interleukin-2 (IL-2) and lipopolysaccharide (LPS).

Results: Female TLR4^{-/-} mice show a significant acceleration of diabetes development compared to TLR4^{+/+} mice ($p < 0.05$). At 120 d of age pancreata of TLR4^{-/-} mice revealed significantly increased proportions of islets with advanced stages of immune cell infiltration compared to TLR4^{+/+} mice ($p < 0.05$). These findings point to a dysregulation of beta cell-directed immune reactivity in TLR4^{-/-} mice. In fact, spleen cells of TLR4^{-/-} mice exhibit an aberrant reactivity towards immunologic stimuli. In response to Con A (2.5 µg/ml, 3 d) TLR4^{+/+} spleen cells showed a 4.5 times higher proliferation rate as TLR4^{-/-} cells ($p < 0.01$). However, IL-2-stimulated (50 ng/ml, 3 d) TLR4^{-/-} cells produced higher amounts of the beta cell toxic mediator tumor necrosis factor α (311 ± 10 pg/ml) than TLR4^{+/+} cells (161 ± 14 pg/ml) ($p < 0.001$). To assess the cellular basis for the functional hyper-reactivity of TLR4^{-/-} cells CD4⁺/CD25⁺ regulatory T-cells (Treg) were enriched from spleen cells. FACS analysis proved a purity of the Treg populations of 96.7% (TLR4^{+/+}) and 96.8% (TLR4^{-/-}). As determined by conversion of the tetrazolium salt WST-1 the TLR4 ligand LPS (5 µg/ml, 3 d) induced a significant, 1.7 fold increased activation of TLR4^{+/+} cells compared to TLR4^{-/-} cells ($p < 0.001$). Observations in T1D patients show an association of earlier disease onset and increased adiposity. Recent studies further identified components of the innate immune system, such as macrophages and TLR, in adipose tissue. Therefore, in a first approach to assess a possible effect of TLR4 on the increase of adipose tissue we monitored the development of body weight in female TLR4^{+/+} and TLR4^{-/-} mice. TLR4^{-/-} mice showed a significant acceleration of body weight development compared to TLR4^{+/+} mice ($p < 0.0001$). Until the age of 21 weeks TLR4^{-/-} mice weighed 1.7 ± 0.2 g (6.9 ± 0.8 %) more than TLR4^{+/+} mice.

Conclusion: Our results in TLR4^{-/-} mice show an acceleration in weight gain and an immunologic hyper-reactivity, possibly due to an insufficient counter regulation in the absence of TLR4. These findings implicate that TLR4 is involved in the regulation of beta cell-directed immunity and body weight development thereby controlling the pathogenesis of insulin-deficiency diabetes in NOD mice.

Identification of a classII-RegII peptide complex in pancreatic lymph nodes that activates autoaggressive T-cells in NOD mice

W. Gurr, M. Shaw, Y. Li, R. Sherwin; Internal Medicine, Yale University, New Haven, United States.

Background and Aims: We have reported that RegII, a beta cell protein associated with islet regeneration, is a target of the autoimmune process leading to diabetes in NOD mice. According to this scenario RegII might be released locally in an attempt to regenerate islets, which in turn might activate RegII, specific autoreactive T-cells thereby promoting inflammation and further release of RegII. Our data indicate that an epitope within the N-terminal fragment of RegII (NtfrII) is specifically targeted by the autoimmune diabetogenic response. Since autoreactive CD4⁺ T-cells specific for islet antigens are activated in the pancreatic lymph nodes, we attempted to quantitate I-Ag7 NtfrII peptide complexes occurring at this site during the pathogenesis of T1DM.

Materials and Methods: To generate an anti I-Ag7 NtfrII peptide complex-directed immune response classII-mismatched, classI-matched mice were immunized with NtfrII-pulsed NOD spleen cells. To generate a phage-displayed antibody library light and heavy chain variable fragments (Vl and Vh) were amplified using cDNA derived from spleen cells of immunized mice as template and primers suitable for the assembling of a mouse scFv cassette in the orientation Vl-(G4S)4-Vh compatible with the phage-display vector pAK100. Phages were selected by a two-step process, first on NtfrII-pulsed and then on unpulsed NOD spleen cells. The selection/reinfection process was performed for three rounds after which phages were rescued from single colonies and analyzed for differential binding to NtfrII-pulsed vs. unpulsed NOD spleen cells. To quantitate I-Ag7 NtfrII peptide complexes pancreatic lymph nodes were removed and single cell suspensions were incubated with a phage displayed specific antibody or a mutated non-binding variant thereof. Bound phages were eluted and used to infect bacteria. A colony count was then obtained.

Results: An antibody (termed D9) was obtained that showed binding to NtfrII-pulsed NOD spleen that was dependent on the pulse strength. Binding also occurred to NOD spleen cells pulsed with RegII indicating that the I-Ag7 NtfrII peptide complex recognized by D9 arises when full length RegII is processed. D9 did not bind to NtfrII-pulsed spleen cells from classII-mismatched mice demonstrating its specificity. The peptide recognized by D9 in context of I-Ag7 was localized between positions 44 and 64 of NtfrII. Quantitation of the I-Ag7 NtfrII peptide complexes in pancreatic lymph nodes of NOD mice showed a progressive increase during the development of diabetes: (phages retrieved from 106 cells): at 6 weeks 54,000 +/- 4,100, at 9 weeks 85,000 +/- 7,700, at 14 weeks 105,000 +/- 9,300. Counts for the mutated, non-binding D9 were < 18,000 for all time points. To determine if the complex detected by the antibody D9 was recognized by autoaggressive T-cells NOD mice were immunized with peptide 44–64 of RegII in alum. Adoptively transferred CD4+ T-cells from these mice targeted and destroyed islets of recipient NOD-SCID mice.

Conclusion: Antibodies recognizing MHC molecules presenting islet autoantigen-derived peptides were isolated from a phage-displayed antibody library. The antibodies provided a means to identify an epitope responsible for the activation of diabetes-related autoaggressive T-cells and to quantitate the complexes presenting it. This approach might lead to the identification of new immune therapeutic targets to prevent the development of T1DM.

Ii-key/MHC class II epitope hybrid technology to detect T cell response to insulin and GAD in type 1 diabetes

M. Vadacca¹, G. Valorani^{2,3}, R. Humphreys⁴, N. Kallinteris⁴, L. Valente¹, G. D'Agostino⁵, P. Pozzilli¹, IMDIAB GROUP¹;

¹Diabetes Department, Università Campus Bio-Medico, Roma, Italy,

²Diabetes Department, University Queen Mary of London, United

Kingdom, ³Livio Patrizi, Foundation, Roma, Italy, ⁴Generex Biotechnology,

Antigen Express, Boston, United States, ⁵Superiore di Sanità, Istituto, Roma, Italy.

Background and Aims: Type 1 diabetes (T1D) develops as a result of pancreatic beta-cell destruction. The immune response involves both cell mediated and humoral reactivity towards insulin GAD and IA-2. In T1D the specific epitopes recognized by pathogenic T cells remain poorly defined and the specific autoreactive T cells are difficult to detect. The design rationale for Ii-key/antigen hybrids was drawn from data previously published and X-ray crystallographic data indicating that the Ii-key binding site lies outside the antigenic peptide-binding trough of MHC class II molecules. In our previous work a series of hybrids has been synthesized containing Ii-key derivatives (beginning with LRMK, the shortest active derivative) coupled to insulin peptides. This offered us an efficient way to augment the binding of epitopes to the antigenic peptide-binding groove and thus enhances epitope immunogenicity. The main objective of the present study was to investigate the cellular immune response in T1D by characterising the cytokines secreted by peripheral blood mononuclear cells (PBMCs) in response to exposure to Ii-key/MHC class II GAD epitope hybrids.

Materials and Methods: Sequences of the human GAD were obtained from Genbank. The deduced protein sequence for Genbank was run through SYFPETHI (<http://www.syfpeithi.de/Scripts/MHCServer.dll/Info.htm>) and the top MHC II epitopes have been scored for each DR allele. Six peptide series (16 hybrids and six epitope-controls) were analyzed. The study was carried out in 8 recent onset T1D subjects (3 males) affected by T1D and in 7 normal subjects. Diagnosis was defined according ADA classification. ELISPOT assays were performed with BD Pharmingen set for IFN- γ according to the manufacturer's instructions. Digitalized images of spots were analyzed with a Eli.Analyse 4.0 software.

Results: All assays were able to detect significant cytokine secretion in response to the polyclonal stimulators PMA/Ionomycin. Two out of 8 patients (25%) demonstrated a positive response to one or more Ii-Key/GAD65 hybrids. None of the control subjects showed a detectable response to stimulation with Ii-key hybrids or peptides.

Conclusion: The Ii-key hybrid technique is a new strategy for augmenting the potency of MHC class-II restricted epitopes resulting in a profound increase in T cell stimulation. Our previous study demonstrated that some Ii-key insulin hybrids, and not the epitope-peptide only, stimulate strong reactivity in T1D subjects. We have here shown a specific response to Ii-key/GAD65 hybrids only in T1D. The combined use of insulin and GAD key-hybrids

might therefore assure a more selective and sensitive cytokine detection in response to antigen stimulation in T1D offering a new highly specific marker of cell mediated immunity in T1D.

Human anti-IA-2 autoantibodies isolated from an immune library by phage display are able to bind to both major autoantigens: GAD65 and IA-2

L. Valera¹, S. Peraldi-Roux², B. Watelet-Jardin¹, V. Lampasona³, C. Granier¹, E. Bonifacio⁴, D. Laune¹;

¹MISCDIA, CNRS FRE 3009, Montpellier, France, ²CPID, CNRS UMR 5232, Montpellier, France, ³Immunology of Diabetes Unit, San Raffaele Scientific Institute, Milan, Italy, ⁴Diabetes research Institute, Munich, Germany.

Background and Aims: The selection of human antibodies directed towards major autoantigens, the glutamate decarboxylase GAD65 and the tyrosine phosphatase like protein IA-2, can provide useful tools to study humoral immune responses in autoimmunity of type 1 diabetes. The aim of our study was to isolate by phage display new human monoclonal autoantibodies to IA-2 and characterize them in order to use these antibodies for an early diagnosis of type 1 diabetes.

Materials and Methods: We report here the molecular cloning and characterization of human anti-IA-2 Fab fragments generated from an immune library derived from the IgG repertoire of patients with type 1 diabetes mellitus. The phage screening was performed after three rounds of panning by enzyme-linked immunosorbent assay (ELISA) with coated IA-2. The specificity of binding and the localization of epitopes was analyzed in several ELISA formats and by Spot technology on cellulose membranes.

Results: We have been successful in selecting six new antibodies against human IA-2 using phage display. These antibodies interestingly had a dual specificity: they bind to both major autoantigens GAD65 and IA-2. After epitope analysis, we found that major epitopes recognized by these autoantibodies are present in the juxtamenbrane domain of IA-2 molecule. Moreover, the analysis of genes encoding these Fab revealed they had some genetical characteristics previously described for GAD65 antibodies and for autoantibodies associated to autoimmune thyroid diseases.

Conclusion: Our study demonstrates that anti-IA-2 antibodies can be isolated from a human immune library derived from patients with type 1 diabetes mellitus. This is the first report describing human antibodies recognizing the two main autoantigens of T1DM: GAD65 and IA-2. Thus, these bispecific autoantibodies could have some conformational epitopes in common, and their identification could be useful for the molecular modelization of both proteins and for the understanding of the induction of type 1 diabetes.

0060

Specific immune response to GAD65 in type 1 diabetic children treated with GAD65 (Diamyd™)

M. Faresjö, M. Hedman, R. Casas, S. Axelsson, J. Ludvigsson; Department of Molecular & Clinical Medicine, Division of Paediatrics, Linköping, Sweden.

Background and Aims: Type 1 diabetes (T1D) is associated with a defect regulation of the immune system and imbalance of T-helper (Th) cells resulting in destructive insulinitis. Treatment with 20 microgram of GAD65 has indicated that beta-cell function can be preserved in LADA patients, and this effect has shown to be significant in T1D patients (10–18 years) still at 15 months follow-up. We hypothesise that treatment with GAD65 can induce GAD65-specific Th- and T-regulatory (Treg) cells, with a subsequent deviation towards a protective immune profile.

Materials and Methods: This phase II Diamyd™ study was designed as a randomised, double-blind, placebo-controlled, multi-centre trial including 70 T1D children (42 females, 28 males, 10–18 years) diagnosed within the previous 18 months, fulfilling the criteria of fasting C-peptide >0.1 nmol/L and presence of GAD65 autoantibodies (>67.3 U/mL) at the screening visit. Thirty-five patients were randomly assigned to 20 microgram of GAD65 (Diamyd™, Diamyd Therapeutics AB, Stockholm, Sweden) and 35 patients to

placebo (Diamyd™ bulk buffer alone) in a primary injection at day one and a booster of the same concentration four weeks later.

Peripheral blood mononuclear cells (PBMC), collected from 70 T1D children before and 15 months after the primary injection with GAD65 (Diamyd™) or placebo and from a reference group (12 healthy children; 8 females, 4 males, 11–15 years), were stimulated with GAD65 (Diamyd™) and phytohaemagglutinin (PHA) for 72 hours.

Secretion of cytokines (IL-5, -6, -10, -12, -13, -17, IFN- γ and TNF- α) and chemokines (IP-10, MCP-1, MIP-1 α , MIP-1 β and RANTES) were detected in cell supernatants by multiplex fluorochrome technique (Luminex). Expression of FOXP3 mRNA was detected together with endogenous rRNA by multiplex real-time RT-PCR.

Correction with Bonferroni's was made to compensate for multiplex comparisons.

Results: The spontaneous secretion of cytokines and chemokines and FOXP3 mRNA expression did not differ between children treated with GAD65 or placebo either before or 15 months after treatment. Further, the mitogen PHA induced prominent response of cytokines and chemokines as well as FOXP3 mRNA in all children regardless of treatment.

However, after in vitro stimulation with GAD65, patients treated with Diamyd differed significantly from the placebo group, 15 months after the immune intervention. Thus, GAD65 induced higher secretion of Th1- (IFN- γ ; $p < 0.0001$), Th2- (IL-5; $p < 0.0001$, IL-13; $p < 0.0001$), Th3- (IL-10 $p < 0.0001$), and Th17- (IL-17; $p < 0.0001$) associated cytokines in Diamyd treated patients. Also, inflammatory cytokines (IL-6; $p = 0.006$ and TNF- α ; $p < 0.0001$) and chemokines (IP-10; $p < 0.05$, MIP-1 α ; $p < 0.05$ and MIP-1 β ; $p < 0.05$) were induced to a higher extent by stimulation with GAD65 15 months after Diamyd treatment. Increased FOXP3 mRNA expression by GAD65 stimulation was observed in T1D children treated with Diamyd ($p < 0.0001$). Even compared to healthy children, GAD65-induced secretion of IL-5, -13, -17 and TNF- α and FOXP3 mRNA were higher in Diamyd treated children ($p < 0.0001$).

Conclusion: Treatment with GAD65 causes a specific immune response to GAD65 remaining still after 15 months, which indicates that a specific cell population has been induced. This may explain the protective effect of GAD65 vaccination on beta-cell function.

Farrall¹², F. Cambien¹², M. Lathrop¹⁰, ¹UMR S 525, INSERM, Paris, France, ²Umr s 525, Université Pierre et Marie Curie-Paris6, France, ³Steno Diabetes Centre, Copenhagen, Denmark, ⁴Department of Medicine, Helsinki University Central Hospital, Finland, ⁵Biomedicum, Folkhälsan Institute of Genetics, Helsinki, Finland, ⁶Diabetology department, Poitiers Hospital, France, ⁷Erm 324, INSERM, Poitiers, France, ⁸Department of Diabetology, Bichat Hospital, Paris, France, ⁹U695, INSERM, Paris, France, ¹⁰CNG, CNRG, Evry, France, ¹¹MRC Mammalian Unit, Mammalian Research Council, Didcot, United Kingdom, ¹²Wellcome Trust Centre for Human Genetics, University of Oxford, United Kingdom.

Background and Aims: Diabetic nephropathy (DN) is likely to be a complex genetic trait. We studied 144 candidate genes for DN to identify susceptibility genes. We report marginal and epistatic genetic effects identified in this dataset.

Materials and Methods: 437 SNPs were investigated for association with overt diabetic nephropathy (persistent albuminuria >300 mg/24h) in a large Type 1 diabetes case/control (1176/1323) study from 3 European populations. Marginal and epistatic effects were investigated through a multi-stage strategy using Random Forest, DICE and haplotypic methods and were tested in men and in women separately. The consistency of the results was assessed by their homogeneity across genders and populations.

Results: Univariate effects – One univariate effect was identified in both gender populations. The T allele of the UNC13b_134327 polymorphism was less frequent in cases than in controls (0.281 vs 0.324), leading to a common Odds Ratio of 0.746 [0.624 – 0.892] ($p = 0.0013$). Epistatic effects – Nine interactions between 2 SNPs were identified among which 3 were consistent in men and women. The effect of the T allele of the UNC13b_134327 SNP observed in univariate analysis was found to be modulated by the PARP1_46691 SNP. Carriers of the T allele at the UNC13b_134327 locus were at lower risk of nephropathy mainly in individuals homozygous for the C allele at the PARP1_46691 locus (OR = 0.594 [0.482 – 0.731, $p < 10^{-6}$]) and not in individuals carrying the PARP1_46691 T allele (OR = 1.187 [0.959 – 1.470], $p = 0.116$), the test for interaction being highly significant ($p < 10^{-4}$). Presence of the C allele at ATP1B2_3623 locus was associated with increased risk of nephropathy only in individuals homozygotes for the ADRA1D_30405 A allele (OR = 1.949 [1.563 – 2.430] $p < 10^{-4}$) while no effect was observed in carriers of the ADRA1D_30405 T allele (OR = 0.859 [0.699 – 1.055], $p = 0.148$). SLC12A3_53289 and EDN1_2688 were found to interact on the risk of nephropathy, homogeneously in men and women. Presence of the C allele at SLC12A3_53289 was associated with an OR of 0.397 [0.267 – 0.587] ($p < 10^{-4}$) in individuals homozygotes for the EDN1_2688 G allele while this OR was 0.957 [0.756 – 1.212] in carriers of the T allele, these two ORs being significantly different ($p < 10^{-3}$).

Conclusion: UNC13b is a strong candidate gene for DN and interacts with PARP1, possibly in the glucose-induced apoptotic pathway. SLC12A3 and EDN1 interact possibly in the regulation of renal sodium excretion and systemic blood pressure. The nature of the interaction between ATP1B2 and ADRA1D is unclear. Further studies are needed to identify the functional variants of those genes and the precise nature of their interactions in the pathogenesis of diabetic nephropathy.

Accelerated nephropathy in type 2 diabetic patients with type III hyperlipoproteinemia (apo E2/2 genotype), and the detrimental effects of their remnant lipoproteins on human mesangial cells

M. Saito, M. Eto;
Clinical Medicine, Ohu University, Koriyama, Japan.

Backgrounds and Aims: In 1977 apolipoprotein (apo) E2 was found to be a causal gene of type III hyperlipoproteinemia (HLP), which occurs in apo

E2/2 genotype subjects and is characterized by increased plasma remnant lipoproteins. On the other hand, in 1994 we first found that apo E2 allele is a genetic factor to promote diabetic nephropathy. Now this finding has been accepted in the world, but the exact mechanism by which apo E2 promotes diabetic nephropathy remains unknown. Most studies on apo E2 allele and diabetic nephropathy have been conducted in the heterozygote apo E3/2 genotype patients partly because of the small sample size of the homozygote apo E2/2 genotype patients. It seems important to investigate the effect of type III HLP (apo E2/2 genotype) on diabetic nephropathy, but no information is available. Therefore, we investigated nephropathy in diabetic patients with type III HLP (apo E2/2 genotype), and effects of remnant lipoproteins from the patients on the human mesangial cells (HMCs).

Materials and Methods: Blood samples were collected after an overnight fast. The diagnosis of type III HLP was made according to the following criteria: increased plasma triglyceride and total cholesterol (chol); apo E2/2 genotype/phenotype and high plasma level of remnant chol (normal range < 5.2 mg/dl). Remnant-chol was measured by the method of Nakajima. Fifteen patients with type III HLP and type 2 diabetes were recruited from our hospitals. Overt nephropathy was diagnosed if they had persistent proteinuria, and/or plasma creatinine level > 1.4 mg/dl. The histological study was performed using renal biopsy specimens in apo E2/2 genotype patient. Remnant lipoproteins were isolated from the type III HLP patients' plasma by ultracentrifugation. Cultured HMCs were incubated with the remnant lipoproteins in the medium. After the incubation, expression of TGF- β mRNA and accumulation of cholesteryl esters (CE) by HMCs were estimated, and the related lipoprotein receptors in HMCs were examined by siRNA method.

Results: Mean age was 60.6 years, BMI 25.4, fasting plasma glucose 147 mg/dl, and HbA1c 8.1%. The patients had increased plasma levels of triglyceride (mean 380 mg/dl) and total chol (mean 260 mg/dl), increased plasma remnant-chol level (mean 51.0 mg/dl) and a high remnant-chol/TG ratio (mean 0.145). The patients had a short diabetes duration of 6.3 years (mean), but a high frequency (46.7%) of overt nephropathy, demonstrating that type III HLP (apo E2/2 genotype) accelerated nephropathy. Histological findings of the kidney in apo E2/2 genotype patient were identical with those in diabetic nephropathy. Immunohistochemical analysis demonstrated a positive staining of apo E and apo B in the glomeruli, suggesting the accumulation of remnant lipoproteins. The effects of remnant lipoproteins on HMCs were estimated. The remnant lipoproteins from the patients stimulated the expression of TGF- β mRNA and the accumulation of CE by HMCs more significantly than those from the controls. The siRNA method showed that VLDL receptor but not LDL receptor was related to the accumulation of CE by HMCs.

Conclusion: The present study first demonstrated that type III HLP accelerates diabetic nephropathy. Increased plasma remnant lipoproteins may cause renal damage by stimulating the expression of TGF- β and the accumulation of CE by HMCs via VLDL receptor.

Ablation of galectin-3 gene accelerates lipid-induced glomerular injury: evidence for a relevant scavenging role of galectin-3

G. Pugliese¹, S. Menini¹, C. Ricci¹, A. Scipioni¹, V. Sansoni¹, C. Pesce², F. Pugliese¹, F. Pricci³, C. Iacobini¹;

¹Department of Clinical Sciences, La Sapienza University, Rome,

²DISTBIMO, University of Genoa, Italy, ³Department of Cell Biology and Neurosciences, National Institute of Health, Rome, Italy.

Background and Aims: It has long been recognized that hyperlipidemia plays an important role in the initiation and progression of renal disease. High saturated fat and/or cholesterol intake in experimental animal models resulted in glomerulosclerosis and tubulo-interstitial injury, associated with renal accumulation of fatty acids and/or cholesteryl esters; lipid-lowering agents were effective in preventing these changes. Galectin-3, a multifunctional lectin with (anti)adhesive and growth-regulating properties, was recently identified as a receptor for advanced glycation endproducts (AGEs) and modified-LDL by promoting the uptake and removal of these potentially harmful molecules. Its expression was found to be increased in kidney and atherosclerotic lesions from both human patients and experimental animals. We previously showed that mice knockout (KO) for galectin-3 are more susceptible to develop glomerular disease induced by diabetes, AGEs and aging, as compared with the corresponding wild type (WT) mice. This study aimed at verifying the

hypothesis that galectin-3 KO mice develop accelerated glomerular disease in response to high-fat diet (HFD)-induced hyperlipidemia.

Materials and Methods: Galectin-3 KO and coeval WT mice were fed a HFD (15% fat + 1.25% cholesterol and 0.5% Na-choleate); mice fed a normal-fat diet (NFD, 4% fat) served as control. Metabolic, renal functional and structural parameters as well as renal/glomerular cell apoptosis and extracellular matrix accumulation, AGEs/AGE-receptors and oxidative stress were assessed in these animals.

Results: Body weights and blood glucose concentrations were not different among the experimental groups throughout the study, serum triglyceride and cholesterol levels increased ~3.5-fold in both WT and KO mice, whereas serum insulin levels and HOMA-IR increased significantly in WT, but not in KO mice fed a HFD vs. the corresponding NFD-fed control animals. KO-HFD mice showed more pronounced changes in renal function and structure as compared with the corresponding WT mice, as evidenced by the significantly higher levels ($P < 0.001$) of proteinuria (8.9 ± 1.2 vs. 4.4 ± 0.9 $\mu\text{g}/\text{mg}$ creatinine), albuminuria (6.5 ± 1.6 vs. 3.8 ± 0.8 $\mu\text{g}/\text{mg}$ creatinine), glomerular sclerosis index, mean glomerular volume (189278 ± 8073 vs. 156024 ± 7174 μm^3) and area (4043 ± 116 vs. 3503 ± 108 μm^2), mean mesangial area (951.8 ± 25.6 vs. 788.4 ± 35.5 μm^2), fractional mesangial area (26.8 ± 0.4 vs. 22.5 ± 0.6 %), glomerular cell apoptosis (0.176 ± 0.032 vs. 0.120 ± 0.029 cells/glom) and renal/glomerular protein and mRNA expression for fibronectin and collagen IV (\cdot). In addition, circulating AGE and isoprostane 8-epi-prostaglandin F $_{2\alpha}$ levels, renal/glomerular content of the glycoxidation product N $^{\epsilon}$ -carboxymethyllysine and the lipoxidation product 4-hydroxy-2-nonenal, expression of RAGE, CD36 and MCP-1, activation of nuclear factor κB and macrophage infiltration were higher and expression of SR-A1 was lower in HFD-fed KO vs. WT mice.

Conclusion: These data show that galectin-3 deficiency is associated with increased susceptibility to hyperlipidemia-induced renal disease, thus indicating a major role for galectin-3 in lipoprotein uptake and metabolism. Supported by the Ministry of University and Research of Italy

Inducible overexpression of angiotensin II in podocytes results in albuminuria and foot process effacement in mice

L. Gnudi¹, A. Dei Cas¹, A. Hayward¹, K. White², B. Davis¹, R. Bilous², S. Marshall², G. Viberti¹;

¹Cardiovascular Division, King's College London,

²Diabetes and Metabolism, Newcastle University, United Kingdom.

Background and Aims: The Angiotensin II/Angiotensin II system is important in wall vessel injury and repair. In the normal glomerulus angiotensin II (Ang-II) is expressed while angiotensin I (Ang-I) is absent. In diabetes there is an upregulation of both Ang-I and Ang-II expression with the latter being of a greater degree. To obtain insights into the role of Ang-I in glomerular pathophysiology we overexpressed it in the podocytes of normal mice.

Materials and Methods: Podocyte-specific overexpression of Ang-I and β -galactosidase cDNA was induced in mice using the *Tet-On* regulatable inducible system. The podocyte-specific promoter podocin was used to drive the expression of the reverse tetracycline transactivator. Mice were studied between 8 and 10 weeks of age. To activate the transgene, Doxycycline (2mg/mL) was administered with water for up to 10 weeks. The following groups of mice were studied: a) transgenic (TG) with doxycycline (DOX), b) TG without DOX, c) controls (C) with DOX and d) C without DOX.

Kidney cortex was collected and prepared for subsequent analysis for β -galactosidase staining, western immunoblotting, immunohistochemistry, and electron microscopy studies. Albumin concentration in the urine was determined by ELISA in 24h collections.

Results: Podocyte positive β -galactosidase staining was present only in TG-DOX treated animals, indicating absence of leaky transgene activity. Western immunoblotting showed a 2–3 fold increase ($p < 0.05$) in Ang-I protein overexpression in the DOX treated TG mice only. Albuminuria was increased significantly by 2–3 fold in the TG-DOX treated mice ($p < 0.05$) as early as 5 weeks after treatment with DOX. At 10 weeks VEGF expression was upregulated by ~70% ($p < 0.05$) but no changes in nephrin expression was observed. Foot process effacement/fusion was increased by 30–40% in Ang-I overexpressing mice ($p < 0.05$).

Conclusion: We have generated a transgenic mouse model of podocyte-specific inducible Ang-I overexpression. This resulted in induction of

albuminuria, upregulation of VEGF, and podocyte foot processes effacement, suggesting a role of Ang-1 in glomerular capillary wall pathobiology.

PKC ϵ is activated under high glucose conditions, and decreases the expression of bone morphogenetic protein 4 (Bmp4) through MAPK-dependent pathway in cultured mouse mesangial cells

S. Maeda¹, N. Osawa^{1,2}, T. Hayashi^{1,3}, T. Uzu², T. Babazono³, Y. Iwamoto³, A. Kashiwagi², R. Kikkawa²;

¹Laboratory for diabetic nephropathy, SNP Research Center, RIKEN, Yokohama, ²Department of Medicine, Shiga University of Medical Science, Otsu, ³Diabetes Center, Tokyo Women's Medical University, Japan.

Background and Aims: Protein kinase C epsilon (PKC ϵ) is a member of the novel PKC subgroups, and has been shown to be increased in the kidney of diabetic animals. The aim of the present study is to know the possible involvement of PKC ϵ in the pathogenesis of diabetic nephropathy.

Materials and Methods: The activity of PKC ϵ was measured using a synthetic substrate specific for PKC ϵ in cultured mouse mesangial cells. The expressions of mRNA for bone morphogenetic protein 4 (Bmp4) and NADPH oxidase 4 (Nox4) were measured by real-time quantitative PCR using SYBR green detection in the cells infected with adenovirus vectors encoding PKC ϵ or LacZ. We also examined the DNA binding activity of AP-1 in PKC ϵ - or LacZ-overexpressing cells by electrophoresis mobility shift assay (EMSA).

Results: To evaluate the role of PKC ϵ in diabetic renal disease, we first examined the activity of PKC ϵ in mouse mesangial cells cultured under high glucose conditions (HG: 25mM D-glucose) for five days, and compared with those in the cells under normal glucose (NG: 5.6mM D-glucose), or conditions where osmolarity had been adjusted with mannitol (osmotic control [OC]: 5.6mM D-glucose + 19.4mM mannitol). We found that the activity of PKC ϵ in cells exposed to high glucose condition was significantly higher than those in the cells under NG or OC (HG: 3293.3 \pm 383.3, NG: 1463.0 \pm 68.8, OC: 1520.3 \pm 143.5, pmol/min/mg protein, mean \pm sd, $p < 0.05$), whereas the mRNA and protein expression of PKC ϵ were not different among those cells. We next examined the several gene expressions in the cells overexpressing PKC ϵ , and found that the expressions of Bmp4 and Nox4 mRNA were significantly decreased in the PKC ϵ -overexpressing cells compared with those in the LacZ-overexpressing cells (Bmp4: PKC ϵ 0.58 \pm 0.13, LacZ 0.96 \pm 0.07, Nox4: PKC ϵ 0.70 \pm 0.04, LacZ 1.13 \pm 0.13, mean \pm sd, $p < 0.0001$). The expressions of fibronectin, type4 collagen $\alpha 1$ were not significantly different between the PKC ϵ -overexpressing and control cells. In contrast, the treatment of the cells with the broad PKC inhibitor, GF109203X (1 μ M) resulted in a significant increase of Bmp4 mRNA, whereas the treatment of Go 6976 (10 μ M), PKC inhibitor specific for α or β isoform, did not affect the Bmp4 expression (GF109203X: 1.71 \pm 0.13, Go 6976: 1.01 \pm 0.07, fold increase, mean \pm sd, $p < 0.0001$ GF109203X vs. control or Go 6976). The DNA binding of AP-1 was remarkably increased in PKC ϵ -overexpressing cells. Furthermore, PKC ϵ -induced decrease of the Bmp4 and Nox4 expression, and increase of DNA-binding activity of AP-1 could be reversed by the treatment of MEK inhibitor, U0126.

Conclusion: These results suggest that the increased activity of PKC ϵ under high glucose condition might decrease the expression of Bmp4 and Nox4 through MAPK pathway, and contribute to the development and progression of diabetic nephropathy.

Short telomers – an independent predictor of mortality in diabetic nephropathy

L. Tarnow¹, M. Lajer¹, R. Nzietchung², A. Benetos², H.-H. Parving^{3,4},
¹Steno Diabetes Center, Gentofte, Denmark, ²Faculte de Medicine, INSERM U684, Nancy, France, ³Department of Endocrinology, Rigshospitalet, Copenhagen, Denmark, ⁴Faculty of Health Science, University of Aarhus, Denmark.

Background and Aims: Telomeres are the repeat DNA sequences located at the end of chromosomes. Telomeres shorten at each cell division, and once shortened to a critical length cells are trapped into replicative senescence

more likely to undergo apoptosis. Furthermore, mean length of the terminal restriction fragments (TRF) have been proposed to play a role in essential hypertension and atherosclerosis. Diabetes and diabetic nephropathy in particular are characterised by an increased risk of cardiovascular morbidity and mortality. This study investigated the prognostic value of telomere length in a large cohort of type 1 diabetic patients with and without diabetic nephropathy.

Material and Methods: Type 1 diabetic patients were included: 157 with overt diabetic nephropathy (89 men, age (mean(SD)) 41 \pm 9 years, duration of diabetes 28 \pm 8 years, GFR 75 \pm 32 ml/min/1.73m²) and a matched control group of 127 patients with longstanding type 1 diabetes and persistent normoalbuminuria (76 men, age 42 \pm 10 years, duration of diabetes 27 \pm 8 years). Patients were followed in a prospective observational follow-up study (follow-up time: 9.3 (0.0–9.5) years). Endpoints were all cause and cardiovascular mortality. Telomere length was measured as TRF from DNA samples extracted from white blood cells

Results: Mean telomere length did not differ between type 1 diabetic patients with and without diabetic nephropathy: 7.2 (0.8) kb versus 7.2 (0.8) kb, respectively ($p=0.8$). TRF was similar in men and women but was inversely correlated with age and systolic blood pressure, $p < 0.05$. TRF was not correlated with HbA_{1c}, albuminuria, GFR, or presence of cardiovascular disease at baseline. During follow-up 38 patients with and 6 patients without nephropathy died, $p < 0.001$. Among patients with nephropathy 19 (36%) patients with TRF in the shortest tertile, 13 (24%) patients with TRF in the middle tertile, and 6 (12%) in the longest TRF tertile died from any cause (log rank test $p=0.02$). The effect of TRF persisted after adjustment for sex, age, systolic blood pressure, smoking and GFR in a Cox proportional regression model. This lower mortality was attributable to fewer cardiovascular deaths.

Conclusion: Short telomere length is an independent predictor of the excess overall and cardiovascular mortality in type 1 diabetic nephropathy.

OP 12 Prevalence of childhood diabetes and mortality in type 2 diabetes

0067

Epidemiology of cystic fibrosis-related diabetes; results from a British cohort of children and adults

A. Adler¹, B. Shine²;

¹Diabetes, Addenbrooke's Cambridge University Hospitals, Cambridge,

²Clinical Biochemistry, John Radcliffe Hospital, Oxford, United Kingdom.

Background and Aims: Individuals with cystic fibrosis have a high prevalence of diabetes, but few estimates of incidence exist. Likewise, few prospective studies have identified risk factors for cystic fibrosis-related diabetes (CFRD). This study sought to determine incidence and risk factors for CFRD from a cohort of individuals with CF in the United Kingdom.

Materials and Methods: 8,029 individuals aged 0–64 years were identified from the UK CF Database, a registry of patients with CF coordinated by the UK Cystic Fibrosis Trust with data from over 60 specialist centres. Patient consent was obtained. Of the patients, 5,196 had no diabetes at baseline (1996–2004) and had at least one follow-up annual visit. Diabetes was defined as either a physician diagnosis of diabetes, a blood glucose of >11.1 mmol/l two hours following an oral glucose tolerance test, or treatment with insulin or oral hypoglycaemic drugs. Follow-up was as calculated time from baseline to the first detection of new diabetes or censoring (death (n=202), loss to follow-up or alive at last visit). Risk factors included clinical and anthropometric characteristics measured at baseline, and were analysed using Cox proportional hazards modelling.

Results: The median age was 12 years and BMI was 17.9 kg/m². 54% were male, and 96% were white. 526 patients developed diabetes during a total of 15,009 person years (median 2.8 years) of follow-up. The annual incidence was 3.5%. Patients who developed diabetes were more likely to have a low body mass index (BMI), pulmonary infections, liver and pulmonary function abnormalities, require antibiotic treatment, have had an organ transplant, and use pancreatic enzyme replacement. In multivariate analyses, female sex (hazard ratio (HR) 1.59 (95% CI 1.32–1.90), pulmonary infection with *Pseudomonas aeruginosa* (1.28, 1.06–1.56), % predicted forced expiratory volume in 1 second (1.021, 1.017–1.026 per 1% decrement), and portal hypertension (2.0, 1.2–3.1) were independently associated with incident diabetes controlling for age, BMI and history of organ transplantation.

Conclusion: This study confirms the very high incidence of CFRD, and shows that pulmonary and hepatic complications precede the onset of diabetes.

Diseases, Jagiellonian University, Medical College, Krakow, Poland,

⁷Department of Pediatrics, Medical University of Lodz, 1st Institute of

Pediatrics, Poland, ⁸Center for Child and Adolescent Endocrinology,

University Children's Hospital, Riga, Latvia.

Background and Aims: Recently, interest in 'neonatal' diabetes increased because a genetic diagnosis may allow patients to come off insulin, improve glycaemic control and possibly neurological features. We aimed to determine the anticipated increase in prevalence and incidence of permanent 'neonatal' diabetes in pediatric and adult care with the new definition.

Materials and Methods: The analysis included 293 (53% male) referrals from 27 countries to the Exeter Laboratory in the period to December 2006. Diabetes was diagnosed before 6 months of life irrespective of current age, had not remitted at time of study. Data on country of referral, age of diagnosis, date of birth and sex were obtained from standardized forms. All referrals were tested for *KCNJ11*-mutations.

Results: Observed minimum prevalence of the five most representative countries was 1.17 (1.01–1.31) per million population, with estimated true prevalence twice as high. Seventy-five percent were aged below 16 years with a median (IQ) of 5.7(2.4–10.2) years. Prevalence was higher for the pediatric versus the adult age range (0.78 (0.54–1.31) vs 0.42 (0–0.50); p=0.009). Age of diagnosis was skewed to a median (IQ) of 6 (1–13) weeks with 62% in the first 8 weeks. During 2000–4, minimum observed incidence was 2.95 (0–49.1) per million live births.

Conclusion: Observed minimum prevalence adjusted for definition was 2 to 25 times higher than previously reported and estimated true prevalence even higher. Results indicate that diabetes diagnosed before 6 months of life is still misclassified and suboptimally treated calling for awareness in pediatric and adult care.

0069

High- medium- and low-molecular weight adiponectin in children: Findings from a population-based cohort

R. Nishimura¹, A. Morimoto¹, T. Matsudaira¹, Y. Miyashita¹, T. Shirasawa²,

E. Takahashi², N. Tajima¹;

¹Department of Internal Medicine, Jikei University School of Medicine,

²Department of Public Health, Showa University School of Medicine, Tokyo, Japan.

Background and Aims: Adiponectin, which has drawn significant attention in clinical research, is a hormone released from adipocytes. Adiponectin is mainly classified into the high-molecular weight (HMW), hexameric medium-molecular weight (MMW) and trimeric low-molecular weight (LMW) adiponectin. In 2006, a number of clinical findings have been reported on the HMW adiponectin isoform, which indicated HMW, rather than total adiponectin levels is better for the prediction of insulin resistance, metabolic syndrome and coronary artery disease. However, there are little reports, to date, which have examined these adiponectin values in a population-based cohort of children.

Materials and Methods: A total of 760 children (374 male and 386 female fourth-graders aged 9–10 years old), who gave informed consent as well as their parents, participated in this study conducted in Ina, Saitama, Japan. These study subjects represented a nearly perfect population-based cohort, accounting for 98.7 / 99.0 (male / female) % of the fourth-graders in the area. Blood samples were drawn from the subjects at the time of their health check-ups to measure their adiponectin isoform values using a commercially available ELISA kit (Daiichi Pure Chemical Co. Ltd., Tokyo, Japan). The correlation between HMW, MMW, and LMW adiponectin and total adiponectin, and between HMW, MMW, and LMW adiponectin and body mass index (BMI) were assessed using Spearman's correlation coefficient. Statistical analyses were made using SPSS program.

Results: The median (intraquartile range) of HMW, MMW, LMW and total adiponectin (µg/ml), and BMI (kg/m²) were 2.5 (1.7–3.5), 1.8 (1.5–2.3), 1.5 (1.2–1.9) and 5.9 (4.7–7.6), and 16.8 (15.6–18.8) for males and 2.7 (1.7–3.8), 1.8 (1.5–2.3), 1.6 (1.2–2.0) and 6.4 (4.8–7.8), and 16.4 (15.3–17.9) for females, respectively. There were no statistical differences in these values by sex except for BMI (P=0.002). HMW, MMW, and LMW adiponectin values were all found to be positively correlated with the total adiponectin value (Spearman's correlation coefficient: r = 0.931, P<0.001; r=0.753, P<0.001; and r=0.562, P<0.001 for males, and r = 0.936, P<0.001; r=0.743, P<0.001; and r=0.560, P<0.001 for females, respectively). HMW and MMW adiponectin showed significant negative weak correlation with the BMI (r = -0.173, P<0.001 and r=-0.144, P=0.005 for males and r = -0.241, P<0.001 and r=-0.155, P=0.002 for females, respectively); however, LMW adiponectin showed no significant relationship with BMI at all (r=-0.005, P=0.919 for males and r=-0.091, P=0.076 for females, respectively).

Conclusion: The present study indicated that the HMW adiponectin negatively significantly correlated with BMI, which indicated that HMW

adiponectin may be the active form of adiponectin in prepubertal children.

The National Diabetes Register of Denmark: mortality and relative mortality of diabetes patients

B. Carstensen¹, P. Ottosen², J. K. Kristensen³, K. Borch-Johnsen¹;

¹Epidemiology, Steno Diabetes Center, Gentofte,

²Research service, National Board of Health, Copenhagen,

³Dept. of General Practise, University of Århus, Denmark.

Introduction and Material: In 2006 a national register of diabetes patients in Denmark was established by the National Board of Health. It is based on existing registers and all data are linked over time and across different data sources by the unique civil registry number allocated to all Danish citizens.

The Danish Diabetes Register is routinely linked with the Danish civil registration system and the register of causes of death in Denmark, thus providing accurate follow-up data for the entire population of patients with diabetes in Denmark.

Studies validating this method have shown that using this type of record linkage is feasible and will capture more than 90% of all patients with diabetes and only include very few persons not verifiable.

Methods: Follow-up of the diabetes patients from date of inclusion till date of death or the end of 2005 was used to calculate the mortality as depending on age and duration of diabetes. Mortality rates were compared with mortality rates in the non-diabetic part of the population by computing the standardized mortality ratio.

Results: Mortality rates in diabetes patients are higher than in the non-diabetic part of the population, but increase slower by age. The standardized mortality ratio (relative risk of death) is about 4 in ages 50 and about 1.8 in age 80, very similar between males and females. Thus the effect of diabetes on overall mortality is the same in males and females. Because of the very different age-distribution in males and females and in particular in persons with diabetes, an overall standardized mortality ratio will falsely show a higher relative mortality for males than for females due to age-confounding.

Conclusion: Diabetes patients have a higher mortality than the general population, but the relative effect of diabetes is strongly decreasing by age. There is not difference in the relative mortality between males and females.

0071

Undiagnosed diabetes – becoming a thing of the past? Data from the English longitudinal Study of Ageing and the Health Survey for England

M. B. Pierce¹, P. Zaninotto¹, N. Steel², J. Mindell¹;

¹Epidemiology and Public Health, University College London, ²Department of Primary Care, University College London, Norwich, United Kingdom.

Background and Aims: Research findings on the prevalence of undiagnosed diabetes and the ratio of undiagnosed to diagnosed diabetes in England, are contradictory. Some studies show that there are as many people with undiagnosed as diagnosed diabetes, others suggest there are much fewer people with undiagnosed disease. None of these studies are current and nationally representative. The aim of the current study is to examine the prevalence and distribution of undiagnosed and diagnosed diabetes, in the population of England aged over 50 years.

Materials and Methods: This was a cross-sectional study carried out 2003/5. Participants were nationally representative samples of 7,657 respondents from the English Longitudinal Study of Ageing (ELSA) and 5818 people from the Health Survey for England 2003 (HSE), aged 50 years and over. Fasting blood glucose was measured in non-diabetic participants; 2683 of the ELSA participants and 448 of the HSE participants. The main outcome measures were:

a. Self-reported doctor diagnosed diabetes

b. Fasting blood glucose of ≥ 7 mmol/l amongst those without self-reported doctor diagnosis of diabetes.

Results: In ELSA the prevalence of undiagnosed diabetes was only 1.7% (95%CI:1.2 to 2.2) and of diagnosed diabetes was 7.5% (95%CI to 6.9;8.2); the ratio of undiagnosed to diagnosed was 1:5 (1:3 in men and 1:10 in women).

The overall prevalence of diabetes (undiagnosed plus diagnosed) was 11.6% (95%CI:10.4 to 12.4) in men and 6.8% (95%CI:6.1 to 7.5) in women. Both undiagnosed and diagnosed diabetes were more common in men than in women ($p < 0.001$). Results from HSE were similar. In ELSA undiagnosed diabetes was commoner in the poorest than the richest women (2.1% vs.0%, $p = 0.012$). In some groups (the richest quintile of women, and those aged 75–79 years) we found no undiagnosed diabetes.

Conclusions: The prevalence of undiagnosed diabetes and the ratio of undiagnosed to diagnosed diabetes were substantially lower than previous estimates. This is probably due to improved clinical methods supported by recent policy initiatives. Our results support the notion that there is no need for a national diabetes screening programme in England and that it is likely that the Vascular Risk Assessment and Control Programme will improve detection in the more difficult-to-reach groups.

Supported by the U.S National Institutes of Aging and a consortium of English Government Departments

0072

Association between serum heat shock proteins and anti-heat shock proteins levels with micro/macrovacular complications in type 1 diabetes: the EURODIAB Prospective Complications Study

D. Burt¹, G. Bruno¹, N. Chaturvedi², C. D. Stehouwer³, S. Pinach¹, D. Witte², J. H. Fuller², P. Cavallo Perin¹, G. Gruden¹;

¹Department of Internal Medicine, University of Turin, Italy,

²Department of Epidemiology and Public Health, Royal Free and University College London Medical School, United Kingdom, ³Department of Internal Medicine, Academic Hospital Maastricht, The Netherlands.

Background and Aims: Heat Shock Proteins (Hsp) are a highly evolutionary conserved family of polypeptides with cytoprotective activity. Hsp normally function intracellularly; however cellular stresses can induce their release into the circulation and elicit an autoimmune response. There is considerable evidence for a relationship between circulating Hsp and anti-Hsp levels and cardiovascular disease (CVD) in the general population. People with type 1 diabetes are particularly at high risk of micro/macrovacular complications; however, no study has been designed to establish whether Hsp/anti-Hsp levels are markers of micro/macrovacular diseases in these patients.

Materials and Methods: We performed a cross-sectional nested case-control study from the EURODIAB Prospective Complications Study. A total of 531 type 1 diabetic patients were studied. Cases ($n = 363$) were defined as those with one or more complications of diabetes and control subjects ($n = 168$) those with no evidence of any complication. Hsp27, Hsp70, Hsp60, anti-Hsp60, and anti-Hsp70 serum levels were measured by ELISA. Total serum immunoglobulin levels were determined by immunonephelometry. Micro/macrovacular complications (retinopathy, nephropathy, neuropathy, CVD), conventional and inflammatory risk factors were assessed.

Results: Hsp27, anti-Hsp60, and anti-Hsp70 were measurable in all samples, whereas Hsp60 and Hsp70 were detectable in less than 5% of the patients. Hsp27 levels were positively correlated with AER ($p = 0.03$) and higher mean values were found in people with nephropathy ($p = 0.07$), proliferative retinopathy ($p = 0.01$), and distal symmetrical polyneuropathy ($p = 0.005$). Anti-Hsp60 levels were positively associated with anti-Hsp70 and IL-6. Anti-Hsp70 levels were negatively correlated with systolic and diastolic blood pressure ($p = 0.004$, $p = 0.001$, respectively), BMI ($p = 0.03$), AER ($p = 0.01$), creatinine ($p = 0.03$), and LDL-cholesterol ($p = 0.05$). Furthermore, mean anti-Hsp70 levels were significantly higher in females ($p = 0.01$), in normotensives ($P = 0.002$), in patients without microvascular complications (retinopathy $p = 0.006$; nephropathy $p = 0.039$; neuropathy $p = 0.006$), and in those treated with ACE-inhibitors ($p = 0.005$). In logistic regression analysis, with respect to values of anti-Hsp70 in the lower quartiles, higher values were associated with a 38% risk reduction of micro/macrovacular complications (OR=0.62, 95% CI 0.33–1.18) and with a 45% risk reduction of developing nephropathy (OR=0.55, 95% CI 0.32–0.95), independently of duration of diabetes, HbA1c, systolic blood pressure, smoking and TNF α . On the contrary, anti-Hsp60 and HSP27 levels in the upper quartile conferred an increased risk of both complications (anti-Hsp60:OR=1.8, 95% CI 0.95–3.3; Hsp27:OR=1.55, 95% CI 0.84–2.86) and nephropathy (anti-Hsp60:OR=1.08, 95% CI 0.63–1.84; Hsp27:OR=1.42, 95% CI 0.83–2.4).

Conclusion: In this large cohort of European type 1 diabetic subjects, we demonstrate an independent association between micro/macrovacular complications and both anti-Hsp70 and Hsp27 circulating levels.

Impact of PPAR-gamma agonists on adipose-tissue insulin resistance in patients with IGT or T2DM and non-alcoholic steatohepatitis (NASH)

A. Gastaldelli¹, B. Balas², J. Hardies³, S. A. Harrison⁴, R. Belfort², K. Brown⁵, S. Schenker⁵, R. DeFronzo², K. Cusi²;

¹Metabolism Unit, CNR Institute of Clinical Physiology, Pisa, Italy, ²Div. Diabetes, UTHSCSA, San Antonio, United States, ³Res. Imaging Ctr, UTHSCSA, San Antonio, United States, ⁴Gastroenterology, Brooke Army Medical Center, San Antonio, United States, ⁵Gastroenterology, UTHSCSA, San Antonio, United States.

Background and Aims: Hepatocellular lipids (Hep-L) accumulation is frequently observed in insulin-resistant states including type 2 diabetes mellitus. We have recently reported that pioglitazone (PIO) treatment improved glucose metabolism, steatosis and necro-inflammation in IGT/T2DM patients and biopsy-proven non-alcoholic steatohepatitis (NASH). Because abnormal lipid metabolism/elevated plasma FFA are believed to play an important role in the development of hepatic steatosis (i.e., fat overflow to the liver) we examined the role of adipose tissue IR and impact of PIO therapy in this cohort of NASH pts.

Materials and Methods: Patients received a hypocaloric diet (~500 kcal/d) and were randomized (double-blind) to PIO (45mg/d) or placebo (Pbo) for 6 months. Before and after treatment pts underwent: 1) liver biopsy; 2) liver fat measurement by magnetic resonance (Hep-L); 3) double-tracer 75g OGTT to assess glucose tolerance, glucose production (EGP) and clearance, and to estimate indexes of IR at the level of adipose tissue (Adip-IR=fasting plasma FFA x insulin conc [FPI]) and liver (Hep-IR=EGP x FPI). 15 control subjects (CT) were also studied in the same way (except for liver biopsy).

Results: Compared to CT, NASH had increased FFA (739±34 vs. CT 596±44 umol/l; p<0.001), impaired FFA suppression during OGTT (360±18 vs 240±19 umol/l; p<0.001), severe Adip-IR (12.1±1.3 vs. 2.7±0.6 mmol/l•mU/l, p<0.0003) and low adiponectin (7.0±1.6 vs. 13.2±2.1 mg/l p<0.001). Hep-L was ~3-fold higher in NASH (p<0.001) and correlated positively with Adip-IR (r=0.35, p<0.05) and negatively with adiponectin (r=-0.31, p<0.03). Hep-IR was associated with high fasting and OGTT FFA (r=0.30, p=0.02). Both Hep-IR and Adip-IR were strongly associated with reduced glucose clearance both fasting (r=0.39 and r=0.37) and during OGTT (r=0.44 and r=0.40, all p<0.002). PIO significantly improved Hep-IR, glucose tolerance and clearance, steatosis and necro-inflammation (all p<0.01–0.001 vs. Pbo). Compared to Pbo, FFA decreased by ~15% with PIO (p<0.02), Hep-L by ~50% (p<0.001) and Adip-IR by 40% (p<0.05). Hep-L decrease was associated with improved Adip-IR and OGTT glucose clearance (r=0.43 and r=-0.55, both p<0.02). Adiponectin increased ~3-fold (p<0.001), correlating strongly with a decrease in L-MRS (r=-0.57, p<0.001), Hep-IR and Adip-IR (r=-0.37 and r=-0.54, p<0.01) and enhanced OGTT glucose clearance (r=0.44, p<0.004).

Conclusion: Patients with IGT/T2DM and NASH showed severe Adip-IR which was associated with elevated liver fat, low adiponectin and hepatic and peripheral insulin resistance. Enhanced adipose tissue function (i.e., improved insulin sensitivity/increased adiponectin) after PIO treatment is likely to play a key role in the metabolic (i.e., hepatic/peripheral insulin sensitivity) and histologic (i.e., reduction in liver fat and associated necro-inflammation) improvements associated with treatment.

Greater reductions in C-reactive protein with rosiglitazone than with glyburide or metformin despite greater weight gain

S. M. Haffner¹, S. E. Kahn², B. Zinman³, R. R. Holman⁴, G. F. Viberti⁵, W. H. Herman⁶, J. M. Lachin⁷, B. G. Kravitz⁸, M. A. Heise⁸;

¹Medicine/Clinical Epidemiology, University of Texas Health Science Center at San Antonio, United States, ²Department of Medicine, VA Puget Sound Health Care System, Seattle, United States, ³Medicine, Mount Sinai Hospital, Toronto, Canada, ⁴Diabetes Trials Unit, OCDEM, Churchill Hospital, Oxford, United Kingdom, ⁵Department of Diabetes & Endocrinology, King's College London School of Medicine, United Kingdom, ⁶Internal Medicine – Metabolism, Endocrinology and Diabetes (MEND), University of Michigan, Ann Arbor, United States, ⁷The Biostatistics Center, George Washington University, Rockville, United States, ⁸GlaxoSmithKline, King of Prussia, United States.

Background and Aims: In ADOPT (A Diabetes Outcome Progression Trial), rosiglitazone (RSG) decreased time to monotherapy failure compared with glyburide (GLY) and metformin (MET) in patients with recently diagnosed type 2 diabetes. We have previously reported that obesity at baseline was the main determinant of C-reactive protein (CRP) in these patients. Previous small, short-term studies have shown that thiazolidinediones (TZDs) can reduce inflammation, as measured by high-sensitivity CRP. However, these studies were not able to determine whether increased weight gain with TZDs might preclude their effects on CRP.

Materials and Methods: Patients from the North American Cohort of ADOPT with a median follow-up of 4.0 years (n = 783) were examined. At baseline, the median BMI was 32.8 kg/m² and was similar in each treatment group. The median baseline CRP values were 4.5 mg/l, 3.7 mg/l and 4.2 mg/l for RSG, GLY and MET, respectively.

Results: While all treatments decreased CRP levels from baseline after 4 years, the reduction by RSG was 47.6% relative to GLY (95% CI = 57.8, 35.0; p<0.0001) and 30.5% relative to MET (95% CI = 43.3, 14.9; p = 0.0004). However, RSG resulted in a 3.85 kg increase in weight compared with GLY (95% CI = 2.39, 5.31) and an 8.56 kg increase compared with MET (95% CI = 7.16, 9.95) at 4 years.

Conclusion: Despite greater weight gain over the 4-year follow-up period, RSG more effectively reduced inflammation than did MET or GLY. Further study is required to clarify the mechanism involved.

Pioglitazone, oedema and congestive heart failure: a meta-analysis of randomised controlled trials

J. De Flines, A. J. Scheen;

Division of Diabetes, Nutrition & Metabolic Disorders and Clinical Pharmacology Unit, University of Liège, Belgium.

Background and Aims: Thiazolidinediones are associated with weight gain and peripheral oedema. In Europe, glitazones can not be prescribed in insulin-treated diabetic patients because of a suspected higher risk of congestive heart failure (CHF). The controversial results of the cardiovascular prevention trial PROactive with pioglitazone (PIO) raised further concern about the risk of CHF. The aims of the present meta-analysis were to evaluate the risk of oedema and CHF in randomised controlled trials (RCTs) with PIO and to compare the risk according to the type of therapy, i.e. PIO as monotherapy, added to another oral antidiabetic drug (OAD) or combined with insulin.

Materials and Methods: We performed an extensive search in the literature and selected all RCTs that randomised at least 50 patients and provided detailed figures on oedema incidence. We restricted our analysis to RCTs of at least 16-week duration with PIO therapy (15–45 mg/day) in order to have a chance to detect clinically meaningful differences in peripheral oedema, CHF and weight gain. The control group may receive either placebo or another OAD (except another glitazone). Odds ratio (OR) of oedema with PIO versus non-PIO were calculated for the pooled trials and analysed separately according to the associated therapy (diet, OAD or insulin). Data of the meta-analysis were also compared to those from the PROactive trial, which was analysed separately because of its specific design and population.

Results: Besides PROactive, we identified 25 RCTs (10 vs placebo, 14 vs another OAD, 1 vs insulin) that met the criteria used for selection: 12 with PIO added to diet alone, 10 with PIO added to one (8) or two (2) OADs, 2 with PIO combined with insulin, 1 with PIO added to any treatment, for a total of 5121 patients in the PIO cohort and 4567 patients in the non-PIO cohort. Overall, the OR of oedema was 2.64 (95% CI 2.22, 3.15) in PIO compared to non-PIO groups ($p < 0.00001$); p for heterogeneity = 0.08. The respective OR were 2.37 (1.85, 3.02), 3.13 (2.29, 4.27), 2.73 (1.77, 4.23) for the three subanalyses of monotherapy, combined therapy, or insulin-treated groups (all $p < 0.00001$). Numbers of CHF cases were low, perhaps because of a careful patient selection, although underreporting could not be excluded. Nevertheless, overall 21 CHF cases were specifically reported in the PIO group compared with only 5 CHF cases in the non-PIO group: none in monotherapy, 17/2227 patients in combined therapy and 4/521 patients with insulin + PIO. Weight gain averaged 2.35 kg in patients receiving PIO as compared to -0.32 kg in patients not receiving PIO. In PROactive, despite a only slightly higher weight difference (PIO +3.6 kg vs placebo -0.4 kg), the incidence of CHF was much higher (281/2605 in the PIO group compared to 198/2633 in the placebo group), possibly because of differences in the assessment of CHF but presumably also because of the specifically selected population at very high cardiovascular risk.

Conclusions: The present meta-analysis showed that PIO is associated with a 2.5 to 3-fold increased risk of oedema, a risk apparently 33% higher in combined therapy as compared to monotherapy. Astonishingly, the risk was not further aggravated in insulin-treated patients, but caution is recommended because of the limited number of trials in those patients. The rather low number of CHF cases reported in RCTs hinders any definite conclusion, although more CHF cases were noticed in the PIO group, confirming the data of the large PROactive trial.

Autonomic neuropathy predisposes to rosiglitazone-induced vascular leakage in insulin treated type 2 diabetesC. J. J. Tack¹, A. J. M. Rennings², M. M. W. Stewart³, P. Smits⁴;¹Internal Medicine, Radboud University Nijmegen Medical Center, The Netherlands, ²Pharmacology-Toxicology, Internal Medicine,

Radboud University Nijmegen Medical Center, The Netherlands,

³Glaxo Smith Kline, Harlow, United Kingdom, ⁴Pharmacology-Toxicology, Radboud University Nijmegen Medical Center, The Netherlands.

Background and Aims: Treatment with thiazolidinedione (TZD) derivatives is associated with fluid related complications, but the exact mechanism is

unclear. One potential mechanism is that TZDs induce arterial vasodilatation resulting in both increased vascular leakage and blood pressure reduction, followed by reflex stimulation of the sympathetic nervous system and renal fluid retention. In subjects with autonomic neuropathy this counterbalance response is thought to be reduced. We investigated whether rosiglitazone (RSG) increases vascular leakage, especially in patients with autonomic neuropathy.

Materials and Methods: We conducted a randomized, double blind, placebo-controlled, parallel study in 40 patients with type 2 diabetes on insulin treatment. Both treatment groups, placebo and RSG, were stratified for sex and autonomic neuropathy assessed with the Ewing score (< 2.5 or ≥ 2.5). We investigated the effects of a 16-week treatment with RSG 4 mg bid on vascular leakage (transcapillary escape rate of albumin, TERalb), body weight, extra cellular volume and total body water, plasma volume (PV), and hemodynamic changes.

Results: RSG improved glycemic control, decreased diastolic blood pressure (-3.9 mmHg, $P=0.03$), increased weight ($+2.0$ kg, $P=0.004$), and increased PV ($+241$ ml, $P=0.02$). RSG tended to increase vascular leakage (Δ TERalb $+1.08\%/hr$, $P=0.09$), but this effect was substantially higher in the subjects with Ewing scores ≥ 2.5 (Δ TERalb $+1.96\%/hr$, $P=0.03$). In addition, the increase in vascular leakage during RSG treatment was highly correlated with the Ewing score at baseline ($r=0.65$, $P=0.02$). There was no correlation between Ewing score and the RSG-induced change in fluid parameters.

Conclusion: RSG increases vascular leakage especially in the co-existence of autonomic neuropathy in insulin treated patients with type 2 diabetes. Whether this in itself is sufficient to cause fluid retention is unclear, because autonomic neuropathy did not exaggerate the hemodynamic and fluid related effects of RSG. Nevertheless, autonomic neuropathy may represent a risk factor for edema formation in response to TZD therapy in insulin treated patients.

Increased incidence of fractures in women who received rosiglitazone in ADOPT (A Diabetes Outcome Progression Trial)S. E. Kahn¹, S. M. Haffner², J. M. Lachin³, W. H. Herman⁴, B. Zinman⁵,R. R. Holman⁶, M. A. Heise⁷, R. P. Aftring⁷, G. F. Viberti⁸;¹Department of Medicine, VA Puget Sound Health Care System, Seattle, United States, ²Medicine/Clinical Epidemiology, University of Texas Health Science Center at San Antonio, United States, ³The Biostatistics Center,George Washington University, Rockville, United States, ⁴Endocrinology and Diabetes (MEND), University of Michigan, Ann Arbor, United States,⁵Medicine, Mount Sinai Hospital, Toronto, Canada, ⁶Diabetes Trials Unit, OCEM, Churchill Hospital, Oxford, United Kingdom, ⁷GlaxoSmithKline,King of Prussia, United States, ⁸Department of Diabetes & Endocrinology, King's College London School of Medicine, United Kingdom.

Background and Aims: Fractures (Fx) occur more frequently in people with type 2 diabetes (T2DM) than in non-diabetics. More Fx adverse events (AE) were reported by subjects randomized to rosiglitazone (RSG) than either metformin (MET) or glyburide (GLY) in A Diabetes Outcome Progression Trial (ADOPT), a clinical trial of initial monotherapy in subjects with newly diagnosed T2DM (median follow-up=4 years). This increase in Fx AE occurred in women but not men.

Materials and Methods: AE in ADOPT were collected prospectively, but analysis of Fx was not prespecified. To explore the time-course of Fx AE in ADOPT and potential risk factors, we examined data from the 1840 women randomized.

Results: In ADOPT, at least one Fx was reported by 111 women (RSG $n=60$, 9.3%, 2.74/100 patient-years [PY]; GLY $n=21$, 3.5%, 1.29/100 PY; MET $n=30$, 5.1%, 1.54/100 PY). The hazard ratio (95% CI) for RSG vs GLY was 2.13 (1.30, 3.51) and for RSG vs MET was 1.81 (1.17, 2.80). The cumulative incidence for RSG, GLY and MET appeared similar for approximately 1 year post-randomisation with divergence of RSG in women but not men after that time. The majority of fractures observed in women who received RSG during ADOPT were in the upper arm (humerus, $n=5$), hand ($n=8$) or foot ($n=22$). Overall, 76.6% of women were post-menopausal at baseline (BL). Among all women in ADOPT, those with Fx were older (58.8 ± 9.6 years [mean \pm SD], range 37–76 years vs 56.2 ± 10.3 years, 26–76 years; $p=0.01$) and more were post-menopausal (84.7% vs 76.1%, $p=0.04$) than those without Fx. BL characteristics were compared within treatment groups (RSG: $n=645$,

2187 PY; GLY: n=605, 1631 PY; MET: n=590, 1948 PY). Fx rates were higher in older women (<65 years vs ≥65 years) taking RSG (2.5/100 PY vs 3.6/100 PY) or GLY (1.1/100 PY vs 1.9/100 PY), but not MET (1.5/100 PY vs 1.6/100 PY). No other differences were apparent in BL characteristics (ethnicity, HbA1c, FPG, BP, weight, BMI, smoking and others) between women with Fx compared to those without Fx. No prior medical history or prior/concomitant medication use could be identified as a potential risk factor for Fx. The pattern of prior/concomitant AE of potential relevance to Fx was comparable among the treatment groups.

Conclusion: Further investigation into the risk factors for increased Fx in women is required to better understand the clinical implications of these findings.

Rosiglitazone decreases serum bone-specific alkaline phosphatase activity in postmenopausal diabetic women

Z. Berberoglu¹, A. GURSOY¹, N. Bayraktar², A. C. Yazici³, N. Tutuncu¹, N. Demirag¹;

¹Endocrinology, Baskent University, ²Biochemistry, Baskent University,

³Biostatistics, Baskent University, Ankara, Turkey.

Background and Aims: The purpose of the present study was to evaluate the effect of rosiglitazone on bone metabolism and to assess the association between the changes in bone turnover parameters and plasma cytokine levels in postmenopausal diabetic women.

Material and Methods: This was an open-label, randomized, controlled trial of 12-week duration. Fifty-six obese, postmenopausal women with newly diagnosed diabetes were studied. The nondiabetic control group comprised 26 healthy subjects matched for age and body mass index. All subjects were instructed to follow a weight-maintaining diet. Half of the diabetic subjects were randomly assigned to receive rosiglitazone (4 mg/day), and the other half remained on diet alone. Before and after the intervention, metabolic bone markers and serum cytokine levels were assessed.

Results: Serum total alkaline phosphatase and bone-specific alkaline phosphatase activities (bsALP) were markedly lower 12 weeks after the initiation of rosiglitazone treatment (82.7±21.9 vs 69.2±16.8 IU/L for total ALP, respectively, $P < 0.001$ and 28.9±9.7 vs 22.7±7.3 IU/L for bsALP, respectively, $P < 0.01$). On the other hand, the values of these parameters did not change in the other two groups. The differences in the changes in these parameters between the rosiglitazone and other two groups were significant ($p < 0.05$ for both total ALP and bsALP, respectively). There were no significant changes in the osteocalcin levels among the three groups. No significant change was observed in the deoxypyridinoline levels in the rosiglitazone group. At the end of 12 weeks, patients in the three groups had significantly decreased interleukin-1 beta and tumor necrosis factor-alpha (TNF- α) compared with baseline. The changes in bsALP levels showed a moderate negative correlation with the change in TNF- α after rosiglitazone and after diet in the diabetic control group ($r = -0.534$, $P = 0.003$ and $r = -0.376$; $P = 0.049$, respectively).

Conclusion: These results suggest that rosiglitazone use is associated with reduced bone formation at earlier stages in postmenopausal diabetic women. However, the cytokine-lowering effects of rosiglitazone and lifestyle changes could reverse early inhibitory effect of rosiglitazone therapy on bone formation. Further studies will clarify the long-term effects of rosiglitazone therapy on bone loss and fracture.

OP 14 Genome-wide association scans

0079

Genome-wide association data highlight an aetiological role for disturbances in cyclin-dependent kinase pathways in type 2 diabetes

N. J. Timpson^{1,2}, E. Zeggini¹, M. N. Weedon³, C. M. Lingren¹, T. M. Frayling³, K. S. Elliott¹, H. Lango³, UK Type 2 Diabetes Genetics Consortium, Wellcome Trust Case Control Consortium, J. R. B. Perry³, N. W. Rayner¹, R. M. Freathy³, J. C. Barrett¹, C. J. Groves¹, A. D. Morris⁴, A. T. Hattersley³, M. I. McCarthy¹;

¹Wellcome Trust Centre for Human Genetics & OCDEM, Oxford University, ²Department of Social Medicine, Bristol University,

³Genetics of Complex Traits/Diabetes Genetics, Exeter University,

⁴Diabetes Research and Population Pharmacogenetics Gr, Ninewells Hospital and Medical School, Dundee, United Kingdom.

Background and Aims: Large-scale genome-wide association (GWA) scans offer the potential to identify novel pathways involved in the aetiology of T2D.

Materials & Methods: The Wellcome Trust Case Control Consortium recently completed a GWA scan (Affymetrix 500K chip) in 1924 UK T2D cases and 2938 controls. Association signals of interest were analysed further in up to 3757 additional T2D cases and 5346 controls from the UK. We also made collaborative use of GWA and replication data from two other studies conducted in European samples (the Diabetes Genetics Initiative and FUSION). The maximal combined data set available for analysis was 32,760.

Results: Amongst several novel extensively-replicated association signals, two map close to or within genes implicated in the regulation of CDK (cyclin-dependent kinase) activity. A cluster of SNPs within the CDKAL1 gene on chr6 displaying T2D-associations in the WTCCC GWA scan (OR 1.20[1.10, 1.31], $p = 2.5 \times 10^{-5}$), showed strong replication in the UK sets ($p = 8.4 \times 10^{-5}$: all UK data $p = 1.3 \times 10^{-8}$) and further support in the DGI and FUSION studies (combined evidence: OR 1.13 (1.09–1.17), $p = 1.4 \times 10^{-12}$). The function of the CDKAL1 product is unknown, but it is homologous to CDK5RAP1, a known inhibitor of CDK5, which a kinase previously-implicated in islet function. On chromosome 9, a second cluster of T2D-associated SNPs from the GWA scan (OR 1.22, 1.09–1.37; $p = 7.6 \times 10^{-4}$) was also confirmed in UK replication samples ($p = 1.7 \times 10^{-4}$; combined $p = 4.9 \times 10^{-7}$) and generated a compelling signal across all studies (OR 1.20 (1.15–1.25) $p = 2.2 \times 10^{-15}$). Haplotype and conditional analyses within the region of association indicate that this signal is driven by an, as yet, untyped (non-HapMap) variant. The chr9 locus lies in sequence devoid of annotated genes, but is ~150kb from the genes encoding the CDK inhibitors, CDKN2A and CDKN2B. For both, overexpression of the murine homologue has been conclusively shown to disturb islet development and/or regeneration and to lead to diabetes. In humans, loss of function due to mutations in CDKN2A is a powerful contributor to the development of neoplasia.

Conclusion: Whilst further studies are required to establish a functional connection between the confirmed T2D-susceptibility variants identified and the genes described, our data provide the first indications that variation in CDK activity is a key pathogenetic mechanism in the development of T2D. This is most likely mediated through effects on islet development, regeneration and function. Since some of the same genes are also implicated in cancer, our data highlight potential shared aetiological pathways influencing both metabolic and neoplastic disease.

Large-scale replication typing of modest signals from genome-wide association studies identifies additional type 2 diabetes susceptibility variants in the *IGF2BP2* and *VEGFA* genes

E. Zeggini¹, M. N. Weedon², C. M. Lindgren¹, T. M. Frayling², K. S. Elliott¹, H. Lango², N. J. Timpson³, UK Type 2 Diabetes Genetics Consortium, Wellcome Trust Case Control Consortium, J. R. B. Perry², N. W. Rayner¹, R. M. Freathy², J. C. Barrett¹, C. J. Groves¹, A. D. Morris⁴, A. T. Hattersley², M. I. McCarthy¹;

¹WTCHG, University of Oxford, ²Genetics of Complex Traits/Diabetes Genetics, Peninsula Medical School, Exeter, ³Dept of Social Medicine, University of Bristol, ⁴Diabetes Research and Population Pharmacogenetics Groups, Ninewells Hospital and Medical School, Dundee, United Kingdom.

Background and Aims: Initial efforts to identify susceptibility variants from genome-wide association (GWA) scans have concentrated on variants which achieve highly significant results in initial analyses. This approach, as executed by the Wellcome Trust Case Control Consortium (WTCCC) and other groups, has already led to identification of several novel susceptibility genes for type 2 diabetes (T2D) including *FTO*, *CDKAL1* and *HHEX*. However these variants, even combined, fail to account for the observed familiarity of T2D, indicating that there are many more T2D susceptibility genes as yet unidentified, most likely to have small or modest effect size. We have combined GWA and large-scale replication data to detect additional T2D susceptibility variants.

Materials and Methods: Starting from GWA data (393,453 SNPs) for 1924 T2D cases and 2938 population controls, we sought to confirm signals of interest in up to 3757 additional cases and 5346 controls from the UK. We also accessed additional GWA and replication data through collaboration with other international consortia (DGI, FUSION). The maximal combined dataset included 32,760 samples.

Results: Proof of principle for the identification of T2D-susceptibility variants of lesser effect was provided by well-established variants in *PPARG* (P12A) and *KCNJ11* (E23K, tagged by a close proxy [$r^2 = 0.9$]). For both, GWA significance values (1df trend test) were modest (both $p = 0.0013$) and effects sizes consistent with previous reports. We used biological candidacy and statistical evidence across multiple GWA studies to prioritise additional variants for replication. SNPs within the *IGF2BP2* gene (coding for a known regulator of insulin-like growth factor-2 translation), showed modest evidence of association in the WTCCC scan (maximal OR 1.15 [1.05–1.25], $p = 1.7 \times 10^{-3}$) with modest replication in the UK samples (all UK data, OR 1.11 [1.05–1.16], $p = 1.6 \times 10^{-4}$). However, evidence across all three studies (and replications) is overwhelming ($p \sim 8.6 \times 10^{-16}$). The signal maps to a 57kb region spanning the promoter and first 2 exons of *IGF2BP2*. Similar analyses identified a further putative T2D-signal located 57kb downstream of the *VEGFA* gene, encoding vascular endothelial growth factor A (maximal OR in UK data, 1.11 [1.05–1.17], $p = 2.0 \times 10^{-4}$), which was also detected in the DGI scan ($p = 4.4 \times 10^{-3}$). Finally, we sought replication of the *SLC30A8* association recently reported in a French GWA scan. The relevant SNP was poorly-captured on the Affymetrix chip used by the WTCCC, but we obtained independent evidence rs13266634 in our UK datasets (OR 1.12 [1.04–1.19], $p = 1.2 \times 10^{-3}$) and when combining all three studies ($p \sim 3.5 \times 10^{-7}$).

Conclusion: By combining multiple GWA scans, and using large-scale replication samples, we have been able to extend the number of multiply-replicated genes (or regions) with a confirmed role in T2D-susceptibility. Supported by Wellcome Trust, European Commission, Diabetes UK, MRC

Background and Aims: Type 2 diabetes (T2D) is rapidly increasing worldwide thereby posing a severe burden on individual and public health. Although this increase can be ascribed to both genetic and environmental factors, the genetic factors have been largely restricted to a few candidate genes based upon our limited knowledge of the pathogenesis of the disease. In an attempt to identify underlying gene loci, the Diabetes Genetic Initiative (DGI) has recently completed a whole genome association study for T2D and 18-related traits (<http://www.broad.mit.edu/diabetes>). To replicate best signals associated with T2D in DGI and diabetes-related traits in conjunction with the results from companion whole genome scans (the FUSION study, the WTCCC, and UKT2D) as well as recently reported risk loci for T2D (Sladek et al.).

Material and Methods: DGI comprised of 1,464 Scandinavian participants with T2D and 1,467 matched control subjects who were genotyped for 500,568 SNPs of which 389,731 SNPs passed stringent quality control criteria (MAF <1%, >95% call rate, HWE $p > 10^{-6}$) using Affymetrix 500K Array. Three case-control samples of European ancestry (comprising a total of 10,850 individuals) were used to replicate original findings: (1) 2830 T2D patients from the Malmo Diabetes Registry and 3550 controls from the Malmo Diet and Cancer study in Southern Sweden (MDC-DR), (2) 1226 T2D patients of European ancestry from the United States matched to 1226 control individuals and 1009 T2D patients and 1009 control individuals from Poland (GCI US).

Results: In the initial replication in 10,850 individuals including 107 best associated signals we identified and confirmed three novel risk loci for T2D: a locus on chromosome 9 near the cyclin-dependent kinase inhibitor 2A and 2B (*CDKN2A/CDKN2B*) (DGI 1.37, 95%CI (1.18–1.59), $p = 3.6 \times 10^{-5}$; replication MDC-DR/GCI 1.16 (1.09–1.27), $p = 2.2 \times 10^{-5}$; and combined OR 1.20 (1.12–1.28), $p = 5.4 \times 10^{-8}$); the insulin-like growth factor 2 binding protein 2 (*IGF2BP2*), locus on chromosome 3 (DGI 1.12 (1.00–1.26); $p = 0.052$, MDC-DR/GCI 1.19, (1.12–1.26), $p = 2.1 \times 10^{-9}$; and combined OR 1.17 (1.11–1.23), $p = 1.3 \times 10^{-9}$); and the cyclin-dependent kinase 5 (CDK5) regulatory subunit associated protein 1-like 1 (*CDKAL1*) on chromosome 6 (DGI 1.17 (1.04–1.31), $p = 7.5 \times 10^{-3}$; MDC-DR/GCI 1.07 (1.01–1.13), $p = 0.011$; and combined OR 1.10 (1.04–1.15), $p = 4.1 \times 10^{-4}$). We also replicated recently published by Sladek et al. risk locus for T2D, *HHEX* (DGI, OR 1.15 (1.04–1.29), $p = 0.01$; replication GCI 1.13 (1.04–1.23), $p = 6.0 \times 10^{-3}$; and combined OR 1.14 (1.06–1.22), $p = 1.7 \times 10^{-4}$).

Conclusions: Whole genome association studies can identify new loci increasing risk for T2D thereby providing novel clues into the pathogenesis of T2D. In our first replication effort, the *CDKN2A/CDKN2B* locus on chromosome 9, *IGF2BP2*, and *CDKAL1* emerged as novel T2D loci. Supported by Novartis foundation

A genome-wide association study identifies glucokinase regulatory protein (GCKR) locus as a novel regulator of blood triglyceride level

M. Orho-Melander¹, O. Melander¹, V. Lyssenko¹, R. Saxena², P. de Bakker², N. Burtt², B. Voight², J. N. Hirschorn², T. Tuomi^{3,4}, B. Isomaa⁴, M.-R. Taskinen⁵, T. E. Hughes⁵, D. Altshuler^{6,2}, L. Groop^{1,3} & S. Kathiresan^{7,2} for the Diabetes Genetics Initiative (DGI),

¹Clinical Sciences in Malmö, Lund University, Sweden, ²Genetic Analysis Platform, and Metabolism Initiative, Broad Institute of Harvard and MIT, Cambridge, United States, ³Department of Medicine, Helsinki University Hospital, Finland, ⁴Biomedicum, Folkhälsan Research Center, Helsinki, Finland, ⁵Novartis Institutes for BioMedical Research, Cambridge, United States, ⁶Center for Human Genetic Research and Department of Molecular Biology, Massachusetts General Hospital, Boston, United States, ⁷Cardiology Division, Massachusetts General Hospital, Boston, United States.

Background and Aims: The Diabetes Genetics Initiative (DGI) recently completed a genome-wide association study for type 2 diabetes (T2D) and 18 other traits including blood lipids. One polymorphism (rs780094) in the glucokinase regulatory protein gene (*GCKR*) achieved genome-wide significance for triglyceride (TG) levels ($P=3.7 \times 10^{-8}$). In the liver, *GCKR* regulates the activity of glucokinase (GCK) and overexpression of *GCK* in rodents results in lower blood glucose and hypertriglyceridemia. We therefore sought to replicate association between rs780094 and TG levels in three independent Swedish cohorts. Given the known role of *GCKR* in glucose metabolism we also examined association of rs780094 to T2D and measures of glucose homeostasis.

Materials and Methods: The DGI study material of 2,931 participants from Finland and Sweden (m/f 1,448/1,482, age 62±11 y, BMI 28±4 kg/m², TG 1.6±1.1 mmol/l, 50% with T2D) was genotyped using the Affymetrix 500K SNP Array. In order to replicate the DGI finding, rs780094 was genotyped in 1) 5,190 individuals composing the Malmo Diet and Cancer Study Cardiovascular Arm (MDC-CVA: m/f 2,140/3,050, age 58±6 y, BMI 26±4 kg/m², TG 1.3±0.7 mmol/l, 8% with T2D), 2) 5,152 patients with hypertension (NORDIL: m/f 2,567/2,585, age 60±7 y, BMI 28±4 kg/m², TG 1.8±1.2 mmol/l, 9% with T2D) and 3) 2,777 T2D patients from the Skania Diabetes Registry (DR: m/f 1,636/1,141, age 61±11y, BMI 30±6 kg/m², TG 2.6±3.1 mmol/l). SNP-phenotype association analyses were performed by multivariate linear regression using an additive genetic model and adjusting for age, sex and diabetes status.

Results: The initial association of rs780094 in *GCKR* was strongly replicated in all cohorts ($P=8.7 \times 10^{-8}$, 3.5×10^{-10} , 1.2×10^{-6} in MDC-CVA, NORDIL and DR, respectively). The minor T allele (frequency 33.5–35.3%) was associated with higher TG and the SNP explained 1.1, 0.4, 0.7 and 0.9% of the trait variance in DGI, MDC-CVA, NORDIL and DR, respectively. TG according to genotypes (CC, CT and TT) were: DGI 1.5±1.0, 1.6±1.2 and 1.8±1.1 mmol/l; MDC-CVA 1.3±0.7, 1.4±0.7 and 1.4±0.7 mmol/l; NORDIL 1.7±1.0, 1.8±1.5, 2.0±1.0, DR 2.4±3.4, 2.7±3.0 and 2.9±2.3 mmol/l. In MDC-CVA the T allele was nominally associated with lower fasting blood glucose ($P=0.02$), lower HOMA-IR ($P=0.01$), and reduced risk for T2D ($P=0.03$). Accordingly, T-allele carriers had lower fasting blood glucose ($p=0.03$) and a trend to lower risk for T2D in the NORDIL sample ($P=0.06$).

Conclusion: We have identified *GCKR* as a novel locus with a strong influence on plasma TG levels. Consistent with experimental data in rodents, *GCKR* variation was associated with opposite effects on TG and blood glucose levels.

Type 2 diabetes (T2D) is a common, polygenic chronic disease with high heritability. Population prevalence is 5–10% and consistently increasing. The purpose of this whole-genome association (WGA) study was to discover novel T2D-associated genes. The subjects were 500 T2D cases and 497 controls from two homogenous founder (Eastern Finns, Ashkenazi Jews) and two heterogeneous (English, Germans) populations. All cases had at least one affected family member. Each subject was genotyped with 315,917 single nucleotide polymorphism markers (SNPs) using the Illumina HapMap derived panel of tagging SNPs. The call rate was 99.5%, reproducibility over 99.9% and concordance with the reference methodology, the Centaurus, over 99.9%. Following a permutation-based statistical correction for multiple testing, the only significant ($p < 2.3 \times 10^{-7}$) gene identified in the WGA study was *TCF7L2*, which has already been discovered and confirmed as a T2D susceptibility gene. Subsequently, we selected ten SNPs in the most promising six chromosomal regions with nominal statistical significance (on their own or as part of a haplotype) for further replication study in an independent case-control set including 2573 T2D cases and 2776 controls from France. Two SNPs (rs1535435, rs9494266) in the same chromosomal region (6q23.3) were found significantly ($p=0.00005$, $p=0.0002$) associated with T2D. The *p*-values for these SNPs from the pooled Mantel-Haenszel analysis of both the GWS and replication data were 0.000001 and 2.28×10^{-7} , respectively. These two SNPs were within a linkage disequilibrium block of 178 kb encompassing 19 introns of the *AHI1* gene. We propose *AHI1* as a novel T2D susceptibility gene. For the first time a WGA study is replicated in an independent population, providing strong evidence for the robustness of the WGA study approach.

Genome wide association scan for type 1 diabetes susceptibility genes in a Danish population

C. A. Brorsson¹, E. Swiergala², R. Bergholdt¹, K. Rapacki³, S. Purcell⁴, L. Field², F. Pociot¹;

¹Steno Diabetes Center, Gentofte, Denmark, ²Department of Medical Genetics, University of British Columbia, Vancouver, Canada,

³Center for Biological Sequence Analysis, Technical University, Lyngby, Denmark, ⁴Center for Human Genetic Research, Massachusetts General Hospital, Boston, United States.

Background and Aims: Type 1 diabetes (T1D) is the result from an immune-mediated destruction of the insulin producing pancreatic β -cells. The disease is believed to be influenced by interactions between multiple risk-conferring genes and environmental factors. In order to further investigate the genetic contribution to T1D we genotyped a Danish case-control material for 58000 SNP and tested these for association to disease.

Materials and Methods: We used Affymetrix GeneChip® Human Mapping Array Xba to genotype each sample on a single array. The resulting genotype calls were analysed using the software PLINK. The first phase of the study comprised of thorough quality tests of the data for issues such as sample contamination, inbreeding, low genotyping rates, relatedness and population stratification which led to samples being excluded. SNPs were removed for failing HWE in controls, low genotyping rate, for being non-polymorphic and differences in genotyping success rates between cases and controls which

contributed to significant false positive findings. After ensuring the highest quality of the data-set the remaining 52000 SNPs and 605 individuals (331 cases and 274 controls) were analysed using basic allelic and model-based tests of association corrected for multiple testing and using permutation with empirically corrected p-values. Furthermore we performed genome-wide sliding-window haplotype tests and a full pair-wise test for epistasis across the genome. A stratified analysis of cases from simplex vs. multiplex families was performed to identify possible differences between these groups. We also performed the same analyses for markers in 12 linkage regions previously reported in T1D.

Results: Every individual test confirmed the importance of the HLA-region on chromosome 6p21.3 for developing T1D. The combination of all tests identified markers in other chromosomal regions which could contribute to T1D development. HLA-region markers were also highly significant in both groups of cases after stratification. However, outside the HLA-region different markers on different chromosomes in the two groups showed the lowest p-values, indicating differences in the genetic contribution between simplex and multiplex cases.

Conclusion: The HLA region is of major importance for the susceptibility to T1D. In combination these tests point to other chromosomal regions outside MHC contributing to T1D susceptibility in the Danish population. The most significant findings will be followed up in a larger case-control material consisting of 2000 cases and 2000 controls of Danish origin to confirm these present results. In addition this study has demonstrated the importance of high quality data for avoiding false positive findings when performing association analyses in complex diseases.

Nuclear FoxO1 controls and integrates key signaling pathways in hepatocytes

M. Naïmi¹, N. Gautier¹, C. Chaussade¹, A. M. Valverde², D. Accili³, E. Van Obberghen¹;

¹Inserm u145, IFR50, Nice, France, ²Consejo Superior de investigaciones Cientificas C/Arturo Duperier 4, Instituto de Investigaciones Biomedicas Alberto Sols, Madrid, Spain, ³Columbia University, College of Physicians and Surgeons, New York, United States.

Background and Aims: Insulin inhibits Forkhead O class (FoxO) transcription factors, which down-regulate the expression of genes involved in metabolism, cell cycle arrest, and apoptosis. After being phosphorylated by protein kinase B (PKB) on S253 in its DNA binding domain, FoxO1 is phosphorylated on T24 and additional sites. Together, these modifications trigger FoxO1 nuclear exclusion. During this process, FoxO1 is thought to retain some transcriptional activity and signaling potential.

Materials and Methods: To evaluate this FoxO1 action, both primary cultures of rat hepatocytes and mice hepatocytes lacking IRS-2 were infected with adenoviral constructs encoding wild-type FoxO1, a transactivation domain-deleted FoxO1 or a FoxO1-ADA mutant, this latter mutant being constitutively nuclear but displaying reduced DNA-binding potential due to a mutation of S253 to D.

Results: Adenoviral-mediated expression of FoxO1-ADA in hepatocytes activates PKB and MAPK pathways, more than wild-type or dominant negative FoxO1. PKB activation cannot be accounted for by a FoxO1-mediated increase in upstream signaling components such as insulin receptor substrate 1 or 2 or by FoxO1-mediated down-regulation of Tribbles homolog 3. In contrast, p38 is required for mTORC2 activation and effects of FoxO1 on PKB, at least in part.

Conclusion: FoxO1 phosphorylated on S253 turns on a feed-forward loop, relayed by p38 and acting to amplify both PKB activation and FoxO1 inhibition through subsequent phosphorylation events. To conclude, FoxO1 controls its own nuclear exclusion by a complex mechanism which involves the modulation of its DNA binding by insulin, p38 and mTORC2 activation, and PKB phosphorylation on S473.

Molecular mechanisms that coordinate regulation of liver metabolism

D. A. Okar¹, S. Baltrusch², K. Zangger³;

¹VA Medical Center, Department of Veterans Affairs, Minneapolis, United States, ²Institute of Clinical Biochemistry, Hannover Medical School, Germany, ³Institute of Chemistry/Organic and Bioorganic Chemistry, University of Graz, Austria.

Background and Aims: The liver has a major role in maintaining glucose homeostasis, especially in response to nutritional excursions such as meal consumption and fasting. We aim to reveal the molecular mechanisms by which hepatic fuel metabolism is regulated because these offer cellular targets for the development of novel diabetes and obesity treatments. The major research focus has been the bifunctional enzyme, 6-phosphofructo-2-kinase/ Fructose-2,6-bisphosphatase (PFK-2/FBP-2), and the regulatory metabolite fructose 2,6-bisphosphate (F-2,6-P₂). We also describe the binding of glucokinase (GK) to the bisphosphatase domain of the bifunctional enzyme which activates both GK and PFK-2. Because changes in the phosphorylation state of Ser-32 in hepatic bifunctional enzyme is involved in modulating both the activities of the bifunctional enzyme (K/B) and the interaction with GK, understanding the molecular mechanism of this post-translational modification is a central aim of our research efforts. Until the recent report of a novel p53-related FBP-2, TIGAR [Bensaad, K, et al. 2006, Cell, 126:1], we had thought that the bifunctional enzyme was the sole enzyme involved in F-2,6-P₂ metabolism. We have now begun to investigate the molecular mechanisms of TIGAR.

Materials and Methods: We used a combination of histidine-specific NMR spectroscopy, steady-state kinetics, point mutagenesis, fluorescent and radio-labeling, and affinity resin pull-down assays to elucidate molecular aspects

of the bifunctional enzyme. Using the cardiac bisphosphatase domain as an NMR-accessible model, we have demonstrated the molecular basis for how post-translational modification of the bifunctional enzyme influences K/B. Using steady-state kinetics and affinity resin pull-down in conjunction with fluorescently labeled proteins, we probed the binding between GK and PFK-2/FBP-2. Using new expression vectors, anion exchange, and size exclusion chromatography we have purified TIGAR from bacterial expression extracts.

Results: Differences in hydrogen bonding within the cardiac and hepatic FBP-2 domains during turnover correlate with the lower activity in the heart isoform. These are relevant to the question of post-translational control of the bisphosphatase activity because the heart domain has the serine site included and can be investigated by histidine-specific NMR. Further, we have revealed that bifunctional enzyme and glucokinase bind in a 1:1 complex that concomitantly activates GK and the PFK-2 activity. The conservation of the signature FBP-2 catalytic residues in TIGAR produces a very similar kinetic mechanism in which a stable His-P intermediate is formed.

Conclusion: The liver bifunctional enzyme coordinates glucose up-take with glycolysis in response to glucose, insulin, and glucagon via changes in the phosphorylation state of Ser-32 which alter activities and the interaction with GK. The coordinating elements are multi-modal, affecting sub-cellular location and catalysis, which may be related to the relevance of these mechanisms to the acute hepatic response to re-feeding after a fast. The *in vivo* results suggest other aspects of the metabolic coordinating role as it influences hepatic lipid metabolism. TIGAR and fructose 2,6-bisphosphate metabolism provide a potential link to apoptosis.

HDAC3 and SMRT are required for inhibition of phosphoenolpyruvate carboxykinase expression by TNF- α

J. H. Yan^{1,2}, Z. G. Gao², G. Yu², Q. He², J. P. Weng¹, J. P. Ye²

¹Department of Endocrinology, the First Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China, ²Department of Antioxidant and Gene Regulation, Pennington Biomedical Research Center, Louisiana State University System, Baton Rouge, United States.

Background and Aims: Phosphoenolpyruvate carboxykinase (PEPCK) is a rate-limiting enzyme in the gluconeogenesis. Inhibition of PEPCK expression by tumor necrosis factor α (TNF- α) occurs at transcriptional level, and contributes to the pathogenesis of hypoglycemia in endotoxin shock. In this study, the molecular mechanism underlying the inhibition was investigated in hepatoma cells.

Materials and Methods: Rat H4IIE cells were treated with cAMP (200 μ M) and TNF- α (20 ng/ml) for induction and suppression of PEPCK expression. Transcriptional activation of the PEPCK gene promoter (-490/+100) was examined using rat PEPCK-Luc reporter in human HepG2 cells and ssIkB α -HepG2 stable cell line in which super suppressor IkB α was consistently expressed. Kinase-specific chemical inhibitors, including Aspirin (NF- κ B), SP600125 (JNK), SB203580 (p38 MAPK kinase), PD98059 (MEK/ERK) and LY294002 (PI3K), were used to evaluate the pathways required for the TNF-inhibition of PEPCK. Nuclear/cytoplasmic shuttling of HDAC3 protein was analysed in H4IIE and ssIkB-HepG2 cells treated with cAMP and TNF- α . The chemical inhibitor of HDACs (Butyrate, TSA) and RNAi-mediated gene knockdown were used to determine the corepressor involved in the p65-mediated inhibition of PEPCK by TNF- α . The interaction of CREB, HDAC3 and SMRT with the PEPCK gene promoter was investigated using ChIP assay and qRT-PCR in H4IIE cells. The classical CRE element (CREB binding site at -91/-84) was mutated in the rat PEPCK promoter through T to G substitution.

Results: In H4IIE cells, cAMP-induced PEPCK expression was reduced in a time-dependent manner by TNF- α at both protein and mRNA levels. Two inhibitors, Aspirin and LY294002, which are known to block NF- κ B activation, were able to block the TNF-inhibition. TNF- α induced the nuclear abundance of HDAC3. This change occurred with IkB α degradation in the cytoplasm. In HepG2 cells, the PEPCK-Luc reporter activity was increased 3 fold by cAMP and the induction was reduced more than 50% in the presence of TNF- α or p65 co-expression. In contrast, TNF- α activity was completely blocked in ssIkB α -HepG2 stable cell line as TNF-induced nuclear translocation of NF- κ B p65 was blocked. Inhibition of HDAC activity by the HDAC inhibitor or HDAC3 knockdown led to restoration

of the PEPCK reporter activity in the presence of TNF- α or p65 co-transfection. Inhibition of SMRT by gene knockdown produced the same effect. In ChIP assay, the interaction of HDAC3 and SMRT with the PEPCK gene promoter was induced by TNF- α . But CREB signal was reduced. The decrease in DNA-binding activity of CREB was not from inhibition of CREB phosphorylation or PGC-1 expression. CREB activity was inhibited by corepressor HDAC3 and SMRT in the PEPCK gene promoter. Point mutation suggested that the classical CRE element was required for TNF-inhibition of PEPCK. This site was a target of TNF- α in the inhibition of PEPCK gene promoter.

Conclusion: Our data support that NF- κ B p65 mediates TNF-inhibition of PEPCK transcription. The inhibition is dependent on the corepressor HDAC3-SMRT, and CREB is a target of the corepressor in hepatocytes. This study suggests a novel mechanism for TNF-inhibition of PEPCK expression and gluconeogenesis.

Transgenic mice overexpressing human fructose-1,6-bisphosphatase in the liver develop glucose intolerance in response to a high fat diet

S. Visinoni, B. C. Fam, A. Blair, C. Rantza, B. J. Lamont, R. Bouwman, J. Favaloro, J. Proietto, S. Andrikopoulos;

Department of Medicine (AH/NH), University of Melbourne, Heidelberg Heights, Australia.

Background and Aims: Fructose-1,6-bisphosphatase (FBPase) is postulated to be a key rate limiting enzyme in the gluconeogenic pathway. We have previously generated transgenic mice overexpressing human FBPase in the liver under the control of the transthyretin promoter. We reported that despite a 2-fold overexpression of liver FBPase, endogenous glucose production and glucose tolerance were normal. However, these mice also displayed transgene expression in the hypothalamus which may have affected the phenotype. We therefore generated a new liver FBPase transgenic mouse line in which the construct was flanked by insulator sequences to protect against site of integration effects. The aim of this study was to further characterise the glucose tolerance phenotype in the original model and the new insulated transgenic mice at two ages (24 weeks and 1 year old), when bred to homozygosity and in response to a 60% high-fat (HF) diet.

Materials and Methods: Glucose tolerance was measured by an intraperitoneal glucose tolerance test at a dose of 2 g/kg for 120 minutes in both male and female transgenic and negative littermate control mice following an overnight fast. Plasma was collected for glucose and insulin measurements. Mice on the HF diet were fed from 12 weeks of age for the duration of 12 weeks.

Results: The insulated heterozygous transgenic mice had a 3-fold overexpression of total liver FBPase mRNA with concomitant increases in FBPase protein and enzyme activity levels (n=4). Of importance, hypothalamic expression of FBPase mRNA was comparable in the insulated transgenic and control littermates (n=3). There was no difference in glucose tolerance in the 24 week old insulated heterozygous transgenic mice compared to the negative littermates (n=16). Similar findings were found in both the original transgenic and insulated transgenic mice at 1 year of age (n=7 for each group) and the homozygote line (preliminary data n=2). Interestingly, the HF fed original and insulated transgenic mice were glucose intolerant compared to their negative littermates (original: 2451.6 \pm 136 mmol/Lx120min; insulated: 2802.5 \pm 382 mmol/Lx120min; control: 1974.3 \pm 106 mmol/Lx120min; n=6-18, p-value < 0.02).

Conclusion: Overexpressing FBPase in the liver appears to have no effect on glucose tolerance in transgenic mice either at 24 weeks or 1 year of age or when bred to homozygosity. In contrast, under high fat feeding conditions, glucose tolerance was impaired. This suggests that FBPase is associated with glucose intolerance and may contribute to the chronic hyperglycaemia observed in Type 2 diabetic patients under conditions of excess fat intake.

In vivo phosphorylation of activating transcription factor 2 (ATF2) in insulin target tissues in mice: effects of insulin and of high-fat diet induced insulin resistance

B. Baan¹, P. J. Voshol², G. C. M. van der Zon¹, J. Kriek¹, E. Korshennikova¹, J. A. Romijn², J. A. Maassen¹, M. Ouwens¹;

¹Molecular Cell Biology, ²Endocrinology, LUMC, Leiden, The Netherlands.

Background & Aims: We have identified activating transcription factor 2 (ATF2) as novel insulin signalling intermediate in cultured cells. Activation of ATF2 and its target genes has been implicated in the regulation of the expression of the genes for insulin and the key gluconeogenic enzyme phosphoenolpyruvate carboxykinase (PEPCK), but has also been linked to beta-cell apoptosis, inflammation and atherosclerosis. To further detail the role of ATF2 in insulin action, we studied the induction of ATF2-phosphorylation by hyperinsulinemia *in vivo*, characterized insulin-regulated ATF2-target genes, and examined the effects of high-fat diet (HFD) induced insulin resistance on ATF2-activity in mice.

Materials & Methods: Chow or HFD-fed mice were infused with insulin while maintaining euglycemia. After sacrifice, tissues were examined for ATF2 phosphorylation by Western blotting and immunohistochemistry and for induction of ATF2 target genes by real-time PCR.

Results: *In vivo* insulin infusion induced a transient phosphorylation of ATF2 in the liver, epididymal adipose tissue and pancreas. In the liver, hyperinsulinemia suppressed the expression of PEPCK, and increased the expression of the ATF2-target genes ATF3, c-jun, and Egr1. shRNA-mediated silencing of ATF2 in cultured cell lines prevented the induction of ATF2-target genes by insulin. In tissues from insulin-resistant HFD-fed mice, a sustained increase in ATF2-phosphorylation and expression of ATF3, c-jun, and Egr1 was found already in the fasting state. Remarkably, livers from HFD-fed mice remained responsive for the induction of ATF2 target genes in response to hyperinsulinemia, whereas suppression of PEPCK was blunted.

Conclusion: ATF2 has a dual role in insulin action *in vivo* as it is activated both by hyperinsulinemia and under conditions of HFD-induced insulin resistance. The increased ATF2 activity in HFD-fed mice suggests a state of chronic inflammation. The intact insulin-mediated induction of detrimental ATF2-target genes in livers from insulin-resistant mice may further accelerate the development of diabetes-associated complications.

Supported by the Dutch Diabetes Research Foundation

confirmed by Western Blot analysis in liver and cell lines. **Real Time PCR:** it was performed for genes of proteins differentially synthesized which were identified by 2D-PAGE and MS. A discrepancy between amount and relative mRNA expression of several proteins was detected. This could be due to a translation block then mTOR activation and expression has been investigated by Western Blot.

Results: Five proteins at present, of the 22 proteins differentially expressed, were identified: PRDX-6, HMGB-1, ANXA-1, Calreticulin and XRN-2. The different expression of these molecules has been confirmed in the two experimental models. It has been detected that in IRKO tissues were increased Calreticulin and ANXA-1 respect to heterozygous and wild type and HMGB-1 was expressed only for IR^{-/-}, differently XRN-2 was found only in IR^{+/+}, and IR^{+/-}. PRDX-6 is a molecule present normally in two forms, oxidated and native and in IR^{+/+} cell line has been found in both forms differently in IR^{-/-} cell line has been detected only the native form. In liver has been detected only oxidated PRDX-6 phenotype. Reduction of insulin signaling induces a decrease proteins and myotubules proteins expression that is associated with related increases in mRNA levels, but, differently, there is a normal production of albumin. Western Blot analysis shown that in IR^{-/-} PEPCK was not expressed and SREBP-1 was over expressed, indicating alterations in glucidic and lipidic metabolism, respectively.

Conclusion:

- Insulin modulates proteins involved in oxidative stress (PRDX-6), inflammatory response (HMGB-1 and ANXA-1), mRNA processing (XRN-2)
- IRKO models shown: increased transcription, translation block, decreased gluconeogenesis and increased cholesterol synthesis.

Background and Aims: Type 2 Diabetes Mellitus (T2DM) is associated with increased insulin resistance levels and hepatic glucose production and defect of glucose stimulated insulin secretion in pancreatic beta cells. The aim of this study is to investigate the role of liver in the pathophysiology of disglycaemia, insulin resistance and T2DM. It has been used on two experimental models of target knockout insulin receptor IR^{-/-}: 1) transformed murine hepatocytes cell lines model – wild type IR^{+/+} and IR^{-/-} – to detect the modulation of insulin signaling in presence or absence of IR (basal conditions); 2) liver tissue from IR^{-/-}, IR^{+/-} and IR^{+/+} to discover differences in insulin substrates expression and activation in diabetic ketoacidotic conditions (pathophysiological conditions).

Materials and Methods: **Experimental models:** *in vitro* culture cell lines of fibroblasts/hepatocytes from IRKO mice transformed by adenovirus SV40; *ex vivo* genetically modified IRKO mouse and littermate control IR^{+/-}, IR^{+/+}. The differences in proteins expression profile and insulin signaling has been analyzed and compared between IR^{+/+}, IR^{+/-} and IR^{-/-} phenotypes. **Proteomic analysis:** proteins from liver and cell lines has been extracted in 8%Urea/2%Chaps and separated in IEF using 18 cm Strips pH 3–10. The proteins expression profile has been investigated by 2D-PAGE Silver Stain Analysis. The statistical analysis of 2D-GEL has been made by IMAGE MASTER 2D-PLATINUM. The proteins of interest have been identified by MALDI-TOF Mass spectrometry (MS). The amount of these proteins has been

Molecular mechanisms implicated in free fatty acid-induced ER stress and pancreatic beta cell apoptosis

L. Ladriere¹, P. Hekerman¹, D. A. Cunha¹, A. Bazarra-Castro¹, F. Ortis¹, D. L. Eizirik¹, M. Cnop^{1,2};

¹Laboratory of Experimental Medicine, Universite Libre de Bruxelles,

²Division of Endocrinology, Erasmus Hospital, Universite Libre de Bruxelles, Belgium.

Background and Aims: Free fatty acids (FFA) cause pancreatic beta cell apoptosis and may contribute to beta cell loss in type 2 diabetes via the induction of endoplasmic reticulum (ER) stress. The molecular mechanisms implicated in FFA-induced ER stress are unknown.

Material and Methods: FACS-purified primary rat beta cells and INS-1E cells were cultured in the presence of oleate and/or palmitate, with or without salubrinal, a selective inhibitor of eIF2 α dephosphorylation. Gene expression was analyzed by real time PCR and protein expression by Western blot. ATF6/XBP-1 and JNK activation was determined by luciferase reporters containing, respectively, unfolded protein and AP-1 response elements.

Results: Palmitate and oleate induced 59 \pm 2 and 22 \pm 2 % apoptosis in primary beta cells after 72 h ($p < 0.01$), while the equimolar combination of both FFA was not toxic. Palmitate induced a marked PERK and eIF2 α phosphorylation in INS-1E cells (up to 9- and 4-fold at 12 h, respectively) compared to oleate (no detectable and 1.5-fold induction at 12 h). Palmitate up-regulated ATF4 mRNA early (2-fold at 6–12 h, $p < 0.05$), while oleate or the FFA combination induced ATF4 later (2-fold at 24 h, $p < 0.005$). Downstream of ATF4, ATF3 and CHOP mRNAs were markedly induced by palmitate (40- and 8-fold increased at 12 h, $p < 0.01$), as compared to oleate (3- and 2-fold induced, $p < 0.05$). Enhanced activation of the eIF2 α pathway by salubrinal (75 μ M) markedly potentiated FFA-induced apoptosis. In the IRE branch, XBP-1 splicing was earlier and more intense with palmitate than with oleate. Palmitate, but not oleate, activated the AP-1 reporter. The chemical JNK inhibitor SP-600125 (25 μ M) and the peptide JNK inhibitor L-TAT-JNKi (1 μ M) reduced palmitate-mediated AP-1 activation by 45% (24 h, $p < 0.05$), and decreased palmitate-induced apoptosis in INS-1E cells by 20% (72 h, $p < 0.05$). All FFA conditions increased BiP expression (2-fold from 12 h on, $p < 0.05$) and activated the unfolded protein response reporter comparably, suggesting that ATF6 activation was similar for all FFA. While high glucose (28 vs 11 mM) potentiated lipotoxicity in INS-1E cells, there was no consistent increase in FFA-induced ER stress signaling. In primary beta cells, palmitate induced ATF3 and CHOP mRNA and splicing of XBP1 after 24 h ($p < 0.05$) similarly at 10 and 28 mM glucose. The non-metabolizable FFA analogues methyl-oleate and -palmitate induced neither ER stress nor beta cell apoptosis, indicating that FFA metabolism is required to activate the ER stress transducers.

Conclusion: Oleate and palmitate trigger a differential ER stress response in beta cells. All FFA activate the ATF6 branch, but palmitate activates IRE more potently. The resulting JNK activation by palmitate contributes to beta cell apoptosis. The marked activation of the PERK pathway by palmitate and the beta cell sensitization to both FFA by salubrinal suggest that this pathway plays an additional and important role in FFA-induced ER stress and beta cell apoptosis.

EPA prevents palmitate-induced β cell lipotoxicity through suppression of SREBP-1c

T. Kato, H. Shimano, M. Nakakuki, T. Matsuzaka, A. Takahashi, N. Yamada; Department of Internal Medicine (Endocrinology and Metabolism), Graduate School of Comprehensive Human Sciences and Center for Tsukuba Advanced Research Alliance, University of Tsukuba, Japan.

Background and Aims: Chronic uptake of excess fatty acids with resultant cellular accumulation of triglycerides is thought to be a part of molecular mechanism of β -cell failure, often referred as lipotoxicity. However, contribution of endogenous fatty acid synthesis to the β -cell lipotoxicity has

not fully been studied. Sterol regulatory element-binding protein (SREBP)-1c is a transcription factor that controls hepatic lipogenesis. SREBP-1c is highly regulated by nutritional states, and inhibited by polyunsaturated fatty acids such as eicosapentaenoate (EPA). Studies with β -cells-specific transgenic mice demonstrated that over-expression of nuclear SREBP-1c causes impaired insulin secretion and glucose intolerance. In the current studies, effects of palmitate (PA) and EPA on insulin secretion of murine islets and involvement of SREBP-1c were investigated.

Materials and Methods: Pancreatic islets isolated from C57BL/6 mice or SREBP-1-null mice were incubated with palmitate (PA) or PA plus EPA. After the incubation, glucose-stimulated insulin secretion (GSIS) or potassium-stimulated insulin secretion (KSIS) were measured with cellular insulin contents. Expression profiles of various related genes were determined at mRNA and protein levels by real-time PCR and immunoblot analyses, respectively. Pancreatic islets were isolated from mice fed control, PA-rich, or PA plus EPA-diet, and diabetic KK-Ay mice treated or untreated with EPA. GSIS and KSIS of these islets were compared.

Results: Incubation of isolated islets from C57BL/6 mice with PA caused inhibition of both GSIS and KSIS in dose-dependent manner. Addition of EPA to PA treatment restored both inhibitions. Concomitantly, PA activated, and EPA suppressed both mRNA and nuclear protein of SREBP-1c, accompanied by reciprocal changes of SREBP-1c-target genes such as IRS-2 and granuphilin. In contrast, PA-inhibitions of GSIS and KSIS were completely cancelled in SREBP-1-null mice. Suppression of IRS-2/Akt pathway in insulin-signaling could be a part of the downstream mechanism for the SREBP-1c-mediated insulin secretion defect because adenoviral constitutive activation of Akt rescued PA-inhibition of insulin secretion. Uncoupling protein-2 also plays a crucial role in the PA-lipotoxicity as confirmed by knockdown experiments, although independent of SREBP-1c. The similar PA-EPA regulation of insulin secretion was observed in islets from C57BL/6 mice pretreated with dietary manipulations. Finally, administration of EPA to KK-Ay mice ameliorated impairment of insulin secretion of their isolated islets.

Conclusions: EPA prevents PA-mediated insulin secretion defect through SREBP-1c inhibition, implicating a therapeutic potential for diabetes related to lipotoxicity.

Endoplasmic reticulum stress markers in pancreatic beta cells from type 2 diabetic subjects

P. Marchetti¹, M. Masini¹, M. Bugliani¹, R. Lupi¹, L. Marselli¹, S. Del Prato¹, G. Weir², D. Eizirik³, M. Cnop³;

¹Department of Endocrinology and Metabolism, University of Pisa,

Italy, ²Joslin Diabetes Center, Harvard University, Boston, United States,

³Laboratory of Experimental Medicine, Free University of Brussels, Belgium.

Background and Aims: Pancreatic beta-cells have a highly developed endoplasmic reticulum (ER), due to their heavy engagement in insulin secretion. ER stress has been associated with beta-cell dysfunction and apoptosis in in-vitro and in-vivo studies. We studied some features of endoplasmic reticulum in beta-cells from human type 2 diabetic patients.

Materials and Methods: Pancreatic samples and isolated islets from 22 non-diabetic (ND; age: 61 \pm 15 yrs; body mass index, BMI: 25.8 \pm 3.4 kg/m²; gender: 10M/12F) and 9 matched type 2 diabetic (T2DM; age: 65 \pm 10 yrs; BMI: 27.3 \pm 3.4 kg/m²; gender: 7M/2F) organ donors were evaluated regarding: glucose-stimulated insulin secretion; apoptosis, as assessed by electron microscopy (EM); morphological and morphometric ER assessment by EM; gene expression determination of ER stress markers in beta-cells prepared by laser capture microdissection and in isolated islets.

Results: Glucose-stimulated insulin release (stimulation index: ND, 2.3 \pm 0.8 vs T2DM, 1.2 \pm 0.4) was lower ($p < 0.01$) and beta-cell apoptosis (ND, 3.1 \pm 0.8 vs T2DM, 6.6 \pm 1.8%) higher ($p < 0.05$) in diabetic than control islets. This was associated with increased ER density volume in T2DM (1.7 \pm 0.1 ml%) compared to ND (0.9 \pm 0.06 ml%) beta-cells ($p < 0.01$). The expression of alpha-mannosidase was higher and that of UDP-glucose glycoprotein glucosyl transferase like 2 (UGGGL2) was lower in T2DM than ND beta-cell preparations, as assessed by microarray and/or real-time RT-PCR. The expression of immunoglobulin heavy chain binding protein (BiP), protein disulfide isomerase (PDI), alpha-glucosidase, X-box binding protein 1 (XBP-1) and C/EBP homologous protein (CHOP) was similar in ND and T2DM beta-cells or isolated islets cultured at 5.5 mmol/l glucose (microarray and

real-time RT-PCR results). However, when isolated islets were cultured for an additional 24h at 11.1 mmol/l glucose, there was the induction of BiP (from 11.6 ± 6.9 to 36.4 ± 14.5 , $p < 0.01$), XBP-1 (from 25.2 ± 12.1 to 119.8 ± 54.5 , $p < 0.05$) and spliced XBP-1 (from 16.8 ± 8.3 to 56.6 ± 37.2 , $p = 0.06$) in T2DM, but not in ND islets.

Conclusions: Beta-cells from T2DM subjects show modest alterations of ER when studied in pancreas samples or isolated islets maintained at physiological glucose concentration. A short period of exposure to increased glucose levels, however, induces the expression of ER stress markers in T2DM, but not in ND islet cells. These results suggest that T2DM beta-cells are more susceptible to ER stress induced by metabolic perturbations.

0094

hFis1-induced mitochondrial fragmentation impairs glucose-stimulated exocytosis and causes apoptosis in INS-1E cells

K.-S. Park¹, A. Wiederkehr¹, Y. Mattenberger², J.-C. Martinou², N. Demareux¹, C. B. Wollheim¹;

¹Cell Physiology and Metabolism, University Medical Center,

²Cell Biology, University of Geneva, Geneva, Switzerland.

Background and Aims: Mitochondria are dynamic organelles that continuously move, fuse and divide. In mammalian cells, several proteins mediating mitochondrial fission or fusion have been identified, the function of which is under investigation. Here, we elucidated the role of mitochondrial fission/fusion in metabolism-secretion coupling and cell survival in insulin-secreting cells.

Materials and Methods: To analyze mitochondrial morphology, we co-transfected INS-1E cells with mitochondrial fission/fusion genes and mitochondrial-targeted red fluorescent protein (mitoRFP). Hormone secretion was measured by co-transfection with human growth hormone (hGH) plasmid. Cytosolic calcium responses were studied by co-transfection with yellowameleon ($YC_{3.6}$). To evaluate cytotoxic effects, INS-1E cells were infected with doxycycline-inducible adenovirus expressing mitochondrial fission/fusion genes.

Results: INS-1E cells displayed a dense network of elongated and interconnected mitochondria in $94 \pm 2\%$ of mitoRFP transfected cells. Consistent with their proposed function, over-expression of hFis1 or Drp1 induced dramatic mitochondrial fragmentation in $64 \pm 6\%$ and $28 \pm 6\%$ of transfected cells, respectively. Dominant negative mutant of Mfn 1 (DN-Mfn1) also induced extensive mitochondrial fragmentation in $54 \pm 6\%$ of the cells. Over-expression of hFis1 reduced glucose stimulated exocytosis of hGH (from $2.0 \pm 0.2\%$ at 2.8 mM to $4.1 \pm 0.3\%$ at 16.5 mM ; expressed as % content) compared to the transfection with empty vector (from $2.1 \pm 0.2\%$ to $5.2 \pm 0.4\%$). Intracellular hGH content was decreased by 35% in hFis1 over-expressing cells. Despite the similar mitochondrial phenotype, DN-Mfn1 over-expression did not attenuate, but slightly increased, the amount of hGH content and glucose-stimulated hGH release. Glucose activation of INS-1E cells results in depolarization of the plasma membrane and calcium influx. Over-expression of hFis1 reduced glucose-stimulated calcium responses by 64%, while KCl (30 mM)-evoked calcium responses were not affected. Adenoviral-driven expression of hFis1, but not of DN-Mfn1, showed marked cytotoxic effects as revealed by MTT assay and increased number of TUNEL-positive cells.

Conclusion: These results show that hFis1 over-expression induces fragmentation of mitochondria, impairs glucose-stimulated hormone secretion, and elicits apoptosis in INS-1E cells. Because DN-Mfn1 over-expression also fragments mitochondria without impairing secretion or cell survival, we suggest that hFis1 induced mitochondrial dysfunction and cell death do not result from mitochondrial fragmentation itself, but instead from other mitochondrial processes.

The gap junctional protein Connexin36 (Cx36) protects pancreatic beta cells against cytotoxic attacks: a possible role in cytokine-mediated beta cell death

F. Allagnat¹, P. Klee², M. Peyrou², D. Martin¹, A. Charollais², D. Caille², J.-A. Haefliger¹, P. Meda²;

¹Department of Medicine, University Hospital, Lausanne, ²Department of Cell Physiology and Metabolism, University of Geneva School of Medicine, Switzerland.

Background and Aims: Type I diabetes develops when most of the insulin-producing cells have been killed by an autoimmune attack, leaving a few survivors which are unable to sustain an adequate insulin secretion and, hence, to control the levels of circulating glucose. The mechanisms whereby these cells survive for years to the immune attack that kills most of their islet partners is obscure. Herein, we investigated whether this mechanism implicates the gap junctional protein connexin36 (Cx36), a critical contributor to glucose-stimulated insulin secretion.

Materials and Methods: Using a variety of transgenic mice and *in vitro* models of islet cells, we investigated whether the levels of Cx36 expression influence an experimentally-induced β -cell apoptosis.

Results: We found that loss of Cx36 sensitizes the β -cells of KO-Cx36 mice, in a gene dosage-dependent way, to both streptozotocin- and alloxan-induced β -cell death. Conversely, over-expression of Cx36 protects the β -cells of transgenic RIP-Cx36 mice against the same drugs. *In vitro*, islets isolated from the latter animals were also protected against a cocktail of pro-inflammatory cytokines (IL-1 β plus TNF α plus IFN γ), whereas islets isolated from KO-Cx36 mice were sensitized to the apoptosis induced by the same cytokines. Thus, loss of Cx36 sensitizes pancreatic β -cells to a variety of cytotoxic conditions *in vitro* and *in vivo*. We further investigated the effects of these pro-inflammatory cytokines on the endogenous Cx36 expression levels. We found that IL-1 β plus TNF α plus IFN γ strongly reduced the levels of Cx36 mRNA and cognate protein in the INS-1E and MIN6 insulin-secreting cell-lines, as well as in isolated mouse islets. To a lesser extent, IL-1 β alone decreased the Cx36 levels in a dose-dependent manner, whereas TNF α and IFN γ had no significant effect on the connexin. The effects of the 3 cytokines on Cx36 expression were prevented after inhibition of the AMPK by compound C, whereas metformin, which activates AMPK in β -cell, reproduced the effect of cytokines on Cx36 expression. The decrease in Cx36 levels observed under the latter conditions correlated with a decrease in gap junction coupling, as assayed by Lucifer Yellow transfer. AMPK phosphorylation was strongly increased by the cytokine treatment, suggesting that the activation of AMPK is central to the cytokine-mediated Cx36 decreased and β -cell apoptosis.

Conclusion: These results reveal an inverse relationship between the level of expression of Cx36 and the degree of β -cell apoptosis, which is controlled by AMPK activity. Since Cx36 protects pancreatic β -cells against a variety of cytotoxic conditions, the data suggest that the AMPK-dependent decrease in the levels of this connexin may contribute to the pathogenesis of type I diabetes.

Essential role for STAT1 in pancreatic β cell death and autoimmune diabetes of NOD mice

M.-S. Lee, S. Kim, H.-S. Kim, K. W. Chung, H. S. Jung, M.-K. Lee, K.-W. Kim; Medicine, Samsung Medical Center, Seoul, Republic of Korea.

Background and Aims: We have reported important roles for STAT1 in the sensitization of pancreatic β -cells to cytokine-mediated apoptosis *in vitro*. However, *in vivo* evidence supporting the role for STAT1 in β -cell death and natural type 1 autoimmune diabetes has not been reported. Furthermore, papers showing protective role of STAT1 against insulinoma cell death or aggravation of autoimmune diseases by targeted disruption of STAT1 have been published, contrary to our *in vitro* data. Thus, the role for STAT1 in β -cell death and type 1 autoimmune diabetes *in vivo* remains unclear.

Materials and Methods: To resolve this issue, we produced NOD/STAT1^{-/-} mice and studied *in vivo* role of STAT1 in β -cell death and autoimmune diabetes.

Results: *STAT1*^{-/-} islet cells were resistant to death by IFN- γ /TNF- α or IFN- γ /IL-1 β . Cytochrome *c* translocation from mitochondria to cytosol by IFN- γ /TNF- α was abrogated in *STAT1*^{-/-} islet cells. The induction of XIAP protein by TNF- α was inhibited by IFN- γ in *STAT1*^{+/+} islet cells but not in *STAT1*^{-/-} islet cells. iNOS induction and NO production by IFN- γ /IL-1 β were impaired in *STAT1*^{-/-} islet cells. The development of diabetes and insulinitis was completely abrogated in NOD/*STAT1*^{-/-} mice. The incidence of diabetes after transfer of CD4⁺ diabetogenic T cells was also significantly decreased in those mice. In NOD/*STAT1*^{-/-} mice, priming of autoreactive T cells was not impaired but Th1 differentiation was impaired. A JAK2 inhibitor upstream of STAT1 attenuated islet cell death by IFN- γ /TNF- α or IFN- γ /IL-1 β , and delayed diabetes onset in NOD/BDC2.5-SCID mice.

Conclusion: These data demonstrating a critical role for STAT1 in β -cell death and autoimmune diabetes *in vivo*, suggest potential therapeutic values of STAT1 or JAK inhibitors in the treatment/prevention of autoimmune diabetes.

OP 17 Cardiovascular disease: role of glycaemia and other factors

0097

Glycaemic control associated with reductions in incidence of macrovascular events

J. M. Foody¹, N. Rosenberg², Y. Wang¹, J. E. Thomas¹;

¹Internal Medicine/Section of Cardiology, Yale University School of Medicine, New Haven, United States, ²sanofi-aventis, U.S., Bridgewater, United States.

Background and Aims: The relationship between glycemic control and the risk of macrovascular events was examined in a retrospective analysis of patients with diabetes from the Integrated Health Care Information System database (IHCIS).

Material and Methods: Retrospective data of 69,418 selected patients with diagnosis of diabetes and at least 1 A1C result were obtained from the IHCIS database. Patient data were examined 6 months prior to index A1C (I-A1C: The first A1C available from the beginning of plan enrollment) to determine baseline demographics, comorbidities, and health utilization characteristics. Survival analysis was conducted to examine the first occurrence of acute myocardial infarction (AMI), coronary artery bypass graft (CABG) surgery or stroke after I-A1C with patients being censored at the end of their health plan enrollment.

Results: Patients (54% male, mean age 57y, and I-A1C 7.6%) were stratified into 4 groups based on I-A1C: <6.0%, 6.0–7.0%, 7.0–9.0%, and \geq 9.0%. With a mean follow-up of 27 months from I-A1C, unadjusted incidence rates in the 4 groups were 76.5, 80.5, 81.7 and 65.2 per 1000 patients/year, respectively. Elevated I-A1C was associated with increased incidence of macrovascular events even after adjustment for comorbidities, diabetes medications, selected lipid lowering and blood pressure control agents and laboratory values at baseline. Figure 1 shows the adjusted Kaplan-Meier curve. Cox proportional hazards regression model shows that elevated A1C was statistically significantly associated with higher risk of macrovascular events. Compared to <6% group, hazard risk for AMI/CABG/stroke elevated 8% in 7–9% ($p < 0.01$) and 15% ($p < 0.001$) in \geq 9% group. Subgroup analysis excluding prior AMI/CABG/stroke showed almost identical survival pattern.

Conclusion: This analysis demonstrates that there is a high incidence of macrovascular events in diabetes patients with A1C >7%. Appropriate glycaemic control may contribute to reducing the risks for macrovascular diseases in patients with diabetes.

Aggressive glycaemic control preserves cardiac function in patients with acute myocardial infarction and diabetes mellitus

L. G. Strongin, N. Beliaeva;

Medical Faculty, State Medical Academy, Nizhny Novgorod, Russian Federation.

Background and Aims: The goal of the current study was to determine whether improved glycaemic control, achieved through an insulin infusion with a variable rate of insulin, has a beneficial effect on left ventricular ejection fraction (LVEF), wall motion index score (WMIS) and mortality

Materials and Methods: A comparison of an intravenous insulin infusion regimen aimed to maintain the blood glucose level between 5 and 7,5 mmol/l (n=26), with routine antidiabetic control (n=35) in the acute period of myocardial infarction (AMI) has been carried out in patients suffered from type 2 diabetes mellitus. Patients were excluded if an illness associated with markedly restricted life expectancy was present. A continuous infusion of short-acting insulin (50 units) in 50 ml 0,9% sodium chloride was initiated using a pump (Perfusor-FM, B. Braun, Melsungen, Germany). The infusion was continued for at least 24 hours. LVEF and WMIS were measured by echocardiography. Outcome variables were compared with the use of Student's t-test, the Chi-square test, the Mann-Whitney U test, Wilcoxon test. Data are presented as medians with interquartile ranges.

Results: Echocardiography shows the improvement of regional function: the wall motion score improved from 1,25 (1,12–1,7) to 1,18 (1,06–1,25) in the insulin infusion group (p=0,01), and increased from 1,31 (1,25–1,43) to 1,34 (1,15–1,8) in the control group (p=0,77). There was a significant improvement in the LVEF over 21-day period on 2,2% in the infusion group (p=0,04), versus 7% decrease of LVEF in the control group (p=0,1). Mortality within 6 months was 15,38 in the insulin – infusion group and 45,7 in the control group (p=0,02).

Conclusion: Tight glycaemic control with insulin therapy following AMI improves left ventricular mechanics and survival in diabetic subjects.

0099

The relationship between the prevalence of cardiovascular disease and the use of insulin among patients with type 2 diabetes mellitus – a large national observational study in a managed care settingP. Sun¹, D. Buesching¹, N. Engel-Nitz², S. Martin¹, V. Fonseca³;¹US Medical Division, Lilly Research Laboratories, Indianapolis, ²i3 Innovus Health Economics & Outcomes, i3 Magnifi, Eden Prairie, ³Endocrinology, Tulane University, New Orleans, United States.

Background and Aims: Cardiovascular disease (CVD) is the leading cause of mortality and major cause of morbidity in patients with type 2 diabetes (T2D). Although the etiological mechanisms responsible for CVD among T2D patients have been extensively examined, the association of insulin use with CVD risk among T2D patients has not been fully understood in a real world setting. To fill this gap, this study aims to examine whether T2D patients using insulin were more or less likely to have CVD than T2D patients not using insulin.

Materials and Methods: This retrospective observational study was based on a de-identified US national health claims database (N:>70 million lives). The study population included 357,655 T2D patients who continuously enrolled in health plans for at least 1 year in a period from 01/01/98–12/31/04. CVD included unstable angina, myocardial infarction, stroke, other cardiac events, other cerebrovascular events, and were identified based on ICD-9CM codes. A logistic regression model was used to examine the odds ratio of having CVD between the patients who used insulin and patients who did not use insulin; and to control for age groups, gender, income, race, residential regions, provider specialties, various co-morbid conditions, medication history, baseline HbA1c level, and length of observation.

Results: With control of the confounding factors mentioned above, the odds ratio of having CVD between patients who used insulin and patients who did not use insulin (referent) was 0.66 (p<0.0005, 95% CI: 0.61538, 0.72002). This odds ratio suggests that T2D patients who used insulin had 34% less odds of having CVD than T2D patients who did not use insulin.

Conclusion: With control of the 31 confounding factors, the odds of having any CVD among T2D patients using insulin were 34% lower than the odds

among T2D patients not using insulin. Thus, the use of insulin is associated with a decrease of CVD. Further research in this area is imperative.

Skin autofluorescence as a marker of tissue AGE accumulation has additional value to the UKPDS risk-score in predicting cardiovascular disease in type 2 diabetesH. L. Lutgers^{1,2}, E. G. Gerrits², H. J. Bilo^{2,1}, A. J. Smit¹;¹Internal Medicine, University Medical Center Groningen, ²Diabetes Center, Isala Clinics, Zwolle, The Netherlands.

Background and Aims: One of the pathogenetic mechanisms of accelerated atherosclerosis in type 2 diabetes mellitus (T2DM) is increased formation and accumulation of advanced glycation endproducts (AGEs). Some AGEs have characteristic fluorescent properties, which can be non-invasively measured as skin autofluorescence (AF). We have previously demonstrated the association and predictive value of skin AF with chronic diabetes complications. This study aims to assess whether skin AF is additive to classical risk factors, as combined in the UKPDS risk-engine, in predicting cardiovascular complications.

Materials and Methods: In 2001, 973 primary care T2DM-patients were included (mean age 66 yrs, mean HbA1c 7.0% and mean diabetes duration of 6.3 yrs). Skin AF, using a prototype of the current AGE reader, and UKPDS risk scores were assessed at baseline. Follow-up ended at January 2005. Primary endpoint was mortality or non-fatal cardiovascular event: coronary heart-, cerebrovascular-, or peripheral vascular disease. Patients were categorized in four groups, either: both AF and UKPDS risk score respectively above (1) and below (2) the median, and, AF (3) or UKPDS risk score (4) above the median (Fig 1, left panel), or: same categories but the UKPDS score set at clinically often used cutoff values of 10% 10 year CVD risk (Fig 2, right panel).

Results: During a median follow-up of about 3.5 years, 6 patients were lost to follow-up. In the remaining 967 patients, there were 161 events. The calculated median UKPDS risk score for CHD and stroke in 3.5 years was

Fig 1

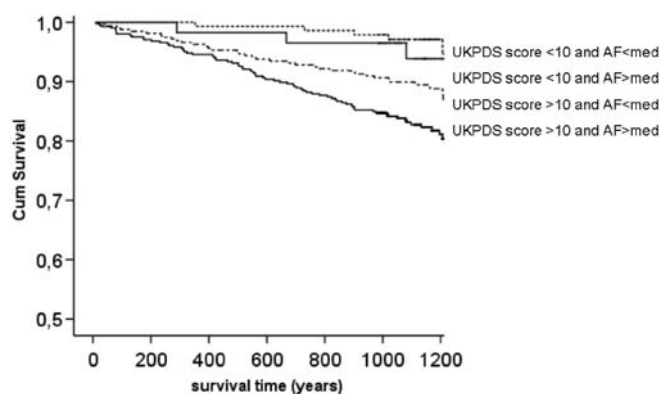

Fig 2

12%. This expected CV-event rate of 12% was not significantly different from the 13% observed CV-event rate in this population. Median UKPDS risk score (10 years) was ~ 30%. Kaplan-Meier survival curves (left panel) showed significant differences between the groups, except between group 3 and 4 ($p < 0.05$). When the UKPDS score was set at cutoff values of 10% 10 year CVD risk, skin AF still provided additive information in the larger ($n = 726$) >10% UKPDS risk group, but not in the small <10% UKPDS risk group (right panel).

Conclusion: Autofluorescence has additional value to the UKPDS risk-score in the risk assessment of cardiovascular complications in T2DM.

Long-term effects of intensive multifactorial treatment on total and cardiovascular mortality in patients with type 2 diabetes

P. Gæde¹, H.-H. Parving², O. Pedersen¹;

¹Department of Diabetology, Steno Diabetes Center, Gentofte, Denmark,

²Department of Endocrinology, Rigshospitalet, Copenhagen, Denmark.

Background and Aims: Intensified multifactorial intervention in high-risk type 2 diabetes patients with the metabolic syndrome including microalbuminuria cuts the risk of cardiovascular events by half. We studied whether the use of intensive multitherapy as compared with conventional therapy in the Steno-2 study affected the 13 years' incidence of total and cardiovascular disease (CVD) mortality as well as a composite of CVD events.

Materials and Methods: 160 patients with type 2 diabetes and microalbuminuria were in the Steno-2 study randomly assigned intensified or conventional multifactorial treatment of multiple risk factors for an average of 7.8 years. All 130 surviving patients examined at end of the intervention trial were offered intensive multitherapy at Steno Diabetes Center and subsequently followed in the post-trial until December 31, 2006 when patients were re-examined after an average of 13.3 years.

Results: During the entire 13.3 year follow-up period 24 patients in the intensive therapy group died compared to 40 patients in the conventional therapy group. Intensive therapy reduced the risk for total mortality by 46% (95% confidence interval, 11 to 68%; $P = 0.015$) corresponding to an absolute risk reduction of 30%, while CVD mortality was reduced by 57 percent (6 to 81%, $P = 0.036$), i.e. 13% in absolute terms and the risk for CVD events defined as a composite of CVD mortality, myocardial infarction, stroke, coronary bypass graft, revascularization, or amputation due to ischaemia was reduced by 59% (37 to 75%, $P = 0.0003$) corresponding to an absolute risk reduction of 29%. These differences in clinical endpoints between groups were achieved despite significant improvements in HbA_{1c}, fasting levels of total-cholesterol, LDL-cholesterol, triglycerides, and systolic and diastolic blood pressure in the conventional therapy group during the observational post trial period to an extent where the two original treatment groups no longer differed significantly for any of these risk variables.

Conclusion: Intensive multifactorial intervention in at-risk patients with type 2 diabetes for an average of 7.8 years has long-term beneficial effects on total and CVD mortality as well as on a composite of CVD events.

0102

Effects of EPA on coronary artery disease in patients with gluco-metabolism derangement: JELIS subgroup analysis

S. Oikawa¹, M. Yokoyama², H. Origasa³, M. Matsuzaki⁴, Y. Saito⁵, Y. Matsuzawa⁶;

¹Division of Endocrinology and Metabolism, Nippon Medical School,

Tokyo, ²Department of Internal Medicine, Kobe University,

³Division of Clinical Epidemiology and Biostatistics, Toyama University,

⁴Department of Medicine and Clinical Science, Yamaguchi University, Ube,

⁵Department of Clinical Cell Biology, Chiba University,

⁶Department of Internal Medicine, Sumitomo Hospital, Osaka, Japan.

Background and Aims: The Japan EPA Lipid Intervention Study (JELIS), a large scale clinical study ($n = 18,645$), examined the preventive effects of eicosapentaenoic acid (EPA) against coronary artery disease (CAD). JELIS demonstrated that EPA significantly decreased the incidence of CAD by

19% compared with non-EPA group (Lancet, in press). A later sub-analysis showed that EPA significantly decreased the incidence of CAD by 22% compared with non-EPA group in the impaired glucose metabolism (IGM) group ($n = 4,565$). The present study was the further sub-analysis of JELIS, and focused on the examination of correlation between fasting plasma glucose (FPG) or hemoglobin A_{1c} (HbA_{1c}) levels and CAD incidence, and the preventive effect of EPA was investigated in the subjects with IGM.

Materials and Methods: As described in the previous report, all subjects had hypercholesterolemia ($TC \geq 250$ mg/dL) treated with statin. Out of them, the subjects were intended as the impaired gluco-metabolism patients having diabetes mellitus at registration or with higher fasting plasma glucose levels ($FPG \geq 110$ mg/dL) and divided randomly into two groups treated with 1,800 mg/day of pure EPA (EPA group) or without EPA (non-EPA group). CAD was monitored for 5 years. CAD was defined as major coronary events including sudden cardiac death, fatal and non-fatal myocardial infarction, unstable angina pectoris, coronary artery bypass surgery or cardiovascular reconstruction. CAD incidences were conducted according to FPG (EPA group, $n = 1,899$ and non-EPA group, $n = 1,862$) or HbA_{1c} (EPA group, $n = 1,540$ and non-EPA group, $n = 1,514$) values at registration. According to the glycemic control criteria of Japan Diabetes Society, FPG was stratified into four levels, <110, 110–129, 130–159 and ≥ 160 mg/dL. Using the stratum <110 mg/dL in the non-EPA group as the referent, hazard ratios (HR) of CAD incidence were calculated in both EPA and non-EPA groups. HbA_{1c} was also stratified into four levels, <5.8, 5.8–6.4, 6.5–7.9 and $\geq 8.0\%$. Using the stratum <5.8% in the non-EPA group as the referent, HR of CAD incidence were calculated in both EPA and non-EPA groups. The incidence of CAD was analyzed by the Cox proportional hazard model, adjusted for gender, age, smoking, prior CAD, and hypertension.

Results: As FPG increased in the non-EPA group, risk of CAD increased ($HR = 1.00, 1.60, 2.03$ and 2.51). In the highest FPG stratum (≥ 160 mg/dL), the incidence of CAD was significantly high ($p = 0.009$). In the EPA group, there was no significant difference in the incidence of CAD ($HR = 1.56, 1.27, 0.83$ and 1.73). Also, as HbA_{1c} increased in the non-EPA group, the risk of CAD increased ($HR = 1.00, 1.19, 1.23$ and 2.66). In the highest HbA_{1c} stratum ($\geq 8.0\%$), the incidence of CAD was significantly high ($p = 0.003$). On the other hand in the EPA group, there was no significant difference in the incidence of CAD ($HR = 0.50, 1.12, 0.99$ and 1.57). CAD risks were lower in all strata of EPA groups compared to non-EPA groups.

Conclusion: These results suggest that the administration of EPA ameliorates CAD in patients with gluco-metabolism derangement.

OP 18 Models of care

Impact of self-monitoring of blood glucose on the management of patients with non-insulin treated diabetes: an open-label parallel group randomised trial

A. J. Farmer¹, A. N. Wade², E. Goyder³, P. Yudkin¹, A.-L. Kinmonth⁴, H. A. W. Neil⁵;

¹Department of Primary Health Care, University of Oxford, United Kingdom, ²Johns Hopkins Bayview Medical Center, Johns Hopkins University School of Medicine, Baltimore, United States, ³SchARR, University of Sheffield, United Kingdom, ⁴General Practice and Primary Care Research Unit, University of Cambridge, United Kingdom, ⁵Division of Public Health and Primary Care, University of Oxford, United Kingdom.

Background and Aims: Self-monitoring of blood-glucose (SMBG) for non-insulin treated diabetes is costly but may lead to improved glycaemic control. Existing evidence is inconclusive, with previous trials using multi-component interventions. We aimed to determine whether self-monitoring, either alone or with additional instruction in incorporating the results into self-care, is more effective than usual care in improving glycaemic control and to explore the impact of monitoring in pre-defined patient groups.

Materials and Methods: Patients with non-insulin treated type 2 diabetes with HbA_{1c} above 6.2% were enrolled into this three-arm trial based in 48 general practices. Patients were randomized to: (i) standardized usual care with three monthly measurement of HbA_{1c} (control), (ii) SMBG with results interpreted by the research nurse in addition to usual care (less-intensive self-monitoring), (iii) SMBG with training in interpreting and applying results of testing to enhance motivation and maintain adherence to diet, physical activity and medication regimens (more-intensive self-monitoring). An intention-to-treat analysis was performed with the primary outcome of 12-month HbA_{1c} adjusted for baseline values. The primary outcome was also analysed for pre-specified sub-groups defined by duration of diabetes, use of oral antidiabetic drugs (OAD) and diabetes-co-morbidity.

Results: A total of 578 people were screened as potentially eligible, of whom 453 met the trial inclusion criteria. Characteristics of patients in the three randomised groups were similar at enrolment with mean (SD) HbA_{1c} 7.5% (1.1). The 12-month HbA_{1c} did not differ between the patients receiving the control, the less-intensive and the more intensive self-monitoring interventions. ($p=0.12$). The mean difference between control and less-intensive self monitoring was -0.14% (95%CI -0.35 to 0.07) and between the control and more-intensive self-monitoring group -0.17% (95%CI -0.37 to -0.03). Change in HbA_{1c} from baseline to 12 months by sub-group are shown in the table. 66% of those receiving the less intensive intervention and 52% of those in the more intensive intervention persisted in regular self-monitoring

Change in HbA_{1c}(%) from baseline to 12-months by sub-group

Mean HbA _{1c} (SD)	Control Group No meter	Less-intensive self-monitoring	More intensive self-monitoring	P value for interaction
Duration of diabetes				
≤median	0.01 (1.03)	-0.12 (0.85)	-0.16 (0.73)	0.82
>median	-0.01 (1.01)	-0.15 (0.80)	-0.18 (0.73)	
Baseline therapy				
Diet only	0.03 (0.80)	0.04 (0.64)	-0.09 (0.72)	0.90
Oral hypoglycaemic drug therapy	-0.01 (1.10)	-0.20 (0.87)	-0.20 (0.73)	
Diabetes related co-morbidity				
No	-0.05 (1.02)	-0.19 (0.88)	-0.28 (0.74)	0.86
Yes	0.20 (1.02)	0.05 (0.56)	0.16 (0.56)	

Conclusion: Our results show no improvement in glycaemic control after one year in patients with non-insulin treated type-2 diabetes using SMBG. There was no evidence of significant glycaemic benefit in pre-defined sub-groups of patients, including those treated by diet or OAD. Current guidelines for the use of self-monitoring of blood glucose require review.

The use of medication in a diabetes management system: an observational 8-year-follow-up study

L. Welschen, M. van Veen, S. Bot, J. Dekker, G. Nijpels;
General Practice, EMGO Institute, Amsterdam, The Netherlands.

Background and Aims: Type 2 diabetes is a progressive disease and in order to prevent complications, it seems that intensive medication treatment is inevitable. The aim of this study was to describe the changes in medication use of patients after their entry into a diabetes management system implemented in a region in The Netherlands in 1997.

Materials and Methods: An observational dynamic cohort study was performed from 1998 till 2005. Clinical data were collected every year as well as data on medication use. To evaluate patients' medication use following entry into the diabetes management system, a study cohort was defined. The measurements of every patient in their first year of entry into the system were set at T=1. Follow-up measurements were defined as T=2, for the second year, to T=8, for the eighth year after entry into the system.

Results: The study cohort started with 4782 patients at T=1. There were 440 patients with a follow-up of 8 years. Mean age of the patients was 62 years at T=1 and 51% were male. Medication use increased during follow-up (Figure 1). At T=8, 13.7% of the patients was using insulin, 26.9% used a combination of insulin and one or more oral hypoglycaemic agents, and 53.2% used only oral hypoglycaemic agents. Mean HbA_{1c} decreased from 7.7% to 7.1% and remained stable. Mean systolic blood pressure increased from 143.3 mmHg to 151.2 mmHg, despite an increase in the use of antihypertensive medicines from 49.5% to 68.2% of the patients. The level of cholesterol improved from 5.5 mmol/l to 4.8 mmol/l.

Conclusion: Medication use of patients in a diabetes management system showed an incredible increase during 8 years of follow-up indicating that type 2 diabetes is a progressive disease. HbA_{1c} showed a sharp decrease after entry in the system and stabilised during follow-up. Cholesterol levels improved every year while the control of blood pressure was still inadequate. An intensive medication treatment is needed for optimal diabetes control.

Fig 1. Use of medication of patients with type 2 diabetes during 8 years of follow-up

0105

Practice nurses as main care-providers for patients with type 2 diabetes in a primary care setting: a randomized controlled trial

S. T. Houweling¹, N. Kleefstra^{2,1}, K. H. Groenier³, B. Meyboom-de Jong³, H. J. G. Bilo^{2,4};

¹Medical Research Group, Langerhans, Zwolle, ²Diabetes Centre, Isala Clinics, Zwolle, ³General Practice, University of Groningen, ⁴Internal Medicine, University of Groningen, The Netherlands.

Background and Aims: In order to maintain quality of care for the increasing number of patients with type 2 diabetes (DM2), treatment of DM2 in the primary care setting is increasingly taken over by practice nurses (PNs). We investigated if this care provided by PNs was at least equal to the care provided by GPs.

Materials and Methods: In a randomized controlled study, we investigated the effects of medical treatment (including prescriptions according to protocol), quality of life (SF-36), diabetes related complaints (DSC-R), and patient satisfaction (PEQD) in patients treated by PNs compared to care provided by GPs; 206 patients from five general practices participated. The

intervention group was treated by PNs using detailed protocols and the control group received “standard” care from their own GPs.

Results: After fourteen months, care in both groups was comparable according to the clinical parameters (HbA1c, blood pressure (BP) and lipid profile). In the group treated by the PNs, significantly more patients were referred to specialists according to protocol including the ophthalmologist (71% vs. 37% ($p<0.01$)). Furthermore, more action was taken when the patient had significant foot problems (57% vs. 27% ($p<0.01$)), and medication dosages were raised more often when considered necessary, except for lipid lowering drugs (hypoglycaemic agents: 83% vs. 50% ($p<0.01$); antihypertensive agents: 50% vs. 29% ($p<0.01$)). The overall quality of life and the number of complications related to diabetes were equal in the two groups. Patients were more satisfied with the care received from the PNs than with the care provided by the GP (PEQD score: 66 vs. 52 ($p<0.01$)).

Conclusion: This study allows the conclusion that PNs who work with strict protocols are capable to offer effective care to patients with DM2 in a primary care setting. PNs follow the quality guidelines, as formulated by the Dutch College of General Practitioners, more consistently than GPs, saving GPs time, whilst providing care of good quality.

Intensified multifactorial treatment of screen-detected type 2 diabetic patients: the ADDITION Netherlands randomised study, one-year results

P. G. H. Janssen¹, K. J. Gorter¹, R. P. Stolk², G. E. H. Rutten¹;
¹Julius Center for Health Sciences and Primary Care, University Medical Center, Utrecht, ²Department of Epidemiology, University Medical Center, Groningen, The Netherlands.

Background and Aims: To evaluate the effectiveness and feasibility of an intensified multifactorial treatment on cardiovascular risk factors in screen-detected type 2 diabetic patients. The presented study is the Dutch part of the ongoing ADDITION study (Anglo-Danish-Dutch Study of Intensive Treatment in People with Screen-Detected Diabetes in Primary Care).

Materials and Methods: Screen-detected diabetic patients, assigned to intensive ($n=255$) or routine treatment ($n=243$) according to Dutch national guidelines, are followed during five years. Here we present first year results. Intensive treatment consisted of pharmacological treatment combined with structured lifestyle education and targeted on HbA_{1c} <7.0%, blood pressure <135/85 mmHg (ACE prescribed above 120/80 mmHg), cholesterol <3.5 mmol/l. Acetylsalicylic acid was prescribed when antihypertensive agents were used. Analysis on ITT, clinical and biochemical variables are compared using ANCOVA with age, gender, BMI, and baseline values as covariates. SF-36 scores are compared between treatment groups (ANCOVA with adjustment for age, gender, and baseline values) and within groups (paired-samples t -tests).

Results: At baseline, the two treatment groups were well matched. Table 1 summarizes changes after one year. Changes in SF-36 scores between baseline and end of the study did not differ significantly between the treatment groups.

Table 1 Changes in variables after one year in both treatment groups

	Routine care ($n=241$)	Intensive treatment ($n=250$)	Difference between groups ^a p value
BMI (kg/m ²)	- 0.3 ± 3.0	- 1.3 ± 2.0	<0.001
Systolic blood pressure (mmHg)	- 19 ± 22	- 34 ± 22	<0.001
Diastolic blood pressure (mmHg)	- 8 ± 10	- 12 ± 11	<0.001
Fasting blood glucose (mmol/l)	- 0.8 ± 2.6	- 1.3 ± 2.3	<0.001
HbA _{1c} (%)	- 0.8 ± 1.4	- 1.2 ± 1.5	<0.001
Cholesterol (mmol/l)	- 0.6 ± 1.1	- 1.3 ± 1.2	<0.001
HDL-cholesterol (mmol/l)	0.09 ± 0.7	0.03 ± 0.2	0.217
LDL-cholesterol (mmol/l)	- 0.5 ± 0.9	- 1.1 ± 1.0	<0.001
Triglycerides (mmol/l)	- 0.3 ± 2.0	- 0.4 ± 1.0	0.111

Data are means ± SD unless otherwise indicated.

^a Difference between treatment groups at end of study, adjusted for age, gender, BMI, and baseline value.

Within both groups General health, Vitality and Mental health, and in the intensive group also Physical functioning improved during follow-up.

Conclusion: Cardiovascular risk factors improved significantly more in the intensively treated group. Health-related quality of life was not influenced negatively by intensive treatment. Intensified multifactorial treatment of screen-detected type 2 diabetic patients in primary care is feasible.

Diabetes type 2 – a chronic disease – how is the clinical practice after implementation of guidelines in Germany? The DIG (Diabetes in Germany) study baseline and 2 years’ data

P. Ott, I. Benke, C. Koehler, M. Hanefeld;
 Zentrum für Klinische Studien, GWT der Technischen Universität Dresden, Germany.

Introduction: As shown in the STENO 2 study the prevention of vascular complications requires an integrated approach with optimal control of the central components of the metabolic syndrome: blood glucose/HbA1c, lipids and blood pressure. The DIG study presents for the first time population based data on the quality of treatment of major coronary risk factors for type 2 diabetes in Germany for a two year period. It offers a clear and realistic picture of the quality of care that patients with type 2 diabetes receive by diabetologists and by general practitioners after the application of national and international guidelines.

Methods: 4020 patients with type 2 diabetes between 35 and 80 years old were recruited by 238 physicians from general and specialised practices across Germany. Medical history, risk factor profile and clinical data were registered. We analysed HbA1c, fasting blood glucose (FBG), postprandial blood glucose (ppBG), blood pressure (RR), triglyceride (TG), HDL- and LDL-Chol at baseline and after 2 years and the administration of medication. 2538 patients were seen at 2 years follow-up.

Results: We found the following results at baseline and (after 2 years): HbA1c:7.0 (7.0) %, FBG:7.5 (7.3) mmol/l, ppBG:9.0 (8.7) mol/l – $p < 0.05$, RR:138.7/81.4 (138.1/80.6) mmHg – $p<0.001$, TG:2.2 (2.2) mmol/l, HDL-Chol:1.3 (1.4) mmol/l – $p<0.001$ and LDL-Chol:3.2 (3.0) mmol/l – $p<0.001$. The patients have after 2 years a significant better control of postprandial blood glucose, blood pressure as well as LDL- and HDL-Cholesterol as at baseline. We found an increase of patients with insulin (1054 at baseline – 1248 after 2 years) and an increase of antihypertensive drugs (for example ACE inhibitors and AT1 blocking drugs: 1453 – 1654) and statins (669 – 972) too.

Conclusion: The level of HbA1c achieved in our study (7%) demonstrates the effectiveness of the structured care system in place in Germany and the value of the application of national guidelines. In concordance with national and international recommendations we found an improvement in the control of blood pressure, lower levels of LDL-Cholesterol and increase in HDL-Cholesterol. This was achieved by a significant increase in insulin treatment, prescription of statins and antihypertensive drugs. Our data suggest a progress in the care for cardiovascular risk factors by implementation of national and international guidelines. But still action is necessary to target major cardiovascular risk factors.

Changing standards of diabetes care in general practice over the last six years: The impact of the National Service Framework and the General Medical Services contract

C. Hilton^{1,2}, D. Russell-Jones^{1,2}, C. Todd³, J. Williams¹;
¹Postgraduate Medical School, University of Surrey, Guildford,
²Cedar Centre, Royal Surrey County Hospital, Guildford, United Kingdom,
³PRIMIS+, Surrey PCT, Farnham, United Kingdom.

Background and Aims: The last six years have been a time of change for diabetes care in the UK, with systematic and structured changes to healthcare taking place. The National Service Framework (NSF) for diabetes was introduced in 2002 and set out key standards to improve overall quality of

care. This was followed by the General Medical Services (GMS) contract (2004) which offered financial rewards for achieving high standards for chronic disease management. This study examines changing standards of diabetes care in general practice between 2001 and 2007.

Materials and Methods: This prospective longitudinal cohort study collected data in 2001, 2003 and 2007 from eight practices in the Guildford and Waverly area (population 74,225 in 2007). Pseudonymised data was extracted for all patients using MIQUEST queries to provide information on predefined indicators of quality of care. Data was analysed using SPSS 14.0.

Results: Between 2001 and 2007 the recorded incidence of diabetes rose from 1.94% to 2.69%. Quality of care improved for all five indicators measured. There was a substantial improvement in average HbA1c between 2001 and 2003 (8.15% to 7.54%, $p < 0.001$) and again between 2003 and 2007 (to 7.24%, $p < 0.001$). The proportion of patients having an HbA1c recorded at least once every 15 months rose from 78.2% in 2001 to 84.0% in 2003 ($p < 0.001$) and to 91.7% in 2007 ($p < 0.001$). The percentage of patients having an HbA1c recorded every 3–6 months (in accordance with the NICE and ADA guidelines) also improved ($p < 0.001$). Average blood pressure fell from 143.5/79.0 in 2001 to 139.1/78.0 in 2003 ($p < 0.02$) and then to 136.4/76.9 in 2007 ($p = 0.001$). In 2001 87.5% of patients were having blood pressure checked 15 monthly, and this rose to 95.9% in 2007 ($p < 0.001$). The percentage of patients receiving a cholesterol check at least once every 15 months rose from 61.2% to 91.5% between 2001 and 2007 ($p < 0.001$), but there was no trend towards improvement of cholesterol values. Over the course of the study there was an increase in 15 monthly recording of BMI from 68.0% to 89.5% ($p < 0.001$), although this was accompanied by a small increase in BMI from 28.6 to 29.2. 94.1% of patients had their smoking status recorded in 2001, and this rose to 99.7% in 2007 ($p < 0.001$). In addition there was a marked drop in the number of recorded smokers from 25.0% in 2001 to 13.1% in 2007 ($p < 0.001$).

Conclusion: Standards of care and data recording have improved substantially since 2001. By 2003 GPs were well placed to respond to the GMS contract, and standards have continued to rise with its implementation. In many cases this has led to a significant improvement in modifiable risk factors for the long term complications of diabetes.

DPP-IV inhibitors influence fat metabolism through modulation of NPY's paracrine antilipolytic action in adipose tissue

K. Kos, A. R. Baker, A. L. Harte, J. P. O'Hare, P. G. McTernan, S. Kumar; Diabetes and Endocrinology, Warwick University, Coventry, United Kingdom.

Background and Aims: Dipeptidyl-IV peptidase (DPP-IV) inactivates the incretin hormone glucagon-like peptide-1 (GLP-1). However, its action is not specific to GLP-1 and neuropeptide Y (NPY) is one of DPP-IV's best substrates. This orexigenic hormone NPY is not only a central neurotransmitter but also found in cerebrospinal fluid and at lower levels in plasma. Recently we have demonstrated its secretion and presence of its receptors in human adipocytes. NPY(1-36) is truncated by DPP-IV to NPY(3-36); as a consequence its affinity changes from NPY receptor Y1, which is mediating the antilipolytic function of NPY, to receptor Y4 and Y5. As such, treatment of Type 2 diabetic patients with DPP-IV inhibitors, which are used as antihyperglycaemic agents, could affect NPY's regulation on fat metabolism. The aim was to investigate whether DPP-IV is expressed in adipose tissue (AT), whether it is associated with NPY receptor expression and whether it affects NPY metabolism.

Materials and Methods: *Ex vivo* human abdominal subcutaneous (AbdSc) AT was taken from women undergoing elective surgery (BMI: 27.5 (mean±SD)±5kg/m², Age: 43.7±10yrs, n=18). Isolated AbdSc adipocytes were treated with 1–100nM rhNPY with and without 1M of DPP-IV inhibitor (Sigma, Poole, UK); glycerol release was measured as an index of lipolysis and DPP-IV mRNA and NPY Y1 expression assessed in AbdSc AT.

Results: Treatment with NPY reduced glycerol release which was further blunted by co-incubation with DPP-IV inhibitor (baseline 234 (mean±SE)±23µmol/l, NPY100: 187±30µmol/l*; NPY100 with DPP-IV inhibitor: 121±14µmol/l**, * $p < 0.01$, ** $p < 0.01$, n=8). DPP-IV is expressed in human subcutaneous tissue and omental AT and the relative DPP-IV mRNA expression was reduced in AbScAT taken from obese subjects versus lean subjects (obese: 77±6signal units (SU) versus lean: 186±29SU*, n=10). NPY Y1 mRNA is expressed in all fat depots and is significantly higher in obese subjects, especially in AbdSc tissue (obese: 1944±111SU versus lean: 711±112SU**, n=10).

Conclusion: The study of the paracrine effects of NPY in AT reveals that NPY is regulated by adipose tissue derived DPP-IV, which was previously thought to be predominantly derived from endothelial vascular cells. The endogenous AT-derived DPP-IV is reduced in obese subjects suggesting that DPP-IV inhibitors may have little effect on AT mass. This may explain the lack of weight loss observed in Type 2 diabetic patients treated with DPP-IV inhibitors. In contrast to this, fat accumulation in the lean may be increased through the enhanced antilipolytic effects of NPY. As we have previously shown NPY is further upregulated by *in vitro* insulin treatment which may have clinical significance in the hyperinsulinaemic patient.

0110

Exenatide improved markers of hepatic function over 3 years in patients with type 2 diabetes

T. Okerson¹, D. Maggs¹, X. Guan¹, C. Bowlus², J. Holcombe³, M. Wintle¹, L. Nielsen¹;

¹Amylin Pharmaceuticals, Inc., San Diego, United States, ²Department of Internal Medicine, University of California Davis, United States,

³Eli Lilly and Company, Indianapolis, United States.

Background and Aims: Type 2 diabetes (T2D), obesity, and nonalcoholic fatty liver disease (NAFLD) are emerging public health concerns that often co-exist with diabetes and obesity as the two most important risk factors for NAFLD. Because exenatide is associated with improvement in glycaemic control and weight reduction, we evaluated the effects of the incretin mimetic exenatide over 3 y in T2D patients not achieving glycaemic control with MET and/or a SU.

Materials and Methods: Patients were enrolled in 30-wk, placebo-controlled trials followed by open-label extensions (64% M, 58±10 y, 99±18 kg, BMI 34±5 kg/m², A1C 8.2±1.0% [mean±SD]). In this ad-hoc analysis, 217 patients

were evaluated for ALT and AST stratified by baseline ALT (normal: $F \leq 19$ IU/L, $M \leq 30$ IU/L) as surrogate markers of NAFLD.

Results: Patients completing 3 y on exenatide had reductions in A1C ($-1.0 \pm 0.1\%$; $p < 0.0001$), weight (-5.3 ± 0.4 kg; $p < 0.0001$), fasting plasma glucose (-1.3 ± 0.2 mmol/L; $p < 0.0001$), and ALT (-4.5 ± 1.1 IU/L; $p < 0.0001$) [mean \pm SE]. Exenatide was generally well tolerated. The correlation coefficient for ALT change vs. A1C change was $r = 0.25$, and for ALT change vs. weight change was $r = 0.31$. Patients with normal baseline ALT (21.3 ± 0.5 IU/L; $n = 101$; $-0.9 \pm 0.1\%$ A1C) had minimal increases in ALT ($+2.3 \pm 1.2$ IU/L; $p = 0.06$) or AST ($+3.0 \pm 0.6$ IU/L; $p < 0.0001$). In contrast, patients with elevated baseline ALT (38.4 ± 1.5 IU/L; $n = 116$; $-1.0 \pm 0.1\%$ A1C) had reductions in ALT (-10.4 ± 1.5 IU/L; $p < 0.0001$) and AST (-4.1 ± 1.0 IU/L; $p < 0.0001$). There was a difference in 3-y weight change for normal vs. elevated baseline ALT (-4.4 ± 0.5 kg vs. -6.1 ± 0.6 kg; $p = 0.03$). Patients with elevated baseline ALT in the weight change quartile with the greatest weight loss ($n = 29$) had the greatest ALT reduction (-16.3 ± 3.1 IU/L; baseline 37.2 ± 2.9 IU/L) coupled with $-2.0 \pm 0.2\%$ A1C and -13.9 ± 0.7 kg.

Conclusion: T2D patients treated with exenatide for 3 years had improvements in hepatic biomarkers, with reductions in A1C and weight. These data support further investigations into possible improvements in NAFLD with exenatide treatment.

0111

Sitagliptin, a selective DPP-4 inhibitor, and metformin have complementary effects to increase active GLP-1 concentrations

E. M. Migoya¹, J. L. Miller¹, P. J. Larson¹, M. R. Tanen¹, D. Hilliard¹, C. F. Deacon², M. J. Gutierrez², S. A. Stoch¹, G. A. Herman¹, P. P. Stein¹, J. J. Holst², J. A. Wagner¹;

¹Merck Research Laboratories, Rahway, United States,

²Department of Medical Physiology, University of Copenhagen, Denmark,

³Division of Comprehensive Neuroscience, Miramar, FL, United States.

Background: The potential complementary effects of sitagliptin (SITA) and metformin (MF) on the incretin axis (GLP-1 and GIP) were assessed.

Methods: A randomized, placebo (PBO)-controlled, double-blind, 4-period crossover study was conducted in 16 healthy adults. In each 2-day treatment period, subjects received either SITA 100 mg q.d., MF 500 mg b.i.d., co-administration of SITA 100 mg q.d. and MF 500 mg b.i.d. or PBO. On Day 1, subjects received study medications in the AM and PM. On Day 2, subjects received study medications in the AM and, at 2 hours postdose, ate a standard meal (765 calories; 25% fat, 55% carbohydrate and 20% protein). Blood samples for active and total GLP-1 and GIP concentrations were collected pre- and at specified times post-meal.

Results: SITA alone and MF alone each increased post-meal incremental active GLP-1 concentrations by 1.5 to 2-times and in combination by >4 -times. Active and total GLP-1 concentrations were increased to a similar extent by MF; SITA increased active but diminished total GLP-1 concentrations (table). Active GIP concentrations increased with SITA, but were unchanged with MF.

Treatment	N	Geometric			
		LS Means	GMR [†]	95% CI [‡]	p-value
Active GLP-1 (pM)					
SITA	16	16.37	1.95	(1.58, 2.40)	<0.001
MF	16	14.81	1.76	(1.43, 2.17)	<0.001
SITA + MF	16	34.68	4.12	(3.35, 5.08)	<0.001
PBO	15	8.41			
Total GLP-1 (pM)					
SITA	16	12.43	0.70	(0.58, 0.85)	<0.001
MF	16	32.14	1.81	(1.49, 2.20)	<0.001
SITA + MF	16	27.82	1.57	(1.29, 1.90)	<0.001
PBO	15	17.77			

[†] GMR = Ratio of the post-meal incremental geometric LS means. Reference: Pbo

[‡] CI = Confidence interval

LS means = Least-squares means

Conclusions: Both SITA and MF increased active GLP-1 concentrations, but through different mechanisms. MF increased both active and total GLP-1 concentrations, suggesting an increase in release of GLP-1. SITA increased

active GLP-1 concentrations, but not total, consistent with inhibition of degradation of the active hormone. The decrease in total GLP-1 with SITA is likely due to feedback inhibition of active GLP-1 on GLP-1 release. Combination of SITA and MF provided a complementary (more than additive) effect on active GLP-1 concentrations. This complementary effect may provide a unique benefit of combination therapy in patients with type 2 diabetes through substantial enhancement of the incretin axis.

Pharmacokinetics and pharmacodynamic effects of oral GLP-1 and PYY3-36: a proof of concept study in healthy subjects

E. Arbit¹, B. Poller², C. Ganzoni³, S. Gass³, I. Gomez-Orellana¹, J. Drewe², C. Beglinger³;

¹Emisphere technologies, Tarrytown, United States, ²Clinical Pharmacology, University Hospital, Basel, Switzerland, ³Gastroenterology, University Hospital, Basel, Switzerland.

Context: Oral formulations of GLP-1 and PYY3-36, two satiety peptides, were studied. An oral dosage form of these peptides would be preferable in many of the possible therapeutic indications.

Objectives: Our objective was to establish the pharmacological profile of increasing oral doses of GLP-1 and PYY3-36 in healthy volunteers. In addition, the pharmacological effects of GLP-1 were investigated. GLP-1 and PYY3-36 were delivered by the oral-enteric route by means of the eligenTM technology.

Setting: Single center escalating dose study with oral applications.

Subjects and Methods: In the first part, GLP-1 was given orally to 6 male subjects; the treatment consisted of one of the following oral doses of either GLP-1 (0.5, 1.0, 2.0 and 4.0 mg) or placebo. In the second part, PYY3-36 was given orally to another 6 healthy male subjects; the treatment consisted of one of the following oral doses of either PYY3-36 (0.25, 0.5, 1.0, 2.0 and 4.0 mg) or placebo.

Results: The oral administration of both peptides induced a rapid and dose-dependent increase in plasma drug concentrations (linear dose-response relationship for GLP-1: $R = 0.96$; $P = 0.011$ and a curve linear dose response for PYY3-36). In addition, oral application of GLP-1 induced a potent effect ($p < 0.05$ vs placebo) on insulin release, whereas oral PYY3-36 induced a trend for inhibition of ghrelin secretion, which was significant ($p < 0.05$ vs placebo) for the highest dose.

Conclusions: This study showed for the first time that satiety peptides such as GLP-1 and PYY3-36, can be delivered orally in humans; GLP-1 was active with regard to stimulation of insulin release and PYY suppressed ghrelin levels after oral administration.

Cmax after oral application of peptides. Data are Mean (SEM)

Doses	PLACEBO	0.5 mg Peptide	1 mg Peptide	2 mg Peptide	4 mg Peptide

Initial combination therapy with sitagliptin and metformin provides effective and durable glycaemic control over 1 year in patients with type 2 diabetes (T2DM): a pivotal phase III clinical trial

D. E. Williams-Herman, J. R. Johnson, J. K. Lunceford; Merck Research Laboratories, Rahway, United States.

Background and Aim: Initial monotherapy is often unsuccessful at getting patients to glycemic goals, and due to the progressive nature of T2DM, patients require intensified treatment in order to maintain or achieve optimal glycemic control. Long-term efficacy and safety of initial combination

therapy with sitagliptin and metformin was assessed in patients with T2DM and inadequate glycemic control (A1C 7.5% to 11%) on diet and exercise.

Methods and Materials: After completing an initial 24-wk placebo-controlled phase, patients continued in a 30-wk, double-blind, active-controlled phase. At Wk 24, patients remained on their previous active treatments: sitagliptin 100 mg/metformin 2000 mg (S100/M2000), sitagliptin 100 mg/metformin 1000 mg (S100/M1000), metformin 2000 mg (M2000), metformin 1000 mg (M1000) (all as divided doses administered b.i.d.); and sitagliptin 100 mg q.d. (S100). Patients on placebo were switched to M2000. This report presents 54-wk results for patients who received active treatment throughout the study.

Results: Of the 1091 patients who were randomized, 748 patients continued into the active-controlled phase: S100/M2000 n=157, S100/M1000 n=148, M2000 n=137, M1000 n=122, S100 n=106. In the all-patients-treated analysis, mean A1C changes from baseline were -1.8% (S100/M2000), -1.4% (S100/M1000), -1.3% (M2000), -1.0% (M1000), and -0.8% (S100). With a mean baseline A1C of 8.7% (8.5% to 8.8% across groups), the proportions of patients with an A1C $<7\%$ at Wk 54 were 67% (S100/M2000), 48% (S100/M1000), 44% (M2000), 25% (M1000), and 23% (S100). Glycemic response was generally durable over time across treatments. For the patients completing treatment through Wk 54, mean A1C changes from baseline were -1.9% (S100/M2000), -1.7% (S100/M1000), -1.6% (M2000), -1.2% (M1000), and -1.4% (S100). The incidence of hypoglycemia (1.1%–2.7%) was low across treatment groups. The incidences of gastrointestinal adverse experiences were similar for the combination groups compared with the respective metformin monotherapy groups.

Conclusions: In this study, the initial combination therapy of sitagliptin and metformin provided durable and substantial glycemic improvements and was generally well-tolerated over 54 wks in patients with T2DM.

Supported by Merck

DPP4 inhibition remained high at 24 hr post dose and was ~ 80 , ~ 70 , and 50% in the 400, 200, and 100 mg dose groups. The most frequently observed adverse events were headache (10.3%), followed by hyperglycemia (8.6%), diarrhea (6.9%), UTI (6.3%), and nausea (5.7%). Edema was reported in the placebo and drug treated subjects; there was no dose relationship in the drug treated subjects. Overall, there was no discernable pattern of drug related adverse events and drug treated patients were similar to placebo. 63.8% of all subjects reported at least one adverse event and all but 2 events were rated mild or moderate. Two serious adverse events were reported, both in the placebo group.

Conclusion: Patients in this study tolerated PHX1149 very well. No safety issues were identified. DPP4 inhibition during the meal test was near maximal and postprandial blood glucose control improved significantly. HbA_{1c} in the high dose group was reduced significantly ($p=0.019$). GLP-1, the biological mediator was increased in all drug treated subjects. Studies in larger patient groups and over longer time periods will be conducted to further characterize this potential new diabetes drug in the class of DPP4 inhibitors.

PHX1149, a selective DPP4 inhibitor, improves postprandial blood glucose control in patients with type 2 diabetes

H.-P. Guler; Phenomix Protocol201 Study Group, Phenomix Corp., San Diego, United States.

Background and Aims: GLP-1 and GIP are important mediators of blood glucose control that are secreted in the GI tract in response to a meal. They increase insulin secretion and decrease glucagon action. DPP4, an ubiquitous serine protease, degrades GLP-1 and GIP within a few minutes. Inhibitors of DPP4 prolong the half life of these two peptides; as a consequence, insulin secretion is increased and hepatic glucose production is suppressed. PHX1149 is a potent and selective, small molecule DPP4 inhibitor that is highly soluble in water and stays in the extracellular space. PHX1149 is excreted renally, is not metabolized, and its half-life is 10 to 13 hr.

Materials and Methods: This was a randomized, double-blind, placebo-controlled, multi-center 28 day study in subjects with type 2 diabetes mellitus. The primary efficacy endpoint was change in the area under the curve (AUC) of postprandial glucose values from Day 1 to Day 28 as measured after a test meal administered in the morning after fasting overnight. 174 subjects were enrolled into 3 active dose groups and one placebo group (1:1:1:1). Subjects had a mean age of 52 years, a mean BMI of 33 kg/m², and a mean baseline HbA_{1c} of 8.7%. The majority (59%) were female. Almost all of the subjects (93%) were on a stable background therapy of metformin only, while 7% were on a combination of metformin and a glitazone. Multiple clinical study sites from the US, Mexico, and Australia participated.

Results: Abstract 0114

	Δ AUC pp glucose [mmol/L*hr]	Δ HbA _{1c} [%]	Δ AUC pp GLP-1 [pmol/L*hr]	Ex vivo DPP4 [%] inhibition during test meal

An approach to translating results of the Hyperglycemia and Adverse Pregnancy Outcome (HAPO) study

D. R. Hadden¹, B. Persson², D. R. Coustan³, A. R. Dyer⁴, M. Hod⁵, L. P. Lowe⁴, B. E. Metzger⁶, J. N. Oats⁷, E. R. Trimble⁸; for the HAPO Study Cooperative Research Group,

¹Regional Centre for Endocrinology and Diabetes, Royal Victoria Hospital, Belfast, United Kingdom, ²Pediatrics, Karolinska Hospital, Stockholm, Sweden, ³Maternal Fetal Medicine, Women and Infants Hospital of Rhode Island, Providence, United States, ⁴Department of Preventive Medicine, Northwestern University Medical School, Chicago, United States,

⁵Obstetrics and Gynecology, Rabin Medical Center, Petah-Tiqva, Israel, ⁶Division of Endocrinology, Metabolism and Molecular Medicine, Northwestern University Medical School, Chicago, United States,

⁷Women's Services, Royal Women's Hospital, Melbourne, Australia, ⁸Clinical Biochemistry, Queen's University of Belfast, United Kingdom.

Background and Aims: There is consensus that overt diabetes mellitus during pregnancy, whether or not accompanied by symptoms or signs of metabolic decompensation, is associated with a significant risk of adverse perinatal outcome; however, the risk of adverse perinatal outcome associated with degrees of glucose intolerance less severe than overt diabetes mellitus remains controversial.

Materials and Methods: Approximately 25,000 pregnant women at 15 collaborating centers in 9 countries [Bellflower CA, Chicago IL, Cleveland OH, Providence RI (USA); Toronto ON (CA); Barbados WI; Manchester, Belfast (UK); Petah Tiqva, Beersheba (IS); Bangkok (Thailand); Brisbane, Newcastle (Australia); Singapore (Singapore); Hong Kong (China)] who met criteria for inclusion underwent a 75 gm oral glucose tolerance test (OGTT) at 24–32 wks gestation (mean 28 wks). Participants and caregivers remained blinded to results of OGTT unless 1 or more values fell outside pre-defined limits (fasting >5.8; 2-hr >11.1; any value <2.5 mmol/L). Sociodemographic and health history data were collected via questionnaire and medical record abstraction. Maternal blood was obtained for measurement of serum C-peptide and hemoglobin A1c (HbA_{1c}) during the OGTT, and cord blood for fetal serum C-peptide and plasma glucose at delivery. A heelprick capillary specimen was taken between one and two hours following delivery for neonatal plasma glucose. Neonatal anthropometrics were obtained within 72 hours, and follow-up data collected at 4–6 weeks post-delivery. The primary outcomes that are being assessed in relation to maternal glycemia are cesarean delivery, increased fetal size (reflected in macrosomia, large for gestational age or obesity), neonatal morbidity (hypoglycemia), and fetal hyperinsulinism.

Results: The analysis of associations between maternal glycemia and these outcomes is beginning at this time. Initial presentation of the findings from these basic epidemiological assessments will be made at the June 2007 Annual Scientific Meeting of the American Diabetes Association (a co-sponsor of the HAPO Study). In this presentation to the Scientific Meeting of EASD, we will highlight the primary findings as the foundation for the presentation of a strategy that can be used to translate the initial results into clinical applications.

Conclusions: This EASD presentation will represent an important contribution to the dialogue that will be needed to use the HAPO Study results to develop “outcome based” criteria for defining clinically significant levels of hyperglycemia in pregnancy.

Prevalence of pre-gestational and gestational diabetes mellitus (GDM) among Asian-American women by ethnic subgroup, 1999–2005

J. M. Lawrence, R. Contreras;

Research & Evaluation, Kaiser Permanente, Pasadena, United States.

Background and Aims: Asian American women have a high prevalence of gestational diabetes mellitus (GDM) compared with women from most other racial/ethnic groups in the US. We ranked their pre-gestational diabetes mellitus (PGDM) and GDM prevalence by country of origin as Asian Americans constitute a very heterogeneous group.

Materials and Methods: For the 18,314 Asian American women who delivered 24,166 singleton pregnancy at ≥ 20 weeks gestation in Kaiser Permanente hospitals in southern California from 1999–2005, we defined PGDM (Type 1 or Type 2 DM) using laboratory, pharmacy, and ICD-9 codes and GDM if they had 2 abnormal results on the 75-g 2-hr or 100-g 3-hr oral glucose tolerance test during pregnancy. Maternal age and ethnic subgroup were obtained from the infant birth certificate. Hmong, Loatian and Cambodians were categorized as “other Southeast (SE) Asian” while other groups were categorized separately when possible. Crude and standardized age-adjusted prevalence of PGDM and GDM per 100 women are reported for each subgroup aggregated over seven years. Logistic regression models using the generalized estimating equations were used to identify differences in prevalence of PGDM and GDM among the groups after adjusting for age. The Cochran-Armitage trend test (2-sided) was done for the 7-year period to assess whether the prevalence of PGDM and GDM was changing and the direction of the change for each group.

Results: Among the 24,166 births to Asian American women, 2.3% of the women had PGDM and 10.1% of the women without PGDM developed GDM. The occurrence of PGDM and GDM increased linearly with age. For PGDM, none (0%) of women less than 20 years old had the condition compared with 5.7% of women age 40 years and older. GDM prevalence increased from 3.2% of women less than 20 years to 19.3% for women age 40 years and older. Indian women had the highest age-adjusted prevalence of PGDM (4.1) and GDM (11.9) while Vietnamese and other SE Asian women had the lowest prevalence (1.1) for PGDM and Japanese women had the lowest (5.0) for GDM. Compared with Indian women and adjusted for age, women in all other groups had a significantly lower prevalence of PGDM, whereas Japanese, Korean, other SE Asian, and other Asian women had a significantly lower prevalence of GDM. PGDM increased over the 7-year period for Japanese, Chinese, Filipino, and Indian women while GDM decreased for Korean and other Asian women. (Tab. 1)

Conclusions: While Asian American women in total have high rates of GDM compared with women of most other race/ethnicities, there is significant variability in the prevalence of diabetes-affected pregnancies by country of origin. We observed almost a four-fold difference for PGDM and over a two-fold difference for GDM between the highest and lowest age-adjusted prevalence of these conditions. Future studies should attempt to disaggregate Asian women by country of origin to more specifically categorize the risks to the mother and offspring associated with diabetes-exposed pregnancies.

0117

Significant effect of maternal DM2 family history on the severity of gestational diabetes mellitus

E. Anastasiou, P. Tourli, K. Terzidis, E. Zapanti, E. Chatzimichelakis, M. Alevizaki;

1st Endocrine Section – Diabetes Centre, Alexandra Hospital, Athens, Greece.

Background: Most epidemiological studies among patients with DM2 report a higher frequency of diabetes history in the maternal rather than the paternal side. This difference has been attributed to a variety of factors including inter alia the influence of the intra-uterine environment. Data is scarce as to whether this pattern is found in women with Gestational Diabetes Mellitus (GDM).

Aim: The aim of this study is to assess the influence of parental family history of DM2 in a large sample of Greek pregnant women.

Patients and Methods: Over a period of 10 years, 6671 pregnant women without known DM underwent a 100g OGTT in the third trimester of pregnancy. For GDM diagnosis the ADA 2000 criteria were used. Among these, 3384 were found with 4 normal values in the OGTT (Group N), 1107 had one abnormal value (Group 1AV), and the remaining 2180 had two or more abnormal values and were diagnosed as GDM (Group GDM). GDM women were treated with diet; insulin was added when optimal glycaemic BG thresholds were not achieved (fasting BG < 95mg and/or 1h-PP < 130mg). Age, pre-pregnancy BMI, and family history of DM were recorded. For statistical analysis odds ratios (OR-95%CI) were calculated, and Tarone's χ^2 for trends and stepwise logistic regression in combination with reverse Helmert contrasts were used.

Results: The DM2 family history per group and the odds ratio (crude and adjusted) for the onset of GDM are presented in the table below

Parental DM History	N (%)	1AV (%)	GDM (%)	GDM vs N		OR(CI) for GDM onset	OR(CI) BMI, Age adjusted
			χ^2	p			
Mother	6.8	10.4	16.5	87.8	<0.001	2.73 (2.20–3.38)	2.27 (1.81–2.86)
Father	8.7	10.4	13.3	19.1	<0.001	1.61 (1.30–1.99)	1.41 (1.15–1.80)

The severity of GDM was expressed in two ways: (i) according to the number of abnormal values in the OGTT, and (ii) according to the use of insulin for optimal glycaemic control. The former (i) is presented in the following table:

OR(CI) for DM2 History adj. BMI, Age	No abnormal glucose values	1 abnormal glucose value	2 abnormal glucose values	3 abnormal glucose values	4 abnormal glucose values
In mother	1(base)	1.59 (1.19–2.13)	2.18 (1.65–2.18)	2.89 (2.18–3.84)	3.92 (2.79–5.51)
In father	1(base)	1.21 (0.92–1.61)	1.64 (1.25–2.15)	1.61 (1.19–2.18)	1.52 (0.99–2.32)

There was a significant correlation between increasing number of abnormal values in OGTT and maternal DM2 history ($p < 0.001$), with no similar finding on the paternal side. Also (ii) insulin treated GDM women presented a significantly higher OR of maternal family history compared to paternal OR=3.30(2.48–4.38) vs 1.73(1.27–2.36) respectively, $p < 0.001$, Tarone's χ^2 test. On the contrary, no difference was found in women treated only with diet: OR=1.75(1.32–2.32) vs 1.55(1.19–2.02) $p = NS$.

Conclusions: Maternal DM2 family history compared to paternal is a stronger independent risk factor for the occurrence of GDM. An interesting finding was that the maternal compared to paternal DM2 family history was significantly more frequent in the subgroup of GDM women with a more severe form of the disease, as expressed by a greater number of abnormal values in the OGTT and the need for insulin treatment

0118

Should we see and treat all women with previous gestational diabetes (GDM) for GDM in their subsequent pregnancies without screening?C. S. Cotzias¹, N. I. M. De-Mendonca¹, T. J. J. Bracewell-Milnes¹, R. Kausahl², J. C. Girling¹, M. Wu³;¹Obstetrics and Gynaecology, ²Endocrinology and Diabetes,³Clinical Governance, West Middlesex University Hospital, Isleworth, United Kingdom.

Aim: To identify whether women with a history of GDM are demographically different from the newly diagnosed GDM population and whether they have different treatment needs and pregnancy outcomes.

To address whether seeing women with previous GDM early in a subsequent pregnancy is likely to offer better diabetic control.

Introduction: Throughout the literature, quoted recurrence rates of GDM in a subsequent pregnancy, range from about 30 – 70% depending on the population studied. In general, the heavier and less Caucasian the population the greater the recurrence rate. Our unit serves a multiethnic community with a high Asian prevalence and our incidence of non-Caucasian ethnicity is over 70% in women with GDM. As such, any women with a history of GDM are seen in the multi-disciplinary combined obstetric endocrine clinic early in their next pregnancy without further screening. They are reminded about the fetomaternal implications of GDM, the importance of the postnatal (PN) Oral Glucose Tolerance Test (OGTT) and the implications of GDM on their long term health. There is an emphasis on education, focussing on lifestyle changes, dietary control, Capillary blood glucose (CBG) monitoring and the importance of exercise is highlighted. Women unable to achieve target CBG levels with diet and exercise alone are commenced on insulin.

Methods: From 2000–2005 inclusive all women treated for GDM in the combined obstetric endocrine antenatal clinic were identified. A retrospective comparison was made between women treated for previous GDM with those newly diagnosed.

Results: From 2000–2005 inclusive there were 474 women treated for GDM in our unit. 419 (88%) notes were reviewed, of which 123 women (29%) had previous GDM and 296 (71%) had not. Women with previous GDM were older (mean age 34 years compared to 32 years in the Newly Diagnosed Group (NDG) and heavier (median BMI 29 kg/m² compared to median BMI 27 kg/m²). There was no difference in ethnicity between the two groups. More women with previous GDM had a first HbA1c ≥ 7 ($p < 0.005$) and were more likely to need insulin in addition to diet and exercise to achieve target CBGs (82 / 123 (66.7%) vs 139 / 296 (47%) $P < 0.0000$). 48/82 (58.3%) of women with previous GDM who required insulin needed it before 28 weeks gestation (when routine GDM screening occurs). This is highlighted by a significantly earlier gestation at which insulin was started in the previous GDM group (median 25.1 weeks vs median 33.4 weeks $P < 0.0000$) compared to the NDG. 66/123 (53.7%) of previous GDMs returned for PN GTT compared to 188/296 (63.5%) of the NDG, and there was no significant difference in the rate of abnormal PN OGTT results. There were no differences in rates of mode of delivery, shoulder dystocia or serious peri-natal complication between the 2 groups.

Conclusion: For an older heavy multiethnic antenatal population we recommend seeing and treating all women with previous gestational diabetes (GDM) for GDM in their subsequent pregnancies without screening, as they seem to have earlier onset more insulin resistant carbohydrate intolerance.

A systematic review on perinatal outcome in women with type 1 vs those with type 2 diabetes mellitusA. García-Patterson¹, M. Balsells², I. Gich³, R. Corcoy¹;¹Servei d'Endocrinologia, Hospital de Sant Pau, Barcelona,²Servei d'Endocrinologia, Hospital Mutua de Terrassa, Terrassa,³Servei d'Epidemiologia Clínica, Hospital de Sant Pau, Barcelona, Spain.

Background and Aims: Increasing attention is paid to pregnancies of women with Type 2 diabetes mellitus (T2DM) due to their increasing prevalence and reports indicating that perinatal outcome can be worse than in women with Type 1 diabetes mellitus (T1DM). We aimed to perform a systematic review on perinatal outcome in women with T2DM vs T1DM.

Materials and Methods: A Medline search was performed using "diabetes AND pregnancy AND (pregestational OR type 1 OR type 2 OR insulin

dependent OR non insulin dependent)" as query and limiting the search to human studies and the period 01/01/1995 – 31/12/2006. Abstracts and papers were reviewed by two independent reviewers and discrepancies settled with a third one. Whenever an abstract could fulfil the entry criteria, the original paper was reviewed. Entry criteria were papers providing original data of pregnancies in women with T1DM and T2DM, with 15 or more pregnancies for each type of diabetes, and reporting information on perinatal outcome. Comparison of background characteristics in women with T1DM and T2DM was performed with ANOVA (quantitative variables) and Mantel-Haenszel (categorical variables) tests. Comparison of outcomes was performed using meta-analysis tools (Review Manager software, v 4.2.10).

Results: Retrieved abstracts were 2781 and reviewed papers 107; 30 papers fulfilled entry criteria. Patients with T2DM were significantly older and heavier than those with T1DM, had higher rates of chronic hypertension, lower rates of prepregnancy care, less years of diabetes duration and better metabolic control throughout pregnancy. Women with T2DM had a higher risk of major congenital malformations (OR 1.33, 95CI 1.00–1.79, p 0.05) and similar risk of stillbirth (OR 1.11, 95CI 0.76–1.61), neonatal mortality (OR 1.54, 95CI 0.88–2.70) and perinatal mortality (OR 1.32, 95CI 0.90–1.92) than women with T1DM.

Conclusion: In a systematic review of the last twelve years, pregnant women with T2DM had worse background characteristics and better metabolic profile than those with T1DM. Perinatal outcome in terms of fetal mortality and major congenital malformations was similar or worse.

0120

Pregnancy outcomes in patients with microalbuminuria and their clinical status 3 years post partum

N. G. Asatiani¹, R. B. Kurashvili¹, M. G. Dundua¹, E. L. Shelestova¹, K. Pagava¹, M. Hod², Smirnov³, V. Vlasov³;

¹Georgian Diabetes Center, Georgian Diabetes Center, Tbilisi, Georgia,

²Dep. of Obstetrics and Gynecology, Rabin Medical Center, Tel-Aviv, Israel,

³Novo Nordisk, Copenhagen, Denmark.

Background and Aims: Of the present work was to assess outcomes of pregnancies proceeding with microalbuminuria and clinical status of these women 3 years postpartum (3yrsPP).

Materials and Methods: In total 176 patients (pts) with type 1 diabetes (T1DM) were enrolled in the study. Based on microalbuminuria (MicrA) levels in the 1st trimester (tr) women were separated into 2 groups (Gr.). Gr.1 – 134 (76.2 %) women with normal urinary albumin excretion (UAE), Gr.2 – 42 (23.8%) women with MicrA (UAE<300 mg/24h). Pts were supervised throughout the pregnancies and delivery; repeated examinations were performed 3yrs PP. Pts with MacrA were not enrolled in the study.

Results: Mean HbA1c in the 1st tr was $7.2 \pm 0.9\%$ (Gr.1) and $6.9 \pm 1.09\%$ (Gr.2), in the 3rd tr it dropped to $5.5 \pm 0.64\%$ (Gr.1) and $5.8 \pm 0.74\%$ (Gr.2), ($P=0.000$; $P=0.000$, respectively). In Gr.1 no MicrA was observed in the 1st tr, though 12 (8.9%) pts had it in the 3rd tr; all Gr.2 pts had MicrA in the 1st tr, 6 (14.2%) of them developed MacrA (UAE>300 mg/24h) in the 3rd tr. During pregnancy Gr.2 pts experienced gradual increase in daily amount of UAE: 1st tr – 124.4 ± 76.7 mg/24 h; 3rd tr – 289 ± 143.3 mg/24h. No correlation between UAE and HbA1c ($r=0.363$, $P=0.036$) was revealed. In Gr.1 and 2, respectively, we registered: preeclampsia – in 6.7% and 30.9% ($P<0.001$); preterm delivery – 13.4% and 33.3% of women ($P<0.001$); mean infant's birth weight – 3435 ± 320 g and 3287 ± 398 g. In Gr.1 – 3 (5.2%) and in Gr.2 – 7 (16.6%) newborns had respiratory distress syndrome. Repeated examinations 3yrsPP showed that HbA1c levels were statistically higher, that at term: $7.8 \pm 1.04\%$ – Gr.1 and $8.4 \pm 1.12\%$ – Gr.2. Kidney function indices worsened 3yrsPP: Gr.1 – 21 (15.6%) pts had MicrA; Gr.2 – 31 (73.8%) pts had MicrA, 7 (16.6%) pts had MacrA, and only 9.5% had NormA. Three (7.1%) Gr.2 pts are on regular hemodialysis; 1 (2.3%) died of acute renal failure, and 1 had kidney transplantation.

Conclusion: If MicrA is present in the 1st tr, pregnancy in T1DM pts more often ends in preeclampsia, preterm delivery and respiratory distress syndrom, than in NormA. In such pts no correlation between UAE and HbA1c is observed during pregnancy. 3yrsPP kidney function significantly deteriorates, including end-stage conditions, if pregnancy proceeded with MicrA.

Vaspin improves insulin sensitivity in obesity

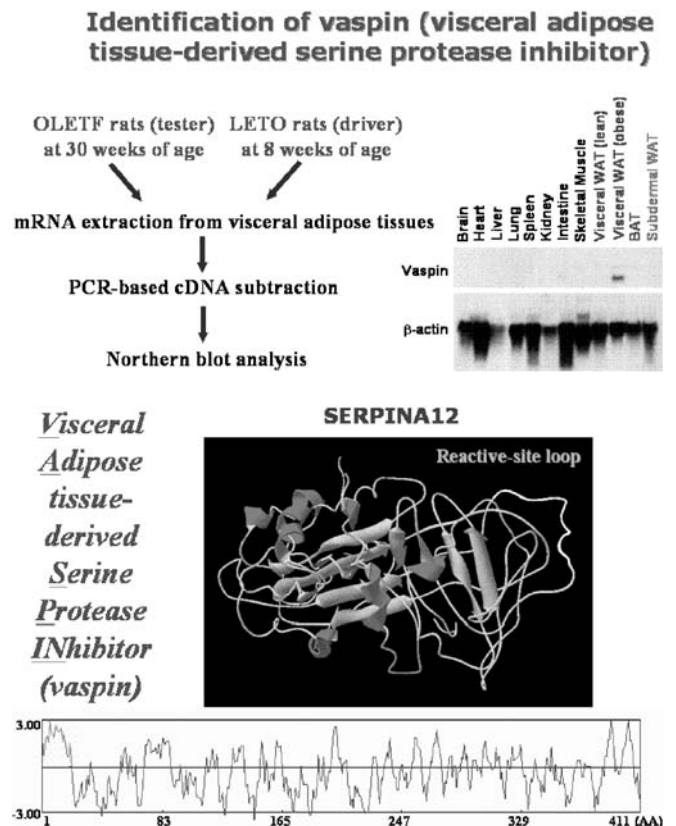

A. Nakatsuka, J. Wada, K. Murakami, S. Teshigawara, R. Yoshikawa, M. Kanzaki, A. Yasuhara, K. Shikata, H. Makino;
Department of Medicine and Clinical Science, Okayama University Graduate School of Medicine, Japan.

Background and Aims: Otsuka Long-Evans Tokushima fatty (OLETF) rat is an animal model of type 2 diabetes, characterized by abdominal obesity, insulin resistance, hypertension, and dyslipidemia. Differential screening of the genes up-regulated in visceral adipose tissues of obese OLETF rats and down-regulated in non-obese and diabetes-resistant Long-Evans Tokushima Otsuka (LETO) rats led to the identification of an insulin sensitizing adipocytokine in obesity; vaspin (visceral adipose tissue-derived serine protease inhibitor), which is a member of serine protease inhibitor (serpin) gene family. Rat, mouse and human mature vaspins are made up of 392, 394 and 395 amino acids, exhibit ~40% homology with alpha1-antitrypsin. Vaspin mRNA is exclusively expressed in visceral adipose tissue in genetically obese rats and also expressed in white adipose tissues of human and its expression is correlated with BMI and insulin sensitivity.

Materials and Methods: To explore the functional role of vaspin in metabolic syndrome, we prepared recombinant human vaspin protein and generated transgenic (Tg) mice overexpressing vaspin under control of AP2 promoter.

Results: Under high fat-high sucrose (HF) chow, ICR mice administered with recombinant vaspin and Tg mice overexpressing vaspin revealed improved glucose tolerance and insulin sensitivity. Epididymal fat and liver weight was reduced in vaspin Tg mice, and their body weight was ~8% less than wild type (WT) mice under HF chow. Although serum adiponectin levels were similar, leptin levels were significantly higher in WT mice (10.9 ± 6.4 ng/ml) compared with TG mice (2.7 ± 2.9 ng/ml).

Conclusion: Vaspin improves insulin sensitivity by acting on insulin target organs and may be a new molecular target in the treatment of metabolic syndrome.

0122

Chemerin is a novel adipokine associated with obesity and metabolic syndromeK. Bozaoglu¹, D. Segal¹, K. Bolton¹, J. McMillan¹, J. Jowett², P. Zimmet², G. Collier^{1,3}, K. Walder^{1,3};¹Metabolic Research Unit, Exercise and Nutrition Sciences, Deakin University, Waurn Ponds, Victoria, ²International Diabetes Institute, Caulfield, Victoria, ³ChemGenex Pharmaceuticals, Waurn Ponds, Victoria, Australia.

Background and Aims: Secreted proteins and cell surface receptors play crucial roles in intercellular signaling and homeostasis and can provide potential targets for developing novel therapies for diabetes. The aim of this study was to establish a novel signal sequence trap technology (SST) to identify secreted and membrane bound proteins that play a role in obesity and type 2 diabetes (T2D).

Materials and Methods: An SST was used to identify genes that encode secreted or membrane bound proteins from *Psammomys obesus*. Gene expression of chemerin and chemerin receptor (CMKLR1) were measured in adipose tissue of *P. obesus* and 3T3-L1 adipocytes by real time PCR. Serum chemerin levels were measured by ELISA in human plasma samples. Data analysis was performed using linear and multivariate regression.

Results: Using the SST, we identified the chemokine chemerin and have shown, for the first time, that both chemerin and its receptor CMKLR1 were highly expressed in adipose tissue of *P. obesus*. Furthermore, chemerin and CMKLR1 gene expression was significantly higher in adipose tissue of impaired glucose tolerant (IGT) and T2D *P. obesus* compared to normal glucose tolerant (NGT) animals ($p=0.004$, $p=0.01$ and $p=0.009$, $p=0.05$ respectively). Real time PCR analysis using fractionated mesenteric adipose tissue from *P. obesus* demonstrated that chemerin and CMKLR1 were predominantly expressed in adipocytes rather than stromal and vascular cells within adipose tissue ($p=0.0001$ and $p=0.01$ respectively). Chemerin gene expression was markedly induced during differentiation of 3T3-L1 adipocytes ($p<0.001$ compared to day 0), while CMKLR1 gene expression was downregulated ($p<0.001$ compared to day 0). Circulating chemerin levels in human plasma samples were not significantly different between NGT and T2D subjects. However, plasma chemerin levels were significantly higher in subjects with BMI >30 kg/m² compared with those with a BMI <25 kg/m² (296.5 ± 61.2 vs 222.7 ± 67.1 , $p<0.001$). After adjusting for age and gender, chemerin levels were significantly associated with measures of body fat (BMI, fat mass, weight and WHR) and metabolic syndrome related phenotypes (fasting glucose, fasting insulin, plasma triglycerides and blood pressure) in NGT subjects. After further adjustment for BMI, plasma chemerin levels were still independently associated with metabolic syndrome related phenotypes including systolic blood pressure ($p=0.001$) and plasma triglycerides ($p=0.009$) but not measures of insulin sensitivity or glucose homeostasis. When the data was adjusted for age, gender, BMI and triglycerides, chemerin levels were only associated with systolic and diastolic blood pressure ($p=0.002$ and $p=0.004$ respectively).

Conclusion: Chemerin is a novel adipokine that exhibits increased gene expression in adipose tissue of obese animals. Subsequent characterization of circulating chemerin levels in human samples demonstrated that chemerin is strongly associated with key components of the metabolic syndrome. These finding suggests that chemerin is a novel adipokine and could be an important contributor to the development of the metabolic syndrome.

Adipocyte adhesion molecule (ACAM) inhibits adipocyte hypertrophy in obesity

K. Murakami, J. Wada, A. Nakatsuka, S. Teshigawara, R. Yoshikawa, M. Kanzaki, A. Yasuhara, K. Shikata, H. Makino; Department of Medicine and Clinical Science, Okayama University Graduate School of Medicine, Japan.

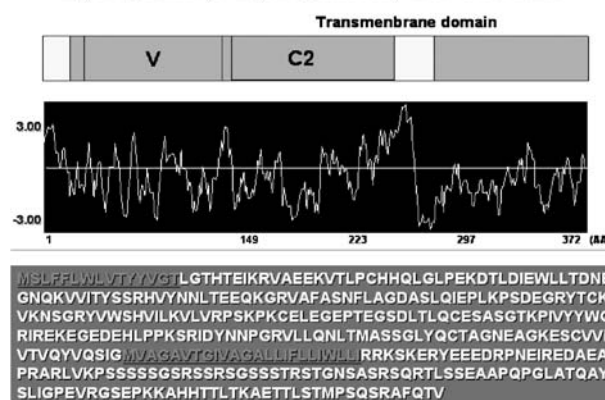

Background and Aims: We identified adipocyte adhesion molecule (ACAM), a novel homologue of cortical thymocyte marker in *Xenopus* (CTX) gene family. ACAM cDNA was isolated during PCR-based cDNA subtraction and its mRNA up-regulated in white adipose tissues (WATs) of Otsuka Long-Evans Fatty (OLETF) rats, an animal model of type 2 diabetes and obesity. ACAM with 372 amino acids has a signal peptide, V-type and C2-type

immunoglobulin domains, single transmembrane segment, and a cytoplasmic tail; the amino acid sequence in rat is highly homologous to mouse (94%) and human (87%). ACAM mRNA was predominantly expressed in WATs in OLETF rats and increased with development of obesity until 30 weeks of age; that is the peak of body weight. Up-regulation of ACAM mRNAs in obesity was also ascertained in WATs of genetically obese db/db mice, diet-induced-obesity ICR mice and human obese subjects. Several stably transfected CHO-K1 cell lines were established and the quantification of ACAM mRNA and cell aggregation assay revealed that the degree of homophilic aggregation well-correlated with ACAM mRNA expression.

Materials and Methods: To explore the functional role of ACAM in the process of metabolic syndrome, we have generated ACAM transgenic (Tg) mice under control of AP2 promotor.

Results: mRNA expression of ACAM was examined and Tg lines were classified as high- (H-), medium- (M-), and low- (L-) expressing Tg mice. Under high fat high sucrose (HF) chow, the increase in body weight was significantly inhibited in ACAM Tg mice compared with wild type (WT) mice and the reduction rate was correlated with ACAM mRNA expression levels, i.e. $\sim 9.2\%$ reduction in M-line and $\sim 56.5\%$ in H-line. In glucose tolerance tests, glucose levels were significantly lower in Tg mice (M-line) compared with WT mice. Daily intake of HF chow was similar in Tg and WT mice; however respiratory exchange ratio was increased in Tg mice compared with WT mice.

Conclusion: Adhesion process mediated by ACAM may have an inhibitory role in adipocyte hypertrophy in the status of obesity. ACAM is one of the candidates for the treatment of metabolic syndrome

Hydrophilicity / Hydrophobicity Plot of ACAM**Cell Aggregation Assay**

The peripheral role of ghrelin: suppression of leptin secretion in human subcutaneous adipocytes

S. J. Goodyear¹, N. F. da Silva¹, K. Kos¹, A. L. Harte¹, E. Sung¹, L. S. Wong², J. P. O'Hare¹, S. Kumar¹, C. Nwokolo³, P. G. McTernan¹;

¹Division of Clinical Sciences, Unit for Diabetes & Metabolism, Clifford Bridge Road, Coventry, ²Division of Surgery, University Hospitals Coventry and Warwickshire NHS Trust, Clifford Bridge Road, Coventry,

³Department of Gastroenterology, University Hospitals Coventry and Warwickshire NHS Trust, Clifford Bridge Road, Coventry, United Kingdom.

Background and Aims: The anorexigenic leptin and orexigenic ghrelin, are peripheral signals that control appetite via the hypothalamic neuropeptide Y (NPY) system. Ghrelin exists in an inactive form (desacetylated) and active (octanoylated) which acts via the GHS-R1a. Although the central action of these peptides has been investigated, their peripheral actions remain unclear. Adipose tissue (AT) has been shown to produce an array of neuropeptides. Due to the importance of AT in the control of energy homeostasis we examined 1) AT expression of ghrelin; 2) the effect of human recombinant (hr) octanoylated ghrelin (OctGhr) and desacetylated ghrelin (DesGhr) on leptin secretion; 3) and the mechanism of action, specifically NFκB activation.

Materials and Methods: *Ex vivo* human abdominal and omental AT was taken from women undergoing elective surgery (BMI:26.2(mean±SD)±1.6kg/m², Age:42.7±1.6yrs, n=38). Western blot procedures determined ghrelin protein expression. Isolated AbdSc adipocytes were treated with 1–100nM of desacetylated or octanoylated ghrelin. Following 48 hours treatment, leptin secretion was measured by ELISA.

Results: *Ex vivo* human abdominal and omental AT was taken from women undergoing elective surgery (BMI:26.2(mean±SD)±1.6kg/m², Age:42.7±1.6yrs, n=38). Western blot procedures determined ghrelin protein expression. Isolated AbdSc adipocytes were treated with 1–100nM of desacetylated or octanoylated ghrelin. Following 48 hours treatment, leptin secretion was measured by ELISA. Ghrelin was expressed in AT and adipocytes in a depot-specific manner. HrOctGhr (Control 5.2±1.4ng/mL; OctGhr: 1nM:4.7±1.7ng/ml; 10nM: 5.0±1.6ng/mL and 100nM: 4.4±1.3ng/ml) as well as DesGhr (1nM: 5.3±1.7ng/mL; 10nM: 4.9±1.4; 100nM: 4.1±1.5ng/ml) reduced leptin secretion and remained significant after BMI adjustment for OctGhr (p=0.029, n=5). NFκB activation studies demonstrated a dose-dependent increase with OctGhr (OctGhr 1nM 21%, 100nM 66%, p=0.01) and DesGhr (DesGhr: 1nM 29%, 100nM 113% p=0.03).

Conclusion: Centrally, leptin is known to antagonise ghrelin action. Our data suggests that both forms of ghrelin, partly produced in human adipose tissue, inhibit leptin production in human adipocytes, as part of a feedback loop. These findings implicate AT as a site of neuropeptide production and energy homeostatic regulation.

0125

IGFBP3 secreted by visceral adipose tissue mediates beta cell mass compensation for obesity

N. Palau, J. Altirriba, S. Piquer, R. Gomis, A. Barbera;

Endocrinology and Diabetes, Hospital Clinic/IDIBAPS, Barcelona, Spain.

Background and Aims: In obesity, an increase in insulin secretion and beta cell mass occurs to cope with the development of insulin resistance in order to maintain glucose homeostasis. This beta cell plasticity is essential to avoid the onset of hyperglycemia, however the molecular mechanisms that regulate this process still remain unclear. Besides storing energy, adipose tissue acts as an important endocrine organ secreting a number of adipokine with important effects in other organs. The aim of this study is to analyze the role of adipokines in the obesity-induced beta cell mass increase.

Materials and Methods: Wistar rats were fed with either standard chow (STD) or cafeteria diet (CAF) (65% of the energy derived from lipids) for 30 days. Pancreas was removed to perform morphometric studies. Adipose tissue from inguinal subcutaneous (iSUB), epididymal (eWAT) and pancreatic visceral (pVIS) depots were excised and incubated for 4 hours in RPMI medium. This conditioned media was later used to culture INS1E cells and to assay its proliferation rate by [³H]-thymidine incorporation. Finally we carried out microarray gene profiling of pVIS from obese and lean animals using Affymetrix RAE 230 2.0 GeneChip. Normalization and

differential expression analysis were performed with RMA and LIMMA software and these results were validated by qRT-PCR in all three adipose depots.

Results: In CAF rats the morphometric and immunohistochemical analysis of the pancreas showed an increase in beta cell mass (STD 6.71 ± 2.33 vs. CAF 10.87 ± 1.62 mg, p<0.01), hypertrophy (STD 119.3 ± 6.6 vs. CAF 128.7 ± 1.85 μm²; p<0.05) and replication (STD 0.38 ± 0.04 vs. CAF 0.68 ± 0.20% Ki67 + nuclei; p<0.05). INS1E proliferation assays revealed a two fold increase in cells cultured with the obese pVIS conditioned media compared to the lean conditioned media (p<0.05). This effect was only observed in visceral depot and it was suppressed by heat inactivation of conditioned medium, suggesting it was protein mediated. From all the genes differentially expressed in the pVIS arrays, 30 were secreted proteins and some of which are involved in proliferation processes. Using qRT-PCR, the expression of these proteins was determined in pVIS, eWAT and iSUB of lean and obese animals looking for adipokines which only show different expression levels in pVIS and could be responsible for the effect of pVIS conditioned media. This led to the identification of insulin-like growth factor binding protein 3 (IGFBP3) as a possible candidate of this effect. IGFBP3, described as a proliferation inhibitor, showed a two fold downregulation in the pVIS from obese rats without any change in its expression in iSUB and eWAT. Moreover, addition of a neutralizing antibody against IGFBP3 to lean pVIS conditioned medium resulted in an increase in INS1E proliferation rate by 66% (p<0.05). Finally, treatment of obese conditioned media with IGFBP3 protein had the inverse effect, and INS1E proliferation rate decreased by 66% (p<0.05).

Conclusion: Results presented indicate that, in obesity, visceral adipose tissue IGFBP3 downregulation is responsible for the increase in beta cell proliferation. This key finding will pave the way for understanding the mechanisms that regulate beta cell mass compensation for obesity.

Visfatin is regulated by rosiglitazone in type 2 diabetes mellitus and influenced by NF-κB and JNK in human abdominal subcutaneous adipocytes

K. C. McGee¹, N. F. da Silva¹, A. L. Harte¹, S. J. Creely¹, M. J. Hill¹, M. Khanolkar², M. Evans², M. V. Chittari¹, S. Kumar¹, P. G. McTernan¹;

¹Unit for Diabetes and Metabolism, University of Warwick, Coventry,

²Heart Research Institute, Cardiff University, Cardiff, United Kingdom.

Background and Aims: Visfatin, a novel adipocytokine shown to exert insulin mimetic effects, is elevated in the serum of Asian diabetics, suggesting a potential role for this protein in the pathogenesis of type 2 diabetes mellitus (T2DM) and cardiovascular disease (CVD). Whilst central adiposity is closely related to insulin resistance, the role of adipose tissue (AT) in the development of these conditions remains unclear.

Materials and Methods: For this study we investigated visfatin levels in Caucasian non-diabetics (ND) and type 2 diabetic (DB) subjects [ND BMI: 26.0(mean SD) ±2.7kg/m²; Age: 38.9(mean±SD) ±12.9yrs, n=23; DB BMI:35.9±7.2kg/m²; Age: 56.0±9.8yrs, n=36] and the influence of the insulin sensitizer, rosiglitazone (RSG). Further analysis examined the *in vitro* intracellular signalling of visfatin in cultured human Abd Sc adipocytes with the effect of insulin and RSG, as well as the influence of NF-κB and JNK inhibition on visfatin protein expression.

Results: *In vivo* studies showed T2DM subjects exhibited higher serum visfatin levels compared with ND subjects (T2DM: 21.8(mean±SEM) ±3.6ng/mL, ND: 13.9±1.5ng/mL, p<0.05). We also examined visfatin levels in T2DM patients pre- and post-treatment with the insulin sensitizer, RSG. Post-RSG treated DB showed significant reductions in serum visfatin and insulin compared to pre-RSG treatment (pre-RSG: 10.77±1.47ng/mL, post-RSG: 7.45±1.60ng/mL, p=0.004). *In vitro* analysis determined that RSG, in combination with insulin, reduced visfatin expression, compared with insulin alone (p<0.001), in a similar manner to other cytokines, such as secreted TNFα and resistin (p<0.001). In determining the intracellular mechanism for activation of visfatin protein expression, *in vitro* studies showed inhibition of NF-κB caused visfatin expression to increase (p<0.01). In contrast, JNK blockade reduced visfatin protein expression (p<0.01); however, together, NF-κB/JNK blockers caused a reduction in visfatin protein expression (p<0.01).

Conclusion: In summary, RSG appears to reduce both circulating visfatin levels as well as regulating protein expression in human isolated adipocytes. Additionally, an NF- κ B & JNK mediated mechanism appears to contribute to the regulation of visfatin, which appears independent of TNF- α and IL-6 influence in human AT. Reduction of visfatin, together with other cytokines, during RSG treatment is a novel finding that may underlie the clinical metabolic effects of rosiglitazone.

Impaired signaling through the PI3K/Akt pathway precedes development of whole-body insulin resistance in young men with low birth weight

C. B. Jensen¹, M. S. Martin-Gronert², H. Storgaard¹, S. Madsbad³, A. A. Vaag¹, S. E. Ozanne²;

¹Steno Diabetes Center, Gentofte, Denmark, ²Department of Clinical Biochemistry, Cambridge University, United Kingdom,

³Department of Endocrinology, Hvidovre University Hospital, Denmark.

Background and Aims: Low birth weight (LBW), a surrogate marker of an adverse foetal environment, is linked to muscle insulin resistance, impaired insulin-stimulated glycolysis and future risk of type 2 diabetes (T2D). Yet, the underlying molecular mechanisms remain largely unknown. We have previously shown reduced protein abundance in skeletal muscle and subcutaneous fat of the p85 α regulatory and p110 β catalytic subunits of PI3-kinase (PI3K), its downstream target protein kinase C zeta (PKC ζ), and the major glucose transporter GLUT4, in young healthy men with LBW at baseline (fasting) conditions. The aim of this study was to investigate whether activation by insulin of its two main signalling pathways, the PI3K-AKT pathway, responsible for most of its metabolic actions, and the Ras-mitogenic-activated protein kinase (MAPK) pathway, which controls cell growth and differentiation, is altered in LBW subjects.

Materials and Methods: Vastus lateralis muscle was obtained by percutaneous biopsy from 20 healthy 19-yr old men with birth weights \leq 10th percentile for gestational age (LBW) and 20 normal birth weight controls (NBW), matched for body fat, physical fitness and whole-body glucose disposal, before (BAS) and after a 4-hr hyperinsulinemic euglycemic clamp (INS). BAS and INS protein expression of IRS1, Akt1, p-Akt, PKC ζ , S6K1, p38 MAPK, JNK1, JNK2, and GLUT4, were determined by Western blotting.

Results: At BAS conditions, LBW subjects had lower p85 α , PKC ζ , and GLUT4 (previously reported), and showed a trend for lower IRS1 (~25%, $p=0.06$), and higher p-Akt (~27%, $p=0.07$). BAS Akt1, S6K1, p38 MAPK, JNK1, and JNK2 were unaltered. In LBW subjects, insulin stimulation increased IRS1 by 2-fold ($p=0.0008$, vs. no change in NBW; LBW-INS vs. NBW-INS, $p=0.15$), increased p85 α by 2-fold ($p=0.00006$, vs. no change in NBW; LBW-INS vs. NBW-INS, $p=0.001$), increased PKC ζ by 60% ($p=0.03$, vs. 2-fold in NBW, $p=0.0001$; LBW-INS vs. NBW-INS, $p=0.00006$), decreased Akt1 by 47% ($p=0.002$, vs. 87% increase in NBW ($p=0.0001$); LBW-INS vs. NBW-INS, $p=0.00005$), increased p-Akt by 3.6-fold ($p=0.0001$, vs. 6.4-fold in NBW ($p=0.00005$); LBW-INS vs. NBW-INS, $p=0.001$), increased S6K1 by 56% ($p=0.002$, vs. 29% in NBW ($p=0.12$); LBW-INS vs. NBW-INS, NS), and increased GLUT4 by 17% ($p=0.04$, vs. a 30% decrease in NBW ($p=0.002$); LBW-INS vs. NBW-INS, $p=0.01$). JNK1, JNK2 and p38 MAPK were not significantly altered by insulin or LBW.

Conclusion: In 19-yr old healthy lean men matched for body fat, physical fitness and whole-body glucose disposal, LBW was associated with marked reductions of two of PI3K's main targets, PKC ζ and p-Akt. Moreover, despite significant reduction at baseline, the p85 regulatory subunit of PI3K was dramatically increased in LBW, as compared to NBW. Increased expression of p85 α is observed in various insulin resistant states, and excess has been shown to impair insulin signalling through the PI3K/AKT pathway. Thus, impaired signalling through the PI3K pathway in skeletal muscle, potentially through increased p85 α expression precedes development of whole-body insulin resistance in subjects with LBW.

Role of decreased JNK and IRS-1 ser307 phosphorylation in the enhanced in vitro glucose transport activity of skeletal muscle from Zucker Diabetic Fatty rats following selective GSK-3 inhibition

E. J. Henriksen, M. K. Teachey;

Department of Physiology, University of Arizona, Tucson, United States.

Background and Aims: Overactivity of glycogen synthase kinase-3 (GSK-3), a multifunctional serine/threonine kinase, is associated with insulin resistance

of skeletal muscle glucose transport activity in type 2 diabetic rodents and humans. However, little is known regarding the potential molecular mechanisms underlying the involvement of GSK-3 in the etiology of this insulin resistance in type 2 diabetes. We therefore assessed the functionality of proximal and distal insulin signaling elements in skeletal muscle of male Zucker Diabetic Fatty (ZDF) rats, a model of type 2 diabetes, following acute in vitro exposure to a selective GSK-3 inhibitor. In addition, ser307 phosphorylation of insulin receptor substrate-1 (IRS-1), which has been implicated in the development of insulin resistance, was also determined in the absence or presence of the GSK-3 inhibitor.

Materials and Methods: Soleus strips isolated from 12-week-old male ZDF rats were incubated for 1 hr in the absence or presence of a maximally-effective concentration of insulin (5 mU/ml) without or with 1 μ M CT98014, a selective GSK-3 inhibitor. Glucose transport activity was assessed by 2-deoxyglucose uptake, and phosphorylation of insulin receptor, IRS-1, Akt, GSK-3, and c-jun N-terminal kinase (JNK) was performed using standard immunoblotting methods.

Results: Insulin-stimulated GSK-3 β ser9 phosphorylation was significantly less (35%, $P < 0.05$) in soleus muscle of ZDF rats compared to insulin-sensitive lean Zucker rats, documenting GSK-3 overactivity. In the absence of insulin, no effects of GSK-3 inhibition on ZDF muscle were detected. GSK-3 inhibition in ZDF muscle induced significant enhancement (28%) of insulin-stimulated glucose transport activity that was associated with significant upregulation of tyrosine phosphorylation of insulin receptor (52%) and IRS-1 (50%) and with enhanced phosphorylation of Akt ser473 (48%) and GSK-3 β ser9 (36%). Moreover, selective GSK-3 inhibition caused a significant reduction in phosphorylation of IRS-1 ser307 (26%) and JNK (31%), a mediator of IRS-1 ser307 phosphorylation.

Conclusion: These results indicate that selective inhibition of GSK-3 activity in isolated skeletal muscle from type 2 diabetic ZDF rats enhances IRS-1-dependent insulin signaling, possibly by a decrease in JNK activation and a diminution of the deleterious effects of IRS-1 ser307 phosphorylation.

Crosstalk of insulin-dependent serine phosphorylation sites Ser-302, Ser-307 and Ser-318 of IRS-1

C. Weigert, M. Kron, A. K. Pohl, H. Runge, H. U. Haring, E. D. Schleicher, R. Lehmann;
Internal Medicine, University of Tuebingen, Germany.

The diverse phosphorylation pattern of the multiple serine/threonine phosphorylation sites of IRS-1 suggest that they act as an orchestra rather than as solists. We aimed to investigate the interplay of the adjacent serine residues Ser302, Ser307, and Ser318 in insulin signal transduction. Phosphorylation kinetics were performed in L6 myotubes. For transient expression of IRS-1 mutants and transfection of siRNA oligonucleotides C2C12 myoblasts were used. Studies on the insulin-stimulated phosphorylation of the three sites showed a sequential phosphorylation: a high basal phosphorylation of Ser302 (maximum after 10 min), a maximum phosphorylation of Ser318 after 30 min, and of Ser307 after 60 min, respectively. We found three different kinases involved in this sequential phosphorylation: PKC ζ in early phosphorylation of Ser318, mTOR or a mTOR-dependent kinase in the later phosphorylation of Ser318, and JNK in phosphorylation of Ser307. The basal phosphorylation of Ser302 appeared to be important for the early phosphorylation of Ser318, which was clearly reduced after mutation of Ser302 to alanine. In contrast, the early phosphorylation of Ser318 appeared not to be necessary for phosphorylation of Ser307. Furthermore, PKC ζ was not necessary for insulin-induced JNK activation or JNK/IRS-1 interaction. Cells expressing a IRS-1 mutant simulating the early phosphorylation pattern (i.e. 302E,307A,318E) showed enhanced insulin-induced AKT phosphorylation. Thus, three adjacent serine residues in IRS-1 are phosphorylated by different kinases with different kinetics after insulin stimulation. Hence, the sequential phosphorylation of these sites exemplarily reflects the complex regulation in the orchestra of IRS-1 phosphorylation sites to mediate the activation and inhibition of insulin signaltransduction.

RNAi-based gene silencing of ribosomal protein S6 kinase 1 protects against leucine-induced insulin resistance in human skeletal muscle

L. Al-Khalili¹, A. Deshmukh¹, F. Salehzadeh¹, R. Fahlman¹, K. S. Nair²;
¹Molecular medicine and surgery, Karolinska Institutet, Stockholm, Sweden,
²Endocrinology Research Unit, Mayo Clinic School of Medicine, Rochester, United States.

Background and Aims: Excessive nutrients, including amino acids, impair insulin action in skeletal muscle. We tested the hypothesis that the branched-chain amino acid leucine induces insulin resistance in primary myotubes via a negative feedback mechanism involving ribosomal protein S6 kinase 1 (S6K1). **Materials and Methods:** primary human skeletal muscle cells were obtained from *rectus abdominus* muscle biopsies from healthy donors and the effect of S6K1 on glucose uptake and metabolism was determined by applying RNA interference (siRNA).

Results: siRNA against S6K1 reduced protein expression 64%. Myotubes were incubated in the absence or presence of leucine (5 mM) for 2 hours. Leucine treatment decreased basal glucose uptake (22%; $P < 0.05$) and glucose incorporation to glycogen (21%, $P < 0.05$). Depletion of S6K1 restored basal glucose uptake and metabolism. Insulin increased glucose uptake and glycogen incorporation to glycogen 2.2 and 1.5-fold, respectively ($P < 0.05$) and depletion of S6K1 enhanced insulin-stimulated glucose uptake (54%; $P < 0.05$). These findings provide evidence for a direct and essential role of S6K1 in the regulation of skeletal muscle glucose metabolism.

Conclusion: Depletion of S6K1 enhanced basal glucose utilization and protects against the development of insulin resistance in response to excessive nutrients caused by leucine. In conclusion, S6K1 plays an important role in nutrient sensing and the regulation of insulin action on glucose transport and metabolism in human skeletal muscle.

Influences of hyperglycaemia, hyperinsulinaemia, and hepatic steatosis on the circadian clock in mouse liver

K. Shima¹, H. Ando¹, N. Matsuzawa¹, T. Takamura¹, A. Fujimura², S. Kaneko¹;

¹Department of Disease Control and Homeostasis, Kanazawa University Graduate School of Medical Science, Kanazawa,

²Department of Pharmacology, Jichi Medical University, Shimotsuke, Japan.

Background and Aims: Major components of energy homeostasis, including feeding behavior and glucose and lipid metabolism, are subjected to circadian rhythms that are regulated by a circadian clock system composed of transcriptional/translational feedback loops involving a set of clock genes. Some of these circadian rhythms are known to be attenuated in obese diabetic patients, and we showed that the rhythmic expression of clock genes is diminished in the liver and visceral adipose tissue of obese diabetic KK-*A^y* mice (Endocrinology 2005). Moreover, mice lacking the molecular clock are obese and develop a metabolic syndrome. Therefore, impairment of the molecular clock in peripheral tissues may be involved in the pathophysiology of obese type 2 diabetes. However, it remains to be determined which pathological alteration is associated with the decreased molecular clock function. To address this issue, we investigated the effects of hyperglycemia, hyperinsulinemia, and steatosis on daily mRNA expression profiles of the clock genes in mouse liver.

Materials and Methods: Male C57BL/6J, db/db, and ob/ob mice were maintained under a condition with controlled temperature and humidity and a 12-h light/12-h dark cycle for more than 2 weeks. A subset of C57BL/6J (B6) mice were given a high-fat diet (60 kcal% fat, 1.27% cholesterol, and 0.5% sodium cholate) for 5 weeks. At 10 weeks of age, animals were sacrificed to obtain blood and liver samples at the following zeitgeber times (ZT): 0, 6, 12, and 18, in which ZT 0 is defined as lights on and ZT 12 as lights off. Transcript levels of clock genes (Clock, Bmal1, Per1, Per2, Cry1, Cry2, Dbp) in each sample were determined by real-time quantitative PCR.

Results: The db/db mice developed obesity (mean body weight 45.4 g; B6, 26.1 g), severe hyperglycemia (440 mg/dl; B6, 151 mg/dl), and mild hyperinsulinemia (12.0 ng/ml; B6, 2.6 ng/ml) at 10 weeks of age. The ob/ob strain developed more severe obesity (52.4 g) and hyperinsulinemia (86.8 ng/ml), but less degree of hyperglycemia (272 mg/dl), than db/db mice. All

of the clock genes examined exhibited significant 24-h rhythmicity not only in control B6 mice, but in both the obese diabetic strains. In accord with our previous findings in KK-*A^y* mice, the phase of molecular clock was not shifted, but the peak transcript levels of most clock genes were significantly attenuated in both db/db and ob/ob mice. Interestingly, the rhythmic mRNA expression of these genes was mildly dampened in db/db mice and greatly attenuated in ob/ob mice. Although severe fatty liver was developed in the mice fed a high-fat diet, as well as db/db and ob/ob mice, hepatic steatosis hardly affected the rhythmic expression of clock genes in the liver.

Conclusion: In the mouse models of obese diabetes, obesity and/or hyperinsulinemia appeared to be more closely associated with the impaired function of molecular clock than hyperglycemia. The rhythmic expression of clock genes was attenuated in the fatty liver of genetically obese models, but not in a non-obese dietary model. Although further studies are needed to clarify the causal relationship between the function of molecular clock and the development of obesity/hyperinsulinemia, current irregular lifestyle patterns might have led to the worldwide increase in obesity/insulin resistance partly through the impairment of molecular clock.

0132

Rhythmic mRNA expression of clock genes is attenuated in peripheral leukocytes of type 2 diabetic patients

H. Ando¹, T. Takamura¹, N. Matsuzawa¹, K. Shima¹, S. Kaneko¹, A. Fujimura²;

¹Department of Disease Control and Homeostasis, Kanazawa University Graduate School of Medical Science, ²Department of Pharmacology, Jichi Medical University, Shimotsuke, Japan.

Background and Aims: Various physiological processes exhibit circadian rhythmicity, which is generated at the cellular level by the core oscillators that are composed of transcriptional/translational feedback loops involving a set of clock genes. Recent studies have suggested that mice lacking the molecular clock are obese and develop a metabolic syndrome. Moreover, we have shown that the rhythmic expression of various genes, including the genes related to molecular clock, metabolism, and cellular processes, is attenuated in the liver and visceral adipose tissue of genetically obese diabetic mice (Endocrinology 2005; Biochem Biophys Res Commun 2006). Therefore, impairment of the molecular clock in peripheral tissues may be involved in the pathophysiology of type 2 diabetes and/or metabolic syndrome. However, it remains to be determined whether the rhythmic expression of clock genes is altered in human subjects with these clinical conditions. To address this issue, we investigated daily mRNA expression profiles of the clock genes in peripheral leukocytes of type 2 diabetic patients.

Materials and Methods: Six non-diabetic subjects (5 males, 23–42 years) and 8 patients with type 2 diabetes (5 males, 45–73 years) were enrolled in this study after written informed consent was obtained from each participant. We excluded subjects who experienced jet lag, shift work, or an acute illness during the 2 weeks preceding the experiment. None of the subjects had insomnia, or were taking psychotropic drugs during the one month preceding the study. The collection of peripheral blood was performed at 9:00, 15:00, 21:00, and 3:00 h beginning at 9:00 h. Immediately after sampling, leukocytes were isolated and stabilized using the LeukoLock system. Transcript levels of clock genes (*CLOCK*, *BMAL1*, *PER1*, *PER2*, *PER3*, *CRY1*, *CRY2*) in each sample were determined by real-time quantitative PCR. The protocol was approved by the relevant ethics committee and was conducted in accordance with the Declaration of Helsinki.

Results: The mRNA expression of *PER1* exhibited a significant 24-h rhythm ($F = 7.7$, $P < 0.001$, one-way ANOVA) with a peak at 9:00 h and a trough at 21:00. In addition, the mRNA expression of *PER3* and *BMAL1* showed 24-h rhythmicity. These significant rhythms were observed not only in whole subjects, but in diabetic patients (*PER1*, $F = 10.6$, $P < 0.0001$; *BMAL1*, $F = 3.0$, $P < 0.05$). However, the peak levels of *PER1* and *BMAL1* were significantly decreased by 31% and 19%, respectively in diabetic patients, compared with non-diabetic subjects.

Conclusion: The rhythmic expression of clock genes in peripheral tissues appears to be dampened not only in obese diabetic mice, but also in patients with type 2 diabetes. Further clinical studies are needed to clarify the causal relationship between the function of molecular clock and the development of type 2 diabetes.

Aldosterone blockade attenuates diabetic neuropathy in streptozotocin-induced diabetic rats

Y. Takeda, H. Takata, A. Zhu, T. Yoneda, M. Mikiya Usukura, Y. Yamamoto, S. Karashima, M. Yamagishi;

Internal Medicine, Graduate School of Medical Science, Kanazawa University, Japan.

Background and Aims: Blockade of angiotensin II (Ang II) using ACE inhibitor or type 1 angiotensin II receptor blocker (ARB) is effective to attenuate diabetic neuropathy. We have reported that not only Ang II but also aldosterone plays a key pathophysiological role in the progression of diabetic renal disease. However, little information is available about the potential benefits of specific mineralocorticoid receptor (MR) blocker, eplerenone, on diabetic neuropathy. We understood this study to determine whether MR exists in the peripheral nerve and to investigate the effects of eplerenone on nerve conduction velocity (NCV) and morphometric change in streptozotocin (STZ)-diabetic rats and compared with the effects of ARB, candesartan.

Materials and Methods: The expression of MR mRNA in the rat peripheral nerve and kidney was measured using a real time PCR. The protein expression was done by Western blot analysis. The NCV of STZ-diabetic rats (DM, n=10), DM rats treated with eplerenone (100mg/kg in rodent chow, n=10) or candesartan (0.2mg/kg/day, intraperitoneally, n=10) for 8 weeks was measured. Mean myelinated nerve fiber area and myelin area were measured in each experimental group.

Results: The MR mRNA expression was detected in rat peripheral nerves and the mRNA levels were almost equal to those in the kidney. The MR protein expression was clearly demonstrated using a Western blot analysis. The NCV of DM rats was 32 m/s (mean), and the treatment with eplerenone or candesartan significantly improved NCV (39 m/s, 46 m/s respectively) ($p < 0.05$). The decreased fiber and myelin sizes seen in DM rats were significantly improved by the treatment with eplerenone or candesartan ($p < 0.05$).

Conclusion: These results suggest that aldosterone blockade may be effective treatment for diabetic neuropathy. Not only Ang II but also aldosterone may possess some pathophysiological roles for the diabetic neuropathy.

Peripheral nerve protective effect of COMP-angiopoietin-1 in db/db diabetic mice

H. Jin¹, T. Park¹, S. Kim¹, J. Park¹, H. Baek¹, C. Kim², D. Kim¹;

¹Division of Endocrinology and Metabolism, Department of Internal Medicine, Chonbuk National University Medical School, Jeon Ju,

²Division of Endocrinology and Metabolism, Department of Internal Medicine, Bu Cheon Se-Jong Hospital, Bu Cheon, Republic of Korea.

Background and Aims: Recently vascular and inflammatory processes have been reported as underlying pathogenesis of diabetic neuropathy. Angiopoietin-1 (Ang1) plays essential roles in regulating vascular growth, development, maturation, permeability, and inflammation. We investigated the effect of cartilage oligomeric matrix protein (COMP)-Ang1 which is a soluble, stable, and potent Ang1 variant on peripheral nerve of diabetic animal model.

Materials and Methods: *db/db* diabetic mice were treated with recombinant adenovirus expressing either COMP-Ang1 or LacZ for 8 weeks. After that, the measurement of intraepidermal nerve fiber and dermal vascular changes in the foot dorsum skin was performed.

Results: COMP-Ang1 significantly decreased blood glucose level during fasting state and after intraperitoneal glucose challenge. In addition, COMP-Ang1 significantly improved the intraepidermal nerve fiber density (8.95 ± 3.30 vs 3.57 ± 0.73 , $P < 0.05$) and total skin capillary length (2.79 ± 0.99 vs 2.04 ± 0.58 , $P < 0.05$).

Conclusion: We demonstrated that COMP-Ang1 can preserve intraepidermal nerve fiber and capillary vessels in the foot dorsum skin of *db/db* diabetic mice through its diverse effects. Although the exact mechanism of COMP-Ang1 will need to be investigated in the future, we propose that COMP-Ang1 can be effective agent to prevent or treat diabetic peripheral neuropathy.

0135

Lack of diabetic peripheral neuropathy progression after three years in patients with mild DPN: experience from the Ruboxistaurin clinical trial

E. J. Bastyr, III, C. Cheng, K. L. Price, K. A. Kles, T. Deal, V. Skljarevski, A. Lledo;

Eli Lilly and Company, Indianapolis, United States.

Background: The time course of progression of mild diabetic peripheral neuropathy (DPN) to clinically meaningful changes is unknown. The objective of this analysis was to evaluate the rate of progression of mild DPN in metabolically well-controlled placebo-treated patients in a clinical trial setting.

Design: Baseline to endpoint mean change was analyzed in placebo-treated patients studied for up to 3 years in a randomized, double-blind, placebo-controlled trial that was stopped for futility at 2 years. This trial evaluated the effect of ruboxistaurin, a PKC β inhibitor, on a composite measure of nerve function (Neuropathy Impairment Score of the Lower Limbs + 4 nerve attributes + vibration detection threshold; NIS(LL) +4+VDT). Mild DPN were identified by sural sensory nerve action potential amplitude $>1\mu\text{V}$. Change in nerve function as measured by composite score, the neurological examination as measured by the NIS(LL) (range 0–88 points), and electrophysiology measured by nerve conduction studies were assessed using last observation carried forward.

Results: 348 placebo-treated patients (49% female, 44.9 years) with diabetes (48% type 1) had a mean HbA_{1c} of 7.5%.

Measure	Baseline	Endpoint	Change at study end
NIS(LL)+4+VDT (pts, n.d.)	10.12	9.50	-0.73*
VDT (JND)	19.39	19.17	-0.26*
NIS(LL) (pts)	4.73	4.46	-0.39*
Peroneal Nerve Conduction Velocity (m/sec)	43.11	42.78	-0.31**
Peroneal Conduction Velocity and Amplitude (mV)	4.61	4.39	-0.18**
Peroneal F Wave Latency (msec)	51.59	51.73	0.13

* $p<0.05$ improved, ** $p<0.05$ worsened, JND=just noticeable difference; n.d.=normal deviates; m/sec=meters/second; msec=milliseconds; mV=millivolts; pts=points

There was statistically significant improvement in a composite of nerve function (NIS(LL) +4+VDT), VDT and the neurological examination (NIS(LL)). There was no statistical change in electrophysiology attributes of latencies (distal onset and F wave), while there was a statistically significant worsening of peroneal and tibial conduction velocities and amplitudes. There was a statistically significant worsening of HbA_{1c} (0.31%). No change in DPN measures reached clinical significance. Intervention with ruboxistaurin did not result in a statistically significant impact on the progression of DPN.

Conclusion: Small changes in progression of neuropathy were observed, therefore in placebo-treated patients with good glycemic control, clinically significant changes in standard measures evaluating disease state progression may require greater than 3 years.

Supported by Lilly Research Laboratories

0136

Chronic treatment with aldose reductase inhibitor zopolrestat suppressed sorbitol, but not fructose, in sural nerves of patients with diabetic neuropathyP. J. Oates¹, S. S. Klioze² & the Zopolrestat Diabetic Neuropathy Study Group.

¹Cardiovascular Metabolic and Endocrine Diseases, ²Clinical Development, Pfizer Global Research & Development, Groton, United States.

Background and Aims: Metabolism of glucose to sorbitol by aldose reductase (AR) has been implicated in the pathogenesis of diabetic neuropathy, and AR inhibitors (ARIs) have effected dose-dependent reductions in nerve sorbitol

(S) and downstream metabolite fructose (F) and caused improvements in human nerve function and structure. However, the optimal degree of suppression of S and F in diabetic human nerve with chronic ARI treatment is unknown. In part to help answer this question, we studied over a period of 18 months the effect of two doses of ARI zopolrestat (Z) on sural nerve polyol content and on nerve function and structure, and on neural signs and symptoms.

Materials and Methods: Protocol 078–107 was a multicenter, double-blind, placebo-controlled, parallel-group study of 436 type 1 and 2 diabetic patients with moderate peripheral symmetrical diabetic polyneuropathy. The study included a subset of 234 patients who completed 18 months of treatment with placebo (P) or Z, 250 mg/day (LZ) or 500 mg/day (HZ). Nerve conduction velocity (NCV) and amplitude (AMP) for six motor or sensory nerve segments and HbA_{1c} were measured at 0, 3, 6, 12 and ~18 months by standard electrophysiological and analytical methods. Quantitative sensory threshold (QST) (vibration; great toe; Vibratron II), neurological signs and symptoms, RR-variation and Quality of Life (QOL) were also assessed at periodic intervals. Sural nerve biopsies were obtained at baseline and at 18 months ($n = 172$), and nerve glucose (G), myo-inositol (MI), S and F were measured. Nerve fiber density (NFD) was determined in chemically-fixed biopsy segments by standard morphometric methods. Data: mean \pm SEM (n); units: NCV, m/sec; S and F, $\mu\text{mole/g}$ protein.

Results: HbA_{1c} values (~8.3%) remained unchanged in all groups, and Z was generally well tolerated. Modest treatment-related improvements in NCV were seen from 6 to 18 months. The average NCV change from baseline to 18 months for all 6 nerve segments ($n = 69$ –84 patient NCVs per nerve type per group) were: P, -0.09 ± 0.11 (6); LZ, $+0.49\pm 0.15$ (6); HZ, $+0.41\pm 0.18$ (6) ($p=0.031$, ANOVA). No treatment-related effects were found for AMP, QST, RR-variation, NFD, signs, symptoms or QOL. While S was unchanged in P (0.50 ± 0.09 (60) at baseline vs. 0.44 ± 0.04 (60) at 18 mo. (NS)), S was reduced 76% in LZ (0.46 ± 0.07 (56) vs. 0.11 ± 0.03 (56)), and by 80% in HZ (0.46 ± 0.07 (56) vs. 0.09 ± 0.02 (56)) ($p<0.0001$, LZ or HZ vs. baseline). In all groups, F was unchanged (P, 2.3 ± 0.1 (60) vs. 2.4 ± 0.1 (60) at 18 mo. (NS); LZ, 2.6 ± 0.2 (56) vs. 2.7 ± 0.2 (56) (NS); HZ, 2.6 ± 0.2 (56) to 2.6 ± 0.2 (56) (NS)), as were G and MI.

Conclusion: The present clinical results are consistent with preclinical data that show 1) ARIs dose-dependently suppress sciatic nerve S and F with suppression of F occurring at doses 3-fold higher than needed to reduce S; and 2) only modest NCV effects occur at ARI doses that lower S without substantially lowering F. The results imply that sorbitol-associated osmotic stress is unlikely to be a key pathogenic factor in human diabetic nerve. Potential therapeutic benefits from ARIs capable of a greater degree of nerve polyol suppression remain to be explored.

0137

Pooled analysis of 7 randomized, controlled trials of pregabalin for the treatment of painful diabetic peripheral neuropathy (DPN): efficacy, safety, tolerabilityR. Freeman¹, J. Rosenstock², B. Emir³, E. Durso-Decruz²;

¹Beth Israel Deaconess Medical Center, Harvard Medical School, Boston,

²Diabetes and Endocrinology Dept, Dallas Diabetes and Endocrine Center,

³Pfizer Global Pharmaceuticals, New York, United States.

Background and Aims: This abstract aims to more fully describe pregabalin for the treatment of painful DPN across its effective dosing range (150–600 mg/d, BID or TID). To this end, we pooled data from 7 randomized controlled trials of 5–13 weeks' duration.

Materials and Methods: 1510 patients comprised the pooled ITT population: 557 received placebo (PBO), and 953 received pregabalin (176, 266, and 511 received 150, 300, and 600 mg/d). The primary efficacy measure in each trial was endpoint (EP) mean pain score (MPS) from patients' daily pain diaries (11-point numeric rating scale [NRS]).

Results: Reductions in MPS from baseline (BL) to EP were significantly larger in pregabalin-treated patients than in those receiving PBO: 150 mg/d, -2.05 ($P=0.0065$); 300 mg/d, -2.36 ($P<0.0001$); 600 mg/d, -2.75 ($P<0.0001$); PBO, -1.49 . Proportions of responders (patients with $\geq 50\%$ reduction in MPS from BL to EP) were also greater than PBO: 150 mg/d, 27% ($P=0.0574$), 300 mg/d, 39% ($P<0.0001$); 600 mg/d, 47% ($P<0.0001$); PBO, 22%. Pregabalin was associated with significantly greater improvement in sleep interference (11-point NRS) from BL to EP than was PBO: 150 mg/d, -1.92 ($P=0.0033$); 300 mg/d, -2.32 ($P<0.0001$); 600 mg/d, -2.62 ($P<0.0001$); PBO, -1.32 . On the

Patient Global Impression of Change, 65%, 74%, and 80% of patients treated with pregabalin 150, 300, and 600 mg/d rated themselves as improved vs 54% of PBO patients ($P < .0001$ for 300 and 600 mg/d vs PBO). Six of the trials included the SF-36 as a measure of health status. Significant improvements were seen on 5 of 8 SF-36 domains among the 300 mg/d pregabalin group and on 6 of 8 domains among the 600 mg/d group. Most treatment-emergent AEs were mild to moderate in intensity and of limited duration. Dizziness and peripheral edema were the most common in the 600-mg/d group, occurring in 34% and 19% of patients vs 6% and 8% of PBO patients.

Conclusion: In a population of over 1500 patients, treatment with pregabalin across its effective dosing range was associated with significant improvement in pain and pain-associated sleep interference, as well as improvement in global health status, in patients with painful DPN.

Antioxidant treatment with α -lipoic acid in diabetic polyneuropathy: a 4-year randomised double-blind trial (NATHAN 1 Study)

D. Ziegler¹, P. A. Low², A. J. M. Boulton³, A. I. Vinik⁴, R. Freeman⁵, R. Samigullin⁶, H. Tritschler⁶, U. Munzel⁶, J. Maus⁶, K. Schuette⁷, P. J. Dyck²; ¹Institute for Clinical Diabetology, German Diabetes Center, Düsseldorf, Germany, ²Department of Neurology, Mayo Clinic, Rochester, United States, ³Department of Medicine, Manchester Royal Infirmary, United Kingdom, ⁴Strelitz Diabetes Research Institutes, Eastern Virginia Medical School, Norfolk, United States, ⁵Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States, ⁶Meda Pharma, GmbH & Co. KG, Bad Homburg, Germany, ⁷Ergomed, GmbH, Frankfurt, Germany.

Background and Aims: To evaluate the efficacy and safety of α -lipoic acid over 4 years in diabetic patients with mild to moderate distal symmetric polyneuropathy.

Materials and Methods: In this multicenter, randomised, double-blind, parallel-group clinical trial 460 diabetic patients with stage 1 or stage 2a polyneuropathy were randomly assigned to oral treatment with α -lipoic acid 600 mg qd (ALA; n=233) or placebo (n=227) for 4 years following a 6-week placebo run-in phase. Primary outcome measure was a composite score including the Neuropathy Impairment Score of the lower limbs and 7 nerve function tests (NIS[LL]+7 tests). Secondary outcome measures included the Total Symptom Score (TSS), Neuropathy Symptoms and Change (NSC), NIS, NIS[LL], individual NIS components, motor and sensory nerve conduction attributes, and quantitative sensory testing (QST). Data analysis was based on the intention to treat.

Results: The demographic variables and the outcome measures at baseline were comparable between the groups as were the HbA1c levels during follow-up. The NIS[LL]+7 tests composite score decreased after 4 years vs baseline by 0.45 ± 0.37 (mean \pm SEM) in the ALA group and increased by 0.34 ± 0.35 points in the placebo group ($p=0.105$). The NIS and NIS[LL] improved by 0.68 ± 0.44 and 0.34 ± 0.30 points on ALA and worsened by 0.61 ± 0.46 and 0.43 ± 0.31 points on placebo, respectively ($p=0.028$ and $p=0.051$). The NIS[LL] muscular weakness subscore improved by 0.21 ± 0.11 points on ALA and deteriorated by 0.17 ± 0.15 points on placebo ($p=0.045$). The NSC score for weakness severity improved by 0.05 ± 0.03 points on ALA and worsened by 0.04 ± 0.03 points on placebo ($p=0.008$). No significant differences between both groups after 4 years were noted for the nerve conduction parameters and QST. The rates of adverse events were comparable between the groups during the study. Serious adverse events and deaths occurred in 88 (38.1%) and 3 (1.3%) patients in the ALA group and 63 (28.0%) and 6 (2.7%) patients in the placebo group, respectively.

Conclusion: In conclusion, 4-year treatment with α -lipoic acid in mild to moderate diabetic polyneuropathy is well tolerated and improves some neuropathic deficits and symptoms, but not nerve conduction. Future long-term trials should not anticipate significant progression of polyneuropathy in diabetic patients.

A bioinformatic approach to identification of novel type 1 diabetes autoantigens

J. C. Hutton, J. M. Wenzlau, K. Juhl, S. Sarkar, L. Yu, G. S. Eisenbarth, J. Jensen, H. W. Davidson; Barbara Davis Center for Childhood Diabetes, University of Colorado Health Sciences Center, Aurora, United States.

Background and Aims: Circulating autoantibodies provide important predictive markers for the underlying autoimmunity that may precede clinical disease by many years at a time when therapeutic intervention may be effective. Currently islet cytoplasmic autoantibodies (ICA), insulin, the 65kD form of glutamate decarboxylase (GAD65) and the protein tyrosine phosphatase IA2 (PTPn) can detect up to 90% or more of patients at risk of developing disease. However it is clear that this list is not exhaustive and other candidates remain to be discovered.

Material and Methods: The Novartis custom oligonucleotide array representing 79 different human tissues was initially queried to determine which genes in the pancreatic islet dataset showed a significantly different signal from the median value of all other tissues (ANOVA cutoff < 0.0002). The subset of these transcripts that displayed a signal 5 fold greater than that of the median of all tissues was filtered to remove transcripts showing low signal strengths (< 200) and those that were expressed at higher levels in pancreas versus islets. The 140 genes that met these criteria were then used to interrogate the Unigene EST expression database to determine the frequency with which each gene was transcribed in 52 different human tissues. The frequency of appearance of cDNA for each gene in the pancreas versus all other tissue was used as an index of tissue specificity of mRNA expression.

Results: A list of 51 candidate islet autoantigens that was compiled list included major known targets of diabetes autoantibodies above as well other putative targets (heat shock protein 90B, carboxypeptidase E, islet glucose 6 phosphatase related protein (IGRP), islet amyloid polypeptide (IAPP), pancreatitis associated protein (humanReg3a /Mouse Reg2) and ICA69 (islet cell antigen 1). Thirteen gene products have been screened to date in immunoprecipitation assays resulting in the detection of one major and one minor target. 60 to 80% of newly-diagnosed patients with type 1 diabetes were seropositive with the former molecule and in combination with other autoantibodies detected in up to 98% of the individuals. Longitudinal studies of high-risk individuals showed that high levels of ZnT8 autoantibodies emerged from 3–4 years of age and generally persisted until onset of disease in the ensuing 1–7 years.

Conclusion: The combined bioinformatics / molecular engineering strategies used to select and develop assays for candidate autoantigens in combination with genetic screening raises to potential of future pediatric screening for type 1 diabetes susceptibility in the general population.

Identification of Slc30A8 as a major humoral autoantigen in type 1 diabetes and a predictive disease marker

J. M. Wenzlau, O. Moua, L. Yu, M. Rewers, G. S. Eisenbarth, J. C. Hutton, H. W. Davidson; Barbara Davis Center for Childhood Diabetes, University of Colorado Health Sciences Center, Aurora, United States.

Background and Aims: A novel β -cell specific target of diabetic autoimmunity in humans was identified using a combination of bioinformatics and molecular engineering to design sensitive and specific assays for circulating autoantibodies. The molecule, Slc30A8, is a 6 transmembrane spanning islet-specific member of the large family of cation-efflux ion transporters that is localized to insulin secretory granule of the beta cell. The present study examines the value of measurement of Slc30A8 autoantibodies in the prediction of clinical disease in genetically at-risk individuals

Material and Methods: Autoantibody assays were conducted using radioimmunoprecipitation assays based on *in vitro* translation of fragments of the COOH terminal cytoplasmic domain of Slc30A8 and a N-terminal/C-terminal fusion protein alongside similar assays for insulin, GAD2 and IA2 autoantibodies. Subjects included 223 new-onset patients ranging from 1–40 years of age, age matched controls and first degree relatives and 10 subjects from the Diabetes Autoimmunity Study in the Young (DAISY) from whom sera was obtained from age 9 months to the appearance of disease.

Results: Assays were initially developed to a series of fragments of variable length from the NH₂ and COOH terminal regions and segments joining the transmembrane segments. Autoreactivity to aa1–74 of the N-terminal measured as the percentage specific binding broadly correlated with that of the full-length sequence ($R^2=0.605$, $P<0.001$, $n=186$) but the assay showed relatively low sensitivity (8.0% sensitivity, 98% specificity, $n=223$). A COOH terminal construct spanning aa268–369 produced a robust and sensitive assay (50% sensitivity, 98% specificity) with an acceptable background (250–350 cpm). A synthetic molecule that combined both N and C-term sequences in a single chain construct separated by a Gly3 linker performed almost as well as the C-term construct in terms of specificity and background and in fact complemented the assay such that the assays in combination detected 63% of new-onset diabetic subjects. When used in combination with the classical biochemical autoantibody markers on a panel of 223 new onset subjects, the number of antibody negative individuals was reduced from 13 to 4 and the number who tested positive for 2 or more autoantibodies was increased from 71.7% to 82.0% ($n=223$, $P=0.013$).

High levels of Slc30A8 autoreactivity did not occur in DAISY subjects until ≥ 3 years of age. In 2 cases, autoreactivity arose within a year preceding clinical diabetes, in other cases Slc30A8 autoantibodies were present up to 7 years prior to disease.

The question of the predictive value of autoantibodies was examined in serum samples from 88 DAISY subjects by assaying Slc30A8 autoreactivity in the first sample to test positive for a single biochemical antibody. Of this group, 36.8% (7/19) of individuals with Slc30A8 antibodies progressed to clinical diabetes compared to 7.3% (5/69) of those without ($P<0.003$ 2-tailed Fisher exact test).

Conclusion: Slc30A8 is a major target of diabetic autoimmunity whose measurement adds power to the risk prediction in pre-diabetes based on autoantibody number especially in older individuals in whom insulin autoantibodies wane with age. Slc30A8, unlike GAD and IA2, has a high β -cell specificity that may be advantageous in monitoring recurrent autoimmunity and possibly β -cell mass in type 1 diabetic subjects.

The decline in circulating Slc30A8 autoantibodies track falling post-prandial C-peptide responses in the years following type 1 diabetes onset in human subjects

M. Walter¹, T. Kaupper¹, A. Ziegler¹, H. W. Davidson², J. M. Wenzlau², J. C. Hutton²;

¹Diabetes Research Institute, Munich, Germany,

²Barbara Davis Center for Childhood Diabetes, University of Colorado Health Sciences Center, Aurora, United States.

Background and Aims: Type 1 diabetes onset in man is typically followed by a honeymoon period with progressive increase in insulin requirements and difficulty of metabolic control. The cellular counterpart of this phenomenon is postulated to be continuing attrition of beta cell mass by cell mediated autoimmunity ultimately leading to complete loss of insulin secreting capacity or achievement of a steady state of beta cell loss and regeneration. Circulating autoantibodies do not necessarily reflect these changes since patients receive autoantigens exogenously (insulin) or immunological memory is maintained by sources of autoantigens located outside of the pancreas (GAD, IA2 and IA2beta). The recent discovery of a major new beta cell specific humoral autoantigen, Slc30A8 provides an opportunity of monitoring changes in beta cell-directed autoimmunity and potentially beta cell mass in this context.

Material and Methods: Sera was obtained from 21 new-onset patients within 2 months of diagnosis and thereafter at 3 monthly intervals for 2 years. C-peptide responses 120min following to a standard meal were measured as an index of endogenous secretory capacity and compared to circulating titers of antibodies directed towards GAD2 (Glutamate decarboxylase 65kD isoform), IA2 (PTPrN) and Slc30A8 using radioimmunoprecipitation assays

based on *in vitro* translation of encoded cDNAs and molecularly engineered constructs.

Results: C-peptide responses generally declined in all patients; in 2 individuals by less than 20% and in 8 more by than 80% over the 2 year follow-up. At the outset 76.2% of patients were seropositive for GADA, 85.7% for IA-2, 66.7% for Slc30A8 C-term and 71.2% for the Slc30A8 N-term/C-term fusion protein construct. All patients had at least one positive autoantibody, 2 patients had GADA only and 1 had IA2 as the only autoantibody. GADA were highly erratic with levels increasing up to 6 fold in 5 patients and decreasing up to 8 fold in the remaining 9. Two individuals who were seronegative at the outset developed low GADA during the course of follow-up. With one exception, IA2 antibodies fell and all individuals showed a progressive decline in Slc30A8 levels that were highly correlated both to disease duration and to the level of C-peptide. Overall the observed annual decline in the 120min C-peptide of $33.4\pm 19.9\%$ /year was matched by a $27.7\pm 9.3\%$ /yr decline in Slc30A8 autoantibodies and a $19.9\pm 15.7\%$ /yr change in IA2 autoantibodies (all data; mean \pm SD, $n=15$).

Conclusion: Slc30A8 autoantibody levels calculated as a proportion of the levels at onset of disease provide a potential index of the decline in functional islet mass post disease onset.

The zinc transporter ZnT8 protects cultured beta cells from oxidative stress-induced cell death

F. Chimienti, S. Libert, T. Pointecouteau, P. Jolivet, R. Garcia-Cuenca; Mellitech, SCIB/DRFMC, CEA Grenoble, France.

Background and Aims: To date, the zinc transporter ZnT8 has been shown to be expressed at the protein level solely in the secretory vesicles of pancreatic beta cells. ZnT8 overexpression amplified insulin release in response to stimulation with high levels of glucose in a beta cell model. Moreover, a genome-wide association study recently strongly associated SNP in SLC30A8, the gene encoding for ZnT8, with type 2 diabetes risk. Undoubtedly, zinc, insulin and glucose homeostasis thus appear to be closely linked. In many cell types, cellular zinc is described as an inhibitor of apoptosis, while its depletion induces cell death in many cell lines; we have previously shown that ZnT8 overexpression significantly protected INS-1E cells from zinc-depletion-induced cell death. Herein we studied the effects of ZnT8 overexpression on oxidative stress-induced cell death in the MIN6 cell line, and show a protective effect against H₂O₂ or xanthine/xanthine oxidase-induced cell death. This protective effect was, at least in part, mediated by overexpression of metallothionein, a small, cysteine-rich, metal-binding protein whose antioxidant role is well documented. Although further studies remain necessary, these results may be of importance for preventing islet cell destruction and prolonging islet graft survival after transplantation in patients with type 1 diabetes mellitus (T1DM).

Materials and Methods: MIN6 cells were transfected with a ZnT8-EGFP expression plasmid. EGFP-positive cell population was selected and used for further experiments. Parental and ZnT-8 overexpressing MIN6 cells were treated with indicated doses of hydrogen peroxide or xanthine/xanthine oxidase before cell death quantification by MTT assay. Apoptosis and necrosis were quantified using a dual-color flow cytometric procedure with fluorescein labeled annexin-V and propidium iodide. Total or differential cell extracts were used for western-blot experiments or HPLC/MS-MS analysis of 8oxodGuo levels. Metallothionein was observed by confocal immunofluorescence microscopy on fixed cells, and “free” cellular zinc levels were measured with a fluorescent probe using a pZnmeter.

Results: ZnT8 overexpression significantly protected MIN6 cells from both hydrogen peroxide- and xanthine/xanthine oxidase -induced cell death. The free zinc levels were higher in ZnT8 overexpressing cells, which also have a higher zinc accumulation capacity. Higher free zinc levels led to upregulation of metallothioneins, which functions at a central node in cellular signaling by both redistributing cellular zinc to apoproteins and interconverting redox and zinc signals, including nitric oxide (NO) signals. Indeed, we also observed that ZnT8 overexpression reduces cellular nitrosative stress markers.

Conclusion: The zinc transporter ZnT-8 plays an important role in the multiple regulation pathways of insulin synthesis/secretion, and we show here that it can also significantly protect beta cells from oxidative stress-induced cell death. This suggests that modulation of zinc homeostasis-

regulating proteins may offer a new target pathway to achieve requirements for preventing islet cell destruction and prolonging islet graft survival after transplantation.

0143

A dominant autoantibody epitope in Slc30A8 maps to a conserved secondary structure in the COOH terminus

H. W. Davidson, J. M. Wenzlau, O. Moua, G. S. Eisenbarth, J. Hutton; Barbara Davis Center for Childhood Diabetes, University of Colorado Health Sciences Center, Aurora, United States.

Background and Aims: The newly discovered type 1 diabetes autoantigen Slc30A8 is a multispanning transmembrane protein that resides in the insulin secretory granule. As such it is presumably incorporated into the plasma membrane upon activation of insulin secretion and may be a beta cell surface marker. A critical immunological question is whether it is contacted by circulating autoantibodies in normal tissue or is only exposed following cell disruption. A more general question is what structural features distinguish it from the many thousand proteins that are expressed in the beta cell to which the immune system is tolerated. Slc30A8 is a member of an exceptionally large gene family (10 genes in man; 1500 overall including invertebrates, plants, prokaryotes and archaeobacteria) which further raises the question as to whether molecular mimicry plays a role in its recognition as an antigen. To address these questions we investigated the location of the major epitopes in the structure that were recognized by circulating autoantibodies in human type 1 diabetic subjects.

Material and Methods: Autoantibody assays were conducted using radioimmunoprecipitation assays based on *in vitro* translation of fragments of Slc30A8 cloned into eukaryote expression vectors. Such constructs included truncated versions of the protein, chimeric constructs between mouse and human Slc30A8 and point mutations that changed individual amino acids in the sequence.

Results: Truncation mutants identified the 104aa COOH terminus (aa265–369) as containing a major epitope. Further deletions and the use of synthetic peptides narrowed the region to a conformational epitope between aa280–349. Mouse / human chimeras identified a cluster of acidic and basic residues as critical residues, surrounding lysine 340, an amino acid that is deleted in the non-immunogenic mouse sequence. Secondary structural prediction and application of molecular threading algorithms (PHYRE) provided a plausible model for the epitope in a 86aa dimeric alpha helix beta barrel structure (75% precision; E value 0.88) that is common to a number of proteins of unrelated protein sequences that share a common property of binding heavy metals. The probable intracellular localization is in the cytoplasmic membrane leaflet similar to other major membrane associated autoantigens IA2, IA2 beta and GAD2.

Conclusion: We have derived a plausible model for major antibody recognition site in Slc30A8 that makes important predictions regarding the relationship of the antigen to proteins of differing primary sequence. Such models can be further refined through crystallographic analysis and to direct futher mutagenesis experiments aimed at exploring the nature and extent of the antibody binding surface .

The long-acting GLP-1 analogue liraglutide regulates zinc transporter mRNA in β cells

N. Magnusson¹, L. Bjerre Knudsen², L. Wogensen³, B. Brock⁴, O. Schmitz⁵, L. Egefjord¹, J. B. Jeppesen¹, J. Rungby¹;

¹Pharmacology and Endocrinology C, University of Aarhus, ²Diabetes Biology & Pharmacology, Novo Nordisk, Måløv, ³Biochemical Pathology, University of Aarhus, ⁴Pharmacology and Pharmacy, University of Aarhus, ⁵Pharmacology and Endocrinology M, University of Aarhus, Denmark.

Background and Aims: Zinc transporters (ZnT)-proteins regulate zinc flux into β -cell vesicles. β -cells depend on zinc for crystallization of insulin. Zinc efflux, which is also regulated by ZnTs controls β -cell mass and glucagon secretion. Recently, the zinc transporter gene ZnT8 was identified as a novel risk factor for type 2 diabetes. We examined whether glucose levels, zinc depletion, GLP-1 or liraglutide affect ZnT mRNA expression.

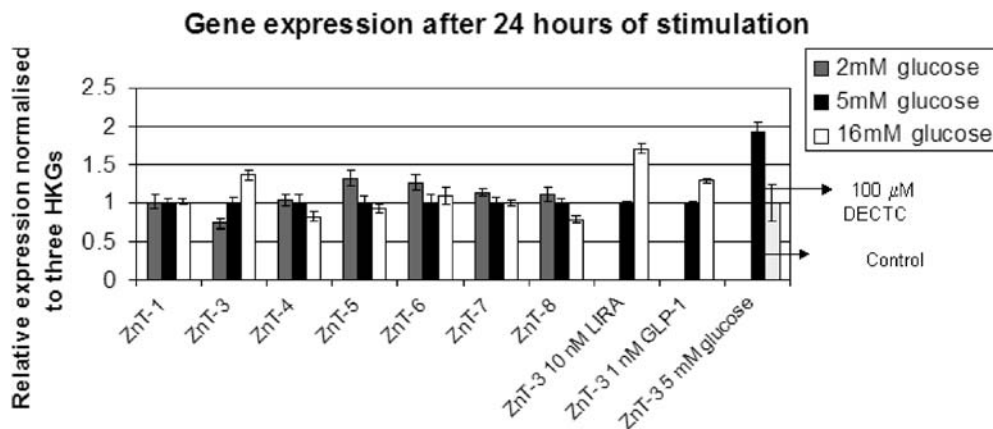

Materials and Methods: The rat β -cell line INS1-E was exposed to 2, 5 or 16 mM glucose for 24 hrs. For zinc depletion the INS1-E cells were exposed to 100 μ M DEDTC for 24 hrs. GLP-1 and liraglutide was added at 5 or 16 nM glucose (GLP-1 1 or 10 nM; liraglutide 10 or 100 nM) for 24 hrs. ZnT mRNA was measured by RT-PCR. Insulin was measured by Elisa. Regulations of genes were considered significant with p-values for relative expressions < 0.05.

Results: Relative to 5 mM glucose, 2 mM glucose caused a down-regulation of ZnT-3 and an up-regulation of most other ZnT mRNA. 16 mM caused ZnT3 up-regulation and down-regulation of other ZnT mRNA. Results were significant for ZnT3, ZnT5 and ZnT8, all transporters with high expression levels in β -cells. Zinc chelation lowered insulin expression and content and – insignificant – insulin secretion along with a ZnT3 up-regulation. Liraglutide augmented glucose stimulated ZnT3 expression (1.73 fold increase), stimulated insulin expression and eliminated the glucose dependant down-regulation of ZnT7 and ZnT8.

Conclusion: ZnT mRNA in β -cells responds to changes in glucose and zinc, supporting the hypothesis that ZnTs participate in insulin processing and that zinc trafficking in β -cells is regulated. Furthermore, long-term (liraglutide) but not short-term (GLP-1) stimulation of the GLP-1 receptor has significant influences on ZnT mRNA expression indicating that this system is a potential target for pharmacological manipulation. Dietary unsaturated fat reduces the postprandial glycaemic index, reduces hepatic lipogenesis but increases adipose tissue lipogenesis and reduces inflammation in diabetic pigs

S. J. Koopmans¹, R. Dekker¹, T. Schuurman¹, M. Ackermans², H. Sauerwein³,

¹Animal Sciences Group, Wageningen University and Research Center, Lelystad, ²Clinical Chemistry, Academic Medical Center, Amsterdam, ³Endocrinology and Metabolism, Academic Medical Center, Amsterdam, The Netherlands.

Background and Aims: Dietary carbohydrates and fats may affect glycaemic control, insulin sensitivity, lipogenesis and inflammation in diabetic subjects. We investigated the long-term effects of diets, supplemented with starch (S), unsaturated fat (UF) or saturated fat (SF), on pre- and postprandial hyperglycaemia and lipidaemia, on insulin sensitivity, muscle and liver lipid content, retroperitoneal fat weight and plasma C-reactive protein (CRP) concentrations in diabetic pigs.

Materials and Methods: Eighteen domestic (Landrace x Yorkshire, D-line) pigs (~30 kg) were treated with streptozotocin (140 mg/kg) and, according to the severity of hyperglycaemia, balanced over 3 diet groups. Mixed meals were fed twice daily (at a gross energy level of 25.10⁶ J/day) for a duration of 10 weeks. Supplemental S, UF, or SF content was 40% of total dietary energy. Permanent blood vessel catheters were used for blood sampling at meal tolerance tests and at hyperinsulinaemic euglycaemic clamps with 6,6-²H-glucose infusion.

Results: Diabetic pigs were non-ketotic and required no insulin therapy to maintain body anabolism, final body weights were ~50 kg. Fasting plasma insulin (~4 mU/L), glucose (~15 mmol/L) and triglyceride (0.5 mmol/L) concentrations were similar among diet groups but fasting plasma NEFA concentrations were higher ($p<0.05$) in the SF group (1.1±0.2 mmol/L) compared to the S group (0.6±0.2 mmol/L) but not to the UF group (0.8±0.2 mmol/L). Postprandial area under the curves (AUC) for glucose but not for insulin and triglyceride responses were lower ($p<0.01$) in the UF group (529±67 AUC) compared to the S group (1121±135 AUC) but not to the SF group (785±51 AUC). Postprandial plasma CRP concentrations were lower ($p<0.05$) in the UF group (60±3 mg/L) compared to the SF group (83±3 mg/L) but not to the S group (79±3 mg/L). Fasting hepatic glucose production (~6 mg/kg.min), insulin inhibited hepatic glucose production (~1 mg/kg.min) and insulin stimulated whole body glucose uptake (~8 mg/kg.min) were similar among diet groups. Liver weight was higher ($p<0.001$) in the SF group (1.47±0.09 kg) compared to the S and UF groups (1.11±0.03 kg). Triglyceride concentration in the liver was higher ($p<0.01$) in the SF group (48.7±12.2 g/kg) compared to the S (20.7±3.3 g/kg) and UF groups (26.9±1.1 g/kg). Triglyceride concentration in muscle was higher ($p<0.01$) in the SF group (20.9±4.2 g/kg) compared to the S group (8.5±1.4 g/kg) but not to the UF group (12.9±3.4 g/kg). Retroperitoneal fat weight was higher ($p<0.05$) in the UF group (571±110 g) compared to the SF group (259±80 g) and the S group (135±57 g).

Conclusion: In diabetic pigs, dietary UF but not SF had a lower postprandial glycaemic index compared to dietary S, but hepatic and whole body insulin sensitivity were not affected by the diets. Pigs on dietary UF showed lower liver weights and liver triglyceride concentrations, higher retroperitoneal fat weight and lower plasma CRP concentrations compared to pigs on dietary SF. This indicates that dietary UF improves lipogenesis in adipose tissue but reduces hepatic lipogenesis and reduces inflammation.

Effect of viscosity of oat fibre on gastrointestinal responses in healthy humans

K. R. Juvonen¹, M. Salmenkallio-Marttila², L. Lähteenmäki², D. E. Laaksonen³, K.-H. Herzig^{4,5}, M. I. J. Uusitupa¹, K. S. Poutanen^{1,2}, L. J. Karhunen¹;

¹Food and Health Research Center, School of Public Health and Clinical Nutrition, University of Kuopio, ²VTT, Biotechnology, Espoo,

³Department of Internal Medicine, Kuopio University Hospital,

⁴Department of Biotechnology and Molecular Medicine, A.I. Virtanen Institute for Molecular Sciences, Kuopio,

⁵Department of Physiology, Oulu University, Finland.

Background and Aims: Viscosity slows gastric emptying and may exert a beneficial influence on appetite. Viscous fibres, including oat fibre, have favourable effects on carbohydrate and lipid metabolism. However, the effect of viscosity in liquid meals in relation to satiety-related gastrointestinal responses has been less well investigated, and was therefore examined in this study.

Materials and Methods: Twenty healthy, normal-weight subjects (4 men/16 women aged 22,6±3,25 years, body mass index (BMI) 21,6±1,32 kg/m²) ingested one of two isocaloric (1250 kJ); carbohydrates 57.9 g, protein 7.8 g, fat 3.3 g, fibre 10.2 g) 300 ml beverages with differing viscosities in a randomised order: a beverage with viscous oat fibre and a beverage with oat fibre with no viscosity (viscosity eliminated by beta-glucanase enzyme). Blood samples were drawn from fasted subjects before and 15, 30, 45, 60, 90, 120 and 180 min after the tested beverages. The blood samples were analyzed to determine plasma glucose, ghrelin, peptide YY, glucagon-like peptide-1 and serum insulin concentrations. Gastric emptying was assessed using the paracetamol absorption test.

Results: The oat fibre beverage in which viscosity was eliminated induced greater increases in concentrations of postprandial glucose ($P<0.001$), insulin ($P=0.008$), glucagon-like peptide-1 ($P=0.037$) and peptide YY ($P=0.051$) and a greater decrease in postprandial ghrelin ($P=0.009$) than the beverage with viscous oat fibre. Gastric emptying was also accelerated after the non-viscous oat fibre beverage ($P=0.034$).

Conclusion: Reducing viscosity of oat fibre in liquid meal accentuates short-term postprandial gastrointestinal responses, implying the importance of viscosity in producing the beneficial effects of oat fibre on glucose and insulin metabolism and gastrointestinal physiology.

Effect of moderate alcohol intake on patients with type 2 diabetes; multi-center, randomised, diet-controlled intervention study

I. Shai¹, J. Vainstein², I. Harman-Bohem³, I. Raz⁴, A. Rudich⁵, M. J. Stampfer⁶;

¹Epidemiology, Ben Gurion University, Beer-Sheva, Israel,

²Diabetes Clinic, Wolfson Medical Center, Holon, Israel,

³Diabetes Unit, Soroka Medical Center, Beer-Sheva, Israel,

⁴Diabetes clinic, Hadassah Hebrew University Medical Center, Jerusalem,

Israel, ⁵Biochemistry, Ben Gurion University, Beer-Sheva, Israel,

⁶Epidemiology, Harvard School of Public Health, Boston, United States.

Introduction: Recent studies suggest that diabetic patients may benefit from the effects of moderate alcohol consumption, but the glycemic effects of such intervention are unclear. Using an interventional approach, we aimed to address the effect of daily moderate alcohol intake on glycemic control in the fasting and postprandial states in type 2 diabetic abstainers, and to determine adverse effects of such intervention.

Methods: One hundred and nine abstainer patients (41–74 yrs old) with established type 2 diabetes were randomised to receive 150 ml wine (intervention) or non-alcoholic diet beer (control) during 3 months of a diet-controlled, multi-center randomized intervention trial. The beverages were consumed during dinner. Diet and alcohol consumption were monitored.

Results: Within the alcohol intervention group, fasting plasma glucose (FPG) decreased from 139.58mg/dL+/-41.0 to 118.01+/- 32.5) after 3 months (Delta=-21.55mg/dL, $P_v=0.015$ as compared to delta of the controls). However, alcohol consumption had no effect on 2-hour postprandial glucose levels ($P_v=0.966$). Patients in the intervention group with higher baseline

HbA1c levels had greater reduction in FPG (age-adjusted correlation = -0.33 , $P = 0.045$). No significant changes were observed in the levels of Bilirubin, Alkaline Phosphatases, ALT or AST, nor were their reported adverse effects. However, participants in the intervention group reported an improvement in the ability to fall asleep ($P = 0.001$ as compared to the controls).

Conclusions: Among abstainers who are type 2 diabetic, initiation of moderate daily alcohol consumption results in decreased FPG but not post-meal glucose. Patients with higher HbA1c may benefit more from the favorable effect of alcohol on glycemic control. Longer studies are needed to determine the efficacy of initiating consumption of moderate alcohol intake among abstainers with type 2 diabetes.

0148

Accuracy of meal carbohydrate content estimation by type 1 diabetics under CSII and MDI

G. Freckmann, I. S. Koch, A. Baumstark, N. Jendrike, A. Abicht, C. Haug; University of Ulm, Institute for Diabetes-Technology, Germany.

Background and Aims: Accurate estimation of the carbohydrate (CHO) content of meals is a prerequisite for making appropriate insulin therapy decisions. Diabetic patients who are skilled in estimating the CHO content of food stuffs are more likely to calculate an appropriate insulin dose for a specific meal. The goal of this study was to determine how well a group of type 1 diabetic patients could estimate the CHO content of multiple meals and quantitate how much their estimates deviated from the actual CHO content of the meal.

Materials and Methods: Seventyfour type 1 diabetic patients, (36f, 38m, age 43.9 ± 12.3 years [mean \pm SD], HbA1c $7.2 \pm 1.2\%$, duration of diabetes 20.6 ± 11.8 years, BMI 25.9 ± 3.8 kg/m², insulin therapy: CSII 48, MDI 26) participated in the study. Twentyfour different test meals (8 breakfasts, lunches and dinners, respectively; 13 cold meals, 11 warm meals) of variable CHO content (min. 54.6g, max. 164.1g) were prepared and presented in random order to the patients. They were asked to estimate the CHO content of each meal in their preferred carbohydrate estimation unit. 12 subjects used KE (= 10g CHO) and 62 used BE (= 12g CHO). The estimated unit was transformed into grams CHO and compared to the CHO calculated for each meal from the nutrition labeling of the package or the nutritional software DGE-PC vers. 2.9.1.007.

Results: The patients' estimation of the test meal CHO content was generally lower than the actual CHO content of the meals. When compared as percent of the calculated CHO content, the mean estimates of the 74 patients were $74.8\% \pm 11.8\%$ (median 74.0%, min. 53.2%, max. 126.9%). The mean relative estimate of warm meals ($71.8\% \pm 13.4\%$) was significantly ($p < 0.001$) lower than the relative estimate of cold meals ($77.4\% \pm 12.5\%$). The relative CHO estimation of test meals showed negative correlation to the carbohydrate content ($r = -0.78$, $p < 0.001$), that is, larger meals were underestimated more than smaller meals.

Conclusion: These results show that the patients in this study generally underestimated the CHO content of the test meals. Warm meals were more difficult to estimate and especially large test meals tend to be underestimated. Bias and variation in CHO counting should be considered in intensified insulin therapy and in the development of algorithms for semi-closed loop insulin infusion.

0149

Fuel metabolism during exercise in eu- and hyperglycaemia in subjects with type 1 diabetes mellitus

L. Jenni¹, S. Allemann¹, M. Ith², C. Oetliker¹, S. Wuerth³, C. Boesch², L. Tappy⁴, P. Diem¹, E. R. Christ¹, C. Stettler¹;

¹Div. of Endocrinology, Diabetes and Clinical Nutrition, University Hospital, Bern, ²Magnetic Resonance Spectroscopy and Methodology – Department of Clinical Research, University, Bern,

³Institute of Sport and Social Sciences, University, Basel,

⁴Dept. of Physiology, University, Lausanne, Switzerland.

Background and Aims: Little is known about the effect of blood glucose levels on local muscle fuel metabolism during exercise in individuals with

type 1 diabetes mellitus (T1DM). Preliminary data revealed similar exercise capacities in eu- compared to hyperglycaemic conditions. The aim of the present study was to assess whether the consumption of intramyocellular lipids (IMCL) and of intramyocellular glycogen was different during aerobic exercise in eu- compared to hyperglycaemic clamp conditions.

Methods and Material: Seven male individuals with T1DM under continuous subcutaneous insulin infusion (CSII) were studied on two occasions. After discontinuation of CSII on the evening before each trial, a variable i.v. insulin infusion was started to reach normal glucose levels overnight. The participants were kept fasting. At 8 a.m. the next day blood glucose was clamped to euglycaemic (target level 5 mmol/l) or hyperglycaemic levels (target level 11 mmol/l) in a randomised, single blinded, cross-over design. Insulin infusion was kept constant according to the patient's CSII basal insulin rate. After stable clamp conditions were reached, IMCL and intramyocellular glycogen (M. quadriceps) were measured using magnetic resonance spectroscopy. The participants then cycled for 120 minutes at a constant power corresponding to 55–60% of their VO_{2max} determined earlier. Respiratory exchange ratio (RER) was measured by spirometry. Directly after the exercise IMCL and intramyocellular glycogen were again measured at the same site using magnetic resonance spectroscopy. Results of the two tests were compared using Student's paired t-test.

Results: Mean age of the participants was 33.5 ± 6.3 years (mean \pm standard deviation), mean body mass index was 24.1 ± 1.2 kg/m². Diabetes duration was 20.1 ± 9.4 years and HbA1c reflected good glycaemic control ($6.7 \pm 0.5\%$). Euglycaemic clamps were at a mean blood glucose of 5.0 mmol/l, whereas mean glycaemic level was at 10.9 mmol/l in hyperglycaemic clamps (difference 5.9 mmol/l, $p < 0.0001$). Insulin levels did not differ between eu- and hyperglycaemic clamp conditions. RER was significantly lower in eu- compared to hyperglycaemic conditions (0.84 and 0.93, respectively, $p = 0.034$), reflecting a higher net lipid oxidation rate in euglycaemic exercise condition. The decline in IMCL during exercise tended to be increased in the eu- compared to the hyperglycaemic exercise condition (16.2% and 11.5%, respectively, $p = 0.18$). In contrast, intramyocellular glycogen consumption was similar in the eu- and the hyperglycaemic condition (31.2% and 35.2%, respectively, $p = 0.56$).

Conclusion: In individuals with T1DM performing aerobic exercise lipid oxidation appears to play a predominant role in euglycaemia and IMCL are suggested to be the main fuel source. In contrast, during hyperglycaemia energy production appears to rely stronger on carbohydrate oxidation. Of note, the latter did not result in an increased consumption of intramyocellular glycogen thereby suggesting that the increased levels of blood glucose provided the main energy substrate in hyperglycaemia.

Objectively measured sedentary time and light-intensity physical activity are independently associated with components of the metabolic syndrome: the AusDiab study

G. N. Healy¹, D. W. Dunstan², J. E. Shaw², P. Z. Zimmet², N. Owen¹;

¹School of Population Health, The University of Queensland, Brisbane,

²Epidemiology, International Diabetes Institute, Melbourne, Australia.

Background and Aims: Physical activity and sedentary behaviour are key modifiable risk factors for components of the metabolic syndrome. However, studies typically have used physical activity variables derived from imprecise self-report measures. We examined the associations of objectively-measured sedentary time and light-intensity physical activity with components of the metabolic syndrome in Australian adults without known diabetes.

Materials and Methods: 70 men and 108 women (mean age 53.4, range 30 to 87) were recruited from the 2004–2005 Australian Diabetes, Obesity, and Lifestyle (AusDiab) study. Physical activity was measured by Actigraph accelerometers worn during waking hours for seven consecutive days, and divided into sedentary time (counts/minute < 100), light-intensity (counts/minute 100–1951), and moderate-to-vigorous intensity (counts/minute > 1952). An oral glucose tolerance test was used to obtain fasting and 2-hr plasma glucose, serum-triglycerides, and HDL-C. Waist circumference and blood pressure were measured at the testing site. Components of the metabolic syndrome were dichotomised according to the current IDF definition, and reported as central obesity, raised triglycerides, blood pressure, fasting plasma glucose, and 2-hr plasma glucose, and reduced HDL-C.

Results: In logistic regression analyses adjusted for age, sex, time accelerometer worn, income, education, and moderate-to-vigorous intensity activity, each additional hour/day of sedentary time was associated with an increased risk of central obesity (OR=1.40, p=0.017); while each hour/day of light intensity activity was associated with a reduced risk (OR=0.69, p=0.009). When waist circumference (cm) was included in the model, each hour/day of sedentary time was associated with an increased risk of raised triglycerides (OR=1.44, p=0.046), raised 2-hr plasma glucose (OR=1.72, p=0.052), and reduced HDL-C (OR=1.56, p=0.009); each hour/day of light-intensity activity was associated with a significantly lower risk of raised triglycerides (OR=0.66, p=0.028), raised 2-hr plasma glucose (OR=0.55, p=0.036), and reduced HDL-C (OR=0.65, p=0.012). The associations of sedentary time and light-intensity activity with raised blood pressure and fasting blood glucose were not statistically significant (p>0.1).

Conclusion: These findings provide some of the first evidence from objective activity data that sedentary time is unfavourably associated with components of the metabolic syndrome, particularly central obesity, triglycerides, 2-hr plasma glucose, and HDL-C, and that light-intensity activity is beneficially associated. Importantly, these associations were independent of moderate-to-vigorous intensity activity. The findings suggest that substituting light-intensity activity for television viewing or other sedentary time may be a practical and achievable strategy to improve metabolic risk in adults.

Changes in gut microflora are responsible for high-fat diet-induced diabetes through a mechanism associated with endotoxaemia

P. D. Cani¹, A. M. Neyrinck¹, K. M. Tuohy², F. Fava², G. R. Gibson², C. Knauf³, R. G. Burcelin³, N. M. Delzenne¹;

¹Unit PMNT, Université catholique de Louvain, Brussels, Belgium,

²Food microbial sciences unit, The University of Reading, United Kingdom,

³IFR31, I2MR, Toulouse, France.

Background and Aims: Diabetes and obesity are two metabolic diseases characterized by insulin resistance and a low grade inflammation. Recently, a very encouraging and innovating hypothesis has been proposed, where a specific gut microbial community would favor the occurrence of the metabolic diseases. However, germ free mice fed a high-fat (HF) obesitogenic diet did not gain weight -whereas HF diet promotes obesity in animals with conventional flora- suggesting that indeed, a bacterially related factor is responsible for HF diet-induced obesity. In the light of the role of gut microbiota for the development of metabolic diseases, we recently reported that HF feeding was associated with a higher plasma endotoxin (LPS) concentration and a lower *Bifidobacterium* spp. caecal content in mice. We reported that metabolic endotoxemia increased the inflammatory tone, triggered body weight gain and shortened the onset of HF induced-insulin resistance and obesity. Thus we tested the hypothesis that modulating endotoxemia by changing gut microbiota profile could be a potent strategy to control the development of metabolic diseases.

Materials and Methods: Since, bifidobacteria have been reported to reduce intestinal endotoxin levels and to improve mucosal barrier function, we specifically increased gut bifidobacteria content of high-fat (HF) diet treated mice by adding prebiotic in the diet (oligofructose, HF-OFS). We correlated microflora changes, which occur through 14 weeks HF diet, control to the occurrence of metabolic disturbances.

Results: HF feeding significantly reduced the levels of bifidobacteria, a dominant member of the intestinal microbiota, as compared to normal chow fed mice (CT). As expected, HF-OFS fed mice totally restored the number of bifidobacteria. HF feeding significantly increased endotoxemia which was normalized to CT when the mice were treated with HF-OFS. To identify whether one specific gut bacteria is involved in the determination of endotoxemia, we performed multiple correlations analysis between the major Gram positive and Gram negative bacteria present in the caecal content of mice. Endotoxemia significantly and negatively correlates with *Bifidobacterium* spp. but no relationship can be shown between endotoxemia and any other bacterial group. Finally, in HF-OFS treated mice, endotoxemia negatively correlates with an improved glucose tolerance, glucose-induced insulin-secretion, a lower fat mass and body weight, and normalized inflammatory tone. Whereas, *Bifidobacterium* spp. significantly and positively correlates with these factors.

Conclusion: The modulation of gut microbiota by increasing bifidobacteria reduces endotoxemia and improves metabolic parameters in high-fat diet fed mice. Together, these findings suggest that gut microbiota contributes to the patho-physiological regulation of endotoxemia, and sets the tone of inflammation for the occurrence of diabetes and obesity. Thus it would be useful to develop specific strategies for modifying gut microbiota in favour of bifidobacteria to promote health in the context of metabolic syndrome.

JNK in macrophages plays a key role in the development of obesity-induced insulin resistance

G. Solinas¹, C. Vilcu², J.-L. Luo³, W. Naugler³, S. Grivennikov³, J. G. Neels², G. K. Bandyopadhyay², J. M. Olefsky², M. Karin³;

¹Dept. of Medicine, Division of Physiology, University of Fribourg,

Switzerland, ²Dept. of Medicine, Division of Endocrinology and Metabolism, University of California, San Diego, CA, United States,

³Dept. of Pharmacology, University of California, San Diego, United States.

Background and Aims: c-Jun N-terminal Kinases (JNKs), which respond to several pro-inflammatory cytokines such as TNF-alpha and IL1, and metabolic stress such as ROS, ER-stress and long-chain saturated fatty acid were proposed to be key players in the development of obesity-induced

insulin resistance. *jnk1^{-/-}* and *jnk1^{+/-}jnk2^{-/-}* mice are resistant to obesity and to obesity-induced glucose intolerance; moreover, acute inhibition of JNK improved insulin sensitivity in obese mice. The current molecular mechanism for JNKs in insulin resistance is based on the direct phosphorylation of IRS2 Ser307 and the equivalent IRS2 site Thr287. Phosphorylation of these sites is believed to decrease the affinity of IRS1-2 for the activated insulin receptor. An increasing body of evidence supports the hypothesis that a chronic low-grade inflammation is involved in the pathogenesis of obesity-induced insulin resistance. Since JNKs are known to regulate the expression of pro-inflammatory genes, and since macrophages were proposed to play a major role in the development of insulin resistance, we have tested the role of JNKs in the hematopoietic tissue using bone marrow transplantation technology.

Materials and Methods: To study the role of JNK in the hematopoietic tissue we have performed bone marrow transplantation in lethally irradiated (10 Gy) mice. We have generated *wt* mice with *jnk1^{-/-}* bone marrow; *jnk1^{-/-}* mice with *wt* bone marrow and as control we have used *wt* mice reconstituted with *wt* bone marrow after the lethal irradiation. Body weight was measured weekly to determine growth curves. Adiposity was measured by MRI and used to determine lean body mass. GTTs, ITT and hyperinsulinemic euglycemic clamps were performed to measure insulin sensitivity. Macrophage number in adipose tissue was measured by immunohistochemistry and expression of pro-inflammatory cytokines was measured in tissues and macrophages cell cultures by real time PCR.

Results and Conclusions: In this study we have tested the role of JNKs in the hematopoietic tissue using bone marrow transplantation technology. We show that *jnk1^{-/-}* mice transplanted with *wt* bone marrow are resistant to diet-induced obesity and have improved glucose tolerance, suggesting that the resistance to obesity observed in *jnk1^{-/-}* is due to a tissue of non-hematopoietic origin. We have discovered that high fat diet-fed *wt* mice transplanted with *jnk1^{-/-}* bone marrow, have improved glucose tolerance and are less insulin resistant than control mice despite having similar body weight and adiposity. Functional studies in isolated macrophages show that JNKs act directly in these cells. In conclusion, we propose a new molecular mechanism for the diabetogenic action of JNK1 where in addition to its action in insulin sensitive tissues, JNK1 also regulates the function of hematopoietic cells, in particular macrophages, and therefore is directly involved in the low-grade chronic inflammation associated with obesity.

The effects adiposity, diabetic status and depot-specificity on the activation of NFκB on JNK in human abdominal adipose tissue

C. M. Kusminski, N. F. da Silva, A. E. Fowler, S. J. Creely, A. L. Harte, A. R. Baker, T. S. Billyard, J. P. O'Hare, S. Kumar, P. G. McTernan; Unit of Diabetes and Metabolism, Warwick Medical School, University of Warwick, Coventry, United Kingdom.

Background and Aims: Central obesity is closely associated with sub-clinical inflammation, insulin resistance and type 2 diabetes mellitus (T2DM); however the precise underlying mechanisms of such associations are unclear. Recent rodent studies have highlighted NFκB and c-Jun N terminal kinase (JNK) as key mediators linking insulin action and inflammation. Therefore the aims this study were to firstly, investigate inflammation within human adipose tissue; in particular, the innate immune signalling pathway in relation to NFκB and JNK activation in abdominal subcutaneous (AbdSc) and omental (Om) human adipose tissue. Secondly, to determine the influence of increasing adiposity and type 2 diabetic status on the level of activation of NFκB and JNK within AbdSc and Om AT depots. Finally, to examine the effects of TNFα, a known mediator of inflammation, on the level of NFκB and JNK activity in isolated human AbdSc adipocytes.

Materials and Methods: Human adipose tissue was collected from patients (age: 44.7±9.3 yrs; BMI: 27.9±7.3 .kg/m²) undergoing liposuction surgery. A total of 32 non-diabetic adipose tissue samples were obtained and sub-divided into AbdSc (n=22) and Omental (n=10) depots. Western blot procedure was used to analyse the expression of key components of the NFκB and JNK signalling pathways. Additionally, isolated human AbdSc adipocytes were treated with human recombinant TNF-α (1–50 ng/ml). Finally, the levels of active NFκB or phosphospecific JNK in both AT depots were assessed using assay-based measures.

Results: Our *ex vivo* analysis firstly demonstrated that the protein expression levels of several intracellular signalling molecules, in particular, IKKβ, IKKγ,

IκBα and IκBα-P were increased in Om AT in comparison to AbdSc AT (p<0.01). Furthermore, the ratio of active NFκB to total NFκB expression (NFκB ratio) was upregulated in Om AT compared with AbdSc, in both lean and obese subjects (p<0.05). In contrast, phosphospecific JNK1 was increased by 5.8-fold in the AbdSc depot (p<0.01) when compared with Om AT. Finally, *in vitro* data revealed that isolated AbdSc adipocytes treated with TNFα exhibited a significant increase in NFκB activity in comparison with control; such enhanced activity further increased over time (2–48 hr, p<0.05). In contrast to rodent studies, JNK activity in response to TNF-α treatment, remained unaltered.

Conclusions: Our findings suggest distinct inflammatory signalling pathways, with increased NFκB activity in human Om AT and increased JNK activity in AbdSc AT. Additionally, NFκB was shown to be influenced by obesity and diabetic status, whilst TNFα treated AbdSc adipocytes led to activation of NFκB and not JNK. Taken together, NFκB may play a more predominant central role in inflammatory-related metabolic disease in comparison to JNK, suggesting a potential role for NFκB as a key therapeutic target.

Regulation of adipokines by hormones and inflammation in human omental adipocytes

E. Maury, K. Ehala-Aleksejev, L. Noël, S. M. Brichard; Endocrinology and metabolism, Catholic University of Leuven, Brussels, Belgium.

Background and Aims: We have identified six adipokines that are oversecreted by omental adipose tissue (OAT) in obesity: 3 chemokines [Growth-Related Oncogen factor (GRO), Regulated upon Activation Normal T cells Expressed and Secreted (RANTES), Macrophage Inflammatory Protein-1β (MIP-1β)], 1 interleukin (IL-7), 1 tissue inhibitor of metalloproteinases (TIMP-1) and 1 growth factor (thrombopoietin, TPO). Enhanced expression of these adipokines in adipocytes did correlate with several features of the metabolic syndrome. The aim of the present study was to examine whether the abnormal hormonal milieu and/or the chronic inflammation state that prevail in obesity could contribute to such dysregulation of adipokine production. We thus examined the effect of some hormones (insulin, glucocorticoids and catecholamines) and the proinflammatory cytokine, TNFα on these adipokines in omental adipocytes.

Materials and Methods: OAT was obtained from patients undergoing elective abdominal surgery. Preadipocytes were isolated and differentiated into mature adipocytes *in vitro*. The adipocytes were cultured in a chemically defined medium. After 12 days of differentiation, 100 nM insulin, 1 μM dexamethasone, 10 μM isoproterenol (a β-adrenergic agonist) or 10–100 nM TNFα were added to the medium for up to 24h. Adipokine expression levels were measured by real-time RTQ-PCR.

Results: Treatment of omental adipocytes with insulin, dexamethasone or isoproterenol induced a significant, but modest increase in GRO and TPO mRNA levels (from ~ 1.3- up to 2- fold) without affecting the other adipokines studied. The second messenger of the β-adrenergic agonist, cAMP produced qualitative similar effects to those of isoproterenol. By contrast, the addition of TNFα to the medium induced a strong rise in the expression of all the adipokines (except for TPO). This rise occurred in a dose-dependent fashion and reached an ~600 fold increase for some of them (i.e. RANTES).

Conclusion: Compared to hormones such as insulin, glucocorticoids and catecholamines, TNFα appears to be a main contributor to the enhanced expression of the investigated adipokines in human omental adipocytes.

Macrophage-adipocyte cross-talk in the initiation of obesity-related insulin resistance and type 2 diabetes: role of adiponectin

I. T. Y. Lau¹, H.-Y. Ye¹, A. Xu^{1,2}, K. S. L. Lam^{1,2};
¹Department of Medicine, The University of Hong Kong,
²Research Centre of Heart, Brain, Hormone, and Healthy Aging,
The University of Hong Kong, China.

Background and Aims: Recent studies suggest that, in obesity, chronic inflammation of adipose tissues (AT) with macrophage infiltration and

enhanced expression of pro-inflammatory cytokines plays a significant role in the development of obesity-related metabolic disorders, such as type 2 diabetes. We have previously demonstrated that adenovirus-mediated over-expression of adiponectin, an insulin-sensitizing adipokine with anti-inflammatory action and reduced expression in obesity, results in a marked down-regulation of several inflammation-related genes, including F4/80 (a macrophage marker) and monocyte chemoattractant protein-1 (MCP-1), in the white AT of db/db diabetic mice (Lam & Xu, *Curr Diab Rep* 2005;5:254-9). As MCP-1 has been suggested to contribute to macrophage infiltration of AT in db/db mice (Kanda et al, *JCI* 2006;116:1494-505), we hypothesize that the reduced expression of adiponectin in obesity may play an important role in initiating the macrophage-adipocyte cross-talk which leads to obesity-related insulin resistance and diabetes. This study aims at determining the time course and magnitude of macrophage infiltration and inflammatory activation in AT, in relation to changes in the AT levels of adiponectin, glucose tolerance and insulin sensitivity, in db/db diabetic mice.

Materials and Methods: At the age of 5, 6, 7, 8, 9, 10, 11, 12 weeks, male db/db mice and lean controls were tested for blood glucose (non-fasting, fasting, and in response to ip. insulin tolerance test and glucose tolerance test), insulin and lipid levels. The mRNA expression level of adiponectin, MCP-1 and F4/80 were determined by real-time PCR in epididymal fat pads obtained after sacrifice of mice at different ages. Immunohistochemistry was performed to assess the severity of macrophage infiltration in AT. Adiponectin and MCP-1 were also measured by ELISA in medium obtained after the fat pads were incubated for 24 hours.

Results: Compared to lean controls, db/db mice had significant increases in the weight of AT in 3 depots (epididymal, perirenal and abdominal subcutaneous) at 5 weeks, accompanied by significant hyperinsulinaemia and hypercholesterolaemia, and a trend towards impaired responses during insulin tolerance test, compared to lean controls. A significant 80% reduction in adipose tissue adiponectin mRNA expression, accompanied by significant reductions in adiponectin in the explant medium, was also seen at 5 weeks, when no significant increase was found in F4/80 mRNA expression or macrophage infiltration of epididymal AT. There was also no significant increase in the release of MCP-1 during AT explant incubation at 5 weeks. Greater weight than controls, accompanied by impaired glucose tolerance, was seen from 6 weeks. Non-fasting hyperglycaemia, compared to lean controls, became evident at 8 weeks. By 10 weeks, fasting hyperglycaemia was established.

Conclusion: These data suggest that reduced adiponectin expression precedes the macrophage infiltration in AT of db/db mice and may contribute, at least in part, to the macrophage infiltration and inflammatory gene activation in white AT in obese animals. Hyperinsulinaemia precedes macrophage infiltration of AT which may, nevertheless, contribute to progressive insulin resistance and development of diabetes in the db/db mice.

Supported by RGC grant.

Materials and Methods: Highly purified monocytes (85–90%) were isolated from healthy control subjects. Differentiation of monocytes into macrophages was achieved by culturing the cells in RPMI supplemented with 20% autologous serum for 8 days. HAECs (passage 3 to 5) were grown to confluence in endothelial growth medium-2. Human monocytes were exposed to 25 ng/ml interleukin-1 β (IL-1 β) and 10 ng/ml interleukin-6 (IL-6) or 100 μ g/ml glycated bovine serum albumin (BSA-AGE) for 24 or 48h. Confluent HAECs were incubated with 40 μ g/ml oxidized low-density lipoprotein (oxLDL) or 100 μ g/ml BSA-AGE for 3, 6, 12, and 24h. At the end of these incubation periods, cells were lysed and CRP mRNA and protein expressions were analyzed by RT-PCR and Western-blot, respectively.

Results: Human monocytes and macrophages constitutively express CRP. Treatment of human monocytes with IL-1 β plus IL-6 for 24 or 48h enhanced CRP both at the gene and protein levels (CRP mRNA expression (% of control values) 24h: control:100 \pm 2, IL-1 β +IL-6:162 \pm 40; CRP protein expression (% of control values): 48h: control:100 \pm 2, IL-1 β +IL-6:180 \pm 37). Inflammatory cytokines induced, to a similar extent, CRP protein expression in human macrophages. Increased CRP protein levels were also observed following exposure of human monocytes to BSA-AGE (CRP protein expression (% of control values): 48h: control:100 \pm 2, BSA-AGE:222 \pm 11). Finally, up-regulation of CRP gene and protein expression was documented in HAECs exposed to BSA-AGE and oxLDL. Induction of endothelial CRP by these factors was time-dependent, with maximal effect occurring around 12h and 24h, respectively.

Conclusion: Our results demonstrate for the first time that CRP is expressed by human monocytes and macrophages under resting conditions. They further establish the role of inflammatory and metabolic factors relevant to diabetes in the regulation of CRP expression in human monocytes/macrophages and endothelial cells. Increased monocyte and vascular CRP expression may contribute, at least in part to the accelerated atherosclerosis associated with human diabetes. Further research is needed to evaluate whether monocyte CRP expression may provide cardiologists with a more precise and specific biomarker for assessing cardiovascular risk in patients with diabetes.

0156

C-reactive protein expression in human monocytes/macrophages and endothelial cells: regulation by inflammatory cytokines and metabolic factors relevant to type 2 diabetes

L. Li, G. Renier;

Vascular Immunology Laboratory, CHUM Research Centre, Notre-Dame Hospital, Department of Medicine, University of Montreal, Canada., Canada.

Background and Aims: C-reactive protein (CRP) is a predictor of future cardiovascular events and diabetes and, may be causally involved in the pathogenesis of atherosclerosis. Besides being synthesized by the liver, CRP is produced by non hepatic cells, including vascular cells. CRP released from these cells may contribute to arterial inflammation and expression of this protein in atherosclerotic plaque. Besides resident vascular cells, inflammatory cells, especially monocytes, may represent a significant source of CRP in humans. While substantial expression of CRP has been documented in peripheral blood mononuclear cells, no studies have determined the level of CRP expression in human monocytes/macrophages. In the present study, we sought to determine the constitutive CRP expression by human monocytes/macrophages and the regulation of this parameter by inflammatory cytokines and metabolic factors relevant to diabetes. The modulatory effect of metabolic factors on vascular CRP expression was further investigated in human aortic endothelial cells (HAECs).

Health-related quality of life in patients with type 2 diabetes: an independent predictor of mortality

N. Kleefstra^{1,2}, G. W. D. Landman³, S. T. Houweling², L. J. Ubink-Veltmaat⁴, B. Meyboom-de Jong⁵, K. H. Groenier⁵, H. J. G. Bilo^{1,6};

¹Diabetes Centre, Isala Clinics, Zwolle, ²Medical Research Group, Langerhans, Zwolle, ³Internal Medicine, Isala Clinics, Zwolle, ⁴t Veen, Huisartsenpraktijk, Hattem, ⁵General Practice, University of Groningen, ⁶Internal Medicine, University of Groningen, The Netherlands.

Background and Aims: Hypertension and dyslipidemia are well known predictors of mortality in type 2 diabetes (T2DM) and should be treated. However, other factors like health related quality of life (HRQOL), which is negatively associated with having diabetes, are separate treatment objectives. This study investigates the relation between HRQOL and total mortality in T2DM.

Materials and Methods: The ZODIAC study started in 1998. A group of 1145 patients with T2DM was seen annually, and data on mortality were assessed 5.8 years later on average. The Rand-36 was used to measure HRQOL. It contains nine health dimensions; and two summary measures can be calculated: the Physical Component Summary (PCS) and Mental Component Summary (MCS). The range of the scale is from 0–100, a higher score meaning better HRQOL. Ten variables were selected for their possible confounding effects in the relationship between mortality and HRQOL: smoking (yes or no), age, sex, duration of diabetes, HbA1c, Cockcroft, BMI, blood pressure, cholesterol/HDL ratio and macrovascular complications. To investigate whether HRQOL was associated with mortality, Cox proportional Hazard modeling was used.

Results: 335 patients died. Date of death could not be traced in 6 patients. Cause of death could not be confirmed for 20 patients. Data on HRQOL were available of 1000 (87%) patients, of whom 857 (75%) were complete. Mean age was 68.2 years, with a median diabetes duration of 6 years. After adjustment for other known risk factors, HRQOL measured with the PCS was inversely associated with mortality (HR: 0.979, 95%CI: 0.966 to 0.992) (Figure: Kaplan- Meier curve PCS: below median versus above median) and MCS was not (HR 1.008 95% CI: 0.994 to 1.022). 145 (32.4%) of 448 patients with PCS scores below median and 69 of 449 (15.4%) above median died; ratio 2.1. Every 1 point decrease on the PCS scale led to an increase of the hazard of mortality of 2.1%, on average. For separate RAND-36 dimensions, significant relationships were found for "Physical Functioning" (HR 0.989 95%CI: 0.982 to 0.996) and "General Health Perception: (HR 0.982 95% CI: 0.971 to 0.994).

Fig. 1

Conclusion: Worse HRQOL (adjusted for well-established risk factors) is associated with a higher mortality in patients with type 2 diabetes after a follow-up of six years. Patients with HRQOL (PCS) below median versus above median have a 2.1-fold increased mortality risk. (Fig. 1)

0158

Quality of life and treatment satisfaction in adults with T1DM treated with CSII or MDI

A. Nicolucci¹, A. Maione¹, M. Franciosi¹, R. Amoretti², E. Busetto³, F. Capani⁴, D. Bruttomesso⁵, P. Di Bartolo⁶, A. Girelli⁷, F. Leonetti⁸, L. Morvuducci⁹, P. Ponzi³, E. Vitacolonna¹⁰;

¹Clinical Pharmacology and Epidemiology, Consorzio Mario Negri Sud, S. Maria Imbaro ²Diabetes Unit, Azienda Ospedaliera S. Giovanni Addolorata, Roma, ³Economics, Fondazione Medtronic Italia, Sesto San Giovanni ⁴Medicine and Ageing, University "G. D'Annunzio", Chieti, ⁵Clinical and Experimental Medicine, University of Padova, ⁶Diabetes Unit, AUSL Provincia di Ravenna, ⁷Diabetes Unit, Spedali Civili di Brescia, ⁸Clinical Sciences, La Sapienza University, Roma, ⁹Diabetes Unit, San Camillo Hospital, Roma, ¹⁰Medicine and Ageing, University "G. D'Annunzio", S. Maria Imbaro, Italy.

Background and Aims: Many clinical trials have investigated and demonstrated the efficacy of Continuous Subcutaneous Insulin Injection (CSII) vs. Multiple Daily Injection (MDI) in individuals with Type 1 Diabetes (T1DM). However, the evidence regarding the quality of life benefits of CSII is conflicting. The aim of this case-control trial was to compare the QoL and treatment satisfaction in a large sample of individuals with T1DM treated either with CSII or MDI.

Materials and Methods: Sixty-two Italian diabetes clinics enrolled 1341 consecutive patients (age 18–55 years), of whom 481 were treated with CSII (cases) and 860 with MDI (controls). During a routine visit, patients completed the Diabetes Specific Quality of Life Scale (DSQOLS), the Diabetes Treatment Satisfaction Questionnaire (DTSQ) and SF-36 Health Survey. All the scores ranged from 0 to 100, with higher scores indicating better QoL or higher satisfaction with therapy.

Results: The proportion of women was higher among cases than controls (57% vs. 46%; $p < 0.0001$). In comparison with controls, cases also had a longer diabetes duration (18 ± 10 years vs. 15 ± 10 years, $p < 0.0001$) and suffered more often from eye complications (32% vs. 22%, $p < 0.0001$) and renal complications (11% vs. 6%, $p < 0.0007$). In the control group, 90% of patients were treated with glargine-based MDI regimens. Groups did not differ with respect to age, school education, occupation and HbA1c levels. Multiple logistic regression, adjusted for socio-demographic and clinical characteristics, showed that, as compared with cases, controls had a more than threefold risk of having a DTSQ score in the lowest quartile (OR=3.3; 95%CI 2.5–5.0) and a 70% higher likelihood of having a score in the lowest quartile for the "diet restrictions" and "fear of hypoglycaemia" DSQOLS scores (OR=1.7; 95%CI 1.3–2.0 for both scores). No difference emerged between the two groups as for SF-36 scores. Results were confirmed when CSII was compared separately with glargine- or NPH-based MDI regimens.

Conclusion: This is the first large scale, office based study describing how CSII affects quality of life and treatment satisfaction when compared with either glargine-based or NPH-based MDI regimens in adults with T1DM. The study documents that, despite more severe diabetes, patients treated with CSII are more satisfied of their treatment, perceive a greater lifestyle flexibility, and show less fear of hypoglycemia.

Rates and risks for suicide attempt in outpatients with diabetes mellitus: results from the Dutch Screening for Depression in Diabetes (DDD) Study

F. Pouwer¹, B. Kilic¹, P. H. L. Geelhoed-Duijvestein², F. J. Snoek¹;

¹Diabetes Psychology Research Group, VU University Medical Center, Amsterdam,

²Internal Medicine, Westeinde Hospital, The Hague, The Netherlands.

Background and Aims: There is convincing evidence of an increased risk for depression in diabetes. However, it is unclear whether this translates into

an elevated risk of suicide attempt. We therefore aimed to: 1) determine the number and percentage of outpatients with diabetes mellitus that report a history of attempted suicide 2) to study current suicide ideation in this particular group, and 3) to explore clinical and socio-demographic factors associated with a history of suicide attempt.

Materials and Methods: Depressive symptoms, including current suicide ideation were assessed in 519 outpatients with diabetes (19–95 years of age) using the Patient Health Questionnaire (PHQ-9). Information regarding type of diabetes, diabetes duration and complications was obtained from the patient's medical charts. Patients with and without a history of suicide attempt were compared using Chi-square tests for categorical variables and Student's t-tests for continuous variables. To explore the strength of the association between sociodemographic/clinical factors and history of suicide attempt univariate logistic regression analyses were used.

Results: 33 patients (6.4%) of 519 reported that they had ever attempted suicide. The most robust predictors of suicide attempt were: history of admission to a psychiatric hospital because of depression (OR 13.5, 95% CI 5.3–34.8), depression treatment in the past (OR 5.1, 95% CI 2.9–9.0), admission to a hospital because of diabetic coma (OR 3.2, 95% CI 1.0–9.8), being partially/fully disabled (OR 3.0, 95% CI 1.4–6.2), having cardiovascular disease (OR 2.5, 95% CI 1.1–5.5), and for men: impotence (OR 8.4, 95% CI 1.6–44.6). Almost three quarter (73%) of the diabetes patients who had ever attempted to commit suicide reported to have had suicidal thoughts during the last two weeks.

Conclusion: Prior research in the general Dutch population showed that the lifetime prevalence of suicide attempt is 2.3%. The prevalence rate of 6.4% in the present sample suggests that a history of attempted suicide is relatively common among outpatients with diabetes. Health care providers should be particularly alert for suicide ideation in patients with a history of inpatient treatment for psychiatric problems and in patients with complications of diabetes.

Interaction of depressive symptoms, diabetes-related distress and glycaemic control in type 2 diabetic patients

M. Pibernik-Okanovic¹, D. Begić², S. Szabo¹, I. Renar¹, Z. Metelko¹;

¹Outpatient Clinic, Vuk Vrhovac Institute,

²Psychiatric Clinic, Rebro University Hospital, Zagreb, Croatia.

Background and Aims: Psychological well-being and diabetes self-management have been shown to be interdependent. However, associations between psychological symptoms and glycaemic control are not quite consistent. This study was aimed at examining patterns of glycaemic control in emotionally burdened subgroups versus symptom-free individuals with type 2 diabetes.

Materials and Methods: A random sample of 470 type 2 diabetic patients (aged 58±8 yrs, 52% female, with diabetes duration of 9±6 yrs, 33% insulin treated) were assessed for depression and diabetes-related distress by using the Center for Epidemiologic Studies-Depression (CES-D) and the Problem Areas in Diabetes (PAID) scales. Relying on the standard cut offs (CES-D>16, PAID>40), four discrete subgroups were analysed: patients with severe depressive symptoms and high diabetes distress, patients with severe depressive symptoms only, patients with high diabetes-related distress only and symptom-free patients. The indicators of glycaemic control, as determined by HbA1C values, were analysed at the point of psychological assessment and one year later. Pearson's correlation coefficients were used to determine univariate associations between glycaemic control, disease-related and psychological variables. Analysis of covariance was used to compare glycaemic control among the four groups while controlling for the disease-related variables.

Results: Twelve percent of the examined patients suffered from severe depressive symptoms combined with high diabetes-related distress, 10% reported severe depressive symptoms, 22% expressed high distress and 56% were symptom-free. The entire group's glycaemic control was associated with diabetes duration ($r=0.14$ $p<0.05$), diabetes therapy ($r=0.17$ $p<0.05$), body mass index ($r=0.12$ $p<0.05$), the CES-D scores ($r=0.10$ $p<0.05$) and the PAID scores ($r=0.27$ $p<0.05$). After controlling for diabetes duration, diabetes therapy and body mass index, the four groups differed with respect to glycaemic control ($F=8.25$ $p<0.0001$). The Tukey's HSD for unequal N indicated that HbA1C values were significantly higher in the depressed-distressed group as

compared to depressed and symptom-free groups (8.6 ± 1.6 vs 7.3 ± 1.3 and 7.6 ± 1.4 ; $p=0.0003$ and $p=0.005$, respectively), whereas the distressed group had higher HbA1C values than the depressed group (8.1 ± 1.7 vs 7.3 ± 1.3 $p=0.05$). After a one-year follow-up, glycaemic control remained associated with depressive symptoms and diabetes-related distress after controlling for diabetes-related variables ($F=6.94$ $p<0.0001$). Between-group differences were significant for depressed-distressed vs depressed group (8.2 ± 1.7 vs 7.3 ± 1.3 $p=0.005$). While the distressed group improved glycaemic control during the follow-up period (8.2 ± 1.7 to 7.6 ± 1.3 $p=0.0004$), the depressed-distressed and depressed groups did not (8.6 ± 1.6 vs 8.2 ± 1.8 $p=0.11$ and 7.3 ± 1.3 vs 7.3 ± 1.3 $p=0.95$ respectively).

Conclusion: Depressive symptoms and diabetes-related distress were both cross-sectionally and longitudinally shown to adversely interact with glycaemic control. Patients suffering from severe depressive symptoms and high diabetes-related distress seem to have the greatest difficulties in achieving good glycaemic control. Screening for both may be recommended in order to provide appropriate psychological help and improve glycaemic control.

Cognitive dysfunction in type 2 diabetes mellitus: comparison with pre-diabetic stages

E. van den Berg¹, G. Biessels¹, G. Nijpels², J. M. Dekker²;

¹Department of Neurology G03.228, University Medical Center Utrecht,

²Institute for Research in Extramural Medicine (EMGO Institute), VU University Medical Center, Amsterdam, The Netherlands.

Background and Aims: Type 2 diabetes (DM2) is associated with cognitive impairments and an increased risk of dementia. DM2 is preceded by a prolonged 'pre-diabetic' stage characterised by insulin resistance and vascular and metabolic risk factors such as hypertension and obesity. The concept of the 'metabolic syndrome' (MS) entails the clustering of these risk factors and as such can be viewed as a pre-diabetic stage. We hypothesise that the cognitive impairments associated with DM2 develop in this pre-diabetic stage, before the actual onset of the hyperglycaemia, and that vascular and metabolic factors related to the MS are the prime determinants of these impairments.

Materials and Methods: Participants were recruited through the 'Hoorn study', a longitudinal cohort study in which detailed metabolic and vascular data were collected in 1989, 1996, and 2001. For the current examination in 2005/2006 three groups were selected according to the risk factor profile at the 2001 survey: control participants (0–1 MS risk factor (ATPIII-criteria); $n=115$), MS without DM2 ($n=98$), and recent onset DM2 (onset after 1996; $n=64$). Performance on 12 neuropsychological tasks, covering 6 cognitive domains, was expressed in standardized z-scores.

Results: Age, sex distribution and education were similar across the groups. The number of MS risk factors was similar in the MS and the DM2 group. We observed small differences between groups on cognition (abstract reasoning: control 0.04 ± 0.10 , MS -0.002 ± 0.11 , DM2 -0.06 ± 0.13 , $p=0.84$; memory: -0.01 ± 0.05 , 0.04 ± 0.05 , -0.10 ± 0.06 , $p=0.2$; information processing speed: 0.13 ± 0.08 , -0.11 ± 0.09 , -0.18 ± 0.11 , $p=0.04$; attention and executive functions: 0.08 ± 0.06 , -0.05 ± 0.07 , -0.17 ± 0.08 , $p=0.04$; visuocognition: 0.16 ± 0.10 , -0.04 ± 0.10 , -0.21 ± 0.13 , $p=0.06$; language: 0.11 ± 0.10 , 0.01 ± 0.10 , -0.22 ± 0.13 , $p=0.11$). The MS group had an intermediate position between the DM2 and control group. As expected, the effects in the early DM2 group were smaller than in previous studies with advanced DM2.

Conclusion: This first analysis of our study population suggests that the cognitive impairment that is associated with DM2 already develops in pre-diabetic stages and progresses gradually thereafter. Future analyses will address longitudinal associations between vascular and metabolic risk factors and cognition, to identify determinants of cognitive dysfunction in the whole population.

A Diabetes and Psychological Treatments Study (ADaPT): preliminary results from a randomised controlled trial

K. Ismail¹, S. M. Thomas², T. Chalder¹, C. Dickens³, F. Creed³, E. Maissi¹, J. Bartlett⁴, U. Schmidt¹, A. Patel¹, J. Treasure¹;

¹Psychological Medicine, Institute of Psychiatry, London,

²Diabetes Centre, Guy's and ST Thomas' NHS Trust, London,

³Psychiatry, University of Manchester, ⁴Medical Statistics, London School of Hygiene and Tropical Medicine, London, United Kingdom.

Background and Aims: Despite intensive medical regimes, suboptimal glycaemic control is common in people with type 1 diabetes. The pooled evidence that psychological treatments are effective in improving glycaemic control is limited. We conducted a multicentre randomised controlled trial to test first, whether motivational enhancement therapy (MET) was more effective than usual diabetes care in improving glycaemic control and second, whether MET plus cognitive behaviour therapy (CBT) was more effective than usual diabetes care in improving glycaemic control in adults with type 1 diabetes and persistent suboptimal glycaemic control.

Materials and Methods: Six nurses were trained to deliver diabetes specific MET and CBT using a standardised manualised training and competency ratings. Trial criteria were adults (18–65 years) with type 1 diabetes (duration > 2 years); local residents of the 9 study hospitals in South London and Manchester, United Kingdom; no advanced diabetes complications or severe mental illness; not pregnant; at least one glycated haemoglobin (A_{1c}) in past 12 months plus current $A_{1c} \geq 8.2$ and $\leq 15.0\%$. After baseline assessments, participants were randomised to 4 sessions of MET over 2 months or 4 sessions of MET plus 6 sessions of CBT over 6 months or usual diabetes care using computerised proportional minimised randomised blocks and allocation concealment. The main outcome was A_{1c} 12 months later (technicians blind to allocation) adjusted for baseline A_{1c} .

Results: Using clinic registers, around 2000 people with type 1 diabetes were screened and 344 were randomised 117, 106 and 121 were assigned to MET (n=117), MET plus CBT (n=106) and to usual care (n=121) respectively. The follow up rate for A_{1c} was 88% (n=305) 12 months later. The average age was 36.0 years (interquartile range (IQR) 28.1–43.8); duration of diabetes was 17.9 years (IQR 10.6–24.8); A_{1c} 9.4% (IQR 8.8–10.2); 60.5% were female; 80.2% were white; 69.5% were employed; 17.9% had a depressive disorder. The nurses had reasonable competency in delivering MET (Motivational Interviewing Competency Scale empathy score 5.2 (SD 0.68) and CBT (Cognitive Therapy Rating Scale-R score 4.5 (SD 9.7)). In the preliminary analysis, the adjusted mean 12 month A_{1c} was 0.2% (95% confidence interval –0.2% to 0.5%) lower in the MET group compared to the usual diabetes care group but this difference was not statistically significant. There was statistically significant evidence that the adjusted mean 12 month A_{1c} was 0.5% (95% confidence interval 0.1% to 0.8%) lower in the MET plus CBT group compared to the usual care group (p=0.008).

Conclusion: In summary in this group of difficult to control diabetes nurse-delivered MET plus CBT was associated with a clinical and statistically significant improvement in glycaemic control but MET alone was not.

Glucose-stimulated oscillations of cAMP in insulin-secreting β cells

O. Dyachok, J. Sageterp, E. Gylfe, A. Tengholm;

Department of Medical Cell Biology, Uppsala University, Sweden.

Background and Aims: Rise of glucose is a primary physiological stimulus for insulin secretion. It results not only in increase of the cytoplasmic Ca^{2+} concentration ($[Ca^{2+}]_i$) but also in a modest rise of the cAMP concentration in pancreatic islets/ β -cells. It is well documented that cAMP amplifies Ca^{2+} -dependent insulin release. Whereas Ca^{2+} signalling has been extensively characterized and found to involve oscillations important for the temporal control of insulin secretion, the kinetics of glucose-triggered cAMP signals is still unknown.

Materials and Methods: MIN6 β -cells were transfected with a translocation reporter based on modified protein kinase A subunit fused to the cyan and yellow fluorescent proteins (CFP and YFP). Changes in CFP/YFP fluorescence ratio depending on cAMP in the submembrane space ($[cAMP]_i$) were recorded with evanescent wave microscopy. Simultaneous recording of $[cAMP]_i$ and $[Ca^{2+}]_i$ was performed in cells loaded with the fluorescent indicator fura-2.

Results: Reminiscent of the $[Ca^{2+}]_i$ response, MIN6 β -cells reacted to rise of glucose from 3 to 11 mM with a modest temporary decrease of $[cAMP]_i$ followed by rapid increase and pronounced oscillations with nadirs well above basal $[cAMP]_i$. The oscillatory patterns varied among cells with frequencies ranging from 0.07 to 1.8 min^{-1} . The glucose-induced $[cAMP]_i$ oscillations were abolished by preventing adenylyl cyclase activation with 3 μM adrenaline or noradrenaline or by enzyme inhibition with 50 μM of 2',5'-dideoxyadenosine. The amplitude of the $[cAMP]_i$ oscillations was reduced by the Ca^{2+} channel blocker methoxyverapamil or removal of extracellular Ca^{2+} . Some cells showed synchronized oscillations of $[cAMP]_i$ and $[Ca^{2+}]_i$.

Conclusion: Contrary to previous reports of a modest glucose-induced increase of total cAMP in β -cells we found that the sugar induces pronounced $[cAMP]_i$ oscillations in the submembrane space, where the nucleotide has important effects on ion channel activity and exocytosis. These oscillations and the interplay between Ca^{2+} and cAMP at the membrane should be important determinants for pulsatile release of insulin.

Generation of sub-membrane cyclic AMP signals by Ca^{2+} and ATP in insulin-secreting cells

J. Sageterp, O. Dyachok, E. Gylfe, A. Tengholm;

Department of Medical Cell Biology, Uppsala University, Sweden.

Background and Aims: cAMP is an important regulator of insulin secretion from pancreatic β -cells. Glucose stimulation of β -cells results in elevation of cAMP. The present study aimed to determine how the cAMP concentration beneath the plasma membrane ($[cAMP]_i$) is affected by the cytoplasmic Ca^{2+} concentration ($[Ca^{2+}]_i$) and by stimulation of metabolism.

Materials and Methods: $[cAMP]_i$ was recorded in MIN6 β -cells with a translocation reporter based on engineered protein kinase A subunits fused to the cyan and yellow fluorescent proteins (CFP and YFP). Changes in CFP/YFP ratio depending on $[cAMP]_i$ were recorded with evanescent wave microscopy, and $[Ca^{2+}]_i$ measured with ratiometric fluorescence imaging and the fura-2 indicator.

Results: Plasma membrane depolarization with 30 mM K^+ in the presence of 3 mM glucose and 250 μM diazoxide induced a prompt rise of $[cAMP]_i$ that was reversed when the K^+ concentration was normalized. Elevation of the glucose concentration to 11 mM in cells hyperpolarized with diazoxide did not significantly change $[cAMP]_i$. However, the presence of high glucose amplified the $[cAMP]_i$ response to depolarization with K^+ in the presence of diazoxide (153 \pm 40% increase of response, n=6, p<0.02). When the glucose concentration was increased from 3 to 11 mM in the presence of 30 mM K^+ and 250 μM diazoxide there was a pronounced rise of $[cAMP]_i$ (104 \pm 20%, n=10, p<0.001), sometimes with superimposed oscillations (frequency=0.19 \pm 0.02

min⁻¹; n=8). A similar, but transient [cAMP]_i elevation was induced by 2 mM α -ketoisokaproic acid (KIC). The [cAMP]_i-elevating effects of glucose and KIC in depolarized cells were not paralleled by increases of [Ca²⁺]_i. Instead, rise of glucose or addition of KIC induced a transient lowering of [Ca²⁺]_i from the level obtained with K⁺ depolarization.

Conclusion: Rise of [Ca²⁺]_i is sufficient to trigger elevation of [cAMP]_i in β -cells. In the presence of elevated [Ca²⁺]_i metabolically generated ATP is a potent stimulus for cAMP production. The interplay between Ca²⁺, ATP and cAMP in the sub-membrane space may help to explain the initiating and amplifying pathways of glucose-induced insulin secretion.

0165

Pulsatile insulin release from single β cells critically depends on cAMP

O. Idevall Hagren, A. Tengholm;

Medical Cell Biology, Uppsala University, Sweden.

Background and Aims: Insulin is secreted in distinct pulses from pancreatic β -cells following elevation of the plasma glucose concentration. The triggering signal for insulin granule exocytosis is a rapid increase in the cytoplasmic Ca²⁺ concentration ([Ca²⁺]_i). cAMP is known to amplify glucose-induced insulin secretion by potentiating the Ca²⁺-dependent exocytosis. However, the kinetics of this process is unknown and the aim of the present study was to investigate the relationship between cAMP signals and pulsatile insulin secretion in single β -cells.

Materials and Methods: Insulin secretion from single MIN6 β -cells was monitored with a fluorescent translocation biosensor (GRP1-GFP₄) reporting formation of phosphatidylinositol-3,4,5-trisphosphate (PIP₃) induced by autocrine activation of insulin receptors on the β -cell surface. Changes in cAMP concentration beneath the plasma membrane ([cAMP]_i) were measured with evanescent wave microscopy and a translocation biosensor based on fluorescence-tagged subunits of protein kinase A (PKA).

Results: Elevation of the glucose concentration from 3 to 11 mM induced a rise of the plasma membrane PIP₃ concentration (161±14 % increase in GRP1-GFP₄ fluorescence) followed by pronounced oscillations from a slightly elevated level (frequency=0.22±0.02 min⁻¹; n=39 cells). Simultaneous recording of [cAMP]_i revealed that each rise of PIP₃ was preceded by an increase of [cAMP]_i. Inhibition of adenylate cyclases with 2',5'-dideoxyadenosine suppressed the PIP₃ oscillations in a concentration-dependent manner. Conversely, elevation of [cAMP]_i with forskolin or IBMX induced an immediate stimulation of PIP₃ formation (87% of the cells) followed by sustained elevation (22%) or continued oscillations (65%; n=67 for IBMX). The time-integrated GRP1-GFP₄ signal was significantly higher in the presence of IBMX than with 11 mM glucose alone (102±38% increase, n=26, P<0.02). Whereas the PKA inhibitor H-89 was without effect on the glucose- and IBMX-induced PIP₃ signals, the effect of cAMP elevation was mimicked by the Epac-activating nucleotide analogue 8-pMeOPT-2'-O-Me-cAMP.

Conclusion: Insulin is released in pulses from individual β -cells. This rhythmicity is intimately controlled by changes in cAMP concentration in the sub-membrane space. The results reinforce the role of Epac in insulin granule exocytosis.

Supported by EFSD/MSD European Studies on Beta Cell Function and Survival

0166

Visualization of single insulin granules in insulin-producing cells by selective photoactivation

S. Baltrusch, S. Lenzen;

Institute of Clinical Biochemistry, Hannover Medical School, Germany.

Background and Aims: Intracellular transport and exocytosis of insulin is a prerequisite for glucose-induced insulin secretion in pancreatic beta cells. The mechanism of insulin storage and release requires proper packaging of the insulin containing dense core vesicles, their translocation, docking and fusion to the plasma membrane. Targeting the granule membrane as well as the cargo of the secretory granules by fluorescent proteins has facilitated detailed knowledge inside these processes during recent years. While total

internal reflection fluorescence microscopy, which allows fluorescence excitation with 100 nm from the plasma membrane, promotes the analysis of docking and fusion of single insulin granules, tracking single insulin granules within the cytoplasm by real-time fluorescence microscopy is so far less accessible. The aim of this study was to visualize single insulin granules in insulin-producing cells with selective photoactivation.

Materials and Methods: Plasmids were generated for expression of fusion proteins of the granule membrane resident phosphatase phogrin or the granule cargo protein neuropeptide Y (NPY) with the photoactivatable fluorescent protein PA-GFP-A206K as well as with the fluorescent protein mCherry. Insulin-producing MIN6 cells were either co-transfected with plasmids expressing Phogrin-PA-GFP-A206K and NPY-mCherry or with plasmids expressing Phogrin-mCherry and NPY-PA-GFP-A206K and cultured for 48 h in DMEM medium with 25 mmol/l glucose. Cells were imaged with an Olympus Fluoview1000 confocal microscope, equipped with a second scan unit for simultaneous photoactivation.

Results: In transfected MIN6 cells NPY-mCherry and Phogrin-mCherry showed distinct colocalization after fixation and immunostaining with insulin, which indicates proper targeting of the generated fusion constructs. Living cells co-transfected with Phogrin-PA-GFP-A206K and NPY-mCherry or with Phogrin-mCherry and NPY-PA-GFP-A206K showed a comparable pattern of punctuated red fluorescence. Overall illumination with a 405 nm laser diode provoked activation of PA-GFP-A206K. The resulting green fluorescence of Phogrin-PA-GFP-A206K and NPY-PA-GFP-A206K was with $\geq 70\%$ colocalized with the red fluorescence of NPY-mCherry and Phogrin-mCherry, respectively. Region selected 405 nm laser light exposure for less than 1 sec resulted in $\geq 50\%$ of the experiments in visualization of three or $\geq 20\%$ of a single granule by green fluorescence. After treatment with 25 mmol/l glucose the marked granules moved significantly faster than in MIN6 cells treated with 3 mmol/l glucose. Acquisition of several layers of the MIN6 cell after photoactivation revealed a deeper spatial insight in the granule movement. Interestingly, in the generated 3-D images the changes in the granule membrane during movement illuminated by Phogrin-PA-GFP-A206K could be clearly distinguished from the granule cargo visualized by NPY-mCherry.

Conclusion: Visualization of single insulin granules by targeting of the granule membrane or its cargo with a photoactivatable protein in combination with a dual scanner confocal microscope is a useful tool to analyze the mechanism of intracellular granule transport. This technique may open the perspective to further elucidate the regulation of different pools of granules within the beta cell also with respect to the secretory defects in type 2 diabetes.

0167

ATP, mitochondrial calcium and mitochondrial pH responses during nutrient activation of the pancreatic β cell

A. Wiederkehr¹, K.-S. Park¹, O. Dupont¹, N. Demaurex¹, T. Pozzan², C. B. Wollheim¹;

¹Department of Cell Physiology and Metabolism, University of Geneva, Switzerland, ²Department of Biomedical Sciences, University of Padua, Italy.

Background and Aims: Nutrient activation of the pancreatic β -cell results in a large number of signals and metabolic changes that stimulate insulin secretion. Here we have studied cytosolic ATP and mitochondrial calcium signals as well as mitochondrial pH changes following the stimulation of β -cells with glucose in order to gain insight into the molecular mechanisms of β -cell activation.

Materials and Methods: For the measurement of mitochondrial pH, the pH sensitive probe mitochondrial AlpHi (mtAlpHi) was cloned into an adenovirus vector. INS-1E cells and freshly isolated rat islets were infected with adenoviruses carrying mtAlpHi or the previously described adenoviruses carrying Luciferase (ATP) or mitochondrial Aequorin (calcium). Fluorescence respectively luminescence of the probes was analysed 2–3 days after infection.

Results: ATP or the connected ATP/ADP ratio is a key regulator of insulin secretion. Consistent with earlier studies we find that glucose stimulation increases ATP levels by 25–35% over the signals measured in non-stimulated β -cells. In INS-1E cells, ATP as well as mitochondrial calcium were found to oscillate with a periodicity of 2–3 minutes. The delay of onset of the signal and the frequency of oscillations was indistinguishable suggesting a causal link between the two parameters. In rat islets very similar ATP oscillations were observed however glucose stimulation only resulted in a single

mitochondrial calcium rise not followed by calcium oscillations. In both systems removal of extracellular calcium prevented mitochondrial calcium signals whereas ATP oscillations persisted. Together the results demonstrate that calcium oscillations are not required to drive ATP oscillations. In contrast the absence of extracellular calcium strikingly affected the observed nutrient dependent net increase in ATP levels. During the initial 4 minutes ATP rose equally in the absence and presence of calcium. Thereafter ATP levels increased steadily in control islets but remained close to constant in the absence of calcium influx. Re-addition of calcium restored normal rates of ATP synthesis. Mitochondrial metabolism and calcium signals are intimately linked to changes in mitochondrial pH. To study how mitochondrial pH relates to calcium and ATP signals in β -cells we have employed organelle targeted mtAlpHi. MtAlpHi fluorescence was pH sensitive in both INS-1E and rat islet β -cells. Titration of the probe *in situ* showed that mitochondrial pH is fairly low (<7.3) in the β -cell when compared with published values for mitochondrial pH in other cell types. Glucose activation consistently resulted in alkalinisation of the mitochondrial matrix. Matrix pH increased gradually to reach a new steady-state 10–15 minutes after glucose addition. The pH increase following glucose was quite large ranging from 0.2–0.6 pH units.

Conclusion: Our results illustrate the calcium dependence of ATP synthesis in β -cells during a second phase of the nutrient response. Furthermore we add mitochondria matrix pH to the list of parameters that respond to nutrients. Matrix pH changes are likely to modulate mitochondrial metabolism thereby the insulin secretory response of the β -cell.

The lipase inhibitor, orlistat blocks glucose-induced Ca^{2+} oscillations and insulin secretion from pancreatic β cells; effects partially reversed by fatty acid

J. T. Deeney, L. Liu, R. Corkey, B. E. Corkey;

Department of Medicine, Boston Medical Center, Boston, United States.

Background and Aims: Glucose-induced insulin secretion is impaired under conditions in which orlistat is used to inhibit lipolysis in rat pancreatic islets. Our goal was to elucidate the mechanism by which the lipase inhibitor, orlistat blocks insulin secretion.

Methods: Insulin secretion from INS-1 (823/13) clonal pancreatic β -cells and dissociated rat pancreatic islets was measured by RIA. Intracellular Ca^{2+} was monitored using fura-2 loaded cells visualized on a Zeiss microscope attached to a time-sharing filter based fluorometer (Ionoptix Corp., MA).

Results: Orlistat (6–50 μM), a non-specific lipase inhibitor, inhibited glucose-induced insulin secretion from INS-1 cells in a concentration-dependent manner. Addition of oleate (0.2 mM, 4:1 molar ratio to BSA) partially reversed the orlistat effects on secretion. Intracellular Ca^{2+} was then monitored to determine if inhibition of insulin secretion was mediated by impaired Ca^{2+} homeostasis. Orlistat (100 μM) inhibited glucose-induced Ca^{2+} oscillations and addition of oleate reversed this inhibition. Orlistat also reduced intracellular Ca^{2+} elevated using KCl in the presence of glucose and diazoxide (400 μM). This reduction was also reversed by the addition of oleate. Preincubation of INS-1 cells with orlistat (100 μM) inhibited KCl-induced plasma membrane depolarization by 30% as monitored with the fluorescent indicator bis-oxonol. Similar effects on glucose-induced insulin secretion and Ca^{2+} homeostasis were found in dissociated rat islet cells using higher concentrations of orlistat (200 μM).

Conclusion: Fatty acids provide lipid signals required for both normal Ca^{2+} homeostasis and insulin secretion. Thus, impaired glucose-induced insulin secretion due to inhibition of lipolysis can be attributed to both the K_{ATP} -dependent triggering pathway as well as the K_{ATP} -independent amplification pathway of secretion.

High-density association mapping and comprehensive tagging of the type 2 diabetes linkage region on chromosome 1q in 4 European populations

I. Prokopenko¹, E. Zeggini¹, N. W. Rayner¹, C. J. Groves¹, R. L. Hanson², B. D. Mitchell³, M. Vaxillaire⁴, S. E. Hunt⁵, L. R. Cardon¹, P. Froguel⁶, S. C. Elbein⁷, A. R. Shuldiner³, P. Deloukas⁵, M. I. McCarthy¹;

¹WTCHG, University of Oxford, United Kingdom, ²NIH/NIDDK, Phoenix, United States, ³School of Medicine, University of Maryland, Baltimore, United States, ⁴Institut de Biologie de Lille Génomique et Physiologie Moléculaire des Maladies Métaboliques, Institut Pasteur, Lille, France, ⁵Wellcome Trust Sanger Institute, Hinxton, United Kingdom, ⁶Division of Medicine, Imperial College, London, United Kingdom, ⁷Division of Endocrinology and Metabolism, University of Arkansas, Little Rock, United States.

Background and Aims: The International Type 2 Diabetes 1q Consortium has undertaken sequential high-density linkage disequilibrium mapping of the extensively-replicated 1q linkage region in the search for the variants responsible.

Materials and Methods: We have extended our existing coverage of the 22.7Mb candidate region (147.0–169.7Mb, NCBI35) by genotyping 1536 additional SNPs in 2198 individuals (1000 cases, mainly probands from extended families, and 1198 matched controls) from four European-descent populations (Amish, French, UK and Utah). The new combined dataset includes 5285 SNPs passing stringent quality control criteria (density~4.3kb) and increases coverage of common variation from ~60% to over 80% ($r^2 \geq 0.8$, pairwise) based on HapMap CEU data. Population-specific single-point analyses and Mantel-Haenszel-based meta-analysis across 4 populations were performed testing additive and dominant/recessive models.

Results: Thirteen SNPs showing highly significant associations with T2D (combined $p < 5 \times 10^{-5}$) were identified by Mantel-Haenszel model-based meta-analysis. The minor allele frequencies observed in each single population were high for all 13 SNPs, ranging from 0.19 to 0.45. This increased density of the genotyping performed in this study provides increased support for the two principal association signals in the region. The first cluster (9 SNPs) falls into a region of extended LD at ~152.1Mb that includes the gene encoding liver pyruvate kinase, *PKLR*. The strongest association in *PKLR* was observed for rs3020781 (OR for C allele 1.33[95%CI 1.16–1.54], additive $p = 1.1 \times 10^{-6}$). The second cluster (4 SNPs) resides within *NOS1AP* (coding for nitric oxide synthase 1 (neuronal) adaptor protein [CAPON]) at ~158.8Mb. The strongest association here was observed with allele T of rs7538490 under the dominant model (OR=1.53[95%CI 1.28–1.81], $p = 1.8 \times 10^{-6}$).

Conclusion: Extended association analyses in the 1q candidate region for T2D have identified several common polymorphisms within 2 genes, *PKLR* and *NOS1AP*, sharing the same association pattern in 4 different populations of European origin.

Franklin, Charité University Medicine, Berlin, Germany, ³Epidemiology, DIFE Potsdam-Rehbrücke, Nuthetal, Germany, ⁴Institute of Molecular Genetic, Russian Academy of Science, Moscow, Russian Federation.

Background and Aims: Evidence for linkage of type 2 diabetes to a region on chromosome 10q23–q25 has been provided in several populations. Among genes in this region is IDE encoding insulin degrading enzyme which serve as a major enzyme responsible for insulin proteolysis. IDE knockout mice show a diabetic phenotype with hyperinsulinemia. Thus, the aim of the present study was to examine the genetic associations between IDE SNPs, insulin

metabolism and the risk for T2DM in the Metabolic Syndrome Berlin-Potsdam (MESYBEPO) and European

Prospective Investigation into Cancer and Nutrition-Potsdam (EPIC-Potsdam) study populations.

Materials and Methods: 12 SNPs from IDE gene were selected and genotyped in the MESYBEPO cohort (n = 1023 (men = 32.6%); subjects with T2DM = 235, IGT+IFG = 312, NGT = 475). The IDE variant (94214145T>C, rs1887922) was additionally genotyped in a nested case-cohort population of incident diabetics of the EPIC-Potsdam cohort (n = 801 cases; n = 2248 controls).

Results: We compared genotype frequencies in subjects with T2DM with those with NGT and found an association for rs1887922 (odds ratio 1.58 [95% CI: 1.03–2.2]; p = 0.036) in women in MESYBEPO. Adjusting for the effect of age strengthened the association (recessive model: p = 0.009). In nondiabetic women, the risk genotype was associated with a reduction in insulin clearance derived from oral glucose tolerance tests (p = 0.043). In the prospective EPIC-Potsdam population the same marker was associated with increased risk of T2DM in the additive inheritance model (RR 1.31 [95% CI: 1.11–1.55]; p = 0.0015).

Conclusion: We demonstrate an association between an IDE SNP and type 2 diabetes in the cross-sectional MesyBepo cohort. This relation to diabetes risk is confirmed in the independent, prospective EPIC-Potsdam cohort. Therefore, this study provides convincing evidence that genetic predisposition to disturbances in the insulin degradation may play a role in the development of T2DM.

Common variation in the *FTO* (fused toes) gene is strongly associated with adiposity measures in the Northern Finnish Birth Cohort of 1966

A. J. Bennett¹, M. N. Weedon², E. Zeggini¹, R. M. Freathy², C. M. Lindgren¹, U. Sovio³, N. J. Timpson⁴, A. Ruokonen⁵, H. Martikainen⁵, A. Pouta⁶, A.-L. Hartikainen⁵, T. M. Frayling², A. T. Hattersley², M.-R. Jarvelin^{3,5}, M. I. McCarthy¹;

¹DRL, Oxford Centre for Diabetes, Endocrinology & Metabolism/Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom, ²Genetics of Complex Traits & Diabetes Genetics, Peninsula Medical School, Exeter, United Kingdom, ³Department of Epidemiology and Public Health, Imperial College London, London, United Kingdom, ⁴MRC Centre for Causal Analyses in Translational Epidemiology, University of Bristol, United Kingdom, ⁵Depts of Clinical Chemistry, Obstetrics and Gynecology, Public Health Science & General Practice, University of Oulu, Finland.

Background and Aims: In large-scale association studies conducted in over 30,000 individuals from multiple populations, we have recently shown that a cluster of variants mapping within the *FTO* (fused toes) gene on chromosome 16 is strongly associated with adiposity. Genotypes at these SNPs are associated with ~3kg difference in adult body weight (attributable to effects on fat mass), and up to ~1.7 fold difference in risk of obesity (BMI>30kgm⁻²). To understand the biochemical and longitudinal consequences of variation at this locus, we typed a representative SNP from this cluster (rs939609) in 4593 individuals from the Northern Finland Birth Cohort of 1966.

Materials and Methods: We sought evidence for associations with longitudinal growth parameters (birth weight, measures of adiposity at age 14 and 31) and metabolic biochemistry available at age 31. Analyses used linear regression assuming an additive model, with stratification by gender and adjustment for possible confounding factors.

Results: No significant associations were seen for early growth variables including birth weight or ponderal index. At age 14, BMI was significantly associated with genotype with each copy of the risk-allele increasing BMI by 0.1kgm⁻² (P=0.04). The association with BMI was more striking at age 31 (0.4kgm⁻² per allele, P=5x10⁻⁵) and clearly reflected a difference in weight rather than height. Adiposity-associated *FTO* genotypes showed modest but non-significant associations with triglycerides (between-homozygote groups difference +0.04 mmol/l) and HDL-cholesterol (between-homozygote groups difference -0.03 mmol/l). These findings were consistent in magnitude with the effects attributable to the observed between-genotype differences in BMI (e.g. within-cohort regression indicates that a 0.8kgm⁻² difference in BMI is associated with a 0.05mmol/l difference in TG, in line with the 0.04mmol/l difference observed at *FTO*). Although variants in this gene are strongly associated (P<10⁻¹⁰) with T2D in case-control studies, we found no significant relationship with fasting glucose in this study.

Conclusion: In this cohort, as with others we have studied, *FTO* genotypes are strongly associated with adult BMI. This association with weight was not evident at birth, but was apparent by age 14. In this young adult population, the effects of this gene on continuous metabolic phenotypes are weak, though consistent in direction and size with the observed effect of *FTO* variation on BMI.

A genome wide scan for linkage in families with early onset maturity-onset diabetes of the young suggests a potential role for genes on chromosomes 2p 3q, 4q and 10q in glucose homeostasis

C. M. Lindgren^{1,2}, B. Barrow², D. Hammersley², M. Shepherd³, K. Elliott¹, N. W. Rayner¹, S. Ellard³, A. L. Gloyn²;

¹Wellcome Trust Centre for Human Genetics, University of Oxford, ²Diabetes Research Laboratories, Oxford Centre for Diabetes Endocrinology & Metabolism, University of Oxford, ³Institute of Biomedical & Clinical Science, Peninsula Medical School, Exeter, United Kingdom.

Background: Maturity-onset diabetes of the young (MODY) is an autosomal dominantly inherited early onset subtype of non-insulin dependent diabetes. To date MODY causing mutations in six different genes have been described. However, these genes only explain around 87% of cases and previous studies have suggested that the remaining cases are heterogeneous. We hypothesised that amongst these, patients with a very young age of diagnosis (<15yrs) may represent a genetically homogenous group and could thus facilitate identification of novel genes. The aim of this study was to identify potential novel loci for further gene candidacy testing for young onset MODY.

Methods: We performed an autosomal genome wide linkage scan in 40 individuals (20 with diabetes) from 5 families with > 6 subjects with onset of diabetes ≤ 15 years. Samples were genotyped using the Illumina IV linkage panel. Extensive quality checks were performed including HapMap concordance rates (0.2%), within genotyping concordance rates (0.4%), and checking of Mendelian inconsistencies. A total of 4,846 markers were subsequently used for linkage analysis using non-parametric linkage analysis as well as a parametric autosomal dominant model taking linkage disequilibrium into account (r²>0.1) as implemented in Merlin. Gene-dropping simulations of the data set were used to generate genome-wide empirical values.

Results: The highest NPL score 3.75 (p_{nominal} < 0.0001, HLOD 1.5), was observed on chromosome 10q. Three additional regions showed an NPL score >3.00 on chromosomes 2p (NPL 3.38, p_{nominal} <0.0005, HLOD 0.83), 3q (NPL 3.10, p_{nominal} =0.0010, HLOD 1.81) and 4q (NPL 3.00, p_{nominal} <0.0015, HLOD 1.43). About 145 genes map to the 1 NPL drop off region of these 4 loci of interest, including several strong biological candidates, potassium channels and cell signalling components.

Conclusions: Our genome wide scan has identified novel loci on chromosomes 2p, 3q, 4q and 10q which potentially harbour novel genes involved in the pathogenesis of early onset MODY. Utilizing families with an early age of diagnosis in combination with advanced bioinformatics to prioritise candidacy, is a strategy to facilitate identification of novel disease loci by linkage mapping.

Common variants in the *TCF7L2* gene increase future risk of type 2 diabetes by causing impaired incretin and β cell function

M. Sjögren¹, M. Orho-Melander¹, P. Almgren¹, K.-E. Eriksson², Å.-L. Lethagen¹, G. Berglund², T. Tuomi³, P. Nilsson², L. Groop^{1,3}, V. Lyssenko¹;

¹Diabetes & Endocrinology, Lund University, Malmö, Sweden,

²Medicine, Lund University, Malmö, Sweden,

³Department of Medicine, Helsinki University Central Hospital, Finland.

Background and Aims: Genetic variants in the gene encoding for the transcription factor-7-like 2 (*TCF7L2*) have been associated with type 2 diabetes (T2D) as well as with impaired β-cell function but the mechanisms have remained obscure. The aim of this study was to prospectively study the

ability of common variants in the TCF7L2 gene to predict future T2D and to explore the mechanisms by which they would increase risk for the disease.

Materials and Methods: 7051 Swedish individuals from the Malmö Prospective Study followed for up to 24 years and 2651 Finnish individuals from the Botnia Prospective Study followed for up to 8 years were genotyped for three SNPs (rs7903146, rs12255372 and rs10885406) in the TCF7L2 gene; part of them underwent extensive metabolic studies.

Results: The CT/TT genotypes of SNP rs7903146 strongly predicted future T2D in two independent cohorts (Swedish: OR 1.58, $p < 0.0001$; Finnish OR 1.61, $p = 0.007$). Carriers of the risk CT/TT genotypes had lower insulin secretion during OGTT (insulinogenic index, $p = 0.0006$; disposition index, $p = 0.005$) than carriers of the CC genotypes in the Malmö study. In the Botnia prospective study, converters carrying the CT/TT genotypes had a more severe deterioration in insulin secretion over time (insulinogenic index, $p = 0.034$; disposition index, $p = 0.003$) as compared to the CC carriers. The risk CT/TT genotypes were also associated with impaired acute insulin response to glucose and arginine (AIR) at both 14 mmol/l ($p = 0.02$) and 28 mmol/l ($p = 0.009$) of glucose as well as with enhanced rate of basal hepatic glucose production (3.2 ± 0.8 vs. 2.8 ± 0.3 , $p = 0.01$). Further refinement of the TCF7L2 locus into HapA and HapB haplotypes suggested a stepwise decrease in AIR ($p = 0.03$) being lowest in HapB, and increase in hepatic glucose production ($p = 0.03$) being highest in HapB. Additionally, the CT/TT carriers demonstrated a significant incretin defect estimated as AUCinsulinOGTT / AUCinsulin IVGTT ($p = 0.0003$) as well as using the formula: incretin effect = $100\% \times (\text{AUC}_i \text{ OGTT} - \text{AUC}_i \text{ IVGTT}) / \text{AUC}_i \text{ OGTT}$ ($p = 0.004$) in individuals with hyperglycemia; the incretin defect was more severe in carriers of HapB than in HapA or HapA (p=0.004) carriers. The glucagonotropic effect of GIP was enhanced in TT carriers as demonstrated by a more steep correlation between fasting GIP and glucagon concentrations in TT than in CC genotype carriers ($r = 0.59$, $p = 0.009$, $n = 21$ and $r = 0.05$, $p = 0.8$, $n = 28$). Also, the insulinotropic effect of GIP was attenuated in TT vs CC carriers as judged from the correlation between 2hr GIP and 2hr insulin (TT and CC, $r = 0.55$, $p = 0.004$, $n = 28$ and $r = 0.35$, $p = 0.2$).

Conclusion: The increased risk of T2D conferred by variants in the TCF7L2 gene involves impaired β -cell function which may partially be due to impaired incretin effect.

diabetic donors. Co-staining of TCF7L2 with RhodZin showed localization of TCF7L2 to β -cells. Although the expression of the insulin gene was markedly decreased in islets from T2DM subjects compared with non-diabetic donors (0.5 ± 0.1 vs 3.8 ± 0.5 ; $p = 0.003$) there was a positive correlation between the mRNA levels of TCF7L2 and insulin ($r = 0.76$, $p = 0.001$). Intriguingly, the insulin gene mRNA correlated inversely with glucose-stimulated insulin release (SI) after normalization for total insulin content ($r = -0.63$, $p = 0.02$). In order to establish to which extent those correlations reflected a cause-effect relationship, islets from non-diabetic pancreas were transfected with TCF7L2 gene resulting in $+121 \pm 52\%$ gene over-expression. In these islets, glucose-mediated insulin response was significantly impaired as indicated by a 35% reduction in the Stimulation Index (1.34 ± 0.28 vs. 1.83 ± 0.3 , $p < 0.05$). No relationship was seen between TCF7L2 and glucagons expression in human islets.

Conclusions: TCF7L2 gene expression is increased in islets from T2DM pancreases. Moreover, over-expression of TCF7L2 gene in non-diabetic islets is associated with impaired glucose-mediated insulin response. These results support the hypothesis that the increased T2DM risk associated with TCF7L2 gene could be mediated by defects of islet function.

TCF7L2 gene increase risk for future type 2 diabetes: study on diabetic isolated islets

R. Mancarella¹, R. Lupi¹, V. Lyssenko², C. Ling², S. Del Guerra¹, M. Bugliani¹, S. Torri¹, M. Galli¹, V. D'Aleo¹, P. Marchetti¹, L. Groop², S. Del Prato¹;

¹Endocrinology and Metabolism – Metabolic Unit, University of Pisa, Italy,

²Diabetes and Endocrinology, University of Lund, Malmö, Sweden.

Background and Aims: Identification of susceptibility genes for type 2 diabetes has not yet been very successful. Most recently, however, two single nucleotide polymorphisms (SNPs) (rs7903146 and rs12255372) in the transcription factor-7-like 2 (TCF7L2) gene were found to be strongly associated with T2DM in several populations. Increased T2DM risk in TCF7L2 variant carriers has been claimed to be associated with impaired insulin secretion. Moreover, TCF7L2 has been implicated in pro-glucagon processing, opening the possibility that TCF7L2 variants may simultaneously affect insulin and glucagon secretion. Therefore, have been performed to assess TCF7L2 expression in T2DM and non-diabetic human islets and to correlate it with pancreatic hormone release.

Materials and Methods: Human pancreatic islets were obtained from 15 non-diabetic (10M/5F, 59 yrs, BMI 26) and 7 T2DM (4M/3F, mean age 68 yrs, mean BMI 28 kg/m²) multi-organ donors. Upon isolation, islets were cultured free floating in M199 culture medium at 5.5 mmol/l glucose. Within 3 days from isolation 24h basal release of insulin and glucagon was determined in the media (IRMA and RIA technique, respectively), and islets were used for RNA extraction. Human TCF7L2 mRNA levels were quantified by Real-Time Quantitative RT-PCR. Finally, non-diabetic islets were transfected with plasmid DNA containing the TCF7L2 gene and glucose-mediated insulin response determined.

Results: TCF7L2 mRNA levels were 5-fold higher in T2DM than in non-diabetic islets (12.5 ± 2.1 vs. 2.9 ± 0.4 ; $p = 0.0002$). Basal insulin release was lower (209 ± 9 vs. 2534 ± 105 $\mu\text{U/ml}$; $p = 0.0002$) whereas glucagon release was higher (55 ± 3 vs. 8 ± 0.4 pg/ml; $p = 0.0002$) in T2DM islets than in those of non-

Loss of PGC-1 β results in reduced exercise performance, ultrastructural alterations and mitochondrial dysfunction in skeletal muscle

C. Zechner¹, L. Lai¹, T. C. Leone¹, P. J. Schaeffer^{1,2}, D. P. Kelly^{1,3};

¹Center for Cardiovascular Research and Cardiovascular Division, Department of Internal Medicine, Washington University in St. Louis, United States, ²Department of Zoology, College of Arts and Sciences, Miami University, Oxford, United States, ³Departments of Pediatrics and Molecular Biology & Pharmacology, Washington University in St. Louis, United States.

Background and Aims: Altered mitochondrial function is one of the earliest defects in diabetic skeletal muscle. Dysregulation of the transcriptional coactivators peroxisome-proliferator activated receptor gamma coactivator (PGC) -1 α and β in muscle has been associated with insulin resistance. Previous studies have shown that PGC-1 α deficiency results in muscle mitochondrial dysfunction and reduced exercise performance in mice. However, the effects of PGC-1 β deficiency on muscle metabolism and function have been examined in less detail. The aim of our study was to determine the skeletal muscle phenotype of PGC-1 β deficient mice.

Materials and Methods: The PGC-1 β gene was disrupted to generate mice with generalized PGC-1 β deficiency (PGC-1 β KO mice). Weight-, age- and sex-matched wild type (WT) mice were used as controls.

Results: Crosses of heterozygous (HET) PGC-1 β KO mice revealed that KO mice were born at reduced Mendelian frequency (WT: 26.8%; HET: 56.0%; KO: 17.2%; n=366; p<0.01). When exercised on a treadmill at low speed (10 m/min for 1h, then 2 m/min increment every 15 min; level), PGC-1 β KO mice only showed a mild performance deficit (WT: 204 \pm 10.02 min; KO: 159 \pm 3.31 ; p<0.05). In contrast, the running performance of PGC-1 β KO mice was drastically reduced compared with WT mice (WT: 18.9 \pm 4.86 min; KO: 3.9 \pm 1.07 min; p<0.05) when exercised at high speed (35 m/min; level). Mitochondrial respiration studies performed on isolated mitochondria from mouse hindlimb revealed a reduction in state 3 respiration in the KO (pyruvate: -27.9%, p<0.05; palmitate: -15.2%, p=0.057). Electron microscopic analysis of KO soleus muscle revealed the presence of a subset of mitochondria with vacuolar degeneration and degenerative features including "swirl-like" structures. While mtDNA was reduced by 12.9% in the soleus of the KO (p<0.05), the RNA expression of genes for fatty acid oxidation (acyl-CoA oxidase, medium chain acyl-CoA dehydrogenase, and muscle carnitine palmitoyl transferase I), glucose metabolism (glucose transporter 4 and pyruvate dehydrogenase kinase 4) and several mitochondrial genes (citrate synthase, cytochrome c oxidase (COX) 2 and ATP synthase β) was unchanged. However, PGC-1 α expression was increased in the soleus of the KO by 42% (p<0.05), suggesting a compensatory response.

Conclusions: PGC-1 β is necessary for full exercise performance and mitochondrial function in skeletal muscle. Loss of PGC-1 β does not result in downregulation of a subset of previously described targets, possibly due to compensatory PGC-1 α upregulation. However, PGC-1 α cannot fully compensate for the loss of PGC-1 β , indicating that PGC-1 α and β have overlapping as well as distinct regulatory roles.

Changes in resting and maximal mitochondrial ATP production in type 2 diabetes; non-invasive investigation by ³¹P-magnetic resonance spectroscopy

M. I. Trenell¹, K. Hollingsworth², E. Lim¹, J. Gerrard¹, R. Taylor¹;

¹Clinical Medical Sciences, ²Clinical Laboratory Sciences, Newcastle University, United Kingdom.

Background and Aims: Defects in mitochondrial function may be central to the development of insulin resistance and type 2 diabetes. Defects in mitochondrial function reduce the ability of muscle to metabolise fatty acids. The associated accumulation of fatty acids in skeletal muscle, in turn, impedes insulin action through inhibition of insulin action in skeletal muscle. It is possible that reduced basal ATP use in people with type 2 diabetes represents reduced insulin-stimulated ATP demand. In recovery from aerobic exercise ATP production is maximal stimulated, independent of insulin. As such,

quantification and comparison of basal ATP use with maximal stimulated ATP production in recovery from aerobic exercise may provide more specific information on mitochondrial function in people with type 2 diabetes than either value in isolation. In the present study we evaluated whether there were changes in basal ATP use and maximal ATP production in type 2 diabetes. This abstract reports baseline data of an ongoing study which observes the effects of increased physical activity upon mitochondrial function and glucose control in people with type 2 diabetes.

Materials and Methods: Volunteers with type 2 diabetes and normal controls underwent assessment of mitochondrial ATP production at rest in the soleus muscle. A ³¹P-Magnetic resonance spectroscopy saturation transfer technique was developed for use at 3 Tesla (coefficient of variation = 4.6%). Basal ATP flux was assessed by observing the change in inorganic phosphate following saturation of γ ATP. Maximal oxidative ATP production was then assessed in recovery from 3 minutes of plantar flexion exercise at 30% maximal voluntary contraction. Maximal mitochondrial ATP production was calculated from the recovery rate of adenosine diphosphate from contraction.

Results: At rest, oxidative ATP production was reduced by approximately 27% in people with type 2 diabetes in comparison with control (8.1 \pm 1.6 vs. 11.1 \pm 0.5 μ mol.g muscle⁻¹.min⁻¹, P<0.05). There were no significant difference in resting phosphocreatine (31.1 \pm 0.6 vs. 33.3 \pm 1.2 mM), adenosine diphosphate (9.5 \pm 0.4 vs. 9.7 \pm 0.1 μ M) and pH (7.04 \pm 0.01 vs. 7.06 \pm 0.01) between the groups (P>0.05). Maximal oxidative ATP production, reported as the recovery half time of adenosine diphosphate was similar between groups (22.7 \pm 5.1 vs. 25.6 \pm 3.8 sec, P> 0.05). There was no difference in end exercise phosphocreatine breakdown during exercise (7.2 \pm 1.7 vs. 8.2 \pm 1.1 mM, P> 0.05) or end exercise pH (7.04 \pm 0.02 vs. 7.02 \pm 0.02, P> 0.05), suggesting that the end exercise metabolic origins were similar between groups.

Conclusion: Our data reveals that basal oxidative ATP use is reduced in people with type 2 diabetes. However, the decrease in basal ATP is not accompanied by a decrease in contraction induced maximal oxidative ATP production.

In vivo and ex vivo quantification of mitochondrial function in type 2 diabetic patients and first-degree relatives

E. Phielix¹, V. Schrauwen-Hinderling¹, M. Mensink¹, M. Hesselink², P. Schrauwen¹;

¹Human Biology, ²Movement Sciences, Maastricht University, The Netherlands.

Background and Aims: Skeletal muscle insulin resistance is an early hallmark in the development of type 2 diabetes. Recently, mitochondrial dysfunction has been implicated in the development of muscle insulin resistance and type 2 diabetes. Here, we examined if mitochondrial function is impaired in diabetic patients and in first-degree relatives of type 2 diabetic patients, a population at increased risk of developing type 2 diabetes.

Methods: So far, 9 diabetic patients (T2D), 12 normoglycemic first-degree relatives (FDR) and 16 controls (C) were included (age (y) 60.4 \pm 5.1, 59.8 \pm 3.1 and 59.9 \pm 2.7; BMI (kg/m²): 28.9 \pm 2.3, 31.3 \pm 4.0 and 28.2 \pm 2.4; VO₂max (ml/kg/min): 27.6 \pm 7.6, 30.3 \pm 7.3 and 31.5 \pm 7.7 respectively). Insulin sensitivity was measured with a hyperinsulineamic euglycemic clamp. *In vivo* mitochondrial function was determined by measuring post-exercise PCr recovery half-time (PCr_{1/2}) using ³¹P-Phosphorus Magnetic Resonance Spectroscopy (³¹P-MRS). *Ex vivo* mitochondrial function was analysed in permeabilized muscle fibers isolated from needle biopsies from the vastus lateralis using high-resolution respirometry. ADP-stimulated state 3 respiration (oxygen consumption upon glutamate+succinate addition), non-ADP stimulated state 4 respiration, FCCP-driven maximal respiratory capacity (state 3u) and respiratory control ratio (RCR; state 3/state 4), were determined in the presence and absence of palmitoyl-carnitine. The RCR reflects the tightness of coupling between the ATP production via oxidative phosphorylation and the respiration-driven proton pumping via the electron transport chain.

Results: Preliminary results show lower insulin sensitivity in T2D compared to C (GIR (umol/kg/min): 16.4 \pm 6.3 vs. 25.9 \pm 9.6, p<0.05, respectively), with intermediate values in FDR (20.0 \pm 8.4, p=n.s for control or diabetic patients). *Ex vivo* mitochondrial oxidative capacity showed a (tendency to) reduced RCR for T2D compared to C and FDR (1.78 \pm 0.4 vs 2.44 \pm 0.6 and 2.28 \pm 0.5, p<0.05 and p=0.07, respectively), implicating less tightly-coupled mitochondria. Furthermore, T2D showed a lower FCCP-driven maximal

respiratory capacity compared to C (40.3 ± 8.7 vs 55.1 ± 15.1 , $p < 0.05$), with again intermediate values for FDR (45.5 ± 15.6 , $p = n.s.$). Addition of palmitoyl-carnitine significantly lowered RCR in both C and FDR, which may indicate fatty acid-induced uncoupling; however, this effect of palmitoyl-carnitine was absent in T2D. ADP-stimulated state 3 respiration ($R = -0.586$, $p < 0.01$) and maximal respiratory capacity ($R = -0.461$, $p < 0.054$) (tended to) correlated strongly with $PCr_{11/2}$, which is a measure of *in vivo* mitochondrial oxidative capacity.

Conclusions: We show that *ex vivo* oxidative capacity of permeabilized fibers is reduced in T2D, with intermediate values in FDR. Importantly, these values are not yet corrected for mitochondrial content and may thus reflect reduced mitochondrial density in T2D. Nevertheless, we also found that RCR, which is independent of mitochondrial content, was reduced in T2D suggesting that their mitochondria are less well coupled. Finally, the strong correlation between *ex vivo* and *in vivo* mitochondrial function indicates that the metabolic abnormalities observed *ex vivo* truly result in a reduced *in vivo* mitochondrial oxidative capacity.

Early or advanced stage type 2 diabetes is not accompanied by *in vivo* skeletal muscle mitochondrial dysfunction

J. J. Prompers¹, H. M. M. De Feyter¹, N. M. A. van den Broek¹, S. F. E. Praet², K. Nicolay¹, L. J. C. van Loon²;

¹Biomedical NMR, Eindhoven University of Technology, Eindhoven,

²Department of Movement Sciences, Nutrition and Toxicology Research Institute Maastricht (NUTRIM), Maastricht University, The Netherlands.

Background and Aims: Several lines of evidence support a potential role of skeletal muscle mitochondrial dysfunction in the pathogenesis of insulin resistance and/or type 2 diabetes. However, it remains to be established whether mitochondrial dysfunction represents either cause or consequence of the disease. We examined *in vivo* skeletal muscle mitochondrial function in early and advanced stages of type 2 diabetes, with the aim to gain insight in the proposed role of mitochondrial dysfunction in the development of insulin resistance and/or type 2 diabetes.

Materials and Methods: 11 long-standing, insulin treated type 2 diabetes patients (T2D), 11 subjects with impaired fasting glucose, impaired glucose tolerance and/or recently diagnosed diabetes (IHG), and 12 healthy, normoglycaemic controls (NGT), all matched for age and body composition and with similar habitual physical activity levels, were studied. *In vivo* mitochondrial function of the vastus lateralis muscle was evaluated from

Fig. 1. τ_{PCr} in NGT, IHG and T2D groups was not significantly different. Bars indicate the mean values for the 3 groups and filled circles represent individual data points.

Fig. 2. IMCL content in NGT, IHG and T2D groups was not significantly different.

post-exercise phosphocreatine (PCr) recovery kinetics using ^{31}P magnetic resonance spectroscopy (MRS). Intramyocellular lipid (IMCL) content was assessed in the same muscle using single-voxel 1H MRS.

Results: ^{31}P MRS parameters for mitochondrial function, i.e. the PCr recovery time constant (τ_{PCr} ; Figure 1), ADP recovery time constant and maximum aerobic capacity, did not differ between groups ($P = 0.4$, $P = 0.14$ and $P = 0.11$, respectively). IMCL content also did not differ significantly between groups ($P = 0.13$; Figure 2).

Conclusion: Subjects with impaired fasting glucose, impaired glucose tolerance and/or recently diagnosed diabetes as well as long-standing, insulin treated type 2 diabetes patients do not show any *in vivo* skeletal muscle mitochondrial dysfunction, when compared to healthy, normoglycaemic controls matched for age and body composition and with similar habitual physical activity levels. These findings imply that mitochondrial function does not necessarily represent either cause or consequence of insulin resistance and/or type 2 diabetes. Impairments in oxidative metabolism in type 2 diabetes patients as observed in previous studies might be secondary to a more sedentary lifestyle and/or impaired insulin signalling.

0179

Short-term elevation of plasma free fatty acids (ffa) decreases skeletal muscle mitochondrial membrane potential in healthy glucose tolerant subjects

D. Tripathy¹, A. Chavez-Velazquez¹, R. Jani¹, M. A. Abdul-Ghani¹, V. Frohlich², S. Padma¹, C. P. Jenkinson¹, F. Folli¹, R. A. DeFronzo¹;

¹Division of Diabetes, Dept of Medicine, University of Texas Health Science Center, San Antonio, ²Cellular & Structural Biology, University of Texas Health Science Center, San Antonio, United States.

Background and Aims: Elevated FFA play a pivotal role in the pathogenesis of insulin resistance. Experimental elevation of FFA produces insulin resistance in a dose dependent manner. Prolonged lipid infusion to cause a physiologic elevation in plasma FFA reduce expression of genes involved in mitochondrial function. Since FFA-induced insulin resistance typically is seen within 2–4 hrs, we examined whether mitochondrial dysfunction plays a role in FFA-induced impairment in insulin action.

Materials and Methods: 8 healthy NGT subjects (4 male / 4 female, age = 34 ± 3 y, BMI = 24.8 ± 1.0 kg/m², FPG = 90 ± 2 , 2 h Glucose 94 ± 2), without family history of T2DM, received a lipid infusion (60ml/h) for 8 hrs and euglycemic insulin clamps (80mU/m²min) with vastus lateralis biopsies before and after 6 hrs of lipid infusion which raised basal FFA from 576 ± 60 to 1382 ± 201 μ m. Mitochondrial membrane potential (Ψ), which is related to state of energization of mitochondria, was determined in skeletal muscles *ex vivo* with tetramethyl rhodamine ester (TMRE), which accumulates in mitochondria in response to change in Ψ . Mitochondrial mass was determined by Mitotracker Red. TMRE and Mitotracker fluorescence was quantitated with confocal laser microscopy. Skeletal muscle mitochondria morphology was examined by EM and mitochondrial DNA copy number was determined by RT-PCR before and after 6 hrs of lipid infusion.

Results: Mitochondria membrane potential (Ψ) decreased by 43% from 0.550 ± 0.06 to 0.283 ± 0.03 arb units, $p=0.02$, after 6 hrs of lipid infusion and the decrement in Ψ correlated with plasma FFA concentrations both at baseline ($r=0.888$, $p=0.008$) and at the end of lipid infusion ($r=0.823$, $p=0.02$). Mitochondrial mass (Mitotracker Red) did not change following lipid infusion (0.527 ± 0.2 to 0.449 ± 0.07 arb units, $p=ns$). Mitochondrial DNA copy number declined from 649 ± 112 to 511 ± 106 copies/genome, $p=0.02$. There was no change in mitochondrial morphology assessed by electron microscopy.

Conclusion: Short-term physiologic increase in plasma FFA conc induces mitochondrial dysfunction in skeletal muscle. This may be an important mechanism by which elevated FFA inhibit basal and insulin stimulated ATP synthesis and induces skeletal muscle insulin resistance in subjects with type 2 diabetes.

Effect of rosiglitazone treatment on *in vivo* mitochondrial function in type 2 diabetic patients

M. Mensink¹, V. B. Schrauwen-Hinderling^{1,2}, M. E. Kooi², M. K. C. Hesselink¹, P. Schrauwen¹;

¹Departments of Human Biology and Movement Sciences, Nutrition and Toxicology Research Institute NUTRIM, Maastricht University, The Netherlands, ²Dept of Radiology, University Hospital Maastricht, The Netherlands.

Background and Aims: Mitochondrial dysfunction has been implicated in the development of insulin resistance and type 2 diabetes mellitus. Using phosphorus Magnetic Resonance Spectroscopy (31P-MRS) we demonstrated that *in vivo* mitochondrial function is indeed reduced in diabetic patients. Rosiglitazone improves glycemic control and enhances insulin sensitivity. One of the underlying mechanisms could be a direct mitochondrial effect, as is suggested by studies in adipocytes. We recently showed that rosiglitazone increased the expression of PGC- α and PPAR β/δ in skeletal muscle of type 2 diabetic patients. In the present study we examined whether rosiglitazone treatment is also associated with an improved *in vivo* mitochondrial function in skeletal muscle.

Materials and Methods: Eight overweight subjects with type 2 diabetes mellitus were treated with rosiglitazone for 8 weeks. Before and after treatment, fasting plasma glucose, insulin and free fatty acids (FFA) levels, insulin sensitivity (hyperinsulinaemic-euglycaemic clamp), and mitochondrial function were determined. To evaluate *in vivo* mitochondrial function, the time to recover half of the phosphocreatine level after exercise was determined by 31P-MRS (PCr half-time). MRS measurements were performed on a 1.5T whole body scanner. A time-series of 120 spectra was acquired (TR=4s) during a protocol consisting of 2 minutes of rest, 5 minutes knee-extension exercise and 5 minutes recovery. Spectra were fitted with AMARES in the jMRUI 3 software package. PCr recovery time-course was fitted with a mono-exponential curve and the recovery half-time was calculated.

Results: Eight weeks treatment reduced plasma glucose (9.3 ± 0.7 to 8.8 ± 0.7 mmol/L), insulin (16.1 ± 2.9 to 13.4 ± 1.8 mU/L) and FFA (430.6 ± 29.8 to 398.5 ± 41.9 μ mol/L), although these differences did not reach statistical significance ($P > 0.05$). The glucose infusion rate (GIR) during the last 30 min of hyperinsulinemia was increased from 19.9 ± 2.8 to 24.8 ± 2.1 μ mol/kg/min ($P < 0.05$), indicating a reduction in insulin resistance. Rosiglitazone treatment did not significantly reduce PCr recovery half-time: 23.8 ± 3.5 to 20.0 ± 1.7 s ($P = 0.23$). Interestingly, the changes in PCr half-time correlated with changes in fasting plasma insulin level ($R = 0.70$, $P = 0.049$), and tended to correlate with fasted plasma glucose ($R = 0.60$, $p = 0.077$). Changes in PCr half-time however, did not correlate with changes in insulin sensitivity ($R = -0.10$, $P = 0.80$).

Conclusion: Although the data should be interpreted with some care regarding the limited number of subjects, rosiglitazone improved insulin sensitivity, while *in vivo* mitochondrial function was not (yet) improved. Moreover, changes in insulin sensitivity were not correlated with changes in mitochondrial function, suggesting that an improved mitochondrial function is not a prerequisite for rosiglitazone-enhanced insulin sensitivity. Interestingly, *in vivo* mitochondrial function improved the most in subjects who showed the largest reduction in plasma insulin and glucose levels. This could suggest that mitochondrial function can be affected by the degree of hyperglycemia or hyperinsulinemia, leaving the option of mitochondrial dysfunction being a consequence rather than cause of the diabetic state.

OP 31 Hypoglycaemia

0181

The ADA definition of hypoglycaemia: quantitatively examined and challenged

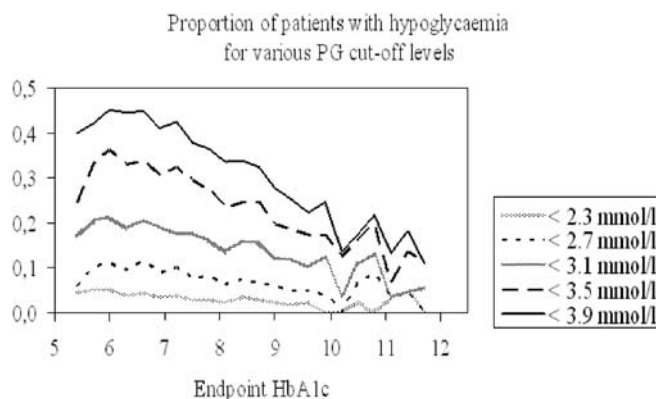

S. G. H. Swinnen¹, P. Mullins², M. Miller³, J. B. L. Hoekstra¹, F. Holleman¹;

¹Dept. of Internal Medicine, Academic Medical Centre, Amsterdam, The Netherlands, ²Dept. of Statistics, University of Auckland, New Zealand, ³Sanofi Aventis, Bridgewater, United States.

Background and Aims: In 2005 the ADA defined hypoglycaemia as an event with a measured plasma glucose (PG) concentration ≤ 3.9 mmol/l, as glucose counterregulation is activated at this level, and because antecedent hypoglycaemia of ≤ 3.9 mmol/l reduces sympathoadrenal and glucagon responses to subsequent hypoglycaemia. Although standardized reporting of hypoglycaemia is desirable, we fear that the ADA definition will limit attempts of both patients and doctors to achieve current HbA1c goals, while avoiding hypoglycaemia. The aim of this study was to investigate the relationships between hypoglycaemia and HbA1c when using various PG cut-off levels for hypoglycaemia.

Material and Methods: Data from 2 randomised clinical trials, examining insulin glargine dose titration in 12138 patients with type 2 diabetes uncontrolled by oral antidiabetic agents, were combined. In both studies hypoglycaemic events and HbA1c were prospectively recorded. The proportion of patients experiencing hypoglycaemia and the event rate during the final 12 weeks of the trials were plotted against endpoint HbA1c, constructing various curves representing pre-defined PG cut-off levels. Hypoglycaemia included all symptomatic and asymptomatic episodes with a measured PG concentration < 3.9 mmol/l and all severe events, defined by 3rd party assistance.

Results: 10502 patients with end of study HbA1c recorded 21265 hypoglycaemic episodes, including 253 severe, 9074 symptomatic and 11938 asymptomatic events. Comparing a hypoglycaemia cut-off level of < 3.1 mmol/l to the ADA definition more than doubles the percentage of affected patients at HbA1c 6.9–7.2% (17.6% vs. 42.6%) (Fig.). Considering event rates the discrepancy is even larger (0.5 vs. 2.5 events per 100 patient days), as the number of events per patient also increases with higher cut-offs. There were 4419 events with PG < 3.1 mmol/l in 1785 patients. Raising the cut-off level to < 3.9 mmol/l adds another 16839 events in a total of 3961 patients. The majority of these events occurred in patients who had also experienced hypoglycaemia below 3.1 mmol/l (9795 events in 1531 patients), versus those who had not (7044 events in 2176 patients). Of the severe hypoglycaemic events, 201 occurred in patients who had at some other time had an event < 3.1 mmol/l. Additionally, we found that further reduced cut-off levels (e.g. 2.7 mmol/l) conceal the increase in hypoglycaemia frequency expected with improved glycaemic control.

Conclusion: The frequency of hypoglycaemia is highly dependent on the PG concentration used for its definition. Raising the PG cut-off level from 3.1 to 3.9 mmol/l mainly identifies more episodes of clinically irrelevant hypoglycaemia. Standardized definitions of hypoglycaemia should be supported by quantitative examinations of hypoglycaemia rates, considering the clinical effects of the proposed cut-off value.

ICV catalase increases counterregulatory responses to hypoglycaemia in rats

C.-Y. Yueh¹, S. Moore¹, M. Osundiji¹, J. Shaw¹, L. Heisler², M. L. Evans¹;
¹Dept of Medicine, University of Cambridge, ²Dept of Clinical Biochemistry, University of Cambridge, United Kingdom.

Although chronic increases in oxidative stress have been causally implicated in the complications of diabetes, there is growing evidence that a short term rise in reactive oxygen species (ROS)- the products of oxidative stress- might play a physiological role in nutritional signalling. One ROS species in particular, hydrogen peroxide (PX), has also been implicated as a brain neurotransmitter. We hypothesised that hypothalamic nutrient-sensing neurons might detect a falling blood glucose by sensing the corresponding fall in hypothalamic PX, leading on to triggering of counterregulatory hormone (CRH) responses. Specifically, we anticipated that brain delivery of the anti-oxidant PX-catabolising enzyme catalase (CAT) during hypoglycaemia would cause PX levels to fall still faster and lead to an earlier triggering of CRH.

We studied overnight-fasted 300g healthy male Sprague Dawley rats with implanted vascular catheters and a single third ventricle (ICV) cannula. Rats underwent 210 min ICV infusion of either CAT (4.14 U/min, n=8) or vehicle (CON, n= 8). 90 min after starting ICV infusions, a stepped hyperinsulinaemic (20 mU/kg/min Humulin S) hypoglycaemic clamp study was started, with plasma glucose lowered sequentially in 40 minute steps to 5, 3.5 and 2.5 mM respectively. We measured plasma insulin, glucose and, for CRH, glucagon (GN) and adrenaline (AD). Plasma glucose thresholds for initiation of CRH for each rat were identified as the point at which responses rose more than 2 SD above starting levels. Baseline data before ICV infusions and at start of clamp studies were identical in both groups. During clamp studies, insulin rose and plasma glucose fell equally in both CAT and CON groups (table below).

	Glucose (mM)				Insulin (ug/l)	
	0 min	40 min	80 min	120 min	0 min	40 min
CON	6.3 ± 0.3	5.0 ± 0.2	3.5 ± 0.1	2.7 ± 0.1	1 + 0	30 + 5
CAT	6.3 ± 0.2	4.9 ± 0.3	3.4 ± 0.1	2.5 ± 0.1	1 + 0	30 + 5

During hypoglycaemia, CRH rose in both groups (figure below). In keeping with our hypothesis, the plasma glucose level at which AD responses were triggered was significantly higher in CAT than CON (3.8 ± 0.4 vs. 2.8 ± 0.4 mM; $p < 0.05$) GN also tended to rise earlier in CAT although differences failed to reach significance (3.9 ± 0.4 vs. 3.1 ± 0.4 mM; $P=NS$). In summary, brain delivery of catalase during hypoglycaemia altered the thresholds for CRH so that defensive hormonal responses were triggered at a higher plasma glucose level than controls. These data are consistent with our hypothesis that hypothalamic glucose-sensing neurones may sense changes in plasma glucose at least in part by sensing local changes in ROS.

Increased hexokinase activity in brain following recurrent hypoglycaemia

M. A. Osundiji, J. Shaw, S. Moore, S. Hoashi, C.-Y. Yueh, M. L. Evans;
 Dept of Medicine, University of Cambridge, United Kingdom.

Background and Aims: Brain is critically dependent on circulating glucose as a fuel source. As blood glucose levels fall, defensive counterregulatory responses are triggered and, if blood glucose falls low enough, cognitive function will become impaired. Recurrent insulin-induced hypoglycaemia as experienced by some diabetic patients can alter glucose thresholds for counterregulatory responses (CR) and perhaps also for cognitive impairment, suggesting that brain can adapt to exposure to hypoglycaemia and/or insulin and that these adaptations have clinical consequences. Following glucose transport into neurones, phosphorylation by hexokinase(s) (HK) is rate limiting for flux of glucose metabolites into downstream intracellular pathways to provide energy to support metabolism. We hypothesised, therefore, that brain might adapt to antecedent insulin-induced hypoglycaemia by an upregulation of HK.

Materials and Methods: Pilot studies using microarray suggested significant upregulation of HK expression in hypothalamus following recurrent hypoglycaemia. Consequently, we examined chronically catheterised (right jugular vein) adult male Sprague Dawley (SD) rats. Animals were exposed to 1 to 4 days of insulin injections (10, 8, 6 and 5 U/kg on days 1 to 4 respectively). The daily insulin dose was reduced to avoid profound hypoglycaemia as CR impairment developed. Plasma glucose was assayed using Analox GM-9 analyser over 90 minutes. At the end of studies, rats were euthanised and brains removed rapidly for *ex vivo* measurement of HK at 0.5mM glucose utilising a reporter assay which couples glucose phosphorylation with oxidation of glucose-6-phosphate.

Results: Despite reducing doses of insulin, nadir plasma glucose levels were significantly lower in rats exposed to four days relative to one-day of hypoglycaemia (table 1) in keeping with the development of defective CR following exposure to hypoglycaemia. Consistent with our hypothesis, recurrent insulin-induced hypoglycaemia significantly increased HK activities in both hypothalamus and brain stem over a period of 1 to 4 days.

	Day 1 (n=5)	Day 2 (n=3)	Day 3 (n=2)	Day 4 (n=5)
Basal plasma glucose (mM)	9.5 ± 0.4	9.3 ± 0.4	8.8 ± 0.2	9.2 ± 0.2
Nadir plasma glucose (mM)	3.6 ± 0.3	2.9 ± 0.4	3.6	*2.7 ± 0.1 (P=0.03)
Hypothalamic HK (mU/mg tissue weight)	0.16 ± 0.02	0.31 ± 0.06	0.37 ± 0.06	*0.57 ± 0.11 (P = 0.03)
Brain stem HK (mU/mg tissue weight)	ND	0.1 ± 0.02	0.182 ± 0.08	*0.252 ± 0.03 (P=0.005)

*= $P < 0.05$ vs first day of data, ND= no data

Conclusion: These findings suggest that brain adapts to recurrent hypoglycaemia by increasing HK activity in both hypothalamus and brain stem. We speculate that this increase in HK may, at least in part, contribute to (1) CR failure as a “maladaptive response” and/or (2) protect against hypoglycaemia-induced cognitive dysfunction as a protective response.

0184

Relationship between prior mild-moderate hypoglycaemic events and the risk of subsequent severe hypoglycaemia in patients with type 2 diabetes mellitus treated with basal insulin according to fasting BG targets: a time-dependent covariate analysis

A. Zisman¹, M. Miller², R. Tanenberg³;

¹Endocrine, Diabetes & Metab, Univ of Miami Miller School of Med, Miami, United States, ²sanofi-aventis U.S., Bridgewater, United States, ³Division of Endocrinology, Brody School of Medicine, Greenville, United States.

Background and Aims: Patients with T2DM often do not meet recommended glycosylated hemoglobin A1C (A1C) goals (<7.0%). Studies have shown that adjusting basal insulin dose to achieve these goals may be limited by hypoglycemic episodes. The aim of this study is to examine the role of prior episodes of moderate hypoglycemia (MMH) and mild hypoglycemia (MH) on the subsequent risks for severe hypoglycemia (SH) and moderate/severe hypoglycemia (MSH) within the context of titration target.

Methods: This analysis of a 24-wk, randomized study investigated the effect of titration algorithms for insulin glargine (GLAR) on SH event rates and glycemic control in patients with T2DM (N=4988). Treatment included once-daily GLAR, titrated weekly according to algorithm group (defined by fasting blood glucose [FBG] goals = 80, 90, 100, 110, or 120mg/dL, respectively). Time to first occurrence of SH and of MSH were studied with and without a prior occurrence of MMH or MH respectively.

Results: Baseline characteristics (mean A1C, 9.2%; body mass index, 34.7kg/m²) and study completion (88.40–90.57%) were similar among titration groups. A Cox proportional hazards model revealed that the risk for a first occurrence of an SH event declined as titration targets increased. Every 10-mg/dL increase in the target yielded an estimated 28.5% reduction in risk (slope coefficient for log hazard, -0.034; P<0.001 based on 107 SH events). This methodology revealed that prior occurrence of an MMH event substantially increased the risk of an SH event in all study arms and reduced the rate of decline in risk with increasing titration target (slope coefficient of log hazard = -0.014, P>0.4, based on 59 SH events with prior MMH). In patients without prior MMH, the decline in risk of SH event with increasing titration target remained statistically significant (slope coefficient for log hazard = -0.034, P<0.005 based on 48 SH events). Also, prior occurrence of MH increased the risk of MSH over 9 fold, but the effect of titration target was not altered.

Conclusion: Prior occurrence of MMH increases risk of an SH event and weakens the decline in SH event risk with increasing targets. Prior occurrence of a mild event does not weaken this effect of titration target on the risk of MSH. Patients experiencing MMH may need to adjust their individual diabetes care plan, but they should not automatically alter titration targets to avoid later SH event. However, avoidance of MSH following a mild event would entail a less aggressive titration target.

This new analysis supports the previous conclusion of the GOT study that targeting an FBG goal of 100–110mg/dL would yield a beneficial balance between glycemic goals and hypoglycemia. (Tab. 1)

Insulin binding to antibodies is a risk factor for inexplicable severe hypoglycaemia in children with type 1 diabetes mellitus

O. Seewi¹, C. Jaeger², R. G. Bretzel², E. Schönau¹;

¹Paediatric Diabetology, University of Cologne, Germany, ²Medical Department III, University of Giessen, Germany.

Background and Aim: Type 1 diabetic patients differ with regard to both, the formation of circulating insulin antibodies, and the incidence of severe hypoglycaemia (SH). Aim of the study: to assess the association of insulin binding to antibodies with the incidence of SH.

Patients and Methods: In a cross sectional study, 73 children with type 1 diabetes mellitus (median age 14 years, duration of diabetes 6 years) were investigated, 22 of whom ever, and 51 never had experienced SH. Of the patients with SH, 16 had experienced SH deemed inexplicable, and 6 had experienced SH which deemed explicable (by missed meals, unplanned physical exercise etc.). Insulin binding was measured by radioimmunoassay, and expressed as ratio bound/unbound insulin; a binding > 15% was considered relevant insulin binding (RIB).

Results: A total of 38 patients displayed RIB (17 of whom had experienced SH), and 35 patients did not display RIB (5 of whom had experienced SH; p=0.0055, Fisher's exact test). Patients with RIB were younger (13 versus 15 years, p=0.006) than patients without RIB. Of the 16 patients with inexplicable SH, 15 displayed RIB, compared to 2 of the 6 patients with explicable SH (p=0.009). The association of any SH, and of inexplicable SH, with RIB was significant (odds ratio 4.8(95%CI 1.5–15.2), and 22.1(95%CI 2.7–179.6), p<0.006). Patients with/without RIB, or with/without SH, were comparable regarding sex, duration of diabetes, number of insulin injections per day, HbA1c and C-peptide levels (ANOVA).

Conclusion: Insulin binding to antibodies > 15% appears to be a strong risk factor for inexplicable severe hypoglycaemias in type 1 diabetic children.

Hypoglycaemia does not increase long-term mortality or morbidity in diabetic patients with myocardial infarction: a report from the DIGAMI 2 trial

L. G. Mellbin¹, K. Malmberg¹, A. Waldenström², H. Wedel³, L. Rydén¹;

¹Department of Cardiology, Karolinska Institutet, Stockholm, Sweden, ²Department of Cardiology, University Hospital, Umeå, Sweden, ³Nordic School of Public Health, Nordic School of Public Health, Göteborg, Sweden.

Background and Aims: Tight, insulin-based glucose control is recommended to diabetic patients (DM pat) with acute myocardial infarction (AMI). A potential draw-back would be if insulin induced hypoglycaemia (HG) had a negative impact of future prognosis.

Materials and Methods: 1253 pat (mean age 68 years; 67% males) with type 2 DM and suspect AMI were followed for a median of 2.1 years. 947 were randomised to insulin infusion during at least 24 hours while 306 were treated routinely. HG (blood glucose<3.0 mmol/L with or without symptoms) was recorded during hospitalisation. Unadjusted and adjusted (age, sex, smoking, previous MI and heart failure, renal function, duration of DM, coronary interventions, blood glucose at randomisation) Hazard Ratios (HR) and 95% Confidence Intervals (CI) for cardiovascular events (CVE = death, MI or stroke) during follow up were calculated.

Results: 153 pat (12.2%) experienced HG. During the first 24 hours 111 (11.7%) insulin-treated pat experienced HG (symptomatic 23.4%) compared

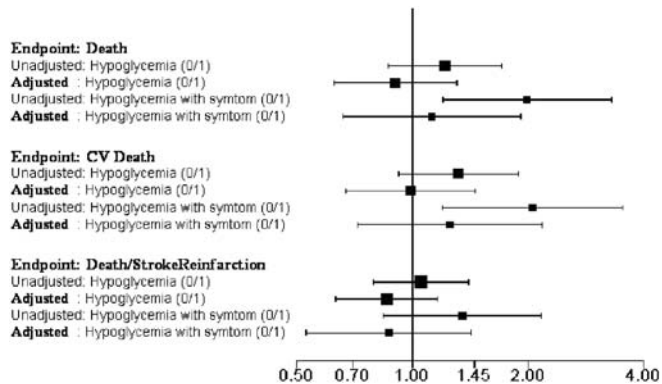

Tab. 1

Treatment Group (Target FBG, mg/dL)	SH Event Occurrence Hazard (SE) events/sbj-y			Risk Ratios	
	All	No prior MMH event	With prior MMH event	Prior event/ no prior event (95% CI)	P value effect of prior event
80	0.088 (0.014)	0.072 (0.040)	0.144 (0.080)	2.01 (1.03, 3.91)	0.039

CI = confidence interval

with 3 (1.0%) pat on routine treatment (symptomatic 33.3%). As outlined in the figure HG was not an independent predictor of subsequent CVE.

Conclusion: Insulin induced HG was not a significant risk factor for subsequent CVE in AMI-pat with type 2 DM. Hypoglycaemia seem to identify patients at high risk for other reasons.

Differential relationship between family relationships and HbA_{1c} by insulin regimen in adolescents with type 1 diabetes

T. Skinner¹, C. de Beaufort², P. G. F. Swift³, F. Cameron⁴; Hvidoere Childhood Diabetes Study Group,

¹Psychology, University of Wollongong, Australia, ²DECCP, Clinique pédiatrique de Luxembourg, Luxembourg, ³Paediatrics, Leicester Royal Infirmary, United Kingdom, ⁴Dep of Endocrinology & Diabetes, Royal Children's Hospital, Melbourne, Australia.

Background and Aims: To establish whether the relationship between family interaction and diabetes outcome, varies as a function of insulin regimen

Material and Methods: Cross-sectional study of adolescents with type 1 diabetes and their parents was conducted in 21 paediatric diabetes centres across 19 countries. Demographic data, details of insulin regimens, severe hypoglycemic events and number of episodes of diabetic ketoacidosis were recorded. Adolescents completed the Diabetes Quality of Life (DQOLY-SF), the Diabetes Family Responsibility Questionnaire (DFRQ) and the HBSC Well-Being questionnaire. Parents completed the DFRQ and the WHO-5 Well-Being questionnaire. A capillary blood sample was drawn from each patient and analyzed centrally for HbA_{1c}.

Results: 2269 adolescents (age 14.5 SD 2.0; duration 6.1 SD 3.5, 49% female) participated, and the insulin regimens were classified as BD Insulin (n = 459) basal bolus regimen (n = 938), CSII pump (n = 336). Those on TD regimens (n = 68) or who could not be readily classified into one of these insulin regimens (n = 468) are not included in this analysis. Mothers of adolescents on CSII pumps had more positive mood than all other regimens, followed by basal bolus and BD regimens (F = 5.3; p < .001), whereas adolescents on basal bolus and CSII regimens reported lower well-being than individuals on BD regimens (t = 2.49; p < .05). Adolescents' perception of parental over-involvement in care was related to HbA_{1c}, emotional well-being, diabetes related worry and impact of diabetes in all insulin regimen groups. However, for parent-adolescent disagreement on diabetes care responsibility, there was no relationship with HbA_{1c} for those on BD or Basal Bolus regimens, but there was for those using CSII pump (F = 7.79; p < .001). Controlling for diabetes centre, age, duration and gender effects does not affect the pattern of these results.

Conclusion: Family interaction may be of more importance for achieving optimal outcomes for individuals using CSII, than in other insulin regimen groups.

Continuous subcutaneous insulin infusion (CSII) of insulin aspart vs. insulin lispro in paediatric subjects (ages 4 to 18 years) with type 1 diabetes (T1D)

C. Ternand¹, S. A. Weinzimer², L. M. B. Laffel³, C. Howard⁴, C.-T. Chang⁴, D. J. Becker⁵;

¹Endocrinology, University of Minnesota Children's Hospital, Minneapolis,

²Pediatric Endocrinology, Yale University School of Medicine, New Haven,

³Pediatric, Adolescent and Young Adults, Joslin Diabetes Center, Boston,

⁴CMR, Novo Nordisk Inc., Princeton, ⁵Dept. of Pediatric Endocrinology,

Children's Hospital of Pittsburgh, United States.

Background and Aims: Insulin aspart and insulin lispro are rapid-acting insulin analogues currently indicated for administration via multiple daily injection (MDI) therapy in children and adolescents, and for use in MDI and CSII therapy in adults with T1D. The aim of this study was to compare the safety and efficacy of insulin aspart vs. insulin lispro administered via CSII in paediatric subjects (4 to 18 years) with T1D.

Materials and Methods: This was a 16-week, open-label, randomised, parallel-group, 45-site, U.S. clinical trial. Subjects ages 4–18 years, diagnosed with T1D ≥ 1 year and previously treated for ≥ 3 months with analogue insulin CSII therapy were randomised 2:1 to receive aspart or lispro for 16 weeks via insulin pump (N = 198 aspart, N = 100 lispro). Standard diabetes safety and efficacy measurements were collected over 13 visits.

Results: Aspart was non-inferior to lispro (as measured by change in HbA_{1c} from baseline to end-of-study [EOS]) (95% CI [-0.27, 0.07]). HbA_{1c} change in HbA_{1c} and fasting plasma glucose (FPG) values were not significantly different between aspart and lispro (Table). The percentage of subjects who achieved their age-specific 2006 ADA paediatric HbA_{1c} targets (< 8.5% for subjects < 6 yrs; < 8% for subjects 6–18 yrs) was insignificantly higher at baseline, but significantly greater in the aspart group vs. the lispro group at Week 16. At Week 16, daily weight-adjusted insulin dose was significantly lower for subjects treated with aspart, as compared to lispro.

		Aspart N=198	Lispro N=100	p-value
HbA _{1c} (mean ± SD), %	Baseline	8.04 ± 0.94	8.15 ± 0.84	0.301
	EOS	7.88 ± 0.93	8.07 ± 0.85	0.238
Δ HbA _{1c} (LS mean ± SE), %	Baseline to EOS	-0.15 ± 0.05	-0.05 ± 0.07	0.241
	EOS	9.25 ± 3.74	10.01 ± 4.59	0.113
FPG (mean ± SD), mmol/l	EOS	9.25 ± 3.74	10.01 ± 4.59	0.113
% subjects at age-specific HbA _{1c} goal	Screening	50.3	40.4	0.138
	Week 16	59.7	43.8	0.014
Weight-adjusted insulin dose, U/kg/day	Week 16	0.86 ± 0.24	0.94 ± 0.23	0.018

There were no statistically significant differences between treatment groups in major hypoglycaemic events (requiring third-party assistance) per subject year (aspart, 0.42; lispro, 0.3 [p=0.482]) or minor hypoglycaemic events (PG < 3.1 mmol/l) per subject year (aspart, 77.18; lispro, 65.95 [p=0.129]). The incidence of hyperglycaemia episodes (PG > 16.67 mmol/l) recorded as adverse events (AEs) was 10.6% and 17.0% in the aspart and lispro treatment groups, respectively. The percentages of subjects experiencing at least 1 AE were similar between treatment groups (aspart, 81.8%; lispro, 83.0%). Treatment with either aspart or lispro did not adversely affect physical examination findings, vital signs, or laboratory parameters.

Conclusion: Insulin aspart is as effective and safe as insulin lispro for CSII use in paediatric subjects 4–18 years of age, with approximately 60% of insulin aspart-treated youth achieving age-specific HbA_{1c} goals.

Lower within-subject variability in pharmacokinetic profiles of insulin detemir in comparison to insulin glargine in children and adolescents with type 1 diabetes

T. Danne¹, L. Endahl², H. Haahr², N. Datz¹, C. Nestoris¹, L. Westergaard², O. Kordonouri¹;

¹Diabetes Centre for Children and Adolescents, Kinderkrankenhaus auf der Bult, Hannover, Germany, ²Novo Nordisk A/S, Bagsvaerd, Denmark.

Background and Aims: Insulin detemir has previously been shown to be associated with a lower within-subject variability compared to other basal insulin preparations in adults with type 1 diabetes. This randomised, double-blind, cross-over trial compared the within-subject variability of pharmacokinetic profiles of insulin detemir and insulin glargine in children and adolescents with type 1 diabetes.

Materials and Methods: Thirty-two children and adolescents with type 1 diabetes (19 girls and 13 boys, 8–17 years of age, BMI: 21.4±2.9 kg/m², HbA_{1c}: 7.9%±1.0%) were randomised to two s.c. doses (0.4 units/kg) of each insulin. There were two dosing visits. Insulin detemir and insulin glargine were injected 24 hours apart at each of two dosing visits. Insulin concentrations were measured at frequent intervals for 16 hours post dosing. Carry-over effect was eliminated due to specific insulin assays without cross-reaction.

Results: Insulin detemir showed significantly less within-subject variability compared to insulin glargine (3.1 and 2.9 fold lower %CV for AUC(0–16h) and Cmax, respectively), see table below. Similar findings were observed when insulin profiles for children and adolescents were analysed separately. No safety concerns were raised during the trial.

Within-Subject Variability (%CV)

	Insulin Detemir	Insulin Glargine	P-values
AUC(0–16h)	10%	31%	< 0.0001
Cmax	12%	35%	< 0.0001

Conclusion: In conclusion, within-subject variability in pharmacokinetic properties was significantly lower for insulin detemir than for insulin glargine in children and adolescents with type 1 diabetes. This indicates a less variable absorption with insulin detemir, which is expected to be associated with a more predictable therapeutic effect in this population.

Continuous glucose monitoring (CGMS) enhances the detection of cystic fibrosis related diabetes (CFRD) in children with cystic fibrosis

S. M. P. O’Riordan^{1,2}, E. F. Roche^{1,2}, S. George^{1,2}, H. M. V. Hoey^{1,2}, C. Costigan³;

¹Paediatric Diabetes and Endocrinology, The National Childrens Hospital, AMNCH, DUBLIN, ²Paediatric Diabetes and Endocrinology, The University of Dublin, Trinity College, Dublin, ³Paediatric Diabetes and Endocrinology, Our Ladys Hospital for sick children, Crumlin, Dublin, Ireland.

Background and Aims: Cystic Fibrosis Related Diabetes (CFRD) and impaired glucose intolerance (IGT) are now frequent complications with improved survival in children with cystic fibrosis (CF). The increased morbidity and mortality associated with CFRD emphasizes the need for accurate screening. Many of the screening tools for the diagnosis of CFRD rely on standardised thresholds in the oral glucose tolerance test (OGTT) derived from epidemiological studies based on non-CF populations for the diagnosis of type 1 and 2 diabetes. Current screening tools are inadequate for the diagnosis of CFRD in children. Aims: to evaluate continuous glucose monitoring (CGMS) in CF children; compare results with OGTT and HbA_{1c} and determine if CGMS enhances the detection of CFRD.

Materials and Methods: 101 CF children had paired screening with OGTT & CGMS: patients commenced CGMS after 1 hour calibration, underwent OGTT and continued CGMS for 48 hours. Assessment was repeated after 6 months. **CGMS analysis:** All cases were individually analysed by experienced physicians in the management of diabetes in children. All CGMS glucose values were carefully analysed for mean glucose, variability (MAGE, MODD & CONGA), duration and degree of hyperglycaemia. Clinical assessment was considered essential and individualised in every case.

Results: Children were categorized as normoglycaemic (NGT), IGT and CFRD. 101 children with CF were screened at baseline and 100(99%) underwent repeat assessment at 6 months. Paired screening identified 12 new cases of CFRD. Insulin therapy was commenced in 12 cases following assessment of OGTT, CGMS and clinical status of each child.

Screening children with CF with OGTT and CGMS at Tme 0 & 6 months

Glucose tolerance category	Baseline OGTT	Baseline CGMS	Baseline Paired Diagnosis	6mths Followup OGTT	6mths Followup CGMS	6mths Followup Paired Diagnosis
NGT	71	60	65	70	65	61
IGT	14	12	11	15	14	11
CFRD	16	29	24†	15	21	28†
Totals	101	101	101	100	100	100

Correlation coefficient r=0.88, p<0.001†

Over a total 12 months time period 8% converted from NGT to IGT; 88% were unchanged and 5% progressed from IGT-CFRD. CGMS correlates well with OGTT at all 5 time points (r=0.75–0.88). CGMS correlated less well with HbA_{1c} (r=0.27, p>0.05) mean 5.5% range 3.8–9.0%). 20% of cases had abnormal HbA_{1c} results; 50% of these were defined as NGT on OGTT and CGMS screening.

Conclusion: HbA_{1c} and OGTT alone are not sensitive screening tools in CF. CGMS enhances early detection of abnormalities of glucose tolerance by revealing important trends that facilitate diagnosis. This report highlights the need to redefine the diagnostic criteria for CFRD, as HbA_{1c} and OGTT are

missing up to 75% and 27% of glucose intolerance in CF children, respectively. We propose annual paired screening OGTT & CGMS in all children with CF over 10 years if there is any clinical suspicion of diabetes development.

The evaluation of bone mineral density in diabetic children with celiac disease and the influence of gluten free diet and diabetes control on bone mineralisation

J. Nazim¹, J. Starzyk¹, E. Czerwiński²,

¹Endocrinology Department, Polish-American Children's Hospital,

²Radiology Department, Jagiellonian University, Medical College, Kraków, Poland.

Background and Aims: The prevalence of celiac disease in children with type 1 diabetes greatly exceeds the prevalence of this disease in general population. Celiac disease in diabetic kids is usually asymptomatic and untreated, may lead to serious complications; one of these is osteopenia. The aim of the study was to determine whether bone mineralisation is reduced in diabetic children and adolescents with celiac disease and the influence of gluten free diet on bone mineral density (BMD).

Materials and Methods: We measured lumbar spine (LS) BMD in 15 children and adolescents aged 5.1–17.8 years (median 10.1 yr) with type 1 diabetes of median duration 4.1 years (0.4–13.1 years) and celiac disease. Control group comprises 10 diabetic children without celiac disease. BMD was assessed by dual-energy x-ray absorptiometry (DXA) at diagnosis of celiac disease, one and two years thereafter. Celiac disease was diagnosed on the basis of intestinal biopsy specimen microscopic examination in children positive for antiendomysial antibodies. All children had silent or subclinical form of the disease. Glycemic control was estimated using glycated hemoglobin measurement by HPLC method (BioRad).

Results: At diagnosis of celiac disease BMD Z-score was reduced in diabetic kids compared to control group (–0.1 to –3.6, mean –1.2±0.8 SD vs –0.7 to 0.9, mean –0.4±0.3 SD) in spite of the similar diabetes control. Four kids with osteoporosis (Z-score < –2SD) had the worst mean year HbA1c in comparison with 4 children with osteopenia (Z-score –1SD to –2 SD) and patients with normal BMD values (8.7% vs 8.3% vs 7.4%). One and two years of gluten free diet improved BMD Z-score in 10 children, in three patients with osteoporosis who were not adherent to the diet, BMD decreased from 0.3 to 0.9 SD despite supplementation of vitamin D and calcium.

Conclusion: Children with type 1 diabetes should be screened towards celiac disease. Gluten free diet and good glycemic control favoured the accrual of bone mass in diabetic children with celiac disease.

were used both within and between the 21 centres. Mean HbA1c = 8.2% SD 1.4, with significant influence of age ($r=0.1$; $p<0.001$), gender (females $8.3\% \pm 1.5$, males $8.1\% \pm 1.3$; $t=3.0$; $p<0.005$), diabetes duration ($r=0.29$; $p<0.001$). 91.7% of girls and 93% of boys stated they miss insulin to control weight “once a month”, 5.1% and 4.2% respectively stated they never miss insulin to control weight. 2.5% and 1.9% respectively stated they omitted insulin once a week and 0.7% and 0.9% respectively stated they did that every day. Multiple regression analysis showed that omission of insulin to control weight was significantly associated with poor HbA1c ($\beta=-.103$, $t=2.558$, $p=0.011$) after controlling for age and gender effect.

Conclusion: Self-reported omission of insulin to control weight in both female and male adolescents was common in this large international cohort. It was associated with poorer glycaemic control. These findings suggest that concerns about weight gain associated with insulin therapy may have significant short and long-term clinical implications. The findings suggest that screening for insulin omission related to weight control might be warranted in paediatric care. Appropriate intervention may involve education, counselling and adjustment of treatment regimens.

⁴Children's Hospital, Leicester Royal Infirmary, United Kingdom,

⁵Centre Differences Study, Hvidøre Study Group, Bagsvaerd, Denmark.

Background and Aims: Large proportion of adolescents with diabetes fail to achieve optimal glycaemic control despite availability of effective medicine. The aim of this study was to examine the extent of self-reported omission of insulin associated with weight concern and the relationship to glycaemic control in a large international cohort of adolescents with type 1 diabetes.

Materials and Methods: Questionnaires were completed by adolescents and their parents/carers in 21 international centres. Questionnaires investigated age, gender, diabetes duration, insulin regimens, insulin adjustments and glycaemic targets as well as psychosocial and service provision factors. HbA1c (DCCT adjusted) was measured centrally.

Results: Questionnaires were completed by 2062 adolescents (age 14.4 y ±/– 2.3 y, male 50.6%, diabetes duration 6.1y ± 3.5). Different insulin regimens

Depot-related differences in insulin action and signaling, gene expression, and adiponectin secretion in human adipocytes differentiated *in vitro* from precursor stromal cells

S. Perrini¹, L. Laviola¹, A. Natalicchio¹, A. Cignarelli¹, M. Melchiorre¹, F. De Stefano¹, C. Caccioppoli¹, M. R. Orlando¹, G. Garruti¹, M. De Fazio², V. Memeo², R. Giorgino¹, F. Giorgino¹;

¹Endocrinology & Met. Diseases, ²General Surgery, University of Bari, Bari, Italy.

Background and Aims: Visceral and subcutaneous fat depots possess different metabolic properties, that can be demonstrated both in whole-tissue specimens and isolated adipocytes. In this study, we have investigated whether human adipocytes obtained from visceral and subcutaneous fat depots retain distinct properties also when they are differentiated *in vitro* from precursor stromal cells.

Materials and Methods: Paired visceral and subcutaneous biopsies were obtained from 15 non-obese, non-diabetic subjects undergoing open abdominal surgery. Precursor cells were isolated, grown to confluence, and differentiated *in vitro* into adipocytes. Terminal differentiation was assessed by visual inspection, Oil-O-Red staining, and gene expression of adipocyte-specific proteins using real-time PCR. Intracellular insulin signaling was studied by immunoblotting with specific antibodies.

Results: Differentiated adipocytes showed marked up-regulation of GLUT4, PPAR γ , C/EBP α , aP2, and adiponectin mRNA levels compared to the pre-adipocytes, whereas GLUT1 expression did not change during adipogenesis. mRNA levels of C/EBP α , adiponectin and aP2 were found to be higher in subcutaneous than in visceral adipocytes. By contrast, basal adiponectin secretion in the culture medium was 3-fold higher in visceral than in subcutaneous adipocytes. When compared to subcutaneous adipocytes, visceral adipocytes also showed 50% higher rates of insulin-stimulated glucose transport, measured by determining 2-deoxy-D-glucose uptake rates. Intracellular insulin signaling was next investigated following stimulation with 10 nM insulin for 5 to 120 min. Insulin-induced phosphorylation of the insulin receptor, IRS-1/2, Akt and Erk-1/2 appeared to be more rapid and tended to decrease at earlier time points in visceral than in subcutaneous adipocytes, in which phosphorylation of these signaling proteins in response to insulin was more gradual and persistent.

Conclusion: Subcutaneous and visceral adipocytes, also when differentiated *in vitro* from precursor stromal cells, retain differences in gene expression, adiponectin secretion, and insulin action and signaling. This suggests that the precursor cells resident in the visceral and subcutaneous fat depots possess inherent and specific metabolic characteristics that are expressed upon completion of the differentiation programme.

Effect of beta-adrenergic stimulation on whole-body and regional abdominal subcutaneous adipose tissue lipolysis in lean and obese men

J. W. E. Jocken¹, G. H. Goossens¹, A. van Hees¹, K. N. Frayn², M. van Baak¹, M. Pakbiers³, W. H. M. Saris¹, E. E. Blaak¹;

¹Human Biology, Maastricht University, The Netherlands,

²Oxford Centre for Diabetes, Endocrinology and Metabolism, Oxford University, United Kingdom,

³Nuclear Medicine, University Hospital Maastricht, The Netherlands.

Obesity is characterized by increased triacylglycerol (TAG) storage in adipose tissue. There is evidence for a blunted catecholamine-induced lipolytic response in adipose tissue of obese subjects. *In vitro* studies suggest that the site of this catecholamine resistance is abdominal subcutaneous adipose tissue. We investigated for the first time *in vivo* whole-body and regional abdominal subcutaneous adipose tissue glycerol metabolism during 3h and 6h [2H5]-glycerol infusion. Arterio-venous differences were measured in 13 lean and 10 obese male subjects after an overnight fast and during intravenous infusion of the non-selective beta-adrenergic agonist isoprenaline (20ng. kg FFM⁻¹. min⁻¹). Lean and obese subjects showed significant but comparable glycerol uptake by adipose tissue (9.7+/-3.4 vs. 9.3+/-2.5 % of total release, P=0.92; P<0.05 compared to zero). Second, obese subjects showed an increased

whole-body lipolytic response, due to their increased fat mass. In contrast, obese subjects showed a blunted fasting lipolysis (glycerol Ra: 7.3+/-0.6 vs. 13.1+/-0.9 micromol. kg FM⁻¹. min⁻¹, P<0.01) and lipolytic response per unit fat mass (delta total glycerol release: 140+/-71 vs. 394+/-112 nmol. 100g tissue⁻¹. min⁻¹, P<0.05) compared with lean subjects. Finally, net TAG extraction was increased in the obese during beta-adrenergic stimulation. In conclusion, a blunted adipose tissue TAG mobilization and increased TAG extraction during beta-adrenergic stimulation may be important factors in the development or maintenance of increased TAG stores in obesity.

Proteomic analysis reveals differential expression of chaperones and redox proteins in human adipose tissue in response to rosiglitazone treatment

M. Ahmed^{1,2}, F. Karpe¹;

¹Oxford Centre for Diabetes, Endocrinology & Metabolism, University of Oxford, United Kingdom,

²Department of Physiology, Ibrahim Medical College, Dhaka, Bangladesh.

Background and Aims: Increased reactive oxygen species (ROS) production and ER stress are positively linked with obesity, insulin resistance and type 2 diabetes. In adipocytes, elevated levels of fatty acids and glucose increase oxidative stress and cause dysregulated production of adipokines suggesting the redox state in adipose tissue as a potentially useful therapeutic target. Rosiglitazone is an insulin sensitizing drug with adipose tissue as its primary target. We, therefore, used the unique potential of the two-dimensional based proteomics and explored the synchronized changes in expression of antioxidants and chaperones in rosiglitazone-treated human adipose tissue.

Materials and Methods: Six healthy moderately obese men aged 42±2 years were treated with rosiglitazone 4 mg BD for 14 days and adipose tissue biopsies were taken at day 0 (without medication), day 1 and day 14. Plasma samples were analyzed for glucose, lipids and insulin to verify global insulin sensitization. Adipose tissue protein profiles were obtained by two-dimensional gel (2-DG) electrophoresis. Spot identification was made by tandem mass spectrometry.

Results: Short-term treatment with rosiglitazone improved glycemic control and reduced plasma insulin and NEFA levels. In adipose tissue, rosiglitazone significantly (p<0.01) reduced the expression of peroxiredoxin-2 whereas superoxide dismutase [Mn] showed increased expression. There was no significant change in the expression of catalase. Another antioxidant, ferritin light chain appeared as a new spot (3 fold change) in response to rosiglitazone. One of the transferrin spots showed significant (p<0.05) increase on day 14. The expression of aldehyde dehydrogenase, which protects against lipid peroxidation-induced stress and insulin resistance, showed 1.5 fold rise but no significant association. Proteins involved in ER stress like endoplasmic (HSP90B1/GRP94), GRP78, and GRP58 showed reduced expression indicating proper protein folding and reduced ER stress. Both HSP27, which prevents activation of IKK- β and HSP20 (HSPb5), which promote survival of cells subjected to different form of stresses, were significantly over-expressed in rosiglitazone treated adipose tissue.

Conclusion: Thus, some of the major changes observed among the mentioned proteins suggest rosiglitazone reduces NF- κ B activation and ROS production, corrects protein folding and reduces ER stress, regulates cytoskeletal assembly as well as enhances adipocyte survival. Such orchestrated changes in expression of multiple proteins may help to explain mechanisms behind improvement of insulin sensitivity in response to rosiglitazone treatment.

In human adipocytes exposed to high glucose and insulin levels, IRS-1 displays altered phosphorylation and may be targeted for degradation

F. Renstrom¹, M. Lundgren¹, S. Lindmark¹, J. W. Eriksson^{2,3};

¹Medicine, Umea University Hospital, Sweden, ²Lundberg Laboratory for

Diabetes Research, Sahlgrenska University Hospital, Gothenburg, Sweden,

³AstraZeneca R&D, Molndal, Sweden.

Background: In human subcutaneous adipocytes exposed to high insulin and high glucose in combination, IRS-1 depletion occurs as a secondary

phenomenon after the development of a defect in insulin-stimulated glucose transport. Insulin-stimulated phosphorylation of IRS-1 at Tyr⁶¹² leads to activation and propagates the insulin signal, whereas Ser³¹² phosphorylation is implicated in IRS-1 deactivation and in insulin-induced degradation of IRS-1. In the present study we aimed to investigate whether alterations in Tyr⁶¹² and Ser³¹² phosphorylation are seen in this model of cellular insulin resistance.

Methods: Abdominal subcutaneous needle biopsies were performed on 17 healthy nondiabetic subjects (7M/10F, age 45±4, BMI 25±1). Isolated adipocytes were cultured for a total of 24 h in 6 mM glucose with or without addition, during the final 2, 6 or the entire 24 h, of high insulin alone (10⁴ μU/mL, n=7) or insulin in combination with high glucose (final conc 20 mM, n=10). Then cells were washed and treated with or without 10³ μU/mL insulin for 15 or 10 min. ¹⁴C-glucose uptake in intact cells was measured, and IRS-1 (total as well as phospho-Tyr⁶¹² and phospho-Ser³¹²) was assessed in cellular lysates with immunoblotting using specific antibodies.

Results: Pretreatment with high insulin + glucose for 2 h or more was associated with a reduced (by ~40–50%, p<0.05) insulin-stimulated glucose uptake capacity. In parallel, there was an increased basal Ser³¹² phosphorylation of IRS-1 (by ~80%, p<0.05). In accordance with this, a ~50% decrease (p<0.05) in the protein level of IRS-1 was evident after 6 and 24 h pretreatments. High insulin levels alone induced a smaller increase in Ser³¹² phosphorylation (by ~40%, p<0.05) and did not consistently alter IRS-1 protein content. However, high insulin levels for 2 h or longer produced an impaired insulin-stimulated glucose uptake capacity (by 30–40%, p<0.05). Moreover, basal Tyr⁶¹² phosphorylation was increased by >400% (p<0.05) following insulin pretreatment with or without high glucose. No change in subsequent insulin-stimulated Tyr⁶¹² phosphorylation was seen, but accordingly the relative effect of acute insulin stimulation was attenuated.

Conclusion: High glucose and insulin levels in combination can enhance IRS-1 phosphorylation at Ser³¹² and this can contribute to impaired insulin signalling and is likely to target IRS-1 to a degradation pathway. These findings in human adipocytes may be of relevance for adipose tissue insulin resistance in type 2 diabetes.

Gender differences in insulin sensitivity also include differences in expression of IRS-1 in subcutaneous adipocytes

F. Pellme, A. Hammarstedt, U. Smith, P.-A. Jansson;

The Lundberg Laboratory for Diabetes Research, Goteborg University, Sweden.

Background and Aims: We have previously shown in male subjects that low adipocyte IRS-1 expression is related to impaired insulin sensitivity in muscle, hypertriglyceridemia, hypoadiponectinemia and atherosclerosis, supporting a significant role of adipose tissue in the Insulin Resistance Syndrome. We have now evaluated gender differences in IRS-1 expression, metabolic profile and circulating markers of endothelial function in non-diabetic first degree relatives of type 2 diabetic patients (FDR).

Materials and Methods: We recruited by advertisement 125 FDR of both genders (Age: 42±7 vs. 39±7 yrs (ns) (Mean±SD); BMI: 25.5±2.5 vs. 24.7±3.6 kg/m², p<0.05; Waist/Hip-ratio: 0.92±0.06 vs. 0.81±0.06, p<0.0001; Cigarette pack years: 3.1±5.7 vs. 2.4±5.1 yrs (ns) in male (n=44) and female (n=77) FDR, respectively). All subjects underwent a modified euglycemic hyperinsulinemic clamp (40 mU/m²/min), monitoring of blood pressure and venous blood sampling. On a separate day a subcutaneous needle biopsy was performed and isolated fat cells were lysed and IRS-1 protein expression quantified by Western blot using rhIRS-1 as reference.

Results: Adipose cell IRS-1 protein content was significantly lower in male FDR (0.24±0.09 vs. 0.34±0.19 arbitrary units, p<0.005), as well as adiponectin (7.2±2.7 vs. 11.7±4.7 μg/ml, p<0.0001), insulin-mediated glucose uptake (11.8±3.0 vs. 14.3 ± 4.1 mg/kg/LBM, p<0.01), Acute Insulin Response (550±530 vs. 1100±1300 mU/l, p<0.01), FFA (460±170 vs. 600±240 μmol/l, p<0.001) and HDL-Cholesterol (1.26±0.29 vs. 1.67±0.37 mmol/l, p<0.0001) whereas male FDR exhibited significantly higher fP-Glucose (4.89±0.63 vs. 4.75±0.31 mmol/l, p=0.05), HbA1c (4.4±0.3 vs. 4.1±0.2 %, p<0.0001), Triglycerides (1.37±0.79 vs. 0.97±0.44 mmol/l, p<0.005), LDL-Cholesterol (3.1±0.8 vs. 2.6±0.7 mmol/l, p<0.001), Systolic Blood Pressure (123±13 vs. 116±11 mm Hg, p<0.01), Diastolic Blood Pressure (77±7 vs. 73±8 mm Hg,

p<0.01), ALT (0.50±0.23 vs. 0.35±0.28 μkat/l, p<0.001), ICAM-1 (218±51 vs. 182±36 ng/ml, p<0.0001) and E-Selectin (47±19 vs. 34±12 ng/ml, p<0.001). The differences remained after adjustments for age and BMI. No gender differences appeared for subcutaneous fat cell size, fs-Insulin, hsCRP, IL-6 and VCAM-1 (not shown).

Conclusion: In conclusion, our data shows that non-diabetic male FDR are less sensitive to insulin and have a less favourable metabolic and vascular risk profile compared to female premenopausal FDR. Reduced adipocyte IRS-1 content may be a predictor of the metabolic syndrome in male FDR.

0198

Adipose tissue expression of the glycerol channel Aquaporin-7 gene is altered in severe obesity but not in type 2 diabetes

J. J. Vendrell¹, V. Ceperuelo-Mallafre¹, M. Miranda¹, N. Vilarrasa², A. Megía¹, C. Gutiérrez¹, J. M. Fernández-Real³, J. M. Gómez², E. Caubet⁴, M. R. Chacón¹;

¹Research Unit, University Hospital Joan XXIII, Tarragona,

²Endocrinology Unit, University Hospital of Bellvitge, Barcelona,

³Diabetes Unit, University Hospital "Dr. Josep Trueta", Girona,

⁴Surgery service, Hospital Sta. Tecla, Tarragona, Spain.

Background and Aims: Aquaporin-7 is required for efflux of glycerol from adipocytes and influences whole-body glucose homeostasis in animal studies. AQP7 gene contains a putative peroxisome proliferator response element (PPRE) and a putative insulin response element (IRE) in the promoter region. Adipose tissue AQP7 expression is regulated by fasting-refeeding, insulin, dexamethasone, TNFα, isoproterenol and PPARα-γ. Studies on AQP7 expression in human adipose tissue are scarce but suggest that AQP7 gene is less expressed in subcutaneous adipose tissue of obese compared to lean men subjects. Three missense mutations (R12C, V59L and G264V) have been identified in human subjects in a Japanese cohort. Functional analysis showed that the permeability of water and glycerol is disturbed in *Xenopus* oocytes expressing G264V mutant protein. The aim was to test the hypothesis that AQP7 gene expression levels may be affected by presence of obesity and type 2 diabetes in humans.

Materials and Methods: Subjects: 47 non-diabetic and 56 type 2 diabetic patients. sMCP-1, sTNFR1, sTNFR2 and sIL-6 measured by ELISA. Plasma glycerol levels were analysed. Subcutaneous adipose tissue gene expression of: AQP7, MCP-1, IL-6, TNFα, PPARγ and SREBP1c genes were measured by real time PCR. Determination of G264V mutation of the AQP7 gene in 178 Caucasian subjects, these included 127 non-diabetic subjects, and 51 type 2 diabetic subjects.

Results: Severely obese subjects showed significantly lower AQP7 expression levels compared with lean and non-severely obese (p<0.001). Moreover, circulating glycerol concentration was significantly lower (p=0.003) in severely obese subjects (μM Glycerol in lean: 361.26 ±165.61; non-severely obese: 451.52 ± 180.22 and severely obese subjects: 233.53 ± 78.10); however no correlation between plasma levels and AQP7 adipose tissue expression was observed. AQP7 expression was negatively related with pro-inflammatory genes (MCP-1: r=-0.203, p=0.044 and TNFα: r=-0.209, p=0.036) and positively associated with PPARγ mRNA expression levels (r=0.265, p=0.012). In linear regression analysis, including sex and presence of type 2 diabetes as confounding variables, AQP7 mRNA expression was positively dependent on PPARγ (B=0.248, p=0.002, in women and B=0.321, p=0.004, in men) and negatively associated with TNFα mRNA in men (B=-0.329, p=0.005). AQP7 expression did not show differences regarding the presence of type 2 diabetes. Frequency of the G264V mutation was 8%. No association between G264V and obesity, type 2 diabetes, AQP7 expression or plasma glycerol levels were observed.

Conclusion: Expression of AQP7 is down-regulated in severe obesity. The expression of this glycerol channel is not affected by type 2 diabetes. The lack of correlation between gene expression and glycerol levels in the human adipose tissue may be explained by the existence of an alternative glycerol channel in the human adipocyte.

The transcriptional repressor REST impairs insulin secretion by controlling the expression of proteins of the exocytotic pathway

D. Martin¹, F. Allagnat¹, R. Regazzi², A. Abderrahmani², G. Waeber¹, P. Meda³, P. Maechler³, J.-A. Haefliger¹;

¹Department of Medicine, University Hospital, Lausanne,

²Department of Cell Biology and Morphology, University of Lausanne,

³Department of Cell Physiology and Metabolism, University Medical Center, Geneva, Switzerland.

Background and Aims: The transcriptional repressor RE-1 silencing transcription factor (REST) restricts some neuronal traits to neurons and pancreatic β -cells, by silencing the expression of these target genes in other cell types. To evaluate the contribution of neuronal traits to the control of insulin release, we repressed their expression by ectopically expressing REST in β -cells.

Materials and Methods: The secretory response of INS-1E and primary β -cells were evaluated after transduction of cells with adenoviruses encoding REST. The consequences of a chronic downregulation of the neuronal traits were analyzed, *in vivo*, using transgenic mice expressing REST in β -cells.

Results: As a consequence of REST expression, the capacity of INS-1E cells to secrete insulin in response to glucose, KCl, and an analogue of Leucine was impaired. In mice islets expressing REST, the first and second phase of insulin secretion were decreased in response to glucose. Analysis of intracellular signaling leading to Ca^{2+} influx suggested perturbed vesicular trafficking or fusion. Consistent with this hypothesis, we identified functional REST binding sites (RE-1) in genes encoding key proteins of the machinery of exocytosis such as SNAP25, Synaptotagmin (SYT) IV, VII, IX or complexin II. Accordingly, their expression was strongly silenced after ectopic REST expression, and a small interfering RNA strategy underlined the crucial role of REST target genes by uncovering the implication of Syt IV and Syt VII in the control of insulin release. We further studied the functional importance of neuronal traits, *in vivo*, by generating transgenic mice expressing REST in β -cells. Whereas these mice featured morphologically normal islets and β -cells, they exhibited defects in insulin secretion and intolerance to glucose. Islets isolated from these mice showed a decreased β -cell secretory function, as revealed by glucose perfusion, which was associated with a decreased expression of the identified target genes participating to exocytosis.

Conclusion: These data document the functional importance of neuronal traits in pancreatic β -cells, providing evidences that their downregulation by the transcriptional repressor REST is detrimental for the exocytotic machinery integrity, thus contributing to β -cell dysfunction and impaired glucose homeostasis.

Knockdown of a downstream effector of the small G-protein Rac 1 by siRNA affects glucose metabolism and insulin secretion in INS-1 β cells

J. Zhang, R. Luo, F. Xie, G. Li;

National University Medical Institutes, National University of Singapore, Singapore.

Background and Aims: Stimulation of insulin secretion by glucose and other secretagogues from pancreatic islet β -cells is mediated by multiple signaling pathways. Our previous work has shown that the small G-protein Rac1 is involved in glucose- and forskolin-stimulated insulin secretion, probably at the level of recruitment of secretory granules through actin cytoskeletal network reorganization. In this study the possible role of two downstream effectors of Rac-1, type 1 α phosphatidylinositol-4-phosphate 5-kinase (PIP5K-1 α) and P21-activated kinase- α (PAK- α), in this scenario was investigated.

Materials and Methods: RNA interference technique was used to knock down PIP5K-1 α and PAK- α in INS-1 β -cells. Cellular F-actin was assessed by using FITC-phalloidin staining under confocal microscopy. Membrane potential was measured by a voltage-sensitive fluorescent probe, bisoxonol. Insulin secretion

upon various conditions was measured by radioimmunoassay. Glucose metabolism was determined by a tetrazolium (MTS) reduction assay.

Results: Reverse transfection of siRNA duplexes targeting PIP5K-1 α reduced its mRNA level by 75% as assessed by real-time RT-PCR. PIP5K-1 α knockdown seemed not to affect cell growth and demise, assessed by flow cytometry. Dramatic changes in cell morphology, disruption of cellular F-actin structure and decrease of F-actin content were observed in the knock-downed cells. The increment of high (16.7 mM) glucose-stimulated insulin secretion was markedly reduced by 40% ($P < 0.01$) in PIP5K-1 α knock-downed cells. Interestingly, the basal insulin release rate in these cells at 2.8 mM glucose was augmented more than double ($P < 0.01$). In addition, PIP5K-1 α knockdown increased glucose metabolism at 2.8 mM, but significantly inhibited (by 29%) glucose metabolism at 16.7 mM ($P < 0.01$). Similarly, the resting membrane potential of knock-downed cells was in a more depolarized status. In contrast to PIP5K-1 α , knockdown of PAK- α in INS-1 cells appeared no significant effects on morphology, glucose metabolism and insulin secretion.

Conclusion: These results indicate that PIP5K-1 α is implicated in not only the distal steps (actin cytoskeleton reorganization and granule recruitment) but also the proximal events (membrane depolarization and glucose metabolism) in the cascade leading to insulin secretion in β -cells.

Expression of mutant Huntingtin disrupts post-Golgi transport in the 832/13 Ins-1 cell line

K. Bacos¹, R. Smith¹, D. Soulet¹, S. Obermüller², A. Lindqvist², M. Björkqvist¹, P. Klein¹, P. Brundin¹, H. Mulder¹, J.-Y. Li¹;

¹Experimental Medical Science, Lund University, Lund, Sweden,

²Clinical Science, Lund University, Malmö, Sweden.

Background and Aims: Huntington's disease (HD) is a severe progressive neurodegenerative disorder. Aside from the neurological symptoms, the prevalence of diabetes is significantly higher among HD patients than in the general population. HD is caused by expansion of CAG-repeats (>37) in the IT15 gene, resulting in an elongated polyglutamine domain in the protein huntingtin. The mutation has been suggested to have several cellular effects; for instance, intracellular trafficking has been shown to be affected in neuronal HD models. We have previously shown that the R6/2 HD mouse model develops diabetes due to a severe degranulation of β -cells and reduced exocytosis of insulin. The aim of the current study was to further characterise this β -cell perturbation.

Materials and Methods: We used confocal microscopy to study morphology and insulin distribution in primary R6/2 β -cells. We studied the effects of expressing normal (17Q) and mutant huntingtin (69Q) in clonal 823/13 Ins-1 cells, using recombinant adenoviruses. Intracellular transport in general and that of insulin vesicles were studied by coexpressing VSVG-YFP or IAPP-GFP with the huntingtin mutants. Fluorescence recovery after photobleaching (FRAP) and inverse FRAP were used to determine pre- and post-Golgi transport.

Results: We observed an altered localisation of insulin in the mouse β -cells, where proinsulin/insulin co-localized with the Golgi apparatus and not the mature insulin granule marker phogrin. Furthermore, we observed that mutant huntingtin impaired glucose stimulated insulin secretion already 48 hours after transduction of 832/13 Ins-1 cells (17Q 47.6 ± 9.0 ; 69Q 27.7 ± 5.2 ng/mg/h, $p = 0.03$). The defect occurred despite unaltered insulin content in the cells (17Q 2.3 ± 0.01 ; 69Q 2.6 ± 0.4 μ g/mg, $p > 0.05$). Using a VSVG-YFP construct we found that delivery of the protein to the plasma membrane was delayed in cells expressing mutant huntingtin compared to cells expressing normal huntingtin (ratio of membrane and cytoplasm fluorescence, 17Q 1.5 ± 0.1 ; 69Q 1.2 ± 0.1 , $p = 0.018$). A combination of FRAP and inverse FRAP showed that while ER-Golgi transport is unaffected, post-Golgi transport in the 69Q huntingtin cells is slower than in 17Q huntingtin cells (two-factor anova, $p = 0.03$). Moreover, we found a reduction in peak insulin granule speed and a substantial loss of insulin granules moving directionally at high speeds.

Conclusion: Taken together these results suggest that expression of mutant huntingtin perturbs the intracellular trafficking in Ins-1 cells and that this may, at least in part, underlie the defects in insulin secretion observed in the same cells.

Ral GTPases as potential regulators of insulin secretion

S. Ljubicic, P. Bezzi, R. Regazzi;

Department of Cellular Biology and Morphology, University of Lausanne, Switzerland.

Background and Aims: RalA and RalB form a special branch within the Ras monomeric GTPase family and have been implicated in the modulation of a variety of cellular processes including exocytosis and endocytosis. The main goal of this project was to investigate the possible role of Ral GTPases in the control of insulin release from pancreatic beta cells.

Materials and Methods: The experiments were performed in the insulin-secreting cell lines INS1E and MIN6B1. Expression of Ral GTPases was measured by RT-PCR and Western Blotting analysis. Activation of Ral GTPases in living cells was assessed by Fluorescence Resonance Energy Transfer (FRET) using a construct including a YFP-labeled RalA and a CFP-labeled Ral effector. The role of Ral GTPases in insulin exocytosis was assessed by transiently overexpressing wild type or constitutively active mutants of RalA and RalB or by reducing the endogenous levels of each of these GTPases by RNA interference.

Results: We found that INS1E and MIN6 cells express both RalA and RalB. Incubation of these cells with 30 mM potassium or 20 mM glucose, 0.01 mM Forskolin and 0.1 mM IBMX led to a rapid activation of Ral GTPases. This activation was prevented by the addition of the Ca²⁺ channel blocker nifedipin (0.01 mM) suggesting that it is probably a consequence of the increase in cytoplasmic free Ca²⁺ concentration following depolarisation of beta cell membrane. Reduction of the endogenous level of RalA or RalB by RNA interference resulted in a significant decrease in secretagogue-induced insulin release, indicating that these small GTPases are required for beta cell exocytosis. However, excessive amounts of Ral GTPases were also deleterious for insulin secretion. In fact, overexpression of wild type or constitutively active mutants of Ral GTPases led to a reduction in insulin exocytosis. This suggests that the level of Ral GTPases has to be maintained in a narrow range to insure an optimal secretory response.

Conclusion: Ral GTPases are activated by insulin secretagogues and participate in the control of insulin exocytosis. Future experiments will need to elucidate the mechanisms leading to the activation of these GTPases and to precisely define their mode of action.

Islet brain 1 is required for glucose-induced insulin secretion and is regulated by the cAMP signaling pathwaysM. Ferdaoussi¹, G. Niederhauser¹, M. Cornu², J.-Y. Yang³, C. Widmann³, B. Thorens², G. Waeber¹, A. Abderrahmani¹;¹CHUV, DBCM, Lausanne, ²CIG, UNIL, Lausanne, ³DBCM, DP, Lausanne, Switzerland.

Background and Aims: The cAMP signalling pathways are involved in several physiological functions of pancreatic β -cells, including the control expression of genes, potentiation of nutrients-induced insulin secretion and the cell-survival/apoptosis. Herein, we investigated whether Islet Brain 1 (IB1), a key modulator for the β -cell tasks, might be a target of cAMP signalling.

Materials and Methods: Expression of IB1 was monitored by real-time PCR, western blotting and a luciferase gene reporter construct under the control of IB1 promoter. Silencing of IB1 expression was performed by using interference RNA strategy. The insulin levels were quantified by ELISA kit according to the manufacturer's protocol (SPI-BIO).

Results: Inspection for putative binding sites of transcription factors within human, rat and mouse promoter region of the gene encoding IB1, revealed the presence of a cAMP-response element (CRE) that is highly conserved among these species. Electromobility shift assays using nuclear extracts from the insulin-producing INS-1E cells demonstrated the ability of this element to bind CRE binding proteins. The implication of the cAMP pathways in the regulation of IB1 expression was then addressed. Real-time PCR and western blotting experiments performed with extracts of rat isolated islets, INS-1E or MIN6 cells cultured in the presence of cAMP-raising agents such as forskolin (F), IBMX (I) or GLP-1, showed a 2–3 fold rise in mRNA and protein levels of IB1. This induction reached a peak at 16hrs and declined at 48hrs. Incubation of transiently transfected INS-1E cells also increased by 2 fold the luciferase

activity of the 731 bp sequence of the human IB1 promoter linked to a luciferase gene, indicating that I/F-mediated effects occur at transcriptional levels. The PKA inhibitor H89 prevented the augmentation of IB1 induced by cAMP-raising agents. Because cAMP signalling is involved in the potentiation of glucose-induced insulin-secretion, we evaluated the potential contribution of IB1 in this β -cell task. Inhibition of IB1 expression levels with the use of interference RNA strategy drastically decreased glucose-induced secretion. The introduction of an IB1-encoding plasmid that was resistant to siRNA restored the capacity of the cells to secrete in response to glucose.

Conclusion: The data indicates that the potent effects of cAMP/PKA pathways in the control of insulin secretion and cell survivals are in part mediated through induction of IB1.

Expression of the synaptogenic adhesion molecules neurexin, neuroligin and SynCAM in islet β cellsA. T. Suckow¹, D. Comoletti², M. Waldrop¹, P. Taylor², S. D. Chessler³;¹Medicine, ²Pharmacy, ³Endocrinology, University of California, San Diego, La Jolla, United States.

Background and Aims: The insulin secreting β -cells share many features with the neurons of the central nervous system. For example, β -cells express high levels of the major inhibitory neurotransmitter GABA and all of the machinery necessary for GABAergic signaling. β -cells also express many of the scaffolding and synaptic vesicle proteins important for neurotransmitter release, several of which have also been implicated as key components of the insulin secretory machinery. Recently, three families of neuron-specific proteins have been identified that seem to be key drivers of synaptogenesis in the central nervous system: the neurexins, the neuroligins and SynCam. The neurexins and neuroligins are cell-surface, synaptic adhesion molecules that interact with each other across the synaptic cleft, seeding the local assembly of the submembrane protein complexes that enable synaptic neurotransmission. Coculture experiments demonstrate that neuroligin-2 and a variant of neurexin-1 β are important for inhibitory synapse formation. Since neuroligin-2 is expressed exclusively at inhibitory synapses in the brain and β -cells express all of the machinery necessary for GABA secretion, we hypothesized that neuroligin-2 and its heterophilic binding partner neurexin are expressed in β -cells. It is also postulated that these molecules are important for the assembly of the insulin secretory apparatus since they can induce assembly of the machinery necessary for neurotransmitter release in neurons.

Materials and Methods: To determine whether neurexin, neuroligin and SynCAM family members are expressed in islets, a combination of RT-PCR, immunohistochemistry and western blot analysis were used. The effect that overexpression of neuroligin family members have on insulin secretion were assessed by transfecting each of the neuroligin family members into the rat β -cell line INS-1 and by quantifying the levels of secreted insulin under basal glucose conditions using an insulin radioimmunoassay.

Results: Here, we demonstrate expression of all neurexin and neuroligin family members at both the RNA and protein levels. Neurexin-1 and neuroligin-2 were detected exclusively in β -cells via immunohistochemistry. SynCAM was also detected in β -cells. Additionally, overexpression of all neuroligin family members increased insulin secretion in INS-1 cells. When insulin secretion was compared in cells transfected with neuroligins relative to mock-transfected cells, 52%, 60%, 135% and 148% increases in insulin secretion were observed in NL-1, -2, -3 and -4 transfected cells.

Conclusion: The neurexins and their trans-synaptic binding partners, the neuroligins, as well as SynCam are expressed on the β -cell surface. Neuroligin-neurexin interactions may play a role in the formation of the submembrane insulin secretory apparatus analogous to their role in synaptic neurotransmission. These findings may have important implications for determination of how specific β -cell plasma membrane regions may be primed for insulin and GABA exocytosis.

Reversible and irreversible changes in arterial gene expression after initiation of hyperglycaemia in pIns-MYCER mice *in vivo*

S. Zervou, S. Pelengaris, D. Epstein, M. Khan;

Biological Sciences, University of Warwick, Coventry, United Kingdom.

Background and Aims: Hyperglycaemia has long been a prime suspect for accelerated CVD in diabetes, yet intervention studies have been disappointing, with most convincing reduction in CVD risk achieved by targeting blood pressure or lipids rather than glucose. We must first expand knowledge regarding the pathogenic effects of hyperglycaemia (independent of other confounding atherogenic features of the metabolic syndrome) and the potential reversibility of such effects when glucose is normalised *in vivo*. In this study, we sought to investigate the immediate and early effects of hyperglycaemia, on gene and protein expression in the arteries of reversible 'diabetes-inducible' pIns-MYCER^{TAM} mice *in vivo*. Following which we examined to what extent the consequences of transient relatively brief exposure to hyperglycaemia *in vivo* were reversible following restoration of normal ambient glucose levels.

Materials and Methods: In pIns-MYCER^{TAM} mice, c-Myc activation by administration of the specific-activating ligand, 4-hydroxytamoxifen (4OHT), induced rapid sub-total β -cell ablation by apoptosis resulting in an entirely predictable timecourse of initiation and progression of hyperglycaemia. Importantly, in these models deactivation of c-Myc results in recovery from diabetes by re-differentiation of surviving beta cells and by regeneration of new beta cells.

The effects of hyperglycaemia were investigated after a series of early and later time-points (n=3 for each). Blood glucose, LDL and HDL cholesterol were recorded for all mice. Mouse aortas were isolated and processed for extraction of either RNA, or for fixation and immunohistochemistry. Global mouse gene expression arrays (Affymetrix) were used to study immediate and early changes in gene expression in the aortic wall following the onset of hyperglycaemia *in vivo*. Microarray data were verified using real-time RT-PCR with the Roche[®] Light Cycler. Changes in mRNA levels were detected, as the result of hyperglycaemia in the mouse artery. Immunohistochemistry was also performed to monitor altered protein expression for a group of cell adhesion molecules, as early indications of vascular effects due to hyperglycaemia.

Results: Several genes were found to increase with the onset of high glucose and decrease to initial levels when hyperglycaemia was corrected, including known-atherosclerosis related genes such as *VCAM-1*, *MMP-9*, *MMP-2*, *vWF*, *VEGF a*, *insulin-related IRS2* and *IGF1*, and others involved in cell turnover such as *p16^{INK4a}* and *caspase 12*, the hyperlipidaemia-related Apo A-II, and those implicated in energy homeostasis such as *leptin* and *adiponutrin*. Surprisingly, given the transitory and brief period of hyperglycaemia, several genes elevated as a result of hyperglycaemia do not reverse when blood glucose is corrected, including those encoding receptors for LDL, Leptin and GLP1. We have confirmed some of these results at the protein level by means of immunohistochemistry of mouse aorta.

Conclusion: As anticipated, hyperglycaemia results in rapid alteration in gene expression in the aorta *in vivo*, some of which fail to reverse after normalisation of blood glucose levels. The obvious potential ramifications of these results to diabetes are that normal glycaemia should be achieved as rapidly and completely as possible; with this in mind our important findings are being examined at a functional level.

Dietary fish-oil preserves cardiac contractile function by upregulation of UCP3 in a rat model of high-fat diet-induced glucose intolerance and cardiomyopathy

M. Ouwens¹, C. E. van den Brom², J. Kriek¹, G. Schaart³, M. K. Hesselink³, P. Schrauwen³, R. Vlasblom², M. Diamant⁴;

¹Molecular Cell Biology, LUMC, Leiden, ²Laboratory for Physiology,

VUMC, Amsterdam, ³Human Biology, Maastricht University,

⁴Endocrinology/Diabetes Centre, VUMC, Amsterdam, The Netherlands.

Background & Aims: Myocardial insulin resistance and lipotoxicity, leading to mitochondrial dysfunction and oxidative stress, have been implicated in the development of diabetic cardiomyopathy (DCM), a common complication in type 2 diabetes mellitus. Uncoupling protein 3 (UCP3) has been proposed to protect against lipid-induced mitochondrial damage, either by exporting excessive fatty acid anions from the mitochondrial matrix and/or by reducing mitochondrial ROS production and lipid peroxide formation, thus being an important protective mechanism in diabetes-related organ damage. We studied whether diet-induced alterations in myocardial insulin sensitivity and *in vivo* cardiac function in rats could be ascribed to changes in UCP3 protein expression.

Materials & Methods: Male Wistar rats, fed isocaloric low-fat- (LF), high-fat- (HF), or high-fat fish-oil-enriched (FISH) diets, underwent an oral glucose tolerance test (oGTT) at day 25, and *in vivo* echocardiography at day 27. Rats were sacrificed at day 28 for analysis of myocardial protein expression and phosphorylation.

Results: No significant differences in body weight gain, fasting plasma glucose and insulin levels were found among the diet-groups. However, compared to LF-diet fed rats, HF- and FISH-diet fed rats showed glucose intolerance in the oGTT ($P < 0.05$). Also insulin-mediated activation of the PKB/Akt-pathway was 40-50% lower in hearts from both HF- and FISH-diet fed rats, compared to LF-diet fed hearts ($P < 0.05$). Interestingly, cardiac contractile function, expressed as fractional shortening and ejection fraction, was similar in FISH- and LF-diet fed rats, but was decreased in HF-diet fed rats ($P < 0.05$ versus FISH). Myocardial protein levels of UCP3 were 1.9-fold increased in FISH-diet fed rats compared to LF-diet fed rats ($P < 0.01$), but failed to rise significantly in HF-diet fed rats.

Conclusion: FISH-oil enriched diet induced myocardial UCP3 expression while preserving cardiac contractile function in rats. We propose that dietary FISH-oil prevents lipotoxic heart disease by upregulation of UCP3, rather than by improving myocardial insulin signalling, in a rat model of diet-induced glucose intolerance.

Evaluation of the effects of fenofibrate and metformin in an experimental model of diabetic cardiomyopathy (DCM)

M. Beylot^{1,2}, F. Forcheron¹, A. Basset², P. Abdallah³, P. Del Carmine³, C. Metais¹, G. Bricca¹;

¹Faculte RTH Laennec, ERI 22, LYON, ²Faculte Rockefeller, ANIPHY, Lyon,

³Faculte RTH Laennec, INSERM U499, LYON, France.

Background and Aims: Diabetes can induce, independently of hypertension and myocardial ischemia, a specific diabetic cardiomyopathy (DCM) characterised by increased triglycerides (TG) stores and appearance of fibrosis in left ventricle (LV). The mechanisms leading to DCM remain to be precised and no specific treatment has been defined. Cardiac specific overexpression of ppar alpha results in a cardiopathy resembling DCM suggesting that ppar alpha agonists, such as fenofibrate used for the treatment of hypertriglyceridemic diatic patients, could have unfavorable effect on DCM. Therefore we evaluated the action of fenofibrate on an experimental model of DCM, the Zucker diabetic rat (ZDF). We evaluated also the effect of metformin, widely used in the treatment of type 2 diabetes.

Materials and Methods: ZDF (n=35) and control (Lean, L, n=15) rats, all receiving a high fat diet, were studied at 7, 14 and 21 weeks. After the initial study at 7 weeks, 10 ZDF received no treatment, 10 received metformin and 10 fenofibrate (oral administrations) until final studies at 14 or 21 weeks. L rats received no treatment. Each study comprised measurements of plasma glucose, TG, insulin levels, energy intake and expenditure (indirect calorimetry) and (for 5 rats of each group at 7,14 and 21 weeks) sampling

of heart (measurement of TG content and relevant mRNA concentrations, histology).

Results: ZDF rats were, compared to L, obese, hypertriglyceridemic and insulin-resistant at 7 weeks, type 2 diabetic at 14 weeks and diabetic with insulin deficiency at 21 weeks. Plasma TAG levels were always high at 14 and 21 weeks ($p<0.001$). ZDF had, at 7 weeks, an increase in LV weight ($p<0.05$) and TG content (1.0 ± 0.1 vs. 0.2 ± 0.1 $\mu\text{moles/g}$ $p<0.01$) with some fibrosis. At 14 and 21 weeks, LV fibrosis and TG content (8.0 ± 1.7 and 3.7 ± 0.6 $\mu\text{moles/g}$ respectively, $p<0.05$ vs L) increased in ZDF rats. Fenofibrate and metformin did not change significantly the evolution of body weight nor energy intake, energy expenditure, evolution of diabetes. Plasma TG were decreased by metformin at 14 ($p<0.01$ vs. untreated ZDF) and 21 ($p<0.05$) weeks, but only at 21 weeks ($p<0.05$) by fenofibrate. LV TG content was decreased by metformin at 14 (1.2 ± 0.2 $\mu\text{moles/g}$, $p<0.01$ vs untreated ZDF) and 21 (0.6 ± 0.1 $p<0.01$) weeks and by fenofibrate at 14 weeks only (2.4 ± 0.3 $p<0.01$). Fibrosis was reduced by both compounds at 14 and 21 weeks. FAS, ACC1, LCAD, FAT, LPL mRNA were comparable in ZDF and L rats and were not modified by either compounds. Fenofibrate increased Acyl-CoA oxidase mRNA at 14 weeks ($p<0.05$) while metformin decreased Acyl-CoA synthase mRNA ($p<0.01$ at 14 and 21 weeks). Surprisingly the receptors of adiponectin, AdipoR1 and R2, mRNA were increased by metformin at 14 and 21 weeks ($p<0.01$)

Conclusion: In this model fenofibrate had no adverse effect on DCM but on the contrary rather favorable actions. Metformin had a clear beneficial effect in reversing both fibrosis and TG accumulation. This data suggests that both compounds could be useful for the prevention and treatment of DCM in humans.

UCP blockade decreases disturbances of contractive reactions of heart and vessels with type 1 experimental diabetes mellitus

O. D. Prysyazhna, V. F. Sagach;

Blood circulation, Bogomolets Institute of Physiology, Kyiv, Ukraine.

Background and Aims: Disorders of mitochondrial function play a significant role in the development of complications of diabetes mellitus according to modern conception. The increased expression of uncoupling proteins (UCP) is one of the most common problems of mitochondrial functioning. An increase of UCP expression leads to the proton leak growth and the reduction of the effectiveness of the mitochondrial respiratory chain work. Such changes lead to reduction of ATP synthesis and increase of the oxidative stress. The purpose of this work is to investigate the influence of inhibitor UCP genipin introduction on complications of diabetes mellitus such as contractive reaction of myocardium and vessels in rats with streptozotocin-induced diabetes mellitus.

Materials and Methods: Streptozotocin 50 mg/kg was intraperitoneally injected to male rats of the weight 180–220g to reproduce experimental model of diabetes mellitus I type. Glucose level control was carried out with glucometer Medisens. The level of blood glucose in diabetic rats was 17.5 ± 0.9 M/l and in control rats – 6.4 ± 0.5 M/l. Endothelium-dependent reactions of aorta and coronary vessels, left ventricular diastolic stiffness and force-loading dependence (Franc-Starling curve) in rats with experimental diabetes mellitus after the single intraperitoneal introduction 10 mg/kg of UCP blocker genipin were studied.

Results: Experimental diabetes mellitus leads to appearance of endothelial dysfunction that is revealed by the essential disturbance of endothelium-dependent reactions of both the aorta and the coronary vessels. In addition, the essential increase of left ventricular diastolic stiffness (considered as end-diastolic pressure rise/load increase) and reduction of Franc-Starling curve phase plateau extension were found at diabetes. The genipin injection, that was done one-hour before the beginning of the experiment, brought restoration of disrupted reactions. Furthermore, dramatic decrease of myocardial oxygen consumption was found after the genipin injection.

Conclusion: This data points to the role of UCP expression growth in the appearance of cardio-vascular complications of type I diabetes mellitus. Thus, the application of UCP blockers is the forward-looking method of angioprotection and curing the vascular complications of diabetes mellitus.

0209

Blockade of angiotensin type 2 receptors decreases diabetes-associated atherosclerosis

A. Koitka, P. Koh, K. Jandeleit-Dahm, M. E. Cooper, T. J. Allen;
Diabetes Complications Laboratory, Baker Heart Research Institute,
Melbourne, Australia.

Background: Activation of the renin angiotensin system has been described in various pathological conditions, including diabetic complications such as atherosclerosis. Angiotensin II acts through two receptors, type 1 angiotensin (AT1) and type 2 (AT2) receptors. Most of the known actions of angiotensin II (Ang II), including vasoconstriction and fibrosis, are considered to be due to AT1 receptor activation. Recent data suggest that the AT2 receptor subtype participates in the regulation of cell growth and inflammation. Therefore, the aim of this study was to investigate the effect of chronic AT2 receptor subtype blockade (AT2RB) by PD123319 in an in vivo model of diabetes-associated atherosclerosis.

Methods: Control and streptozotocin-induced diabetic apolipoprotein E (ApoE)-deficient mice received PD123319 (5 mg. kg⁻¹.day⁻¹ via Alzet osmotic minipump) or no treatment (buffer alone) for 20 weeks ($n=8/\text{group}$). Aortic plaque deposition was assessed by Sudan IV staining and subsequent en face quantification. Markers of inflammation were measured using real-time RT-PCR and immunohistochemistry.

Results: Diabetes was associated with a greater than five-fold increase in plaque area (Table1) as well as increased complexity in the aorta in association with a significant increase in aortic AT2 receptor expression (1.2 ± 0.1 in control mice vs. 6.7 ± 0.3 in diabetic mice, $p<0.01$), collagen content, macrophage and alpha-smooth muscle actin-positive cell infiltration, as well as increased monocyte chemoattractant protein-1 (MCP1) and vascular cell adhesion molecule-1 (VCAM-1) expression. The increase in plaque area with diabetes was attenuated by approximately 50% with the AT2RB in diabetic mice but not in control mice. The benefits of the AT2RB were seen at all three sites of the aorta (Table1). This occurred despite similar glycated haemoglobin ($16.3\pm 1.4\%$ in diabetic mice vs. $16.9\pm 1.2\%$ in AT2RB-treated diabetic mice) and similar blood pressure (135 ± 10 mmHg in diabetic mice vs. 129 ± 5 mmHg in AT2RB-treated diabetic mice). Mean \pm SEM shown, * $p<0.01$ vs. control; † $p<0.05$, ‡ $p<0.01$ vs. diabetic.

Conclusions: Diabetes-associated atherosclerosis is ameliorated by AT2 receptor blockade, independent of glucose or blood pressure. This suggests that the atherosclerotic effects of Ang II are at least partly mediated via the AT2 receptor subtype. The specific role of the AT2 receptor in diabetes-associated atherosclerosis remains to be confirmed using a non-pharmacological strategy such as similarly designed experiments in recently generated diabetic ApoE/AT2 double-knockout mice.

Quantification of plaque area (%)

Group	Total	Arch	Thoracic	Abdominal
Control mice	2.2 \pm 0.3	5.3 \pm 1.0	0.8 \pm 0.1	2.2 \pm 0.4
AT2RB-treated control mice	2.9 \pm 0.3	6.2 \pm 1.5	1.6 \pm 0.2	2.3 \pm 0.5
Diabetic mice	14.4 \pm 2.1*	32.3 \pm 2.7*	11.0 \pm 2.8*	8.8 \pm 1.8*

Coronary and aortic vascular pathology in a diabetic porcine model

M. van den Heuvel¹, W. Kerver¹, S. Kazim¹, O. Sorop¹, R. Dekker²,
S. J. Koopmans², D. J. Duncker¹, W. J. van der Giessen¹,
H. M. M. van Beusekom¹;

¹Experimental Cardiology, Erasmus Medical Center, Rotterdam, ²Animal Sciences Group, University of Wageningen, Lelystad, The Netherlands.

Background and Aims: Cardiovascular disease is a major cause of morbidity and mortality in patients with diabetes mellitus (DM). They are prone to diffuse and accelerated forms of atherosclerosis. In coronary artery disease, this increases the likelihood of revascularization therapy, even with use of

drug eluting stents (DES). While DES effectively reduce in-stent neointimal formation, DM still remains an independent risk factor for restenosis possibly because of exacerbated endothelial dysfunction.

We used a porcine model of streptozotocin induced DM to examine the vascular healing response to coronary DES implantation. In addition we studied the effects of diet and commonly used oral anti-diabetic combination therapy on early aortic plaque formation.

Materials and Methods: DM was induced by a slow and titrated infusion of streptozotocin ($\pm 130\text{mg/kg}$) to give subtotal pancreatic beta-cell destruction. DM was allowed to settle and stabilize for a few weeks before the experiments started.

1) Paclitaxel eluting stents (PES) were implanted in coronary arteries under guidance of quantitative coronary angiography. PES were placed in both control pigs (C, $n=5$) and diabetic pigs (D, $n=5$) for 5 weeks to study maximal intimal thickening in response to stenting.

2) For aortic plaque formation, both DM (D) and control (C) pigs were fed a cafeteria diet (saturated fat, cholesterol and sucrose rich, CD, $n=8$) or a healthy diet (unsaturated fat, carbohydrate rich, HD, $n=7$) for 8 weeks. One group of DM pigs on CD was treated with oral anti-diabetics (metformin 1g/day + pioglitazone 20mg/day , TD, $n=8$). Histology, immunohistochemistry and Sudan IV fat staining were performed. Morphometry and planimetry were analysed with a computerised system.

Results: Postprandial (3 h) glucose levels were significantly increased in DM pigs in both experiments (D vs C: 24 ± 11 vs. 6 ± 1 mmol/l, $p<0.01$; D-CD vs. C-CD: 26 ± 15 vs. 7 ± 1 mmol/l, $p<0.05$). Histology and immunocytochemistry showed no clear Langerhans islets in diabetic pancreas sections, only single beta cells, with an 88% reduced insulin staining ($p<0.01$). Therefore, a poorly controlled disease state of DM was created. Liver sections of diabetics on CD showed a marked steatosis (D-CD vs. C-HD: 23 ± 10 vs. $0\pm 0\%$, $p<0.01$), a DM type 2 feature. 1) Five weeks after PES placement, an increased neointimal response was found in DM pigs (D vs C: 2.9 ± 2.9 vs. 1.7 ± 0.3 mm², $p=0.05$). Interestingly, the aortic endothelium in diabetics showed an increased percentage of active von Willebrand factor (vWf) (D vs. C: 40 ± 18 vs. $22\pm 8\%$, $p<0.03$). 2) A CD for 8 weeks induced aortic fatty streak formation in diabetics leading to an increased percentage of early plaque area as compared to both controls on HD and diabetics on HD (D-CD vs. C-HD/D-HD: $16\pm 15\%$ vs. $0.1\pm 0.1\%$, $p=0.03$). Anti-diabetic combination therapy did not affect post-prandial (3 h) glucose levels, the percentage of liver steatosis or aortic fatty streak formation (D-TD vs. D-CD: 23 ± 17 vs. 26 ± 15 mmol/l; 12 ± 11 vs. $23\pm 10\%$; 7 ± 12 vs. $16\pm 15\%$).

Conclusion: This DM porcine model shows 1) an increased neointimal response to injury (PES) 2) accelerated diet-induced liver steatosis and atherogenesis, which are unresponsive to anti-diabetic combination therapy. A specific feature, endothelial dysfunction with a prothrombotic status (increased vWf), is likely to play a role in the cardiovascular pathology of DM.

OP 36 Nephropathy: treatment

0211

Study on effects of polysaccharides extracted from the fruits of *Lycium barbarum* on reducing blood glucose and preventing diabetic nephropathy

G. Sun¹, Y. Zhang¹, S. Wang¹, J. Huang¹, L. Zhang², Z. Sun², P. Huang³, J. Schrezenmeir⁴;

¹Nutrition and Food Hygiene, Southeast University, School of Public Health, Nanjing, China, ²Nutrition and Food Hygiene, Southeast University, School of Clinical Medicine, Nanjing, China, ³Nutrition and Food Hygiene, Southeast University, School of Basic Medical Sciences, Nanjing, China, ⁴Nutrition, The Federal Research Centre for Nutrition and Food, Institute for Physiology and Biochemistry of Nutrition, Kiel, Germany.

Background and Aims: *Lycium barbarum* polysaccharides (LBP) extracted from *Lycium barbarum* has been reported to decrease the blood glucose level and improve the insulin sensitivity of the diabetic model animals. However there is no report concerning the diabetic complications. The aims of the present study are to attempt to clarify whether LBP can prevent the occurrence or reduce the progression of diabetic nephropathy.

Materials and Methods: Diabetes was induced by the injection of small dose streptozotocin (STZ) combined with high-fat feeding consisting of 10% sucrose, 10% lard, 10% plant oil and 5% casein. 32 diabetic rats were randomly allocated to four groups: diabetic control, LBP low dose (20mg/kg/d), LBP medium dose (40mg/kg/d), and LBP high dose (80mg/kg/d) group. The experiment lasted 30 days. The levels of glucose, lipids, insulin, advanced glycosylation endproducts (AGEs), creatinine, superoxide dismutase (SOD) and malondialdehyde (MDA) in serum and creatinine in urine, hemoglobin-A_{1c} (HbA_{1c}), and interleukin-8 (IL-8) expression of renal cortex were determined.

Results: At the end of the experiment the fasting blood glucose of rats in diabetic control group, LBP low, medium, and high dose groups were 23.86 ± 4.62 , 8.22 ± 1.63 , 6.85 ± 2.13 , and 7.14 ± 1.05 mmol/l respectively and the differences between diabetic control group and three LBP treated groups were significant ($p<0.05$). LBP increased the level of insulin in serum and the insulin sensitivity index (ISI) of the diabetic rats. Correspondingly islet cell mass was higher in the LBP group compared to the model control. The mean AGEs level in serum of LBP high dose group rats was the lowest among all groups which was $2.73\pm 0.84\mu\text{g/ml}$, and that of diabetic control group was the highest ($5.22\pm 0.80\mu\text{g/ml}$). The HbA_{1c} -values of the three LBP treated groups ($6.3\pm 1.3\%$, $5.8\pm 1.1\%$ and $5.2\pm 0.9\%$) were lower than ($p<0.05$) that of the diabetic control group ($7.7\pm 1.3\%$). LBP decreased the 24 hours urine volumes and creatinine levels in serum and increased the endogenous creatinine clearance of diabetic rats. The histopathological examination of their kidneys confirmed lower progression of nephropathy in the LBP groups. LBP decreased the IL-8 mRNA expression and all the LBP treated groups had significant difference comparing to the diabetic control group ($p<0.05$). The levels of SOD and MDA in serum of LBP high dose group were 226.5 ± 12.7 NU/ml and 8.5 ± 0.8 nmol/ml which were significantly different from that of diabetic control group (180.6 ± 37.6 NU/ml and 11.7 ± 3.9 nmol/ml). However LBP had no effect on the lipids in serum. LBP had protecting effects on the islets particularly the β -cells.

Conclusion: LBP decreased the blood glucose level, improved the insulin sensitivity, ameliorated the kidney function and histopathology in diabetic rats. The mechanism might include reducing glycemia, oxidative stress, formation of AGEs, IL-8 expression in the kidney, and promoting regeneration of the pancreas islets. LBP may be a candidate for treating diabetes and preventing the development of diabetic nephropathy.

Heat shock protein expression in early diabetic nephropathy

F. Barutta¹, S. Pinach¹, J. Forbes², R. Chiarle³, S. Giunti¹, M. Arnstein²,
P. Cavallo Perin¹, G. Camussi¹, M. E. Cooper², G. Gruden¹;

¹Department of Internal Medicine, University of Turin, Italy, ²Diabetes and Metabolism Division, Baker Heart Research Institute, Melbourne, Australia, ³Department of Biomedical Sciences and Human Oncology, University of Turin, Italy.

Background and Aims: Heat Shock Proteins (Hsp), a highly evolutionary conserved family of intracellular proteins, are induced by cellular stresses and play an important role in cytoprotection. In diabetic nephropathy the metabolic and the haemodynamic insults result in osmotic, oxidative, and haemodynamic stress on target cells, thus representing potential Hsp inducers. Furthermore, the phosphorylated form of Hsp25 (P-Hsp25) plays a key role in cytoskeleton remodelling and has been implicated in the pathogenesis of proteinuric conditions. Our aim was to study both Hsp expression and distribution in the diabetic kidney in early experimental diabetes.

Materials and Methods: Diabetes was induced in eight-week-old male Sprague-Dawley rats by tail-vein injection of streptozotocin at a dose of 50 mg/kg in citrate buffer, following an overnight fast. Control rats were injected with citrate buffer alone. Diabetic (DM n=6) and control (ND n=6) animals were euthanised 4 weeks following induction of diabetes; kidneys were removed, fixed in 10% formalin, and embedded in paraffin. Hsp25, P-Hsp25, Hsp60, and Hsp70 expression was studied by immunohistochemistry on 4µm kidney sections. Briefly, sections were dewaxed and rehydrated, and antigens demasked by boiling in citrate buffer. After quenching for endogenous peroxidase activity and blocking of both endogenous avidin-binding activity and non-specific binding sites, sections were incubated with either specific anti-Hsp or nonimmune isotypic control antibodies for 1 hour at room temperature. The signal was detected using the LSAB+ system-HRP and quantification of the percentage area of staining/number of positive cells was performed in 11 randomly selected renal tubulointerstitial fields and 20 glomeruli for each section in a blinded manner by two independent observers. To identify Hsp-positive cells within the glomeruli, sections were double stained by immunofluorescence with specific glomerular cell markers.

Results: In control animals there was a progressive increase in Hsp25, Hsp60, and Hsp70 expression along the corticopapillary axis. In the medulla Hsp25, Hsp60, and Hsp70 expression was significantly greater in diabetic rats than in control animals, particularly in the outer medulla (Hsp60: DM 36.07±0.10 vs. ND 4.7±1.73, p<0.01; Hsp70: DM 36.2±3.24 vs. ND 24.1±1.46, p<0.05; Hsp25: DM 22.23±2.55 vs. ND 9.97±5.12, p<0.01). Within the glomeruli, cells staining positively for Hsp60 and Hsp70 were almost absent in control animals, while 1 or 2 Hsp70-positive cells per glomerulus were found in the diabetic rats (P<0.001). There was no significant difference in glomerular Hsp25 expression between diabetic and control rats; whereas P-Hsp25 expression was significantly greater in the diabetic rats (DM 10.3±0.5 vs. ND 3.9±0.3, p<0.001). Furthermore, double staining showed that podocytes were the predominant glomerular cell type overexpressing P-Hsp25.

Conclusion: In early experimental diabetes there is an overexpression of Hsp25, Hsp60, and Hsp70 in the medulla, possibly due to osmotic stress. The overexpression of P-Hsp25 in the diabetic glomeruli may be implicated in podocyte functional and structural abnormalities.

Effect of all-trans retinoic acid on treatment of type 2 diabetes

C. Kim¹, J. Kang¹, S. Lee¹, S. Ihm¹, H. Yoo¹, H. Jung², J. Nam², C. Ahn²;

¹Internal Medicine, Hallym University Sacred Heart Hospital, Anyang-si, Gyeonggi-do, ²Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea.

Background and Aims: Diabetic nephropathy is the most common cause of end-stage renal disease, and with increasing number of diabetes patients and old people, over 40% of ESRD patients have this disease. Hyperglycemia, advanced glycation end-product, increased polyol pathway, oxidative stress, activation of transforming growth factor-β1 (TGF-β1) are interrelated in the pathogenesis of diabetic nephropathy. All-trans retinoic acid (ATRA) is reported to suppress interstitial proliferation and glomerular inflammation, and prevent renal damage in diabetic rats. Moreover, retinoic acid is reported

to block lipid peroxidation in streptozotocin-induced diabetic rats, and other studies also support the protective effect of retinoic acid in progression of type 2 diabetic nephropathy. Therefore, in this study, we examined the effect of ATRA in improving diabetic nephropathy by measuring the amount of urine albumin excretion (UAE) after administrating ATRA to Otsuka Long-Evans Tokushima Fatty (OLETF) rat. And in rat mesangial cell (RMC), we administered ATRA to see its inhibitory action on production of TGF-β1. Moreover, we examined changes in protein kinase C (PKC) and reactive oxidative stress (ROS) after the administration of ATRA.

Materials and Methods: We orally administered 10 mg/kg body weight ATRA to 20 OLETF rats for 16 weeks. And, we administered vehicle to 20 OLETF rats and 10 Long-Evans-Tokushima-Otsuka (LETO) rats for the same period. At 44 weeks of age albumin excreted into the urine was measured by an immunoturbidimetric method. After incubation of quiescent RMC with 10⁻⁸, 10⁻⁷, 10⁻⁶, 10⁻⁵ M ATRA for the given period (6, 24, 48 hrs) in a media containing 30 or 5 mM glucose. We measured the concentration of TGF-β1 with the quantitative sandwich enzyme immunoassay technique. PKC assay were performed using SDS-PAGE and immunoblotted with an anti-PKC isoforms. And, we examined changes in DCF-sensitive reactive oxidative stress (ROS) after the administration of ATRA.

Results: Sixteen weeks after the administration of ATRA, daily UAE of the ATRA-treated OLETF rats was lower than that of non-treated OLETF rats (0.07±0.03 vs. 0.17±0.15 mg/mgCr, P=0.008). Also, a decrease of fasting glucose in serum was observed in ATRA-treated OLETF rats when compared with non-treated OLETF rats (133.1±16.2 vs. 148.5±21.3 mg/dL, P=0.014). ATRA-treated OLETF rats showed decreased total cholesterol, triglyceride, and LDL-cholesterol levels compared with not-treated OLETF rats. In RMC, treatment with ATRA showed dose and time-dependent decreases in TGF-β1 levels, PKC activity and DCF-sensitive cellular ROS.

Conclusion: In this study, we demonstrated that the administration of ATRA resulted in amelioration of UAE, glucose, and lipid profile in OLETF rats. Moreover, ATRA treatment suppressed TGF-β1 synthesis induced by high glucose stimulation. Also high glucose-induced ROS and PKC increments in RMCs are effectively suppressed by ATRA. It is of interest that ATRA treatment suppressed UAE and TGF-β1 synthesis, which was mediated by significant reduction of PKC activity and ROS production. Our results suggest that ATRA has a potentially therapeutic role for diabetic nephropathy.

Edaravone protects from endothelial barrier injuries under diabetic condition

K. Sarai, Y. Shikata, K. Shikata, K. Ohmori, N. Watanabe, J. Wada, H. Makino;

Department of Medicine and Clinical Science, Okayama University Graduate School of Medicine, Okayama, Japan.

Background and Aims: The primary pathway involved in enhanced endothelial barrier permeability is paracellular transport of fluid and macromolecules through intercellular gaps following the disruption of intercellular adherens junction and focal adhesion complexes. An increase in vascular permeability is a fundamental feature of inflammation and essential component of macrophage migration. Edaravone is a potent scavenger of hydroxyl radicals. It also improves in endothelial-dependent vasodilation in smokers, suggesting the protective effect on endothelial cell monolayers. These observations suggest the protective effect of edaravone on systemic vascular endothelial disorders including diabetes mellitus. We have reported the pivotal role of macrophages in the progression of diabetic nephropathy, as a major consequent of vascular disorder. To elucidate the effectiveness of edaravone against the progression of diabetic nephropathy, we investigated the protective effects of edaravone on endothelial barrier dysfunction in diabetes mellitus using experimental diabetic rats and cultured glomerular endothelial cells.

Materials and Methods: 1) Glomerular endothelial cells (GE cells) were preincubated with hyperglycemic (30 mM) media for 48 h and then treated with 9 mM edaravone for 30 min before co-culture with THP-1 cells. To monitor the effects of edaravone on adhesion of THP-1 cells on GE cells, numbers of CD34 positive cells were counted using immunofluorescent microscopy. 2) To investigate the renoprotective effect of edaravone in experimental diabetic rats, we induced diabetes in 6 week-old male Sprague-Dawley (SD) rats by intravenous injection with streptozotocin followed by intraperitoneal injection with edaravone(3mg/Kg) for 10 weeks. Blood glucose, urinary creatinine and urinary albumin excretion (24 h) were monitored. We also

evaluated the histological changes, infiltration of macrophages (ED1- positive cells), and expression of TGF- β and type IV collagen in renal glomeruli using harvested kidneys.

Results: 1) Immunofluorescent microscopy and co-culture study revealed that stress fiber formation and intercellular gap were observed and the number of THP-1 cells on a GE cellmonolayer was increased under the high glucose condition. Furthermore, THP-1 cells were chiefly observed at cell-cell contact area of GE cells, suggesting the migration process out of vascular lumen in vivo. On the other hand, edaravone induced cortical actin ring enhancement instead of stress fiber and intracellular gap formation in GE cells and reduced the number of THP-1 cells significantly. 2) Edaravone improved glomerular hyperfiltration and reduced urinary albumin excretion in experimental diabetic rats. Immunohistochemical studies revealed that the number of ED1 positive cells and expression of type IV collagen in glomeruli were significantly decreased by edaravone.

Conclusion: In the present study, edaravone revealed the protective effects against renal injuries in diabetic rats. Morphological study using co-culture system of both GE cells and THP-1 cells suggested that the endothelial barrier enhancement in a GE cell monolayer resulting in the inhibition of macrophage migration into glomeruli might be essential for edaravone to exert a renoprotective effect in diabetic rats. Edaravone may be beneficial for diabetic vascular complications via novel protective effects on endothelial barrier functions.

Continuous subcutaneous insulin infusion is more effective than multiple daily insulin injection in preventing albumin excretion rate increase in type 1 diabetic patients

G. Lepore¹, A. R. Dodesini¹, D. Bruttomesso², S. Costa², M. Bonomo³, E. Meneghini³, A. Corsi¹, I. Nosari¹, R. Trevisan¹;
¹Diabetes Unit, A.O.Ospedali Riuniti, Bergamo, ²Unit for Metabolic Diseases, University of Padua, ³Unit of Diabetology, A.O.Niguarda Cà Granda, Milan, Italy.

Background: Although the DCCT trial has demonstrated the importance of intensive management of diabetes in reducing microalbuminuria in patients with type 1 diabetes, there are still little data as to whether continuous subcutaneous insulin infusion (CSII) may provide greater benefit than multiple daily insulin injection (MDI). Recent meta-analysis also indicates that CSII provides a glycemic control slightly superior to MDI.

Aims: To compare the effect of CSII vs MDI on albumin excretion rate in a large group of type 1 diabetic patients.

Material and Methods: Design: a 3-year prospective observational follow-up study. Patients: 110 type 1 diabetic patients treated with CSII (52 M/58 F, age 40 \pm 10 yrs, diabetes duration 19 \pm 9 years, HbA_{1c} at entry 8.8 \pm 1.5 %) were compared with 110 patients treated with MDI matched at baseline for age, sex, diabetes duration and HbA_{1c} (52 M/58 F, age 41 \pm 13 yrs, diabetes duration 20 \pm 11 yrs, HbA_{1c} 8.9 \pm 1.4 %). At entry in each group 90 patients had normal albumin excretion rate and 20 had persistent microalbuminuria. All of them were treated with maximal tolerated dose of ACE-inhibitors.

Setting: Diabetes Unit – Hospital of Bergamo, Unit for Metabolic Diseases – University of Padua and Unit of Diabetology – Niguarda Hospital of Milan, Italy.

Main outcomes measurements: albumin excretion rate (AER), individual measures of GFR (estimated by MDRD formula), HbA_{1c} and BP were assessed every four months. Data is shown as mean \pm SD, otherwise stated.

Results: In CSII group HbA_{1c} was lower than in MDI group after 1 year (8.1 \pm 0.9 vs. 8.6 \pm 1.2%; $p < 0.005$) and after three years of follow-up (8.1 \pm 0.9 vs. 8.4 \pm 1.3%; $p < 0.005$). Blood pressure and estimated GFR were similar in the two groups during the whole study period. AER [median (range)], similar at baseline [6.0 (1 – 165) μ g/min in CSII group vs. 4.6 (1 – 111) in MDI group, NS, did not change significantly in both groups at 1 year. On the contrary AER was significantly lower in the patients treated with CSII both at the second year ($p < 0.05$) and at the third year follow-up [4.8 (1 – 109) μ g/min vs 6.4 (1 – 178), $p < 0.001$]. This significant difference between CSII and MDI groups was observed even when normo- and micro-albuminuric patients were analysed separately. Of note in microalbuminuric patients, despite HbA_{1c} in CSII group was similar (during the follow-up) to that of MDI group (8.6 \pm 1.2 vs. 8.9 \pm 1.7%, NS), AER decreased from 38 (21 – 165) μ g/min at entry to 19(3 – 109) ($p < 0.01$)

in CSII group, while it increased from 35 (20 – 111) to 42 (4 – 178) in MDI group. In particular 9 patients out of 20 regressed to normoalbuminuria in CSII group, whereas only 2 out of 20 regressed to normoalbuminuria in MDI group.

Conclusion: This data suggests that CSII therapy may be useful in decreasing the progressive increase in albumin excretion rate in type 1 diabetic patients. Since the decrease in HbA_{1c} in CSII group was small when compared to that observed patients treated with MDI, the suggestion is that a lower glucose variability may be the reason for the difference in AER between the two insulin treatments.

0216

Effects of long-term fenofibrate treatment on markers of kidney function in type 2 diabetes: FIELD Helsinki substudy

A. Hiukka¹, E. Leinonen¹, C. Forsblom^{2,3}, P.-H. Groop^{2,3}, M.-R. Taskinen¹;
¹Department of Medicine, Helsinki University Central Hospital and Biomedicum, ²Department of Medicine, Division of Nephrology, Helsinki University Central Hospital, ³Folkhalsan Institute of Genetics, Folkhalsan Research Center, Biomedicum Helsinki, Helsinki, Finland.

Background: Fenofibrate was associated with less albuminuria progression in the FIELD study. We explored the changes in commonly available markers of kidney function during fenofibrate treatment in a FIELD Helsinki cohort not using additional statin.

Subjects and Methods: 170 patients with type 2 diabetes recruited to the FIELD study in Helsinki were randomly assigned to micronised fenofibrate 200mg/day or placebo in a double-blind design for 5 years. In this substudy, we measured plasma creatinine (P-Crea), overnight urine albumine excretion rate (nU-Alb), diurnal proteinuria and creatinine (dU-Prot and U-Crea), and calculated creatinine clearance (Crea-Clearance), and estimated glomerular filtration rate (eGFR) by the Cockcroft-Gault equation. For urinary albumin/creatinine ratio (Alb/Crea) we used the spot sample data obtained in the main FIELD study. Mann-Whitney U-test was used to compare the change from baseline between the groups.

Results: Due to intensified treatment during the study, mean blood pressure (from 144/88 to 137/80mmHg, $p < 0.001$) and mean fasting plasma glucose (from 8.0 to 7.5 mmol/L, $p = 0.007$) decreased in both groups and HbA_{1c} remained at 7.2%. Medications were similar between the groups, except for the study drug. S-Crea increased with fenofibrate but U-Crea remained comparable between the groups, resulting in decreases in both Crea-Clearance and eGFR in the fenofibrate group. Alb/Crea and dU-Prot remained unchanged, whereas nU-Alb showed a minor decrease in both groups ($p = 0.004$).

Conclusion: Fenofibrate is known to reversibly raise both P-Crea and U-Crea levels. We are the first to show the contemporary decrease in Crea-Clearance and eGFR. Such changes will complicate the clinical surveillance of kidney function during fenofibrate treatment. In contrast to the main FIELD study, we did not find evidence for a beneficial effect of fenofibrate on albumin excretion rate.

	Baseline		5 th year		P value
	Placebo	Fenofibrate	Placebo	Fenofibrate	
P-Crea, μ mol/L	73 66–78	73 68–85	74 63–85	87 75–101	<0.001
U-Crea, mmol/L	5.4 4–7.4	5.7 4.7–7.9	5.4 3.9–7.3	6.1 4.3–7.6	0.855

0217

Isosteviol as novel oral anti-diabetic agent for treatment of type 2 diabetes and the metabolic syndrome – a *in vivo* study on diabetic KKAY-mice

P. B. Jeppesen, I. Nordentoft, R. Abudula, J. Hong, K. Hermansen; Dept. of Endocrinology and Metabolism C, Aarhus University Hospital, Aarhus Sygehus THG, Denmark.

Background and Aims: Isosteviol (ISV) is a unique novel chemical entities being the backbone in a group of substances with proven anti-diabetic capabilities in both man and rodent. In this present study we investigate if ISV possesses beneficial effects on the metabolism and gene expression in the diabetic KKAY-mouse.

Materials and Methods: 20 KKAY-mice, age 5 weeks, were divided into 2 groups and treated for 9 weeks with; A: standard chow diet (control); B: standard chow diet + 0.02 g/kg BW of ISV; D: 20 normal C57BL-mice fed with standard chow diet (control to A). Hormones and lipids were measured from blood sample at start and end of the treatment period. Fasting blood glucose as well as BW was measured 3 times during the study. At the end of the study mRNA was purified from Islets and different key genes was investigated as expression level compared to the control KKAY group.

Results: No difference in fasting plasma glucose or insulin was seen at the onset of the study. After 9 weeks of treatment, ISV exerted beneficial effects on metabolism in the diabetic KKAY-mice i.e.: 1.) reduction in p-glucose (A vs. B by 59% ($p < 0.01$)) and 2.) decreased p-insulin concentration, indicating increased insulin sensitivity, (A vs. B by 62% reduction ($p < 0.05$)), respectively. At the end of the study there was a marked decrease in the glucose insulin index for the ISV group vs. KKAY control (6932 vs. 1596 unit, $p < 0.01$). P-TG concentration was significantly lowered for the groups treated with ISV by 74% ($p < 0.01$). BW was reduced significantly for the ISV group by 13%. Islets from group B vs. A experienced an increased expression of PDX1, Beta2, GLUT2, Ins1 and decreased expression of C/EBPalpha and 11beta-HSD-1 ($p < 0.05$), respectively

Conclusion: This study demonstrates that ISV may be used as a new insulin sensitiser in the treatment of type 2 diabetes. ISV co-regulate many of the target genes. The large increase in GLUT2 expression indicates improved glucose sensitivity. The down regulation of 11beta-HSD-1 by ISV is potentially very interesting since 11beta-HSD-1 expression and activity are increased in islets of diabetic ZDF rats and Troglitazone concomitantly prevents both the increase in 11beta-HSD-1 and diabetes development. ISV comprises a new class of anti-diabetic agents addressing several aspects of the abnormal metabolism accompanying type 2 diabetes.

CS-917, a fructose 1,6-bisphosphatase inhibitor, reduces plasma glucose by suppressing hepatic glucose production, whereas metformin stimulates gastrointestinal glucose uptake

A. Okuno, J. Tanaka, K. Takahashi, J. Ogawa, Y. Hagiwara, S. Kanda, T. Yoshida; Biological Research Laboratories II, Daiichi Sankyo Company, Limited, Tokyo, Japan.

Background and Aims: CS-917 is a novel inhibitor of fructose 1,6-bisphosphatase, a rate-limiting enzyme in gluconeogenesis (GNG). *In-vivo* studies in Goto-Kakizaki (GK) rats have shown that CS-917 reduces glucose production, while metformin (MET) appears to accelerate glucose utilisation. Thus, CS-917 and MET appear to have different mechanisms of action. In this study, we evaluated the effect of both agents on glucose uptake/release in GK rats *in vivo*, and in human cells *in vitro*.

Materials and Methods: Plasma levels of glucose (PG) and lactate were measured 3 hours after oral administration of CS-917 (15mg/kg) or MET (300mg/kg) to fasted and non-fasted GK rats. Blood samples were taken from the hepatic vein, portal vein and abdominal aorta. The difference between the PG and lactate levels in blood entering and leaving the liver and the gastrointestinal tract was calculated as a measure of glucose uptake/release. The impact of CS-917 (0.003–100 μ M) or MET (0.3–1000 μ M) was also

investigated *in vitro*. In primary human hepatocytes, GNG was determined by measuring glucose concentration in the culture medium. Similarly, using colon carcinoma (Caco-2) cells, glycolysis was determined by measuring glucose utilisation, lactate concentration and the appearance of anionic metabolites of 14 C-glucose in the culture medium.

Results: CS-917 (15mg/kg) reduced hepatic glucose production and inhibited hepatic lactate clearance in fasted rats (see Table). MET (300mg/kg) increased gastrointestinal glucose uptake and increased gastrointestinal lactate production in non-fasted rats. CS-917 (0.01–1 μ M) inhibited hepatocyte GNG in a dose-dependent manner ($IC_{50} = 0.041$ – 0.061μ M). In contrast, MET (0.3–100 μ M) did not inhibit hepatocyte GNG. MET (100–1000 μ M) stimulated glycolysis in Caco-2 cells in a dose-dependent manner. CS-917 (10–100 μ M) did not alter glucose utilisation by Caco-2 cells or the appearance of anionic metabolites.

Glucose and lactate release/uptake *in vivo* following oral administration of CS-917 or MET

	Control	CS-917	MET
	mg/dL		
Liver (fasted rat)	(n=9)	(n=10)	(n=10)
Glucose release	72 \pm 10	8 \pm 2*	89 \pm 10
Lactate uptake	14.2 \pm 2.5	-3.2 \pm 1.4*	17.5 \pm 2.0
GI tract (non-fasted rat)	(n=9)	(n=9)	(n=10)
Glucose uptake	23 \pm 6	13 \pm 5	53 \pm 4*
Lactate release	4.1 \pm 1.0	-2.4 \pm 1.9*	17.9 \pm 1.5*

GI = gastrointestinal; mean \pm standard error; * = $P < 0.05$ versus control (t-test).

Conclusion: These results suggest that CS-917 and MET reduce PG through different mechanisms of action. CS-917 appears to suppress hepatic glucose production by directly inhibiting GNG, while MET stimulates gastrointestinal glucose uptake. Thus, CS-917 offers a novel mode of action that warrants further investigation for the treatment of hyperglycaemia in type II diabetes.

Pharmacokinetics and pharmacodynamics of a single oral dose of the insulin analog IN-105, in tablet form, in normal healthy volunteers, in the presence of food

S. Suryanarayan^{1,2}, A. Khedkar¹, A. Vedala¹, H. Iyer¹, K. Anil³, S. Desai³, S. Savale³, A. Atignat³;

¹Research and Development, Biocon Limited, Bangalore, India,

²Visiting Faculty, Diabetes & Endocrinology Division, Department of Molecular Medicine and Surgery, Karolinska Institute, Stockholm, Sweden,

³Human Pharmacology Unit, Clinigene Limited, Bangalore, India.

Background and Aims: IN105 is a modified insulin analog that is more resistant to proteolytic digestion compared to normal insulin and was found to be orally bioavailable in animal models and has the advantage of coming in through the portal vein. The aim was to study the safety, pharmacodynamics and pharmacokinetics of IN105 in Normal Healthy volunteers.

Materials and Methods: In the first of 2 Phase I studies, escalating doses, starting from 5 mg, 10 and 15 mg of IN105 were given to each of 12 overnight fasted, Normal healthy male volunteers (age range: 18 to 45, fasting glucose 70–110mg/dl & weight within 10% of ideal body weight from the table of desirable weights of adults – Life Insurance Corporation of India.), in consecutive study periods, spaced by a week each, to determine the Pharmacokinetics and Pharmacodynamics of the product. Subjects whose blood glucose fell by more than 30% in a given period were maintained on the same dose of IN105 for subsequent periods. 11 volunteers completed the study, with the cause of 1 dropout unrelated to drug administration. In the 2nd Phase I study, tablets delivering 5 or 10 mg of IN105 were given 20min, 10min and 2 minutes before a high carbohydrate breakfast, to overnight fasted subjects, in consecutive study periods to determine food effects on the absorption and action of IN105. These studies were preceded by a screening period which was used to determine a subject's response to a 5 mg dose of IN105 under fasted conditions, and based upon whether their blood glucose fell by more than 30%, they either remained on a 5mg dose or escalated to a 10mg dose for the subsequent food effects study periods. The plasma

insulin levels achieved with 10mg of IN105 from the first Phase 1 study were considered adequately high to allow any food effects to be observed. 14 normal healthy male volunteers (inclusion criteria as for the first Phase 1 study), participated in this study, with 1 dropout with a cause unrelated to drug administration. Immunoreactive insulin levels in the blood were measured along with the C-peptide and glucose levels. Mass spectrometry was also used to verify the presence of intact IN105 in the Plasma and distinguish it from human Insulin.

Results: IN105 in a tablet form was found to be safe in Normal Healthy volunteers. The most common adverse event in the first study was hypoglycemia, all of which was found to be drug related (n=7). In both studies, IN105 levels were detected in blood within a few minutes of dosing. IN105 levels peaked at approximately 20 minutes and the maximum pharmacodynamic effects appear at approximately 40 minutes post dosing. IN105 is absorbed when taken 2 minutes before a meal also. However, the best absorption occurs when taken 20 minutes before a meal. There is pharmacokinetic dose response with increasing dosing of IN105 and there is a predictable pharmacodynamic response of individual subjects to a given dose, over the periods studied.

Conclusion: IN-105 is safe and has pharmacodynamic and pharmacokinetic response of a rapid acting insulin.

Mean (SE) Change from Baseline in AUC/T for Glucose during OGTT

0220

Safety and preliminary efficacy of PPM-204, a novel pan-PPAR agonist, in treatment-naïve type 2 diabetic subjects

A. Katz¹, K. Weisel¹, L. Hickey¹, B. Tammara¹, G. Skoglund², W. Spinelli³, K. Nolop⁴, X. Meng¹;

¹Early Development & Clinical Pharmacology, Wyeth Research, Collegeville, United States, ²Wyeth Nordic, Wyeth Research, Solna, Sweden,

³Medical Research, Wyeth Research, Collegeville, United States,

⁴Development, Plexxikon, Berkeley, United States.

Background and Aims: The safety and anti-hyperglycemic effects of PPM-204, a novel pan-PPAR agonist, were studied in treatment-naïve type 2 diabetic subjects.

Materials and Methods: Eighty-seven treatment-naïve type 2 diabetic subjects (53 male and 34 female, with the following baseline characteristics {mean ± SD}: age 56.6 ± 8.4 years, BMI 30.8 ± 3.9 kg/m², and fasting glucose 158.4 ± 43.5 mg/dL) were randomized to receive one of three oral doses of PPM-204 (25, 75, or 225 mg/d), pioglitazone 30 mg/d, or placebo once daily for 28 days. Four-hour oral glucose tolerance tests (OGTT) were performed before and after 28 days of treatment. Other efficacy and pharmacodynamic parameters included fasting glucose and insulin, adiponectin, and fructosamine. Safety evaluation included edema assessment, body weight, total body water (TBW) and extracellular fluid (ECF) using deuterium and NaBr.

Results: Time-adjusted area under the curve (AUC/T) for glucose and insulin during a four-hour OGTT decreased in a dose-dependent manner. Mean change from baseline in AUC/T for glucose was -1.4, -10.4, and -36.5 mg/dL in the 25, 75, and 225 mg/d groups respectively, 11.9 for placebo, and -11.8 for pioglitazone. Mean change from baseline in AUC/T for insulin was -46.6, -28.3, and -58.6 pmol/L in the 25, 75, and 225 mg/d groups, respectively, -6.9 for placebo, and -10.7 for pioglitazone. After 28 days of treatment, fasting glucose decreased significantly in the 225 mg/d and the pioglitazone-treated groups and fasting insulin decreased significantly in the 225 mg/d group. Adiponectin increased in a dose-proportional manner to approximately 57% and 195% in the 75 and 225 mg/d groups and by 93% in the pioglitazone group. Fructosamine did not change significantly in any of the groups.

No subjects were discontinued because of adverse events (AEs) and no serious AEs occurred in the study. Four mild AEs of edema were reported (one in the placebo group, two in the 75 mg/d, and one in the 225 mg/d). No dose-dependent trends in AEs, vital signs, or ECGs occurred in the study. Mean body weight remained unchanged in all dose groups. TBW and ECF did not change significantly in any of the groups. Hemoglobin and hematocrit decreased in the 225 mg/d group by approximately 6% and 5%, respectively. In the 225 mg/d cohort, serum creatinine increased by approximately 11%, urea increased by approximately 27%, and creatine kinase did not change significantly.

Conclusion: PPM-204, given once daily for 28 days, lowered glucose and insulin in a dose-dependent manner, and was safe and well tolerated in treatment-naïve type 2 diabetic subjects at doses of 25, 75, and 225 mg/d.

Continuous subcutaneous insulin infusion therapy versus multiple daily injection therapy in patients with type 1 and type 2 diabetes mellitus: meta-analysis and systematic review

K. Horvath¹, K. J. Jeitler², A. Berghold³, T. W. Gratzner², T. R. Pieber², A. Siebenhofer¹;

¹EBM Review Center, Department of Internal Medicine, Medical University Graz, ²Institute of Medical Technologies and Health Management, Joanneum Research, Graz, ³Institute for Medical Informatics, Statistics and Documentation, Medical University Graz, Austria.

Background and Aims: Increasingly, continuous subcutaneous insulin infusion (CSII) is considered a valuable treatment option for patients with type 1 (T1DM) and type 2 (T2DM) diabetes mellitus in many health care systems; however, possible beneficial effects in terms of glycaemic control remain to be evaluated.

Materials and Methods: To compare the effects of CSII to multiple daily insulin injections (MDI) on glycaemic control and the risk of hypoglycaemic episodes in adult patients with T1DM and T2DM, a systematic literature search was conducted in the electronic databases MEDLINE, EMBASE and CENTRAL up to March 2007 for randomized controlled trials. A systematic review and meta-analyses were performed.

Results: T1DM: In 17 studies fulfilling the inclusion criteria, 908 patients were included. 11 Studies were conducted before the year 1990 and only three after the year 2000. Study periods lasted from a minimum of 5 weeks to a maximum of 2 years. Our meta-analysis found a between-treatment difference of -0.63% HbA_{1c}/HbA₁ in favour of CSII vs. MDI therapy (although a high degree of heterogeneity was detected). Median rates of mild or overall hypoglycaemic events per patient per time period were available from seven studies and were comparable between the different interventions: 1.9 (0.9 to 3.1) vs. 1.7 (1.1 to 3.3) events/patient/week for CSII and MDI therapy respectively. Incidence of severe hypoglycaemia was generally low and statistically different in two trials favouring CSII treatment. Total daily insulin requirements were found to be lower with CSII than with MDI therapy.

T2DM: Both studies fulfilling our inclusion criteria were conducted after the year 2000 and included a total of 234 patients. Follow-up was 24 and 52 weeks. In both trials CSII treatment resulted in a statistically not significant reduction of HbA_{1c} of -0.1% when compared to treatment with MDI. Also, the incidence of mild hypoglycaemic events was comparable between the intervention groups (1.1 [CSII] vs. 1.2 [MDI] events/patient/week in one and 0.8 [CSII] vs. 1.2 [MDI] events/patient/30 days in the other trial). No severe hypoglycaemic episodes were detected in one study and a rate of 0.1 [CSII] vs. 0.2 [MDI] events/patient/year in the other.

Conclusion: In this most extensive and up-to-date meta-analysis, CSII therapy in patients with T1DM resulted in a greater reduction of HbA_{1c}, seemingly without a higher rate of hypoglycaemia. This confirms current indications for CSII in patients with frequent hypoglycaemia with MDI.

In T2DM patients, CSII provides similar glycaemic control when compared to MDI therapy. The rates of hypoglycaemic episodes were comparable between the two insulin treatment strategies, indicating that CSII therapy is safe. The benefit of CSII for T2DM patients cannot be documented in terms of improved HbA_{1c} for an average patient.

Superior glycaemic control, less nocturnal hypoglycaemia and less weight gain with insulin detemir relative to NPH insulin in subjects with T1DM treated for 24 months using a treat-to-target concept

P. C. Bartley¹, M. Bogojev², J. Larsen³, S. C. Tamer², A. Philotheou⁴;

¹Department of Medicine, University of Queensland, St. Leonards, Australia, ²Clinic of endocrinology and metabolic diseases, Diabetes Center, Skopje, Macedonia, ³Novo Nordisk A/S, Bagsvaerd, Denmark, ⁴Faculty of Health Sciences, University of Cape Town, South Africa.

Background and Aims: This 24-month, multi-national, open-label, parallel group trial investigated the long-term efficacy and safety of insulin detemir

(IDet) and NPH insulin (NPH), both in combination with mealtime insulin aspart (IAsp), in subjects with T1DM using a treat-to-target concept.

Materials and Methods: A total of 497 men and women (men: 55%, mean age: 35 yrs, duration of diabetes: 13 yrs, BMI: 24.7 kg/m², HbA_{1c}: 8.3%) were randomised 2:1 to IDet (n=331) or NPH (n=166). Basal insulin was initiated once daily (evening) at comparable doses in both groups. Subjects were individually titrated based on self-measured plasma glucose (PG) levels aiming for pre-breakfast and pre-dinner PG targets ≤ 6 mmol/L (108 mg/dL) using simple algorithms with specific dose adjustments. A second basal morning dose was added if the average fasting PG ≤ 6.0 mmol/L, but the average pre-dinner PG remained ≥ 6.0 mmol/L after optimisation of the evening and bolus insulin doses.

Results: After 24 months, HbA_{1c} was superior with IDet compared to NPH: (IDet: 7.36, NPH: 7.58%, mean difference (IDet-NPH): -0.22% point, [95% CI: -0.41 ; -0.03%]) with reductions of 0.9 and 0.7% points, respectively. A higher proportion of subjects treated with IDet reached an HbA_{1c} $\leq 7\%$ in the absence of confirmed hypoglycaemia during the last month of treatment (IDet: 22% vs. NPH 13%, $p=0.019$). The risk of major and nocturnal hypoglycaemia was respectively 69% and 46% lower with IDet than with NPH ($p<0.001$). Fasting PG (FPG) was lower with IDet (IDet: 8.35, NPH: 9.43 mmol/L, $p=0.019$) as was within-subject variability in FPG as estimated by the SD (IDet: 2.18 vs. NPH: 2.52 mmol/L, $p<0.001$), whereas variation in pre-dinner PG was comparable in the two groups (IDet: 2.50, NPH: 2.46 mmol/L, $p=NS$). The shape of the 9-point PG profiles differed between treatments ($p=0.004$) with higher pre-dinner and lower FPG concentrations with IDet. Body weight gain was lower with IDet than with NPH (IDet: 1.7 kg, NPH: 2.7 kg, $p=0.024$), while hip/waist ratio and skinfold thickness were comparable in the two groups (NS). Insulin antibodies (IDet-specific and cross-reacting) increased in the IDet group during the first 64 weeks, but decreased slightly during the last 40 weeks. The overall safety profile was similar in the two groups, but hypoglycaemia was reported as serious adverse events (SAEs) in a higher proportion of subjects on NPH, while withdrawal due to adverse event were slightly more frequent with IDet (3.9% vs. 0.6%) and included 4 deaths (all considered as unlikely related to trial drug). SAEs considered possibly or probably related to trial drugs were reported in 4.2% vs. 6.7% of subjects on IDet and NPH, respectively.

Conclusion: Long-term (24 months) treatment with the insulin analogues IDet+IAsp was superior to NPH+IAsp in reducing HbA_{1c}, with added benefits of less hypoglycaemia at night and less weight gain. This treatment regimen was safe and the antibody development stabilised shortly after 1 year.

Intraperitoneal versus subcutaneous insulin administration in type 1 diabetes: preliminary results of a prospective randomized cross-over trial

E. van Ballegoie^{1,2}, S. J. J. Logtenberg³, N. Kleefstra^{3,1}, S. T. Houweling¹, K. H. Groenier⁴, H. J. G. Bilo^{3,5};

¹Langerhans, Medical Research Group, Zwolle,

²Internal Medicine, Bethesda General Hospital, Hoozeveld, ³Diabetes

Centre, Isala Clinics, Zwolle, ⁴General Practice, UMCG, Groningen,

⁵Internal Medicine, UMCG, Groningen, The Netherlands.

Background and Aims: As part of an ongoing cross-over trial to compare the effects of intraperitoneal (IP) insulin to subcutaneous (SC) insulin in poorly controlled type 1 diabetes (HbA_{1c} $>7.5\%$ and/or ≥ 5 hypoglycaemic events/week), preliminary data on glycaemic control, quality of life (QOL) and treatment satisfaction (TS) of 25 subjects enrolled thus far are reported.

Materials and Methods: At the end of a 3 month run-in phase, subjects are randomised to receive insulin either by IP (implantable pump; MIP 2007C, Medtronic) or SC administration. After a 6 month treatment phase, subjects crossed over to the other treatment mode. Glycaemic control was assessed with HbA_{1c}, frequency of hypoglycaemic events and time spent in euglycaemia. QOL was assessed with the SF-36 and the WHO-5. TS was assessed with the DTSQ. Data of the 1st trial phase were analyzed with t-test and general linear model.

Results: Enrolment started March 2006. Baseline characteristics: 11 males, 14 females; mean age 43.8 ± 11.6 years; mean diabetes duration 22.2 ± 10.6 years; mean HbA_{1c} $8.5 \pm 1.1\%$; HbA_{1c} $>7.5\%$ in 20 subjects; hypoglycaemic events ≥ 5 /week in 14 subjects. By March 2007, 19 subjects had completed the 1st treatment phase. One subject is lost to follow-up (IP-group) due to reasons unrelated to the study. There were no significant differences at the start of

the 1st phase between groups (table). HbA_{1c} decreased during the 1st half of the treatment phase and during the total treatment phase with IP insulin with 0.59% and 0.26% respectively, compared to 0.08% and 0.06% with SC insulin respectively (differences non-significant). Time spent in euglycaemia increased after 3 months IP insulin with 18.2% compared to a decrease with SC insulin of 3.8% (mean difference 22.1%; 95% CI 5.1, 39.0; p=0.01). At the end of the treatment phase the difference did not reach statistical significance. However, after 6 months, WHO-5 scores had increased significantly in the IP-group compared to the SC-group (mean difference 21 points; 95% CI 6.1, 35.6; p=0.01); differences in SF-36 summary scores did not reach statistical significance. DTSQ scores increased 8.4 points (95% CI 4.8, 12.1; p<0.001) in the IP-group compared to the SC-group. Perceived hypo- and hyperglycaemic events decreased significantly in the IP-group compared to the SC-group (p=0.020 and p=0.024, respectively).

Conclusion: Interim data suggest that IP insulin infusion tends to improve glycaemic control and increases time in euglycaemia, TS and QOL in otherwise poorly controlled type 1 diabetes. Further evaluation, especially after termination of the cross-over phase will determine whether these effects are sustainable and significant at the individual level.

Patient characteristics at start first treatment phase

	IP Insulin in 1 st phase	SC Insulin in 1 st phase
Number of subjects (M/F)	3/6	4/6

PREDICTIVE 303 Study: Implementation and outcomes of a simplified self-titration dosing guideline for insulin detemir in patients with type 2 diabetes

L. Meneghini¹, C. Koenen², W. Weng³, J.-L. Selam⁴;

¹Diabetes Research Institute, University of Miami Miller School of Medicine, United States, ²Novo Nordisk A/S, Bagsvaerd, Denmark, ³Novo Nordisk Inc., Princeton, United States, ⁴Endocrinology, Diabetes Research Center, Tustin, United States.

Background and Aims: The PREDICTIVE 303 study (N=5604) was part of the global PREDICTIVE study to evaluate the efficacy and safety of insulin detemir. The PREDICTIVE 303 study utilised a randomised controlled design to compare a simplified patient self-adjusted dosing algorithm (G1) to a standard-of-care physician-driven adjustments (G2), using insulin detemir in predominantly primary care settings over a period of 6 months. The primary objective of the study was to show that G1 was non-inferior to G2 in terms of HbA_{1c} reduction from baseline.

Materials and Methods: Detemir was started once daily at bedtime as an add-on therapy to any other glucose-lowering regimens, or as a replacement of previous basal insulin in patients with type 2 diabetes. Study sites were randomised to either G1 or G2. Patients from G1 sites adjusted their detemir dose every 3 days based on mean fasting blood glucose (FBG) values using a simplified algorithm: mean FBG < 4.4 mmol/L, reduce dose by 3U; between 4.4 – 6.1 mmol/L, no change; > 6.1 mmol/L, increase by 3U. Detemir dose for patients from G2 was adjusted by physicians according to the standard of care.

Results: Mean HbA_{1c} decreased from 8.5% at baseline to 7.9% at 26 weeks for G1, and from 8.5% to 8.0% for G2 (between group p=0.0106). FBG values decreased by 1.8 and 1.2 mmol/L for G1 and G2, respectively (between group p<0.0001). The mean daily detemir doses at 26 weeks for the patients in G1 and G2 groups were 0.7 and 0.5 U/kg, respectively. Body weight change from

baseline at 26 weeks (Δ BW) was minimal (0.1 kg for G1 and -0.2 kg for G2, between group p=0.0676). When patients were stratified into quintiles according to baseline BMI, mean weight changes were: +0.97, +0.31, -0.19, -0.41, and -0.45 kg in the BMI quintiles: ≤ 25 , > 25 and ≤ 30 , > 30 and ≤ 35 , > 35 and ≤ 40 , and > 40 kg/m², respectively. At 26 weeks, 88% of all patients remained on once-daily detemir therapy. The rates of hypoglycaemia (event/patient/year) were calculated based on episodes reported for the four weeks prior to each visit. The rates decreased significantly from 9.0 at baseline to 6.4 at 26 weeks for G1, and from 9.5 to 4.9 for G2 (p < 0.0001 vs. baseline for both groups).

Conclusion: Better glycaemic control was achieved in the patient self-titration group than in the physician-driven titration group. The majority of the patients were managed on once-daily detemir therapy. The use of detemir in this predominantly primary care setting resulted in significant improvements in glycaemic control without weight gain in the overall population. The simplified patient-driven titration algorithm appears to be safe and effective compared to physician-driven insulin dose adjustments.

OP 39 Retinopathy: clinical observations

The distribution of macular hard exudates is related to future visual acuity in subjects with type 2 diabetes

I. M. Stratton¹, P. H. Scanlon², R. R. Holman¹, R. J. Stirling³, H. L. Lipinski³, S. J. Aldington^{3,2};

¹Diabetes Trials Unit, Oxford Centre for Diabetes, Endocrinology and Metabolism, Oxford, United Kingdom,

²Ophthalmology, Cheltenham General Hospital, United Kingdom,

³Metabolic Medicine, Imperial College London, United Kingdom.

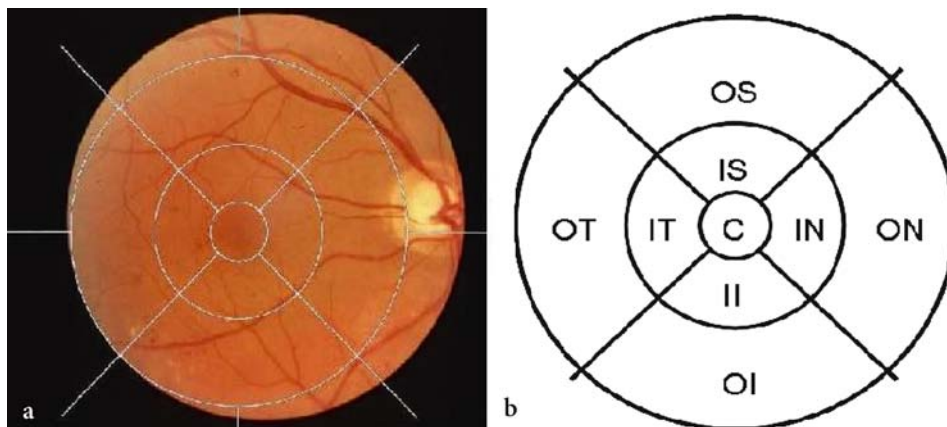

Background and Aims: To examine whether the geographical distribution of hard exudates (HE) in the macula field in subjects with type 2 diabetes (T2DM) is related to subsequent visual acuity (VA).

Materials and Methods: The UK Prospective Diabetes Study (UKPDS) was a randomised clinical trial of therapies of newly diagnosed T2DM in 5102 subjects who had four field retinal photographs taken at entry and then at 3 yearly intervals. Photographs were graded using the ETDRS system. Those subjects with HE in the macular field were retrieved, digitised, and diagonal lines superimposed intersecting at the foveal centre, defining nasal, superior, temporal and inferior regions, each split into inner and outer areas, and centre. HE in each of these 9 fields were recorded as none, definite HE ETDRS standard level 2, level 3, level 4 or worse. VA was measured with LogMAR charts (5 letters per line). Association of HE score by region with VA 3 years after HE appearance was analysed using mixed models. These adjusted for age, gender, biochemical variables and duration of diabetes. Levels of HE in each sector were included in the model in a step-wise fashion, and estimates obtained for the influence of HE in each sector on subsequent VA.

Results: Of 4738 who ever had a photograph of sufficient quality taken, 746 subjects had HE recorded at level 2 or higher at any time (15.7%). Photographs for those with at least 2 good quality photographs three years apart and VA assessed at coincident visits were used in this analysis. In 168 eyes in 132 patients with newly emergent HE (i.e. with at least one earlier photographs with no evidence of HE) the distribution of HE was non uniform (table 1), Chisquared on 24 degrees of freedom=145, $p<0.0001$. In 255 subjects contributing 1 or 2 eyes over up to 21 years (833 eyes), HE level 3 or worse was associated with reduced LogMAR letter count 3 years later, in IN field 7.9 (2.6) (mean (s.e.)) letters were lost, II field 7.9 (3.0) and OI field 4.9 (2.4).

Conclusion: The geographical distribution of HE is not uniform across the macula field. Those with HE in IN, II and OI sectors of the macula field had worse vision 3 years later than those with HE elsewhere. The distribution of HE in diabetic retinopathy may be an important indicator of reduced visual acuity. (Fig. 1)

Fig. 1a and 1b
Example scanned right macular image with grid applied and identity of regions within overlay grid (for right eye)

Regional distribution and severity of HE (n=no of eyes, %=proportion)

Region	Grade 0 n (%)	Grade 2 n (%)	Grade 3 n (%)	Grade 4 n (%)
Centre (C)	112(56.7%)	44(26.2%)	12(7.1%)	0(0%)
Inner superior (IS)	122(72.6%)	28(16.7%)	16(9.5%)	2(1.2%)
Outer superior (OS)	97(57.7%)	33(19.5%)	31(18.9%)	7(4.2%)

Flicker-induced vasodilation of retinal arteries decreases with increasing stages of diabetic retinopathy

A. Mandecka¹, J. Dawczynski², M. Blum³, N. Müller¹, C. Kloos¹, W. Vilser⁴, G. Wolf¹, U. Müller¹;

¹Internal Medicine III, Friedrich Schiller University Jena, ²Department of Ophthalmology, Friedrich Schiller University Jena, ³Department of Ophthalmology, Helios Klinikum Erfurt, ⁴Imedos, Jena, Germany.

Background and Aims: Stimulation of the retina with flickering light increases retinal arterial and venous diameter in animals and humans. Nitric oxide appears to be a mediator of the retinal vasodilation to flicker. The reduction of flicker induced retinal vasodilation is considered as a vascular/endothelial dysfunction. We investigated the response of retinal vessels on flickering light in patients with diabetes mellitus in different stages of diabetic retinopathy (DR).

Materials and Methods: We studied 54 healthy volunteers (age 41±16), 68 type 1 diabetic patients (age 47±15, duration of diabetes 17±10 years) and 172 type 2 diabetic patients (age 61±10, duration of diabetes 11±7 years). The diameter of major temporal retinal arteries and veins was measured continuously online with a Dynamic Vessel Analyzer (IMEDOS GmbH Jena, Germany). Each test consisted of an 80-s baseline plus three 20-s periods of flicker stimulation followed by an 80-s period of observation. The fundus examination was performed after induction of mydriasis with tropicamide 1% eye drops. The diabetic retinopathy was classified using ETDRS-criteria as no DR (NDR), mild nonproliferative DR (mild NPDR), moderate nonproliferative DR (MNPDR) and severe nonproliferative DR (SNPDR).

Results: In retinal vessels, the response to stimulation with diffuse luminance flicker was significantly diminished in diabetic patients compared to healthy volunteers. In healthy controls, flicker stimulation increased the retinal arterial diameter by 3.58±2% and in diabetic patients by 2.17±2.4% ($p<0.001$). This response was significantly decreased regardless of type of diabetes. In non-diabetic controls flicker stimulation increased venous retinal diameter by 4.5±2.3% and by diabetic patients by 3.6±2.2% ($p=0.008$).

The retinal arterial diameter change was 3.5 ± 2 , 2.6 ± 2.4 , 2 ± 2.7 , 1.6 ± 2.1 and 1.4 ± 1.8 % in the control group, NDR group, mild NDR group, moderate NDR and severe NDR group, respectively. The retinal arterial response in all diabetic patients without retinopathy was significantly decreased in comparison to healthy subjects ($P=0.003$). Despite of no significant difference in age between diabetic patients without retinopathy and moderate NDR group, the retinal response was, in patients with moderate NDR, significantly decreased ($P=0.048$).

The arterial and venous flicker response is also significantly decreased if approximately age-equivalent subgroups of diabetic patients and subjects 40–70 years of age were analyzed.

Conclusion: Flicker responses of retinal arteries and veins are abnormally reduced in patients with diabetes mellitus, regardless of the diabetes type. This decreased response deteriorated with increasing stages of diabetic retinopathy. The response was already low before the clinical appearance of retinopathy. The noninvasive testing of the function of retinal autoregulation using the Dynamic Vessel Analyzer offers promising perspectives to become a useful tool for the detection of diabetic vessel pathology.

Endothelial perturbation: A link between non-dipping and retinopathy in type 2 diabetes?

S. T. Knudsen¹, P. Jeppesen², C. A. Frederiksen³, N. H. Andersen³, T. Bek², J. Ingerslev⁴, C. E. Mogensen⁵, P. L. Poulsen⁵;

¹Medical Dept. M/C (Diabetes & Endocrinology), Aarhus University Hospital, ²Dept. of Ophthalmology, Aarhus University Hospital,

³Dept. of Cardiology, Aarhus University Hospital, ⁴Centre for Haemophilia and Thrombosis, Aarhus University Hospital, ⁵Medical Dept. M (Diabetes & Endocrinology), Aarhus University Hospital, Denmark.

Background and Aims: Reduced diurnal blood pressure (BP) variation (“non-dipping”) is associated with both micro- and macrovascular complications in patients with type 2 diabetes. In non-diabetic subjects, non-dipping is associated with endothelial dysfunction. The relation between endothelial perturbation and diurnal BP variation in diabetic subjects has not previously been studied. We examined the relationship between non-dipping, markers of endothelial activation, and severity of retinopathy in patients with type 2 diabetes.

Materials and Methods: A total of 76 subjects, stratified to four gender-, age-, and duration-matched groups of each 19 subjects participated. Group A: non-diabetic subjects; Group B-D, type 2 diabetic subjects. Group B: no retinopathy; Group C: minimal background retinopathy; Group D: diabetic maculopathy. All subjects underwent 24-h ambulatory BP monitoring. Von

Fig. 1. Systolic night/day blood pressure ratio in the four groups. Group A: non-diabetic subjects. Group B: type 2 diabetic subjects without retinopathy. Group C: type 2 diabetic subjects with minimal background retinopathy. Group D: type 2 diabetic subjects with diabetic maculopathy.

Data are mean \pm SE. * $P<0.05$ vs. Group A and B.

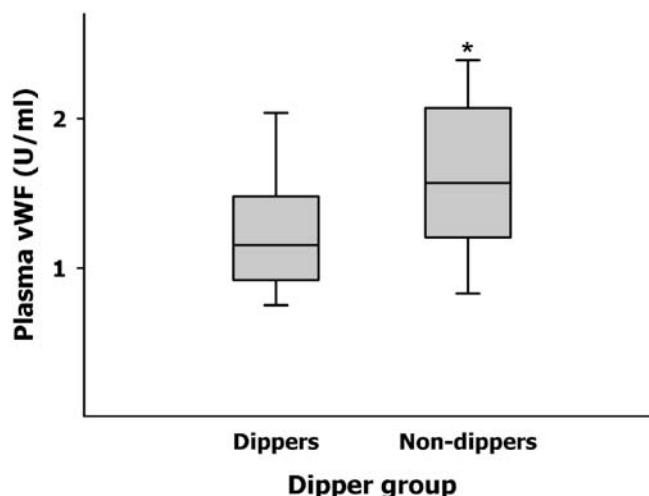

Fig. 2. Plasma levels of von Willebrand factor in systolic dipping and non-dipping type 2 diabetic subjects. Bars represent medians, and boxes indicate IQRs. * $P<0.01$ vs. dippers

Willebrand factor (vWF), fibrinogen, E-selectin, and ICAM-1 were measured in plasma.

Results: Systolic night/day BP ratio increased gradually in Groups A to D: $85.2 \pm 5\%$, $85.7 \pm 7\%$, $88.5 \pm 6\%$, and $90.5 \pm 7\%$, respectively, $P<0.05$. Among diabetic patients, non-dippers had significantly higher plasma levels of vWF and fibrinogen than dippers (median/interquartile range 1.7/1.4–2.1 vs. 1.2/0.9–1.5 U/ml, $P<0.01$ and 3.6/3.6–3.7 vs. 2.9/2.5–3.6 g/l, $P=0.01$). Plasma levels of fibrinogen and ICAM-1 were higher in diabetic than in non-diabetic subjects (3.3/2.6–4.0 vs. 2.5/2.4–2.8 g/l and 218/192–268 vs. 191/160–217 ng/ml, respectively, $P<0.01$ for both), but did not differ significantly between retinopathy groups (B-D).

Conclusion: Non-dipping is associated with elevated plasma levels of proteins related to endothelial cell activation as well as with retinopathy in subjects with type 2 diabetes. This finding suggests a possible mechanism linking non-dipping with microvascular complications in these subjects.

Birth order is a predictor for proliferative retinopathy in type 1 diabetic sibs (The FinnDiane Study)

K. Hietala^{1,2}, C. Forsblom^{1,3}, P. Summanen², P.-H. Groop^{1,3};

¹Folkhalsan Institute of Genetics, Folkhalsan Research Center, Helsinki,

²Department of Ophthalmology, Helsinki University Central Hospital,

³Division of Nephrology, Department of Medicine, Helsinki University Central Hospital, Finland.

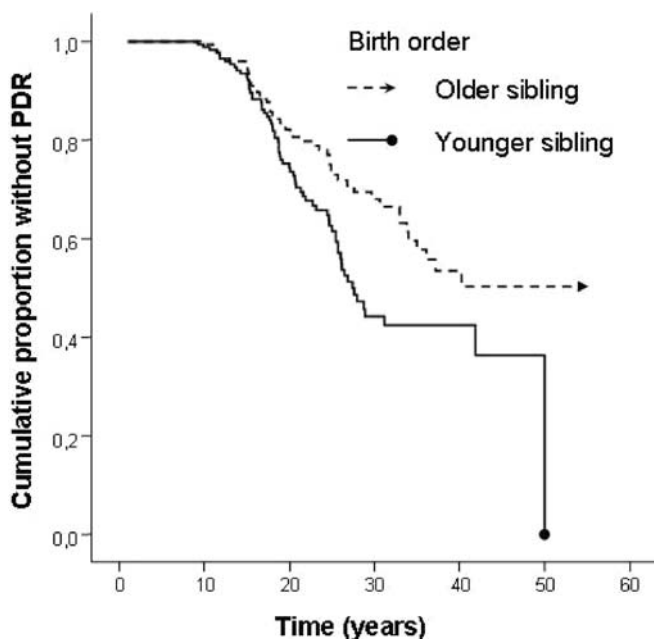

Background and Aims: Diabetic nephropathy and retinopathy (DRP) show familial clustering. Apart from conventional risk factors, such as blood pressure, glycemic control and duration of diabetes, it is not clear which non-genetic familial factors contribute to the risk of DRP. It can be hypothesized that the level of diabetes care of young children is likely to be affected by the number of siblings as well as by their birth order. Therefore, the aim was to study whether the number of siblings and their birth order is associated with the development of proliferative retinopathy (PDR) in type 1 diabetic (T1D) sibs.

Materials and Methods: The FinnDiane-study has so far examined around 4800 patients with T1D. Among them we found 199 families with at least two siblings with T1D. The ophthalmic records were obtained from 388/417 (93%) patients and fundus photographs from 262/388 (68%) patients of 196/199 families. In families with more than two siblings the siblings were paired using all possible combinations. A total of 208 sibpairs were thus formed. Four twin pairs were excluded from the calculations. The DRP-status was classified based on fundus photographs and/or repeated clinical ophthalmic examinations using a modified ETDRS-grading scale. Due to clustered data (sib pairs) with a binary outcome measure (PDR yes/no) odds ratios were

estimated using generalized estimating equations with logit link function. A Kaplan-Meier model was used for survival analysis.

Results: The mean age at onset of T1D was 15.6 (SD 11.6) years and duration of T1D was 25.5 (12.1) years. Male/female ratio was 216/172. PDR occurred in 116/388 patients (29.9%). The median number of siblings in the family was 4 (IQR 3–6). There was an increased risk of PDR for the younger siblings (OR 1.5, 95% CI 1.07–2.2, $p=0.022$) which increased further (OR 2.2, 1.2–4.0, $p=0.01$) when adjusted for HbA_{1c}, blood pressure, age at onset and triglycerides. Number of children in the family ($p=0.78$) and sex of siblings ($p=0.35$) had no effect in this analysis. A higher risk for younger siblings was shown as well by survival analysis (LogRank $p=0.006$).

Conclusion: The birth order, but not the number of siblings appears to predict the development of PDR in sib pairs implicating a possible role for social factors in the pathogenesis of PDR.

Proteomic approach to identify novel soluble factors secreted by pancreatic stellate cells with paracrine effects on ARIP ductal cell model

M. Lucas¹, E. Mato², S. Barceló¹, A. Novials², R. Gomis¹;

¹Endocrinology and diabetes, IDIBAPS-Hospital Clinic, Barcelona,

²Diabetes Unit, Sardà Farriol Foundation, Barcelona, Spain.

Background and Aim: Active pancreatic stellate cells (PaSCs) secrete many soluble factors important in pancreas physiology. Most of them are associated with fibrosis and matrix turnover. Other roles including paracrine effects on progenitors have not been investigated. In pancreas, there is no consensus on the nature of the adult pancreatic stem cells or where these progenitors are located. Several authors have proposed that a subpopulation of ductal cells has the capacity of transdifferentiation into endocrine phenotype, but the external and morphogenic signals that determine their differentiation are still unknown. The aim of this study was to analyse the secretome of PaSC in order to identify novel soluble factors that could have paracrine effects on ductal cells.

Materials and Methods: PaSC were isolated and expanded from pancreas of lactating rats. The culture medium of PaSC (conditioned medium) was collected and used to treat ARIP ductal cells for 24 or 72 hours. Proliferation and viability assays were performed by BrdU and MTT, and gene expression of CK19 (ductal marker) and PDX1 (endocrine marker) were quantified by Real-Time PCR. The soluble factors of the conditioned medium were identified by proteomics using two-dimensional electrophoresis (2D) coupled to mass spectrometry MALDI-TOFF and peptide mass fingerprint (Aldente (Expassy)). Identified proteins (focus proteins) were validated by RT-PCR, and mapped onto Ingenuity Pathways. Also ELISA assay was performed.

Results: PaSC conditioned medium inhibited proliferation of ARIP cells 40% as compared to control media without affecting cell viability. Additionally, conditioned media-treated cells showed 5.4-fold PDX1 mRNA levels and 0.48-fold CK19 mRNA levels compared to control cells, being these differences statistically significant (Student's t-test). 112 protein spots identified in the conditioned medium were then selected for analysis, and 72 of these were successfully identified. 19 of them were soluble factors (with signal peptide), and were included in clusters of development/differentiation, chaperones, proteases, immune response, transport related proteins, GTPases, extracellular matrix and retinol related proteins. Proteomic data mining by Ingenuity Pathway Analysis displayed several significant networks. One of them highlighted TGFβ1 as a non-focused protein. Presence of this factor in the conditioned medium was confirmed by ELISA immunoassay (48.95±5.18 pg/mL), and ARIP cells were shown to express TGFβ1 receptors. To evaluate the importance of TGFβ1 in this cellular model, we blocked their effects with a pan-neutralizing antibody. The results showed that the rate of proliferation was recovered to initial levels, but TGFβ1 had no effect on the PDX1 expression increase. Finally, the secretome identified three novel proteins: PEDF, LIF and Wnt5b, all of them involved in differentiation and developmental processes in different biological systems.

Conclusion: We characterised for the first time the PaSC secretome. This secretome inhibits proliferation and induces changes of gene expression in ARIP ductal cell line. TGFβ1 secreted by PaSC has the antiproliferative effect, whereas novel soluble factors identified such as PEDF, LIF and Wnt5b, could be involved in the PDX1 and CK19 transcription changes

Hedgehog signaling during expansion and beta cell differentiation of human pancreatic islet-derived mesenchymal (hPIDM) cells

R. Gallo¹, V. Tellone¹, G. Bernardi¹, P. Marchetti², M. Masini², E. Ferretti³, A. Gulino³, F. Dotta¹;

¹Dept. Internal Medicine and Endocrine Sciences, University of Siena,

²Dept. Endocrinology and Metabolism, University of Pisa, ³Dept. Experimental Medicine and Pathology, University of Rome, Italy.

Background and Aims: Hedgehog (Hh) signalling is a key regulator of cell fate and differentiation, as well as of stem/progenitor cell maintenance

and self-renewal in many organs. “*In vitro*” generation of regulated insulin-producing cells from stem/progenitor cells is crucial to develop a proper cell-therapy as a cure for type 1 diabetes. In the light that Hh signalling plays an important role both in endocrine pancreas development and in the regulation of insulin secretion in beta cell lines, we have studied the expression of Hh pathway components during expansion and beta-cell differentiation of primary precursor cells derived from human pancreatic islets.

Materials and Methods: Human Pancreatic Islet-Derived Mesenchymal (hPIDM) cells were obtained by plating human pancreatic islets in tissue culture dishes with RPMI 1640 medium containing 10% FBS. hPIDM cells, cultured for 21 days in serum-free RPMI, were differentiated into a pancreatic endocrine phenotype. Origin and phenotype of proliferating and differentiated hPIDM cells were studied by immunofluorescence, electron microscopy, FACS, and Real-Time-PCR analysis. To study the Hh signalling we evaluated, by real time RT-PCR, expression of target genes Gli1 and Gli2, activators of Hh pathway, and of repressor Gli3, in human islets and in proliferating as well as differentiated hPIDM cells. The effect of Hh signalling on proliferation of hPIDM cells was evaluated using cyclopamine, a known inhibitor of Hh pathway.

Results: Human pancreatic islets attached within 24 hrs in “*in vitro*” culture, showing a central “core” of aggregated cells surrounded at the periphery by a migrating population of flattened epithelial cells. Double immunofluorescence analysis, for Ki-67, nestin, C-peptide and PDX-1, after 3 and 6 days of culture, showed proliferating cells deriving from β -cells. These cells were maintained in culture for up to 20 passages and approximately 10^{10} cells were obtained from each original islet seeded. FACS, immunofluorescence and Real-Time-PCR revealed a transition from endocrine to mesenchymal phenotype of such proliferating cells (hPIDM). These cells, in serum free RPMI, generated “islet-like” aggregates showing C-peptide and glucagon induction, by immunofluorescence analysis, and beta-cell like secretory granules, by electron microscopy. Real-Time-PCR confirmed an acquired endocrine pancreatic phenotype of these aggregates. In addition, Gli1 and Gli2 mRNA levels were highly upregulated, paralleled by down-regulated Gli3, in hPIDM cells vs. human islets, in accordance with an activation of Hh signalling in hPIDM cells. Interestingly, in hPIDM-derived islet-like aggregates, an inhibition of the Hh pathway was confirmed by reduction of Gli1 and Gli2 and induction of Gli3 expression. Cyclopamine administration decreased the proliferating rate of hPIDM cells in a dose-dependent manner.

Conclusion: Taken together, these results indicate a direct involvement of Hh signalling in the β -cell-mesenchymal transition occurring in “*in vitro*” cultured human islets. Based on these data Hh signalling could contribute either to stimulate proliferation, or to maintain a “precursor” phenotype in the hPIDM cells.

A CK19+ population of insulin-producing surrogate cells generated from mouse embryonic stem cells

O. Naujok¹, F. Francini¹, A. Jörns², S. Lenzen¹;

¹Institute of Clinical Biochemistry, Hannover Medical School, Germany,

²Center of Anatomy, Hannover Medical School, Germany.

Background and Aims: Embryonic stem (ES) cells are a potential source for insulin-producing cells, which have the potential to differentiate into tissues from all three germ layers. The scarcity of donor islets of Langerhans for therapy of type 1 diabetes mellitus has focused research on the development of surrogate cells with characteristics similar to those of pancreatic beta cells. It was therefore the aim of this study to develop a differentiation protocol, which drives differentiation of ES cells towards insulin-producing cells and to combine this with a technique for separation of these insulin-positive cells.

Materials and Methods: A 2.9 kb promoter fragment of the Krt19 gene (cytokeratin 19) was cloned to drive the expression of eYFP in stably transfected ES-D3 cells. eYFP+ and eYFP- cells were FACS sorted on d12, d19 and d26 of differentiation and gene expression was examined by qPCR analyses. The differentiation stages were additionally studied by electron microscopy (EM) and immunohistochemistry.

Results: The pCK19-eYFP construct was successfully integrated into ES cells. Analysis of the gene expression of the endogenous cytokeratin 19 revealed a 4 to 7 fold higher cytokeratin 19 expression in eYFP+ cells when compared to eYFP- cells. Carbonic anhydrase 2, as a second marker for ductal cell progeny, showed a 2 fold increase in eYFP+ cells at day 12 and a 9 fold

increase in expression in eYFP+ cells at day 26 when compared to eYFP- cells. Quantitative analysis of gene expression revealed a low expression of insulin in eYFP+ and eYFP- cells up to day 19. A significant 80 fold increase in insulin gene expression was observed in eYFP+ cells on day 26 as compared to day 12 and day 19. Compared with eYFP- cells insulin gene expression on day 26 was higher by a factor of 38, whereas the level of insulin gene expression in eYFP- cells did not change significantly. Glucagon gene expression was not detectable at day 12 and day 19. While glucagon gene expression remained barely detectable at day 26 in eYFP+ cells, it increased to appreciable levels in eYFP- cells 12 times higher than in eYFP+ cells. Ultrastructure of differentiated eYFP+ cells, in contrast to eYFP- cells, exhibited clear signs of differentiation comprising subcellular organelles for synthesis, processing, storage and release of insulin. Moreover, eYFP+ cells showed positive staining for C-peptide and insulin in the cytoplasm providing evidence for ongoing active pre-proinsulin biosynthesis and for insulin processing, while CK19-cells were negative for C-peptide.

Conclusion: Cytokeratin 19 is a marker for pancreatic duct cells. Duct cells have been considered to be a pool for newly derived beta cells during organogenesis of the pancreas. Following this assumption, we have set up a separation strategy using FACS sorting of fluorescent eYFP+ and non-fluorescent eYFP- cells. Gene expression analysis of the endogenous CK19 revealed, that this gene is predominantly expressed in the FACS-sorted eYFP+ population. Thus, our selection procedure purifies ductal progenitor cells and separates them successfully from an eYFP-, non-ductal cell population. A detailed molecular, biochemical and morphological analysis revealed that eYFP+ cells represent a population of differentiated ES cells, which express the insulin prohormone gene, and process, store and release insulin.

Generation and characterization of human beta cells long term cultures

L. Labriola¹, M. G. Peters², K. Krogh¹, I. Stigliano², M. C. C. Machado³,

E. Bal de Kier Joffe², L. Puricelli², M. C. Sogayar^{1,4};

¹NUCEL- Cell and Molecular Therapy Center, USP, São Paulo -SP, Brazil,

²Institute of Oncology, UBA, Buenos Aires, Argentina,

³Surgery, School of Medicine, University of São Paulo, Brazil,

⁴Biochemistry, Chemistry Institute, USP, São Paulo, Brazil.

Background and Aims: The use of primary beta-cells in biochemical and molecular research is limited by the availability of pancreatic endocrine tissue. The *in vitro* culture of insulinomas, which are rare pancreatic tumors arising from beta-cells, provides an attractive tool to study cell proliferation and insulin synthesis and secretion. However, only few human beta-cell lines have been described, with long-term passage resulting in loss of insulin secretion. Therefore, we set out to establish and characterise human insulinoma cell cultures.

Materials and Methods: Three *ex-vivo* primary cultures (APM, VGA and CPR) were obtained from independent donors after surgical resection and tissue processing. In order to further characterise these cultures, we assessed insulin and C-peptide levels by electrochemiluminescence. Specific antigenic characteristics were determined by immunofluorescence (IF) and Western blotting (WB) assays. Beta-cell markers were examined by Real-time RT-PCR. We also examined serum starvation and Doxorubicin-induced apoptosis, tumorigenicity by *in vivo* assays, cell migration and invasion by wound healing, Transwell and zymography assays.

Results: *Ex-vivo* primary cultures obtained from independent human insulinomas (APM, and CPR cultures) and VGA cultures derived from a human nesidioblastosis case, were cultured up to passage number 15 (approximately 20 weeks), presenting a similar doubling time (40h). APM cells were 1.5 times more sensitive to apoptosis induced by serum starvation than the other cell lines, while only CPR cells were sensitive to Doxorubicin (48h treatment, 0.5–12 μ M), with an IC50 of 5.1 μ M. We observed that these cell cultures produce and secrete human insulin and C-peptide, but none of them display glucose-induced insulin secretion. IF assays revealed that the APM, CPR and VGA cultures express Chromogranin A, Insulin, C-peptide, Glut2 and PDX-1, while no positive staining was detected for Glucagon, Desmin, Vimentin and CK19, confirming the beta-cell nature of these cell cultures. Furthermore, using IF and WB, we determined that all of these cultures express beta1-integrin and beta-catenin, but only APM was positive for E-cadherin. All beta cell lineages survived an anchorage independent culture forming spheroids, while only APM proliferated under these conditions. VGA cells presented the highest motility, as demonstrated

by wound healing assays (VGA: 30% of wound coverage vs. 17% displayed by the other cell lines, at 18h post-healing). All cell lines secreted similar MMP9 activity while no MMP2 was detected. However, none of them were able to invade an extracellular matrix substrate, as shown by Transwell assays.

Finally, *in vivo* tumorigenesis assays in nude mice showed no tumor formation when VGA cells were tested and mice were examined three times a week for up to 60 days after cell suspension inoculation.

Conclusion: We have developed three human beta cell lines that maintain the characteristic antigenic and insulin secretion profiles of the original tumors. Although the behavior of these cell lines does not perfectly mimic the primary beta-cell physiology, they are extremely valuable tools for the study of molecular events underlying beta-cell function and dysfunction.

OP 41 Novel biomarkers for coronary vascular disease

0233

The inflammation marker YKL-40 is elevated in patients with type 2 diabetes and is associated with an increased mortality rate in normal individuals after adjustment for risk factors of cardiovascular events

C. N. Rathcke¹, I. Raymond², C. N. Kistorp¹, J. Faber¹, H. Vestergaard¹; ¹Dep. of Endocrinology, Herlev Hospital, Herlev, ²Dep. of Cardiology, Gentofte Hospital, Gentofte, Denmark.

Background and Aims: Patients with type 2 Diabetes (T2D) have an increased mortality due to cardiovascular disease (CVD). We have previously found that the inflammation marker YKL-40 is elevated in patients with T2D and is correlated with insulin resistance and concentrations of fatty acids and triglycerides, but not with CRP nor with parameters of the glycaemic profile. Furthermore, patients suffering from acute coronary syndrome have elevated levels of YKL-40. All together this indicates a specific association to the accelerated atherosclerosis in patients with T2D. In the present study we focus on normal individuals without any history of CVD to state the baseline correlation between levels of YKL-40 and the development of CVD and the mortality status. The follow-up period was 5 years.

Materials and Methods: Blood and urine samples were provided from 658 normal individuals aged 50 to 89 years recruited from general practices in a community of Copenhagen, Denmark. 32 participants were excluded because of prevalent heart failure, renal insufficiency and lack of follow-up data including a total of 626 participants in the study. Participants were examined between September 1998 and January 2001 and were followed up until December 2003 with respect to mortality status and the development of CVD. Median follow-up period was 5.0 (0.17–5.28) years. Codes of diagnosis for CVD were pre-specified according to the International Classification of Diseases (ICD-10) and were cross-checked with the discharge registry of The Danish National Board of Health, which records all primary hospital discharge diagnoses in Denmark. Deaths from CVD were ascertained from central registers in the Danish National Board of Health and verified by study physicians from death certificates.

Results: Concentrations of YKL-40 were significantly elevated in patients with T2D compared with healthy individuals (149,14 ng/ml vs. 100,14 ng/ml, $p < 0,0001$). The absolute unadjusted increase in mortality risk for patients with YKL-40 > median (59,50 mg/ml) vs. YKL-40 ≤ median was 15,4% (24% vs. 9%, $p < 0,0001$). After adjustment for the cardiovascular risk factors of age, sex, smoking, diabetes, hypertension and ischemic heart disease, total cholesterol, CRP and serum creatinine the hazard ratio

of mortality for values of YKL-40 > median (59,5 ng/ml) was 1,63 (95% confidence interval (CI) 1,30–2,01). Additional adjustment for urinary albumin/creatinine ratio and NT-proBNP did not attenuate the predictive value of YKL-40 significantly (HR, 1,54; CI, 1,21–1,95, $p < 0,0001$). YKL-40 was not found to be a specific predictor of coronary heart disease, stroke or cardiovascular death.

Conclusion: YKL-40 is elevated in patients with T2D and is an independent predictor of death of all causes without specific prediction of macrovascular disease or cardiovascular death.

0234

Adam17 is elevated in pre-diabetic and diabetic patients

M. Cardellini, R. Menghini, S. Rizza, R. Lauro, M. Federici;
Department of Internal Medicine, University of Rome “Tor Vergata”, Italy.

Background and Aims: The Regulated Membrane Proteolysis Network (RMPN) is a system that controls the shedding of several cell surface-anchored molecules such as cytokines, growth factors and receptors and is modulated by metalloproteases belonging to the ADAMs family, particularly ADAM17. This system sustains chronic inflammation that may play a role in the pathogenesis of insulin resistance and related endothelial dysfunction. To investigate if an activation of the RMPN is related to the glucose metabolism impairment we studied two different cohorts: 1) healthy first degree relatives of type 2 diabetic patients (FDRs) and 2) atherosclerotic patients (diabetics, DM2, or nondiabetics, ATS) who underwent to carotid endoarterectomy.

Materials and Methods: In the first cohort (35 healthy FDRs) we evaluated insulin sensitivity by euglycemic-hyperinsulinemic clamp study, the carotid artery intima-media thickness, as an early manifestation of atherosclerosis, and the endothelial dysfunction by flow mediated vasodilation (FMD). Monocytes were isolated from peripheral blood in order to assess expression of LOX-1, CCR-2, ADAM17 and TIMP-3 genes and some soluble molecules, such as sICAM-1, sVCAM-1, sTNFRI, sRIL-6 and IL-6, were measured to evaluate the membrane proteolytic cleavage through elisa assays.

In the second cohort (n=70, DM2=21, ATS=49) we analyzed expression of ADAM17 in the atherosclerotic plaques obtained from carotid endoarterectomy.

Results: In FDRs, both insulin sensitivity ($r = -0,381$ $p = 0,04$) and intima-media thickness ($r = 0,545$ $p = 0,003$) were significantly correlated with plasmatic levels of soluble receptor of interleukin 6 (sR-IL6), a specific substrate for ADAM17. Next, we dichotomized FDRs in insulin sensitive and insulin resistant using the glucose disposal rate. We observed that ADAM17 expression was significantly increased in insulin resistant (n= 17) compared with insulin sensitive (n=18) subjects ($p = 0,03$).

In the second cohort, we found that the expression of ADAM17 is higher in plaques from diabetic patients than in non-diabetic patients ($p = 0,05$) and it correlates with HOMA-IR ($r = 0,42$, $p < 0,04$) and fasting plasma glucose ($r = 0,315$, $p < 0,02$).

Conclusions: Our data suggest that ADAM17 expression and activity is increased in prediabetic subjects showing early atherosclerosis and in patients affected by atherosclerosis and diabetes compared with normoglycose tolerant atherosclerotic patients.

0235

Inverse correlation between activated protein C generation and carotid atherosclerosis in type 2 diabetic patients

K. Matsumoto¹, Y. Yano¹, R. Araki², M. Suematsu-Urawa¹, H. Akatsuka¹, T. Suzuki¹, Y. Sasaki¹, N. E. Bruno¹, A. Katsuki¹, E. C. Gabazza³, Y. Sumida¹;

¹Division of Diabetes, Metabolism and Endocrinology, Mie University Graduate School of Medicine, Tsu, Mie, ²Department of Internal Medicine, Mie National Hospital, Tsu, Mie, ³Department of Immunology, Mie University Graduate School of Medicine, Tsu, Mie, Japan.

Background and Aims: Activated protein C (APC), generated on endothelial cells after cleavage of protein C by the thrombin-thrombomodulin complex, is a key regulator of the clotting system and immune responses. Previous studies have shown that less numbers of and less activity of thrombomodulin

on endothelial cells from vascular areas with atherosclerosis have decreased APC generation. These observations suggest that insufficient APC generation is associated with more progressive forms of atherosclerosis. This study aimed at studying the relationship between the degree of atherosclerosis as measured by the intima-media thickness (IMT) of carotid artery and APC generation in type 2 diabetic patients.

Materials and Methods: This study comprised 87 type 2 diabetic patients and 35 normal subjects. The degree of APC generation was assessed by the plasma level of activated protein C-protein C inhibitor complex (APC-PCI). APC-PCI, a marker of ongoing protein C activation, was measured by enzyme-linked immunoassay. The mean IMT of carotid artery was measured by ultrasonography. The plasma levels of thrombin-antithrombin complex (TAT) and platelet-derived growth factor (PDGF) were measured by enzyme-linked immunoassays.

Results: The plasma level of TAT, a sensitive marker of coagulation activity was significantly increased in diabetic patients compared with normal subjects ($1,28 \pm 0,88$ vs. $2,00 \pm 1,06$ ng/ml; mean \pm SD, $p < 0,01$). This observation confirmed the existence of hypercoagulability in diabetic patients. The plasma level of APC-PCI ($1,79 \pm 0,77$ vs. $1,01 \pm 0,56$ ng/ml; $p < 0,001$) was significantly lower in type 2 diabetic patients than in normal subjects. The mean IMT ($0,669 \pm 0,140$ vs. $0,881 \pm 0,242$ mm; $p < 0,01$) was significantly increased in type 2 diabetic patients as compared to normal subjects. Univariate analysis showed a significant and inverse correlation between the plasma level of APC-PCI and the mean IMT ($r = -0,32$, $p < 0,005$), and multivariate regression analysis showed that both were significantly and independently correlated ($p < 0,05$). Moreover, the plasma level of APC-PCI was significantly and inversely correlated with PDGF ($r = -0,30$, $p < 0,01$) in all diabetic patients. PDGF participates in the pathogenesis of vascular remodeling and atherosclerosis. We have reported that APC directly inhibits the secretion of PDGF from macrophages, endothelial and epithelial cells. Thus, decreased APC generation may favor increased production and secretion of PDGF and this may explain the inverse correlation between the plasma levels of PDGF and APC-PCI in type 2 diabetic patients.

Conclusion: These results suggest that decreased APC generation is associated with vascular atherosclerotic changes in type 2 diabetic patients.

Visceral fat thickness measured by ultrasonography is associated with carotid intima-media thickness even among diabetic men with normal waist circumference

S.-K. Kim, S.-W. Park, Y.-W. Cho;
Department of Internal Medicine, College of Medicine, Pochon CHA University, Sungnam, Republic of Korea.

Background and Aims: The simple way of assessing visceral fat accumulation is measuring waist circumference. However, there might be substantial variations in the visceral fat amount among persons with similar waist circumference because waist circumference itself could not discriminate between visceral fat and subcutaneous fat. In this study, we investigated whether measurement of visceral fat amount by ultrasonography may have an additional role in assessing atherosclerotic burden in men with type 2 diabetes.

Materials and Methods: Two-hundred and thirteen Korean men with type 2 diabetes mellitus were participated in this study. Abdominal obesity was defined as waist circumference ≥ 90 cm, which is an Asian criterion for abdominal obesity. Visceral fat thickness (VFT) defined as the distance between the anterior wall of the aorta and the internal face of the rectoabdominal muscle was measured by ultrasonography, and 47.6 mm of VFT was selected as the cutoff for excess accumulation of visceral fat (visceral obesity). Atherosclerotic burden was assessed by a measure of carotid arterial intima-media thickness (IMT).

Results: Among subjects with abdominal obesity (n=97), 20 subjects (21%) had no visceral obesity (Group 1). In contrast, among the subjects without abdominal obesity (n=116), 55 patients (47%) showed visceral obesity (Group 2). The subjects in group 2 showed higher VFT compared to those in group 1 ($58,4 \pm 10,5$ vs. $37,8 \pm 11,5$ mm, $P < 0,001$), even though subjects in group 2 had significantly lower waist circumference ($85,1 \pm 3,1$ vs. $94,7 \pm 5,4$ cm, $P < 0,001$). There were no differences in age, HbA1c, total cholesterol, and HDL-cholesterol concentrations between two groups. However, maximal carotid IMT ($0,93 \pm 0,35$ vs. $0,72 \pm 0,23$ mm, $P < 0,001$) and mean carotid IMT (0.73

± 0.22 vs. 0.63 ± 0.176 mm, $P < 0.001$) were significantly increased in group 2 compared with group 1.

Conclusion: About half of diabetic men with normal waist circumference had visceral obesity when assessed by ultrasound-measured VFT. Those who had visceral fat accumulation showed a higher carotid IMT regardless of their waist circumference. In addition to waist circumference, simultaneous measurement of VFT may provide an additional role in assessing atherosclerotic burden in men with type 2 diabetes.

OP 42 Metabolism in vasculature

Insulin receptor substrate 1 and 2 are key regulators of vasoactive responses in skeletal muscle arteries

W. Bakker¹, P. Sipkema¹, C. D. A. Stehouwer², V. W. M. van Hinsbergh¹, E. C. Eringa¹;

¹Laboratory for Physiology, Institute for cardiovascular research, Amsterdam,

²Internal Medicine, Academic Hospital Maastricht, The Netherlands.

Background and Aims: Insulin actions in vasoreactivity and glucose uptake are regulated by insulin receptor substrates (IRSs). In the microcirculation insulin exerts vasodilator effects through activation of Akt and Nitric Oxide and vasoconstrictor effects through activation of endothelin-1. IRS1 and IRS2 are thought to be involved in the development of insulin resistance and the metabolic syndrome, which is associated with a diminished activity of insulin to stimulate vasodilation. The aim of this study was to determine the exact role of IRS1 and IRS2 in vasoactive responses in micro- and macrocirculation of skeletal muscle.

Material and Methods: To investigate insulin-mediated vasoreactivity and maximal passive response, we used gracilis and femoral artery of IRS1 KO, IRS2 KO mice and their wild type (WT) littermates. The arteries were isolated and studied in a pressure myograph under physiological conditions.

Results: In the WT mice, the maximal inner diameters of the gracilis and femoral artery were $128\mu\text{m}\pm 4$ and $311\mu\text{m}\pm 9$ respectively. Furthermore, insulin induced an endothelin-1 dependent vasoconstriction and an Akt-dependent vasodilator response in the gracilis artery of WT mice. Mice lacking IRS1 were insulin resistant and mice lacking IRS2 were diabetic. In the IRS1 KO and IRS2 KO mice, the maximal diameters of the gracilis and femoral artery were reduced by $24\%\pm 1$ and $15\%\pm 5$ for IRS1 KO and $20\%\pm 3$ and $14\%\pm 2$ for IRS2 KO respectively, compared to their WT littermates. Furthermore, insulin had no effect on the diameter, but showed an impaired vasoconstriction and a reduced Akt-dependent vasodilator response in the gracilis artery of both IRS1 and IRS2 KO mice.

Conclusions: Genetic deletion of either IRS1 or IRS2 results in a reduction of the maximal diameter of both micro- and macrocirculation of skeletal muscles, which implies that IRS1 and IRS2 regulate structural remodelling of skeletal resistance arteries. In addition, both IRS1 and IRS2 seem to be involved in both vasodilator and vasoconstrictor effects of insulin in the microcirculation of skeletal muscle. This suggests that IRS1 and IRS2 are key regulators in insulin dependent vasoactive responses in skeletal muscle arteries.

0238

Insulin-like effect of adiponectin to vasodilate against endothelin-1-mediated vasoconstriction in muscle

C. T. Bussey, S. Rattigan, M. G. Clark, S. M. Richards;

Muscle Diabetes Research Group, Menzies Research Institute, Hobart TAS, Australia.

Background and Aims: We recently reported that insulin opposes vasoconstriction due to endothelin in the constant-flow pump-perfused isolated rat hindlimb preparation, possibly by acting through nitric oxide release. Insulin has not been found to dilate against any other vasoconstrictor in perfused hindlimb, making endothelin unique in this respect. Adiponectin exhibits a number of actions similar to insulin, for example stimulation of glucose uptake in incubated muscle, and reduction of glucose release from hepatocytes. A number of recent studies have also indicated that adiponectin acts acutely to increase nitric oxide production by the endothelium, and it has been shown to relax isolated aortic rings pre-constricted with prostaglandin F₂. These data suggest that adiponectin may act in a similar manner to insulin to vasodilate against endothelin-1. However, to date no study has examined the vasoactivity of adiponectin in an intact vascular system. The aim of this study was therefore to determine whether adiponectin opposes the vascular actions of endothelin-1 in an intact perfused muscle system.

Materials and Methods: Adiponectin was expressed in *E. coli* and purified using an N-terminal His tag. SDS-PAGE gels showed the recombinant adiponectin to be mainly the trimer or low molecular weight form.

Adiponectin (final concentration 10ug/ml) was infused for 20min in the constant flow pump-perfused isolated rat hindlimb. Infusion of endothelin-1 (1nM) commenced 10min after the adiponectin infusion started, and continued for 10min after adiponectin infusion ceased, to examine reversal of adiponectin-induced changes. Perfusion pressure, oxygen consumption and release of lactate into the venous effluent were monitored.

Results: Endothelin-1 infusion increased perfusion pressure by 25 mmHg and exhibited a type A vasoconstrictor effect by increasing oxygen uptake and lactate release. Infusion of adiponectin reduced the endothelin-1-induced perfusion pressure increase by approximately 60%, blunted the increase in oxygen consumption and almost completely abolished the lactate release caused by endothelin-1. Removal of adiponectin during continued endothelin-1 infusion did not result in an immediate rapid rise in perfusion pressure or lactate release, suggesting that the actions of adiponectin do not reverse rapidly.

Conclusion: To our knowledge, this is the first time that adiponectin vasoactivity has been demonstrated in an intact vascular system. We have shown that adiponectin has similar actions to insulin in opposing vasoconstriction due to endothelin-1 in the isolated perfused rat hindlimb. This suggests that in addition to its effects on skeletal myocyte glucose uptake, adiponectin may also be involved in the vascular control of muscle insulin action.

0239

Oleate induces an insulin resistance “selective” for the PI3-K/Akt pathway in cultured human and rat vascular smooth muscle cells

P. Del Mese, I. Russo, G. Doronzo, L. Mattiello, M. Viretto, G. Anfossi, M. Trovati;
Department of Clinical and Biological Sciences, University of Turin, Orbassano, Italy.

Background and Aims: Increased Free Fatty Acids concentrations (FFAs) are a link between obesity and insulin resistance, because FFAs interfere with insulin signaling, inducing the so called “lipid toxicity”. Relevant targets of insulin action are Vascular Smooth Muscle Cells (VSMC): the FFA influence on insulin signaling in these cells, however, is not known. We aimed at investigating whether oleate (a 18-carbon cis-monosaturated FA) influences the insulin-induced activation of the Phosphatidylinositol 3-kinase (PI3-K)/Akt/p70S6K and of the Mitogen-Activated Protein Kinase (MAPK) pathways in VSMC from humans and from lean and obese Zucker rats.

Materials and Methods: Protein expression and phosphorylation of Akt, p70S6K, ERK1/2 and JNK1/2 were evaluated by Western blots after 6h incubation with 2nM insulin in aortic VSMC from humans, lean insulin sensitive and obese insulin resistant Zucker rats, in the absence and in the presence of a 30-min preincubation with oleate 100μM (n=8)

Results: Data are expressed as mean±SEM. In human VSMC: i)oleate did not induce phosphorylation of Akt, p70S6K, ERK1/2, and JNK1/2; ii)the insulin-induced Akt phosphorylation (162.3±2.5% of baseline, p=0.0001) was blunted in the presence of oleate (103±3.1% of baseline); iii)the insulin-induced p70S6K phosphorylation (175.6±1.9% of baseline, p=0.001) was blunted in the presence of oleate (101.4±3.5% of baseline); iv)the insulin-induced ERK1 and ERK2 phosphorylation (206.8±4.6% and 177.1±3.1% of baseline, respectively, p=0.0001 for both) was not modified in the presence of oleate (202.1±2.4% and 170.5±4.1% of baseline, ns vs insulin alone); v)the insulin-induced JNK1 and JNK2 phosphorylation (240.2±2.6% and 192.6±3.0% of baseline, respectively, p=0.0001 for both) was not modified in the presence of oleate (229.3±2.8% and 195.5±1.9% of baseline, ns vs insulin alone). In VSMC from lean and obese Zucker rats, oleate did not induce phosphorylation of Akt and ERK1/2. Insulin-induced phosphorylation of Akt and ERK1/2 was smaller in VSMC from obese than in those from lean Zucker rats (p=0.0001 for Akt, p=0.003 for ERK1, p=0.001 for ERK2). Both in lean and in obese Zucker rats, oleate reduced the insulin-induced phosphorylation of Akt (p=0.001 for both), but not that of ERK1/2. In the presence of insulin+oleate, no significant difference was observed between Akt phosphorylation in lean and obese Zucker rats.

Conclusions: In human VSMC, oleate influences insulin signaling by inhibiting the PI-3K/Akt/p70S6K pathway without affecting the MAPK pathway, thus inducing a “selective” insulin resistance. Furthermore, our study confirms our previous observation that in cultured VSMC from obese Zucker rats the insulin-induced activation of both PI3-K and MAPK pathways is similarly impaired: however, when VSMC are incubated “in

vitro” with oleate at concentrations occurring “in vivo” in insulin resistant states, we can observe the “selective” inhibition of the insulin activated PI-3K pathway that has been described “in vivo” or “ex vivo” in insulin resistant states. This “selectivity”, therefore, seems not to be an intrinsic characteristic of these cells but a phenomenon induced by circulating factors increased in insulin resistant states, such as FFAs.

The TACE/TIMP3 dyad regulates the inflammatory infiltrate caused by obesity in vascular and metabolic tissues

M. Federici¹, R. Menghini¹, S. Menini², R. Amoroso¹, L. Fiorentino¹, M. Serino¹, G. Pugliese², R. Khokha³, R. Lauro¹;

¹Dept. of Internal Medicine, University of Tor Vergata, Rome, Italy,

²Dept. of Clinical Sciences, University of La Sapienza, Rome, Italy,

³Dept. of Medicine, Ontario Cancer Institute, Toronto, ON, Canada.

Background and Aims: We recently observed that a reduction in Tissue Inhibitor of Metalloproteinase-3 (TIMP-3) couples the onset of type 2 diabetes to vascular inflammation in Insulin Receptor heterozygous knockout mice. TIMP3 is the major inhibitor of TNF-α Converting Enzyme (TACE or ADAM17) as well as cognate proteases such as ADAM10,12,15, all acting via a process called REGULATED MEMBRANE PROTEOLYSIS to shed from plasma membrane several growth factor and cytokines. This shedding process generates soluble factors with paracrine/endocrine activity. ADAMs were hypothesized to play a role in inflammatory and metabolic disorders, but no mechanistic evidences were provided.

Materials and Methods: First, we treated 3T3F442A preadipocytes with free fatty acids (FFA) to study TACE activation. Next, to test the therapeutic role of the TACE/Timp3 dyad in metabolic and vascular complications of obesity, we studied WT, Insr+/-, Timp3-/-, Tace+/-, double Insr+/-/Timp3-/- and double Insr+/-/Tace+/-, all fed a HFD.

Results: We found in preadipocytes that FFA caused TACE serine phosphorylation (p<0.01 versus basal) and increased TNF-α shedding (p<0.01 versus basal), an effect abolished by TACE inhibitor, TAPI-1. Then, in the same cell model we observed TACE overexpression is coupled to 8-fold increase of MCP1 expression (p<0.01 versus mock cells). Effect of HFD in animal models revealed that both glucose tolerance and insulin sensitivity were significantly reduced in double Insr+/-/Timp3-/- compared to other genotypes (p<0.001 for both intraperitoneal glucose and insulin tolerance test). We found by immunohistochemistry analysis that HFD caused: increased MCP1 expression and macrophage accumulation in multiple organs including WAT, liver, aorta and kidney in Insr+/-/Timp3-/- mice but not in Insr+/-/Tace+/- mice, while WT, Insr+/- and Timp3-/- mice had an intermediate phenotype. In the liver of Insr+/-/Timp3-/- we found increased steatohepatitis (grade 3) compared with WT, Insr+/- and Timp3-/- mice (all grade 1) and Insr+/-/Tace+/- mice (grade 0). In the aorta of Insr+/-/Timp3-/- we observed presence of fatty streaks and increased RAGE expression. No morphological alterations were found in WT, Insr+/- and Timp3-/- mice and Insr+/-/Tace+/- . A similar pattern of mixed inflammation/lipotoxicity was found in the kidney with the following grading: Insr+/-/Timp3-/- > WT > Insr+/-/Tace+/- .

Conclusion: Our results suggest that the TACE/Timp3 pathway integrates signals derived from High Fat Diet to trigger the development of inflammatory burden associated to diabetes, atherosclerosis, glomerulopathy and steatohepatitis. Our results suggest that TACE inhibitors should be tested for treatment of obesity-related metabolic and vascular diseases.

OP 43 Metformin and sulfonylureas

0241

Metformin activates the AMP-activated protein kinase in hepatocytes by changes in adenine nucleotides

B. Guigas^{1,2}, M. Foretz³, X. Stephenne⁴, E. Sokal⁴, B. Viollet³, L. Hue²;
¹Dept. of Molecular Cell Biology, Leiden University Medical Center, The Netherlands, ²Hormone and Metabolic Research Unit, Université catholique de Louvain and Christian de Duve Institute of Cellular Pathology, Brussels, Belgium, ³Department of Genetics, Development and Molecular Pathology, Institut Cochin, Paris, France, ⁴Laboratory of Paediatric Hepatology and Cell Therapy, Université catholique de Louvain and Cliniques St Luc, Brussels, Belgium.

Background and Aims: The precise mechanism of action of metformin, one of the most prescribed drugs for type 2 diabetes, still remains incompletely elucidated. During the last years, metformin has been shown to activate the AMP-activated protein kinase (AMPK), which is considered as a cellular energy sensor. This remarkable effect, which was observed in several tissues, could explain some of the cellular effects of metformin. However, the exact pathway(s) involved in AMPK activation by the drug are still elusive. Indeed, while metformin has been previously shown to induce specific inhibition of the mitochondrial respiratory-chain complex 1 in the liver, early works performed on various cell lines suggested that the biguanide activated AMPK without increasing AMP-on-ATP ratio. The aim of this study was to test the hypothesis that AMPK activation by metformin was associated with modification of adenine nucleotides in liver cells.

Materials and Methods: Hepatocytes were isolated from both rat and mouse livers and from human liver segments unused for transplantation. Primary cultured hepatocytes were treated with increasing dose of metformin (100 μ M – 1000 μ M) for 24h following determination of AMPK activity (after both PEG fractionation and immunoprecipitation of α 1 and α 2 subunits separately) and expression, ACC phosphorylation and intracellular concentrations of adenine nucleotides. The mitochondrial oxygen consumption rates were measured on both intact and permeabilized hepatocytes isolated from wild-type and AMPK α 1 α 2 liver specific knockout mice and incubated for 30 min with metformin.

Results: Here we report that metformin concentrations higher than 250 μ M activated AMPK in primary cultured hepatocytes from both rat and human, this effect being clearly associated with an increase in AMP-on-ATP ratio. Interestingly, human hepatocytes exhibited very low level of AMPK α 2 expression and activity (less than 2% of the total activity) compared with rats and metformin only activated this AMPK isoform. In addition, we also demonstrated that the specific inhibitory effect of metformin on the mitochondrial respiratory-chain complex 1 evidenced in hepatocytes from wild-type mice was still present in mice lacking both liver α 1 and α 2 AMPK catalytic subunits.

Conclusion: We conclude that (i) AMPK activation by metformin is associated with significant modifications of adenine nucleotides in hepatocytes and that (ii) inhibition of the respiratory-chain complex 1 by metformin is independent of AMPK.

Impact of metformin treatment on glycaemic control and cardiovascular risk-factors in patients with poorly controlled type 1 diabetes (T1DM)

P. K. Jacobsen¹, S. S. Lund¹, L. Tarnow¹, A.-S. Astrup¹, A. C. Alibegovic¹, P. Hovind¹, L. Pietraszek¹, M. Frandsen¹, I. Parving¹, P. Rossing¹, H.-H. Parving², A. A. Vaag¹;
¹Steno Diabetes Center, Gentofte, ²Dep of Medical Endocrinology, University of Copenhagen; Rigshospitalet, Denmark.

Background and Aims: Despite intensive insulin-treatment many patients with T1DM have longstanding poor glycaemic control. Metformin is an oral hypoglycaemic agent that improves insulin-action in patients with type 2 diabetes. We aimed to investigate the effect of one year treatment with metformin versus placebo in patients with T1DM and persistent poor glycaemic control.

Materials and Methods: One hundred patients with T1DM, preserved hypoglycaemic awareness and poor glycaemic control ($HbA_{1c} \geq 8.5\%$) during one year prior to enrolment were included in a one month run-in period on placebo treatment. Hereafter patients were randomised (baseline) to receive treatment with either metformin (1g twice-daily) or placebo (double-masked) for 12 months. Patients continued ongoing insulin-therapy and usual out-patient clinical care. Changes in insulin doses were allowed. The primary endpoint was baseline adjusted changes in HbA_{1c} . Patients were evaluated at baseline and after 12 months.

Results: At enrolment mean (SD) HbA_{1c} was: metformin (n=49): 9.48% (0.99); placebo (n=51): 9.60% (0.86). After 12 months the mean (95% CI) baseline-adjusted change in HbA_{1c} was: metformin: -0.10% (-0.32; 0.12); placebo: -0.23% (-0.45; -0.01). Mean (95% CI) baseline-adjusted differences after 12 months during metformin versus placebo: HbA_{1c} 0.13% (-0.19; 0.44), $p=0.422$; Total daily insulin-dose: -5.6 U/day (-8.4; -2.7), $p < 0.001$; Body-weight: -1.74 kg (-3.32; -0.17), $p=0.030$; Fasting LDL-cholesterol: -0.27 mmol/l (-0.56; 0.33), $p=0.080$ (in subjects with stable lipid-lowering therapy: $p=0.018$). The reported number of minor and major hypoglycaemic events was not significant different between treatments. Mean (SD) compliance with the study-medication was: metformin: 85.7% (17.5); placebo 86.5% (15.7). In subgroups of patients with baseline BMI ≥ 25 , ≥ 27 or ≥ 30 kg/m² or with baseline HbA_{1c} above the median ($HbA_{1c} > 9.15\%$) there was no significant change in HbA_{1c} after one year between treatments or within the metformin treated group alone. Adjustment for baseline insulin-dose did not change the between treatment effect on HbA_{1c} substantially.

Conclusion: In patients with poorly controlled T1DM, metformin treatment does not improve glycaemic control after one year. However, metformin might have other potential beneficial effects on CVD risk-factors such as insulin-dose, body-weight and LDL-cholesterol.

0243

Impact of chronic metformin and sulfonylureas treatment in diabetic patients developing an acute myocardial infarction

M. Zeller¹, N. Danchin², J.-M. Pernes³, P. Steg⁴, D. Carrie⁵, P. Quandel⁶, G. Amat⁷, E. Durand², J.-P. Cambou⁸, G. Mulak⁸, T. Simon²;
¹Cardiology, CHU Dijon, ²Cardiology, HEGP, Paris, ³Cardiology, Hôpital Privé Antony, ⁴Cardiology, CHU Bichat, Paris, ⁵Cardiology, CHU Toulouse, ⁶Cardiology, CH Roubaix, ⁷Cardiology, CH Vichy, ⁸Société Française de Cardiologie, ⁹Pharmacology, CHU St Antoine, Paris, France.

Background and Aims: Little information is available on the impact of chronic oral antidiabetic medications on outcomes in patients developing an acute myocardial infarction. Aim: To assess early and 6-month mortality according to the prior use of metformin and sulfonylureas in diabetic patients admitted for AMI in a nationwide French registry.

Materials and Methods: The FAST-MI registry included consecutive patients admitted for ST-elevation or non-ST elevation myocardial infarction ≤ 48 hours of symptom onset, in 223 French intensive care units over 2 months from October 2005. In-hospital and 6-month outcome was compared for all 1,316 diabetics. In diabetic patients, 4 groups were defined according to their antidiabetic treatment before admission: no SU and no metformin (S- M-, n=594), SU alone (S+, n=264), metformin alone (M+, n=257), and combination of SU and metformin (S+M+, n=201).

Results: Age was 71 \pm 12 for M-S-, 68 \pm 10 for M+, 71 \pm 11 for S+ and 67 \pm 11 years for S+M+ ($p < 0.001$). GRACE risk score was higher in S-M- (173 \pm 39) and S+ (168 \pm 38), compared with M+ (163 \pm 36) and M+S+ (162 \pm 36) ($p=0.001$). HbA_{1c} (available in half of the patients) was higher in M+S+ (8.0 \pm 1.6%) compared with S-M- (7.5 \pm 1.6), S+ (7.3 \pm 1.4) or M+ (7.4 \pm 1.4) ($p < 0.005$) and entry glycaemia was also higher (2.39 \pm 1.18 g/L) vs. S+ (2.10 \pm 0.98), M+ (1.90 \pm 0.67) or S-M- (2.07 \pm 1.18) ($p < 0.001$).

Five-day mortality was 6.1% (M-S-), 3.5% (M+), 2.3% (S+) and 0.5% (M+S+) ($p < 0.001$). Six-month survival was 80%, 86%, 87% and 95%, respectively ($p < 0.001$) (Figure). Using Cox multivariate analysis, the odds ratio for 6-month mortality compared to the M-S-group were: 0.84 (95%CI: 0.56–1.25, $p=NS$) for M+, 0.65 (95%CI: 0.43–0.97, $p < 0.05$) for S+ and 0.27 (95%CI: 0.13–0.54, $p < 0.001$) for M+S+.

Conclusion: In this real world registry, the combined use of sulfonylureas and metformin was associated with improved early and 6-month survival after acute myocardial infarction. Similar outcomes were observed for patients on

metformin or sulfonylureas alone, but using multivariate adjustments, only sulfonylureas alone was significantly associated with improved survival.

Treatment with insulin secretagogues and cancer-related mortality in type 2 diabetic patients. A cohort study

M. Monami¹, C. Lamanna¹, M. Petracca², D. Balzi³, I. Dicembrini², N. Marchionni¹, C. M. Rotella², E. Mannucci¹;

¹Critical Care Medicine and Surgery, Unit of Gerontology – University of Florence, Italy, ²Clinical Pathophysiology, Section of Endocrinology – University of Florence, Italy,

³Local Health Unit 10, Epidemiology Unit, Florence, Italy.

Background and Aims: Recent evidence suggests that some hypoglycemic treatments could affect the incidence of malignancies. In particular, metformin has been associated with a reduced incidence of cancer. Conversely, sulfonylureas and insulin have been found to be associated with increased cancer-related mortality; insulin treatment, in particular, seems to be associated with a higher incidence of colorectal cancer. This study was aimed at the assessment of cancer-related mortality in type 2 diabetic patients treated with different hypoglycemic drugs.

Materials and Methods: A retrospective observational cohort study was performed on a consecutive series of 3002 type 2 diabetic outpatients. Cancer-related death was identified through the City Registry Office

Results: During a mean follow-up of 4.3 ± 2.5 years, 87 cases of cancer-related death were recorded, with a yearly incidence rate of 0.70%. Patients receiving secretagogues ($n=1241$) showed a significantly higher mortality than the rest of the sample (unadjusted OR [95% CI] 1.76 [1.15–2.69], $p=0.009$), which was maintained after adjustment for sex, age, duration of diabetes, HbA1c, BMI, Charlson's Comorbidity Scale (CCS), smoking status and alcohol abuse (HR 2.29 [1.21–4.02], $p=0.003$). Conversely, no significant association of cancer-related mortality was observed with insulin sensitizers ($n=1302$) or exogenous insulin ($n=764$). In order to exclude the possible effect of drug interactions, a separate analysis was performed in patients treated with only one hypoglycemic agent. When compared with those receiving no drug treatment for diabetes ($n=727$), patients on secretagogue monotherapy ($n=372$) showed a significantly higher cancer-related mortality (unadj. OR 2.29 [1.10–4.82]; $p=0.028$). Insulin treatment ($n=421$) was also associated with a higher cancer-related mortality (OR 2.26 [1.10–4.69]; $p=0.28$). After adjustment for age, sex and CCS, both insulin secretagogues (HR 2.25 [1.10–4.78]; $p=0.034$) and insulin (HR 2.11 [1.01–4.50], $p=0.048$) were associated with a significantly higher cancer-related mortality in comparison with patients receiving no drug treatment. Among patients on secretagogue monotherapy, glyburide was associated with a higher cancer-related mortality (unadjusted OR 4.41 [1.23–15.90]; $p=0.023$) in comparison

with subjects receiving other drugs of the same class, which was confirmed at multivariate analysis after adjustment for age, sex, and CCS (HR 4.31 [1.16–16.00]; $p=0.029$). Conversely, monotherapy with insulin sensitizers ($n=444$) was not associated with significant differences in cancer-related mortality in comparison with patients receiving no hypoglycemic drugs (OR 0.77 [0.28–2.15], $p=0.621$).

Conclusion: Insulin secretagogues and, to a lesser extent, exogenous insulin, appear to be associated with increased mortality for cancer, even after adjustment for multiple confounders. This issue deserves further investigation through epidemiological studies on larger samples of patients.

OP 44 Treatment of type 1 diabetes in pregnancy

0245

Hypoglycaemia during first trimester of pregnancy in type 1 diabetes

M. García Domínguez, L. Herranz de la Morena, L. Sáez de Ibarra, E. Moya Chimenti, L. Pallardo Sánchez, Servicio de Endocrinología y Nutrición, Hospital Universitario La Paz, Madrid, Spain.

Background and Aims: It is widely assumed that women with type 1 diabetes are at increased risk of hypoglycaemic episodes, particularly of severe hypoglycaemia, during the first trimester of pregnancy. Our objective was to investigate frequency and characteristics of hypoglycaemia, during first trimester of pregnancy, in women with type 1 diabetes.

Materials and Methods: We conducted a longitudinal survey, comparing glycaemic parameters between preconception and first trimester of pregnancy, in 64 women with type 1 diabetes (mean age 31.9 ± 2.9 , mean diabetes duration 13.8 ± 7.2), who were attended at the Diabetes and Pregnancy Unit from preconception throughout pregnancy. All women were requested to perform home blood glucose monitoring using the same type of glucose meter. Glucose readings stored in the meter were downloaded to a computer at each visit. The mean number of glucose readings/day was 4.9 ± 1.3 during preconception and 4.8 ± 0.9 during first trimester. Severe hypoglycaemia was defined as any hypoglycaemic episode for which external help was required. Frequency of non-severe hypoglycaemia (percentage of glucose readings below 50 mg/dl) and nocturnal hypoglycaemia (proportion of all hypoglycaemic episodes that were nocturnal), mean glucose levels, mean standard deviation of mean glucose and mean bedtime glucose levels were obtained from the glucose readings. HbA1c was measured during preconception and at 12 weeks gestation.

Results: Both during preconception and first trimester, only 5 women (7.8 %) were affected by severe hypoglycaemia. Only two patients (3.1 %) had severe hypoglycaemia during preconception and during first trimester. Frequency of non severe hypoglycaemia did not differ significantly between preconception and first trimester (4.3 ± 3.7 vs. 4.6 ± 2.7 %; $p = 0.557$). Nocturnal hypoglycaemia was significantly higher during first trimester than during preconception (27.8 ± 27.4 vs. 14.2 ± 26.2 %; $p = 0.000$). HbA1c (6.7 ± 0.7 vs. 6.4 ± 0.6 %, $p = 0.000$), mean glucose levels (140.7 ± 18.6 vs. 136.1 ± 15.3 mg/dl, $p=0.011$) and mean standard deviation of mean glucose (69.5 ± 13.5 vs. 65.2 ± 11.2 mg/dl, $p = 0.000$) were significantly lower during first trimester. Mean bedtime glucose levels (164.3 ± 33.8 vs. 164.9 ± 23.8 mg/dl) and mean daily insulin dose (0.62 ± 0.15 vs. 0.64 ± 0.15 U/kg) did not differ significantly.

Conclusion: Women with type 1 diabetes who attend a preconception programme are not at increased risk of severe hypoglycaemia during the first trimester of pregnancy. The overall frequency of non-severe hypoglycaemia is not different during preconception and first trimester; however, a shift towards nocturnal hypoglycaemia during the first trimester of pregnancy is observed. This trend does not seem related to bedtime glucose levels nor to a change in insulin dose.

0246

Foetal outcomes associated with glargine's use during pregnancy: the Italian National Survey

E. Torlone, G. Di Cianni, M. Bonomo, G. Capuano, A. Di Benedetto, M. Dolci, I. Franzetti, M. Imbergamo, V. Manicardi, D. Mannino, A. Napoli, L. Sciacca, L. Tonutti, E. Vitacolonna, A. Lapolla; on behalf of the Italian Diabetes and Pregnancy Study Group, Italian Society of Diabetology, Roma, Italy.

The long-acting insulin analog glargine (IAG) is largely used as a basal-bolus regimen in type 1 diabetes mellitus (T1DM), however its use is not still recommended during pregnancy. We promoted a national, multicentre, retrospective study to determine the rate of congenital malformation in a large group of offspring of mothers with T1DM who were treated with IAG before and during pregnancy. The observation's period included all pregnancies ended before August 31 2006. We collected data on 107 T1DM pregnancies from 29 Italian centres and evaluated both maternal data and foetal outcomes. The rate of congenital malformation (CM) was compared with published data. The mean maternal age was 30.4 ± 4.7 years, diabetes duration 15.8 ± 7.7 years, White's Classes B=23%, C=25%, D=35%, R=16%, RF=1%). IAG was started 10.3 ± 6.9 months before conception as a basal-bolus regimen with an average dose of 19.2 ± 7.5 IU/die. The pregnancy was unplanned in 92% of cases and the first diabetes assessment occurred at 8.7 ± 4.1 weeks of pregnancy (Mean HbA1c 7.7 ± 1.3 %, range 5.3–13.8%). IAG was continued until the end of pregnancy in 38.3% of case, whereas it was stopped during the first trimester of gestation in 61.7%. Results: Glycemic control improved during the whole pregnancy with a mean HbA1c of 6.5 ± 0.9 % at the end of pregnancy. Spontaneous and elective abortions occurred in 5 and 2 women respectively. 100 babies were delivered at 36.7 ± 2.1 week (pre-term deliveries 30.0%, caesarean sections 75.5%) with mean birth weight of 3298.0 ± 717.4 g (LGA 42.7%). CM were reported in 5 newborns (5.0%), involving cardiovascular ($n=2$), genitourinary system ($n=2$, 1minor), and syndactylia ($n=1$). The rate of CM is not different from that reported in other studies regarding pregnancies of T1DM women treated with other insulins.

Conclusions: Our survey, performed in a large cohort of T1DM pregnant women, suggest that insulin glargine does not seem to affect embryo-foetal development.

0247

Use of insulin aspart from pregnancy planning may reduce the incidence of severe hypoglycaemia – data from the insulin aspart pregnancy study

S. Heller¹, E. Mathiesen², P. Damm³, M. Hod⁴, A.-S. Pade Hansen⁵, K. Kanc Hanzel⁵;

¹Clinical Sciences Centre, University of Sheffield, United Kingdom,

²Dept. Endocrinology, Rigshospitalet, Copenhagen, Denmark,

³Obstetric Clinic, Rigshospitalet, Copenhagen, Denmark,

⁴Perinatal Division, Tel Aviv University, Petah-Tiqva, Israel,

⁵Novo Nordisk A/S, Bagsvaerd, Denmark.

Background and Aims: Planning of pregnancy in order to achieve optimal glucose control has been shown to reduce malformations and early fetal losses in pregnant women with type 1 diabetes. Whether pregnancy planning also reduces the risk of severe hypoglycaemia is unknown. In this controlled trial,

Tab. 1 Abstract 0247

Severe and Nocturnal (0:00-06:00) hypoglycaemia. Rate is episodes/exposure year.

All severe hypoglycaemic episodes, number (rate)						
Population based on time of randomization	Planning phase		Pregnancy		Post partum	
	IAsp	HI	IAsp	HI	IAsp	HI
Prior to pregnancy	13 (0.9)	34 (2.4)	15 (0.6)	60 (1.9)	1 (0.2)	17 (2.2)
Early pregnancy	-	-	98 (1.7)	114 (2.2)	37 (2.6)	16 (1.5)
Nocturnal severe hypoglycaemic episodes, number (rate)						
Population based on time of randomization	Planning phase		Pregnancy		Post partum	
	IAsp	HI	IAsp	HI	IAsp	HI
Prior to pregnancy	5 (0.3)	21 (1.5)	3 (0.1)	31 (1.0)	1 (0.2)	5 (0.7)
Early pregnancy	-	-	23 (0.4)	28 (0.5)	9 (0.6)	6 (0.6)

women were randomised to insulin aspart or human insulin. The primary endpoint was severe hypoglycaemia (requiring third party assistance) during pregnancy.

Materials and Methods: Mealtime insulin aspart (IAsp) was compared with human insulin (HI) in 99 subjects (IAsp:44, HI:55), randomised prior to known pregnancy and 223 subjects (IAsp:113, HI:110) randomised in early pregnancy. NPH insulin was used as basal insulin throughout. Severe hypoglycaemia was recorded prospectively before pregnancy (where possible), during pregnancy and post-partum. Subjects were followed throughout pregnancy with one visit per trimester and at 6 weeks postpartum.

Results: The observed rates of severe hypoglycaemia in subjects treated with IAsp pre-pregnancy were consistently lower than for HI treated subjects for the periods before pregnancy, during pregnancy and post pregnancy. The risk of severe hypoglycaemia was evaluated by the relative risk (RR) using a gamma frailty model. The estimated risk was 77% lower for IAsp than for HI during pregnancy (RR: 0.33; 95% CI: [0.09; 1.27], non-significant, $p=0.11$). The estimated risk for the period prior to pregnancy was 66% lower (RR=0.34; 95% CI: [0.07; 1.71], non-significant, $p=0.19$). Post partum, the estimated risk was 92% lower (RR: 0.08, 95% CI: [0.01; 0.84], $p=0.04$). Overall, nine subjects in each treatment group had 15 (IAsp) and 60 (HI) episodes during pregnancy, suggesting that the observed differences were mainly due to a lower number of recurrent episodes of severe hypoglycaemia for IAsp treated subjects. There was a trend for the observed rate (episodes/exposure year) of severe hypoglycaemia during pregnancy for subjects treated with IAsp pre-pregnancy (0.6) to be lower than for subjects who initiated IAsp early in pregnancy (1.7). This was also true for severe nocturnal hypoglycaemia during pregnancy (0.1 vs. 0.4). No subjects experienced hypoglycaemic coma during the trial. During pregnancy mean HbA_{1c} was the same in both treatment groups, 6.0% in the second trimester and 6.2% in the third trimester.

Conclusion: These results suggest that the use of insulin aspart from the planning phase of pregnancy might reduce the incidence of severe hypoglycaemia before, during and after pregnancy, although the statistical power to establish this was limited by the relatively small numbers. (Tab. 1)

Supported by Novo Nordisk A/S

detection limit in all other samples analysed. HI levels in cord blood were widely distributed in both treatment groups, median levels were 67.5 pmol/L (IAsp) and 286.5 pmol/L (HI), with an estimated ratio (IAsp/HI) of 0.40, suggesting less hyperinsulinaemia in infants from the IAsp group ($p=0.073$).

Conclusions: Levels of specific and cross-reacting AB were similar between IAsp and HI groups, and did not increase during pregnancy. The significant correlation between the level of cross-reacting AB in cord blood and maternal cross-reacting AB indicated a possible transfer of maternal AB across the placenta. On the contrary, cord blood analysis provided no clear evidence of transfer of IAsp across the placenta.

Changes in maternal insulin AB levels during pregnancy.

No increase in insulin antibodies during pregnancy in type 1 diabetes treated with insulin aspart

E. Mathiesen¹, D. McCance², P. Damm³, R. Kaaja⁴, M. Hod⁵, F. Dunne⁶, L. Jensen⁷, H. Mersebach⁷;

¹Dept. Endocrinology, Rigshospitalet, Copenhagen, Denmark,

²Regional Centre for Endocrinology and Diabetes, Royal Victoria Hospital, Belfast, United Kingdom, ³Obstetric Clinic, Rigshospitalet, Copenhagen, Denmark, ⁴Naistenklinikka, Helsinki University Hospital, Finland,

⁵Division of Maternal Fetal Medicine, Rabin Medical Center, Petah-Tiqva,

Israel, ⁶Dept. Medicine, Galway University College Hospital, Ireland,

⁷Novo Nordisk A/S, Bagsvaerd, Denmark.

Background and Aims: The development of insulin antibodies (AB) during pregnancy was assessed in women with type 1 diabetes, as part of the largest (n=322) randomised controlled study of a rapid acting insulin analogue in pregnancy to date. The potential transfer of insulin and AB to the child was assessed by analysis of umbilical cord blood.

Material and Methods: Mealtime insulin aspart (IAsp) was compared with human insulin (HI) in subjects who were pregnant or planning pregnancy at enrolment. NPH was used as basal insulin in both groups. Insulin AB were measured in a sub-group of 97 subjects (IAsp:50; HI:47). Antibodies were detected by radio-immunoassay, and insulin levels by ELISA. Maternal AB were assessed at baseline and gestational week (GW) 36. Cord blood samples were analysed for AB (IAsp:36; HI:29) and insulin levels (IAsp:14; HI:16) post delivery.

Results: Antibody levels specific to HI or IAsp remained low throughout pregnancy. A small but significant decrease was observed in maternal cross-reacting AB levels from baseline to GW 36 ($p=0.012$). No correlation was observed between total daily insulin dose and the level of cross-reacting AB at GW 36 in either treatment group. There was a significant correlation between the level of cross-reacting AB in cord blood and maternal cross-reacting AB measured at GW 36 ($R^2=0.91$ $p<0.0001$). The analysis of insulin in cord blood detected IAsp in one sample (22.9 pmol/L), however the validity of this sample was questionable, as the HI level was unphysiologically high (10950 pmol/L), and it was omitted from analysis. Levels of IAsp were below the

OP 45 Incretin effects: clinical

Four weeks of near-normalization of blood glucose restores the insulin response to GIP and improves the insulin response to GLP-1 in patients with type 2 diabetes

P. V. Højberg^{1,2}, T. Vilsbøll², M. Bache¹, F. K. Knop², R. Rabøl¹, T. Krarup², J. J. Holst³, S. Madsbad¹;

¹Endokrinologi, Hvidovre Hospital, Hvidovre,

²Internal Medicin, Gentofte Hospital, Denmark, ³Medical Physiology, Panum Institute, University of Copenhagen, Denmark.

Background and Aims: The incretin effect is attenuated in patients with type 2 diabetes mellitus, primarily because of a defect in beta-cell responsiveness to glucose-dependent insulinotropic polypeptide (GIP), while insulin response to glucagon-like peptide-1 (GLP-1) stimulation is relatively more preserved. The aim of the present study was to investigate whether 4 weeks of near-normalization of blood glucose (BG) could improve the insulin responses to GIP and GLP-1 in patients with T2DM.

Materials and Methods: Eight patients with T2DM in poor glycemic control (BMI: 31.1 ± 3.9 kg/m², HbA_{1c}: 8.6 ± 1.3 %, mean BG: 13.8 ± 4.3 mM (three days seven points glucose profiles); mean \pm SD), were investigated before and after four weeks of near-normalization of BG using insulin treatment. HbA_{1c} after four weeks of insulin treatment was 7.5 ± 1.1 %, and mean BG was 7.4 ± 1.2 mM. Before and after insulin treatment the patients underwent three hyperglycemic clamps (15 mM) in random order, with infusion of either GLP-1 ($\frac{1}{2}$ pmol/kg/min), GIP ($\frac{1}{2}$ pmol/kg/min) or saline during 120 minutes. Insulin responses were evaluated as the incremental area under the plasma insulin curve from 0–120 minutes. For comparison eight control subjects were evaluated.

Results: Before and after near-normalization of BG, the insulin responses were: during GIP infusions (4.9 ± 1.1 nM/120 min vs. 20.7 ± 10.4 , $P < 0.04$); during GLP-1 infusions (6.2 ± 1.5 nM/120 min vs. 23.2 ± 12.5 , $P < 0.008$) and during saline infusions (3.0 ± 0.8 nM/120 min vs. 10.2 ± 4.1 , $P < 0.008$). Corresponding values in the control subjects were 148.9 ± 32.1 ; 175.6 ± 36 ; 57.3 ± 12.5 nM/120 min, respectively (GLP-1 vs. GIP; NS; GLP-1/GIP vs. saline; $P < 0.05$)

Conclusion: The results indicate that near-normalization of blood glucose for four weeks improves beta-cell responsiveness to both GLP-1, GIP and glucose per se with a factor 3–4. Nevertheless the insulin responses are still only 10–20 % of those observed in the control subjects.

Mechanisms of exenatide attenuation of postprandial hyperglycaemia in T2DM subjects

E. Cersosimo;

Medicine/Diabetes, University of Texas, San Antonio, United States.

Background and Aims: Chronic exenatide therapy markedly attenuates the rise in postprandial hyperglycemia and causes a modest reduction in fasting glucose concentration. Our aim was to examine the mechanisms responsible for these beneficial effects on glucose homeostasis

Materials and Methods: Six T2DM subjects (45 ± 8 y; 2F/4M; BMI = 31 ± 2 kg/m², FPG = 171 ± 18 mg/dl, HbA_{1c} = 8.1 ± 0.8 %) taking metformin (n=3) or a sulfonylurea (n=3) received a mixed meal tolerance test (MMTT) before (PRE) and (POST) 2 weeks after exenatide, 5 µg sc bid during the first week and 10 µg sc bid during the second week. Exenatide was not given on the day of the POST study. The mixed meal contained 600 cal and 75 grams of glucose labeled with 100 µCi of [¹]-¹⁴C-glucose. Three hours prior to and for 6 hours after the ingestion of the meal subjects received a primed continuous infusion of 3-[³H]-glucose. The total rate of appearance of glucose in the systemic circulation (RaT), the rate of oral glucose appearance (RaO), endogenous (EGP) glucose production and splanchnic glucose uptake (SGU = 75 grams minus RaO from 0–360 min) were measured with the dual isotope technique, and hepatic insulin sensitivity (HIS) was calculated as [100/EGPxFP1]. Plasma glucose, insulin, glucagon, and glucose kinetics were measured for 6 hours after the meal was consumed.

Results: In the PRE study, FPG (171 ± 18 mg/dl) increased to a mean of 225 ± 23 mg/dl during the MMTT, insulin increased from 11 ± 2 to 15 ± 3 µU/ml, and

glucagon remained unchanged (58 ± 8 vs. 57 ± 7 pg/ml). Following 2 weeks of exenatide (POST study), FPG decreased to 132 ± 13 mg/dl and mean PG during the MMTT declined to 173 ± 16 mg/dl (both $p < 0.01$ vs. PRE). Insulin increased from 7 ± 3 to 18 ± 4 µU/ml and glucagon decreased from 66 ± 6 to 60 ± 8 pg/ml (both $p < 0.01$, PRE vs. POST); body weight did not change significantly (87.4 ± 6.2 to 86.6 ± 4.8 kg, $p = \text{NS}$). After exenatide, basal EGP decreased from 2.3 ± 0.1 to 1.8 ± 0.2 mg/kg.min ($p < 0.05$), and the incremental area under the curve (AUC) for RaO over 6-hour post-meal was reduced by ~50%, ($p < 0.01$). In the PRE study 43.3 ± 4.2 grams of the ingested glucose appeared in the systemic circulation over 6 hours compared with 23.2 ± 4.9 grams in the post-exenatide study ($p < 0.01$). Thus exenatide induced a ~60% (32.7 ± 4.2 vs. 52.5 ± 4.9 grams, $p < 0.01$) increase in SGU (plus delayed gastric emptying), and HIS increased ~50% from 4.3 ± 0.4 to 6.7 ± 0.6 (mg/kg.min)⁻¹ (µU/ml)⁻¹ ($p < 0.05$). In summary, exenatide treatment of T2DM subjects for two weeks: i) decreased FPG by inhibiting basal EGP; ii) attenuated the postprandial glycemic excursion by enhancing the suppression of endogenous glucose production during the meal and augmenting splanchnic glucose uptake; iii) increased insulin secretion (Δ Insulin/ Δ Glucose); and iv) suppressed glucagon levels during the meal.

Conclusion: Chronic exenatide therapy (exenatide was not given on the day of MMTT and plasma exenatide levels were undetectable) profoundly influences splanchnic (hepatic) glucose handling by enhancing hepatic insulin sensitivity and augmenting splanchnic glucose uptake of ingested glucose. The role of delayed gastric emptying is yet undetermined. Glucagon-like-peptide 1 may represent the long-sought for "gut factor".

One year treatment with exenatide improves β cell function and glycaemic control in metformin treated type 2 diabetes patients

M. C. Bunck¹, M. Diamant¹, A. Cornér², B. Eliasson³, J. L. Malloy⁴, R. M. Shaginian⁵, W. Deng⁴, D. M. Kendall⁴, M.-R. Taskinen², U. Smith³, H. Yki-Jarvinen², R. J. Heine¹;

¹Department of Endocrinology, VU University Medical Center, Amsterdam, The Netherlands, ²Department of Medicine, Helsinki University Hospital, Finland, ³Lundberg Laboratory for Diabetes Research, Sahlgrenska University Hospital, Goteborg, Sweden,

⁴Amylin Pharmaceuticals, Inc., San Diego, United States,

⁵Eli Lilly and Company, Nederland, Houten, The Netherlands.

Background and Aims: Traditional blood glucose lowering therapies do not sustain adequate glycaemic control in the majority of patients. Preclinical and clinical studies with exenatide, an incretin mimetic have shown improvements in β-cell function. In this investigator designed study, we compared the effect of one year exenatide vs. insulin glargine on β-cell function, measured with an euglycaemic-hyperinsulinaemic (5 mM) followed by a hyperglycaemic (15 mM) clamp combined with additional arginine stimulation.

Materials and Methods: Sixty-eight metformin-treated patients with DM2 (mean \pm SD: age 59 ± 8 y; HbA_{1c} 7.5 ± 0.8 %; BMI 31 ± 4 kg/m²; body weight 91.5 ± 13.1 kg) were randomised to exenatide (n=36; 5µg BID for 4 weeks, 10µg BID with treat to HbA_{1c} target ≤ 7 %, maximum dose 20µg TID thereafter) or insulin glargine (n=32; treat to fasting plasma glucose (FPG) target < 5.6 mmol/L). β cell function was assessed as the week 52 to baseline ratio in glucose-potential (15 mM) of arginine stimulated C-peptide secretion during the first 10 min following the arginine bolus. Additional endpoints included first and second phase C-peptide secretory response after IV glucose, HbA_{1c}, body weight and safety.

Results: Interim analysis from 48 of the 68 randomised subjects showed arginine stimulated C-peptide secretion to be 125% [95% CI 0.91 to 1.64, $p < 0.0001$] greater after 1 year treatment with exenatide (n=26) as compared to insulin glargine (n=22) (mean ratio relative to baseline, for exenatide and insulin glargine \pm SEM: 2.45 ± 0.16 vs. 1.15 ± 0.06 , respectively). First phase glucose-induced C-peptide secretion was 52% [95% CI 0.27 to 0.80, $p < 0.0001$] greater after 1 year of exenatide compared to insulin glargine therapy (exenatide 1.76 ± 0.12 vs. insulin glargine 1.21 ± 0.09). Second phase C-peptide secretion increased 175% [95% CI 1.31 to 2.28, $p < 0.0001$] more with exenatide (2.94 ± 0.21) than glargine (1.14 ± 0.06). After 1 year, both therapies reduced HbA_{1c} similarly: exenatide by -0.77 ± 0.13 %, and glargine by -0.94 ± 0.17 % difference 0.29% [95% CI -0.09 to 0.66%, $p = 0.13$]. Exenatide significantly reduced body weight compared to insulin glargine (-3.88 ± 0.8 kg vs. $+1.4 \pm 1.1$ kg respectively; difference -5.2 kg [95% CI -8.0

to -2.4kg , $p=0.0005$). The adverse event rate was comparable to previous exenatide trials: 17 of the 36 (47%) exenatide treated patients experienced mild to moderate nausea while none of the glargine treated patients did. Hypoglycaemic events were more common in the glargine treated group than in the exenatide treated group (25% vs. 14% respectively).

Conclusion: One year of exenatide therapy, as compared to insulin glargine, markedly improved different indices of β -cell function, i.e. glucose and arginine induced insulin secretion, along with similar glycaemic improvement. In addition, patients treated with exenatide lost weight whereas patients treated with glargine gained weight.

Treatment with glucagon-like peptide 1 leads to blood glucose normalization in patients with type 2 diabetes after coronary artery bypass surgery

B. Gallwitz¹, K. Müsigg¹, A. Öncü¹, P. Lindauer¹, A. Heining², A. Fritsch¹, H. Aebert³, J. J. Holst⁴, K. Unertl⁴, H.-U. Häring¹;

¹Department of Endocrinology, Diabetology, Nephrology, Angiology, and Clinical Chemistry, University Hospital of Internal Medicine, Tübingen, Germany, ²Department of Anesthesiology and Intensive Care Medicine, University Hospital of Tübingen, Germany, ³Department of Thoracic, Cardiac, and Vascular Surgery, University Hospital of Tübingen, Germany, ⁴Department of Medical Physiology, The Panum Institute, University of Copenhagen, Denmark.

Background and Aims: Hyperglycemia, a common feature of the critically ill, has been associated with a poor outcome after major surgery in patients with type 2 diabetes. Intensive insulin therapy (IIT) improves the outcome of prolonged critically ill patients, but the broad clinical application is limited by its practicability and the risk of hypoglycemia. The incretin hormone glucagon-like peptide-1 (GLP-1) only stimulates insulin secretion under hyperglycaemic conditions. Furthermore, it suppresses glucagon secretion, slows gastric emptying, induces satiety, and improves beta cell function as well as left ventricular and systemic hemodynamics in type 2 diabetes. Therefore, the glucose-lowering effect of GLP-1 was studied in patients with type 2 diabetes after coronary artery bypass surgery.

Materials and Methods: Twenty patients with type 2 diabetes who had undergone coronary artery bypass surgery were randomised to receive either IIT according to the intensive care unit algorithms (ten men; age, 67.8 ± 2.3 yrs; body mass index, 30 ± 1 kg/m²; glycosylated hemoglobin, $7.1 \pm 0.3\%$) or a continuous intravenous GLP-1 infusion (3.6 pmol x kg x min) within the first 12 hours postoperatively (eight men, two women; age, 62.5 ± 2.2 yrs; body mass index, 28 ± 1 kg/m²; glycosylated hemoglobin, $6.6 \pm 0.3\%$). Blood was drawn in 2-hr intervals for measurement of glucose (glucose oxidase), insulin, C-peptide, glucagon, and GLP-1 (specific immunoassays). Statistics were done with repeated-measures analysis of variance and Duncan's post hoc tests.

Results: During the intravenous infusion of GLP-1, plasma glucose concentrations were significantly lowered due to stimulation of endogenous insulin secretion and inhibition of glucagon secretion. There were no statistical differences in blood glucose between both treatment groups. No hypoglycaemic events were recorded during the experiments. The incidence of complications were comparable in both groups (SIRS, duration of antibiotic treatment and duration of ICU-treatment).

Conclusion: With GLP-1 a normalization of glucose metabolism is feasible under ICU-conditions.

0253

Characterization of antibody positive diabetes across the age groups of 15–59 years

E. Bakhtadze, C. Cervin, E. Lindholm, G. Sundkvist, L. Groop; Diabetes and Endocrinology, Lund University, Malmö, Sweden.

Background and Aims: Type 1 diabetes in children is characterised by autoimmune destruction of pancreatic β -cells and presence of certain high-risk HLA genotypes, the Ins VNTR polymorphisms in the insulin gene and a polymorphism in the PTPN22 gene. In adults, the same situation is often referred to LADA or latent autoimmune diabetes in adults. However, the phenotype of autoimmune diabetes across different age groups is not well established. Our aim was therefore to genetically and metabolically characterise autoimmune diabetes across the age groups of 15–59 years.

Materials and Methods: We determined the HLA-DQB1 genotypes, the Ins VNTR polymorphisms as well as the PTPN22 polymorphisms and measured GADA, and IA-2A antibodies and fasting C-peptide concentrations in 1,869 younger (15–34 years old) and 1,619 elderly (40–59 years old) Swedish diabetic patients.

Results: Altogether, 67% of the young and 13% of the elderly patients were Ab+. There were more females among elderly than among younger Ab+ patients (49% vs. 39%; $p=0.009$). Elderly Ab+ patients had significantly ($p<0.0001$) higher BMI (26 ± 5 vs. 23 ± 4 kg/m²), more often a family history of diabetes (63% vs. 23%), were less often treated with insulin (60% vs. 93%) and had higher C-peptide concentrations (0.41 ± 0.48 vs. 0.30 ± 0.26 nmol/l). BMI correlated positively ($p<0.0001$) with C-peptide concentrations in young ($r=0.29$) and elderly ($r=0.46$) Ab+ patients. r -value significantly differ between them ($p=0.005$). The frequencies of HLA-DQB1 *0302/X was higher among young than elderly Ab+ patients (26% vs. 15%; $p=0.013$), whereas, that of HLA-DQB1 *0201/*0302 was similar (27% vs. 27%; $p=0.93$). Elderly Ab+ patients with Ins VNTR AA (0.27 vs. 0.48 nmol/l; $p=0.01$) and Ins VNTR CC (0.33 vs. 0.68 nmol/l; $p=0.0009$) genotypes had lower C-peptide concentrations than non-risk Ins VNTR genotype carriers.

Elderly Ab- patients had significantly ($p<0.0001$) more often a family history of diabetes (70% vs. 45%), were less frequently treated with insulin (23% vs. 60%) and had higher C-peptide concentrations (0.97 ± 0.55 vs. 0.79 ± 0.54 nmol/l) than younger Ab- patients. BMI correlated positively ($p<0.0001$) with C-peptide concentrations among both young ($r=0.63$) and elderly ($r=0.44$) Ab- patients, but r value did not differ. The frequency of the Ins VNTR CC (class IIIA/IIIA) genotype was higher in young than elderly Ab- patients (66% vs. 60%; $p=0.036$). Young Ab- patients with risk HLA-DQB1 (0.63 vs. 0.84 nmol/l; $p=0.0007$) and PTPN22 CT or TT (0.64 vs. 0.83 nmol/l; $p=0.002$) genotypes had lower C-peptide concentration than non-risk HLA-DQB1 and PTPN22 CC genotype carriers. However, elderly Ab- patients with risk HLA-DQB1 (0.86 vs. 0.97 nmol/l; $p=0.009$) had lower C-peptide concentrations than non-risk HLA-DQB1 genotype carriers. In linear regression analysis factors associated with decreased C-peptide concentration were: in Ab+ patients, decreased BMI ($p<0.0001$), older age at onset ($p=0.012$) and absence of family history of diabetes ($p=0.031$) and in Ab- patients, decreased BMI ($p<0.0001$), younger age at onset ($p<0.0001$) and risk HLA-DQB1 ($p=0.02$), PTPN22 CT or TT ($p=0.008$) genotypes.

Conclusion: Despite a marked increase in BMI with age, Ab+ patients aged between 15–59 years show similar reduction in β -cell function and similar frequency of high-risk HLA-DQB1 genotypes as well as of Ins VNTR polymorphisms. Obesity is thus not an uncommon corollary of autoimmune diabetes in adults. Absence of islet antibodies makes younger and elderly diabetic patients more alike.

The PTPN22 1858T gene variant is associated with reduced residual insulin secretion and worst metabolic control in type 1 diabetes

A. Petrone¹, M. Spoletini¹, M. Capizzi¹, S. Zampetti¹, S. Zavarella¹, C. Venditti¹, C. Foffi¹, I. Alemanno¹, IMDIAB Group², P. Pozzilli², R. Buzzetti¹;

¹Clinical Sciences, "Sapienza" University, Rome,

²Endocrinology, Campus Biomedico, Rome, Italy.

Background and Aims: Different factors (i.e. genetic background) may be responsible for the heterogeneity of beta-cell function detectable at onset of type 1 diabetes (T1DM). The C1858T missense variation of the Protein Tyrosine Phosphatase Non receptor (PTPN22) gene, which encodes for a powerful inhibitor of T-cell activation, known as LYP, has been recently reported to be associated with T1DM and other autoimmune diseases. A recent study has provided evidence that the PTPN22 C1858T variant is a marker of disease progression from pre-diabetes to clinical disease. The present study was designed to investigate whether PTPN22 gene is associated with a different degree of beta-cell loss at diagnosis and can influence the residual beta-cell function in the course of the 12 months after disease onset. **Materials and Methods:** N=120 consecutive T1DM subjects with age ranged from 5 to 36 years (mean age 14.9±7.8) were evaluated. The C1858T SNP was genotyped using the fluorogenic 5' nuclease assay (ABI, Foster City, USA). Insulin requirements, glycosylated haemoglobin (HbA1c) and C-peptide levels were determined at diagnosis and every 3 months for 12 months, in all subjects. HbA1c was measured by a column assay (Bio-Rad) and C-peptide levels by a radioimmunoassay (Bio-Rad). The variance of the investigated variables, during follow up, was analyzed using the general linear model repeated-measures procedure. The model includes "between-subjects" factors that divided the population into groups according to their genotype to investigate their effect on variance, using age and gender as covariates.

Results: C-peptide levels of subjects carrying the 1858T susceptible variant of PTPN22 gene were significantly lower than those of T1DM patients homozygous for C1858 from time of disease onset through follow up (p=0.01). Moreover the levels of HbA1c in T1DM subjects carrying the 1858T variant of PTPN22 gene were significantly higher compared to T1DM homozygous for C1858 (p=0.02). The trend in the pattern of C-peptide and HbA1c levels in the two groups, stratified according to the 1858T variant was similar during the follow-up. The insulin requirement at diagnosis and after 3, 6, 9 and 12 months did not show any significant difference between subjects with or without the 1858T variant at PTPN22 locus. Additionally we observed a correlation between C-peptide levels and age at diagnosis in T1DM subjects from time of disease onset through follow-up (p=0.016).

Conclusion: The implication of our study is that PTPN22 T1858 individuals had experienced a more destructive beta-cell damage in the pre-diabetic-period and maintain significant lower levels of C-peptide compared to the C1858 homozygous worsening the metabolic control (HbA1c levels). The present results could be useful for designing trials aimed to prevent the progression of beta-cell destruction.

The +49AG variant of the CTLA4 gene (IDDM12) is associated with ketoacidosis at disease onset and with anti-GAD antibody titres during disease progression in children with newly diagnosed type 1 diabetes

L. B. Nielsen¹, H. Mortensen¹, S. Poerksen¹, P. Hougaard², H.-J. Aanstoot³, K. Robertson⁴, C. Pfluger⁵, N. Schlotz⁵, S. Gammeltoft⁶, L. Hansen⁷;

Germany, ⁶Biochemistry, Glostrup University Hospital, Glostrup, Denmark,

⁷Novo Nordisk A/S, Bagsvaerd, Denmark.

Background and Aims: The cytotoxic T lymphocyte antigen 4 (CTLA4) gene is associated with common autoimmune disorders like type 1 diabetes (T1D), rheumatoid arthritis, and Grave's disease. In the Japanese population the G allele of the +49AG variant on the CTLA4 gene tend to associate with higher levels of GAD autoantibodies and also shown association ketoacidosis at disease onset. The aim of this study was to investigate the impact of three

common genetic variants of the CTLA4 gene, Thr17Ala/+49AG (rs231775), CT60 (rs3087243), and JO30 on disease severity and autoimmune activity in children and adolescents the first 12 months after diagnosis of T1D.

Materials and Methods: The study is a multicenter longitudinal investigation with 18 participating paediatric centres from 15 countries in Europe and Japan (84% Caucasians). Clinical information and blood samples were collected from 275 children less than 16 years at diagnosis of T1D and during the following 1, 6, and 12 months. PCR-RFLP analysis was performed for genotyping the population for the three variants on the CTLA4 gene.

Results: In accordance with previous investigations in Japanese populations we find an association between carriers of the G allele (alias Ala phenotype) of the +49AG variant and high levels of GAD autoantibodies 12 month after disease onset (p=0.03). In addition we find a significant association between the GG genotype carriers and diabetic ketoacidosis at onset (OR=2.2, [1.04–4.67]). We did not find significant associations to the CT60 and JO30 variants with any of the clinical variables investigated.

Conclusion: These findings substantiate the involvement of the CTLA4 gene in the pathogenesis of T1D, linking the +49AG variant to a more severe onset of T1D and a more aggressive autoimmune activity during disease progression.

SUMO4 M55V, in IDDM5 locus, polymorphism increases susceptibility to type 1 diabetes in HLA-DR3 and DR4 positive Swedish patients

S. K. Sedimbi, X. Luo, C. B. Sanjeevi;

Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden.

Background and Aims: Small ubiquitin-related modifier 4 (SUMO4) is a protein encoded by SUMO4 gene in the IDDM5 locus in chromosome 6q25. It encodes the SUMO4 protein, suggested to be a post-translational modifier of the inhibitor for nuclear factor-κB (IκB). A nonsynonymous SNP (rs237025; 163A>G) causing a methionine-to-valine substitution at codon 55 (M55V) in SUMO4 protein was reported to be associated with T1DM in Asians but not in Caucasians. The current study aims to test the significance of M55V association to T1DM in a large cohort of Swedish Caucasians and to test the whether M55V is associated in those carrying high-risk HLA class II molecules, MICA alleles (5 and 5.1) and autoantibodies (GAD 65 and IA-2). **Materials and Methods:** The study included 673 T1DM patients and 535 age and sex matched healthy controls (0–35 years) collected as a part of two major studies (The Swedish Childhood Diabetes Study and The Diabetes Incidence Study (DIS) in Sweden). HLA and MICA typing was performed using PCR-SSOP, and autoantibodies were measured for glutamic acid decarboxylase isoform 65 (GAD 65) and islet antigen-2/ tyrosine phosphatase (IA-2) using radio ligand binding assay, previously. PCR-RFLP using Sequence Specific Primers was done to identify the genotype and allele variations in SUMO4.

Results: Our data suggests that SUMO4 M55V is not associated with susceptibility to T1DM in Swedish Caucasians. When we stratified our patients and controls based on heterozygosity for HLA-DR3/DR4 and SUMO4 genotypes (AA or AG or GG), SUMO4 GG further increased the relative risk conferred by HLA-DR3/DR4 to T1DM [from OR= 5.77, 95% CI= 4.22–7.88, P = <0.0001 (HLA-DR3/DR4 alone) to OR= 8.34, 95% CI= 4.07–17.13, P = <0.0001 (HLA-DR3/DR4 with SUMO4 GG)], whereas SUMO4 AA decreased the relative risk [from OR= 6.91, 95% CI= 4.93 – 9.67, P = <0.0001 (HLA-R3/DR4 alone) to OR= 3.66, 95% CI= 2.22 – 6.02, P = <0.0001 (HLA-DR3/DR4 with SUMO4 AA)]. SUMO4 M55V was no associated with autoantibody positivity to either GAD65 or IA-2 as well as high-risk MICA alleles 5 and 5.1 in T1DM patients.

Conclusion: We conclude that SUMO4 M55V is associated with T1DM in those carrying high-risk HLA-DR3 and DR4, but not by itself.

Adiponectin and coronary artery disease risk in apparently healthy men and women: the EPIC-Norfolk Prospective Population Study

M. Cote¹, A. Cartier¹, I. Lemieux¹, J.-P. Despres¹, N. J. Wareham², J. J. P. Kastelein³, K.-T. Khaw⁴, S. M. Boekholdt⁵;

¹Quebec Heart Institute, Hopital Laval Research Centre, Quebec, Canada,

²Medical Research Council Epidemiology Unit, University of Cambridge, United Kingdom, ³Department of Vascular Medicine, Academic Medical Center, Amsterdam, The Netherlands, ⁴Department of Public Health and Primary Care, Institute of Public Health, University of Cambridge, United Kingdom, ⁵Department of Cardiology, Academic Medical Center, Amsterdam, The Netherlands.

Background and Aims: Several recent studies have reported a relationship between adiponectin levels and cardiovascular disease. Increased plasma adiponectin levels have generally been associated with a lower risk of myocardial infarction among men without previous cardiovascular disease, independently of traditional cardiovascular risk factors. However, inconsistent results have been reported among prospective studies regarding the ability of adiponectin to predict cardiovascular risk. The purpose of the present study was to evaluate in a prospective case-control analysis nested in the European Prospective Investigation into Cancer and Nutrition (EPIC)-Norfolk cohort, the association between adiponectin levels and the development of future coronary artery disease (CAD) in healthy men and women aged 45 to 79 years who developed fatal or nonfatal CAD during follow-up.

Material and Methods: 1034 cases were matched to 1920 controls who remained free of CAD, by age, gender and enrolment time. Baseline non-fasting plasma adiponectin concentrations were determined by ELISA.

Results: Adiponectin levels were lower in cases than in matched controls (10.1 vs. 10.7 ug/ml; for cases and controls, respectively, $p=0.005$). Significant differences in HDL cholesterol levels (1.37 vs. 1.27 ug/ml, $p<0.0001$) and waist circumference (90.9 vs. 94.0 ug/ml, $p<0.0001$) were observed between cases and controls, respectively. The unadjusted odds ratio for future CAD according to adiponectin levels (as continuous variable, per adiponectin unit) was 0.76 (95% CI, 0.64–0.90; $p<0.001$). However, after adjustment for body mass index, waist circumference and established cardiovascular disease risk factors, this relationship was no longer significant. Furthermore, stratification of men and women on the basis of low vs. high adiponectin (median value: 8.2 vs. 12.2 ug/ml, for men and women, respectively) and low vs. high waist circumference (median value: 95.9 vs. 82.9 cm, for men and women, respectively) indicated that risk of CAD was more closely related to the presence of a high waist circumference than to low adiponectin levels. A similar analysis revealed that low HDL cholesterol levels (<1.15 mmol/l vs. <1.45 mmol/l, for men and women, respectively) were predictive of an increased CAD risk in both men and women, irrespective of adiponectin levels.

Conclusion: These results suggest that though low adiponectin levels are associated with an increased CAD risk in men and women they do not appear to provide additional predictive value beyond established cardiovascular risk factors such as elevated waist circumference and low HDL cholesterol levels.

Serum adiponectin predicts development of ESRD and the ADIPOQ_prom2G/A polymorphism is associated with diabetic nephropathy in patients with type 1 diabetes

A. Jorsal¹, L. Tarnow¹, M. Lajer¹, H.-H. Parving^{2,3}, P. Rossing¹;

¹Steno Diabetes Center, Gentofte,

²Department of Medical Endocrinology, Rigshospitalet, Copenhagen,

³Faculty of Health Science, University of Aarhus, Denmark.

Background and Aims: Patients with diabetic nephropathy have a high risk of end-stage renal disease (ESRD) and cardiovascular morbidity and mortality. Adiponectin is a hormone exclusively produced by adipocytes and possesses anti-inflammatory, anti-atherogenic and cardioprotective properties. Adiponectin levels in patients with type 1 diabetes are increased compared with healthy subjects and increased levels are associated with

microangiopathy in type 1 diabetes. The aim of this study was to investigate serum levels of adiponectin and 8 frequent polymorphisms in the *adiponectin* gene in relation to diabetic nephropathy, ESRD, cardiovascular events, and mortality in type 1 diabetic patients.

Materials and Methods: Our study was a prospective observational follow-up study; including 438 type 1 diabetic patients with overt diabetic nephropathy and a matched control group of 442 patients with longstanding type 1 diabetes and persistent normoalbuminuria. The patients were followed for 8.1 (0.0–12.8) years (median [range]). Cases with diabetic nephropathy included 267 men and 171 women; age 42.3 ± 10.4 years [mean \pm SD], duration of diabetes 28.4 ± 8.8 years, GFR 66 ± 28.1 ml min⁻¹ per 1.73 m². Normoalbuminuric controls included 233 men and 207 women; age 45.4 ± 11.5 years, duration of diabetes 27.7 ± 10.1 years.

Results: Serum adiponectin was measured in 199 patients with diabetic nephropathy. 12 patients (12%) with adiponectin levels below the median and 28 patients (30%) with levels of adiponectin above the median reached ESRD during follow-up (hazard ratio 3.44 [1.77–6.78], $p < 0.001$; covariate-adjusted (sex, age, systolic BP, HbA_{1c}, GFR, and cholesterol at baseline) hazard ratio 2.44 [1.17–5.08], $p = 0.017$). Furthermore, 8 variants in the *adiponectin* gene were analyzed. The A-allele of ADIPOQ_prom2G/A (rs17300539) was associated with diabetic nephropathy (A-allele frequency: 9.4% versus 6.6% in cases and controls, respectively, $p = 0.014$). None of the adiponectin polymorphisms was associated with serum levels of adiponectin or renal/cardiovascular outcome in patients with type 1 diabetes.

Conclusion: In conclusion, the ADIPOQ_prom2GA polymorphism is associated with diabetic nephropathy and higher serum adiponectin levels predict development of ESRD in Danish Caucasian patients with type 1 diabetes.

0259

Serum adiponectin and progression of diabetic nephropathy in type 1 diabetic patients (The FinnDiane Study)

M. T. Saraheimo^{1,2}, C. Forsblom^{1,2}, L. Thorn^{1,2}, J. Waden^{1,2}, N. Tolonen^{1,2}, J. Frystyk³, A. Flyvbjerg³, P.-H. Groop^{1,2};

¹Folkhälsan Institute of Genetics, Folkhälsan Research Centre, Helsinki, Finland, ²Department of Medicine, Helsinki University Central Hospital, Division of Nephrology, Finland,

³Aarhus University Hospital, Medical Department M (Diabetes and Endocrinology) and the Medical Research Laboratories, Denmark.

Background and Aims: Serum adiponectin concentrations are increased in type 1 diabetic patients with nephropathy. The mechanisms responsible for the increase are still unclear, but adiponectin has been suggested to mitigate renal tubular injury and thus to prevent further progression of diabetic nephropathy. Adiponectin has also been suggested to reduce both micro- and macrovascular complications, but in contrast to this high, rather than low, adiponectin levels have been associated with increased mortality in patients with chronic kidney disease. The aim of this study was to elucidate whether serum adiponectin is associated with progression of diabetic nephropathy in type 1 diabetic patients.

Materials and Methods: This is a prospective follow-up study, which is part of the nationwide Finnish Diabetic Nephropathy Study (FinnDiane). 1385 type 1 diabetic patients were followed for 5.0 ± 2.2 years. Patients were divided at baseline into three groups according to their urinary albumin excretion rate (AER) in three consecutive overnight or 24 hour urine collections: 882 patients with normoalbuminuria [NA] (AER < 20 ug/min), 229 with microalbuminuria [MI] (20 ug/min $< AER < 200$ ug/min) and 274 with macroalbuminuria [MA] (AER > 200 ug/min). Progression of albuminuria was the main outcome. Adiponectin was measured by a time-resolved immunofluorometric assay (TR-IFMA), and the values were log-transformed and adjusted for age, BMI and sex before analysis.

Results: 165 patients (69 NA, 37 MI and 59 MA) progressed either to the next albuminuria level or ESRD. No difference in adiponectin concentrations was observed between progressors and non-progressors in NA (11.3 ± 5.4 vs. 11.9 ± 5.4 mg/l, $p=0.4$) or MI (12.0 ± 6.0 vs. 12.4 ± 6.1 mg/l, $p=0.7$) patients. In the MA patients, progression to ESRD was associated with higher adiponectin in the entire group (22.9 ± 12.1 vs. 16.0 ± 8.2 mg/l, $p<0.001$) and also when men (19.8 ± 11.2 vs. 13.7 ± 6.7 mg/l, $p<0.001$) and women (28.5 ± 11.9 vs. 18.7 ± 8.9 mg/l, $p<0.001$) were analyzed separately. Progression to ESRD was associated with HbA_{1c}, S-creatinine, AER and triglycerides, but not with age, waist-hip

ratio and blood pressure. In a multiple logistic regression analysis, adiponectin, HbA_{1c}, S-creatinine and triglycerides were independent predictors of ESRD ($R^2 = 0.315$), while gender did not enter the model.

Conclusion: High serum adiponectin levels predict the progression from macroalbuminuria to end-stage renal disease in type 1 diabetic patients.

0260

Low and middle molecular weight adiponectin isoforms and polymorphisms of the adiponectin gene are associated with the incidence of nephropathy in type 2 diabetic subjects

F. Fumeron^{1,2}, R. Aubert¹, R. Jaziri^{1,2}, F. Péan¹, S. Maimaitiming^{1,2}, N. Bellili^{1,2}, R. Roussel^{1,2}, S. Hadjadj³, M. Marre^{1,2};

¹INSERM, U695, Paris, ²Faculté Xavier Bichat, Université Paris France,

³Endocrinologie, Centre Hospitalier Universitaire, Poitiers, France.

Background and Aims: Low adiponectin levels are found in type 2 diabetes and coronary heart disease, while high levels are associated with diabetic nephropathy. Adiponectin circulates in various isoforms: low (LMW), middle (MMW) and high molecular weight (HMW). It has been suggested that the amount of HMW isoform is the most important correlate of insulin sensitivity. Nevertheless, only few studies measuring isoforms have been performed with respect to clinical phenotypes. Our aim was to assess the association between total plasma adiponectin and adiponectin multimers at entry, and 4-year incidence of myocardial infarction (MI) and/or renal disease (RD) in type 2 diabetic subjects from the DIABHYCAR prospective study. The association of adiponectin (total and isoforms) with three adiponectin gene (ADIPOQ) SNPs (-11391G>A, +45T>G, +276G>T) was also investigated.

Material and Methods: Participants were the 3123 French type 2 diabetic subjects with micro- or macro-albuminuria from the DIABHYCAR study. Plasma total adiponectin and multimers were assayed by ELISA (ALPCO Diagnostics™). These measurements were performed on plasma samples drawn at the beginning of follow-up in all patients with incident MI (n=95) or incident RD (n=75) and in controls matched for sex, age, MI and genotypes.

Results: In people with incident RD, the MMW and LMW isoform concentrations at entry were significantly higher than in matched controls 1.66µg/mL vs 1.37µg/mL, p=0.018 and 2.20µg/mL vs. 1.94µg/mL, p=0.048, respectively). Total adiponectin and all isoforms concentrations were lower in subjects with incident MI, but none of these differences was significant. Nevertheless, when excluding subjects with incident RD, HMW levels were lower in MI (2.16µg/mL vs. 2.62µg/mL, with a borderline significance (p=0.07). We had previously shown that the -11391G>A and +45T>G ADIPOQ SNPs were associated with the risk to develop renal disease (RD) in the DIABHYCAR study. These SNPs were also associated with adiponectin levels. Total, HMW and MMW adiponectin concentrations were higher in -11391A carriers than in -11391 GG homozygotes (7.42µg/mL vs. 5.72µg/mL, p<0.0005; 3.55µg/mL vs. 2.33µg/mL, p<0.0005; 1.69µg/mL vs. 1.36µg/mL p=0.025, respectively). In subjects with +45GG genotype, all adiponectin related concentrations were higher than in +45T carriers (8.89µg/mL vs. 5.90µg/mL, p=0.011; 3.10µg/mL vs. 2.48µg/mL, p=0.008; 2.05µg/mL vs 1.40µg/mL, p=0.013; 2.52µg/mL vs 1.95µg/mL, p=0.019, for total, HMW, MMW, LMW adiponectin, respectively). There was no interaction of genotypes with sex or disease on adiponectin related measurements.

Conclusion: In type 2 diabetic subjects, an elevation of MMW and LMW adiponectin isoforms precedes the onset of RD. Moreover, the genotypes associated with elevated levels of adiponectin are those associated with the incidence of RD. These results support the hypothesis of a causal role of elevated adiponectin levels in diabetic nephropathy.

RCT of continuous glucose monitoring devices on HbA_{1c} – The MITRE Study

S. Newman¹, S. Hurel², D. Cooke¹, L. Steed¹, J. Ahlquist³, J. Weaver⁴, D. Kerr⁵, M. Barnard⁶, A. Casbard⁷, S. Meredith⁷, A. Nunn⁷;

¹CBSSM, UCL, London, ²Diabetes & Endocrinology, UCLH, London,

⁴Diabetes & Endocrinology, QEH, Newcastle,

⁵BDEC, RBCHT, Bournemouth, ⁶Diabetes & Endocrinology,

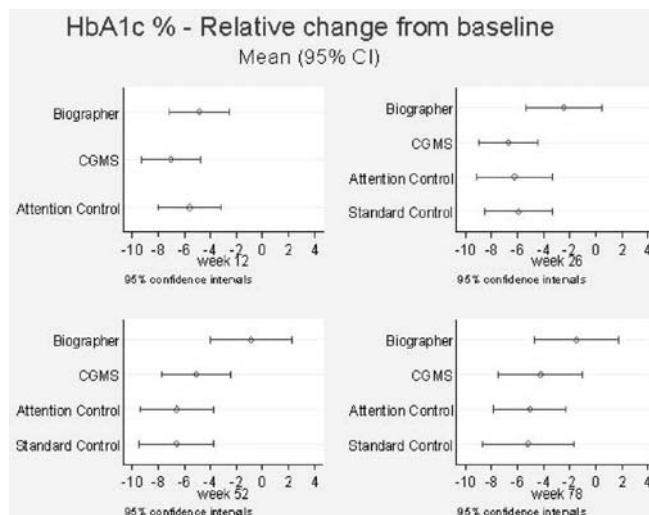

Whittington Hosp., London, ⁷CTU, MRC, London, United Kingdom.

Background & Aims: Minimally invasive continuous glucose monitoring devices have been developed on the assumption that periods of detailed continuous information will lead to improved metabolic control. This RCT was designed to evaluate the efficacy of two such devices in poorly controlled, insulin-requiring people with diabetes.

Materials and Methods: 102 patients were randomly assigned to the CGMS (Minimed), 100 to the Biographer (Animas), 102 to Standard Care and 100 to an Attention Control group. The last group was to control for the impact of increased levels of contact with health care professionals in the 2 device groups. HbA_{1c} was assessed at 3 (excluding Standard Care), 6, 12 and 18 months. The primary outcome was the mean % change in HbA_{1c} from baseline. In addition the proportion of patients in each group showing a 12.5% reduction in baseline HbA_{1c} was calculated.

Results: The mean percentage change in HbA_{1c} from baseline for each of the 4 groups and 95% CIs are displayed for each timepoint. Only those patients for whom an HbA_{1c} was available in a specified window of time, around the scheduled research visit, have been included. Mean HbA_{1c} declined from baseline in all groups, although the effect waned with time. At 18 months the decline ranged from a little over 1% (Biographer) to between 4 and 5%. No significant differences were found between the groups at any time-point. A per-protocol analysis, specifying a minimal amount of use of the two monitors, produced similar results. The proportion of patients showing a reduction of 12.5% from their baseline HbA_{1c} at each timepoint is displayed (see table). At all timepoints the proportion with a relative reduction of at least 12.5% ranged from 15% (Biographer) to 29% (CGMS). No differences were found between the groups at any time point.

Conclusion: These results suggest that the effectiveness of the 2 monitors is no different to standard care or treatment of a similar intensity. A secondary analysis, where minimum usage of the devices was required, indicated no advantage of the devices on HbA_{1c}. All groups showed a sustained reduction in HbA_{1c} suggesting that trial participation lead to improved metabolic control. This may have obscured any effects of the devices. (Tab. 1)

Tab. 1 Abstract 0261

Proportion of Patients Achieving a 12.5% Reduction in HbA_{1c} from Baseline

Increased postprandial hyperglycaemia due to rising preprandial glucose: Results from a 40-day home use study using the FreeStyle Navigator® Continuous Glucose Monitoring System

T. C. Dunn, K. Rebrin, T. A. Peyser;
Abbott Diabetes Care, Alameda, United States.

Background and Aims: Continuous glucose monitoring provides patients with both more glucose values and glucose trend information to improve glycemic control. Meal-related glycemic profiles were collected from a 40-day home use study with the FreeStyle Navigator® System (“CGM”, investigational device) and analyzed for the effect of premeal glucose and trend on postmeal glycemic state.

Materials and Methods: Subjects (T1DM or T2DM, n = 122) were masked to the sensor data and alarms for the first 20 days, and unmasked thereafter. The system stored glucose values every 10 minutes and meal times were entered by the participant, resulting in 3,505 analyzable profiles. The premeal trend was determined in the 40 min premeal. The premeal and 3hr postmeal glucose for each profile were categorized as hypoglycemic (<3.89 mmol/L), euglycemic (3.89–10 mmol/L), or hyperglycemic (>10 mmol/L). Statistical analyses were performed for the categories of hyperglycemia, hypoglycemia and trend stability. Stable trend was defined within -1.7 to 1.7 (mmol/L)/hr.

Results: Premeal, the rates of hypoglycemia, euglycemia, and hyperglycemia were 4%, 63% and 33%, while postmeal the rates were 4%, 50% and 45%, respectively (Table 1). For the entire study, the rate of postmeal hyperglycemia was found to vary due to premeal trend, with rates of 48% hyperglycemia for unstable premeal trend, compared to 44% for stable trend (p=0.019). During the masked phase (n=1999), the effect of premeal trend on postmeal hyperglycemia was significant (p=0.016), with 49% postmeal hyperglycemia for unstable premeal trends compared to 44% for stable premeal trends. However, during the unmasked phase (n=1506), this effect disappeared and rates of 46% and 44% were not different (p=0.260). This suggests that even in this study, in which patients were given *no explicit instructions* on modifying therapy based on CGM, patients made improvements in their treatment based on the additional data.

A major finding of this study is that patients do not adequately treat (or compensate) for hyperglycemia at mealtimes. When the premeal glucose trend was stable, patients who were hyperglycemic remained hyperglycemic after the meal in 66% of the cases. Also, there was a significant difference in glycemic outcome depending on the glucose trend at the start of the meal. For

Premeal Glycemic Range	Premeal Glycemic Trend (mg/dL)/min	Premeal Glycemic Trend (mmol/L)/hr	Postmeal Glycemic Range			n

	-1 to -2	-3.3 to -6.7	0%	77%	22%	9
	< -2	< -6.7	33%	50%	17%	6

Shaded rows have n < 35 (< 1% of the 3505 total observations).

Tab. 2. Frequency of postmeal glycemic range by premeal glycemic range and premeal glycemic trend for the entire study

example, with premeal euglycemia and rapidly rising trend (> 3.3 (mmol/L)/hr), postmeal hyperglycemia rates were 50%, as opposed to only 33% with stable or falling trend.

Conclusion: These findings represent an important opportunity for additional intervention by HCPs to help patients improve glycemic control using CGM, and specifically trend arrows. As CGM becomes more widely used, HCPs may encourage patients to treat hyperglycemia more aggressively, especially when the glucose trend indicates a rising premeal glucose. This may enable patients to reduce exposure to post-prandial hyperglycemia in the short term and to reduce A1C in the long-term. (Tab. 2)

Improved glycaemic control in intensively treated subjects with type 1 diabetes using Accu-Chek® advisor insulin guidance software

S. Garg, S. L. Ellis, C. Beatson, P. Gottlieb, R. Gutin, T. Bookout, C. Figal, B. Snyder;
Young Adult Clinic, Barbara Davis Center for Childhood Diabetes, Aurora, United States.

Background and Aims: Day to day management of insulin could be significantly improved with the availability of computerized insulin algorithms for home use. This study was designed to evaluate the effect of

Fig. 1a-b Abstract 0263

the Accu-Chek Advisor Insulin Guidance Software on glycemetic control in patients with type 1 diabetes.

Materials and Methods: This was a one year open label randomised study of 123 subjects assigned to either the Accu-Chek[®] Advisor Insulin Guidance Software program for personal data assistant (PDA) or the control group. The study included adults 18–60 yrs with type 1 diabetes and A1c values between 7.5–11%. The primary endpoint of the study was a difference in the A1c values. Data for blood glucose (BG) values, testing frequency, glucose excursions, hypoglycemic events (all, nocturnal and severe), insulin dose, weight and BMI, were recorded.

Results: All baseline demographics were similar in the two groups. The mean A1c values were significantly lower at 3 and 6 months in the experimental group (Figure 1a). Mean change in A1c at 6 months from baseline was -0.8% vs. -0.1% in the experimental and control groups, respectively ($p=0.0015$). Within target range (WTR) glycemia was significantly increased in the experimental group ($p=0.0076$; Figure 1b). Body weight, total, basal and bolus insulin dosages were similar in the two groups. Severe hypoglycemic events and BG testing frequency were higher in the experimental group.

Conclusion: This is the first report that shows improved glycemetic control can be maintained over 1 year in patients with type 1 diabetes by using the Accu-Chek[®] Advisor Insulin Guidance Software with no change insulin dose or weight. Day to day management of glycemetic control can be significantly improved using computerized insulin dosing software. (Fig. 1a–b)

Supported by Roche Diagnostics

cholesterol, systolic and diastolic blood pressure improved significantly more in the intervention group compared with the control group, but the change in HbA1c was not significant. In patients without a history of cardiovascular disease the difference in 10 year UKPDS CHD risk estimate was 2.1% better in the intervention group. (Tab. 1)

Conclusion: Delegation of routine diabetes care to a practice nurse combined with computerised decision support and benchmark information improved the (intermediate) patient outcome of diabetes care significantly. This was also translated in improvement of the 10 year UKPDS CHD risk score.

Task delegation and computerised decision support improve cardiovascular risk for type 2 diabetes patients. A randomised controlled trial in primary care

F. G. W. Cleveringa, K. J. Gorter, M. van den Donk, G. E. H. Rutten;
General Practice, Julius Centre for Health Science and Primary Care,
Utrecht, The Netherlands.

Background and Aims: In The Netherlands most type 2 diabetes (DM2) patients are treated in primary care. Coronary heart disease (CHD) causes 70% of the mortality and reducing cardiovascular risk is a priority. However, implementing guidelines in primary care appears to be difficult, and at least 30% of DM2 patients do not meet the strict targets for good glycaemic and cardiovascular control. Most interventions aiming to improve diabetes care showed improvements in the process of care, but not in patient outcome. The Diabetes Care Protocol (DCP) combines task delegation, computerised decision support, and benchmark information, but it is not known whether this will improve patient outcome.

Aim: To study the effect of DCP on cardiovascular risk factors for DM2 patients in primary care.

Materials and Methods: 48 primary care practices participated in a cluster randomised trial. 26 practices started with DCP (intervention group) and 22 practices continued usual care (control group). A practice nurse registered all clinical parameters in the DCP software. Mean changes between intervention and control group for HbA1c, systolic and diastolic blood pressure, total cholesterol and HDL-cholesterol were calculated (independent samples t-test) and corrected for clustering (generalized linear models). For patients without a history of cardiovascular disease (CVD) we also calculated the change in 10 year UKPDS CHD risk estimate (www.dtu.ox.ac.uk).

Results: 2390 patients participated, 1363 intervention group and 1027 control group. At baseline the clinical parameters were comparable. Total

Problems and their resolves in diabetes screening

I. V. Misnikova, A. V. Dreval, I. A. Barsukov;

Endocrinology, Moscow Regional Research Clinical Institute, Russian Federation.

Background and Aims: WHO recommends oral glucose tolerance test (OGTT) as being single best choice, but if it is not possible to perform OGTT fasting plasma glucose (FPG) alone may be used for epidemiological purposes. Aim of study was to estimate influence of OGTT exclusion from diabetes screening to prevalence of hyperglycemic state.

Materials and Methods: Study was population-based screening for IFG, IGT and T2D. Personal data of participants were obtained from municipal medical insurance data of two Moscow County districts (100 666 inhabitants). 8000 subjects (age 18–90 years) was randomised. Invitation letters and information brochures were sent to them. 2638 subjects agreed to took part in the study. All participants gave their informed consent and study was approved by the ethic committee of the Moscow Region Research Clinical Institute. FPG was measured in all participants. A standard 75 g OGTT was performed using HemoCue analyzers in subjects previously undiagnosed with diabetes (2508 subjects). Diagnosis of IFG, IGT, T2D followed the 1999 World Health Organization (WHO) criteria. Of the inhabitants, 1,63 % subjects had previously been diagnosed with T2D and were excluded from subsequent analyses.

Results: In total, 2188 subjects (87,24%) had normal glucose tolerance (NGT). The figures for IFG were 58 subjects (2,31%), for IGT 120 subjects (4,78%), for IFG + IGT 44 subjects (1,75 %) and finally T2D was diagnosed among 98 participants (3,9%). When we excluded the results of OGTT, prevalence of T2D decreased to 3,15% (79 subjects). The figure of IFG became 112 subjects (4,47%). The amount of subjects with NGT increased up to 2317 subjects (92,38%). In the structure of early abnormalities of glucose homeostasis the main part occupied by IGT (54,5%), IFG 26,13 % and IFG+IGT 19,82%. We estimated the necessity of OGTT in groups with different FPG level. Among subjects with FPG < 4 mmol/l IGT was not diagnosed at all. Prevalence of IGT among subjects with FPG 4–4,5 mmol/l is very low (0,28%). There are no patients with T2D among subjects with FPG < 4,7 mmol/l. Prevalence of T2D among subjects with FPG 4,7–5,5 mmol/l is very low (0,16%).

Conclusion:

- 1) Hyperglycemic abnormalities are revealed by OGTT more often (12,76 %, include T2D 3,9%) than by measurement FPG only (7,62% include T2D 3,15 %).
- 2) Exclusion of OGTT from screening will result in undiagnosing of main part of early abnormalities of glucose homeostasis (54,05%).
- 3) The exclusion of OGTT from screening of subjects with FPG < 4,7 mmol/l does not influence on prevalence of T2D.

0266

Predictors of incident diabetes mellitus in Basrah, Iraq

A. A. Mansour;

Medicine, Basrah College of medicine, Basrah, Iraq.

Background: New-onset diabetes was associated with a 90% increase in risk of all-cause mortality and a 120% increase in risk of cardiovascular mortality compared with study participants without diabetes. The aim of this study was to study prospectively the predictors of incident diabetes mellitus in Basrah, Iraq with special emphasis on predictive performance of four anthropometric variables of obesity, body mass index (BMI), waist circumference (WC), waist-to-hip ratio (WHpR) or waist-to-height ratio (WHtR).

Material and Methods: Total of 13730 (7101men and 6629 women) cohort free of diabetes at baseline were followed for a mean of 5 years (January 2001 to end of December 2006).

Results: There were 935(6.80%) cases of incident diabetes (513 men and 422 women). All anthropometric indices (BMI, WC, WHpR WHtR) were higher among those with incident diabetes ($P < 0.001$). In both sexes WHpR has the strongest associations with incident diabetes that was gender insensitive ($AUC = 0.74$ in males and 0.72 in females) followed by WC then BMI which

has the weakest association with incident diabetes. On multivariable logistic regression, only hypertension (OR, 1.66; 95% CI, 1.41 to 1.96; $p < 0.001$) was associated with incident diabetes. All anthropometric indices were significantly associated with incident diabetes except WHtR. No association between incident diabetes and gender, age, stroke, and ischemic heart disease.

Conclusion: In both sexes WHpR has the strongest associations with incident diabetes, followed by WC then BMI which has the weakest association with incident diabetes while WHtR has no association. Hypertension is the only non anthropometric variable associated with incident diabetes.

0267

Diabetes is associated with inflammation independent of obesity: a community-based sample of routine care patients

K. L. Pedula, G. A. Nichols, T. A. Hillier;

Science Program Department, Kaiser Permanente Center for Health Research, Portland, United States.

Background and Aims: Inflammation has been shown to be associated with cardiovascular disease (CVD), the leading cause of death among persons with type 2 Diabetes (T2DM). Additionally obesity, a risk factor for T2DM, has been linked to inflammation. The objectives of this study were to assess the relationship between inflammatory markers and T2DM and to determine if this relationship persists after adjusting for obesity and other comorbidities.

Materials and Methods: Among a large USA health plan sample with electronic medical records for all laboratory tests, we identified persons who had a complete blood count (CBC) that included both a white blood cell (WBC) count and platelet (PLT) test in 2005. These tests are widely available as part of routine outpatient care and are known to be early markers of low-level inflammation. CBC tests ordered during a hospitalisation or for an emergency care visit were excluded. Also excluded were persons with diagnoses of cancer or HIV. Patients were stratified into 2 groups: all persons with T2DM; and a random sample of persons without diabetes matched on age, gender, and body mass index (BMI) to the T2DM group. Using electronic medical records, we linked individuals to other comorbidities (e.g., diagnosis of CVD, hypertension, dyslipidemia). We then used multivariable models to compare WBC and PLT between T2DM and controls across the levels of BMI while adjusting for comorbidities.

Results: A total of 17,036 patients were included in the final analyses. Average age was 64.8 (± 12.3) years and 49% were male. BMI averaged 32.6 (± 7.3) kg/m² with 13% of matched pairs having a BMI > 40 kg/m². Relative to controls, average WBC counts were significantly higher in T2DM cases across all BMI levels (see Table). Average PLT levels were only marginally associated with diabetes status. Adjustment for hypertension, CVD, and dyslipidemia attenuated these associations slightly, but the relationships remained significant. Within the T2DM group, anti-hyperglycemic therapy (insulin or oral hypoglycemic agents) was not associated with WBC counts or PLT levels

Conclusion: Inflammatory markers are consistently higher in persons with T2DM relative to controls, irrespective of obesity status. Further investigation is necessary to assess the contribution of hyperglycemia and other diabetes characteristics to this increased inflammation in order to identify possible mechanisms for reducing the burden of CVD in T2DM.

BMI (kg/m ²)	Mean White Blood Cell Count (x 10 ⁹ /L)*			Mean Platelet Count (x 10 ⁹ /L)*		
	T2DM	Control	p-value	T2DM	Control	p-value
< 25	7.7	7.0	<0.001	258.3	251.5	0.076
25 – 30	7.5	6.9	<0.001	243.6	247.0	0.087
31 – 40	8.3	7.3	<0.001	247.8	251.4	0.028
> 40	8.5	7.7	<0.001	268.6	270.0	0.678

Abdominal obesity: a predictor of type 2 diabetes and cardiovascular disease in a primary care cross sectional study

S. Massano-Cardoso¹, E. Mendes², D. Carvalho³; on behalf of the W-Risk investigators,

¹Instituto de Higiene e Medicina Social, Faculdade de Medicina de Coimbra, Coimbra, ²APMCG, Associação Portuguesa dos Médicos de Clínica Geral, Lisboa, ³Endocrinology, Diabetes and Metabolism, Faculdade de Medicina/Hospital de S. João, Porto, Portugal.

Background and Aims: There is not enough evidence on prevalence of abdominal obesity (AO) associated with diabetes in Portugal. A descriptive analysis of data from a Primary Care Physician (PCP) population aged ≥ 18 years in Portugal was used to assess how AO is associated with diabetes, cardiovascular risk (CVR) factors and presence of a CV disease.

Materials and Methods: W-Risk (Body Weight Deviations and Risk Situations) was a non-interventional cross-sectional study conducted in 2005. A standardised questionnaire was completed in 14,695 subjects consulting their PCP ($n=1,500$). Demographic data, weight, waist circumference (WC), CVR factors, physical exercise and concomitant treatment were collected. AO is defined as a WC in women ≥ 80 cm and in men ≥ 94 cm. The prevalence was standardised to the general population.

Results: A total of 14,695 subjects were included with a mean age 55.5 ± 16.2 ; 65.8% were female.

Prevalence of AO was 66.3% in men and 82.9% in women. The prevalence of diabetes was 9.2%, being 10.5% in men and 7.6% in women. The prevalence of diabetes was stepwise increased through the gender specific quartiles of AO as shown in table 1:

Sex	1 st Quartile AO	2 nd Quartile AO	3 rd Quartile AO	4 th Quartile AO
Males	8.9%	15.2%	23.3%	30.3%
Females	4.2%	10.1%	16.3%	24.2%

The age adjusted odds ratios of different CVR factors and respective CIs (95%) for AO versus normal WC are shown in table 2:

Variable	Women	Men
Diabetes	3.3 (2.5 – 4.5)	2.3 (1.9 – 2.8)
Hypertension	2.8 (2.2 – 3.6)	2.8 (2.4 – 3.3)
Hypertriglyceridaemia	2.8 (2.2 – 3.6)	2.8 (2.4 – 3.3)
Total Hypercholesterolaemia	1.8 (1.6 – 2.1)	1.7 (1.5 – 1.9)
High LDL	1.7 (1.4 – 2.0)	1.8 (1.5 – 2.0)
Low HDL	1.9 (1.6 – 2.3)	1.8 (1.6 – 2.1)
Smoking	0.8 (0.6 – 1.06)	0.5 (0.45 – 0.66)
Physical exercise	0.8 (0.7 – 0.9)	0.8 (0.7 – 0.9)

The relative risk of diabetes and CV disease comparing the 4th AO quartile to 1st is shown in table 3:

	Males	Females
Diabetes	3.4 (2.4 – 4.7)	5.8 (3.9 – 8.6)
Angor	3.2 (1.6 – 6.2)	3.9 (1.8 – 8.3)
Myocardial Infarction	3.2 (1.5 – 6.6)	2.2 (0.4 – 12.1)
Stroke	2.1 (0.8 – 5.5)	3.1 (0.96 – 10.0)

Conclusion: Our results show that in Portugal, in PCP practice, and using IDF criteria for defining AO, AO is highly prevalent, especially in women. Subjects with AO are more likely to have diabetes, hypertension and hypertriglyceridaemia in both gender. Identification of subjects who have AO may provide opportunities to early identify patients who are likely to have diabetes and CVR.

Comparison of anthropometric indicators for obesity as predictors of diabetes incidence in Mauritius

R. Nyamdorj^{1,2}, Q. Qiao^{1,2}, S. Söderberg^{3,4}, J. Pitkaniemi¹, P. Zimmet⁴, J. Shaw⁴, G. Alberti², V. Pavvaday⁶, P. Chitson⁶, J. Tuomilehto^{1,2};

¹Public Health, University of Helsinki, Finland, ²Health Promotion and Chronic Diseases Prevention, National Public Health Institute, Helsinki, Finland, ³Medicine, Umeå University Hospital, Sweden, ⁴International Diabetes Institute, Caulfield, Victoria, Australia, ⁵Endocrinology and Metabolic Medicine, Mint Wing, St Marys Hospital, London, United Kingdom, ⁶Ministry of Health and Quality of Life, Port Louis, Mauritius.

Backgrounds: Obesity is a risk factor for diabetes and CVD. The definition of obesity is important for the purpose of intervention. There is controversy regarding which anthropometric measures best defines obesity and conveys highest risk for diabetes.

Aims: To compare different anthropometric indicators of BMI, waist circumference (WC), WHR, and waist to height ratio (WSR) as predictors of diabetes incidence in Mauritian Indians and Creoles living in Mauritius.

Methods: Three population-based surveys were conducted in Mauritius in 1987, 1992, and 1998. According to the participation in these surveys, participants were divided into 4 subgroups as shown in table 1.

Results: Hazard ratios (HRs) for diabetes incidence were estimated applying an interval censored survival analysis using age as timescale for each ethnic group based on baseline obesity indicators. All models in the data analysis were adjusted for cohort and baseline fasting glucose. A paired homogeneity test was performed in order to test equality of regression coefficients in the survival analysis between BMI and WC (or WHR or WSR). All linear hypotheses concerning the regression coefficients were tested using R-program 2.2.1 for diabetes incidence. We chose 5% significance level. A significant result from the paired homogeneity test indicates that the two indicators have a different effect on incident diabetes.

The number of participants and the incidence rates are shown in table 1.

Cohorts	Men % (number)	Women % (number)	Total % (number)
1987–1992	11.5 (393)	7.6 (380)	9.6 (773)
1992–1998	11.3 (575)	11.8 (686)	11.6 (1261)
1987–1998	13.8 (58)	20.3 (74)	17.4 (132)
1987–1992–1998	22.9 (844)	20.1 (993)	21.4 (1837)
Total	16.6 (1870)	15.2 (2133)	15.9 (4003)

Table 1. Diabetes incidence (%) and the total number of non diabetic individuals at baseline in four subgroups (cohorts)

The HR for diabetes incidence was slightly lower for BMI than for central obesity indicators but their 95 % CIs overlapped (table 2).

	MAURITIAN INDIAN		CREOLES	
	Men	Women	Men	Women
BMI	1.64 (1.48–1.82)	1.54 (1.38–1.72)	1.99 (1.68–2.35)	1.44 (1.22–1.70)
WC	1.74 (1.56–1.93)	1.56 (1.40–1.74)	2.14 (1.81–2.54)	1.49 (1.26–1.76)
WHR	1.66 (1.51–1.81)	1.56 (1.42–1.71)	2.01 (1.74–2.32)	1.51 (1.31–1.73)
WSR	1.80 (1.62–2.00)	1.60 (1.44–1.77)	2.27 (1.92–2.69)	1.46 (1.24–1.71)

Table 2 HRs (95 % CIs) for diabetes incidence corresponding to a one SD increase in obesity indicators, estimated separately for each indicator

Paired homogeneity tests showed BMI did not differ from central obesity indicators except for in Mauritian Indian men where WSR was better than BMI ($p = 0.03$) with regard to the prediction of incident diabetes.

Conclusion: BMI was as strong as central obesity indicators in the prediction of diabetes incidence in this population.

0270

Body mass index is strongly associated with impaired insulin sensitivity in Europeans from 19 countries, independent of age, sex, social class and smoking habits: the RISC Study

N. M. Lalic¹, P. M. Nilsson², J.-Å. Nilsson², R. Gabriel³, C. Anderwald⁴, B. Balkau⁵ & the RISC Investigators,

¹Institute for Endocrinology, School of Medicine, Belgrade, Serbia,

²Department of Clinical Sciences, Lund University, Malmö, Sweden,

³Unidad de Investigacion, Hospital Universitario La Paz, Madrid, Spain,

⁴Department of Internal Medicine 3, Endocrinology and Metabolism, General Hospital, Vienna, Austria, ⁵Inserm U 780 – IFR 69, Epidemiological and Biostatistical Research, Villejuif, France.

Background and Aims: Impaired insulin sensitivity (IS) is associated with a large number of cardiovascular risk factors, including obesity and smoking. As subjects from low social class tend to be more obese and smoke more, it is of interest to test whether impaired IS differs with social class. This study was aimed to analyse the relationship among IS, obesity, social background parameters and smoking habits in European healthy individuals.

Materials and Methods: We investigated 1284 subjects from 19 academic centres all over Europe as part of the ongoing EGIR-RISC Study. These subjects were selected as healthy and with a low cardiovascular risk profile. At baseline a clinical examination was carried out (weight, height, waist circumference, blood pressure) together with a self-administered questionnaire (social background, lifestyle). All subjects underwent a standardised euglycaemic hyperinsulinemic clamp for measurement of SI, reflected by the M/I level (mg/kg/min/insulin level during the last 40 min of clamp).

Results: There were in total 575 men and 709 women, stratified for occupational category: non-manual (n= 969; 75.5%), self-employed (n= 66; 5.1%) and manual (n= 249; 19.4%). Mean M/I was 14.1+/-7.1 mg/kg/min/nM. No significant difference was seen in M/I (p=0.094), between occupational groups adjusted for age (p= 0.41), sex (p<0.001), body mass index (BMI) (p<0.001), and study centre (p<0.001), in general or stratified for gender. The same results were obtained with waist circumference replacing BMI. No interaction with waist and social class was noticed (p= 0.69). However, the BMI correlated significantly with M/I (p<0.001), but was not associated with smoking, after adjusting for all other factors including social class. BMI differed between manual and non-manual female workers (25.5 vs. 24.7 kg/m²; p= 0.045), but not between corresponding categories of male workers.

Conclusion: In this study, obesity is found to be strongly associated with impaired IS independently of other covariates, especially of social background and smoking habits in healthy subjects across Europe. The results imply that prevention of obesity should therefore be the main objective to prevent impairment of IS in all subjects at risk, irrespective of their social background.

Body mass index is an important risk factor for developing type 2 diabetes in Japanese

J. Yatabe, H. Sanada, M. S. Yatabe, Y. Kusano, S. Hashimoto, T. Watanabe; Internal Medicine III, Fukushima medical University, Japan.

Background and Aims: Some prospective studies have examined the relationship between obesity/overweight and the incidence of type 2 diabetes in Japan. The purpose of this study is to establish causal connections among individuals who are overweight and the onset of diabetes in a retrospective cohort study.

Materials and Methods: Our investigation included 1,044 men and 608 women, aged 33 to 75 years at baseline who had a voluntary complete medical checkup. The participants were followed for 10 years. Onset of diabetes was identified by an annual 75-g oral glucose tolerance test (75g-OGTT). Participants with fasting plasma glucose \geq 126 mg/dl, 2-h glucose level in a 75g-OGTT \geq 200 mg/dl and/or those receiving medical treatment for type 2 diabetes during the previous year were counted as new-onset diabetics. We used the χ^2 -test to compare relevant characteristics of participants at baseline and to estimate the odds of developing type 2 diabetes based on risk factors. We applied the Cox proportional hazards model to assess the independent contribution of BMI to the risk for developing type 2 diabetes.

Results: During the follow-up period, we diagnosed 95 men and 53 women with newly-onset type 2 diabetes. A Kaplan-Meier survival curve for 10 years showed the cumulative probability of developing type 2 diabetes was higher in participants who were moderately (BMI 25.0–27.4 kg/m²) or considerably overweight/obesity (BMI \geq 27.5 kg/m²) (Figure). The analysis indicated that BMI is a strong risk factor (odds ratio: 5.61, p < 0.01). Elevated TC (odds ratio: 1.51, P < 0.05), TG (odds ratio: 4.54, P < 0.01), HOMA-IR (odds ratio: 2.88, P < 0.01), and decreased HDL-C (odds ratio: 2.41, P < 0.01), but not fasting plasma glucose were associated with increased risk of new-onset type 2 diabetes. In the Cox proportional hazards model, the risk of diabetes mellitus increased with increasing BMI even after adjusting for age, sex, blood pressure, hyperlipidemia, and insulin resistance. In the final model, setting BMI less than 25 as a reference group, the odds ratio of diabetes mellitus was 3.66 for those with a BMI of 25–27.4 and this increased to 4.18 for participants with a BMI of 27.5 or higher (Table).

Conclusion: BMI is an independent and dose-dependent risk factor for type 2 diabetes in overweight Japanese patients. Management of body mass is therefore important for the prevention of type 2 diabetes.

Combined information from type 2 diabetes susceptibility genes, implications for risk prediction and treatment outcome: the Hoorn study

L. M. 't Hart¹, J. M. Dekker², E. C. van Hove¹, E. Reiling¹, G. Nijpels², R. J. Heine², J. A. Maassen^{1,2};

¹Molecular Cell Biology, Leiden University Medical Center, Leiden, ²EMGO Institute, Vrije Universiteit Medical Center, Amsterdam, The Netherlands.

Background and Aims: Progress in identifying susceptibility genes for T2DM has been slow and for the few genes identified so far the associated risks are generally low. In this study we evaluated whether combinations of several different susceptibility genes improve disease prediction in the Dutch Hoorn study cohort. Furthermore we evaluated whether this kind of information can be used in treatment of subjects with type 2 diabetes mellitus.

Materials and Methods: Single nucleotide polymorphisms (MAF >10%) in four different genes (*PPARG* (P12A), *KCNJ11* (E23K), *TCF7L2* (rs4506565) and *ABCC8* (rs1799854)) were genotyped in 1055 participants of the Hoorn study (505 T2DM, 550 NGT). These four genes were chosen based on the fact that they are either A: unambiguously associated with T2DM in several large population-based studies and meta-analysis or B: associated with the disease in our Hoorn study cohort and at least one other Dutch cohort (*ABCC8*). Response to treatment was analysed in 156 subjects with T2DM who participated in a two-year intervention study aiming at improved glycaemic control. Subjects were stratified according to risk allele count prior to the analysis (low <2, medium 3–5, high >6 risk alleles). The difference between fasting glucose levels before and after the study was used as outcome variable.

Results: The observed single gene effects were comparable to those in literature for Caucasian populations (odds ratios ranging from 1.1 to 1.4). Four gene risk allele counts were made for each individual and compared between cases and controls. The odds of having T2DM increased by 1.23 (95% CI 1.12–1.35) with each additional risk allele. Comparing the extremes of the distribution (0–1 risk alleles (2%) versus 7 or 8 risk alleles (4%) even increased the odds to 9.7 (95% CI 2.5–37.2). We next evaluated whether there are differences in response to intensified diabetes treatment between those with a low (n=15), medium (n=109) or high number of risk alleles (n=32). Baseline characteristics (glucose, insulin, HbA1c, duration of diabetes, use of medication etc) were not significantly different between the three groups. After the 2 year intervention study those with a high number of risk alleles showed significantly more often and the largest response to the intensified diabetes treatment and education program (delta fasting glucose -0.6 ± 0.3 , -0.5 ± 0.3 and $+0.6 \pm 0.4$ mmol/l for high, medium and low resp, $p=0.02$ and $p=0.04$ for high or medium vs. low). As expected the use of medication increased during the intervention but this could not explain the observed differences in response.

Conclusion: We conclude that combined information from type 2 susceptibility genes can be used to identify subgroups with markedly different risks of developing type 2 diabetes. Furthermore our data suggest that this type of information can also be used in treatment and programs aiming at prevention or delay of diabetes and its complications in those with the largest a priori risk. Additional larger studies, including pharmacogenetic, intervention and prevention studies are needed to confirm and substantiate our results.

The prevalence of the mitochondrial DNA 16189 variant in Czech diabetic and non-diabetic population and its associations with thinness, birth weight and insulin resistance but not with type 2 diabetes

M. Vankova, P. Lukasova, J. Vcelak, D. Vejrazkova, H. Kvasnickova, K. Vondra, B. Bendlova;

Dept. of Molecular Endocrinology, Institute of Endocrinology, Prague 1, Czech Republic.

Background and Aims: Type 2 diabetes (T2D) is a multifactorial disorder in which variants in mitochondrial DNA (mtDNA) could play a role. Some studies have shown that the mode of inheritance of T2D performs an excess of maternal transmission, but only a minority of mtDNA mutations have been identified in diabetics. A common mtDNA variant 16189 is positively associated with insulin resistance, T2D or metabolic syndrome in different populations. In this study we investigated whether 16189 variant is associated with risk diabetogenic parameters in Czech population.

Materials and Methods: 267 T2D patients (60.5±8.5 years) and 159 unrelated non-diabetics, including 71 healthy offspring of T2D and 88 controls (34.6±11.4 years) were selected. Subjects underwent anthropometric measurement, fasting biochemical examination and non-diabetics also OGTT and ivITT. Detailed anamnestic data were recorded by questionnaire. The 16189 variant was identified by PCR-RFLP (MnlI) of blood DNA. All samples positive for the 16189 variant were sequenced. Statistical analyses were performed using NCS 2004 software.

Results: In contrast to other published studies, the variant 16189 was found more commonly in non-diabetics (13.8%, but in controls 21.6%) than in the diabetic cases (9.7%). Frequency of variant between diabetics and controls was significantly different ($p=0.004$). Most diabetics reported having a maternal family history rather than paternal (49.8% vs. 30.6%), but frequency of variant in diabetics with maternal and paternal family history of diabetes is similar. Age of T2D diagnosis is not dependent on presence of the variant. Diabetics with the variant had significantly higher triglycerides than those with wild type ($p=0.01$) and higher cholesterol ($p=0.05$). Non-diabetics with the variant had higher stimulated C peptide than those with wild type ($p=0.04$) and higher growth hormone in 60 min OGTT ($p=0.01$). Fasting glucose, insulinemia, indices of insulin resistance and beta cell function and blood pressure were not different between groups. Non-diabetic women with the variant had significantly less subcutaneous fat ($p=0.02$) and higher muscle/fat mass ratio ($p=0.04$) than those with wild type and lower BMI ($p=0.05$). Birth weight was significantly lower in subjects with variant ($p=0.04$) than in wild types.

Conclusion: The frequency of 16189 variant in Czech diabetic patients is similar to other published Caucasian populations, while the frequency of variant in non-diabetics is markedly higher than those other Caucasians and this difference is more apparent in controls, i. e. healthy subject without T2D in parents. We demonstrated a significant association between the variant and thinness in non-diabetic women and also with lower birth weight. We did not confirm any association with T2D or clear association with metabolic syndrome (except for triglycerides in causes). However, higher C peptide during OGTT in non-diabetics with the variant suggests possible beginning of the insulin resistance. The finding of much higher growth hormone in 60 min OGTT in non-diabetics with the variant is of metabolic interest.

Diabetes due to the mt3243 A>G mutation among young adult diabetic subjects in Sri Lanka – prevalence and clinical heterogeneity

P. Katulanda^{1,2}, D. R. Matthews³, C. Groves¹, A. Barrett¹, M. I. McCarthy¹, A. L. Gloyn¹;

¹Diabetes Research Laboratories, Oxford Centre for Diabetes Endocrinology and Metabolism, Oxford, United Kingdom, ²Dept of Clinical Medicine, Faculty of Medicine, Colombo, Sri Lanka, ³Oxford Centre for Diabetes Endocrinology and Metabolism, University of Oxford, United Kingdom.

Background and Aims: The maternally inherited mt3243 mutation is associated with a variable clinical phenotype including diabetes and deafness

(MIDD). A genetic diagnosis can assist with clinical management and genetic counselling. MIDD has been reported to account for 0.5–3% of diabetes among other populations, however the frequency of this mutation in Sri Lanka (SL) is not known. The aim of our study was to determine the prevalence and clinical characteristics of patients with the mt3243 mutation in a large cohort of SL patients with young onset diabetes.

Materials and Methods: DNA was available from 1007 subjects (age of diagnosis of diabetes 16–40 yrs, age at recruitment \leq 45 yrs). The cohort was screened by quantitative real time PCR on an ABI 7900HT system using sequence specific TaqMan probes. Samples with heteroplasmy \geq 5.0% were considered positive.

Results: 9 (4 males) mutation positive subjects were identified (prevalence 0.9%). Their mean characteristics were; % heteroplasmy 35.2 (SD 23.0; range 13–87), age at diagnosis 26.0 (SD 4.8) vs. 31.9 yrs (SD 5.6) in non-mutation carriers (NMC) ($p=0.002$), BMI 18.6 (SD 2.6) vs. 25 (SD 15.0) kgm² ($p<0.0001$). Maternal family history of diabetes was present among 66.0% of carriers vs. 42.0% NMC ($p = ns$), a personal history of hearing impairment was seen among 33.0% of carriers vs. 6.3% NMC ($p=0.017$). One mutation positive subject (11.1%) has the metabolic syndrome vs 60.0% of NMC. Insulin treatment from diagnosis was used in 4 (44.0%) of carriers compared to 16.0% of NMC ($p=0.04$). Clinical neuropathy was present in 22.2% of carriers compared to 3.0% of NMCs ($p<0.001$). Glomerular filtration rate of < 60 ml/min/m² was present in 44.4% compared to 5.0% NMCs ($p=0.001$).

Conclusion: In this large cohort of young-onset diabetic subjects from SL the mt 3243 A>G mutation was detected in 0.9% of patients. Those with the mutation have a higher prevalence of neuropathy and low renal function. Our study demonstrates that a maternal family history of diabetes and either a personal and/or family history of deafness distinguish less than half (44.0%, 4/9) of patients with MIDD from Sri Lankan subjects with young-onset diabetes. Therefore, additional characteristics such as BMI, absence of metabolic syndrome and age of diagnosis of diabetes should be considered when referring patients for genetic testing.

A complex investigation of maternally inherited diabetes and deafness (MIDD) including clinical characteristics, C-peptide secretion, HLA-DR and -DQ status and autoantibody pattern

N. Hosszúfalusi¹, V. Karcagi², R. Horváth², E. Palik¹, J. Varkonyi¹, K. Rajczy³, Z. Prohászka¹, I. Karadi¹, L. Romics¹, P. Pancel¹;

¹3rd Dept. of Internal Medicine, Semmelweis University,

²Dpt, Johann Béla National Epidemiology Center, ³Dpt, National Institute of Hematology and Immunology, Budapest, Hungary.

Background and Aims: A point mutation of mitochondrial DNA (A3243G) is associated with maternally inherited diabetes and deafness (MIDD). The misclassification of MIDD was reported previously. Our aim was to characterise MIDD with detailed investigation.

Materials and Methods: Six patients with MIDD and one mutation-positive relative with normal glucose tolerance (NGT) from two families were examined. The A3243G and the HLA-DR, -DQ status were tested in leukocytes. Fasting serum C-peptide was measured in all subjects and compared with controls having NGT ($n=14$). C-peptide response to an intravenous glucose load (IVGTT) was investigated in the diabetic patients not treated with insulin ($n=3$) and in the mutation-positive healthy subject and compared with the controls. Clinical characteristics and the presence of islet cell specific (ICA, GAD, IA-2) and mitochondrial autoantibodies were also tested. All data are presented in mean \pm SD.

Results: The A3243G heteroplasmy value varied between 5–30 % in the carriers. Apart from the subject with NGT each A3243G carrier had hearing impairment. The A3243G carriers were smaller (height: 158.3 \pm 10.8 cm vs. 171.8 \pm 10.2 cm) and had lower body mass index (BMI: 20.53 \pm 2.05 kg/m² vs. 27.16 \pm 3.62 kg/m²) compared with the controls ($p=0.018$, $p=0.0009$, respectively). All mutation-positive subjects carried the HLA-DR1-DQ5 haplotype, and either the -DQ5 or the -DQ6 allele. The fasting serum C-peptide levels of the A3243G carriers varied between 0.79–6.57 ng/ml and did not differ from the controls (2.19 \pm 2.01 ng/ml vs. 2.08 \pm 0.73 ng/ml, respectively). All A3243G carriers had measurable fasting C-peptide levels including the two diabetic patients with long disease duration. A missing first phase and a decreased second phase of insulin response was detected in the

A3243G carriers compared with controls based on the curves of serum C-peptide measured during an IVGTT ($p<0.0001$). The same abnormality was detected in the A3243G carrier with NGT. However, the serum C-peptide levels of the A3243G carriers did not differ from the controls at 120 min during the IVGTT (2.59 \pm 0.20 ng/ml vs. 2.37 \pm 0.53 ng/ml). Circulating islet cell antibodies (ICA) were present in three patients with MIDD. GAD, IA-2 and mitochondrial antibodies were not found. The diagnosis of MIDD was delayed in each case. The disease was previously considered as type 1, LADA or type 2 diabetes.

Conclusion: A missing first phase and a decreased second phase of C-peptide response to intravenous glucose load was characteristic for A3243G carrier status in our study. However, the fasting and the 120 min serum C-peptide levels did not differ from the controls. Patients with MIDD having long diabetes duration still had measurable fasting C-peptide. Circulating ICA was present in some patients but GAD, IA-2 and mitochondrial antibodies were not detected. All subjects had HLA-DR1-DQ5 haplotype, and either -DQ5 or -DQ6 alleles. The diagnosis of MIDD was delayed in each case. The referred cases demonstrate that the clinical features of diabetes are sometimes not enough for the proper etiologic classification.

Clinical and genetic study of Thai patients with fibrocalculous pancreatic diabetes

T. Snabboon¹, W. Plengpanich¹, S. Sunthornyothin¹, R. Rerknimitr¹, P. Kongkam¹, S. Suwanwalaikorn¹, V. Vorasuk Shotelersuk²;

¹Internal medicine,

²Pediatrics, Chulalongkorn University, Bangkok, Thailand.

Background: Fibrocalculous pancreatic diabetes (FCPD) is classified as a secondary cause of diabetes mellitus (DM) resulting from pancreatic exocrine dysfunction. Recently, mutations in the SPINK1 gene have been reported in patients with FCPD.

Objective: To perform a detailed clinical and molecular analysis of patients with FCPD from thirteen unrelated Thai families.

Material and Methods: Genomic DNA was prepared from 13 probands and 10 family members. All exons of the SPINK1 gene of all probands were amplified by polymerase chain reaction, and directly sequenced. Clinical courses of pancreatic disease and DM of patients and their family members were reviewed.

Results: The age of onset of DM in our patients is ranged from 15 to 32 years old. All of the 13 probands had large intraductal pancreatic calculi; however, 4 of them did not have symptoms of abdominal pain or exocrine pancreatic dysfunction. Sequencing analysis of the SPINK1 gene successfully identified mutations in 8 probands. The heterozygous mutations for N34S, IVS3+2G>A and 206C>T were found in five, two and one probands, respectively. The SPINK1 206C>T (T69I) mutation has not been previously reported. In addition, a novel heterozygous for IVS1-4C>A polymorphism was identified in remaining five probands with no definite pathogenic mutations in the coding regions.

Conclusions: Of the 13 probands with FCPD, 8 were found to carry mutations in the SPINK1 gene, suggesting this gene is responsible for the majority of FCPD in Thai patients. In addition, a novel SPINK1 gene mutation has been identified in our study.

A case of hepatocyte nuclear factor-1 alpha diabetes (the new mutation in body 3)

M. D. Jesic¹, S. Sajic¹, M. Maringa², M. M. Jesic³, D. D. Micić⁴;

¹Endocrinology, University Childrens Hospital, Belgrade, Serbia,

²Genetic, IntegraGen GmbH, Bonn, Germany,

³Neonatology, University Childrens Hospital, Belgrade, Serbia,

⁴Center for Metabolic Disorders in endocrinology, Institute of Endocrinology, Diabetes and Diseases of Metabolism, Belgrade, Serbia.

Background and Aims: MODY3 belongs to monogenic forms of diabetes mellitus and is caused by monoallelic mutation in gene for transcription factor HNF-1alpha, essential for regulation of beta-cell function. Clinical

presentation of MODY3 is similar to that of type 1 diabetes. Although MODY 3 patients are not threatened by ketoacidosis, good metabolic control is important for prevention of chronic diabetic complications.

Materials and Methods: We present a 37-year old female (BMI 23.8 kg/m²) with insulin treated diabetes mellitus since age 14 and a family history of diabetes (father died in August 2006, and also had insulin treated diabetes mellitus since age 16). By the end of 2006 in her daughter aged 10.5 years (BMI 20 kg/m²) metabolic glucose disorder was revealed. Genetic testing for MODY due to “vertical line diabetes” was done by analyzing maternal and daughter’s DNA. All of the exons were polymerase chain amplified on the intron sequences. The obtained genetic fragments were then sequenced. When in euglycemia, glucagon (1 mg i.v.) stimulation test was done in the mother. Oral tolerance test to glucose with insulinemia and blood analysis for antibody presence to portions of pancreatic cells and their products were done in the daughter.

Results: In the daughter and her mother we identified identical mutation that has not been described in the literature until now – TCF 1 exon 2 c.368>C p.Leu 123 pro heterozygote mutation sequence HNF – 1 alpha (TCF 1). Maternal glucagon testing showed preserved endogenous insulin secretion 23 years after diagnosed diabetes mellitus (glycemia 0. min. 6.5 mmol/l-insulin 3.46 mUI/mL, glycemia 6.min. 7.1 mmol/l- insulin 8.21 mUI/mL). Following these findings, the mother was gradually transferred from insulin to sulphonylurea therapy – gliklazid (30 mg/daily), and after 2 months her HbA1c decreased from 6.7% to 6.1%. In the daughter we disclosed a marked insulinopenia (in the 60th min the maximal insulin rate was 18.6 mUI/mL at glycemia 16.9 mmol/l), while antibodies (GAD, anti IA2, antiinsulinic) were negative. Therefore, we attempted treatment with small doses of sulphonylurea – gliklazid (20 mg/daily). After 3 months the impression was that the treatment gave good results; glycemia was practically normalised, there was no hypoglycemia, and after initial 7.9% her HbA1c decreased to 5.8%

Conclusion: Treatment with small doses of sulphonylureas can be successful, not only in children with MODY3, but also in vertical line diabetic relatives previously on long-term insulin therapy; however, its long-term safety and efficacy will have to be confirmed. Early diagnosis of HNF-1alpha diabetes is important in planning treatment, monitoring complications and genetic counseling of affected families.

Pancreatic exocrine deficiency is common in MODY 3

M. Vesterhus¹, S. Johansson², H. Rader¹, A. Molven³, P. R. Njolstad²;

¹Dept. of Pediatrics, Haukeland University Hospital, Bergen,

²Dept. of Clinical Medicine, University of Bergen,

³The Gade Institute, University of Bergen, Norway.

Background and Aims: Exocrine pancreas dysfunction is seen in 10–30% of patients with type 1 and 2 diabetes, and is also found in patients with MODY5. The molecular factors involved are not understood. We have recently identified a novel syndrome of autosomal dominantly inherited diabetes and exocrine pancreas dysfunction due to mutations in the carboxyl ester lipase (CEL) gene. We wanted to investigate the prevalence of pancreatic exocrine dysfunction in the Norwegian MODY3 population and its relationship to common variants of *CEL*.

Materials and Methods: An invitation letter and a tube for stool sampling was sent to all 119 patients registered with a genetically verified diagnosis of MODY3 in the Norwegian MODY Registry. The response rate was 60.5%, and 70 patients (22 men, 48 women; mean age 40.4 years) were included. Pancreatic exocrine deficiency measured as fecal elastase deficiency (FED) was defined as moderate if faecal elastase-1 (E1) was less than 200 µg/g in two tests and severe if less than 100 µg/g in at least one of two tests. Increased fecal fat excretion was defined as more than 7 g/day in a 72-h stool collection.

Results: We found a prevalence of moderate and severe FED of 2.9% (2/70) and 8.6% (6/70), respectively, in the MODY3 patients. Six patients with FED returned a 72-hour stool collection and all had increased fecal fat excretion (mean 13.5 ± 7 g/day) The patients with FED were significantly older than the group with normal E1 (mean age 55, 68 and 38 years for patients with severe FED, moderate FED or normal elastase, respectively), and had significantly longer duration of diabetes (33, 36, and 19 years, respectively). There was no difference in BMI or age at diagnosis of diabetes. Fecal fat excretion did not correlate with either BMI or fecal elastase within the group of patients with

exocrine deficiency, but the number was small. The *CEL* gene was successfully sequenced in 50 (of the 70) patients. Of these, 10 patients (20%) had single base insertions. *CEL* insertions were found in 33.3% (2/6) of the patients with FED who were sequenced, compared to 18.2% (8/44) of patients with no insertions (OR=2.25, not significant). No patients had deletions in the *CEL* gene. Age at diagnosis of DM and BMI were similar between groups.

Conclusion: We found a prevalence of pancreatic exocrine deficiency of 11.4% in the Norwegian MODY3 population, similar to findings in type 1 and 2 diabetes patients. Those patients with FED who delivered stool samples all had increased faecal fat excretion, underscoring the potential clinical importance of the exocrine defect. *CEL* insertions showed a tendency to correlate with exocrine deficiency, supporting previously published findings in a cohort of type 1 and 2 diabetic patients.

Diagnosis and treatment of permanent neonatal diabetes mellitus:

US experience

J. Stoy¹, S. A. W. Greeley², L. H. Philipson¹;

¹Department of Medicine,

²Department of Pediatrics, University of Chicago, Chicago, United States.

Background and Aims: Mutations in the genes *KCNJ11* and *ABCC8* are important causes of permanent neonatal diabetes. Here we report 8 patients initially diagnosed with type 1 diabetes (T1D) but who have diabetes due to a mutation in *KCNJ11*. Recent reports have shown these patients can be successfully switched from insulin to oral sulfonylurea therapy.

Materials and Methods: The patients were from across the US and we used Oragene™ DNA Self-Collection kits to obtain a saliva sample for DNA. *KCNJ11* was amplified in two segments using PCR and both strands sequenced.

Results: Eight out of 18 patients diagnosed with diabetes before 6 months of age had a *KCNJ11* mutation. The median age at diagnosis of diabetes in the 8 patients was 4 weeks (0 to 26 wk) with median birth weight 2732 g (1531 to 2920 g) corresponding to the 7th percentile for male patients and the 14th percentile for females.

We identified 4 different mutations: H46Y in a mother and son; R201H in 4; and R201C and V59M in 1 patient each. Three of these patients were admitted to the University of Chicago General Clinical Research Center for transition from insulin to glyburide. Case 1, a 6 year-old (yo) female diagnosed with T1D at 1 month (mo) had the R201C mutation. Transition to oral glyburide resulted in cessation of insulin by day 14. The initial post-insulin glyburide dose was 1.2 mg/kg/day, but subsequently decreased to 1.0 mg/kg/day due to occasional modest hypoglycemia. Pre-transition HbA1c was 9.3% and decreased to 7.4% by 1 mo and 6.1% at 2 mo post-insulin cessation. This patient also had celiac disease with positive tissue transglutaminase antibodies. Case 2, a 3 yo female diagnosed at 6 mo with diabetic ketoacidosis (DKA) had the R201H mutation. She transitioned off insulin (day 4) with a lower daily dose of glyburide (0.8 mg/kg/day); current glyburide dose is 0.95 mg/kg/day. Her parents reported a yellowish discoloration of her teeth which improved after instructions to not chew the glyburide pills. Her father had GAD-antibody positive T1D diagnosed at 29 yo. Case 3, a 2.5 yo male diagnosed at 5 mo in severe DKA had the V59M mutation. He had developmental delay consistent with the intermediate DEND (Developmental delay, Epilepsy and Neonatal Diabetes) syndrome. Initial glyburide dose was 1.0 mg/kg/day (off insulin day 5); current glyburide dose is 0.83 mg/kg/day. Pre-transition HbA1c was 8.5 % and decreased to 6.9 % by 1 mo. The remaining patients are being transitioned to glyburide using an outpatient protocol. A 5 yo female (R201H) has successfully transitioned with a glyburide dose of 0.90 mg/kg/day divided in 5 doses. Her pre-transition HbA1c was 7.8 % and decreased to 6.4 % by 2 mo. The others are in progress (a 36 yo mother and 16 yo son with H46Y and 14 and 17 yo males with R201H). One of these had a mild self-resolving transaminitis at 3 wk of glyburide therapy.

Conclusion: These findings confirm that patients with diabetes due to a *KCNJ11* mutation have a low birth weight and a variable age at diagnosis of diabetes from <1 wk to 6 mo. The results show that salivary samples can be used to obtain an appropriate DNA sample for genetic analysis even in young children. Oral sulfonylurea therapy has allowed for life-changing modification of diabetes management in these children. Since we estimate only a small fraction of cases in the US have been discovered there is a need to increase efforts to find all cases in order to improve control and quality of life of all who could potentially benefit from sulfonylurea therapy.

0280

Comparison of prioritisation strategies for selecting subjects with apparent type 1 diabetes for MODY gene sequencing

K. R. Owen¹, M. P. Selwood², D. Swan¹, A. J. Farmer², M. I. McCarthy¹;

¹Diabetes Research Laboratories, University of Oxford,

²Primary Health Care, University of Oxford, United Kingdom.

Background and Aims: Young adults with diabetes represent a difficult diagnostic challenge. Differential diagnosis includes type 1 (T1DM), type 2 and rare genetic subtypes. It can be particularly difficult to differentiate T1DM from Maturity-onset diabetes of the young (MODY) because they present in similar ways, but those misdiagnosed as T1DM often have the most to gain from making a correct aetiological diagnosis due to the potential to stop insulin treatment. The standard criteria used for diagnosing MODY are onset of diabetes ≤ 25 yrs and autosomal dominant family history (FH) but it is not known whether selection criteria based on pathophysiology are superior. We aimed to test this hypothesis.

Materials and Methods: We examined a community-ascertained population diagnosed with diabetes ≤ 45 yrs. Type 1 diabetes was defined as permanent insulin treatment since diagnosis ($n=51$). Available data included FH, anthropometry, GAD antibodies and fasting biochemistry. Subjects were first selected from the group using standard MODY criteria. We then selected subjects on the basis of residual insulin secretion ≥ 3 years post-diagnosis (c-peptide detectable and HOMA% B > 20). We compared the individuals identified by these methods.

Results: 8 cases (16%) were selected who fitted standard MODY criteria. However all 8 had typical T1 features: all GAD antibody +ve, median [IQR] c-peptide undetectable [0–0.15] nmol⁻¹ and HOMA%B 1.4 [1.2–4.3].

3 cases were identified using pathophysiological criteria. All 3 were GAD antibody -ve. One was found to have features inconsistent with MODY (insulin resistance). The remaining 2 had evidence of residual β -cell function 10 and 26 years post-diagnosis with HOMA% B values of 33 and 22 respectively. They were older at diagnosis, but were otherwise indistinguishable from the main T1DM cohort. They have been referred for genetic testing (involving sequential re-sequencing of the HNF-1 α and 4 α genes).

Conclusion: In summary, in a cohort with apparent T1DM, using traditional MODY criteria alone to identify candidates for testing has poor specificity. Using an alternative approach based on pathophysiology identified 2 individuals (4% of the cohort) with features consistent with a transcription factor mutation. Our pilot data suggests that diagnostic pathways for MODY based on pathophysiology are feasible.

The prevalence estimation of PNDM in Poland: the relative contribution of mutations in KCNJ11 and ABCC8 genes

T. Klupa¹, A. Gach², A.-M. Patch³, J. Skupien¹, I. Pietrzak², S. Ellard³,

A. Hattersley³, W. Mlynarski², M. T. Malecki¹, J. Sieradzki¹;

¹Department of Metabolic Diseases, Jagiellonian University, Krakow,

Poland, ²Clinic of Pediatrics, Institute of Pediatrics, Medical University of

Lodz, Lodz, Poland, ³Institute of Biomedical and Clinical Science, Peninsula Medical School, Exeter, United Kingdom.

Background and Aims: Mutations in the KCNJ11 and ABCC8 genes encoding the Kir6.2 and SUR1 subunits of the beta cell KATP channel, respectively, have recently been shown to be a common cause of permanent neonatal diabetes mellitus (PNDM). The aim of the study was to estimate the prevalence of PNDM in Poland and to determine the relative contribution of mutations in the KCNJ11 and ABCC8 genes to its development.

Materials and Methods: To dissect the genetic background of PNDM in Poland, the Nationwide Registry was established in 2004. The patients with the permanent diabetes diagnosed before 6 months of age were recruited through contact with physicians and direct appeals for patients through the national media. The search for the presence of mutations in the KCNJ11 and ABCC8 genes is being done by direct sequencing.

Results: The Polish Nationwide Registry of PNDM currently includes 40 patients meeting PNDM criteria. This corresponds to the prevalence of 1/950,000 in the general population of Poland. However, if we consider the population below the age of 18, the prevalence was about 1/300,000. This difference may reflect a more efficient screening in the pediatric population,

alternatively, a lower survival of adult PNDM patients, or both. So far, the KCNJ11 gene has been sequenced in 39 PNDM subjects with mutations found in 16 subjects. Seven subjects carried the R201H mutation, three had the V59M substitution, two patients were carriers of the R50Q, the H46L, the G53D, the E229K and the K170N mutation, respectively. 14 patients were switched to sulphonylurea (SU) compounds, however 2 subjects were transferred back to insulin due to socioeconomic reasons or health problems unrelated to diabetes (hepatitis C). For 2 individuals the transfer is in process. So far, the ABCC8 gene has been sequenced in 8 PNDM patients, in whom KCNJ11 mutations were excluded. So far, 3 PNDM patients were identified to be ABCC8 gene mutation carriers. They were carriers of the F132V, the R826W substitutions, one patient was a carrier of two, N23H and R286W, mutations. In spite of a long exposure time to large doses of SU, we were not able to transfer off insulin the carrier of the F132V mutation. The carrier of two mutations, N23H and R286W, is sufficiently controlled on diet alone. The R826W mutation carrier remains yet to be exposed to SU.

Conclusion: We report that PNDM frequency may be much higher than previous estimates. About 40% of PNDM cases may be explained by KCNJ11 mutations. ABCC8 mutations seems to be common in the KCNJ11 negative patients.

PS 3 Genetics and epidemiology of metabolic syndrome, stroke and hypertension

0282

The clinical value of alanine aminotransferase as predictor of the metabolic syndrome in an overweight/obese paediatric population

M. van Vliet¹, M. Diamant², I. A. von Rosenstiel¹;

¹Paediatrics, Slotervaart Hospital Amsterdam, ²Endocrinology, VU University Medical Centre, Amsterdam, The Netherlands.

Background and Aims: Among children, the global prevalence of obesity and components of the metabolic syndrome (MetS), including glucose intolerance, insulin resistance (IR), dyslipidaemia, and hypertension is increasing at an alarming rate. However, the occurrence and clinical significance of non-alcoholic fatty liver disease (NAFLD), a feature that may underlie the abnormalities of the MetS, has not as yet been established in paediatrics. Alanine aminotransferase (ALT), a valid marker of NAFLD, is associated with the components of the MetS, but is not considered as part of its definition. In the present study, we examined the association between ALT values and the features of the metabolic syndrome in a cohort of overweight and obese children aged 3 to 17 years.

Material and Methods: In total, 298 overweight and obese children (according to age-adjusted criteria; mean age 10.5±3.3 years) who were referred to an outpatient clinic of a community hospital in Amsterdam (period 2004–2006), underwent an oral glucose tolerance test (OGTT). Additionally, anthropometric parameters and fasting blood samples were collected to assess lipid profiles and liver enzymes. Metabolic syndrome and insulin resistance were defined according to criteria of the American Academy of Paediatrics. Participants were divided into two groups according to ALT values based on established criteria: those with ALT ≤30 U/L (normal group) and with ALT >30 U/L (high group).

Results: The population consisted of 165 boys (55%) and 133 girls (45%) of multiethnic origin: 64 (21%) were of Caucasian and 234 (79%) of non-Caucasian origin (76 (26%) Turkish, 67 (22%) Moroccan, 32 (11%) Surinam and 59 (20%) children of other origin. Insulin resistance was present in 35%, dyslipidaemia in 51%, hypertension in 25% and metabolic syndrome in 28% of the children, showing no raised occurrence in the non-Caucasian group. Elevated ALT levels were found in 16.4% (n=49) of the study population (23.0% boys, 8.3% girls, p<0.001). The age- and gender-adjusted BMI was significantly higher in the high versus normal ALT group (BMI 173% (±21) vs. 162% (±23), p=0.002). The prevalence of IR and MetS was significantly higher in the high ALT group compared to the normal ALT group (p<0.001 and p<0.02, respectively). ALT was positively correlated with low HDL levels (odds ratio (OR) 1.02 (CI95% 1.003–1.037), p=0.02), and high triglyceride levels (OR 1.02 (CI95% 1.005–1.04), p=0.013). Overall, no difference in ALT was found between the Caucasian and non-Caucasian group.

Conclusion: In an overweight/obese multiethnic paediatric urban population, IR and MetS and its associated abnormalities are highly prevalent. Additionally, a high percentage of elevated ALT, suggesting NAFLD, was found, especially in boys. Elevated ALT appeared to be strongly associated with IR and MetS. Longitudinal large-scaled studies should establish the predictive value of these findings, in particular of elevated ALT, in the development of type 2 diabetes and cardiovascular disease in children and adolescents.

0283

Associations of sitting time with components of the metabolic syndrome in adults without diagnosed diabetes – The AusDiab Study

D. W. Dunstan¹, N. Owen², J. Salmon³, G. Healy², K. Ball³, J. E. Shaw¹, P. Z. Zimmet¹;

¹Epidemiology and Clinical Research, International Diabetes Institute, Caulfield, ²School of Population Health, The University of Queensland, Brisbane, ³School of Exercise and Nutrition Sciences, Deakin University, Burwood, Australia.

Background and Aims: Several studies have shown that sedentary behaviour may be an important contributor to poor health outcomes. However, most studies have focused on leisure time behaviours such as time spent watching

television. Less is known about the association of sedentary behaviours in both leisure and non-leisure time on metabolic outcomes. We have examined the associations of self-reported time spent sitting and components of the metabolic syndrome in Australian adults without diabetes.

Materials and Methods: The Australian Diabetes, Obesity and Lifestyle Study (AusDiab) is a nationally representative population-based survey of 11,247 adults aged ≥ 25 years with baseline measurements obtained between 1999 and 2000. The present analyses include a total of 5,749 adults who attended the 5-year follow-up and who were free from diagnosed diabetes. Fasting measures of plasma glucose, serum triglycerides and HDL-C and 2hrPG were obtained from an oral glucose tolerance test. Self-reported time spent sitting (hrs/day) was assessed using an interviewer-administered questionnaire. Waist circumference, height and resting blood pressure were measured at the testing site. The log transformation of the triglyceride measure was used in the analysis. All regression models were adjusted for age, education, employment status and physical activity time. Data are presented as regression coefficients (95% CI).

Results: The mean (SD) sitting time (hrs/day) for women and men was 5.1 (2.6) and 5.5 (2.7) respectively. In both men and women, sitting time was positively associated with 2hrPG, log-transformed triglycerides, and waist circumference and inversely associated with HDL-C (P value range: 0.001–0.01). The mean differences between the top tertile and bottom tertile were: 2hrPG [men: 0.2 mmol/l (0.01 to 0.40), women 0.3 mmol/l (0.14 to 0.44)], log-transformed triglycerides [men 0.1 (0.05 to 0.16), women 0.1 (0.06 to 0.14)], waist [men 2.4 cm (1.3 to 3.4), women 3.3 cm (2.2 to 4.4)] and HDL-C [men –0.06 mmol/l (–0.09 to –0.03), women (–0.05 mmol/l (–0.09 to –0.02))]. Systolic and diastolic blood pressure were positively associated with sitting time in women only (both P = 0.01). No association was observed with FBG. The associations observed for 2hrPG and log-triglycerides in women and log-triglycerides and HDL-C in men remained significant (P ≤ 0.003) following further adjustment for waist circumference. In regression models containing both weekday and weekend sitting time as covariates, weekday sitting time was associated with log-triglycerides in men and women (both P < 0.01) and HDL-C and waist in men (P < 0.001). Weekend sitting time was associated with 2hrPG in both men and women (both P < 0.05) and log-triglycerides (P = 0.04) and waist (P = 0.001) in women.

Conclusion: These findings highlight the unique deleterious relationships of sedentary behaviour (indicated by sitting time) and components of the metabolic syndrome, independent of physical activity time. Population strategies to reduce the risk of developing the metabolic syndrome should focus not only on increasing physical activity, but also on reducing sedentary behaviours, such as time spent sitting.

0284

Relationship between polymorphism in the aldosterone synthase gene (CYP11B2) and risk for type 2 diabetes and the metabolic syndrome in a French population: THE DESIR STUDY

N. Bellili¹, R. Roussel^{1,2}, R. Jaziri¹, S. Maimaitiming¹, B. Balkau³, J. Tichet⁴, F. Fumeron¹, M. Marre^{1,2};

¹INSERM, U695, Paris, ²Assistance Public-Hôpitaux de Paris, Service d'Endocrinologie, Diabétologie, Nutrition, Groupe Hospitalier Bichat Claude Bernard, Paris, ³INSERM, U258-IFR69, Villejuif, ⁴Institut Régional Pour la Santé, IRS, Tours, France.

Background and Aims: The aldosterone synthase (CYP11B2) is an enzymatic mitochondrial complex catalysing the key step in the synthesis of aldosterone. It plays a major role in regulating blood pressure and may affect glucose homeostasis. CYP11B2 affect gene expression and thus might modulate cardiovascular risk factors. We investigated the impact of the -344 T/C and 5945 G/A polymorphisms of CYP11B2 gene in the DESIR study for the risk of type 2 diabetes (T2D), hypertension and Metabolic Syndrome (MS IDF definition).

Materials and Methods: 2576 men and 2636 women from the general population, aged 30–65 years, took part in the DESIR (Epidemiologic Data on Insulin Resistance Syndrome) study, from 1994 to 2003 and were evaluated every three years. Genotyping for –344 T/C and 5945 G/A in CYP11B2 was done by high-throughput techniques (Molecular Beacon® and TaqMan®, Abgene for –344C/T and 5945 G/A respectively). Chi₂ test and ANOVA were used to test the effects of the genotypes with adjustment for age in the whole population and after stratification according to gender.

Results: Allelic frequencies were 55% and 45% for T and C respectively and 71% and 29% for G and A respectively. Distributions of genotypes were in

Hardy-Weinberg equilibrium. The -344C/T SNP was associated with the presence of hypertension in women at inclusion: 194 (35.6%), 290 (28.4%) and 107 (25%) for TT, TC and CC respectively, $p=0.008$. It was also associated with the incidence of T2D in men at the end of study: 29 (5.3%), 78 (8.2%) and 33 (9%) for TT, TC and CC respectively, $p=0.029$. The 5945 A/G polymorphism was associated with the incidence of T2D in all participants: 93 (5%), 101 (6.4%), 7 (2.3%) for GG, GA and AA respectively, $p=0.008$. In men, the 5945 G/A SNP was associated with the prevalence of hypertension at baseline: 412 (50.4%), 314 (43%), and 62 (33.8%) for GG, GA and AA respectively, $p=0.050$, and incidence of hypertension: 354 (43.3%), 325 (44.7%), 52 (33.8%) for GG, GA and AA respectively, $p=0.044$. The 5945 G/A was associated with the incidence of MS in men at last visit: 220 (28.5%), 177 (27.3%) and 24 (18.6%) for GG, GA and AA respectively, $p=0.037$.

Conclusion: In this large prospective follow-up study, we found that genetic variation in the Aldosterone Synthase gene affects risk for T2D, hypertension and MS. This data provides a rationale to target this gene for pharmacological manipulations aimed at reducing cardiovascular risk.

0285

TNF- α -308 G/A and NOS3 rs3800787 SNPs interaction with features of the metabolic syndrome (The Segovia Study)

J. L. González-Sánchez, M. T. Martínez-Larrad, M. J. Martínez-Calatrava, C. Zabena, M. Serrano-Rios; Internal Medicine II, Hospital Clínico San Carlos, Madrid, Spain.

Background and Aims: To determine whether the -308 G/A polymorphism of the TNF- α gene has a gene-gene interaction with NOS3 rs3800787 SNP on the association of both gene on insulin resistance and other features of the metabolic syndrome (MS) in a representative sample of the Spanish population, we genotyped 751 unrelated subjects recruited from a cross-sectional population-based epidemiological survey in Segovia, Spain (The Segovia Study Group).

Materials and Methods: Anthropometric parameters: BMI, waist to hip ratio (WHR). OGTT, fasting and 2 hrs glucose, serum insulin, adiponectin levels; lipid profile. Plasma soluble TNF- α receptor 2 (sTNFR2), PAI-1 levels were measured. Insulin resistance was assessed by HOMA-IR. Categories of glucose tolerance (ADA Clinical Practice Recommendations 2006). MS was defined according to the 2005 IDF criteria.

Results: TNF- α genotype distribution: -308 G/G 73.1%, -308 G/A 24.8%, -308 A/A 2.1%. Subjects carrying the -308 A allele had higher 2-hours postload glucose and insulin concentrations as compared to -308 G/G homozygotes. Patients with type 2 diabetes carrying the -308 A allele had higher sTNFR2 and lower adiponectin levels than -308 G/G homozygotes. Plasma levels of sTNFR2 were positively correlated with BMI, and WHR among type 2 diabetic subjects. Interestingly diabetic subjects carrying the -308A allele had higher sTNFR2 levels, WHR, insulin 2 hours, PAI levels, and lower adiponectin concentrations as compared with -308 G/G homozygous. As regard to the rs3800787 SNP of NOS3 gene, the C allele was associated with a higher OR for MS (OR 1.44, 95% CI 1.02–2.03) and for decreased HDL-cholesterol (OR 1.71, 95% CI 1.11–2.63). Moreover C allele carriers had higher mean of fasting glucose, and HOMA-IR than those with the -308 G/G genotype. No gene-gene interaction on features of MS was detected between both SNPs.

Conclusion: Our findings indicate that both SNPs are individually associated with features of MS. TNF- α -308A allele could be associated with a higher risk for abdominal obesity, but not for type 2 diabetes, whereas the C allele of NOS3 gene could potentially confer a higher risk for MS as a categorical variable.

0286

Association of variants of neuropeptide Y receptors with susceptibility to obesity and type 2 diabetes

C. C. Elbers^{1,2}, J. V. van Vliet-Ostapchouk³, N. C. Onland-Moret^{1,2}, M. H. Hofker³, Y. T. van der Schouw², C. Wijmenga¹;

¹Complex Genetics Group, Biomedical Genetics, UMC Utrecht,

²Julius Center for Health Science and Primary Care, UMC Utrecht,

³Molecular Genetics, Maastricht University, The Netherlands.

Background and Aims: In a previous study we used bioinformatics tools to identify candidate genes for both obesity and T2D. One interesting group of

genes, neuropeptide Y receptors (NPYRs), were further investigated. NPYRs are known to be involved in the regulation of eating behaviour. The aim of the study is to investigate the role of genetic variation in five NPYRs (NPY1R, NPY2R, NPY3R, NPY4R, NPY5R) for susceptibility to T2D and obesity.

Materials and Methods: Tagging single nucleotide polymorphisms (SNPs) were selected for each gene and genotyped in 502 T2D cases and 920 unrelated controls (the Breda study). In addition 364 healthy males (the Hamlet study) were genotyped to study the effect of the tag SNPs on different measures of obesity.

Results: The minor alleles of variants in NPY5R and NPY1R were under-represented in T2D cases (odds ratio (OR) 0.88, 95% CI 0.75–1.04 for rs11724320 in NPY5R and OR 0.86, 95% CI 0.72–1.03 for rs9764 in NPY1R) compared to controls in the Breda study. We also saw significantly fewer individuals with one or two copies of the minor allele of rs11724320 in NPY5R in the T2D group (OR 0.79, 95% CI 0.63–0.99). Experiments to establish the effect of genetic variants in NPYRs on measures of obesity in the Hamlet study are currently ongoing.

Conclusion: Our data may suggest that variants in NPY1R and NPY5R are protective against T2D in a Dutch population.

A putative role of variations in the endocannabinoid receptor 1 gene (CNRI) in stroke

C. Roos¹, M. Benzinou^{2,3}, O. Melander¹, M. Sjögren¹, P. Almgren¹, M. Svensson¹, L. Rosberg¹, B. Isomaa⁴, G. Berglund¹, T. Hedner⁵, L. Groop^{1,6}, P. Frougel^{2,3}, M. Orho-Melander¹;

¹Clinical Sciences, Diabetes and Endocrinology, Lund university, Malmö, Sweden, ²CNRS 8090-Institute of Biology, Pasteur Institute, Lille, France,

³Genomic Medicine, Hammersmith Hospital, Imperial College London, United Kingdom, ⁴Folkhälsan Research Center, Genetic Institute, Helsinki, Finland, ⁵Clinical Pharmacology, Sahlgrenska Academy, Göteborg, Sweden,

⁶Medicine, Helsinki University Central Hospital, Finland.

Background and Aims: The endocannabinoid (EC) system plays an important role in the regulation of food intake, energy metabolism, atherogenesis and stroke. Treatment with EC receptor 1 (CB1) antagonists reduce food intake, improve glucose metabolism and modulate lipid levels suggesting them as potential drugs in treatment of cardio- and cerebrovascular diseases. Animal studies have demonstrated the importance of ECs in cerebral regulation during and after ischemia and addressed the beneficial effect of CB1 antagonists in reducing the infarction size. A large-scale genetic analysis of the CB1 gene (CNRI) has recently revealed a few variations in CNRI, among them rs806381, in association with obesity and type 2 diabetes (T2D). Herein we challenge the question if rs806381 is associated with or predicts morbidity and mortality to stroke in three large Scandinavian cohorts.

Materials and Methods: The rs806381 was genotyped on ABI7900 in three large cohorts: 1) 4,660 Finnish individuals participating in the Botnia T2D family study and followed for a mean time of 11 years (Botnia: m/f 2,146/2,514, age 58±14 y, BMI 27±4 kg/m², 34% with T2D). During the follow-up time 23.4% of the individuals died, of these 125 due to stroke [including both thrombotic stroke (TS) and cerebral haemorrhage (CH)]. 2) 5,190 Swedish individuals composing the population based cohort of Malmo Diet and Cancer Study Cardiovascular Arm (MDC-CVA: m/f 2,140/3,050, age 58±6 y, BMI 26±4 kg/m², 8% with T2D) were followed for a mean time of 10.5 years. During this time, 167 individuals had stroke (133 TS and 20 CH) and 13 patients died of stroke. 3) A cohort of 5,152 Swedish patients with hypertension (NORDIL: m/f 2,567/2,585, age 60±7 y, BMI 28±4 kg/m², 9% with T2D). In NORDIL, 162 individuals had experienced stroke (136 TS and 19 CH) and of these 18 had died of stroke. Analyses were performed using Cox- or logistic regression adjusted for age, sex and diabetes status, or by chi² tests. Survival analyses in Botnia families were stratified for sex and by using a robust variance estimate adjusted for within family dependence by treating each pedigree as an independent entity.

Results: The frequency of the rs806381 minor G-allele was 34.5, 32.9 and 33.4% in Botnia, MDC-CVA and NORDIL, respectively. The rs806381 GG-genotype predicted stroke mortality in Botnia T2D families (HR=2.2 [1.4–3.5], $p=0.00050$). In line with this, the GG-genotype was a predictor of stroke mortality (HR=3.9 [1.0–14.7], $p=0.049$) and of CH (HR=3.9 [1.3–11.2], $p=0.012$) but not of TS (HR=1.2 [0.7–1.9], $p=0.47$) in MDC-CVA. Finally, the GA and GG genotypes were more common among patients with stroke

compared to subjects without (66.0 vs. 55.1%, $p=0.0060$) in the NORDIL cohort. This association was significant for TS (66.2 vs. 55.2%, $p=0.011$) but not for the small number of CH patients (68.4 vs. 55.4%, $p=0.36$).

Conclusion: We demonstrate that variation in *CNR1* is associated with stroke and predicts stroke morbidity and mortality.

0288

Impaired glucose tolerance is a risk factor for stroke in a Japanese sample – the Funagata Study

T. Oizumi¹, M. Daimon¹, Y. Jimbu¹, K. Wada¹, W. Kameda¹, S. Suga¹, H. Yamaguchi¹, H. Ohnuma¹, M. Tominaga², T. Kato¹;

¹Department of Neurology, Hematology, Metabolism, Endocrinology and Diabetology (DNHMED), ²Laboratory Medicine, Yamagata University School of Medicine, Yamagata, Japan.

Background and Aims: Abnormal glucose tolerances such as impaired glucose tolerance (IGT) as well as diabetes are well-established risk factors for cardiovascular disease (CVD). CVD includes several medical conditions, such as stroke and coronary heart disease (CHD), and thus, the observed risk for CVD represents a risk of the combined outcomes of these medical conditions. Both diabetes and IGT seem to be well-established risk factors for CHD. Furthermore, the risk of diabetes for stroke has also been shown in many studies. However, IGT has not been established as a risk factor for stroke. A high prevalence of abnormal glucose tolerance, including IGT, in patients who have had a recent ischemic stroke has been reported, thus, IGT may also be a risk factor for stroke. Increased risks for future stroke in patients with transient ischemic attacks or minor ischemic stroke as well as in those with CHD have been reported; therefore, at least in some high-risk populations, IGT seems to be a risk factor for stroke. We, here, conducted a cohort study consisting of the participants of the Funagata study, a community-based study, to determine whether or not IGT is a risk factor for stroke.

Materials and Methods: The incidence of stroke and CHD of a cohort population ($n=2938$) consisting of participants of the Funagata study held in 1990–1997 was assessed by studying questionnaires, death certificates, and residence transfer documents through 2002. Glucose tolerance at the baseline was classified by the criteria of the 1998 World Health Organization (WHO) (normal glucose tolerance (NGT)($n=2189$), IGT ($n=320$), and diabetes ($n=286$)). The cumulative incidences among the groups were compared using the Kaplan-Meier product-limit method, and Cox's proportional hazard model was adopted.

Results: During the 147-month (mean 116.5) follow-up, 158 (NGT, IGT and diabetes: 94,35, and 29) and 94 (54, 16, and 24) participants experienced a stroke and CHD, respectively. The stroke risk was significantly higher in the participants with IGT (age-, sex-, and hypertension-adjusted hazard ratio [HR]:1.51, 95% CI: 1.02–2.24, $p=0.039$) and tended to be higher in those with diabetes (HR:1.47, 95% CI:0.96–2.25, 0.079) than it was in those with NGT. There was no significant association between IGT and the risk of CHD (HR: 1.21, 95% CI:0.69–2.13, 0.509), while diabetes was a significant risk for CHD (HR:1.97, 95% CI: 1.18–3.28, 0.010).

Conclusion: Impaired glucose tolerance is an independent risk factor for future stroke in a Japanese population. (Fig. 1)

Fig. 1

0289

A functional promoter polymorphism of *XBPI* gene is associated with younger age of onset of type 2 diabetes and susceptibility to hypertension

T. Kakimoto¹, H. Furuta¹, T. Shimada¹, Y. Furukawa¹, S. Matsuno¹, A. Kusuyama², M. Nishi², H. Sasaki¹, T. Sanke³, K. Nanjo¹;

¹The First Department of Medicine, ²Department of Metabolism and Clinical Nutrition, ³Department of Clinical Laboratory Medicine, Wakayama Medical University, Wakayama city, Japan.

Background and Aims: The X box-binding protein 1 (XBPI) is a transcription factor that modulates endoplasmic reticulum (ER) stress through transcriptional regulation of proteins, such as molecular chaperones. ER stress inhibits insulin receptor signaling through activation of c-Jun N-terminal kinase (JNK) and subsequent serine phosphorylation of insulin receptor substrate-1, and overexpression of XBPI improved these disorders. XBPI heterozygous mice exhibited increased ER stress, hyperactivation of JNK, reduced insulin receptor signaling, systemic insulin resistance and glucose intolerance. The -116C/G polymorphism in the promoter region of *XBPI* gene has been reported to be associated with bipolar disorder. The XBPI expression is positively regulated by itself and the -116C/G polymorphism exists in the putative XBPI binding site. It has also been reported that XBPI-dependent transcription activity of the promoter with the -116G allele was lower than that of the C allele and induction of XBPI expression after ER stress was markedly reduced in the lymphocytes derived from subjects with the G allele. In this study, we examined the role of the -116C/G polymorphism in type 2 diabetic patients.

Materials and Methods: A total of 813 Japanese subjects were studied (407 type 2 diabetic patients and 416 non-diabetic controls). The DNAs were obtained from peripheral blood. The -116C/G polymorphism was genotyped by PCR-RFLP method using a restriction enzyme, BstE II. The genotype distribution obtained was in compliance with the Hardy-Weinberg equilibrium.

Results: The frequency of G/G, C/G and C/C genotypes was 49%, 41% and 10% for type 2 diabetic patients, and 47%, 44% and 8.7% for non-diabetic controls, respectively. No significant difference was observed between these two groups ($P=0.58$). We next divided the patients into two groups (G/G vs. C/G+C/C) and compared their clinical characteristics. Age of onset in the patients with G/G genotype (46.7 ± 10.2 years, mean \pm SD) was younger than that in C/G+C/C group (49.0 ± 9.9 years) ($P=0.026$). Furthermore, the prevalence of hypertension was higher in the patients with G/G genotype (60%) than that in C/G+C/C (48%) ($P=0.014$). However, no association was found between the -116C/G polymorphism and other characteristics (max body mass index, dyslipidemia, retinopathy and nephropathy).

Conclusion: Thus, this data suggest that the -116C/G polymorphism is associated with younger age of onset of diabetes and susceptibility to hypertension in Japanese type 2 diabetic patients.

Two-hour glucose predicts the development of hypertension over five years: the AusDiab study

E. L. M. Barr¹, E. J. Boyko^{1,2}, P. Z. Zimmet¹, J. E. Shaw¹;

¹Epidemiology, International Diabetes Institute, Melbourne, Australia,

²Medicine, University of Washington, Seattle, United States.

Background and Aims: Elevated 2-hr plasma glucose (2hPG) concentration from an oral glucose tolerance test (OGTT) predicts a higher risk of subsequent

cardiovascular disease and is more strongly related to this outcome than is fasting plasma glucose (FPG). Mechanisms underlying these associations are not well understood. A recent clinical trial among persons with IGT (STOP-NIDDM) demonstrated that a reduction in 2hPG was accompanied by lower blood pressure values and a lower risk of hypertension compared to controls. We examined the association between glucose measurements and risk of hypertension in a prospective observational study.

Materials and Methods: The Australian Diabetes, Obesity, and Lifestyle Study (AusDiab) examined 4,413 persons without hypertension at baseline (1999–2000) and at a 5 year follow-up examination (2004–5). Measurements at both time points included blood pressure (mean of 2 readings), a 75g OGTT, fasting insulin, anthropometrics, dietary and alcohol intake based on the Cancer Council of Victoria food frequency questionnaire, and physical activity based on the Active Australia questionnaire. Hypertension was defined as a systolic pressure ≥ 140 or a diastolic pressure ≥ 90 mmHg or antihypertensive medication use. HOMA-S was calculated as a measure of insulin sensitivity using the HOMA2 calculator. Differences in BMI and waist circumference between baseline and follow-up were calculated. Multivariable linear and logistic regression methods were used to estimate associations between glycaemia and hypertension risk at 5 years as a binary outcome and systolic and diastolic blood pressure as continuous outcomes while adjusting for covariates and cluster sampling.

Results: After additional exclusions for pregnancy, inadequate fasting, and missing blood pressure measurements, 4,306 subjects remained (mean baseline age 47.7 years, 56.9% female), of whom 14% developed hypertension over 5 years. Higher FPG and 2hPG were significantly related to greater risk of hypertension in univariate analyses [odds ratio for a 1 standard deviation increase (95% confidence interval) in FPG 1.28 (1.19 to 1.38); 2hPG 1.36 (1.27 to 1.46)]. The risk associated with 2hPG remained after adjustment for age, gender, FPG, BMI (baseline and difference), waist circumference (baseline and difference), education, exercise, alcohol intake, and smoking [1.15 (1.05 to 1.25)], but the association between FPG and hypertension diminished [1.06 (0.94 to 1.20)]. Further adjustment for HOMA-S did not change these findings. The relationship between 2hPG and hypertension was linear and apparent throughout the range of glucose values. The same results were seen after exclusion of persons on antihypertensive medication at 5 years or those with diabetes at baseline. Higher baseline 2hPG was more strongly associated with an increase in systolic than in diastolic blood pressure over 5 years.

Conclusion: Higher 2hPG predicted hypertension occurrence over 5 years. This association was not explained by adjustment for other factors measured in this study related to hypertension or glycaemia, and was present even within the normal range for 2hPG. If this association is demonstrated in other studies, interventions aimed at reducing the 2hPG level may potentially yield additional benefits through reduction of hypertension incidence.

PS 4 Genome-wide association scans and bioinformatic tools for identifying candidate pathways

0291

Genome-wide scan of type 2 diabetes-related quantitative traits in French-Canadian hypertensive families

J. Vcelak^{1,2}, O. Seda¹, P.-L. Brunelle¹, A. Gurau¹, E. Merlo¹, D. Gaudet³, F. Gossard¹, T. A. Kotchen⁴, A. W. Cowley⁵, J. Tremblay¹, P. Hamet¹; ¹Research Centre, CHUM, Montreal, Canada, ²Department of Molecular Endocrinology, Institute of Endocrinology, Prague, Czech Republic, ³Genomic Medicine Center, Hospital Complex of Sagamie, Chicoutimi, Canada, ⁴Department of Medicine, Medical College of Wisconsin, Milwaukee, United States, ⁵Department of Physiology, Medical College of Wisconsin, Milwaukee, United States.

Background and Aims: The identification of genomic determinants responsible for common multifactorial diseases like type 2 diabetes mellitus (T2DM) and hypertension is facilitated in large families from relatively genetically-isolated populations with a demonstrated founder effect. The French-Canadian population from the Saguenay-Lac-St-Jean (SLSJ) region of Quebec (Canada) lives in a relatively geographic and genetic enclave unique in its detailed genealogical annotation originating from ancestors of French descent who migrated to this region from the end of the 17th century. The aim was to analyse the genomic components of complex traits of insulin resistance, known to be prevalent in hypertensive subjects.

Materials and Methods: 108 families were primarily selected on the basis of having ≥ 2 siblings with primary hypertension and dyslipidemia. Additional selection criteria were the absence of gross obesity, T2DM and renal dysfunction. Other siblings, parents and children who did not necessarily fulfil these criteria were then also enrolled in the study. 664 subjects were examined under a wide spectrum of biochemical parameters, particularly fasting glucose (G_o) and fasting insulin (I_o) for this study. Bioimpedance (RJL Sorba System) was gauged to quantify water distribution and body fat mass, supplemented by complete anthropometric measurements. 204 selected subjects without any contraindications were invited for additional extensive phenotyping after the withdrawal of their antihypertensive and lipid-lowering medications. For better assessment of insulin sensitivity and glucose effectiveness, the intravenous glucose tolerance test (ivGTT) was performed and evaluated using Bergman's minimal model (MINMOD software).

Genotyping: More than 400 microsatellite markers and 58 000 SNPs (Affymetrix 50K Chip, Xba240) covering the entire genome were used.

Statistical analysis (software): Genome-wide linkage and haplotype identification (SOLAR, MERLIN) were undertaken with genome-wide association (FBAT, NCCS).

Results: The table following the abstract shows a summary with the chromosomal localisation of the highest statistical results for the genomic components of complex traits of insulin resistance and T2DM in hypertensive families from SLSJ.

Conclusion: These results suggest that it is possible to distinguish the genetic determinants of two major features abnormal glucose metabolism: impaired insulin secretory capacity and systemic insulin resistance. (Tab. 1)

The recently identified type 2 diabetes gene *CDKAL1* is widely expressed and its expression in pancreatic beta cells is affected by glucose concentration

V. Steinthorsdottir¹, I. Reynisdottir¹, G. Thorleifsson¹, S. Ghosh¹, R. Benediktsson², G. Sigurdsson², A. Kong¹, M. Gurney¹, J. R. Gulcher¹, U. Thorsteinsdottir¹, K. Stefansson¹;
¹deCode genetics, Reykjavik, ²Dept. of internal medicine, Landspítali Haskólasjúkrahús, Reykjavik, Iceland.

Background and Aims: In our genome wide association study on type 2 diabetes (T2D), a variant we had previously identified in *TCF7L2* stood out as the most significant finding. In addition, a variant of the *CDKAL1* gene was found to be associated with increased risk of T2D in a nearly recessive manner, with genotype odds ratio for the homozygous carrier 1.45 and 1.55 for individuals of European and Asian ancestry respectively. The function of the *CDKAL1* gene product was unknown but it is similar to another protein, CDK5RAP1, an inhibitor of the CDK5/p35 complex in neuronal tissue. This complex is also expressed in pancreatic beta cells and, in the presence of its active form, insulin expression is decreased under glucotoxic conditions. This led to the suggestion that CDKAL1 may be an inhibitor of the CDK5/p35 complex in beta cells, similar to the role of CDK5RAP1 in neuronal tissue. Furthermore, we have shown that the risk variant of *CDKAL1* is associated with reduced insulin secretion and this effect is mostly seen for the homozygote where a 24% reduction in insulin response is observed compared to the heterozygous carriers or non-carriers. This is in line with the nearly recessive mode of inheritance observed for this variant with respect to disease risk. The aim of this study was to gain insight into the functional role of *CDKAL1* by analyzing its expression, particularly in pancreatic beta cells.

Materials and Methods: To determine tissue distribution of *CDKAL1* human cDNA libraries from various tissues, including colon, liver, pancreas, small intestine and brain, were screened for *CDKAL1* expression by PCR. The rat pancreatic beta cell line INS-1 was cultured in the presence of variable glucose concentration, ranging from 2.5–30 mM, to evaluate whether *CDKAL1* expression is regulated by glucose concentration. The mRNA expression of *CDKAL1* was evaluated using rat specific TaqMan probes. As controls, mRNA expression of insulin and beta actin was similarly measured.

Results: *CDKAL1* mRNA expression was detected in all the human tissues tested, including the pancreas. Expression of *CDKAL1* in rat INS-1 cells varied according to glucose concentration in the culture medium with reduced expression detected under glucotoxic conditions compared to normal glucose concentration.

Conclusion: *CDKAL1* expression in pancreatic beta cells is sensitive to glucose concentration. It is possible that this response to glucose may be affected in individuals carrying the variant of *CDKAL1* that is associated to T2D. This could explain the reduced insulin secretion observed for these individuals in response to an oral glucose tolerance test.

Polymorphisms near the HHEX gene are associated with type 2 diabetes in the Dutch Breda cohort

N. C. Onland-Moret^{1,2}, J. V. van Vliet-Ostaptchouk^{3,4}, C. C. Elbers^{1,2}, T. W. van Haften⁵, M. H. Hofker^{3,4}, C. Wijmenga^{1,6};
¹DBG-Dept. of Medical Genetics, University Medical Center Utrecht, ²Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, ³Department of Pathology and Laboratory Medicine, University Medical Center Groningen, ⁴Dept. Molecular Genetics, Maastricht University, ⁵Dept. of Internal Medicine, University Medical Center Utrecht, ⁶Department of Genetics, University Medical Center Groningen and University of Groningen, The Netherlands.

Background and Aims: Recently, three novel susceptibility loci that contribute substantially to type 2 diabetes risk were identified in a large genome-wide scan in French individuals. One of the new loci contains the Hematopoietically Expressed Homeobox (HHEX) gene encoding a transcription factor. In this study, we aimed to replicate this finding in a Dutch cohort.

Materials and Methods: The two most associated common variants rs7923837 and rs1111875 located near the HHEX gene were genotyped in 501 unrelated type 2 diabetes patients and in 920 healthy control subjects, using logistic regression analysis, where individuals homozygous for the

common allele were the reference group. Haplotype analysis was performed using the COCAPHASE package of UNPHASED program.

Results: For both rs7923837 and rs1111875 variants the carriers of major allele had a significantly increased risk for type 2 diabetes compared with non-carriers with an odds ratio (OR) of 0.64 (95% CI 0.44–0.92) (P=0.017) and 0.60 (0.43–0.84) (P=0.003).

The population-attributable risks for diabetes due to the at-risk alleles of rs7923837 and rs1111875 were estimated to be 7.3% and 11.4%, respectively. Since the HHEX gene is involved in the Wnt signaling pathway, as is TCF7L2, the major determinant of type 2 diabetes risk, we examined a possible gene-gene interaction using the case-only design. The analysis revealed that amount of minor homozygotes for both rs7923837 and rs1111875 was significantly increased in the at-risk TT genotype carriers for rs7903146 in the TCF7L2 (P=0.007 and P=0.037, respectively). The analysis of haplotypes derived from the three SNPs showed that the haplotype carrying three protective alleles was significantly more frequent in controls compared with patients (24.4% vs 16.8%, respectively, P=5.4x10⁻⁵).

Conclusion: These data provide replicating evidence that variants near HHEX contribute to the risk of type 2 diabetes in a Dutch population and suggest the possible interaction between the HHEX and the TCF7L2 genes.

T1DBase: integration of public and private data in a type 1 diabetes community website

E. M. Hulbert¹, E. C. Adlem², D. B. Burdick¹, J. E. Allen², V. M. Cassen¹, O. S. Burren², K. F. Friery¹, G. E. Dolman², B. C. Healy², L. S. Wicker², J. A. Todd², N. Goodman¹, L. J. Smink²;
¹JDRF Center for Bioinformatics, Institute for Systems Biology, Seattle, United States, ²Juvenile Diabetes Research Foundation/Wellcome Trust Diabetes and Inflammation Laboratory, University of Cambridge, United Kingdom.

Background and Aims: T1DBase (<http://T1DBase.org>) is a website and database that supports the type 1 diabetes (T1D) research community, including the type 1 Diabetes Genetics Consortium (<http://t1dgc.org>). The site integrates public and user-contributed data to let researchers share data with collaborators and analyze their own data in the context of public information.

Methods: T1DBase integrates many datasets including: annotated genomes for human, mouse, and rat; T1D susceptibility regions; SNPs from dbSNP and HapMap which have been mapped to NCBI human builds 34, 35 and 36; gene association from the Genetic Association Database; gene models; NOD mouse congenic strains; the Beta Cell Gene Expression Bank, which combines functional annotation with beta cell expression under various conditions (with D. Eizirik); tissue-specific gene expression; T1D microarray data; protein interactions; and biological pathways. Tools include: GBrowse genome browser; search optimized for gene names and other biological identifiers; Beta Cell Gene Atlas, which compares gene expression across pancreatic tissues; Microarray Viewer; T1DMart, a BioMart-style query tool for marker and genotyping data; Gene Dossier, which scores a list of genes for T1D relevance and provides an overview of data we have about each gene; BLAT, to map sequences to genomes; EMBOSS, a sequence manipulation suite of tools; Connect-the-Dots, to translate gene identifiers; Cytoscape and the Cytoscape Pathway Builder; and Gaggles, a suite of interactive data analysis tools. Poster Pages are user contributed web documents that can be used to distribute experimental results, explain findings, or review a topic. Posters Pages are created using a wiki editor, and are easily configurable. Current Poster Pages include supplemental data and descriptions of genotyping data, a summary of a gene family and its contribution to T1D, and the methods description for the Beta Cell Gene Atlas. Private Poster Pages also exist where collaborators share experimental results and hypotheses. Users can save lists of genes or markers in folders which can be saved for future visits, shared among collaborators, or made public. In addition, T1DBase provides folders based on published T1D studies. Folders act as the starting point for the various tools. As a user works through tools on the website, genes can be added and removed from the current working list then sent to the next tool. Public data on T1DBase is freely available, but access to user contributed data is controlled by the contributor. Registered users can securely view private data including folders and Poster Pages. On request, we can add private data,

such as gene models, candidate genes, genotypes, or microarray results which authorized users can analyze and view in combination with public data.

Conclusion: T1DBase combines public and private datasets in a T1D relevant manner, providing an integrated and up-to-date view. Users can incorporate their own data and view it in the context of other available data, despite the fact that public source databases may be out of sync. Users who choose to make their contributed data public enrich T1DBase for other users.

Biological pathway analysis for type 2 diabetes using genome-wide association data

M. N. Weedon¹, J. R. B. Perry¹, E. Zeggini², H. Lango¹, C. M. Lindgren², R. Freathy¹, K. S. Elliot², B. Shields¹, N. J. Timpson², N. W. Rayner², C. J. Groves², A. T. Hattersley¹, M. I. McCarthy², T. M. Frayling¹;

¹Genetics of Complex Traits, Peninsula Medical School, Exeter,

²Wellcome Trust Centre for Human Genetics & OCDEM, University of Oxford, United Kingdom.

Background and Aims: The underlying pathophysiology of type 2 diabetes is still unknown. Recently, using a genome-wide association (GWAS) approach, nine common variants have been identified that predispose to type 2 diabetes. We hypothesized that a large number of risk variants of smaller effect remain to be found. One approach to prioritizing follow-up of a GWAS is to identify biological pathways where there was a significant excess of associations compared to that expected under the null distribution. This approach may also provide a global insight into the genetic basis of T2D.

Materials and Methods: The Wellcome Trust Case Control Consortium (WTCCC) recently completed a GWAS comparing 1924 UK type 2 diabetes patients and 2938 UK population controls using the Affymetrix GeneChip Human Mapping 500k Array Set. We used data from the WTCCC, and the Kyoto Encyclopedia of Genes and Genomes (KEGG) to test 198 human pathways. We totaled the trend test chi-sq for all SNPs in all genes (as defined by the NCBI and 25kb flanking sequence) in a KEGG defined pathway. This observed chi-sq total was compared to that of a distribution of 100,000 permuted chi-sq totals from an equivalent-sized random selection of genic SNPs from across the genome.

Results: The pathways showing the strongest association were the WNT signaling (P < 0.00001), Adherens Junction (P < 0.00001), and cell cycle (P < 0.00001) pathways. The WNT signaling and Adherens Junction pathway associations remained even when TCF7L2 variants were removed from the analyses (P = 0.03). The cell cycle pathway association was not explained by the recently identified CDKN2A/B or CDKAL1 signals (P = 0.00002). There was no evidence for other candidate pathways, for example oxidative phosphorylation P = 0.99.

Conclusion: In conclusion, we have identified biological pathways likely to be involved in the etiology of type 2 diabetes. Genes in these pathways should be prioritised in genome-wide association follow-up studies.

Whole genome expression profiling in lympho-monocytes identifies a significant correlation between over-expression of MAPK pathway and degree of IMT in healthy young volunteersD. Ardigò¹, L. Franzini¹, E. Derlindati¹, R. Navon², I. Steinfeld², Z. Yakhini², A. Dei Cas¹, V. Spigoni¹, S. Valtuena¹, I. Zavaroni¹;¹Internal Medicine, University of Parma, Italy,²Agilent Laboratories, Agilent Technologies, Tel Aviv, Israel.

Background and Aims: Preliminary data show significant differences in gene expression profile (GEP) of circulating leukocytes in presence of several cardiovascular (CV) factors, such as smoking, hypercholesterolemia, hypertension, and insulin resistance. However, no data are available investigating whether GEP correlates with markers of vascular damage, such as intima-media thickness (IMT).

Material and Methods: To address this aim, IMT and GEP were evaluated in a group of 48 apparently healthy young-adults [21M/27F, age 36±8 y], volunteering for CV risk assessment. IMT was measured by ultrasound examination with an automated edge-detection system (Carotid Analyzer, MIA-LLC, US), whereas GEP of peripheral blood mononuclear cells (PBMC) was assessed using whole genome dual-dye arrays from Agilent. Enrolled subjects were free of diabetes, CV and chronic inflammatory diseases, and did not take pharmacological medications. Measurements were also made of multiple anthropometric, metabolic, and hemodynamic variables.

Results: Subjects were stratified in quartiles of IMT and clinical characteristics compared by one-way ANOVA with linear contrast. An increase in IMT was significantly correlated with several established CV risk factors, including increased age ($p=0.023$), male gender (0.008), smoking (0.008 for pack-years of cigarettes), BMI (0.027), waist (0.001), plasma glucose (0.010) and LDL-cholesterol concentration (0.014), and decreased HDL-cholesterol (0.002). A total of 320 genes resulted differentially expressed (174 up- and 146 down-regulated) in subjects with high IMT (4th quartile, IMT from 0.9 to 1.05 mm) compared to low IMT (1st quartile, 0.6 to 0.75 mm), using Bonferroni-corrected t-test with a level of significance of $p<0.001$. The Gene Ontology (GO) analysis on differentially expressed genes identified the presence of a significant over-representation of several biological process terms related to the MAPK system (protein kinase cascade $p=0.0048$; stress-activated protein kinase signaling pathway 0.0051; JNK cascade 0.0051; MAPKKK cascade 0.029), and the MAPK signaling pathway resulted the most represented pathway within KEGG and Biocarta encyclopedias ($p=0.00059$, figure). We also found significant direct correlation between the expression level of several MAPK-related genes and IMT in the entire sample set by Bonferroni-corrected ANOVA and Pearson's correlation analysis ($p<0.001$).

Conclusion: In conclusion, the presence of vascular damage (as assessed by increased IMT) is associated with a significantly different gene expression profile in circulating mononuclear cells, whose primary signature is an over-expression of several genes related to the MAPK pathway, a crucial cross-point for inflammation, cell differentiation and survival. (Fig. 1)

PS 5 Genetics and epidemiology of type 1 diabetes and LADA

0297

Family history of diabetes is a strong risk factor for LADA and may be mediated by reduction of insulin secretion.**Results from the Nord-Trøndelag Health Study**V. Grill¹, K. Midthjell², S. Carlsson³;¹University Hospital of Trondheim, Dept. Cancer Research and Molecular Medicine, Norway, ²HUNT Research Centre, Dept. Community Medicine and General Practice, Verdal, Norway,³Division of Epidemiology, Stockholm City Council, Sweden.

Aim: To investigate the association between family history of diabetes (FHD) and prevalence and incidence of LADA compared to traditional type 1 and type 2 diabetes.

Materials and Methods: Cross-sectional data from 64,498 men and women of the Nord-Trøndelag Health Study including 128 cases of LADA; 1,134 cases of type 2 and 123 cases of traditional type 1 diabetes. In addition, prospective data on 46,210 subjects, including 80 cases of LADA, observed between 1984–86 and 1995–97 were available. Patients with LADA had antibodies against GAD and were insulin independent at diagnosis. Information on FHD was obtained by questionnaire.

Results: FHD was associated with a 4 times (Odds Ratio (OR)=3.88, 95% CI=2.73–5.52) increased prevalence of LADA. Corresponding estimates for type 2 diabetes and traditional type 1 diabetes were 4.2 (95% CI=3.72–4.75) and 2.78 (95% CI=1.89–4.10), respectively. LADA patients with FHD had lower levels of C-peptide (541 vs. 715 pmol/l) and were more often insulin treated (47% vs. 31%), than patients without FHD. Similar associations with FHD were found in type 2 diabetes. The occurrence of LADA was twice as high in those with male compared to female relatives with diabetes (95% CI=1.07–3.66). Prospective data indicated that subjects with siblings with diabetes were 2.5 times as likely to develop LADA during 11-years of follow-up compared to those without (95% CI=1.39–4.51).

Conclusion: This study indicates that FHD is a strong risk factor for LADA and that the influence of family history may be mediated through a heritable reduction of insulin secretion.

0298

Prevalence of metabolic syndrome in latent autoimmune diabetes in adults (LADA): data from a multicenter investigation (LADA China)Y. Xiang¹, Y. Lin¹, G. Huang¹, X. Yan¹, H. Peng², Z. Liu³, W. Hagopain², R. D. G. Leslie⁴, Z. Zhou¹;¹Diabetes Center, Institution of Metabolism and Endocrinology of Central South University, Changsha, China, ²Diabetes Immunology Immunogenetics, Pacific Northwest Research Institute, Seattle, United States, ³Division of Endocrinology and Metabolism, Department of Internal Medicine, Charlottesville, United States, ⁴Dept of Diabetes and Metabolic Medicine, St. Bartholomew's Hospital, London, United Kingdom.

Background and Aims: Metabolic syndrome (MS) is prevalent in type 2 diabetics and general population in China. This analysis is aimed at investigating the prevalence of MS in Chinese LADA patients according to IDF criteria.

Materials and Methods: Patients in this analysis were recruited from LADA China Study 1, which was a multicenter investigation of 46 hospitals from 25 cities throughout China. We discriminate LADA patients from more than 5000 newly diagnosed type 2 diabetics by antibodies to glutamic acid decarboxylase (GADA) assays. GADA were tested centrally using a validated radioimmune precipitation assay, with 82% sensitivity and 98% specificity in the workshop (DASP2005). Those who at least accept serum triglycerides and high density lipoprotein cholesterol determination were included into this analysis.

Results: According to the IDF 2005 criteria, prevalence of MS in Chinese LADA patients was 43.8% (123/283). This prevalence was significantly lower than 58.4% (2394/4097) in type 2 diabetics (data also from LADA China Study 1). Compared with males, more female LADA patients had MS [56.5% (61/108) vs. 36.0% (63/175), $P<0.05$]. LADA with higher GADA index (GADA \geq 0.3) had significantly lower prevalence [18.9% (14/74) vs. 52.6% (110/209), $P<0.01$] of MS than the patients with lower GADA index

(0.3>GADA \geq 0.05). Based upon Waist Circumference (WC) in IDF criteria as cutoff point, prevalence of LADA in newly diagnosed type 2 diabetics was significantly higher in males whose waist circumference (WC) were less than 90cm than those whose WC were over 90cm (8.3% vs. 4.7%, $P<0.01$). The similar difference was also found between female patients with WC below 80cm and upon 80cm (7.5% vs. 5.2%, $P<0.05$).

Conclusion: MS is frequently found in Chinese LADA patients. Preliminary data showed that prevalence of MS in LADA is associated with gender, GADA titer and central obesity. The further study is needed.

We acknowledge all the members of LADA China Study Group. The study is supported by the European Foundation of Study of Diabetes (EFSD).

0299

LADA China Study 1: prevalence of latent autoimmune diabetes in adults among Chinese newly diagnosed type 2 diabetics

Z. Zhou¹, Y. Xiang¹, L. Yang¹, G. Huang¹, X. Yan¹, H. Peng², Z. Liu³, W. Hagopian², R. D. G. Leslie⁴;

¹Diabetes Center, Institution of Metabolism and Endocrinology, Changsha, China, ²Diabetes Immunology Immunogenetics, Pacific Northwest Research Institute, Seattle, United States, ³Division of Endocrinology and Metabolism, Department of Internal Medicine, Charlottesville, United States, ⁴Dept of Diabetes and Metabolic Medicine, St. Bartholomew's Hospital, London, United Kingdom.

Background and Aims: Latent autoimmune diabetes in adults (LADA) and in the young (LADY) is prevalent in Caucasian populations. No data has been collected prospectively in large-scale from different parts of China. LADA China Study 1 is aimed at defining the prevalence of LADA and LADY among type 2 diabetics in 46 centers from 25 cities throughout China.

Materials and Methods: This Study started in June 2006 and finished in January 2007. Entry criteria include diagnosis of diabetes at age over 15 years, duration of less than 1 year, and non-insulin requirement for the first 6 months of diagnosis. Antibodies to glutamic acid decarboxylase (GADA) were tested centrally using a validated radioimmuno precipitation assay, with 82% sensitivity and 98% specificity for GAD65Ab in the workshop (DASP2005).

Results: The positivity for GADA was found in 6.2% (313/5041) of patients initially diagnosed T2DM, with significant difference to other large-scale investigations, such as UKPDS (9.8%, 361/3672, $P<0.01$), ADOPT (4.2%, 170/4066, $P<0.01$), and Ehime (3.8%, 188/4980, $P<0.01$). There was no geographic difference between north China (6.9%, 154/2230) and south China (5.7%, 159/2811) in this study. Gender difference between males (6.5%, 195/3004) and females (5.8%, 118/2037) was not found as well. The GADA positivity was 11.7% (28/239) in group aged 15–29yr, which was higher than 30–44yr group [vs. 7.4% (108/1462), $P<0.05$], 45–59yr group [vs. 5.1% (111/2168), $P<0.01$], and ≥ 60 yr group [vs. 5.8% (66/1142), $P<0.01$]. The positivity in 30–44yr group was higher than 45–59yr group ($P<0.01$) but without any differences with ≥ 60 yr group.

Conclusion: We conclude that LADA and LADY are prevalent among newly diagnosed phenotypic type 2 diabetic patients in China, and that LADY is more common than LADA in Chinese. The study is ongoing.

We acknowledge all the members of LADA China Study Group. The study is supported by the European Foundation of Study of Diabetes (EFSD).

0300

Serum concentrations of adiponectin, interleukin – 6 and tumor necrosis factor – alpha in latent autoimmune diabetes of adults (LADA)

E. Hatzigelaki, K. Kantartzis, M. Panagiotidou, I. Garofallakis, Th. Economopoulos, S. A. Raptis;
2nd Dept. of Internal Medicine, Research Institute and Diabetes Center, Athens University. "Attikon" University General Hospital, Athens, Greece.

Background and Aims: Adipokines play a critical role in generating or maintaining insulin resistance in both subjects with type 2 diabetes and non-diabetics. Adiponectin is inversely and interleukin (IL) – 6 and tumor necrosis factor – alpha (TNF- α) are positively associated with body mass index (BMI) and insulin resistance. In type 1 diabetes, plasma adiponectin concentrations were found to be higher than in healthy subjects, but the physiologic relevance of this finding it still unknown. IL-6 and TNF- α were

reported to be higher than in healthy subjects mainly in newly diagnosed type 1 diabetes, suggesting a role of them in its pathogenesis. The role of adipokines in the Latent Autoimmune Diabetes of Adulthood (LADA), which shows characteristics of both type 1 (progressive autoimmune-mediated destruction of β -cells) and type 2 diabetes (insulin resistance), has not been investigated yet.

Materials and Methods: In a cross-sectional setting, we measured fasting adiponectin, IL-6 and TNF- α levels and explored their relationships to metabolic parameters, as insulin sensitivity (estimated by homeostasis model assessment – HOMA-IR) and BMI and to β -cell function in patients with LADA (n=31), with type 1 diabetes (n=41) and in healthy controls (n=72). Patients with LADA were identified by their age at diagnosis of diabetes (>30 years), a type 2 diabetes phenotype and the presence of GAD 65 and IA-2 antibodies.

Results: Patients with LADA had lower, compared to patients with type 1 diabetes, plasma adiponectin levels, adjusted for gender, age and BMI ($p=0.006$), and comparable levels to healthy controls. Serum IL-6 concentrations, adjusted as above, significantly differed between the three groups (ANOVA, $p<0.0001$), being in LADA patients lower than in type 1 diabetics ($p=0.045$) and higher than in healthy controls ($p<0.0001$). TNF- α serum levels were not different in the three groups. No association of IL-6 or TNF- α with adiponectin levels were found in either of the groups. Also, there was no association of IL-6 or TNF- α levels with diabetes duration. In LADA, adiponectin was significantly associated with female sex ($p=0.012$) and negatively with BMI (adjusted for sex and age $p=0.033$) and HOMA-IR (adjusted $p=0.005$), whereas in patients with type 1 diabetes only with female sex ($p=0.03$). Serum IL-6 concentrations were correlated with BMI in LADA diabetics (adjusted $p=0.05$) and healthy controls (adjusted $p=0.0004$), but not with HOMA-IR in either group. IL-6 in type 1 diabetes and TNF- α in all groups showed no correlation with these parameters. A highly significant inverse association of adiponectin, but not IL-6 and TNF- α levels with fasting C-peptide concentrations was found in LADA (adjusted $p=0.0011$) and in type 1 diabetes ($p=0.0009$), but not in healthy controls ($p=0.68$).

Conclusion: Serum concentrations of adiponectin and IL-6 in LADA are higher than in healthy controls and lower than in type 1 diabetes. While the association of adiponectin levels with C-peptide concentration implies that hypoinsulinemia is a principal reason for this increase, the increase of IL-6 levels possibly reflects the underlying inflammatory process. However, levels of both adipokines were also affected by adiposity and especially these of adiponectin inversely correlated with insulin resistance, suggesting a physiologic role similar to healthy subjects. As in healthy controls, in LADA patients TNF- α seems to have a paracrine effect that is more important than the systemic effect.

0301

Latent autoimmune diabetes in adults should be suspected in Korean diabetic patients with low C-peptide level and without metabolic syndrome

S.-H. Lee, J.-H. Kim, M.-J. Kang, H.-S. Kwon, S.-J. Yoo, K.-H. Yoon, B.-Y. Cha, H.-Y. Son;
Division of Endocrinology and Metabolism, Department of Internal Medicine, Kangnam St.Mary's Hospital, Seoul, Republic of Korea.

Background and Aims: Latent autoimmune diabetes in adults (LADA) is a subgroup of diabetes which resembles the clinical characteristics of type 2 diabetes (T2DM) but positive for islet-related autoantibodies. We aimed to establish the prevalence and characteristics of LADA and compare it with T2DM in Korean patients.

Materials and Methods: From 2003 to 2006, anthropometric measurements and biochemical studies including IA-2 antibodies and glutamic acid decarboxylase(GAD) antibodies were done in 938 adults who visited a tertiary care institution for the management of diabetes. Type 1 diabetes (n=49) and other types of diabetes (n=9) were excluded in this study. The diagnosis of LADA was made with the fulfillment of i) onset of diabetes at age \geq 30, ii) presence of circulating islet autoantibodies, iii) lack of requirement of insulin at least 6 months after diagnosis.

Results: The prevalence of LADA was 4.8% (n=45). Among them, 32 were positive for GAD antibody, 8 were positive for IA-2 antibody, and 5 were positive for both antibodies. These patients had a significantly lower C-peptide level (0.81 \pm 0.76 vs. 1.62 \pm 1.44 ng/mL; $p<0.0001$), waist circumference (83.8 \pm 9.6 vs. 88.1 \pm 10.2 cm; $p=0.02$), waist-hip-ratio (0.91 \pm 0.07 vs. 0.94 \pm 0.08; $p=0.04$) and triglyceride (115.2 \pm 61.2 vs. 163.1 \pm 130.6 mg/dL; $p<0.0001$)

than patients with T2DM. They also had a significantly lower prevalence of hypertension (35.5% vs. 55.1%; $p=0.01$) while the rate of insulin treatment (37.8% vs. 25.5%; $p=0.01$) and history of weight loss and/or 3p sign (43.2% vs. 26.9%; $p=0.01$) were higher than that of T2DM. LADA constituted 10% among the patients without metabolic syndrome, while it constituted 3.2% among the patients with metabolic syndrome.

Conclusion: LADA takes a considerable proportion in Korean diabetic patients, and they are characterised by lower parameters of insulin resistance than T2DM. Therefore, LADA should be suspected in patients with low C-peptide level, especially in those without metabolic syndrome.

0302

Latent autoimmune diabetes in adults (LADA) in the UK South Asian population

A. Britten¹, K. Jones¹, C. Törn², M. Hillman², B. Ekholm², S. Kumar³, A. Barnett¹, A. Kelly¹;

¹Medicine, Birmingham University, United Kingdom,

²Medicine, University Hospital, Lund, Sweden, ³Diabetes and Metabolism, Warwick Medical School, Coventry, United Kingdom.

Background and Aims: Type 2 diabetes is five-fold more common among UK-resident South Asians than indigenous white Caucasians. In many populations, a subset of patients initially diagnosed with type 2 diabetes show evidence of a slowly-evolving autoimmune form of diabetes, known as Latent Autoimmune Diabetes in Adults (LADA). The prevalence of LADA in South Asian populations is not well established and the disease is poorly characterised in this ethnic group.

The aim of this study was to investigate the frequency of LADA in UK-resident South Asians of Punjabi origin and to characterise the clinical phenotype and genetic basis of the disease in this population.

Materials and Methods: 500 individuals with type 2 diabetes and 206 control subjects of Punjabi origin were recruited. The subjects were analysed for circulating autoantibodies to GAD65 and IA-2 and genotyped for alleles of the *HLA-DRB1*, *-DQA1*, *-DQB1* and *MIC-A* genes and the *INS-VNTR*.

Results: Antibodies to GAD65 and IA-2 were detected in 13/500 (2.6%) individuals with type 2 diabetes (eight GAD65-positive [1.6%], six IA-2-positive [1.2%], one GAD65/IA-2 double-positive) and 8/206 (3.9%) control subjects (three GAD65-positive [1.5%] and five IA-2-positive [2.4%]). There was no significant difference in the antibody titre between the diabetic and control subjects.

At the HLA locus the *DRB1*04*, *DQA1*03* and *DQB1*0302* alleles were increased in frequency among the IA-2-positive diabetic subjects compared with those lacking this marker ($p=0.020$, $p=0.066$ and $p=0.015$). A similar trend was also observed in the control group. The *DRB1*03*, *DQA1*05* and *DQB1*02* alleles were more frequent among the GAD65-positive diabetic subjects than the antibody-negative subjects ($p=NS$), but no such trend was observed in the control group.

There was no association between *INS-VNTR* genotypes and antibody positivity. The *MIC-A6* allele was significantly less frequent among the IA-2-positive diabetic subjects compared with the antibody-negative diabetic subjects ($p=0.044$), but no association was seen between antibody positivity and the *MIC-A5.1* allele.

Mean weight and body mass index (BMI) were significantly lower in the antibody-positive diabetic subjects compared with the antibody-negative diabetic subjects (weight, 70.1kg vs. 77.3kg, $p=0.029$; BMI, 25.9kg/m² vs. 28.7kg/m², $p=0.032$). IA-2-positive diabetic subjects had a significantly lower mean HbA_{1c} level than IA-2-negative subjects (5.6% vs. 7.0%, $p=0.046$).

Insulin treatment was more common in the antibody-positive group. Of the GAD65-positive diabetic subjects, six (75%) were treated with insulin and two (25%) with oral hypoglycaemic agents (OHA). Of the IA-2-positive diabetic subjects, two (33%) were treated with insulin, three (50%) with OHAs and one (16.7%) with diet. The latter four individuals had a duration of diabetes of less than four years. In contrast, among the antibody-negative diabetic subjects, only 87 (18.2%) were treated with insulin.

Conclusion: LADA is uncommon in the Punjabi population living in Birmingham, UK. The presence of islet autoimmunity was associated with a similar HLA profile to that reported in other populations, but no associations with the *INS-VNTR* or the *MIC-A5.1* allele were observed. Autoantibody-positive diabetic individuals had a similar clinical phenotype to that reported in other ethnic groups.

Low risk HLA genotype is associated with less destruction of beta cells persisting 12 months after diagnosis

M. Spoletini¹, A. Petrone¹, M. Capizzi¹, S. Zavarella¹, S. Zampetti¹, G. Leto¹, I. Alemanno¹, IMDIAB Group², P. Pozzilli², R. Buzzetti¹;

¹Clinical Sciences, "Sapienza" University, Rome, Italy,

²Endocrinology, "Campus Biomedico", Rome, Italy.

Background and Aims: The role of HLA genes in the susceptibility to type 1 diabetes (T1DM) is well known, however remains to be established whether the degree of beta-cell destruction depends on different HLA genetic risk. The aim of this study was to evaluate the influence of *DRB1** and *DQB1** genes on the rate of beta-cell loss in a prospective series of $n=120$ consecutive newly-diagnosed T1DM subjects in the course of 12 months after disease onset.

Materials and Methods: $N=120$ consecutive T1DM subjects with age ranged from 5 to 36 years (mean age 14.9 ± 7.8) were evaluated for HLA-*DRB1* and *DQB1*. The HLA genotypes were classified in three risk categories, based on the absolute risk values previously estimated in the Italian population: high risk for *DRB1*03-DQB1*0201/DRB1*04-DQB1*0302* genotype (*DRB1*04* different from 0403, 06, 11); moderate risk for *DRB1*04-DQB1*0302/DRB1*04-DQB1*0302, DRB1*03-DQB1*0201/DRB1*03-DQB1*0201, DRB1*04-DQB1*0302/X* (*X* different from *DRB1*02, 03, DRB1*04-DQB1*0302* (*DRB1*04* not 0403, 06, 11) or *DQB1*0602*) genotypes and *DRB1*03/X* (*X* different from *DRB1*02, 03, DRB1*04-DQB1*0302* (*DRB1*04* not 0403, 06, 11) or *DQB1*0602*); low risk for the remaining genotypes. Insulin requirements, glycated haemoglobin (HbA_{1c}) and C-peptide levels, were determined at diagnosis and every 3 months for 12 months, in all patients. HbA_{1c} was measured by a column assay (Bio-Rad) and C-peptide levels by a radioimmunoassay (Bio-Rad). The variance of investigated variables during follow up was analyzed using the general linear model for repeated-measures procedure.

Results: Baseline C-peptide in T1DM subjects with low HLA genetic risk showed a similar trend but significantly higher levels compared to patients with moderate and high HLA genetic risk from time of diagnosis up to 12 months ($p=0.007$ and $p=0.0002$, respectively). We also observed a significant positive correlation between C-peptide levels and age at diagnosis from the time of disease onset through the 12 months of follow up ($p=0.016$).

Conclusion: Both HLA markers and age at onset of T1DM are independent factors which influence beta-cell destruction from the time of disease onset up to 12 months of follow-up. These results are useful for designing trials for future therapies aimed to prevent the progression of beta-cell destruction in recent onset T1DM.

Chemokine CXCL10 gene polymorphisms are associated with type 1 diabetes

E. Ramos-Lopez, W. Bartsch, P. Brück, H. Kahles, M. Penna-Martinez,

J. Herwig, K. Badenhoop;

Endocrinology, Diabetes and Metabolism, University Frankfurt am Main, Germany.

Background and Aims: CXCL10 and CXCL9, two CXCR3 chemokines belong to a group of structurally related molecules, which regulate cell trafficking of diverse cells including activated T-helper 1 lymphocytes (TH1 cells), natural killer cells and monocytes. In patients with type 1 diabetes high levels of CXCL10 also known as chemokine interferon γ inducible protein (IP-10) have been found. Additionally, in a mouse model of virus induced diabetes CXCL10 was found as the key mediator to induce insulinitis and T-cell mediated destruction of β -cells. Therefore we investigated the role of CXCL10 and CXCL9 gene polymorphisms in German type 1 diabetes families.

Materials and Methods: German type 1 diabetes families [181, (573 subjects)] were genotyped for the CXCL10_89 and 120 families (360 subjects) for the CXCL10_90 polymorphism within the CXCL10 gene as well as 182 families (552 subjects) for the CXCL9_99 polymorphism within the CXCL9 gene, using real time PCR. Genotype-, haplotype-frequencies and linkage disequilibrium (LD) were estimated using Unphased version 2.403. A corrected P (P_c) <0.05 was considered significant.

Results: The allele "G" of the CXCL10_89 polymorphism was more often transmitted to the affected offspring (103 times vs. 73 times, $P=0.023$) as well

as the haplotypes CXCL10_89G-CXCL10_90T (72. times vs. 43 times, $P=0.006$), while the haplotype CXCL10_89A-CXCL10_90T was less frequently transmitted (47 times vs. 69 times, $P=0.041$). No differences were observed in the transmission of the CXCL9_99 polymorphism.

Conclusion: CXCL10 gene polymorphisms but not CXCL9 are significantly associated with type 1 diabetes in the German population. Functional studies are underway to put these findings into physiological contexts.

Genetic analysis of putative loci located in regions 1q42, 2q34-q35, 16q22-q24 and 5q33.1-q34.1 in Russian families with type 1 diabetes

V. V. Nosikov¹, A. Chernyshova¹, L. I. Zilberman², T. L. Kuraeva¹, N. M. Tsitlidze², V. A. Peterkova², I. I. Dedov²;

¹Molecular Diagnostics and Genomic Fingerprinting, National Research Centre "GosNII genetika", ²Department of Juvenile Diabetes, Endocrinology Research Centre, Moscow, Russian Federation.

Background and Aims: Type 1 diabetes mellitus (T1DM) is a complex disorder with multiple genetic loci. In the current study, we have performed the sibpair analysis to localize minimal regions of linkage with T1DM in regions 1q42, 2q34-q35, 16q22-q24 and 5q33.1-q34.1.

Materials and Methods: All families in this study (35 affected and 66 discordant sibpairs) are Caucasian Russians with nondiabetic parents. Polymorphous markers were amplified using PCR and primer sequences from GenBank. Combined transmission/disequilibrium test (TDT) and sib TDT (S-TDT) were used for data analysis.

Results: To minimize a region of linkage with T1DM on chromosome 16q22-q42 we used five polymorphous microsatellites. Only slight linkage evidence has been obtained for markers *D16S3098*, *D16S422*, *D16S3118* and *D16S3073*. The peak of linkage has been obtained for *D16S750* marker (MLS = 1.63, $p < 0.03$; $Z' = 2.20$, $p < 0.03$) located between *D16S3118* and *D16S3073* markers. The MLS and Z' values are significantly lower in Russian families in comparison with families from United Kingdom (Mein et al, Nature Genetics, 19, 297) but the peak of linkage locates in the same area of chromosome 16. To estimate a level of linkage with T1DM of interleukin 12B gene (*IL12B*) located in 5q33.1-q34.1 region we have used two markers: *C1159A* SNP in 3'-untranslated region of *IL12B* gene and polymorphous microsatellite *D5S2060* located at a distance 0.54 Mb from *IL12B* gene. No linkage evidence has been obtained for these markers in Russian families with T1DM. To minimize a region of linkage with T1DM on region 1q42 we have studied a linkage with T1DM of five polymorphous markers: *DIS1617*, *DIS1668*, *DIS103*, *DIS225* and *DIS1644*. MLS values was higher 2.50 for all these markers and the peak of linkage has been obtained for *DIS1617* marker (MLS = 3.42, $p < 0.01$; $Z' = 3.63$, $p < 0.01$) located between *DIS1644* and *DIS1668* markers. The position of maximal linkage, MLS and Z' values completely consist with the data obtained earlier by Concannon et al (Nature Genetics, 19, 292–296). To minimize a region of linkage with T1DM on region 2q31-q34 we have studied a linkage with T1DM of five polymorphous markers: *D2S137*, *D2S164*, *D2S143*, *D2S301* and *D2S157*. The peak of linkage has been obtained for *D2S137* marker (MLS = 3.18, $p = 0.008$; $Z' = 3.23$, $p < 0.005$).

Conclusion: The genetic analysis of loci located in regions 1q42, 2q34-q35, 16q22-q24 and 5q33.1-q34.1 in Russian families with T1DM has shown the strong linkage of 1q42 and 2q34-q35 regions and the relatively slight linkage of 16q22-q24 region with T1DM.

Gene expression and genetic association studies suggest a role for the Parkinson's gene *PINK1* in the pathogenesis of type 2 diabetes

P. W. Franks^{1,2}, C. Scheele³, R. J. F. Loos², A. R. Nielsen⁴, B. K. Pedersen⁴, N. J. Wareham⁵, J. A. Timmons^{6,7};

¹Genetic Epidemiology & Clinical Research Group, Umea University Hospital, Sweden, ²Genetics Group, MRC Epidemiology Unit, Cambridge, United Kingdom, ³Department of Cellular and Molecular Biology, Karolinska Institute, Stockholm, Sweden, ⁴Department of Infectious Diseases, University of Copenhagen, Denmark, ⁵MRC, MRC Epidemiology Unit, Cambridge, United Kingdom, ⁶Programme for Genomics and Bioinformatics, Karolinska Institute, Stockholm, Sweden, ⁷School of Life Sciences, Heriott-Watt University, Edinburgh, United Kingdom.

Background and Aims: PTEN induced putative kinase 1 (*PINK1*) locates to the mitochondria and mutations at the *PINK1* locus cause mitochondrial dysfunction, energy depletion and autosomal recessive Parkinson's disease.

Materials and Methods: We measured *PINK1* transcripts levels in skeletal muscle and adipose tissue of 53 adults (61.1 ± 9.1yrs): 12 were non-obese (BMI < 27) with normal glucose tolerance (NGT), 14 were obese (BMI > 35) with NGT, 13 were non-obese/type 2 diabetics (T2D), and 14 were obese/T2D. We also tagged the *PINK1* gene in 1703 adults (55.9 ± 10.0yrs) and tested associations for the 10 *PINK1* tagging SNPs (derived via pair-wise tagging in the CEU HAPMAP panel) and indirect measures of lipid and glucose oxidative capacity.

Results: In the expression study, 3 transcripts were examined (*PINK1*, *naPINK1*, *DDOST*), which were all down-regulated by ~30% in T2D skeletal muscle vs. the NGT control muscle (*PINK1*: $p < 0.05$, *naPINK1*: $p < 0.05$, *DDOST*: $p < 0.001$). In obese vs non-obese NGT individuals, *PINK1* expression was unaltered, while expression of both *naPINK1* and *DDOST* were reduced (*naPINK1*: $p < 0.01$, *DDOST*: $p < 0.01$). In the genetic studies, the tagging SNPs were simultaneously regressed against the metabolic traits with adjustment for age, sex, exam date, and BMI using stepwise regression models. Modest evidence for association was observed for all traits: fasting glucose (rs3131713: $p = 0.098$), 2hr glucose (rs10799655: $p = 0.042$), LDL (rs650616: $p = 0.097$), total cholesterol (rs650616: $p = 0.021$), triglycerides (rs3738136: $p = 0.014$; rs2298299: $p = 0.067$), fasting NEFA (rs650616: $p = 0.04$) and VO_{2max} (rs12410193: $p = 0.025$). Owing to the modifying effects of obesity on *PINK1* transcript levels observed in the expression studies, we tested for interaction between BMI and each of the associated genotypes on their respective phenotypes. For rs650616, a strong interaction with BMI was observed on NEFA levels ($p = 0.0076$), where the minor allele was associated with higher NEFA in non-obese ($p = 0.0008$), but in obese, the minor allele tended to associate with lower NEFA levels ($p = 0.065$). A tendency for interaction between rs12410193 and BMI on VO_{2max} was also observed ($p = 0.079$), where the minor allele was associated with higher VO_{2max} in non-obese ($p = 0.007$) but not in obese ($p = 0.75$) individuals.

Conclusion: In skeletal muscle of obese or diabetic individuals, *PINK1* transcript levels are significantly down-regulated compared with the levels in tissue of non-obese NGT individuals. Furthermore, sequence variation across the *PINK1* gene influences levels of post-challenge glucose, lipids, and maximal oxidative capacity. Obesity modifies these relationships, such that the genetic associations for NEFA and VO_{2max} are strong in non-obese individuals and weak or absent in obese. We conclude, therefore, that the *PINK1* gene may be involved in the pathogenesis of T2D, possibly through defective lipid and glucose oxidation.

Minor contribution of Smad7 and KLF10 variants to genetic susceptibility of type 2 diabetes

B. Neve^{1,2}, R. Gutierrez-Aguilar¹, Y. Benmezroua¹, B. Balkau³, M. Marre⁴, N. Helbecq⁵, G. Charpentier⁶, R. Sladek⁷, P. Froguel^{1,2};

¹Cnrs, umr8090, Institute of Biology, Lille, France, ²Genomic Medicine, Imperial College, London, United Kingdom, ³Inserm U780-IFR69, and University Paris-Sud, Villejuif, France, ⁴EA3516, Xavier Bichat, Faculty of Medicine, University Paris VII, Paris, France, ⁵Inserm, u744, Pasteur Institute, Lille, France, ⁶Department of Diabetes, Sud Francilien Hospital, Corbeil-Essonnes, France, ⁷Departments of Human Genetics and Medicine, Faculty of Medicine, McGill University and Genome Quebec Innovation Centre, Montreal, France.

Background and Aims: It has been shown that transgenic mice over expressing Smad7 in pancreatic cells developed overt type 2 diabetes (T2D). Both KLF11, which gene variants have been shown to be involved in genetic susceptibility to T2D, and the highly homologous KLF10 regulate expression of Smad7. If the TGFbeta-induced transcription factor KLF10 and KLF11 affect transcriptional regulation of the same set of genes (including TGFbeta signaling pathway inhibitor Smad7), we may expect they contribute similar to the development of T2D. This study aimed to assess the genetic contribution of SMAD7 and KLF10 genes to susceptibility to T2D.

Materials and Methods: We screened both genes to identify rare variants and frequent variants by direct sequencing and genotyped those variants. Rare variants were analyzed for cosegregation with T2D in the pedigrees of the proband families. We assessed T2D association of frequent gene variants in a two-stage design case/control study. We compared the allelic distribution of 6 frequent Smad7 SNPs and 6 frequent KLF10 SNPs between 358 T2D and 352 normoglycaemic subjects. Then, statistically significant differences in allele distribution were confirmed in a population sample of 2066 T2D and 1107 normoglycaemic subjects.

Results: The combined analysis of the case/control studies showed two variants with modest T2D association. The Smad7 intron 2 variant showed a significant T2D association under a recessive model ($P = 0.007$, Odds ratio = 0.62, 95% confidence interval = 0.44–0.88; $P = 0.03$ when adjusting for age, sex and BMI in a nominal regression model). The KLF10 variant located in the 3'-UTR showed a significant T2D association under a recessive model ($P = 0.009$, Odds ratio = 0.81, 95% confidence interval = 0.69–0.95; $P = 0.04$ when adjusting for age, sex and BMI in a nominal regression model).

Conclusion: The observed modest T2D association for Smad7 and KLF10 gene variants suggests that they may contribute to a particular genetic background that increases the susceptibility to development of T2D. Further investigations are needed to assess whether the potential effects of Smad7, KLF10 and KLF11 gene variants on TGF-beta signaling is the pathogenic mechanisms that contributes to development of T2D.

Evidence that the LARS2 gene represents a novel type 2 diabetes mellitus susceptibility gene

E. Reiling¹, G. C. M. Janssen¹, P. J. A. van den Broek¹, E. C. van Hove¹, J. A. Maassen^{1,2}, L. M. 't Hart¹;

¹Molecular Cell Biology, Leiden University Medical Center, Leiden, ²EMGO institute, VUMC, Amsterdam, The Netherlands.

Background and Aims: It is known that mitochondrial dysfunction can lead to an increased risk for type 2 diabetes mellitus (T2DM). LARS2 encodes for the mitochondrial leucyl tRNA synthetase (LeuRS), which is essential for mitochondrial protein synthesis. Previously we have shown that an H324Q polymorphism associates with an enhanced risk for T2DM in populations from the Netherlands, Denmark and the UK. We now performed an extensive functional study in order to find the pathogenic mechanism of the H324Q variant.

Materials and Methods: We used recombinant wild type and mutant LeuRS for measuring enzyme activity and misacylation in vitro with ³H-labeled

leucine and isoleucine. LeuRS expression levels and mitochondrial function were assessed in heterozygous patient fibroblasts.

Results: First we assessed the LeuRS expression levels in patient fibroblasts, but observed no differences. We therefore measured the enzyme activity of both wild type and mutant LeuRS in vitro, but no significant differences were observed. Next the misacylation rate was measured. We found an approximately 3-fold increased misacylation rate ($p < 0.001$). An increased misacylation is likely to induce a higher error rate in mitochondrial protein synthesis, resulting in impaired ATP synthesis. AMPK and its downstream target ACC are phosphorylated by an increased AMP / ATP ratio, which results in a switch to fatty acid oxidation. We therefore analyzed the phosphorylation status of ACC as a readout of possible energy depletion in patient fibroblasts. Our results indeed suggest that ACC phosphorylation is increased in H324Q carriers, which indicates an impaired ATP production.

Conclusion: In conclusion we have shown that the LARS2 gene represents a T2DM susceptibility gene in several Caucasian populations. The H324Q variant results in an approximately 3-fold increased misacylation rate and an increased ACC phosphorylation. This indicates that mitochondrial dysfunction due to the H324Q variant in LeuRS results in impaired ATP synthesis which enhances susceptibility to develop type 2 diabetes.

Effects of genetic variation in the human retinol binding protein-4 gene (RBP4) on insulin resistance and fat depot specific mRNA expression

A. Tönjes¹, M. Geyer¹, N. Klötting¹, T. E. Graham², J. Berndt¹, Y. Böttcher¹, B. Enigk¹, M. R. Schön³, B. B. Kahn², M. Blüher¹, M. Stumvoll¹, P. Kovacs¹; ¹IIRD Medical Department, University of Leipzig, Germany, ²Division of Endocrinology, Diabetes, and Metabolism, Beth Israel Deaconess Medical Center, Boston, United States, ³Department of Surgery, University of Leipzig, Germany.

Objective: Serum Retinol Binding Protein 4 (RBP4) is a new adipocyte-derived signal that may contribute to insulin resistance. Therefore, the RBP4 gene represents a plausible candidate gene involved in susceptibility to type 2 diabetes mellitus (T2DM) and related traits.

Research design: In this study, the RBP4 was sequenced in DNA samples from 48 non-related Caucasian subjects. Five novel and 3 known single nucleotide polymorphisms (SNPs) were identified. Four SNPs, representative of their linkage disequilibrium groups were further genotyped in 504 diabetic and in 681 non-diabetic subjects.

Results: In non-diabetic subjects, 1 haplotype [C-G-T-T] was associated with significantly higher glucose infusion rate and lower waist-to-hip ratio (adjusted $P < 0.05$). This haplotype also showed association with significantly lower mRNA levels in visceral adipose tissue in a subgroup of non-diabetic subjects with measurements of *RBP4* mRNA expression in visceral and subcutaneous fat depots. In addition, three SNPs (rs3758358, rs3758539, rs10882283) were significantly associated with circulating free fatty acids (FFA) ($P < 0.05$), which was reflected in subsequent haplotype analyses, where 1 haplotype was significantly associated with FFA and 2 other haplotypes were associated with body mass index ($P < 0.05$). However, no association of T2DM with any of the genotyped SNPs or their haplotypes was found.

Conclusions: Our data indicate a minor role of *RBP4* genetic variation in susceptibility to insulin resistance, possibly through an effect on *RBP4* expression.

Genetic polymorphisms explain variation in the ability to regulate fat oxidation

E. Corpeleijn¹, L. Petersen², T. Sørensen², W. H. M. Saris¹, O. Pedersen³, P. Froguel⁴, E. E. Blaak¹; the NUGENOB consortium,

¹Department of Human Biology, Nutrition and Toxicology Research Institute Maastricht (NUTRIM), Maastricht University, The Netherlands,

²Institute of Preventive Medicine, Danish Epidemiology Science Centre, Copenhagen University Hospital, Denmark,

³Steno Diabetes Center, Copenhagen, Denmark, ⁴CNRS UPRES A8090, Institut Biologie de Lille, Institut Pasteur de Lille, France.

Background and Aims: A low fasting fat oxidation and a disability to stimulate fat oxidation in response to a high fat diet are predisposing factors for obesity and type 2 diabetes. In the present study, the variation in fat oxidation rates was studied in relation to 42 common single nucleotide polymorphisms (SNPs) in 26 candidate genes in overweight subjects. The selected genes were associated with the regulation of lipid and glucose metabolism, regulation of adipocyte differentiation and function, production of adipocytokines, hypothalamic regulation of appetite and efficiency of energy expenditure.

Materials and Methods: In 722 overweight to obese subjects (541 women, BMI = 35.8 ± 4.8 , age = 36.6 (range 20 to 51) and 181 men, BMI = 34.9 ± 4.8 , age = 38.7 (range 21–51)) from 8 European centres, whole body energy expenditure and fat oxidation were measured with indirect calorimetry one and a half hours before and three hours after a high fat load containing 95 energy % of fat (60 E% saturated fat, energy content equals 50% of estimated resting energy expenditure). Fasting and postprandial fat oxidation were expressed as % of average energy expenditure during fasting or postprandial, respectively. DNA was extracted from buffy coats and genotyped with the LightCycler assay, TaqMan assay or direct sequencing. Only statistically significant results ($P < 0.05$) are presented. Results are explorative and are not corrected for multiple testing.

Results: After adjustment for centre and gender, a lower fasting fat oxidation was related to the -178 A>C SNP of *CD36*, a fatty acid transporter, and the T6905 C>G SNP of protein convertase subtilisin/kexin type 1 (*PCSK1*), which plays a key role in regulating insulin biosynthesis and can cleave proopiomelanocortin. Fasting fat oxidation was higher in subjects with the 17 C>G SNP of sterol regulatory element binding transcription factor 1 (*SREBF1/SREBP1*), a gene regulator involved in cholesterol and fatty acid biosynthesis pathways, and the 1044 A>G SNP of ectonucleotide pyrophosphatase/phosphodiesterase 1 (*ENPP1*), which may interact with insulin receptor beta-subunit autophosphorylation. The ability to increase fat oxidation after a high fat load was reduced in subjects with the 1431 C>T SNP of peroxisome proliferative activated receptor gamma isoform 2 (*PPARG2*), an important gene in adipocyte function, and increased with the -174 G>C SNP of *IL-6*, a pro-inflammatory cytokine associated with insulin resistance, and the -829a A>G SNP of WW domain containing adaptor with coiled-coil (*WAC*), involved in adipocyte function. Further adjustment for fat mass, HOMA index for insulin resistance and circulating free fatty acids did not change the outcome.

Conclusion: Variants of genes which are associated with fatty acid uptake, lipid storage, fatty acid oxidation and inflammation may explain part of variation in fasting fat oxidation (e.g. *SREBF1*, *CD36*, *ENPP1*, *PCSK1*, *PGC-1a*) as well as the ability to increase fat oxidation in response to a high fat load (e.g. *IL-6*, *PPARG2*, *WAC*) in human adiposity.

FABP2 promoter polymorphism may exert its functional impact on glucose metabolism due to variability in GIP secretion

D. Rubin, U. Helwig, J. Schrezenmeier;

Institute of Physiology and Biochemistry of Nutrition, Federal Research Centre for Nutrition and Food, Kiel, Germany.

Background and Aims: The intestinal fatty acid-binding protein gene is proposed as a candidate gene for diabetes because the protein it codes is involved in fatty acid absorption and metabolism. Variation in the intestinal fatty acid binding protein (*FABP-2*) promoter is associated with an increase in postprandial triglycerides and a decrease in insulin sensitivity in the presence of the rare Thr54Thr exon polymorphism. This study investigated the functional impact of the *FABP2* promoter haplotype and Ala54Thr exon polymorphism on the postprandial enterocrine response to a mixed meal to elucidate the underlying mechanisms for this association.

Materials and Methods: 167 men from the Metabolic Intervention Cohort Kiel (MICK) were genotyped for the *FABP2* promoter haplotype and Thr54Ala exon polymorphism by the TaqMan method. Glucose dependent insulinotropic polypeptide (GIP), insulin, glucose and triglycerides were measured after ingestion of a standardized mixed meal.

Results: 28.5% of subjects were homozygous carriers of the rare *FABP2* promoter haplotype ($n=37$). Homozygous carriers of rare *FABP2* promoter haplotype showed significantly lower postprandial GIP levels (AUC: 22.4 vs. 25.5 ng/ml, $p=0.04$), lower postprandial insulin sensitivity (HOMA) ($p=0.01$) and higher insulin secretion (HOMA β -cell) ($p=0.02$) when compared to carriers of the common *FABP2* promoter haplotype. This effect was independent of the common A54T *FABP2* exon polymorphism.

Conclusion: The rare *FABP2* promoter haplotype may exert its deleterious effects on insulin sensitivity and triglyceride metabolism by decreased postprandial secretion of GIP.

Low-density lipoprotein receptor-related protein (LRP5) C/T polymorphism in the exon 18 in relation to the beta cell secretion

B. Bendlová¹, M. Vanková¹, P. Lukasová¹, A. Zemanová¹, K. Zajicková², D. Vejrazková¹, J. Vcelak¹, K. Vondra², J. Vrbkova²;

¹Department of Molecular Endocrinology, ²Department of Clinical Endocrinology, Institute of Endocrinology, Praha 1, Czech Republic.

Background and Aims: Low-density lipoprotein receptor-related protein 5 (*LRP5*) acts as a membrane co-receptor in the Wnt signaling pathway and thus affects bone accrual and development. Data from knock-out mice have shown that *LRP5* could play a role in the lipid and glucose metabolism. *LRP5* might modulate the glucose-induced insulin secretion through the insulin signaling cascade and the hepatocyte nuclear factors regulation. Diabetes mellitus type 2 (DM2) as well as polycystic ovary syndrome (PCOS) are often

accompanied by the defect in insulin secretion. The aim of the presented study is to compare the frequency of C/T (c.4037: A1330V) polymorphism in the exon 18 of *LRP5* gene in the sets of DM2 and PCOS patients, offspring of DM2 and healthy controls without the family history of DM2 and to evaluate beta-cell secretion and lipid levels of the study subjects in the relationship to the described polymorphism.

Materials and Methods: The study involved 1122 people. Detailed biochemical and anthropometric characteristics of 368 patients with DM2 (M/F 129/239; age 61.0±7.6/59.0±8.7 years; BMI 29.8±4.4/31.8±5.6 kg/m²); 297 women with PCOS defined according to ESHRE consensus (age 27.1±6.6 years; BMI 26.7±6.5 kg/m²); 165 offspring of DM2 (OD) (56/109; age 39.8±10.7/37.0±11.7 years; BMI 26.8±4.4/25.1±4.2 kg/m²) and 292 controls (C) (97/195; age 29.0±8.8/29.3±10.2 years; BMI 23.8±3.0/22.5±3.6 kg/m²) were collected. Oral glucose tolerance test (oGTT) with sampling for blood glucose, insulin, C-peptide and proinsulin in 0, 30, 60, 120, 150 and 180th minute was done (except of DM2 patients). Total cholesterol, HDL-cholesterol and triglycerides were determined in basal blood sample. The C/T polymorphism in the *LRP5* gene was assessed by PCR with a mismatched primer introducing a restriction site for *Adel* enzyme. Statistics was done using NCSS 2004 and Statgraphics (chi-square, Mann-Whitney, ANCOVA).

Results: The genotypic distribution (CC/CT/TT) was not significantly different between DM2, PCOS, OD vs. C: DM2 – 72.8/23.6/3.5; PCOS – 80.1/18.5/1.4; OD – 76.9/21.2/1.8; C – 77.7/21.3/1.0 [%] though higher frequency of T allele carriers in DM2 group was found (still NS). T allele carriers had higher levels of fasting and stimulated C-peptide and insulin in comparison with CC homozygotes, the significance was achieved in healthy controls without family history of DM2 (AUC – the area under the oGTT curve: AUC C-peptide, p=0.004; AUC insulin, p=0.02). There was no difference in insulin sensitivity and lipid spectra among CC/CT/TT genotypes.

Conclusion: Our study suggests that the polymorphism C/T (A1330V) of the *LRP5* gene is associated with higher fasting and stimulated insulin and C-peptide levels. *LRP5* seems to be another candidate gene for the beta-cell secretion.

Association between the ACE gene I/D polymorphism and insulin sensitivity in healthy subjects

F. Bonnet¹, S. Patel², I. M. Ibrahim², M. Laville¹, B. Balkau³, M. Walker²;
¹Centre for Research in Human Nutrition, INSERM U449, Dept of Endocrinology, Lyon, France, ²Newcastle University, School of Clinical Medical Sciences, United Kingdom, ³U 258, INSERM, Villejuif, France.

Background and Aims: Angiotensin-converting enzyme (ACE) is a key enzyme in the renin-angiotensin system (RAS) modulating the synthesis of angiotensin II and inactivation of bradykinin. The ACE gene has an insertion/deletion (I/D) polymorphism, with the D allele being associated with higher ACE levels. Recent studies suggested that the blockade of RAS is associated with a reduced incidence of type 2 diabetes. However, data about the potential influence of the ACE I/D genotype on insulin resistance have been so far contrasting and have included a limited number of subjects and/or only used surrogate markers of insulin sensitivity. We investigated the relationship between the ACE I/D polymorphism and insulin sensitivity, as assessed by the euglycemic clamp, in a cohort of healthy subjects participating in the RISC study (Relationship between Insulin Sensitivity and cardiovascular disease study).

Materials and Methods: Healthy subjects aged 30–60 yrs were recruited at 19 centres in 14 European countries. Each subject underwent anthropometric and metabolic assessment, including a 75-g oral glucose tolerance test (OGTT). Whole body insulin sensitivity (M/I value) was assessed by an hyperinsulinemic-euglycemic clamp and the ACE I/D polymorphism was genotyped using a PCR based method. Variables with a skewed distribution were log-transformed before analysis.

Results: The study cohort consists of 1286 subjects (579 men and 707 women) aged 43.8±8.3 yrs, with a mean BMI of 25.5±4.0 kg/m². Age, BMI, waist, fat-free mass and physical activity did not differ by ACE genotype. Fasting glucose and insulin were similar among genotypes, but 2h glucose levels were higher in DD than in ID and II subjects (DD:5.9±1.7; ID: 5.7±1.5; II: 5.5±1.5 mmol/l, p=0.002 after adjustment for sex, age, centre, BMI and waist). Subjects with the DD genotype were more likely to have impaired glucose tolerance than those with the ID and II genotypes (13.1% vs. 8.7%,

p=0.02). Insulin sensitivity was lower in subjects with the DD genotype than in those with the II genotype [135.7±63.4 vs. 147.4±65.1 (μmol/min/kgFFM)/(nmol/l), p=0.02]. There were no associations between the ACE genotype and plasma adiponectin level nor the insulinogenic index from OGTT. In multiple regression, after correction for age, sex, centre, BMI and waist, the ACE I/D genotype was independently related to insulin sensitivity (M/I value) and to the 2h glucose levels with increased insulin sensitivity and a lower 2h plasma glucose level among those with the II genotype, as compared to those with the DD or I/D ACE genotype.

Conclusion: ACE I/D polymorphism is associated with whole body insulin sensitivity and with 2h glucose levels in healthy subjects but is independent of circulating adiponectin levels. These findings confirm potential interactions between the renin-angiotensin system and glucose metabolism.

A meta-analysis of QTL for diabetes-related traits in rodents

H. Al-Hasani¹, C. Schmidt¹, N. P. Gonzaludo¹, S. Dahm², J. Schuchhardt³, F. Kleinjung³, S. Wuschke¹, H.-G. Joost¹;
¹Pharmacology, German Institute of Human Nutrition, Nuthetal,
²Epidemiology, German Institute of Human Nutrition, Nuthetal,
³Bioinformatics, Microdiscovery GmbH, Berlin, Germany.

Background and Aims: Cross-breeding experiments with different mouse and rat strains have successfully been used by many groups to identify genetic loci that predispose for insulin resistance and diabetes. In order to provide a statistical assessment of these QTL as a basis for a systematic investigation of candidate genes, we have performed a meta-analysis of genome-wide linkage scans for diabetes-related component traits.

Materials and Methods: From a total of 44 published rodent cross-breeding experiments (30 for mouse, 14 for rat), we compiled a list of 170 QTL for blood glucose, insulin levels, and glucose tolerance. Collectively, these studies include data from 39 different parental mouse and rat strains and >11,000 individual animals. The peak markers for 134 mouse QTL and 36 rat QTL were mapped to the mouse chromosomes using NCB's UniSTS and a rat-mouse synteny database. The results of the studies were analysed using the truncated product method (TPM).

Results: The analysis revealed significant evidence (LOD score > 4.3) for linkage of blood glucose, insulin levels, and glucose tolerance to 26 different segments on 15 different mouse chromosomes. Of these, 15 segments have also been found significantly linked with body weight and body fat. Conversely, 11 segments show linkage with diabetes but not with obesity-related traits, respectively, indicating the presence of distinct body-weight dependent and independent consensus regions for diabetes component traits. The most prominent regions with linkage for glucose, insulin, and glucose tolerance (LOD scores 10.5 – 17.4) on mouse chromosomes 2, 4, 7, 9, 11, 13, and 19 cover only about 10% of the mouse genome but contain >30% of all known QTL for blood glucose, insulin levels, and glucose tolerance. On the other hand, for >30% of the mouse genome no QTL were found to map within the designated region. For a systematic investigation of candidate genes, we performed an extensive analysis of the haplotype structure of the consensus QTL regions by integrating high-density SNP maps of multiple parental strains using a Hidden-Markov model. In addition to >30 previously known genes involved in insulin action, including *DPP4* (dipeptidyl-peptidase 4), *FOXA2* (forkhead box A2), *SCD1* (stearoyl-Coenzyme A desaturase 1), *STAT3* (signal transducer and activator of transcription 3), and *TCF7L2* (transcription factor 7-like 2), we identified several novel candidate genes that may regulate blood glucose, insulin levels, and glucose tolerance.

Conclusion: Our results demonstrate the presence of numerous distinct consensus QTL regions with highly significant LOD scores that control glucose homeostasis. Our study may provide guidance for a further systematic investigation of candidate genes within the consensus QTL regions and presents a new resource for the identification of positional candidates in QTL studies.

Variant of Transcription Factor 7-like 2 (TCF7L2) gene and the risk of posttransplant diabetes mellitus (PTDM) in renal allograft recipients

E. Kang^{1,2}, M. Kim³, Y. Kim³, K. Hur¹, S. Han¹, S. Chun¹, C. Ahn¹, B. Cha¹, S. Kim³, H. Lee¹;

¹Internal Medicine, ²Brain Korea 21 for Medical Science,

³Surgery, Yonsei University College of Medicine, Seoul, Republic of Korea.

Background and Aims: Posttransplantation diabetes mellitus (PTDM) is a major complication after kidney transplantation. Defect in insulin secretion plays a pivotal role in the pathogenesis of PTDM. Transcription factor 7-like 2 gene (*TCF7L2*) polymorphism was reported to be associated with type 2 diabetes and possibly associated with insulin secretory defect. The aim of this study was to investigate the association between genetic variations in the *TCF7L2* and PTDM in renal allograft recipients.

Materials and Methods: A total of 516 unrelated renal allograft recipients without previously known diabetes were enrolled. We genotyped six single nucleotide polymorphisms (SNPs) (rs11196205, rs4506565, rs12243326, rs7903146, rs12255372, and rs7901695) in the cohort consisting of 120 PTDM patients and 396 No-PTDM patients. The genotyping of *TCF7L2* polymorphism was performed using real-time PCR.

Results: Rs4506565, rs7901695, and rs7903146 were in complete linkage. Rs7903146 genotype distribution was as follows: CC 94.4% and CT 5.6%. Patients with CT genotype at rs7903146 was significantly associated with PTDM (odds ratio 2.477, 95% CI: 1.148–5.346, $p=0.017$). Effect of genotype remains significant after multivariate logistic regression for PTDM (odds ratio 2.716, 95% CI: 1.120–6.586, $p=0.011$).

Conclusion: These data suggest evidence that *TCF7L2* rs7903146 genetic variation is associated with increased risk of PTDM in renal allograft recipients.

Common variants of the TCF7L2 gene are associated with increased risk of type 2 diabetes in a UK-based South Asian population

S. Rees¹, S. Bellary¹, A. Britten¹, A. Dixon¹, P. O'Hare², S. Kumar², A. Barnett¹, A. Kelly¹;

¹Medicine, Birmingham University, ²Diabetes and Metabolism, Warwick Medical School, Coventry, United Kingdom.

Background and Aims: The South Asian population is genetically heterogeneous, comprising of individuals originating from India, Pakistan and Bangladesh. The risk of type 2 diabetes (T2DM) in this ethnic group is high; almost 6-fold greater in UK-based South Asian populations than in the local white Caucasian population. Despite this, there have been relatively few genetic association studies carried out in South Asian populations. Recently, the transcription factor 7-like 2 (*TCF7L2*) gene has emerged as a forerunner in the search for T2DM susceptibility genes, with significant associations being reproduced in a large number of independent studies. Only two of these studies, however, have investigated populations of South Asian origin, and neither has studied a cohort originating from the north of the Indian subcontinent. In this study we investigated the association of common polymorphisms within the *TCF7L2* gene with T2DM in a well characterized UK-based South Asian population of Punjabi origin.

Materials and Methods: Subjects with T2DM (N = 831) and non-diabetic control subjects (N = 436) of Punjabi ancestry were recruited as part of the United Kingdom Asian Diabetes Study (UKADS). We genotyped four SNPs (rs7901695, rs7903146, rs11196205 and rs12255372) that showed association with T2DM in a previous study by Grant *et al.* Genotyping was carried out using TaqMan SNP Genotyping assays. Alleles and genotypes were tested for association with T2DM using standard X^2 analyses. Association between genotypes and continuous variables was tested using analysis of variance. The significance of the relationship between odds ratio (OR) and minimum age threshold was determined using linear regression. All statistical analyses were performed in SPSS 13.0.

Results: In agreement with previous studies, the minor allele of each SNP was significantly associated with T2DM. The strongest association was seen for the variant rs11196205, with an OR of 1.51 (95% CI 1.17 – 1.93, $p = 1.1 \times 10^{-3}$). Genotypes of the variants studied were not associated with any clinical, biochemical or morphological characteristic in either cases or controls. The inclusion of young individuals in a control group can interfere with association tests, as these subjects may develop T2DM later in life. To examine this potential effect, we compared allelic ORs calculated using subsets of our control group defined by different minimum age thresholds. There was a highly significant, positive relationship between the control group age cut-off and the OR of the association test ($p \leq 6.3 \times 10^{-9}$ for all SNPs); an increase of minimum age from 35 to 47 years resulted in an average increase in OR of 0.18.

Conclusion: In conclusion, our results add to the rapidly expanding body of evidence that implicates *TCF7L2* as an important risk factor for T2DM in multiple ethnic groups. This study also highlights the importance of applying a minimum age threshold when recruiting control subjects from a population at high risk of disease. Including young subjects could significantly dilute the genetic effects observed and have implications for the power to detect an association, especially when investigating polymorphisms with lower ORs than *TCF7L2*.

0317

Gestational diabetes is associated with a common variant of the transcription factor 7 like 2 (TCF7L2) gene

A. Katsarou, K. Lynch, N. Shaat, R. Håkansson, A. Nilsson, B. Lernmark, C.-D. Agardh, Å. Lernmark;

Department of Clinical Sciences/Malmö, Lund University, Malmö, Sweden.

Background and Aims: Recent studies have reported that variants in the transcription factor 7 like 2 gene confer risk for type 2 diabetes. The aim of the study was to investigate whether the rs7903146 variant of the *TCF7L2* gene that confers risk for type 2 diabetes also confers risk for gestational diabetes or type 1 diabetes.

Materials and Methods: We genotyped the rs7903146 variant of the *TCF7L2* in 883 mothers with gestational diabetes (GDM), 194 mothers with type 1 diabetes (T1D) and 1367 healthy controls using TaqMan allelic discrimination assay. The serum blood samples from all women were taken at the time of delivery and were collected as dried blood spots. GAD65, IA-2 autoantibodies and antibodies against insulin were determined in cord blood taken at delivery in standard radioligand binding assays.

Results: The T allele of the rs7903146 was positively associated with gestational diabetes (OR 1.4 [1.2–1.6], $p<0.0001$). The heterozygous CT-genotype and the homozygous TT-genotype carriers had an 1.4-fold increased risk (95%CI 1.2–1.6, $p=0.0003$) and an 1.9-fold increased risk (95%CI 1.4–2.6 $p<0.0001$) respectively, compared to the wild type CC-genotype carriers in GDM women. No significant difference was found between the three genotype frequencies of the rs7903146 in women with type 1 diabetes. Approximately 61% and 6% of children born to T1D and GDM mothers, respectively, were positive for autoantibodies against GAD65, IA-2 and antibodies against insulin in the cord blood. The association between *TCF7L2* and gestational diabetes remained statistically significant even after adjusting for age, gestational week at birth and parity and after excluding the cord blood antibody positive GDM women.

Conclusions: The rs790346 variant of the *TCF7L2* gene is associated with an increased risk for gestational diabetes but not for type 1 diabetes. The same variant has been shown to confer risk for type 2 diabetes in several studies. Gestational diabetes is defined by a similar pathogenetic background with type 2 diabetes, since it is characterized mainly by insulin resistance. It is, therefore, possible that these two diseases share also a common genetic background.

Expression of the transcription factor 7-like 2 (TCF7L2) gene in adipocytes is down regulated by insulin both in vitro and in vivo

M. Ahlén, L. Johansson, C. Cervin, M. Ridderstråle;
Clinical Sciences – Diabetes and Endocrinology, Lund University, Malmö, Sweden.

Background and Aims: Variants in the gene coding transcription factor 7-like 2 (*TCF7L2*, former *TCF-4*) have recently shown strong association to type 2 diabetes. Two risk haplotypes have been defined, HapA was associated with increased body mass index (BMI) and HapB_{T2D} was associated with decreased BMI. *TCF7L2* may play a role in both glucose homeostasis and adipogenesis, thus suggesting a connection between expression of *TCF7L2* variants and BMI. Our aim was to characterize the *TCF7L2* mRNA expression and the regulation of the expression in adipose tissue.

Materials and Methods: We quantified *TCF7L2* mRNA levels in cultured human adipocytes incubated with glucose, palmitate or oleate with or without insulin, and in biopsies from visceral (VAT) and subcutaneous (SAT) adipose tissue of 38 obese non-diabetic subjects using Real Time PCR. Two variants of *TCF7L2*, rs10885406 and rs7903146 (representing HapA and HapB_{T2D} respectively) were genotyped. The influence of haplotype and different clinical traits on expression levels were investigated.

Results: *In vitro* insulin decreased the *TCF7L2* mRNA expression in a non-glucose dependent fashion by approximately two thirds ($p < 0.05$). When adipocytes were incubated with free fatty acids, the inhibitory effect of insulin was diminished by half with palmitate ($p = 0.064$) and by a third with oleate ($p = 0.027$). In the biopsy study we found no correlation between *TCF7L2* mRNA expression and measures of obesity, except for a weak trend between SAT *TCF7L2* expression and homeostasis model assessment for insulin resistance ([HOMA] $r = 0.40$, $p = 0.058$). *TCF7L2* expression levels were higher in VAT compared to SAT ($p = 0.00029$). Similar results were found when restricting analysis to HapA carriers ($n = 28$, $p = 0.00038$) while non-HapA carriers showed no difference in *TCF7L2* expression between VAT and SAT ($n = 5$, $p = 0.88$).

Conclusion: *TCF7L2* expression is inhibited by insulin and seems to increase in subjects that are insulin resistant and in those carrying the HapA haplotype. These findings further emphasize the role of *TCF7L2* in both glucose homeostasis and adipogenesis.

0319

The Pro12Ala PPARgamma-2 polymorphism is associated with insulin resistance, but not with adiposity or dislipidaemia in a non-diabetic population from Gran Canaria

A. M. Wägner^{1,2}, M. Boronat¹, F. Varillas³, J. C. Rodríguez⁴, A. Caballero⁴, F. J. Nóvoa¹;

¹Endocrinology, Hospital Universitario Insular de Gran Canaria, Las Palmas de GC, Spain, ²Endocrinology, Steno Diabetes Center, Gentofte, Denmark, ³Endocrinology, Hospital General de Fuerteventura, Puerto del Rosario, Spain, ⁴Research Unit, Hospital Dr Negrín, Las Palmas de GC, Spain.

Background and Aim: The Pro12Ala polymorphism in the peroxisome proliferator-activated receptor (PPAR) gamma-2 gene is associated with type 2 diabetes and insulin resistance. However, results on its effects on obesity and dislipidaemia are inconsistent. The aim of this study was to assess the effect of the Pro12Ala polymorphism on insulin resistance, adiposity and dislipidaemia in a population-based sample.

Patients and Methods: For this cross-sectional, population-based study, the Pro12Ala polymorphism of the *PPARgamma-2* gene was genotyped in a sample of 907 people (583 with normal glucose tolerance (NGT), 205 with impaired glucose regulation (IGR, including impaired glucose tolerance and impaired fasting glucose) and 119 with type 2 diabetes (DM)) from the city of Telde (Gran Canaria, Canary Islands, Spain). Due to the low frequency of 12Ala homozygotes ($N = 5$), the latter were pooled with heterozygotes for analysis. Anthropometric parameters included BMI and waist and hip girth; total body fat was estimated by bio-impedance; insulin resistance was estimated using the homeostasis model of assessment (HOMA); triglycerides, total cholesterol and HDL cholesterol were measured using enzymatic methods. Comparison between groups was performed using chi-square for frequency comparisons, and Student's *t* and Mann-Whitney's *U* tests for quantitative variables.

Results: 12% of NGT, 7.8% of IGR and 10.9% of DM were carriers of the 12Ala allele (ns). Among the non-diabetic subjects, Ala carriers showed less insulin resistance (HOMA of 1.30 (0.32–6.70) vs 1.57 (0.04–12.16), $p = 0.017$), but similar triglycerides, HDL cholesterol, BMI (27.2±4.3 vs 28.1±5.0 Kg/m²), waist girth (94.1±12.3 vs 95.7±13.4 cm), waist/hip ratio (0.93±0.08 vs 0.92±0.08) and total body fat (29.4 (12.8–44.6) vs 31.1 (7.2–56.4)%).

Conclusions: In this Canarian, population-based study, the Pro12Ala *PPARgamma-2* polymorphism is associated with insulin resistance, but not with adiposity or dislipidaemia.

0320

Association of SNPs in the PPARG gene with the development of type 2 diabetes and their interaction with physical activity. The Finnish Diabetes Prevention Study

T. O. Kilpeläinen¹, T. A. Lakka^{1,2}, D. E. Laaksonen^{1,3}, L. Jaana⁴, J. G. Eriksson^{4,5}, T. T. Valle⁴, H. Hämäläinen⁶, P. Ilanne-Parikka^{7,8}, S. Keinänen-Kiukaanniemi^{9,10}, V. Lindi¹¹, J. Tuomilehto^{4,5}, M. Uusitupa¹¹, M. Laakso³;

¹Institute of Biomedicine, Physiology, University of Kuopio, ²Kuopio Research Institute of Exercise Medicine, ³Department of Medicine, Kuopio University Hospital, ⁴Department of Health Promotion and Chronic Disease Prevention, Diabetes Unit, National Public Health Institute, Helsinki, ⁵Department of Public Health, University of Helsinki, ⁶Research Department, Social Insurance Institution, Turku, ⁷Finnish Diabetes Association, Tampere, ⁸Research Unit, Tampere University Hospital, ⁹Department of Public Health Science and General Practice, Unit of General Practice, Oulu University Hospital, ¹⁰Department of Sports Medicine, Oulu Deaconess Institute, ¹¹School of Public Health and Clinical Nutrition, Clinical Nutrition, University of Kuopio, Finland.

Background and Aims: The Ala12 allele of the Pro12Ala polymorphism in the peroxisome proliferator-activated receptor gamma (*PPARG*) gene was associated with an increased risk of type 2 diabetes (T2D) in the Finnish Diabetes Prevention Study (DPS). However, most other studies indicate that the Ala12 is protective against T2D. Furthermore, some data suggest that the association of the Pro12Ala polymorphism on glucose and insulin metabolism may be altered by physical activity. We studied the associations of seven single nucleotide polymorphisms (SNPs) in the peroxisome proliferator-activated receptor gamma (*PPARG*) gene with the conversion from impaired glucose tolerance (IGT) to type 2 diabetes (T2D), and the interactions of the SNPs with physical activity.

Materials and Methods: Overweight individuals with IGT who participated in the Finnish Diabetes Prevention Study (DPS) ($n = 479$) were followed on average 4.2 years. Physical activity was assessed yearly with a 12-month validated questionnaire.

Results: In Cox regression analyses, the rare alleles of rs17036314 and rs1801282 (Pro12Ala) predicted conversion to T2D ($p = 0.038$ and $p = 0.037$, respectively), but only rs17036314 predicted T2D after adjustment for baseline fasting glucose ($p = 0.030$). The change in the total amount of physical activity, stratified by median, modified the association of rs17036314 and rs1801282 (Pro12Ala) with the risk of T2D during the intervention ($p = 0.002$ and $p = 0.033$, respectively, for interaction between physical activity change and genotype); an increase in physical activity seemed to remove the effect of the risk alleles. The distinct rs1152003 polymorphism interacted with the study group on the conversion to T2D ($p = 0.027$), and tended to increase the risk of T2D in the intervention group ($p = 0.050$). No interaction between rs1152003 and the change in physical activity was found.

Conclusion: The rs17036314, rs1801282 (Pro12Ala) and rs1152003 were associated with the risk of T2D in the DPS. Increased physical activity seemed to decrease the effect of the risk alleles of rs17036314 and rs1801282 on the conversion to T2D. The effect of rs1152003 was modified by other lifestyle changes or the lifestyle intervention as a whole.

Is the Pro12Ala polymorphism of the peroxisome proliferator-activated receptor gamma gene associated with type 2 diabetes? A meta-analysis

I. Vardarli;

Johannes Gutenberg Universität, Mainz, Germany.

Background and Aims: Type 2 diabetes (T2DM) is one of the major public health problems. Many candidate genes for T2DM were investigated. Conflicting findings have been published concerning the association of the Pro12Ala polymorphism of the peroxisome proliferator-activated receptor gamma (PPAR γ) gene with type 2 diabetes. To give an update on this issue a meta-analysis was performed in this study.

Materials and Methods: Electronic databases (PubMed, EMBASE, Cochrane Library) were searched (last search February 3rd, 2007) for studies and reviews dealing with the Pro12Ala polymorphism of the PPAR γ gene and T2DM using a systematic strategy. Reference lists of all identified studies were also searched. Efforts were made to identify non published studies. During meetings scientists investigating this issue were contacted and programs and presentations were screened. Additionally, the scientific sessions abstracts archive (2003–2006) of the American Diabetes Association (ADA) was searched. Studies were selected following a priori defined inclusion criteria. Identified data were systematically collected and assessed. Quality of the studies were evaluated using a quality score. Pooled estimates were obtained using the DerSimonian and Laird random effects model. Estimates are given as odds ratio (OR) for the Ala allele (Ala/Ala + Pro/Ala vs. Pro/Pro), and for the Pro allele (Pro/Pro + Pro/Ala vs. Ala/Ala) with the 95% confidence interval (CI). For the estimation of heterogeneity chi-square test was used. Publication bias was tested by using funnel plot, the Begg's and Egger's methods. To explain the heterogeneity, subgroup analyses (e.g. for body mass index (BMI) in cases and definition of controls by oral glucose tolerance test (OGTT)) and meta-regression were performed. For the statistical analyses RevMan 4.2.8, Stata 9 and PS (power calculation) software were used.

Results: 405 studies were identified, of those 31 underpowered case-control studies with 33 datasets with a total of 29,284 subjects (14,771 cases, 14,513 controls) with various ethnic groups investigating the genotype distribution of the Pro12Ala polymorphism of the PPAR γ gene in patients with T2DM and non-diabetic controls (datasets with subjects declared to be exclusively with impaired glucose tolerance (IGT) or impaired fasting glucose (IFG) were excluded) fulfilled the inclusion criteria and were selected for inclusion in this study. There is a significant heterogeneity ($P < 0.00001$) between the studies. The random effects meta-analysis showed a significant association between the Ala allele and T2DM (OR 0.86; 95% CI 0.75–0.97; $P = 0.02$). There was no evidence for publication bias. In subgroup analyses OR for the Ala allele was lower for mean BMI < 30 kg/m 2 in cases. The meta-regression showed that mean BMI (< 30 kg/m 2) of cases ($P = 0.004$) and definition of controls by OGTT ($P = 0.032$) are effect modifiers which affect the pooled estimate of OR for the Ala allele. Genotype information for Ala/Ala were available for 21 of 33 datasets. In those, for the Pro allele the random effects model showed a significant association with T2DM (OR 1.52; CI 1.17–1.98; $P = 0.002$; test for heterogeneity: $P = 0.59$).

Conclusion: There is an association between the Pro12Ala polymorphism of the PPAR γ gene and T2DM. BMI in cases and definition of controls by OGTT are effect modifiers. Sufficiently powered studies on this issue should be stratified by individual BMI of cases, and non-diabetic controls should be defined by OGTT.

PS 8 Epidemiology: treatment

Results of the International Diabetes Management Practices Study (IDMPS), year 2: pattern of care in patients with type 1 diabetes

J. C. N. Chan; on behalf of the IDMPS Group.

Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Shatin, Hong Kong.

Background and Aims: Despite the findings of the DCCT, comparing intensive to conventional treatment, and the recommendations of the ADA, EASD and IDF, a large number of patients with diabetes are not well controlled, emphasizing the need for implementation of measures designed to improve the quality of diabetes care. In this regard, our aim was to gather data on current practices in the management of patients with diabetes worldwide and to evaluate the degree of compliance with international guidelines.

Material and Methods: The IDMPS is an international, multicenter, observational study performed in 27 countries within Africa, Asia, Eastern Europe, the Middle East and Latin America. Data are being collected from patients with Type 1 and Type 2 diabetes (≥ 18 years), seen in current medical practice in 1-year cycles (a 2-week cross-sectional recruitment period, followed by a 9-month longitudinal period for Type 2 patients) for 5 years. Here, we report results for patients with Type 1 diabetes collected during the second cross-sectional period (Year 2) in 8 countries. In addition to monitoring HbA $_{1c}$ and FBG, information about insulin self-injection, self-titration, diabetes education and frequency of visits to their physician was collected. Data were analyzed using standard descriptive methods.

Results: 940 patients with Type 1 diabetes (50.5% men; mean age: 34.1 \pm 12.6 years) were recruited during November and December 2006. The mean BMI was 24.0 \pm 3.9 kg/m 2 for men and 24.0 \pm 4.8 kg/m 2 for women. In the past 3 months, patients had visited a specialist in diabetes 1.3 \pm 1.4 (median: 1.0) times and a GP 1.0 \pm 1.5 (median: 0; range: 0–12) times. Diabetes education was provided by diabetes educators to 52.2% of patients, 2.3 \pm 2.1 times (median: 2.0) within the last 12 months. Overall, 86.8% of patients had HbA $_{1c}$ tested at least once with a mean of 2.0 \pm 1.1 (median: 2.0) tests within the past year; the mean time elapsed since last HbA $_{1c}$ measurement was 3.8 \pm 7.7 (median: 1.0) months. The mean last available HbA $_{1c}$ was 8.3 \pm 2.0%. 24.4% of patients had an HbA $_{1c}$ $< 7\%$, 27.6% between 7% and 8%, and 48% $> 8\%$. Self-injection of insulin was reported in 93.5% of patients and self-titration in 66.2%. 28.7% of patients were considered to be on target according to the physician, and among these the mean HbA $_{1c}$ was 7.0 \pm 1.6%. Laboratory testing for FBG was performed 5.8 \pm 10.4 (median: 3.0) times/year. The mean last available FBG (laboratory) was 163.0 \pm 78.6 mg/dL and 17.2% had a FBG ≤ 100 mg/dL; 75.4% of patients had a glucometer at home, and 76.7% self-monitored their blood glucose (SMBG). FBG was monitored by SMBG 15.9 \pm 15.1 (median: 10.0) times/month and post-prandial glucose 12.8 \pm 15.8 (median: 7.0) times/month. The use of SMBG was associated with a higher number of patients reaching target according to the investigator (84.6% vs. 15.4%). SMBG and the investigator's statement that the patient had reached target were associated with a better glycemic control in terms of laboratory HbA $_{1c}$ and FBG values.

Conclusion: Our data show that patients with Type 1 diabetes are poorly controlled (in terms of HbA $_{1c}$ and FBG), despite being monitored regularly for their condition. This suggests that improvement of education and commitment of both patients and their providers is necessary to achieve a more interactive and effective care provision to these patients.

Results of the International Diabetes Management Practices Study (IDMPS), year 2: pattern of care in patients with type 2 diabetes

H. Ilkova;

Department of Internal Medicine, Division of Endocrinology, Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey.

Background and Aims: Despite the recommendations of the ADA, EASD and IDF, a large number of patients with diabetes are not well controlled, emphasizing the need for implementation of measures designed to improve the quality of diabetes care. In this regard, our aim was to gather data on

current practices in the management of patients with diabetes worldwide and to evaluate the degree of compliance with international guidelines.

Material and Methods: The IDMPs is an international, multicenter, observational study performed in 27 countries within Africa, Asia, Eastern Europe, Middle East and Latin America. Data are being collected from patients with Type 1 and Type 2 diabetes (≥ 18 years), seen in current medical practice in 1-year cycles (a 2-week cross-sectional recruitment period, followed by a 9-month longitudinal period for Type 2 patients) for 5 years. Here, we report results for patients with Type 2 diabetes collected during the second cross-sectional period (Year 2) in 8 countries. To measure the degree of glucose metabolism control, HbA_{1c} and fasting blood glucose (FBG) values were collected. Data were analyzed using standard descriptive methods.

Results: 4312 patients with Type 2 diabetes (47.8% men; mean age: 58.3 \pm 11.2 years), were recruited during November and December 2006. The mean BMI was 27.4 \pm 4.4 kg/m² for men and 28.4 \pm 5.6 kg/m² for women. In the past 3 months, patients had visited a specialist in diabetes 1.5 \pm 1.7 (median: 1.0) times and a GP 0.9 \pm 1.5 (median: 0; range: 0–20) times. In 23.6% of patients, HbA_{1c} was never tested; 76.4% of patients had HbA_{1c} tested at least once with a mean of 2.0 \pm 1.2 (median: 2.0) tests within the past year; the mean time elapsed since the last HbA_{1c} measurement was 2.8 \pm 5.5 (median: 1.0) months. The mean last available HbA_{1c} was 8.0 \pm 2.0%. 32.7% of patients had an HbA_{1c} <7%, 26.5% between 7% and 8%, and 40.8% >8%. Laboratory testing for FBG was performed 5.3 \pm 7.3 (median: 4.0) times/year. Mean FBG (laboratory) was 158.8 \pm 64.0 mg/dL and 12.7% had a FBG \leq 100 mg/dL. Among patients receiving insulin (alone or in combination with oral glucose lowering drugs (OGLD)), 67.0% had a glucometer at home, 68.6% self-monitored their blood glucose (SMBG), and FBG was being monitored by SMBG 11.3 \pm 10.7 (median: 8.0) times/month and post-prandial glucose 7.9 \pm 9.3 (median: 4.0) times/month. 37.3% of patients were considered to be on target according to the physician's opinion; among these 79.9% were tested and had a mean HbA_{1c} of 6.7 \pm 1.3%.

Conclusion: Our data show that 1/3 of patients with Type 2 diabetes are controlled (in terms of HbA_{1c}) as shown in DECODE and NHANES studies. This highlights that a more interactive and effective care provision has to be actively pursued to ameliorate the glycemic control of patients with Type 2 diabetes.

Results of the International Diabetes Management Practices Study (IDMPS), year 2: compliance with international guidelines of the management of patients with type 2 diabetes

J. J. Gagliardino;

Faculty of Medical Sciences, CENEXA (UNLP-CONICET), La Plata, Argentina.

Background and Aims: Despite the recommendations of the ADA, EASD and IDF, a large number of people with diabetes are not well controlled. In this regard, our aim was to gather data on current practices in management of people with diabetes worldwide and to evaluate the degree of compliance with international guidelines.

Material and Methods: The IDMPs is an international, multicenter, observational study performed in 27 countries within Africa, Asia, Eastern Europe, the Middle East and Latin America. Data are being collected from people with Type 1 and Type 2 diabetes (≥ 18 years), seen in current medical practice in 1-year cycles (a 2-week cross-sectional recruitment period, followed by a 9-month longitudinal period for Type 2 patients) for 5 years. Here, we report results for people with Type 2 diabetes collected during the second cross-sectional period (Year 2) in 8 countries. In addition to measuring the degree of glucose metabolism control, information about patient education, care delivery and monitoring were collected. Data were analyzed using standard descriptive methods.

Results: 4312 people with Type 2 diabetes (48% men; mean age: 58.3 \pm 11.2 years), were recruited during November and December 2006. The mean BMI was 27.4 \pm 4.4 kg/m² for men and 28.4 \pm 5.6 kg/m² for women. In the past 3 months, patients had visited a specialist in diabetes 1.5 \pm 1.7 (median: 1.0) times and a GP 0.9 \pm 1.5 (median: 0; range: 0–20) times. Diabetes education was provided by diabetes educators to 35% of patients (49% of insulin-treated patients), 2.9 \pm 4.1 (median: 2.0) times within the last 12 months, and was individual in 72.1% of patients being trained. Only 76% of patients had HbA_{1c} tested at least once with a mean of 2.0 \pm 1.2 (median: 2.0) tests within the past year. The mean HbA_{1c} was 8.0 \pm 2.0%. Moreover, only 33% of patients had an

HbA_{1c} <7%. Laboratory testing for FBG was performed 5.3 \pm 7.3 (median: 4.0) times/year. The mean FBG (laboratory) was 158.8 \pm 64.0 mg/dL and only 13% of patients had a FBG \leq 100 mg/dL. Among patients receiving insulin (alone or in combination with oral glucose lowering drugs (OGLD)), 67% had a glucometer at home and 69% self-monitored their blood glucose (SMBG); FBG was monitored by SMBG 11.3 \pm 10.7 (median: 8.0) times/month and post-prandial glucose 7.9 \pm 9.3 (median: 4.0) times/month. Target treatment levels were achieved for blood pressure in 20% of patients, for LDL (<100 mg/dL) in 33%, for HDL (>40 mg/dL) in 62%, and for triglycerides (<150 mg/dL) in 54%. The percentage of patients screened for diabetes complications is given in the Table.

Table. Frequency of screening for diabetes complications.

	Screened at least once within the past year	Never tested
Lipid abnormalities	61%	15%
Cardiovascular disease	51%	21%
Microalbuminuria	47%	33%
Retinopathy	47%	29%
Neuropathy	47%	36%
Diabetic foot ulcer	46%	38%

Conclusion: Our data show that the current management practices of people with Type 2 diabetes poorly complies with most international guidelines. This suggests that improvement of education and commitment of both patients and their care providers is necessary to achieve a more interactive and effective care provision to these patients.

Results of the International Diabetes Management Practices Study (IDMPS), year 2: baseline characteristics and treatment regimens in patients with type 1 diabetes

P. Aschner; on behalf of the IDMPS group,

Oficina de Investigaciones, Universidad Javeriana, Bogota, Colombia.

Background and Aims: Despite the findings of the DCCT, comparing intensive to conventional treatment, and the recommendations of the ADA, EASD and IDF, a large number of patients with diabetes are not well controlled, emphasizing the need for implementation of measures designed to improve the quality of diabetes care. In this regard, our aim was to gather data on current practices in the management of patients with diabetes worldwide and to evaluate the degree of compliance with international guidelines.

Material and Methods: The IDMPs is an international, multicenter, observational study performed in 27 countries within Africa, Asia, Eastern Europe, the Middle East and Latin America. Data are being collected from patients with Type 1 and Type 2 diabetes (≥ 18 years), seen in current medical practice in 1-year cycles (a 2-week cross-sectional recruitment period, followed by a 9-month longitudinal period for Type 2 patients) for 5 years. Here, we report results for patients with Type 1 diabetes collected during the second cross-sectional period (Year 2) in 8 countries. Data were analyzed using standard descriptive methods.

Results: Overall, 940 patients (50.5% men) with Type 1 diabetes were recruited during November and December 2006. The mean age was 34.1 \pm 12.6 years, mean BMI 24.0 \pm 3.9 kg/m² for men and 24.0 \pm 4.8 kg/m² for women, and mean disease duration 11.8 \pm 9.0 years. The mean last available HbA_{1c} was 8.3 \pm 2.0%; 24.4% of the patients had an HbA_{1c} <7%. Mean last available FBG (laboratory) was 163.0 \pm 78.6 mg/dL. The mean systolic/diastolic blood pressure was 120/74 mmHg. Target treatment levels were achieved for LDL (<100 mg/dL) in 43.3% of patients, for HDL (>40 mg/dL) in 75.8%, and for triglyceride (<150 mg/dL) in 81.0% of patients. The mean time since start of insulin therapy was 10.8 \pm 8.5 years and the mean daily dose was 0.75 \pm 0.30 U/kg. A basal + prandial insulin regime was used in 56.1% of patients with a mean daily dose of 0.82 \pm 0.29 U/kg (0.39 \pm 0.21 U/kg for basal insulin and 0.43 \pm 0.21 U/kg for prandial insulin); mean HbA_{1c} was 8.3 \pm 2.0%. Premixed insulin alone was used in 22.3% of patients with a mean daily dose of 0.68 \pm 0.27 U/kg; mean HbA_{1c} was 8.3 \pm 2.1%. Only 14.0% of patients were using basal insulin alone (mean daily dose: 0.53 \pm 0.28 U/kg; mean HbA_{1c}: 8.5 \pm 2.1%) and

0.7% prandial insulin alone (mean daily dose 0.49 ± 0.19 U/kg; mean HbA_{1c} : $7.9 \pm 1.4\%$). Among patients with $HbA_{1c} < 7\%$, 9.4% were treated with basal insulin alone, 61.3% with basal+prandial insulin, 0.6% with prandial insulin alone and 23.2% with premixed insulin alone.

Conclusion: The analysis of data from the second cross-sectional period of the IDMPS (Year 2), shows that the majority of Type 1 patients analyzed did not achieve the recommended treatment goals for HbA_{1c} and FBG. Thus, measures designed to improve these results, probably related to overall education of patients and members of the health care team, are urgently needed to reduce the current and future increases in the demand for care and the costs resulting from this poor diabetes control worldwide.

Results of the International Diabetes Management Practices Study (IDMPS), year 2: baseline characteristics and treatment regimens in patients with type 2 diabetes

S. H. Baik;

Division of Endocrinology, Department of Internal Medicine, Korea University Guro Hospital, Seoul, Republic of Korea.

Background and Aims: Despite the evidence provided by the UKPDS and the recommendations of the ADA, EASD and IDF, a large number of patients with diabetes are not well controlled. In this regard, our aim was to gather data on current practices in the management of patients with diabetes worldwide and to evaluate the degree of compliance with international guidelines.

Material and Methods: The IDMPS is an international, multicenter, observational study performed in 27 countries within Africa, Asia, Eastern Europe, the Middle East and Latin America. Data are being collected from Type 1 and Type 2 diabetic patients (≥ 18 years) seen in current medical practice in 1-year cycles (a 2-week cross-sectional recruitment period, followed by a 9-month longitudinal period for Type 2 patients) for 5 years. Here, we report results for patients with Type 2 diabetes collected during the second cross-sectional period (Year 2) in 8 countries. Data were analyzed using standard descriptive methods.

Results: Overall, 4312 patients with Type 2 diabetes (47.8% men), were recruited during November and December 2006. The mean age was 58.3 ± 11.2 years, mean BMI 27.4 ± 4.4 kg/m² for men and 28.4 ± 5.6 kg/m² for women and mean disease duration 8.3 ± 7.5 years. The mean last available HbA_{1c} was $8.0 \pm 2.0\%$ and 32.7% of patients had an $HbA_{1c} < 7\%$. The mean last available FBG (laboratory) was 158.8 ± 64.0 mg/dL. Mean systolic/diastolic blood pressure was 134/80 mmHg. Target treatment levels were achieved for LDL (< 100 mg/dL) in 32.5% of patients, for HDL (> 40 mg/dL) in 62.0%, and for triglyceride (< 150 mg/dL) in 53.8%. A regimen of diet and exercise was reported in 3.6% of patients (mean HbA_{1c} : $7.4 \pm 1.7\%$). Among patients treated with oral glucose lowering drugs (OGLD) only (66.9%; mean HbA_{1c} : $7.8 \pm 1.9\%$), combined therapy was more frequent than monotherapy (59.7% vs. 40.3%), the preferred combination being sulphonylureas + metformin (more than 80%), and 10.4% of patients received more than two OGLD. Among patients treated with both OGLD and insulin (15.7%; mean HbA_{1c} : $8.7 \pm 2.1\%$; mean insulin dose: 0.46 ± 0.28 U/kg), the mean time since start of insulin therapy was 3.0 ± 3.8 years. The association of OGLD and premixed insulin (mean daily dose: 0.56 ± 0.20 U/kg) was observed in 37.6% of OGLD+insulin treated-patients, and that of OGLD and basal insulin in 60.2% (of whom 10.2% had prandial+basal insulin; mean daily dose of basal insulin alone: 0.33 ± 0.20 U/kg; basal+prandial: 0.38 ± 0.20 U/kg). Among patients treated with insulin only (13.8%; mean HbA_{1c} : $8.4 \pm 2.1\%$; mean insulin dose: 0.75 ± 0.30 U/kg), premixed insulin alone was used in 49.2% of patients, basal insulin alone in 26.3%, basal+prandial insulin in 18.5% and prandial insulin alone in 2.4%. The percentage of patients reaching target $HbA_{1c} < 7\%$ was 37.2% in patients receiving OGLD alone, 16.9% in those receiving OGLD+basal insulin, 19.6% in those receiving OGLD+basal+prandial insulin and 21.3% in those receiving OGLD+premixed insulin.

Conclusion: Our data show that the majority of Type 2 patients analyzed did not achieve the recommended treatment goals for HbA_{1c} and FBG. Thus, measures designed to improve these results are urgently needed to reduce the current and future increases in the demand for care and the costs resulting from this poor diabetes control worldwide.

Association between mean daily dose of insulin in adult type 1 patients and diabetes prevalence in 24 Ukrainian regions

M. D. Khalangot¹, V. I. Kravchenko¹, M. D. Tronko¹, Y. B. Kulchinska¹, A. M. Vaiserman²;

¹Epidemiology, Institute of Endocrinology and Metabolism, Kiev,

²Modelling of Aging, Institute of Gerontology, Kiev, Ukraine.

Background and Aims: We investigated whether insulin requirement in type 1 diabetes (T1D) patients can change systematically and is influenced by the same factors that determine the regional differences in T1D prevalence. For this purpose, we have compared the rate of insulin requirement among T1D adults in 24 Ukrainian regions.

Materials and Methods: Data consists of prevalent cases of T1D in Ukraine by the end of 2006. The completeness of the Ukrainian T1D register is estimated to be 91.1%. Cases are restricted to persons over 14 years at the moment of being added to the Ukrainian register, diagnosed with T1D before age 30 (n=26 796). Prevalence of T1D was calculated based on the official statistical data. 95% confidence intervals were determined through arcsine transformation. Data about HbA_{1c} levels were available for the 1129 persons included in T1D register.

Results: Differences in T1D prevalence among 24 Ukrainian regions were obtained ($\chi^2=648.30$, $p < 0.001$). In the “minimal” regional cluster (MIC) the prevalence rate was 0.60 (0.58–0.62) %; in “intermediate” – 0.68 (0.67–0.69) %; in “maximal” (MAC) – 0.86 (0.83–0.89) %. For 23 633 patients with data about the daily insulin dose (DID) available, the mean disease duration (DD) was 14.86 ± 10.75 years. For patients with DD up to 15 years (n=13 677), DID is increasing linearly with DD (see figure): $DID = 0.73 \times DD + 43.74$ ($R=0.899$, $p < 0.001$). The subsequent increase of DD is not followed by DID rate alteration. The median insulin doses standardized according to DD were lowest in the MIC and highest in the MAC populations: 45.89 (45.28–47.19) and 56.59 (53.33–57.88) units/24h, respectively; $p < 0.01$. The level of HbA_{1c} in the MAC T1D patients was significantly higher than those in the MIC ($9.52 \pm 2.24\%$, n=240, and $8.57 \pm 3.29\%$, n=111, respectively; $p < 0.01$). A positive linear relationship between DID and T1D prevalence in 24 Ukrainian regions was detected.

Conclusion: The obtained linear relationship between DD and DID might be caused by reduction of islet function in T1D patients. Our findings are consistent with those in the literature which noted an inverse linear relation between the residual beta-cell secretion and the duration of type 1 diabetes. It can be suggested that residual insulin secretion in T1D is associated with the regional T1D prevalence.

Fig. 1. Insulin daily doses (mean \pm SE) in type 1 diabetes patients (n=13677) with disease duration up to 15 yrs.

Which patients are suitable for continuous subcutaneous insulin infusion (CSII) in Japanese type 1 diabetes mellitus?

K. Taki, R. Nishimura, Y. Miyashita, K. Fujimoto, N. Tajima; Diabetes and Endocrinology, Tokyo Jikei University school of Medicine, Tokyo, Japan.

Background and Aims: Not many patients with type 1 diabetes mellitus were treated with continuous subcutaneous insulin infusion (CSII) in Japan. In this study, we attempted to determine which patients were suitable for CSII in Japanese type 1 diabetes mellitus.

Materials and Methods: Since March 2005, a total of 21 patients with type 1 diabetes mellitus had been introduced to CSII in our university hospital. We have divided these 21 cases into a CSII effective group, whose difference in Hemoglobin A1c (HbA1c) before introduction of CSII and that after three months was greater than the median, and a CSII ineffective group, whose difference in HbA1c was less than the median. Body mass index (BMI) (kg/m²), age at diagnosis of type 1 diabetes mellitus (years), the duration of type 1 diabetes mellitus (months), age at introduction of CSII (years), Urine C peptide (µg/day), HbA1c (%), total cholesterol (mg/dl), triglycerides (mg/dl), and total daily insulin dosage (IU) were compared between the CSII effective group and the CSII ineffective group. Statistical analyses (t-tests) were performed using SPSS software.

Results: There were 10 cases in the CSII effective group and 11 in the CSII ineffective group. The mean ± standard deviation of HbA1c before introduction of CSII in the CSII effective group (9.6±2.4%) was significantly higher than that of the CSII ineffective group (7.7±6.8%) (p<0.001). No significant differences existed for the other parameters between the CSII effective group and the CSII ineffective group – BMI: 22.0±3.8/23.0±4.6 kg/m² (p=0.62), the duration of type 1 diabetes mellitus: 105.8±94.1/131.9±112.4 (months) (p=0.33), age at diagnosis of type 1 diabetes mellitus 30.5±15.3/ 30.7±20.8 (years), age at introduction of CSII: 39.3±13.1/41.8±13.3 (years) (p=0.74), Urine C peptide: 11.8±9.7/11.9±5.4 µg/day (p=0.40), total cholesterol: 194.0±45.9/169.0 ±39.7 mg/dl (p=0.61), triglycerides: 99.7±33.6/76.0±31.0 mg/dl (p=0.87), and total daily insulin dosage: 41.3±13.3/40.9±12.9 IU/day (p=0.73).

Conclusion: Our results suggest that type 1 diabetes mellitus patients in Japan with poor glycemic control using multiple daily insulin injection therapy should try CSII to improve their HbA1c levels.

0329

Glycaemic control goal attainment among type 2 diabetic patients who initiated oral combination therapy in Europe

G. Krishnarajah¹, F. Alvarez-Guisasola², S. Tofe Povedano³, Q. Zhang¹, G. Nocea Pulfer⁴, D. Yin¹, A. Pfeiffer⁵;

¹Outcomes Research, Merck & Co, White house station, United States, ²Centro de Salud La Calzada II, Gijón, Spain, ³Hospital Son Dureta, Palma de Mallorca, Spain, ⁴Outcomes Research and Pricing Support, Merck Sharp & Dohme de España S.A, Madrid, Spain, ⁵Charité University Medical School Berlin, Campus Benjamin Franklin, Berlin, Germany.

Objective: To assess the level of adequate glycemic control in the real life practice settings in European countries in adult patients with type 2 diabetes mellitus (T2DM) who added a sulfonylurea (SU) or glitazone (PPAR) to metformin(MF) monotherapy.

Materials and Methods: Retrospective clinical chart review and patient survey at the point of visit (June 2006–Feb 2007) were conducted in 7 countries (Finland, France, Germany, Poland, Norway, Spain, and United Kingdom). Patients were aged ≥30 years at time of T2DM diagnosis and added a SU or PPAR to previous MF mono-therapy irrespective of whether those drugs were discontinued afterwards. Patients with gestational DM or T1DM were excluded. All patients gave informed consent. The information of each patient on HbA1c, medication use and co-morbid conditions were extracted from their clinical charts, for up to 7 months baseline period (before SU or PPAR addition) and for a minimum of one year follow-up period (between therapy addition and date of survey). Glycemic goal attainment at HbA1c < 6.5% was assessed according to the IDF (2005) recommendations using the last available HbA1c value during follow-up.

Results: 2039 patients (75.3% initially added SU to MF and 24.7% added PPAR) were included with mean age 62.9 yrs (SD 10.5), average 8.1 yrs (SD 5.1) of T2DM duration, 54.7% males, and 96.9% Caucasians. (Tab. 1)

Conclusions: In this study involving seven European countries, after adding a SU or PPAR to their MF monotherapy, approximately 74% of patients with T2DM failed to attain glycemic control goal. More tolerable and effective oral hypoglycemic therapies may be needed to help these patients attain and maintain goal.

0330

An evaluation of glycaemic control following switching from soluble regular human insulin to either insulin lispro or other analogue insulins in people with type 1 diabetes in UK general practice

C. D. Poole¹, C. J. Currie², A. J. Tynan³, A. Simpson³;

¹Healthcare Research, 360° Research, Penarth, United Kingdom,

²Department of Medicine, Cardiff University, United Kingdom,

³European Health Outcomes Research, Eli Lilly and Company Limited, Windlesham, United Kingdom, ⁴European Medical Department, Eli Lilly and Company Limited, Windlesham, United Kingdom.

Background and Aims: Switching treatment can occur for a variety of reasons. A number of short acting insulin (SAI) treatments are available and used mainly to improve prandial glucose control. The purpose of this study was to evaluate the impact of switching from an insulin regimen that included soluble regular human insulin (RHI) to a similar regimen that included either insulin lispro (IL) or an alternative short acting insulin analogue (IA) as short acting insulin analogue (SAIA) therapies.

Materials and Methods: Data were extracted from the General Practice Research Database (GPRD), a resource that describes the primary care histories of around 7% of the UK population. Among all subjects with type 1 diabetes (T1DM) who switched between either RHI or SAIA, the vast majority (96.6%) had been given RHI as their first prescription for short-acting insulin, and thus formed the focus of this study. Subjects with T1DM were selected having been treated with RHI for at least one year prior to switching to one SAIA, and had continued for at least one year with no other change in insulin therapy over these two years. Interpolated paired-sample comparisons of HbA1c were made for the four quarterly periods post-switching.

Results: 438 people switched from RHI to IL (RHI-IL) and 477 patients switched from RHI to IA (RHI-IA). The patient characteristics in each group with T1DM were as follows for RHI-IL and RHI-IA, respectively: age, 38.2 and 39.0 years (p=0.428); percent male, 53.4% and 58.7% (p=0.110). In both groups HbA1c decreased significantly from baseline to Q1 (−0.12%, p<0.001);

Tab. 1

Country	N	HbA1c at baseline (%) mean±SD*	HbA1c during follow-up (%) mean±SD*	Mean HbA1c change from baseline (%) mean±SD*	Goal attainment rate during follow-up at HbA1c < 6.5%*
Total	2039	8.1±1.4	7.2±1.1	0.90±1.5	25.8%
Finland	195	7.8±1.2	7.2±1.2	0.6±1.3	29.7%
France	163	8.1±1.4	7.1±1.0	1.1±1.7	28.8%
Germany	410	7.8±1.4	7.1±1.0	0.7±1.3	24.6%
Norway	64	8.6±1.8	7.4±1.1	1.2±1.9	17.2%
Poland	296	7.8±1.1	7.1±1.1	0.7±1.2	28.0%
Spain	502	8.0±1.5	7.1±1.3	0.8±1.6	30.5%
United Kingdom	409	8.6±1.4	7.3±1.2	1.3±1.4	17.9%

* Indicates significant difference among countries, at p<0.05

Q2 (−0.18%, $p < 0.001$); Q3 (−0.27%, $p < 0.001$); and Q4 post-switching (−0.30%, $p < 0.001$). Patients switched to lispro showed a trend towards greater improvement in glycaemic control than those switched to other analogue insulins (Q3 average improvement −0.38% vs. −0.20%, respectively [$p = 0.065$; Figure]).

Conclusion: Patients with T1DM treated in UK general practice showed significant improvement in glycaemic control when switched from soluble regular human insulin to short-acting insulin analogues. There was evidence of insulin lispro being more effective in improving glycaemic control than other insulin analogue therapies, though this study was under-powered (60%) to detect a statistically significant difference at the 5% level.

Compliance to treatment and reaching metabolic goals are better in OAD treated diabetics than insulin treated diabetics in Turkish population

S. Ucak, E. Satir, D. Tural, T. Kilicdagi, K. Aydin, S. Dal, I. Hacibekiroglu, A. Cifcibasi, T. Hacibekiroglu, O. Basat, Y. Altuntas; Endocrinology & Metabolism, Sisli Etfal Research and Training Hospital, Istanbul, Turkey.

Background and Aims: The aim of this study was to assess the success rates of reaching HbA1c goals in different treatment groups.

Materials and Methods: This was a single-centre, retrospective study including 3000 patients admitted to our diabetes outpatient clinic as a primary care unit after year of 2005. All data obtained from patients files which were archived in our outpatient clinic. Duration of disease, type of diabetes, HbA1c levels (3 months intervals in a year), type of treatment were evaluated. All parameters were also evaluated at the end of a year long follow up. HbA1c levels were compared at the beginning and the end of the study. Rate of patients reaching the HbA1c goals according to IDF, AACE and ADA were determined. A p value less than 0.05 was considered significant.

Results: A total number of 3000 diabetic patients were recruited for the study. 3.1% of patients had type 1 diabetes mellitus and 96.9% had type 2 diabetes mellitus. Female rate was 58.2% while male rate was 41.8%. There were 4 different treatment groups. 1-Diet group ($n = 140$), 2-OAD group (excluding glitazones) ($n = 1238$), 3-insulin group ($n = 765$), and 4- insulin+ OAD group ($n = 812$). According to IDF and AACE criteria rate of patients reaching $HbA1c \leq 6.5\%$ was 32% in total group. At the end of one year it was 45%. In diet group 92% of patients and one year later 100% of patients reached the goals. In OAD group The rate was 61% and next year it was 69%. In insulin group 15% of patients and one year later 33% of patients reached the goal HbA1c levels. In insulin+ OAD group rates were 10% and 21% respectively. All these changes were statistically significant ($p < 0.05$). According to ADA

criteria patients reaching HbA1c levels $\leq 7\%$ were 40% in total group and the end of one year 59%. In diet group 95% of patients and one year later 100% of patients reached the goals. In OAD group the rate was 75% and next year it was 83%. In insulin group 23% of patients and one year later 52% of patients reached the goal HbA1c levels. In insulin+ OAD group rates were 16% and 32% respectively. All these changes were statistically significant ($p < 0.05$). In OAD group number of visits were decreasing while HbA1c levels were increasing ($r = -0.2$, $p = 0.001$). In insulin group similar correlation was observed between number of visits and HbA1c levels ($r = -0.2$, $p = 0.005$).

Conclusion: A big number of patients with diabetes mellitus seem to reach HbA1c goals in different treatment groups. Especially the rate was greater in OAD group than insulin group. This might be due to the fact that patients under OAD treatment have a shorter duration of diabetes and their better compliance to therapy regimen.

PS 9 Diabetes mortality and hospitalisation in different populations

0332

Diabetes mortality in Serbia 1980–2005: characteristics and trends

I. Rakocevic, D. Miljus, J. Malogajski, S. Plavsic, J. Jankovic, N. Mickovski, S. Zivkovic, S. Savkovic;

Department for prevention and control of noncommunicable diseases, Institute of Public Health of Serbia, Belgrade, Serbia.

Background and Aims: In 1980 there were 960 deaths (2%) for which diabetes was certified as the underlying cause of death in Serbia. Diabetes related death rate had been steadily increasing since that period. Today diabetes is the 5th leading cause of death and the 5th leading cause of burden of disease in the country. The purpose of this work is to determine the characteristics and trends of diabetes mortality among the Serbian population from 1980 through 2005 and to provide suggestions to health policy-makers.

Materials and Methods: Deaths caused by diabetes mellitus occurred during the period 1980–2005 were obtained. For each gender the following parameters were calculated: crude mortality rates and standardized rates by means of the direct method using the World population as standard, for the 25 years studied. Trend analysis in mortality was performed using a regression model. Standardized rates were adjusted to a regression straight line regarding the death year and theoretical rates were calculated. With these calculations the percentages in changes of mortality rates were estimated and a projection has been calculated until the year 2015.

Results: The significant increasing trend of diabetes mortality in Serbian population during the 25-yr study period is observed ($p < 0.001$). Standardized mortality rates due to diabetes mellitus had increased from 9.37/100,000 to 13.48/100,000 in males and from 10.78/100,000 to 13.40/100,000 among females over the study period. From 1980 to 2005 females had a higher mortality than males, however diabetes mortality rates among males increased significantly (43.8%) compared to females (24.4%), with annual percentage change for both genders 1.3. Regression-based linear trends in diabetes mortality indicate an even growth in all age groups, although the annual percentage change is most prominent in the 75–79 yr age group for females (2.1%/yr) and in the 80–84 yr age group for males (2.8%/yr). Projections of diabetes mortality trends into the year 2015 show linear increase for both genders.

Conclusion: Our results indicate that diabetes mortality has been markedly increasing in the Serbian population, primarily in males and persons aged 65 years or more. These findings could be related to population aging, increased prevalence of obesity and sedentary lifestyle. It also highlights the need for targeted diabetes prevention and treatment. Three main strategies are proposed to deal with the problem: develop national policies, strategies and plans for prevention and care; promote and implement community participation in prevention and care; specific monitoring of health and quality of care in elderly people with diabetes.

0333

Mortality risk in children and young adults with type 1 diabetes: the population-based registry of the Province of Turin, Italy

G. Novelli¹, G. Bruno¹, F. Cerutti², A. Soddu¹, S. Piano¹, C. Tringali¹, B. Aimone¹, P. Cavallo Perin¹, G. Pagano¹;

¹Internal Medicine, University of Turin,

²Dept. of Pediatrics, University of Turin, Italy.

Background and Aims: Studies performed in Northern European countries have reported two-fold higher mortality risk in young people with type 1 diabetes than in general populations. As most of early diabetes-related deaths (diabetic ketoacidosis, hypoglycemia) could have been prevented, monitoring the number of these cases over time is relevant to assess whereas quality of diabetes care should be improved. We have assessed mortality risk in an Italian incident cohort with type 1 diabetes onset in period 1974–2000.

Materials and Methods: Two lists of incident people with type 1 diabetes in the Province of Turin, Italy were employed: 1) the hospital-based cohort of cases aged 0–14 years in the period from January 1, 1974 to December 31, 1983, identified through the regional paediatric hospital ($n = 157$, completeness of ascertainment 95%); 2) the population-based cohort of incident cases aged 0–29 years in the period from January 1, 1984 to December 31, 2000

($n = 1056$, completeness of ascertainment 99% in age-group 0–14 yrs; 97% in age group 15–29). The relevant time scale for the analysis was time since diabetes onset to death or to 31 December 2003. Information about deaths and the causes of death was obtained from the demographical files of towns of residence, hospital discharges and autopsy records. Only three patients were lost to follow-up. Mortality rates were calculated dividing the number of deaths occurring during the study period by the number of person-years of observation. Standardized mortality ratios (SMRs) for all-cause mortality were computed using the Italian population as standard, by 5-yr age-group, sex, and calendar period (1974–83, 1984–88, 1989–93, 1994–98 and 1999–2003).

Results: The study base included 1213 incident cases in period 1974–2000; at the onset of the disease, 677 were aged 0–14 yrs and 536 were aged 15–29 yrs. During mean follow-up of 15.8 yrs (range 1.96–29.9), there were 19 deaths in 15 967.9 person-years of observations, giving an all-cause mortality rate of 1.19/1000 person-years (95% CI 0.76–1.87). With respect 9.54 expected deaths, we observed 19 cases, giving an SMR 1.96 (1.25–3.08), with a tendency toward lower excess in incident cases in childhood (SMR=1.84, 95% CI 0.92–3.67) than in adulthood (SMR=2.06, 95% CI 1.14–3.73), although not statistically significant. Mean duration of diabetes was 13.4 (SD 7.4, range 2.0–24.4) in people who died and 13.3 (7.4) in those who survived. In no case death occurred at the time of diabetes onset or in childhood. Out of 19 deaths, 8 were clearly diabetes-related (diabetic ketoacidosis, hypoglycemia, end-stage renal disease).

Conclusion: this report of the population-based registry of the Province of Torino points out that children and young adults with onset of diabetes in period 1974–2000 experienced a two-fold higher mortality risk than Italian people of similar age and sex. The impact of the disease on survival might be declining over time, and monitoring the number of these events over time is crucial as these data may serve as a reflection of the quality of health care in the community.

0334

All-cause mortality in hospitalized patients with type 2 diabetes mellitus

P. S. Koureta, A. Angelis, A. Kramvis, A. E. G. Alaveras;
1st Medical Department, Red Cross Hospital, Athens, Greece.

Background and Aims: Many clinicians believe that diabetes mellitus exerts an excess risk of death among those patients need to be hospitalized for any reason. Although certain complications, such as cardiovascular disease are certainly more common among diabetic patients, others like common infections and in-hospital mortality related to those complications are not well studied.

Materials and Methods: A retrospective cohort study was conducted, comparing all patients with any common infection hospitalized in our clinic during a decade, (1990–2000), to matched patients hospitalized for any reason other than infection. The risk ratios of death attributable to diabetes mellitus, as well as to infectious or cardiovascular disease between those with and without diabetes were calculated, using multiple logistic regression analysis models. The results were adjusted for possible confounding factors (age, sex and history of cancer).

Results: The cohort consisted of 4959 patients, 2583 hospitalized for any common infection (491 (19.01%) with diabetes and 2092 without) and 2376 matched for age and sex patients, hospitalized for any reason other than infection (337 (14.18%) with diabetes and 2039 without). The risk of acquiring an infectious disease was 47% higher for diabetic patients compared to those without diabetes (OR=1.47 95% CI 1.23–1.77 $p < 0.001$). There were 96 (11.59%) deaths among the 828 diabetic patients and 406 (9.83%) deaths among 4131 non-diabetic patients. The overall risk of death, for patients hospitalized for any reason, did not differ between patients with and without diabetes (OR=0.91 95% CI 0.53–1.56). The risk of death did not differ between diabetic and non-diabetic patients with concomitant cardiovascular disease (interaction OR=0.98 95% CI 0.58–1.66) or any common infection (interaction OR=1.23 95% CI 0.71–2.16). Generally, the risk of death was about six times higher for patients hospitalized with cardiovascular disease (OR=5.6 95% CI 3.69–8.59 $p < 0.001$) and about two times higher for patients hospitalized with any common infection (OR=2.1 95% CI 1.57–2.74 $p < 0.001$), compared to patients hospitalized for any other reason.

Conclusion: Although patients with diabetes mellitus are more prone to complications such as common infections, they do not seem to suffer an excess risk of dying when they need to be hospitalized for any reason, even for those diabetic patients with concomitant cardiovascular disease or any common infection.

0335

Changes in mortality pattern over the last six decades in type 2 diabetes patients with onset between 30 and 60 yearsS. Ioacara¹, C. Ionescu-Tirgoviste¹, E. Farcasiu¹, O. Bradescu¹, C. Guja¹, M. Pallayova²;¹“N. Paulescu” Institute of Diabetes, Bucharest, Romania,²Physiology and Sleep Laboratory, PJ Safarik University, Kosice, Slovakia.

Background and Aims: To analyze the changes in age at onset, disease duration, age at death and cause of death in patients with noninsulin-treated Type 2 Diabetes Mellitus (T2DM) deceased between 1943 and 2005.

Materials and Methods: We performed a retrospective study in noninsulin-treated T2DM patients, registered at Bucharest Diabetes Centre, Romania and deceased between 1943 and 2005. We analysed 5856 deaths, 3299 (56.3%) males (M) and 2557 (43.7%) females (F). For each patient, the age at diabetes onset, disease duration, cause of death and sex were recorded. Body mass index (BMI) at onset was obtained for a subgroup of 2632 cases. Statistical analysis used (non)parametrical tests as appropriate.

Results: The major changes in mortality according to 6 “decades” of year of death are presented in table 1.

Overall, comparing with females, males had a significantly lower age at onset (52.1±6.0 years M vs. 53.0±5.7 years F, $p<0.001$), age at death (65.0±9.0 years M vs. 65.6±8.7 years F, $p=0.005$) and BMI (27.1±4.3 Kg/m² M vs. 28.8±5.4 Kg/m² F, $p<0.001$); there was no difference by gender for disease duration (12.8±8.2 yrs.). The major causes of death during the 1996–2005 period were: cardiovascular diseases (60.8%, from which 18.6% stroke), malignancies (17%), diabetes (6.8%), gastrointestinal and hepatic diseases (6.2%), infectious diseases (4.9%), chronic renal failure (1.2%), diabetes coma (0.1%) and others (3%). The percentage of infectious diseases related deaths decreased 3.4 times from 1943 to 2005, while cardiovascular diseases related deaths rose 1.5 times during the same period.

Conclusion: Comparing the 1996–2005 with the 1943–1955 period, we found no significant change in age at onset, 8.2 years increase ($p<0.001$) in mean disease duration at death (also clearly showed by the Kaplan-Meier survival curves, Log rank test $p<0.001$), 7.8 years increase ($p<0.001$) in mean age at death and 3.3 Kg/m² increase in mean BMI at onset. Males have a significantly lower age at death than females, not because of a lower survival period but because of a lower age at diabetes onset. The percentage of infectious diseases related deaths decreased 3.4 times from 1943 to 2005, while cardiovascular diseases related deaths rose 1.5 times during the same period.

0336

Insulin titration; gaining an understanding of the burden of type 2 diabetes in Europe (INSTIGATE): number of French patients admitted in hospitals at time of insulin initiationM. A. Charles¹, S. Tcherny-Lessenot², J. Pentel², C. Salaun-Martin², L. Timlin³, S. Cleall³, F. Fagnani⁴;¹INSERM, U780, Villejuif, France, ²Lilly France, Suresnes, France,³EHOR, Eli Lilly and Company, Windlesham, United Kingdom,⁴D. Cemka Eval, Bourg La Reine, France.

Background and Aims: INSTIGATE study provides data from clinical practice on people with Type 2 diabetes who have not achieved adequate glycaemic control and are being initiated on insulin therapy. Objective of this analysis is to describe baseline characteristics of French patients enrolled in the study in terms of demographics, diabetes history, glycaemic control, and resource utilization.

Materials and Methods: 580 physicians (470 diabetologists and 110 primary care physicians), selected by a stratified random procedure respectively from a database of 1000 diabetologists and a database of 300 primary care physicians high prescribers of insulins, were solicited to participate in the study. Among them, 65 physicians (50 diabetologists and 15 primary care physicians) accepted to participate. To date, 41 physicians (34 diabetologists (18 in hospitals and 16 in private practice) and 7 primary care physicians) have enrolled at least one patient. Data on the 178 patients enrolled in France were analyzed.

Results: Enrolled patients (male 57%) had a mean age of 64.8± 11.2 (SD) and mean BMI of 29.4 ± 6.2 (SD). They had been diagnosed diabetes 13.0± 8.1 (SD) years ago with a mean HbA1C at diagnosis of 8.9 ± 2.3 (SD). At time of insulin initiation, 50% of patients were inpatients. In the previous 6 months, 28.2% were admitted at hospital at least once, mean duration of stay was 6.4 ± 2.7 days for acute complications and 4.1± 3.5 days for long-term complications, 87.4% consulted their primary care physician, 75.3% consulted their endocrinologist. In the previous 12 months, patients received one antidiabetic medication in 15.2% of cases, 2 in 40.4%, 3 in 30.3% and more than 4 in 9.6%. The most frequent treatment observed was progression from 1 to 2 oral therapies and then to insulin for 23.0% of patients. Other treatments frequently observed were: progression from double oral therapy to insulin in 18.4%, progression from 1 to 2 and to 3 oral agents and then to insulin 12.6%, and progression from single oral therapy to insulin in 12.1%.

Conclusion: In our sample of French patients enrolled in INSTIGATE study, half of patients were admitted to the hospital to initiate insulin therapy. There are a number of treatment pathways followed by patients prior to insulin initiation.

Patients with type 2 diabetes in hospitals. Therapy and diabetic complications assessment of 11.197 in-patients from 153 medical centres in Poland

B. Kozłowska-Boszkó, T. Lietz, M. Wronka, P. Markiewicz;

Medical Department, Bayer Schering Pharmaceuticals, Warsaw, Poland.

Background and Aims: The aim of the study was to assess the clinical profile of type 2 diabetes (T2D) patients hospitalized for various reasons in Polish medical centres. We evaluated type and quality of antidiabetic treatment before the admission, type of diabetic complications and reasons for hospitalization.

Materials and Methods: This non-interventional, cross-sectional study, involving 11 197 in-pats (46% men, 54% women, age 61±11 and 62±11 yrs, respectively), was conducted between April 2005–March 2007 in 153 medical centres in Poland. For each patient information on demographic data, diabetes diagnosis and complications was documented by the physician using the standardized individually-numbered case-report form. Information about treatment prior to hospital admission was also collected. A biometric evaluation was carried out according to a statistical analysis plan at the end of the study.

Results: Diabetes and diabetes-related complications were the main reason for hospitalization and involved 75,5% of all admission causes. The prevalence of cardiovascular complications was significantly higher than that of microvascular complications (64,6% vs 49,7%; $p<0,05$). The most prevalent cardiovascular diseases (CVD) included hypertension, coronary heart disease and congestive heart failure which were responsible for hospital admission of 37,2%, 20,2% and 13,5% of all pts, respectively. In patients with early diagnosed T2D (< 1 year before hospitalization) the prevalence of

Table 1

Year of death	1943-1955	1956-1965	1966-1975	1976-1985	1986-1995	1996-2005
n	278	387	1605	1706	715	1165
Age at onset (years)	53.1±5.9	51.8±6.2*	52.7±5.8 ^{NS}	52.2±6.1*	52.3±6.0 ^{NS}	52.7±5.5 ^{NS}
Disease duration (years)	6.0±3.8	11.6±7.2**	11.3±7.2**	13.5±8.1***	15.4±8.6***	14.2±9.1***
Age at death (years)	59.2±7.2	63.4±8.4**	63.9±8.0**	65.8±8.9***	67.8±8.9***	66.9±9.4***
BMI (Kg/m ²)	-	25.7±3.4	27.2±4.6 ^{NS}	28.0±4.6***	28.3±5.0***	29.0±6.8***

^{NS} not significant, * $p<0.05$, ** $p<0.01$, *** $p<0.001$ vs. first available “decade”

CVD was significantly higher than the prevalence of microvascular diabetic complications (42% vs 21%; $p < 0.05$). Despite the marked increase in the rate of microvascular complications observed in pts with advanced T2D (diagnosis > 5 yrs before hospitalization), CVD remained the most prevalent complication (73% vs 66%; $p < 0.05$). The quality of diabetes control was rated by doctors as “good” only in 5.3% of all patients, independent of time of T2D diagnosis. Sulphonylureas and metformin were used prior to hospital admission by 55% and 37% of patients, respectively. The usage of alpha-glucosidase inhibitor, acarbose, was low (7.8%), however, it was significantly higher in pts with advanced diabetes in comparison with pts with early T2D diagnosis (10.9% vs 4.4%; $p < 0.05$).

Conclusion: Our study shows that CVD is the leading cause of hospital admissions of diabetic patients in Poland. Hypertension, coronary heart disease and congestive heart failure are the main reasons for hospitalization. The prevalence of CVD is very high even in patients with early diagnosed T2D. In Poland sulphonylureas and metformin are most often prescribed oral hypoglycemic drugs, however the quality of diabetes control remains low, even in doctor’s opinion.

Cardiovascular disease prediction and type 2 diabetes: Framingham risk versus metabolic syndrome criteria

J. Saumell¹, J. J. Cabre², J. L. Piñol³, M. Baldrich², F. Martin², B. Costa⁴, J. Basora³;

¹Basic Health Area Reus-4, ²Basic Health Area Reus-1,

³Central Service Primary Care Reus,

⁴Basic Health Area Reus-2, Catalan Health Institute, Reus, Spain.

Background and Aims: Is not well established if the Metabolic Syndrome (MS) is better predictive of cardiovascular disease (CVD) than other methods, like Framingham risk score (FRAM). So, the objective is comparing the MS criteria (according to NCEP-ATPIII) with the Framingham risk score in the prediction of CVD and of type 2 diabetes (T2D).

Materials and Methods: Prospective cohorts study of 8 year follow-up (1998–2005), in two Basic Areas of urban Health (43.000 individuals). Randomized sample of subjects older than 40 years, registering sociodemographic data and those precise for the calculation of the FRAM and MS approaches (NCEP-ATPIII) (range 0–5 components); cardiovascular events and incident cases of T2D. The statistical tests (ROC curves and areas under the curve (AUC)) were carried out separately for genders (because the MS criteria differs).

Results: 943 individuals between 40–75 years (applicable margin to FRAM) (588 women). The MS was good predictor of CVD in men and women (AUC 0.63/0.68, respectively) and of incident cases of T2D in women (AUC 1.0, front 0.45 in men). On the other hand, the FRAM was better predictor of CVD in men (AUC 0.72 front 0.68 in women) and only predicted well new cases of T2D in women (AUC 0.87 front 0.22 in men).

Conclusion: The presence of MS is good predictor of CVD and of new cases of T2D, but mainly of these last. Although the MS doesn’t predict the CVD the same as the FRAM, it’s useful like easy tool of detection of subjects at high risk.

Results of the International Diabetes Management Practices Study (IDMPS), year 2: cardiovascular risk factors in patients with type 2 diabetes

N. Hancu; on behalf of the IDMPS Group,

Clinical Center of Diabetes, Nutrition and Metabolic Diseases, Iuliu Hatieganu University of Medicine, Cluj-Napoca, Romania.

Background and Aims: Despite the recommendations of the ADA, EASD and IDF, a large number of patients with diabetes are not well controlled. In addition, patients with Type 2 diabetes are exposed to arterial hypertension and dyslipidemia and thus a further increased cardiovascular risk. We aimed to gather data on current practices in the management of patients with diabetes worldwide and to evaluate compliance with international guidelines.

Material and Methods: The IDMPS is an international, multicenter, observational study performed in 27 countries within Africa, Asia, Eastern Europe, the Middle East and Latin America. Data are being collected from patients with Type 1 and Type 2 diabetes (≥ 18 years) seen in current medical practice in 1-year cycles (a 2-week cross-sectional recruitment period, followed by a 9-month longitudinal period for Type 2 patients) for 5 years. Here, we report preliminary results from patients with Type 2 diabetes collected during the second cross-sectional period (Year 2) in 8 countries. To measure the degree of glucose metabolism control, HbA_{1c} and FBG values were collected in addition to information on blood pressure and lipid level control. Data were analyzed using standard descriptive methods.

Results: 4312 patients with Type 2 diabetes (47.8% men; mean age: 58.3 \pm 11.2 years) were recruited during November and December 2006. The mean last available HbA_{1c} was 8.0 \pm 2.0%. In addition, only 32.7% of patients had an HbA_{1c} <7%, although all patients were receiving some form of anti-diabetic therapy; 37.3% of patients were considered to be on target according to the physician’s opinion, and among these the mean HbA_{1c} was 6.7 \pm 1.3%. The mean values of other cardiovascular risk factors were as follows: systolic/diastolic blood pressure: 134/80 mmHg; LDL: 133.2 \pm 132.6 mg/dL (median: 115.0); HDL: 48.6 \pm 31.0 mg/dL (median: 44.0); triglycerides: 179.5 \pm 167.9 mg/dL (median: 141.0). Among 3342 patients with SBP ≥ 130 mmHg and/or DBP ≥ 80 mmHg, 1044 were not reported by the physician as having hypertension

and 2298 were reported as having hypertension, of whom 2222 were receiving antihypertensive treatment (Table). Similar results were found for patients with dyslipidemia (Table).

Table.

Risk factor (no. of patients**)	Not diagnosed*	Diagnosed*	
		Treated	Not treated
Hypertension*** (n=3342)	31.2%	66.5%	2.3%
LDL > 100 mg/dL (n=1506)	27.8%	60.1%	12.1%
HDL < 40 mg/dL (n=916)	25.6%	63.5%	10.9%
Triglycerides > 150 mg/dL (n=1400)	16.4%	68.1%	15.5%

*based on physicians' reporting; **for whom information on physician classification was available ***SBP \geq 130 mmHg and/or DBP \geq 80 mmHg
The percentage of patients reaching the triple target of HbA_{1c} <7%, blood pressure <130/80 mmHg and LDL <100 mg/dL was only 1.7%.

Conclusion: Our data show that patients with Type 2 diabetes are poorly controlled, in terms of HbA_{1c} and other cardiovascular risk factors, despite having had full access to specific drugs treating all these conditions. This suggests that more appropriate guidance, education and commitment are necessary to optimize the effective use of drug therapy by patients with Type 2 diabetes worldwide.

Increased prevalence of cardiovascular disease and risk biomarkers in patients with unknown type 2 diabetes visiting cardiology specialists – results from the DIASPORA Study

T. Schönendorf¹, E. Karagiannis², E. Erdmann³, G. Lübben³, B. Jenke¹, M. Löbig⁴, T. Forst¹, A. Pfützner¹;

¹IKFE Institute for Clinical Research and Development, Mainz, Germany,

²Diabetes, Takeda Pharma, Aachen, Germany,

³Cardiology, University Hospital, Cologne, Germany.

Background and Aims: Patients with Type 2 Diabetes suffer from excess cardiovascular risk and mortality. Early improvement of glycemic control and treatment of metabolic and vascular insulin resistance is required to improve patients' prognosis.

Materials and Methods: We performed this analysis of the patient population participating in the cross-sectional DIASPORA trial to investigate, whether knowledge about the glycemic disease status of patients visiting a specialist cardiology ward is associated with a different prevalence of macrovascular disease and plasma concentrations of several cardiovascular risk markers. The participating sites were asked to include 30 consecutively appearing patients at risk or confirmed of having CAD, without any other exclusion criteria. Patients with known diabetes mellitus were documented and patients with unknown glycemic status were asked to participate into a 75g oral glucose tolerance test (OGTT). A blood sample was drawn for assessment of cardiovascular risk parameters (hsCRP, lipids, IL-6, MMP-9, MCP-1, sCD40L, ICAM, VCAM, E-selectin). Prevalence of macrovascular diseases (infarction (MI), stroke, angina pectoris (AP), peripheral or coronary artery disease) was assessed by a standardised questionnaire.

Results: A total of 539 patients with complete data sets could be included into the analysis (355 women, 184 men, age(mean \pm SD): 68 \pm 7 yrs). Patients without diabetes (NoD; n = 184) had a lower prevalence of macrovascular disease (58 %) than patients with previously unknown diabetes (NEW; n = 84, 73 %, p<0.05 vs. non-diabetic group) or patients with impaired glucose tolerance or impaired fasting glucose (IGT; n = 115, 70 %, p=0.077; patients with known diabetes: OLDD; n = 156, 65 %, n.s.). An impaired laboratory risk marker profile was seen in patients with unknown diabetes or IGT vs. the non-diabetic group for hsCRP (e.g. NEW; 3.6 \pm 2.6 mg/l vs. NoD: 2.8 \pm 2.1 mg/l, p<0.05); MMP-9 (637 \pm 529 vs. 441 \pm 302 ng/ml, p<0.001); VCAM (810 \pm 319 vs. 707 \pm 235 ng/ml, p<0.005); E-selectin (62 \pm 29 vs. 43 \pm 19 ng/ml, p<0.001), which was accompanied by a significantly higher prevalence of MI and AP (NEW/IGT vs. NoD: p<0.05 in both cases). No significant differences between the groups were seen for IL-6, ICM, sCD40L, MCP-1, or the lipid values.

Conclusion: Patients visiting cardiology specialists with previously unknown deterioration of glycemic control (diabetes or IGT) had a higher prevalence

of macrovascular disease and an impaired laboratory risk marker profile as compared to patients with treated diabetes or without the disease. Our study confirms the importance of early diagnosis and appropriate treatment of diabetes patients suffering from macrovascular disease.

0341

Risk of coronary artery disease associated with initial sulphonylurea treatment of type 2 diabetes: a matched case-control study

S. M. Sadikot;

Jaslok Hospital & Research Centre, Mumbai, India.

Background and Aims: Although glycemic control reduces cardiovascular risk, there have been concerns about reducing blood sugar with sulphonylureas. These agents are not entirely specific for beta cells, but also bind to ATP sensitive potassium channel receptors in the heart that could prevent ischemic preconditioning. Sulphonylureas are frequently prescribed as initial monotherapy or with the addition of metformin for up to 10 years, and may influence the risk of coronary events. However, the possible association between sulphonylurea treatment at diagnosis of diabetes and the subsequent development of CAD has not been studied. Further, newer sulphonylureas have a lower binding affinity to cardiac ATP sensitive potassium channel receptors and may not harm the heart. The aim of this CAD risk matched, case control study was to assess the association between different initial sulphonylurea treatments and the subsequent development of acute coronary events in type 2 diabetic patients.

Material and Methods: In a multicenter, retrospective, matched, case control study conducted in India, on type 2 diabetic outpatients with a complete case record going back to the date of diagnosis, with no history of CAD at the first clinical examination, the estimated 20 year CAD risk at diagnosis was calculated using the UKPDS risk engine. Cases were defined as patients who developed CAD during the period between the diagnosis of type 2 diabetes and the date of selection. Controls were identified as those patients free of CAD up-to the date of selection. The matching variable was the 20-year CAD risk score at diagnosis of diabetes. The odds-ratio of the retrospective frequency with which cases and controls received glibenclamide, glipizide, glimepiride, gliclazide or metformin as the first drug at diagnosis, or as the second add on drug was used to estimate the relative risk of CAD associated with the initial use of each drug.

Results: In 2733 patients free of CAD at diagnosis of type 2 diabetes, 76 developed stable angina, unstable angina or myocardial infarction. The remaining 2657, provided 152 matched controls. The hazard of developing CAD (95% CI) increased by 2.4 fold (1.3 to 4.3, P=0.004) with glibenclamide, 2 fold (0.9 to 4.6, P=0.099) with glipizide, and 2.9 fold (1.6 to 5.1, P= 0.000) with either. The hazard decreased 0.3 fold (0.7 to 1.7, P=0.385) with glimepiride, 0.4 fold (0.7 to 1.3, P=0.192) with gliclazide, and 0.4 fold (0.7 to 1.1, P=0.09) with either. There was no risk of CAD with metformin (Table 1).

Conclusion: Initiating treatment of type 2 diabetes with glibenclamide and glipizide is associated with increased risk of CAD in comparison to gliclazide

Table 1: Risk of developing coronary artery diseases with initial oral hypoglycaemic treatments in type 2 diabetes

Initial drug		Cases with CAD (n=76)	Controls without CAD (n=152)	Odds ratio (95% CI)	P
Glibenclamide	Yes	31	34	2.4 (1.3-4.3)	0.004
	No	45	118		
Glipizide	Yes	12	13	2.0 (0.9-4.6)	0.099
	No	64	139		
Glimepiride	Yes	7	20	0.7 (0.3-1.7)	0.385
	No	69	132		
Gliclazide	Yes	11	33	0.6 (0.3-1.3)	0.192
	No	65	119		
Older agents (Glibenclamide or Glipizide)	Yes	43	47	2.9 (1.6-5.1)	0
	No	33	105		
Newer agents (Gliclazide or Glimepiride)	Yes	18	53	0.6 (0.3-1.1)	0.09
	No	58	99		
Metformin	Yes	19	37	1.0 (0.5-2.0)	0.913
	No	57	115		

or glimepiride. If confirmed, this may be important because present guidelines do not distinguish between individual sulfonylureas. (Tab. 1)

Longitudinal study of primary and secondary medication adherence for cardometabolic therapies associated with type 2 diabetes

A. J. Karter¹, M. M. Parker², H. H. Moffet², J. Y. Liu², A. T. Ahmed²;

¹Division of Research, Kaiser Permanente, Bainbridge Island,

²Division of Research, Kaiser Permanente, Oakland, United States.

Background and Aims: Medication non-adherence is well-documented, but may be underestimated. Pharmacy databases reveal medication dispensing (utilization) but generally not prescribing data. Thus, “primary non-adherence” (i.e., prevalence of patients who never fill a new prescription) could not be obtained from electronic pharmacy records alone. Further, refill-based adherence measures (e.g., proportion of days not covered) generally require at least two dispensings for the index to be stable, and thus excluded those who haven’t filled a new medication at least twice (“early non-persistence”); therefore only “secondary adherence” (ongoing use with multiple fills) is typically reported.

Materials and Methods: We sought to identify all new prescriptions (no evidence of use in the previous 2 years) for antihyperglycemic, antilipemic and antihypertensive medications recorded by providers in an electronic medical record system from January 1, 2006 to June 30, 2006, among 210,000 diabetics members of an ethnically-diverse, managed care population (Kaiser Permanente). Using a “new user” design, we estimated medication adherence longitudinally, evaluating primary non-adherence, early non-persistence, and secondary adherence.

Results: We identified 49,403 new prescriptions ordered for 36,695 diabetic patients. 5.2% of these patients never filled their first new prescriptions during the study period (primary non-adherence). Among those 94.8% of patients who did fill their first prescription, 23.8% never refilled the prescription (early non-persistence). 26.1% of persistent patients (two or more dispensings) had poor secondary medication adherence (<80% of time with sufficient medication supplies).

Conclusion: While a small proportion of patients fail to fill their first prescription, a substantial proportion of primary adherent patients fail to pick up their first refill (i.e., early non-persistent). Thus, approximately one-quarter of patients fail to transition to being ongoing medication users. This form of nonadherence has been inadequately captured in previously published pharmacy-based studies of medication adherence. Further research and intervention development needs to include this at-risk group of nonadherent patients.

Significant impact of the presence of type 2 diabetes on the cardiovascular risk conferred by the plasminogen activator inhibitor-1 -675 5G/4G polymorphism

A. Muendlein¹, C. H. Saely^{1,2}, T. Marte^{1,2}, P. Rein^{1,2}, F. Schmid^{1,2}, L. Koch^{1,2}, P. Langer¹, S. Aczel^{1,2}, H. Drexel^{1,2};

¹VIVIT Institute, Feldkirch, Austria,

²Internal Medicine, Academic Teaching Hospital Feldkirch, Austria.

Background and Aims: The -675 5G/4G polymorphism of the plasminogen activator inhibitor-1 (PAI-1) gene has been associated with increased plasma levels of PAI-1 and, in some studies, with increased vascular risk. Hardly any data on the vascular risk conferred by this polymorphism are available for patients with type 2 diabetes (T2DM). We therefore aimed at investigating i) the association of this polymorphism with angiographically diagnosed coronary artery disease (CAD) and ii) its impact on future vascular events in patients with T2DM and in nondiabetic individuals.

Materials and Methods: Genotyping was performed in 672 consecutive Caucasian patients (463 men and 209 women, mean age 62 ± 10 years) undergoing coronary angiography for the evaluation of stable CAD. Prospectively, we recorded vascular events over 4 years.

Results: The prevalence rates of the 5G/5G, the 5G/4G, and the 4G/4G genotypes were 17.6%, 52.7%, and 29.7% in patients with T2DM (n = 148) and 23.5%, 48.3%, and 28.2% in non-diabetic subjects (n = 524). In non-diabetic subjects the homozygote PAI-1 4G/4G genotype after adjustment for age, gender, hypertension, smoking, BMI, LDL cholesterol, and HDL cholesterol was significantly associated with significant stenoses (adjusted odds ratio (OR) 1.77 [95% CI 1.13–2.78], p=0.013), whereas no such association was observed in patients with T2DM (OR 0.81 [0.34–1.93]; p = 0.635). An interaction term T2DM x 4G/4G genotype was significant (p = 0.026), indicating that the association of the polymorphism with CAD was significantly stronger in non-diabetic subjects than in patients with T2DM. Also prospectively, the 4G/4G genotype conferred an increased risk of vascular events in non-diabetic subjects but not in T2DM patients, with hazard ratios of 1.66 [1.05–2.64], p=0.031 and 0.72 [0.33–1.60], p = 0.423, respectively (adjusted for age, gender, hypertension, smoking, BMI, LDL cholesterol, and HDL cholesterol). Again, an interaction term T2DM x 4G/4G genotype was significant (p = 0.042).

Conclusion: We conclude that presence of T2DM significantly modulates the vascular risk conferred by the PAI-1 -675 5G/4G polymorphism.

0344

The M55V polymorphism in SUMO4 gene is associated with macrovascular complications in type 2 diabetes

T. Shimada¹, Y. Furukawa¹, H. Furuta¹, S. Matsuno¹, A. Kusuyama², M. Nishi², H. Sasaki¹, T. Sanke³, K. Nanjo¹;

¹The First Department of Medicine, ²Department of Metabolism and Clinical Nutrition, ³Department of Clinical Laboratory Medicine, Wakayama Medical University, Wakayama City, Japan.

Background and Aims: The small ubiquitin-like modifier (SUMO) family has emerged as one of key regulators of cellular stress responses. SUMO4, a novel member for the family, conjugates with inhibitor- κ B (I κ B α) and negatively regulates the nuclear factor- κ B (NF- κ B) signaling pathway. A single amino acid substitution, Met to Val at codon 55 (M55V), of SUMO4 has been identified and it has been reported that the Val type has lesser effect on suppression of NF- κ B transcriptional activity than the Met type. Because the NF- κ B activation is a key event in the development of diabetic vascular complications, the M55V polymorphism may be associated with increased risk of diabetic vascular complications through higher NF- κ B activation. We examined the role of the M55V polymorphism on vascular complications in type 2 diabetic patients.

Materials and Methods: The SUMO4 M55V polymorphism was genotyped using TaqMan SNP genotyping assay system. We examined the association between the M55V polymorphism and the prevalence of macro- and micro-vascular complications in 423 Japanese type 2 diabetic patients. The diagnosis of coronary heart disease (myocardial infarction and angina pectoris) was based on symptoms and ischemic changes in an electrocardiogram, either at rest or exercise test, or on findings from coronary angiography. Cerebral infarction was diagnosed by a history of acute neurological deficits, together with positive findings on computed tomography and/or magnetic resonance imaging of the brain. Patients with \geq grade 2 on the La Fontaine classification, with overt proteinuria and/or an elevated serum creatinine level (\geq 1.2 mg/dl), and with \geq simple retinopathy were assumed to have peripheral vascular disease, nephropathy and retinopathy, respectively.

Results: We found the V allele was more frequent in the patients with the history of coronary heart disease than in those without it (p=0.033). The V allele was also frequent in the patients with the history of cerebral infarction than in those without it (p=0.016). In the logistic regression analysis, the risk of coronary heart disease and cerebral infarction was significantly higher in patients with the V/V genotype than in those with the M/M genotype (odds ratio [OR] 2.76, 95% confidence interval [CI] 1.12–6.78, p=0.027 for coronary heart disease and OR 4.12, 95% CI 1.49–11.36, p=0.006 for cerebral infarction, respectively). Adjustment for sex, duration of diabetes, smoking status, hypertension status and dyslipidemia status did not appreciably change the associations (OR 2.85, 95% CI 1.08–7.49, p=0.034 for coronary heart disease and OR 3.83, 95% CI 1.25–11.74, p=0.019 for cerebral infarction, respectively). No significant differences were observed for other diabetic vascular complications such as peripheral vascular disease, nephropathy and retinopathy according to genotypes and alleles.

Conclusion: Our results suggest that the SUMO4 M55V polymorphism is associated with increased risk of coronary heart disease and cerebral infarction in type 2 diabetic patient.

Type 2 diabetes eliminates the relative protection against death in women
G. W. D. Landman¹, N. Kleefstra^{2,3}, S. J. J. Logtenberg², H. J. G. Bilo^{2,4}, K. H. Groenier⁵;

¹Internal Medicine, Isala Clinics, Zwolle, ²Diabetes Centre, Isala Clinics, Zwolle, ³Langerhans, Medical Research Group, Zwolle,

⁴Internal Medicine, University of Groningen,

⁵General Practice, University of Groningen, The Netherlands.

Background and Aims: Several studies have suggested that, unlike in the general population, diabetic women have an even higher relative mortality rate than diabetic men. At the same time, the specific risk factors that are associated with mortality in both sexes are mostly comparable. We aimed to examine mortality rates of diabetic women and men compared to the general population and to identify gender specific risk factors for all cause mortality in a cohort of patient with type 2 diabetes mellitus (T2DM) in the Netherlands.

Materials and Methods: The ZODIAC study started in 1998. A group of 1145 patients with T2DM was seen annually, and data on mortality were assessed 5.8 years later on average. Mortality rates in male and female patients were evaluated using standardized mortality ratios (SMR) and the association of mortality with established risk factors was evaluated with the Cox Proportional Hazard Ratio. The following variables were selected in the model as possible risk factors: Smoking (yes or no), age, duration of diabetes, HbA1c, eGFR (Cockcroft), body mass index (BMI), hypertension (yes or no), Cholesterol/HDL ratio and macrovascular complications (yes or no).

Results: The study population consisted of 658 women and 487 men, a total of 335 patients died. SMR for all cause mortality was 2.15 (CI 1.85–2.49) in women and 1.75 (CI 1.48–2.05) in men. In diabetic women mortality was associated with age (HR 1.11; CI 1.09–1.14), glycaemic control (HbA1c) (HR 1.25; CI 1.12–1.41) and with macrovascular complications (HR 1.91; CI 1.36–2.70). In diabetic men mortality was associated with age (HR 1.06; CI 1.03–1.09), smoking (HR 1.78; CI 1.23–2.57), eGFR (HR 0.97; CI 0.96–0.99), and macrovascular complications (HR 1.51; CI 1.00–2.28).

Conclusion: Having diabetes appears to eliminate the relative protection women have on mortality compared to men. Our results reemphasize the magnitude of the association between diabetes and mortality. There were comparable risk factors in both genders, however, glycaemic control in women, smoking and eGFR in men appeared to be gender specific in this Dutch cohort of patients with T2DM.

These results confirm that the intensity of diabetes management should not be gender specific; women with diabetes mellitus type 2 should be treated (as aggressively) as men.

0346

Increased risk of type 2 diabetes in men when compared to premenopausal as well as postmenopausal women, aged 35–66 years

A. Hilding¹, A.-K. Eriksson², S. Efendic¹, C.-G. Östenson¹;

¹Dept. of Molecular Medicine and Surgery, The Endocrine and Diabetes

Unit, ²Dept. of Medicine, Unit of Clinical Epidemiology, Karolinska Institutet, Stockholm, Sweden.

Background and Aims: Prevalence of newly diagnosed type 2 diabetes (T2D) is two-fold higher in men than in women in a diabetes screening program in Stockholm, Sweden. We have studied the impact of menopause on this gender difference.

Materials and Methods: Healthy Swedish men (n = 3,128) and women (n = 4,821), aged 35–56 years, living in the Stockholm area, participated in a baseline investigation, performed 1992–1994 and 1996–1998, respectively. Approximately 50% had a family history of diabetes (FHD). They all underwent an oral glucose tolerance test (OGTT) and responded to a questionnaire regarding e.g. lifestyle and for women menopausal status and hormone replacement therapy (HRT). Of those not having newly diagnosed T2D at baseline (65 men and 63 women) and still living in the same area, 87% of the men (2,383/2,746) and 76% of the women (3,329/4,365) were reinvestigated with a new OGTT and questionnaire ten or eight years later,

respectively. Newly diagnosed T2D at the follow-up examination was found in 99 men and 58 women. Odds ratios (OR) for T2D was assessed, adjusted for major confounders, e.g. age, FHD, BMI, physical activity and smoking.

Results: At both baseline and follow-up the prevalence of newly diagnosed T2D was higher in men than in women, 2.1% and 4.2% respectively for men vs. 1.3% and 1.7% respectively for women. At baseline the female study sample comprised both premenopausal and postmenopausal (median duration two yrs) women. Menopausal status was however not associated with T2D, adjusted OR was 0.81 (95%CI: 0.33–1.95) when comparing pre- and postmenopausal women. At baseline a similar increased risk of T2D was found in men when compared to premenopausal women, OR=1.89 (1.06–3.36) as when compared to postmenopausal women, OR=1.93 (1.05–3.54). The OR for T2D associated with male sex was 1.70 (0.81–3.57) when compared to postmenopausal women not treated with HRT. At follow-up the majority of the women, now aged 46–63 yrs, were postmenopausal (median duration six yrs), and only a limited number of cases were identified among the premenopausal. Thus, comparison between men and postmenopausal women at follow-up again showed an increased risk of T2D in men, OR=2.33 (1.49–3.67). Specifically, when comparing men with the subgroup of postmenopausal women not treated with HRT OR=1.72 (1.00–2.98).

Conclusion: Our data in Swedish middle-aged subjects indicate that menopausal status has no obvious influence on the risk of T2D in women, and that men are at an increased risk as compared to women, irrespective of menopausal status.

Perinatal mortality, preterm birth and macrosomia in offspring of women with type 1 diabetes in Norway

I. Eidem^{1,2}, L. C. Stene^{1,2}, T. Henriksen³, K. F. Hanssen^{2,4}, S. Vangen^{1,5}, G. Joner^{2,6};

¹Division of Epidemiology, Norwegian institute of Public Health,

²Diabetes Research Centre, Aker and Ullevål University Hospitals,

³Department of Obstetrics and Gynaecology, the National Hospital,

⁴Department of Endocrinology, Aker University Hospital,

⁵Department of Obstetrics and Gynaecology, Ullevål University Hospital,

⁶Department of Paediatrics, Ullevål University Hospital, Oslo, Norway.

Background and Aims: The St. Vincent declaration (1989) stated that within a five-year period, the risk of adverse pregnancy outcome among women with type 1 diabetes should be lowered to a level equal to the background population. Recent European studies have shown that this goal has not yet been met. The objective of the study is to compare pregnancy outcome in women with type 1 diabetes with the Norwegian background population.

Materials and Methods: By a record linkage of the Norwegian Childhood Diabetes Registry (NDR) of Norway and the Medical Birth Registry of Norway, we designed a population based cohort study with a highly reliable type 1 diabetes diagnosis from the NDR. From 1975 to 1998, 1025 births of women with type 1 diabetes occurred in our cohort. From 1999 to 2004, 419 births occurred.

Results: We present preliminary results for perinatal mortality (stillbirth after 28 completed weeks of pregnancy or postnatal death up to 7 days after birth), preterm birth (< 37 completed weeks of gestation) and macrosomia (birth weight >= 4500g). Among women with type 1 diabetes the perinatal mortality for the period 1975–98 was 1.9% compared with 0.89% in the background population RR (relative risk) 2.2 (95% CI: 1.4–3.4). For the period 1999–2004 the perinatal mortality was 1.7% among women with type 1 diabetes and 0.55% in the background population RR 3.1 (95% CI: 1.5–6.5). The risk of preterm delivery 1975–98 was 27.4% among women with type 1 diabetes and 6.5% in the background population RR 4.2 (95% CI: 3.8–4.7). For the period 1999–2004 the risk was 27.6% among women with type 1 diabetes and 7.7% in the background population RR 3.6 (95% CI: 3.1–4.2). The risk of macrosomia was for the period 1975–98 8.1% among women with type 1 diabetes and 3.3% in the background population RR 2.4 (95% CI: 2.0–3.0). For the period 1999–2004 the risk was 12.2% among women with type 1 diabetes and 4.6% in the background population RR 2.7 (95% CI: 2.1–3.5).

Conclusion: Based on our results, Norwegian women with type 1 diabetes still have a higher risk of perinatal mortality, preterm birth and macrosomia in their babies compared to women in the background population.

Gestational hypertension and the offspring's manifestations of metabolic syndromeS. Miettola¹, A.-L. Hartikainen², A. Bloigu³, A. Ruokonen⁴, M.-R. Järvelin^{5,6}, A. Pouta⁷;¹Department of medicine, University of Oulu, Finland,²Department of Obstetrics and Gynecology, University of Oulu, Finland,³Department of Public Health, National Public Health Institute, Oulu, Finland, ⁴Department of Clinical Chemistry, University Hospital of Oulu, Finland, ⁵Department of Epidemiology and Public Health, Imperial College of London, United Kingdom, ⁶Department of Public Health Science and General Practise, University of Oulu, Finland, ⁷Department of Child and Adolescent Health, National Public Health Institute, Oulu, Finland.

Background and Aims: The impact of de novo hypertension in pregnancy, i.e. pre-eclampsia (PE) and transient gestational (nonproteinuric) hypertension (GH), on the long-term outcome of offspring is poorly understood. There are no previous studies on the association between maternal GH and offspring's metabolic outcomes. Three previous studies have shown that children born to mothers with PE had slightly more elevated blood pressures (BP) than the reference group.

Material and Methods: The data for the study were obtained from the Northern Finland 1986 Birth Cohort (NFBC 1986) and included all singleton pregnancies of the 9247 mothers and their offspring born in 1985–86. The clinical follow-up of the offspring was conducted at age 16 years with 74% response rate (N=6798). We allocated the mothers into three different groups: 1) GH group with BP >140/>90 mmHg (n=267) 2) PE group with BP >140/>90 mmHg and proteinuria (n=182) 3) reference group with normal BP (n=7006).

Results: Offspring of the mothers with GH had higher BP compared to the reference group (Table 1). They also had higher fasting cholesterol and apolipoprotein B levels. No difference was seen in HOMA-S levels. Adjustments for birth weight, gestational age and current BMI did not change these differences. There were no differences in the BP, lipid, glucose or insulin levels between the offspring of the PE mothers and the reference group.

Conclusions: The features of metabolic syndrome were clearly seen in the offspring of GH mothers. This risk group should be noted already in childhood by planning preventive strategies already before potential clinical manifestation of metabolic syndrome.

Table 1. Metabolic outcome measures between the offspring of mothers with GH and the reference offspring.

Variable	Reference (n=7006) Mean (95% CI)	GH (n=267) Mean (95% CI)	GH vs. Reference P value*
SBP, mm Hg	115 (115–115)	120 (118–122)	<0.001
DBP, mm Hg	67 (67–68)	71 (70–72)	<0.001
MAP, mm Hg	83 (83–84)	87 (86–88)	<0.001
BMI, kg/m ²	21.1 (21.0–21.2)	21.6 (21.1–22.1)	0.088
LDL, mmol/L#	2.17 (2.16–2.19)	2.27 (2.19–2.36)	0.054
HDL, mmol/L#	1.38 (1.37–1.39)	1.40 (1.36–1.45)	0.494
Cholesterol, mmol/L#	4.18 (4.16–4.20)	4.35 (4.24–4.47)	0.007

Socio-economic position at birth, but not birth weight, is independently related to metabolic syndrome at age 50

N. Unwin, M. Pearce;

Institute of Health and Society, Newcastle University, United Kingdom.

Background and Aims: The risk of cardiovascular disease in middle to older age has been associated with measures of socio economic status throughout the life course. It has been suggested that associations found with anthropometric measures at birth are strongly confounded by factors related to socio-economic status in early and later life. However, this remains controversial and difficult to test given the rarity of data sets that contain all the variables of interest at different stages of life. Our aim was to investigate the relationship between metabolic syndrome at age 50 and socio-economic status at different points in the life course, and to examine potential determinants of any associations found.

Materials and Methods: We used data from a cohort of 1142 births in May and June 1947 in the North of England on whom detailed social and anthropometric data were collected up to the age of 15. Birth weights were standardised for gestational age and gender. At age 50 years, 412 study members (180 men and 212 women, representative of the original cohort) attended for a clinical examination, which included anthropometry, blood pressure, fasting lipids and glucose, and questionnaire data on diet, smoking, alcohol consumption and physical activity. Data on social class (SC) were available at birth, and ages 25 and 50 years, and divided into three categories (social class 1&2; 3 non-manual and manual; 4&5 and unemployed). Metabolic syndrome (MS) was defined following the IDF 2005 definition. Results are described for men and women together, with any differences between them highlighted.

Results: MS was present in 27.6% (33.7% men and 22.9% women, p=0.018). It was strongly related to low SC at birth (11.6%, 26.3% and 34.9% across the three groups respectively, p for trend = 0.004), not at age 25 (p=0.5) and associated with SC at age 50 (22.9%, 29.1% and 37.0%, p=0.02). The relationship of MS with SC at birth was largely independent of SC at 50: unadjusted odds ratio for SC 3 vs SC 1 at birth 4.3 (95% CIs 1.6 to 12.1); OR adjusted for SC at age 50, 3.7 (1.3 to 10.6). There was no evidence of a relationship between social mobility between birth and 50 (up or down) and risk of MS. Of the components of MS, low SC at birth was associated with higher waist circumference, triglycerides and low HDL cholesterol, but not with fasting glucose or blood pressure. There was no relationship (p > 0.2) between birth weight and MS at age 50. Low SC at birth was not associated with birth weight, but was associated with earlier age of weaning (means across the three sc groups: 168 days, 159 and 151, p for trend 0.02). Low SC at birth was associated with smoking at age 50, total pack years smoked and with low levels of physical activity at age 50, but not with measures of diet. However, controlling for all of these factors significantly related to SC at birth had limited impact on the relationship with metabolic syndrome at age 50 (adjusted OR for MS, lowest compared to highest SC 3.4, 1.2 to 9.8).

Conclusion: SC at birth, but not birth weight, was strongly, and independently, associated with the risk of metabolic syndrome at age 50. This may represent the influence of early life experience on programming future metabolism, or the fact that low SC in infancy is associated with the accumulation of risk over the life course. Our data largely support the former hypothesis, given the independent association of SC at birth with MS at age 50.

Association of intrauterine exposure to maternal diabetes and obesity and type 2 diabetes in youth: SEARCH Case-Control (SEARCH CC) StudyD. Dabelea¹, E. J. Mayer-Davis², A. Pande³, R. B. D'Agostino Jr.³, A. D. Liese², K. Narayan⁴, R. F. Hamman¹;¹Preventive Medicine and Biometrics, University of Colorado Health Sciences Center, Denver, United States, ²Epidemiology and Biostatistics, University of South Carolina School of Public Health, Columbia,³Public Health Sciences, Wake Forest University School of Medicine,⁴Epidemiology, Emory University School of Public Health, Atlanta, United States.

Background and Aims: Intrauterine exposure to maternal diabetes is associated with an increased risk for type 2 diabetes (T2DM) in the offspring.

Several studies have also shown an independent association of maternal obesity with excessive fetal adiposity, but there are limited data on long-term consequences on offspring T2DM risk. We hypothesized that exposure to maternal DM and maternal obesity *in utero* would be independently associated with increased T2DM in African American (AA), Hispanic (H), and non-Hispanic white (NHW) youth.

Materials and Methods: We used data from SEARCH CC, an ancillary study to SEARCH for Diabetes in Youth. Seventy-nine youth with T2D age 10–24 yr attended a research visit at the Colorado and South Carolina sites, where non-diabetic control youth (n=190) were also recruited. Information on *in utero* exposure to maternal diabetes was recalled by biological mothers. Maternal pre-pregnancy body mass index (BMI) based on self-reported weight and measured height was used to estimate *in utero* exposure to overweight/obesity (BMI ≥ 25).

Results: Prevalence (%) of *in utero* exposure to diabetes was higher among youth with T2DM than among controls (30.4 v 6.3, $p < 0.0001$), and it was similarly higher across racial/ethnic groups (30.2 v 3.8 for AA; 35.7 v 6.5 for H; 27.3 v 7.5 for NHW; respectively, $p = 0.7$ for interaction between race and DM exposure). In multiple logistic regression, after adjusting for offspring age, sex and race/ethnicity, *in utero* exposure to maternal DM [Odds Ratio (OR) 5.7 (95% CI=2.4–13.4)] and *in utero* exposure to maternal obesity [2.8 (95% CI=1.5–5.2)] were independently associated with T2DM in the offspring. Adjustment for other potential confounders (paternal DM, birth weight, breastfeeding, maternal age at index pregnancy, education, income, smoking and alcohol consumption during pregnancy, and current BMI) did not substantially alter these associations. When current offspring BMI z-score was added to the model, the OR for the association between *in utero* exposure to DM and offspring T2DM was unchanged. However, the OR for the association between *in utero* exposure to maternal obesity and offspring T2DM was attenuated toward to the null value (OR=1.1; 95% CI=0.5–2.4), suggesting complete mediation through obesity development in offspring of obese mothers.

Conclusion: Exposure to maternal DM *in utero* is strongly associated with T2DM in youth in all ethnic groups, including African Americans, Hispanics, and non-Hispanic White youth, with a magnitude of effect similar to that seen among Pima Indians. Exposure to maternal obesity *in utero* is independently associated with T2DM, but this association is completely mediated through development of obesity in the offspring.

Depressive symptoms and risk of type 2 diabetes and prediabetes in a prospective study of middle-aged Swedish men and women

C.-G. Östenson¹, A.-K. Eriksson¹, F. Granath², A. Hilding¹, S. Efendic¹, A. Ekblom²;

¹Molecular Medicine and Surgery,

²Medicine, Karolinska Institutet, Stockholm, Sweden.

Background and Aims: Depression is suggested to be a risk factor involved in the development of type 2 diabetes (T2D). The aim of the present study was to analyse depressive symptoms in association with T2D and prediabetes.

Material and Methods: The study group consisted of 5432 subjects that were followed-up in a prospective population-based cohort of 6725 Swedish middle-aged persons with normal glucose tolerance (NGT) in five municipalities (Stockholm Diabetes Prevention Programme). Glucose tolerance was measured by OGTT at baseline and 51.9% of study persons had a family history of diabetes by study design. Depressive symptoms at baseline were measured by 6 questions with four answering alternatives (ranging from “never” to “frequently”), concerning sleep difficulties, apathy, anxiety, depression, tiredness and back/shoulder pain during the last twelve months. Each answer was given 1–4 points and a summed index score for all 6 questions (reliability measured by Cronbach’s alpha 0.75 for men and 0.78 for women) was created and divided into quartiles, where the lowest scoring quartile was considered unexposed to depressive symptoms. Glucose tolerance at follow-up 8–10 years later was measured by OGTT. Odds ratios (OR:s) for a state of prediabetes (impaired fasting glucose, IFG; impaired glucose tolerance, IGT; and IFG + IGT) or T2D at follow-up, were estimated in association to depressive symptoms at baseline and controlled for potential baseline confounders.

Results: At follow-up, 111 men and 60 women with baseline NGT had developed T2D and a total of 255 men and 181 women were classified with a state of prediabetes. About 60% of T2D cases were detected by OGTT and 40% were self-reported to have occurred at any point during the follow-up period. The mean index sum of depressive symptom points for men were 11.2 \pm 3.3 and for women 13.4 \pm 3.6. In men, age-adjusted OR:s for T2D in association with depressive symptoms were 3.6 (CI 1.9–6.7) for the upper quartile and 1.8 (1.0–3.4) for middle quartiles (2nd + 3rd quartiles). Corresponding estimates for pre-diabetes in men were 1.7 (1.2–2.5) in the upper quartile and 1.0 (0.7–1.4) in middle quartiles. When adjusted for BMI, family history of diabetes, smoking, physical activity at leisure time and socio-economic position the OR:s for T2D in men were 2.6 (1.3–5.0) and 1.5 (0.8–2.9), respectively for upper and middle quartiles and for pre-diabetes 1.5 (1.0–2.2) and 1.0 (0.7–1.4). In women, age-adjusted OR for T2D was 0.9 (0.4–1.7) for the upper quartile and 0.8 (0.4–1.4) for the middle quartiles. OR:s for prediabetes were 1.8 (1.1–2.9) and 1.6 (1.0–2.4) for upper and middle quartiles, respectively. When adjusting for all named potential confounders OR for T2D in women was 0.6 (0.3–1.2) in the upper quartile and 0.7 (0.4–1.4) in middle quartiles and for prediabetes 1.4 (0.8–3.3) and 1.5 (0.9–2.3) for upper and middle quartiles, respectively.

Conclusions: The results indicate that depressive symptoms increase the risk of T2D and pre-diabetes in Swedish middle-aged men. No association between depressive symptoms and T2D was present in women in this study, although there was a weak association to prediabetes.

Trends in mental health in the diabetes population of Alberta, Canada, 1996–2005L. C. Brown^{1,2}, L. W. Svenson^{1,3}, C. A. Beck^{4,5}, S. U. Vermeulen², J. A. Johnson^{1,2};¹School of Public Health, University of Alberta, Edmonton,²Alliance for Canadian Health Outcomes Research in Diabetes, Institute of Health Economics, Edmonton,³Health Surveillance Branch, Alberta Health and Wellness, Edmonton,⁴Department of Community Health Sciences, University of Calgary,⁵Department of Psychiatry, University of Calgary, Canada.

Background and Aims: Research demonstrates an association between diabetes and several mental illnesses, including depression, bipolar disorder, and schizophrenia. Comorbid mental illness has been shown to increase the risk of complications, functional disability, healthcare expenditures, and mortality in people with diabetes.

Materials and Methods: Diagnostic codes (ICD-9-CM/ICD-10-CA) were extracted from population-based administrative health databases maintained by the Alberta Ministry of Health and Wellness for affective disorders, anxiety disorders, and organic and non-organic psychoses among individuals 20 years of age and older from the province of Alberta, Canada. Individuals with diabetes were identified using the algorithm from the National Diabetes Surveillance System (NDSS). Descriptive analyses present trends over time (1996–2005) and average annual prevalence of mental illnesses for people with and without diabetes. Rates were age-standardized using the 2001 Alberta population as the reference.

Results: People with diabetes had a higher prevalence of all mental illnesses compared to people without diabetes, and this finding was consistent over the examined time period (1996–2005). Affective and anxiety disorders were more than 30% higher ($p < 0.05$) in people with diabetes, but the excess was limited to people under the age of 50. The prevalence of non-organic psychoses were more than 2.0 times higher ($p < 0.05$) in people with diabetes, with increasing frequency in people with diabetes in the past five years. The increased risk of psychoses in diabetes was apparent across all ages ($p < 0.05$).

Conclusion: People with diabetes had a higher prevalence of affective disorders, anxiety disorders, and organic and non-organic psychoses compared to their non-diabetic counterparts. Given the increased prevalence of mental illness in people with diabetes, research should focus on strategies to minimize complications and mortality in this population with comorbidity.
Supported by Alberta Health and Wellness

Prescriptions costs and socioeconomic differences in prevalence of diabetes: the population-based Torino StudyG. Bruno¹, L. Karaghiosoff², F. Pomero¹, O. Segre¹, C. Zucco¹, F. Merletti³, G. Costa², R. Gnani²;¹Internal Medicine, ²Public Health,³Cancer Epidemiology Unit, University, Torino, Italy.

Background and Aims: Current comprehensive economic data on the costs of diabetes are required for policy decisions to optimise resource allocation and to evaluate different approaches for disease management. No population-based data are available at present in Italy. As part of a surveillance programme based on administrative data, we have assessed variations in prevalence of diabetes by age, sex and socio-economic status and prescription costs in an Italian population-based cohort.

Materials and Methods: People with diabetes residents of Torino on July 31, 2003 ($n = 897,743$) were identified through three data sources: the regional register of persons with diabetes, the file of persons discharged from hospitals with a diagnosis of diabetes (ICD9-CN = 250) and the file of persons who received at least two prescriptions of antidiabetic drugs (ATC = A10). Data sources were linked to the Torino population register to obtain individual data on educational level and census tract median income. Missing cases were estimated by using the capture-recapture method. All prescriptions registered in the 12-months period August 1, 2003– July 31, 2004 were examined to compare prevalence of treatment and costs in diabetic ($n = 34,420$) and non-diabetic people ($n = 867,500$). All rate ratios were age and sex-standardized.

Results: Diabetes prevalence adjusted for undercount was 4.91% (95% CI 4.69–5.22) among men and 4.68% (4.41–5.08) among women. Prevalence ratios between low and high socio-economic level were 1.54 (1.48–1.59) in men, and 2.42 (2.32–2.54) in women. Results were not modified by age; indeed, prevalence ratios were higher in low than in high socioeconomic level and in women than in men in all age groups (< 65, 65–74, >74 yrs). In most categories prevalence of treatment was higher among diabetic people than among those without diabetes, with a prevalence ratio = 3.67. The highest prevalence was found for cardiovascular drugs (particularly for expensive drugs such as ACE-inhibitors, ARB and calcium-antagonists), which were prescribed to 79.9% of diabetic people.

Conclusion: this study shows: 1) feasibility of a surveillance program of diabetes using routinely collected data; 2) increasing temporal trend in prevalence; 3) socio-economic inequalities in risk of the disease, particularly in women, in all age groups; 4) four-fold higher prescriptions cost in diabetic than in non-diabetic people.

Lifetime risk of diabetes: the AusDiab studyA. Peeters¹, D. J. Magliano^{1,2}, W. J. Nusselder³, E. L. M. Barr², D. Liew¹, P. Z. Zimmet², J. E. Shaw²;¹Epidemiology & Preventive Medicine, Monash University, Melbourne,Australia, ²International Diabetes Institute, Caulfield, Australia,³Public Health, Erasmus MC, Rotterdam, The Netherlands.

Background & Aims: Incidence rates for diabetes are increasing rapidly worldwide with a doubling in prevalence in some countries such as Australia since the 1980s. There has been no estimate of the implications of this on the lifetime risk of developing diabetes, or duration of life that a population can expect to live with and without diabetes. The aim of this paper is to estimate the lifetime risk of diabetes, the number of years lived free of, and the number of years lived with diabetes for the Australian adult population from the year 2000.

Material and Methods: Data from the Australian, Diabetes, Obesity and Lifestyle (AusDiab) study (a national population based study of 11,247 adults aged ≥ 25) were used to estimate the age-specific incidence rate of diabetes. Presence of diabetes was assessed based on a single oral glucose tolerance test. Age-specific mortality rates for the diabetic and non-diabetic populations were estimated by combining national mortality rates with the age-specific prevalence of diabetes and relative risk of mortality in people with diabetes from AusDiab. These three transition rates were used to construct multi-state life tables, to simulate the progress of a cohort of 25 year old Australians. From these life tables, residual lifetime risk of diabetes, average life years lived free of diabetes, and average life years lived with diabetes were derived. Life tables were also constructed for a cohort of people with diabetes from age 25, from which life expectancy of a diabetic population was derived.

Results: Within the AusDiab population, the observed incidence of diabetes was 7.8 per 1000 person years. The crude relative risk of mortality associated with diabetes was 4.2, but this varied by age, with relative risks decreasing with increasing age. If the rates of mortality and diabetes incidence observed in the year 2000 continued we would expect 20% of 25 year olds to develop diabetes by age 65, and 37% to develop diabetes at some time throughout their life. A cohort of twenty-five year old Australians has a remaining life expectancy of 54 years (until age 79) – with 47 of these expected to be lived free of diabetes and seven with diabetes. Due to their increased risk of mortality, the diabetic population has a decreased life expectancy. A 55 year old person with diabetes can expect to live four years less than a person free of diabetes at age 55, and 10 years less than a 55 year old person who remains diabetes-free throughout life.

Conclusion: Based on the mortality and diabetes incidence rates observed in the year 2000, diabetes will exert a significant burden on the future health of Australians, with more than a third of individuals developing diabetes within their lifetime. An appreciation of the implications of the current trends is imperative for appropriate public health and clinical responses.

The challenges of diabetes care in changing times

T. Dugal;

Diabetes and Endocrinology, St Georges Hospital, Tooting, London, United Kingdom.

Background and Aims: Provision of specialist services in primary care has been shown to be associated with reduced admission rate. With the drive to get diabetes care in the community, integration of primary and secondary health care to facilitate patient care is an important step in improving patient outcomes. We present a baseline and follow up audit of 26 practices in South West London. Data was collected from computerised diabetes registers on a template. Development of structured professional education to facilitate patient repatriation through a pioneering programme, Community Rolling Education Programme (CD-REP) was also initiated to enhance patient care and awareness. The introduction of recent Department of Health "Payment by results" and "Quality outcomes framework" scores has contributed to improvement of care in primary care. This audit looks at the impact of all these factors on care of patients with diabetes in community.

Materials and Methods: Data of 4167 patients was collected over fifteen months. 2250 males, mean age 62 years and 1917 females, mean age 65. Prevalence of diabetes matched national average of 3%. Ethnicity of the population was mixed. 48% were on oral hypoglycaemics, 22% diet controlled and 16% on insulin. The body mass index (BMI) was normal (<25) in 25% and 63% were pre-obese or obese. 67% patients had blood pressure within the guidelines (<145/85). 44% had HbA1C less than 7.4% and 12% had more than 10%. Total cholesterol (TC) was below target in 57%. HDL cholesterol was >1mmol/L in 82% and LDL was >3mmol/L in 41%. Primary care had 44% patients, while 33% were managed in shared care; in 22% care was not recorded. Mean age was 64 years in practice only and 61 years in shared care. 8% patients had T1 diabetes (T1DM) and 92% T2 diabetes (T2DM). Only 3% of T1DM was managed in community, 97% was in shared care. 51% of T2DM were managed in shared care and 49% in practice only. 75% of diet controlled patients were in primary care, 60% of patients on oral hypoglycaemics were in shared care. 95% patients on insulin were in shared care.

Results: It was noted that surveillance of patients with diabetes in the community improved with more patients reaching targets for blood pressure and TC although no change in HbA1C was noted. There was variation by where the care was delivered. HbA1C was 7.6% (7.5–7.7)* in practice and 8.2 (8.1–8.3)* in shared care. Mean systolic pressure was 139 mmHg (138–140)* in practice patients and 137 mmHg (136–138)* in shared care. The outcomes monitored over two years in a sub group of patients transferred from shared care to primary care showed an increase in HbA1C from 6.9% (S.D 0.94) to 7.1 (S.D 1.2), creatinine increased from 86.2 (S.D 22.700 to 93.5 (S.D 29.00, TC 4.3 (S.D 0.78) to 4.2 (S.D 0.69). The number of referrals to secondary care also fell by 16% in this period.

Conclusion: The quality of care has improved in the community but tighter glucose control is needed. Specialist backup and support should be available to primary care to have seamless diabetes care and cannot be undermined. This role needs to be developed further also for exchange of expertise, patient repatriation and education in the community. Department of health targets have also meant better care of diabetes in the community. Further and on going assessment of the changing patterns of care are needed.

National Health Interview Survey in Taiwan is analyzed. Among them, 401 cases (17%) are diabetic. Mean \pm SD of age for non-diabetic and diabetic subjects are 739 \pm 6.5 and 740 \pm 6.5 respectively. The analyzed health outcomes include stroke, TIA, kidney diseases, uremia, joints replacement, fall experience, fracture experience, urine incontinence, feces incontinence, use of audiphone, glaucoma, ablespsia, teeth function, daily functional status, use of emergency room, hospitalization, use of dental services, body mass index, depressive symptoms, cigarette smoking, betel quid chewing, physical laboring, and exercise. Chi-square test and logistic regression were applied to examine their correlations.

Results: The analyses of chi-square tests show that diabetes patients report a significantly higher rate in terms of stroke, TIA, kidney diseases, joints replacement, fall experience, urine incontinence, stool incontinence, daily functional disability, obesity, depressive symptoms, emergency room and hospitalization utilization, and an obviously lower rate in terms of physical laboring work and dental services utilization. When sex and the other aforementioned significant variables are controlled, the result shows that DM patients have higher odds of TIA (Odds ratio=1.60, 95% CI 1.07–2.40), kidney diseases (Odds ratio=1.62, 95% CI 1.08–2.42) and lower odds of engaging in physical laboring work (Odds ratio=0.66, 95% CI 0.47–0.95).

Conclusion: Findings show that DM does have negative impacts on old patients' health and lifestyle. It is very important to enhance self-management in diabetes patients so as to prevent from advanced health decline.

0356

The impact of diabetes mellitus on the health of the Taiwanese elder population

T.-Y. Tai¹, W.-C. Chang²;

¹Director General Office, Taipei Jen Chi Relief Institution,

²Division of Gerontology Research, National Health Research Institutes, Taipei City, Taiwan.

Background and Aims: According to the National Health Insurance (NHI) claim data, the prevalence rate of DM in Taiwan read 3.8% in 2002 and is increasing at an average rate of 0.2% every year. The health care expenditure spent on diabetes patients accounts for approximately 11.5% of the total NHI cost. In this study, we aim to examine the relationships between diabetes and other health outcomes of Taiwanese old people.

Materials and Methods: A national-representative, multistage stratified systematic sample of 2353 individuals aged 65 and over from the 2005

The Environmental Determinants of Diabetes in the Young (TEDDY) Study

M. Rewers; on behalf of the TEDDY INVESTIGATORS, Barbara Davis Center for Childhood Diabetes, University of Colorado, School of Medicine, Denver, United States.

Background and Aims: The incidence of type 1 diabetes (T1D) has doubled in the US and Europe during the past 20 yrs, likely due to changes in early childhood infectious or dietary exposures. To determine the cause of T1D, the TEDDY consortium follows intensively large cohorts of genetically susceptible infants born in Finland, Sweden, Germany and the U.S. (Georgia, Florida, Washington and Colorado).

Materials and Methods: The study aims to screen for HLA-DR,DQ genotypes associated with T1D over 360,000 newborns and to enroll 7,800 high-risk infants in intensive follow-up including measurement of autoantibodies to insulin, GAD65 and IA-2, infectious exposures and dietary biomarkers every 3 months. Monthly stool samples, questionnaires and diary kept by parents provide additional exposure data. Candidate environmental exposures assessed prospectively by repeated measurements are formally evaluated by time-to-event analyses using as the endpoints development of islet autoantibodies and progression to T1D.

Results: Between Sept. 2004 and March 2007, 146,900 newborns from the general population, including 2,320 first degree relatives of T1D patients, were screened for HLA-DR,DQ genotypes associated with T1D. Of the 7,040 eligible high-risk infants found so far, 2,900 have been enrolled into follow-up. The prevalence of the highest-risk HLA-DR3/4,DQB1*0201/0302 genotype in general population newborns screened by TEDDY does not correlate with previously published T1D incidence gradient from high-risk Scandinavians to moderate-risk US non-Hispanic whites (NHW) to low risk US Hispanics and Germans (Table). There is a significant heterogeneity, by population, in the prevalence of the HLA-DR3/4,DQB1*0201/0302 genotype ($p < 0.0001$) and in additional elevated risk genotypes that TEDDY is screening for. Examples of environmental exposures studied and their cumulative incidence in infants enrolled in TEDDY so far ($n=2,507$) are shown in the Table. Only in Finland BCG vaccination is given shortly after birth, later in the first year of life in Sweden and rarely in the other populations. The exposure to cow's milk in infancy is also dissimilar by the study population ($p < 0.01$).

Conclusion: There are major inter-population differences in the prevalence of candidate T1D genetic and environmental risk factors within the U.S. and Western Europe.

Prevalence (%) of selected candidate risk factors

Population	Finland	Sweden	US NHW	US Hispanics	Germany
T1D incidence /100 000/yr	41	39	28	14	14
HLA-DR3/4,DQB1*0302 [%]	1.9	3.4	2.3	1.9	1.8
BCG vaccination at birth [%]	30	0.5	0.1	0	0.5
Fed cow's milk by 3 months of age [%]	72	71	73	90	53

The development of humoral immunity against insulin after rotavirus infection in infancy

J. Aarnisalo^{1,2}, M. Mäkelä^{1,2}, J. Marttila^{1,2}, R. Veijola³, O. Simell⁴, M. Knip^{5,6}, O. Vaarala⁷, J. Ilonen^{1,8};

¹Immunogenetics Laboratory, University of Turku, ²Department of Virology, University of Turku, ³Department of Pediatrics, University of Oulu, ⁴Department of Pediatrics, University of Turku, Finland, ⁵Department of Pediatrics, University of Tampere, ⁶Hospital for Children and Adolescents, University of Helsinki, ⁷Laboratory of Immunobiology, The National Public Health Institute, Helsinki, ⁸Department of Clinical Microbiology, University of Kuopio, Finland.

Background and Aims: Failure in the development of tolerance to dietary bovine insulin has been implicated to be of importance in the initiation of type 1 diabetes (T1D) associated autoimmunity. We studied the association between rotavirus infections and elevated bovine insulin-binding antibodies in a large cohort of prospectively observed children with HLA-conferred susceptibility to T1D.

Materials and Methods: Serum bovine insulin-binding IgG antibodies, rotavirus IgG and IgA class antibodies and respiratory syncytial virus (RSV) IgG antibodies were measured at the age of 3, 6, 12, 18 and 24 months in prospective series of 100 children who seroconverted to positivity for at least two of the T1D-associated autoantibodies (ICA, IAA, GADA, IA-2A) during prospective observation. Controls ($n=483$) matched for HLA-DQB1 risk alleles were also studied. The effect of early rotavirus and RSV infection on the subsequent development of antibodies to bovine insulin and beta-cell autoantibodies was analysed.

Results: Rotavirus infection before the age of 6 months was associated with increased levels of bovine insulin-binding antibodies at the age of 6 and 12 months ($p=0.037$ and 0.077 , respectively, MWU-test). Rotavirus infection occurring by 12 months of age was associated with increased bovine insulin antibody levels at the age of 18 months ($p=0.045$) and by 18 months of age with increased bovine insulin antibody levels at the age of 18 months ($p=0.012$). In addition, among children infected with rotavirus during the first 6 months of life the seroconversion rate for any of the four autoantibodies and for IAA, in particular, by the age of 2 years was higher compared to uninfected children ($p=0.011$ and 0.046 , respectively, Fisher's exact test). In contrast, we observed no effect of early RSV infection on bovine insulin antibody levels.

Conclusion: These data confirm our previous findings on the effect of early rotavirus infections on the development of bovine insulin humoral immunity. Moreover, the results suggest a role of early rotavirus infection in the development of T1D-associated autoimmunity. Early rotavirus infection may increase gut permeability and thus break tolerance to dietary bovine insulin and other beta-cell antigens in genetically susceptible children.

Enterovirus RNA in serum of children with newly diagnosed type 1 diabetes and islet cell autoantibody-positive subjects in a population with a low incidence of type 1 diabetes

O. Diaz-Horta¹, L. Sarmiento², E. Cabrera-Rode¹, I. Cuba¹, G. Molina¹, M. Fonseca², A. Diaz³, P. Gonzalez⁴, L. Lekuleni², L. Heng-Hung²;

¹Immunology and Genetics on Diabetes, National Institute of Endocrinology, ²Enterovirus, Institute of Tropical Medicine "Pedro Kouri", ³Endocrinology, Hospital Univeritario "Eliseo Noel Caamaño", ⁴Endocrinology, Hospital "William Soler", Havana, Cuba.

Background and Aims: The penetrance of type 1 diabetes mellitus (T1DM) in a genetically susceptible population is largely determined by environmental influences amongst which the human enteroviruses are prominent putative factors. The aim of this study was to determine the occurrence of enterovirus-RNA in serum of children with type 1 diabetes at onset and ICA-positive subjects in a population with low incidence of type 1 diabetes and high circulation of enteroviruses.

Materials and Methods: Serum samples were collected children with newly diagnosed type 1 diabetes ($n=34$); islet autoantibody-positive ($n=32$) and -negative ($n=31$) first-degree relatives of type 1 diabetic patients; and control

subjects ($n=194$). Enteroviral RNA was assessed using a highly sensitive reverse transcriptase-polymerase chain reaction method.

Results: The frequency of positive signals corresponding to enteroviral sequence amplification was higher in newly diagnosed T1DM children (9/34, 26.5%) and islet autoantibody-positive first-degree relatives (5/32, 15.6%) than in their corresponding matched controls (2/68, 2.9%, $p=0.0007$ and 0/64, 0.0%, $p=0.0033$, respectively). The presence of enteroviral RNA appeared to be associated with severe diabetic ketoacidosis at onset ($\text{pH}<7.1$, $p=0.0328$) and high ICA titres (≥ 20 JDF units, $p<0.05$).

Conclusion: Despite there is a high circulation of enteroviruses and a low type 1 diabetes incidence in the Cuban population, the presence of enteroviral RNA is associated with type 1 diabetes and β -cell autoimmunity similarly to European countries in which this scenario is inverted.

Enterovirus genomes in the blood in children with T1DM at disease onset and one year later

G. Bianchi¹, A. Salvatori¹, A. Baj², L. Nespoli¹, A. Toniolo², A. De Paoli¹;

¹Pediatric Department, ²Microbiology, Università dell'Insubria, Varese, Italy.

Background and Aims: Enteroviral (EV) infections have been proposed as one triggering environmental factor leading to T1DM. The mechanism(s) through which EV collaborate to beta cell destruction is still unclear. Human EV have long been known as agents of acute diseases, chronic infections being rarely documented. Objectives and hypotheses: To assess whether T1DM were associated with chronic EV infection, we evaluated the presence of EV RNA genomes both at the time of clinical onset and one year later.

Materials and Methods: Blood samples of 68 T1D patients (38 boys; age 2–18 years) have been investigated. Detection of EV genomes was performed by RT-PCR using different primer pairs directed to conserved genomic regions. Sensitivity of the amplification methods in use was 10 genome equivalents per reaction tube. Direct sequencing of purified amplicons allowed identifying EV at the species level.

Results: At onset, EV genomes were detected in 46/68 patients (67%). No viral genomes were detected in 18 healthy control children. Direct amplicon sequencing showed that viruses of the HEV-B and HEV-C species were particularly prevalent. Retesting positive patients one year after clinical onset showed that EV genomes were present in only 1/46 children.

Conclusion: The results confirm the temporal association of EV infection with the onset of T1DM. We were unable to show persistent EV infection in the blood of most pediatric patients. This, however, does not exclude chronic infection of pancreatic islets.

0361

Epigallocatechin 3-gallate protects pancreatic Ins-1 cells against 2,3,7,8-tetrachlorodibenzo-p-dioxin-induced acute toxicity

V. De Tata, L. Martino, M. Novelli, M. Masini, P. Masiello;
Dept. of Experimental Pathology & B.M.I.E., University of Pisa, Italy.

Background and Aims: The increasing prevalence of type 2 diabetes prompted several scientist to suggest that environmental contaminants, in addition to obvious nutritional habits, could increase the risk of diabetes development. In this context, dioxins are considered the only environmental contaminants so far identified that could exert widespread effects in the general population. Several epidemiological studies have demonstrated a positive correlation between dioxin exposure and glucose metabolism disorders including diabetes. In order to clarify the biological basis of this correlation we have

previously demonstrated that 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) is highly toxic for INS-1 cells and that, even at very low doses, markedly impairs glucose-stimulated insulin secretion. The aim of this research has been to investigate the protective effect of the green tea polyphenol epigallocatechin 3-gallate (EGCG) against the TCDD-induced toxicity in INS-1 cells.

Materials and Methods: INS-1 cells were exposed for 1 hr to TCDD alone or in the presence of different concentrations (0–200 μM) of EGCG. We have then assayed: 1) cell survival; 2) the morphological alterations by electron microscopy; 3) the mitochondrial membrane potential by cytofluorimetry; 4) the variations in the intracellular calcium concentration by fluo-3/AM-based fluorimetry; 5) glucose-stimulated insulin secretion.

Results: Our results show that EGCG was able to significantly increase the survival of INS-1 cells after 1 hr incubation with TCDD. This protective effect was clearly dose-related and was evident, and quantitatively remarkable for the higher TCDD doses (cell survival was 2.5- and 6-fold higher in 200 μM EGCG-treated cells for 25 and 50 nM TCDD, respectively; $p<0.01$). The ultrastructure of TCDD-exposed INS-1 cells was also well preserved in the presence of EGCG. One of the most interesting consequences of TCDD treatment was a remarkable activation of autophagy, indicated by the presence of several large autophagic vacuoles containing identifiable organelles, such as mitochondria or degraded membranes. In EGCG-protected cells no autophagic vacuoles were found and interestingly numerous apoptotic bodies were evident in the cytoplasm of surviving cells. EGCG had no effect on the TCDD-induced increase in the intracellular calcium concentration, but partially prevented the TCDD-induced mitochondrial depolarization. EGCG was also able to prevent completely the TCDD-induced impairment of glucose-stimulated insulin secretion.

Conclusions: Our research clearly shows that EGCG is highly effective in preventing the TCDD-induced toxicity in INS-1 cells, in terms of both cell survival and preservation of their physiological properties. This protective effect could be related to the reported inhibitory effect of EGCG on the Aryl Hydrocarbon Receptor (AhR). EGCG indirectly inhibits AhR by binding the accessory protein Hsp90 and thus probably blocking the TCDD-induced activation of the MAPKs signal transduction pathway.

A cross-sectional study of the association between persistent organic pollutants and glucose intolerance and insulin

M. E. Jørgensen¹, K. Borch-Johnsen², P. Bjerrregaard¹;

¹Centre for Health Research in Greenland, National Institute of Public Health, Copenhagen, ²Steno Diabetes Centre, Gentofte, Denmark.

Background: Experimental evidence supports the hypothesis that persistent organic pollutants (POPs) may cause type 2 diabetes. However, epidemiological studies do not convincingly support an association. The Inuit population in Greenland, which is highly exposed to POPs due to a high intake of sea mammals and fatty fish, has experienced a rapid increase in diabetes prevalence over the last 30 years. Thus the aim was to study the association between POPs and diabetes and impaired glucose regulation in a population-based design.

Methods: From 1999 to 2002 the Greenland population study was carried out among adult Inuit living in Greenland. The examination included a 75g OGTT, anthropometric measurements, a structured interview, and blood tests. P-glucose, s-insulin, lipids were analysed, and PCB153 and p,p'-DDE were analysed in a sub-group as biomarkers of POP exposure. Associations were adjusted for age, sex, waist circumference, HDL cholesterol and triglycerides.

Results: Data on POPs were available on 692 individuals, 305 men (mean age 50 years) and 387 women (mean age 49 years). The table shows mean levels of POPs (geometric means) according to glucose tolerance status. (Tab. 1)

Tab. 1

	N (%)	PCB153 ng/g lipid	Mean PCB153 ng/g lipid, adjusted	p-value	p,p'-DDE ng/g lipid	Mean p,p'-DDE ng/g lipid, adjusted	p-value
Diabetes	71(10.3)	777	752	0.63	1494	1445	0.52
Non-diabetes	621(89.7)	653	722		1240	1358	
IGR	254(36.7)	774	731	0.82	1443	1361	0.90
Non-IGR	438(63.3)	600	722		1153	1370	

There was no association between POPs and fasting glucose or between POPs and fasting insulin or HOMA index of insulin resistance.

Conclusions: No association was seen between POPs and glucose intolerance or markers of insulin resistance. Prospective studies are needed to clarify whether POPs are involved in glucose intolerance or insulin resistance.

Whole grain, bran, and germ intake and risk of type 2 diabetes

R. M. Van Dam^{1,2}, J. S. L. De Munter³, D. Spiegelman^{4,5}, M. Franz¹, F. B. Hu^{1,2},

¹Department of Nutrition, Harvard School of Public Health, Boston, United States, ²Channing Laboratory, Department of Medicine, Brigham and Women's Hospital, and Harvard Medical School, Boston, United States, ³Institute of Health Sciences, Vrije Universiteit Amsterdam, The Netherlands, ⁴Department of Epidemiology, Harvard School of Public Health, Boston, United States, ⁵Department of Biostatistics, Harvard School of Public Health, Boston, United States.

Background and Aims: Control of body weight by balancing energy intake and energy expenditure is of major importance for the prevention of type 2 diabetes, but the role of specific dietary factors in the etiology of type 2 diabetes is less well established. We evaluated intakes of whole grain, bran and germ in relation to risk of type 2 diabetes in prospective cohort studies.

Materials and Methods: We followed 161,737 U.S. women of the Nurses' Health Studies (NHSs) I and II, without history of diabetes, cardiovascular disease, or cancer at baseline. The age at baseline was 37–65 years for NHSI and 26–46 years for NHSII. Dietary intakes and potential confounders were assessed using regularly administered questionnaires. We documented 6,486 cases of type 2 diabetes during 12–18 years of follow-up. Other prospective cohort studies on whole grain intake and risk of type 2 diabetes were identified using searches of MEDLINE and EMBASE up to January 2007, and data were independently extracted by 2 reviewers.

Results: The median whole grain intake in the lowest and highest quintile of intake was 3.7 and 31.2 g per day for NHSI and 6.2 and 39.9 g per day for NHSII. After adjustment for potential confounders, the relative risks for the highest as compared with the lowest quintile of whole grain intake was 0.63 (95% confidence interval [CI] 0.57–0.69) for NHSI and 0.68 (95% CI 0.57–0.81) for NHSII (both: P-value, test for trend <0.0001). After further adjustment for body mass index, these relative risks were 0.75 (95% CI 0.68–0.83; P-value, test for trend <0.0001) and 0.86 (95% CI 0.72–1.02; P-value, test for trend 0.03) respectively. Associations for bran intake were similar to those for total whole grain intake, whereas no significant association was observed for germ intake after adjustment for bran. Based on pooled data for 6 cohort studies including 286,125 participants and 10,944 cases of type 2 diabetes, a 2 serving per day increment in whole grain consumption was associated with a 21% (95% CI 13%–28%) decrease in risk of type 2 diabetes after adjustment for potential confounders and body mass index.

Conclusion: Whole grain intake was inversely associated with risk of type 2 diabetes, and this association was stronger for bran than for germ. Findings from prospective cohort studies consistently support increasing whole grain consumption for the prevention of type 2 diabetes.

Association studies on *DDOST*, *PRKCSH* and *LGALS3* in Finnish type 1 diabetic patients (the FinnDiane Study)

A. Hoverfält^{1,2}, J. M. Söderlund^{1,2}, R. Sallinen^{1,2}, J. Vesa^{1,2}, K. Pettersson-Fernholm^{1,2}, R. Kilpikari^{1,2}, C. Forsblom^{1,2}, M. Wessman^{1,2}, P.-H. Groop^{1,2};

¹Folkhälsan Institute of Genetics, Folkhälsan Research Center, Biomedicum Helsinki, Finland, ²Department of Medicine, HUCH, Division of Nephrology, Helsinki, Finland.

Background and Aims: Chronic hyperglycaemia results in formation and accumulation of advanced glycation end-products (AGEs) in diabetes. AGEs can directly disturb normal function of proteins/macromolecules although the impairment caused by AGEs is mainly receptor mediated. The genes encoding AGE-receptor 1 (*DDOST* on chromosome 1p36.1), 2 (*PRKCSH* on 19p13.2), and 3 (*LGALS3* on 14q21-q22) have been suggested to play a role in the pathogenesis of diabetic micro- and macrovascular complications. The aim of this case-control study was to examine whether single nucleotide polymorphisms (SNPs) in the *DDOST*, *PRKCSH*, and *LGALS3* genes are associated with type 1 diabetes (T1D) or with its micro- and macrovascular complications.

Materials and Methods: 1273 well-phenotyped Finnish T1D patients were studied and grouped into patients with normoalbuminuria (n=457), microalbuminuria (n=271), macroalbuminuria (n=364), and end-stage renal disease (n=181) based on their urinary albumin excretion rate in at least two out of three timed urine collections. Furthermore, 702 Finnish non-diabetic subjects served as controls for the T1D patients. Four SNPs (rs631357, rs640742, rs2070660, rs686658) in the *DDOST* gene, five SNPs (rs34100, rs34088, rs313624, rs11557488, rs311778) in the *PRKCSH* gene, and six SNPs (rs8007614, rs3825613, rs1009977, rs4644, rs10498475, rs2274273) in the *LGALS3* gene were chosen based on the HapMap data. Ten out of the 15 SNPs studied were tagSNPs. Genotyping was performed using the ABI Prism 7900 Sequence Detection System. Association with categorical variables was tested using the χ^2 -test and with continuous variables using the one-way ANOVA. Statistical analyses were performed using the SPSS 12.0.1 for Windows.

Results: All SNPs were in Hardy-Weinberg equilibrium. No association between the SNPs and T1D, diabetic nephropathy or related quantitative variables (blood pressure, estimated GFR, serum creatinine, triglycerides, total cholesterol, HDL cholesterol, glycated hemoglobin A1c) was observed. Furthermore, no association with retinopathy, coronary heart disease, acute myocardial infarction or stroke was observed.

Conclusion: These preliminary data do not indicate the involvement of the *DDOST*, *PRKCSH* and *LGALS3* genes with T1D or with the diabetic micro- and macrovascular complications.

0365

ACE I/D polymorphism predicts end stage renal disease and or mortality in type 1 diabetic patients except for those with already advanced nephropathy: the follow up of the Genesis/Genediab Studies

M. Fysekidis^{1,2}, S. Hadjadj³, R. Roussel^{1,2}, N. Bellili², S. Madani², F. Fumeron², H. Leblanc⁴, J. Gautier⁴, L. Weekers⁵, B. Bauduceau⁶, G. Charpentier⁷, M. Virally⁸, F. Alhenc-Gelas⁹, P. Lefebvre⁵, M. Marre^{1,2};

¹Diabetology, Bichat Hospital, APHP, Paris, France, ²Inserm, U695, Paris, France, ³Division of Diabetes, CHU, Poitiers, France, ⁴Diabetology, St Louis Hospital, APHP, Paris, France, ⁵CHU du Sart Tilman, Division of Diabetes, Liège, Belgium, ⁶Department of Endocrinology, Army Hospital, St Mandé, Bégin, France, ⁷Diabetology, CHU Sud Francilien, Corbeil-Essones, France, ⁸Diabetology, Lariboisiere Hospital, APHP, Paris, France, ⁹U652, INSERM, Paris, France.

Background and Aims: Angiotensin Converting Enzyme (ACE) activity controls renal hemodynamics and its insertion /deletion (I/D) polymorphism was reported to affect development and progression of diabetic nephropathy in type 1 diabetes(T1D).We tested its impact on the risk for End Stage Renal Failure (ERSD) and mortality in prospective follow up of two cohorts of 856 T1D patients from France and Belgium (Genesis/Genediab).

Materials and Methods: Of the 533 participants of the Genediab study 332 agreed in prospective follow up as well as 524 out of 588 of the Genesis study. They were originally included between 1994 and 2000 on the basis of having insulin treatment before the age of 35 years and background retinopathy. They had a follow up until 31/12/2006 for the occurrence of ESRD or death. The tested hypothesis was that the 182 participants with II genotype will display less events than the others. Survival analysis was performed and adjustments were made using the Cox model.

Results: At baseline 463 subjects had no nephropathy, 222 incipient, 205 established and 186 advanced (plasma creatinine > 150 $\mu\text{mol/l}$) nephropathy. Age, sex ratio, HbA1c and diabetes duration were similar between groups. There was an expected association between nephropathy stage and ACE I/D polymorphism at baseline (χ^2 for trend II vs ID/DD :6.6. $p<0,05$). During follow up 141 events occurred the odds ratio for participants with II genotypes vs others was 0,55(95% CI 0,32–0,94). However, only 23 events occurred in participants without nephropathy at baseline, 13 with incipient nephropathy, 34 those with established and 79 among those with advanced nephropathy (nephropathy stage effect : $p < 0,0001$). When both nephropathy stage and ACE I/D genotype effects entered together in the Cox model the II genotype effect disappear OR 0.820 (95% CI 0,45–1,51; $p=0,48$) due to the lack of II genotype effect among the participants with advanced nephropathy at the baseline. Treatment with ACE inhibitors did not alter the result.

Conclusion: The ACE II genotype protects from the development and progression of diabetic nephropathy, and from the risk for ESRD and mortality as well. However its effect disappears in people with already advanced nephropathy.

0366

Evaluation of the association between adiponectin promoter polymorphisms and nephropathy in type 1 diabetes

D. Zhang, J. Ma, K. Brismar, S. Efendic, H. F. Gu;
Molecular Medicine and Surgery, Rolf Luft Center for Diabetes Research, Karolinska Institutet, Karolinska Hospital (Solna), Stockholm, Sweden.

Background and Aims: Recent reports have demonstrated that the adiponectin promoter single nucleotide polymorphism (SNP) -11391G/A is associated with nephropathy in type 1 diabetic (T1D) patients in the Danish, but not in the French, Finnish and Swedish populations. The present study aims at evaluation of the association between adiponectin promoter SNPs and nephropathy in T1D.

Materials and Methods: Three adiponectin promoter SNPs, including -11426A/G, -11391G/A and -11377C/G, were genotyped with dynamic allele specific hybridization (DASH). The subject material includes 1177 (female 599/male 578) American T1D patients with and without diabetic nephropathy (DN). All are European descents and belong to the Genetics of Kidneys in Diabetes (GoKinD) study.

Results: The G allele of SNP-11377C/G was found to be associated with DN in the female T1D patients ($P=0,022$, OR=1.352, CI 95% 1.044–1.752). The haplotype A-G-G constructed with three studied promoter SNPs is also associated with DN in female T1D patients ($P=0,011$, OR=1.417, CI 95% 1.149–1.685). It has previously demonstrated that transcriptional stimulatory protein (SP1) has stimulatory effects on adiponectin promoter activity. We have extended this finding: first, we found four binding sites of SP1 in the adiponectin promoter; second, the G allele of SNP-11377C/G alters the sequence for one of SP1 binding sites.

Conclusion: The adiponectin promoter polymorphisms are associated with DN in T1D in the GoKinD material. SNP -11377C/G may play a role in the regulation of adiponectin promoter activity.

The GoKinD study sample collection is supported by the Juvenile Diabetes Research Foundation in collaboration with the Joslin Diabetes Center and George Washington University, and by the United States Centers for Diabetes Control and Prevention

0367

The prevalence of diabetic foot in patients with diabetic nephropathy

A. Y. Tokmakova, G. Y. Strakhova, G. R. Galstyan;
Diabetic Foot Care Department, National Research Centre for Endocrinology, Moscow, Russian Federation.

Background and Aims: The aim of this study was to investigate the prevalence of diabetic foot syndrome in diabetic population with diabetic nephropathy in Moscow.

Materials and Methods: 346 diabetic patients with diabetic nephropathy were recruited (220 women and 126 men, mean age of $60.37\pm 13,93$ yrs, diabetes duration $14.68\pm 9,16$ yrs, HbA1c $8.43\pm 1,6\%$). They were divided into 3 groups: the 1st group included 136 patients with microalbuminuria; the 2nd group – 110 patients with proteinuria and the 3rd group – 100 patients with chronic renal failure. There was no statistical difference between groups ($p>0,05$) in sex, age, duration of diabetes, HbA1c level. The proportion of patients with type 1 diabetes in the 3rd group was significantly greater at 37% compared with 14% in the 1st group and 15% in the 2nd group ($p<0,001$). We evaluate the prevalence of foot ulcers, Charcot osteoarthropathy, amputations (minor/major) and degree of peripheral vascular disease (PVD).

Results: Results are reported in the table 1. There was significant difference of foot ulcers in patients with proteinuria and chronic renal failure than in patients with microalbuminuria (64% and 58% vs. 32%, $p<0,0001$). The ratio of neuropathic to ischemic ulcers didn't differ significant between the groups. The total number of amputations in the 2nd and the 3rd groups was also significantly higher than in the 1st group ($p<0,05$ and $p=0,0001$, respectively). The presence of Charcot osteoarthropathy was significantly higher in the 3rd group ($p<0,001$ vs the 1st group, $p<0,05$ vs. the 2nd group). When type 1 patients were excluded, the number of ischemic ulcers in the 3rd group increased up to 51.4% and the number of major amputations – to 50%, but these differences were not significant.

Conclusion: Diabetic patients with chronic renal failure have extremely high risk for developing Charcot osteoarthropathy. The prevalence of foot ulcers was higher in patients with proteinuria than in patients with microalbuminuria ($p<0,0001$) and renal failure ($p>0,05$). There was a trend to more severe PVD in patients with more severe diabetic nephropathy.

Table 1.

	Group 1 (n=136)	Group 2 (n=110)	Group 3 (n=100)
Neuropathic foot ulcers	30 (68,2%)	45 (64,3%)	36 (62,1%)
Ischemic foot ulcers	14 (31,8%)	25 (35,7%)	22 (37,9%)
Minor amputations	11 (78,6%)	24 (72,7%)	15 (68,2%)
Major amputations	3 (21,4%)	9 (27,3%)	7 (31,8%)
Charcot osteoarthropathy	5 (3,7 %)	8 (7,3 %)	17 (17 %)

0368

Close similarities in urinary albumin excretion between type 2 diabetes and LADA versus type 1 diabetes – results from the Nord-Trøndelag Health Study 1995–97 (HUNT2)

M. Radtke¹, T. I. Lund Nilsen², K. Midtjell³, V. Grill¹;

¹Department of Cancer Research and Molecular Medicine, Faculty of Medicine, Norwegian University of Science and Technology, Trondheim, ²Department of Public Health, Faculty of Medicine, Norwegian University of Science and Technology, Trondheim, ³HUNT Research Centre, Faculty of Medicine, Norwegian University of Science and Technology, Verdal, Norway.

Background and Aims: Microalbuminuria is considered the earliest sign of microvascular damage in diabetes, but it is not clear whether a particular type of diabetes influences urinary albumin excretion. We wanted to compare urinary albumin excretion in type 1, type 2 diabetes and late autoimmune diabetes in the adults (LADA) as part of an all-population epidemiological survey.

Materials and Methods: Albumin/Creatinine ratio was measured in three urine samples from all diabetic (n=1525) and hypertensive non-diabetic (n=5436) subjects and from a 5% random sample (n=2104) from the large (n=64931) Nord-Trøndelag Health Survey, performed 1995–96.

Results: Mean Albumin/Creatinine ratio [mg/mmol](CI), adjusted for age, gender, smoking, blood pressure, cholesterol/HDL-cholesterol ratio, BMI and diabetes duration was highest in the LADA 1.32 (1.10–1.58) and the type 2 diabetes group 1.25 (1.16–1.3), and non-significantly lower in the type 1 diabetes group 1.05 (0.84–1.31), the hypertensive group 0.99 (0.96–1.02) and lowest in the random selected group 0.95 (0.90–0.99). Dichotomizing for HbA1c or hypertension revealed effect modifications. Thus, lower albumin excretion in type 1 diabetes was restricted to the 50% of subjects with lower HbA1c (tendency) or lower blood pressure(significant).

Conclusion: A higher albumin excretion in type 2 diabetes and LADA than in type 1 diabetes indicates closer resemblance of LADA to type 2 than type 1 in terms of complications. It may also indicate that albumin excretion in type 2 diabetes is increased by factors additional to the standard ones for microalbuminuria and cardiovascular disease.

Progression of glucose tolerance in kidney transplant recipients: pre- and post-transplantation OGTT analysis

F. Moreau¹, S. Caillard², L. Eprinchard², M. Pinget¹, T. Hannedouche², B. Moulin², L. Kessler¹;

¹Endocrinology and Diabetology, ²Nephrology and Renal Transplantation, University Hospital, Strasbourg, France.

Background and Aims: Post-transplant diabetes mellitus increases the morbidity of kidney transplant recipients. Transplant patients developing diabetes are vulnerable to the usual metabolic complications but also to a higher risk of graft failure and cardiovascular diseases. Identify subjects with risk of new-onset diabetes after transplantation is of great importance. We evaluated glucose tolerance in kidney transplant patients before and after kidney transplantation.

Materials and Methods: OGTT were performed consecutively in all patients on waiting list for kidney transplantation with fasting blood glucose <6.9 mmol/L and at least 6 months after kidney transplantation.

Results: From Jan 2005 to March 2007, OGTT were performed in 154 patients. Pre-transplant OGTT revealed 4 cases of diabetes (2,6%) and 33 cases of impaired glucose tolerance (21%). 83 patients underwent a kidney transplantation. Post-transplant OGTT was performed in 38 of these 83 patients. Post-transplant OGTT showed that 50 % of patients had glucose metabolism abnormalities: 26% (10/38) were diabetic and 24% (9/38) had impaired glucose tolerance while 66% (25/38) had normal OGTT and 34% (13/38) impaired glucose tolerance before transplantation. 4/10 of these new-onset post-transplantation diabetes occurred in subjects with pre-transplantation impaired glucose tolerance. Diabetes and impaired glucose tolerance were observed in 24% and 16% of cases respectively after transplantation in patients with normal glucose tolerance before transplantation (n=25). Mean age of patients who developed diabetes and impaired glucose tolerance was 53 and 55 years old respectively, mean BMI was 25 and 27 kg/m² respectively. Among patients with pre-transplant impaired glucose tolerance (n=13), 33% have post-transplant diabetes and 33% have impaired glucose tolerance after transplantation. Patients with pre-transplant impaired glucose tolerance who developed post-transplant diabetes have a mean BMI of 29 kg/m² before transplantation.

Conclusion: One third of kidney recipients with pre-transplant impaired glucose tolerance had post-transplant diabetes mellitus. These results suggest that OGTT should be performed before transplantation in all patients in order to detect patients with high risk of post-transplant diabetes and to adapt the immunosuppressive therapy.

PS 15 Classification of IGT, type 2 diabetes and metabolic syndrome

0370

The risk of diabetes in the metabolic syndrome is extremely high if the appropriate reference category is used

E. Bonora¹, S. Kiechl², J. Willeit², R. C. Bonadonna¹, M. Muggeo¹;

¹Endocrinology and Metabolic Diseases, University of Verona, Italy,

²Neurology, University of Innsbruck, Austria.

Background and Aims: The Metabolic Syndrome is a risk factor for type 2 diabetes (T2DM). However, previous studies demonstrated that any component of the Metabolic Syndrome can predict T2DM. Among subjects without the Metabolic Syndrome many have one or two components of the syndrome, and this may lead to an underestimate of the true diabetes risk in these subjects. In the present study we assessed the risk of T2DM in subjects with the Metabolic Syndrome using different reference categories.

Materials and Methods: We calculated the 10-yr risk of T2DM in 857 subjects aged 40–79 years from the general population living in Bruneck, north-eastern Italy. Diabetes was diagnosed according to ADA 1997 criteria (fasting glucose only). The Metabolic Syndrome was diagnosed by NCEP-ATP III criteria.

Results: Incident cases of T2DM were 76. In the 169 subjects with the Metabolic Syndrome at baseline the sex- and age-adjusted odds ratio (OR) for T2DM was 4.4 (95% CI 2.7–7.2, p<0.001). As compared to subjects without any metabolic components of the Metabolic Syndrome the ORs in those with 1, 2, 3, 4/5 components were 6.4 (0.8–49.6, p=0.08), 18.5 (2.5–139, p=0.005), 22.2 (2.9–172, p=0.003) and 119 (15.1–942, p<0.001), respectively (overall p<0.001). Among components of the Metabolic Syndrome, IFG was the strongest risk factor (sex- and age-adjusted OR 12.2, 7.1–20.5, p<0.001), but also high waist circumference (5.4, 3.0–9.5, p<0.001), hypertension (4.4, 2.1–9.0, p<0.001), high triglycerides (1.7, 1.1–2.8, p=0.03) and low HDL-cholesterol (1.8, 1.0–3.1, p=0.05) were predictors of T2DM. The risk of T2DM was very high in subjects with the Metabolic Syndrome also when insulin sensitivity was normal (quartiles 1–3 of HOMA-IR)(ORs 12.3, 1.4–109, p=0.024 in those with 3, and 38.0, 3.1–471, p=0.005 in those with 4/5 abnormalities vs. those with no abnormality).

Conclusion: The risk of T2DM in subjects with the Metabolic Syndrome is very high when the reference category is composed by subjects without any metabolic abnormality. The risk is high also when insulin resistance was estimated to be normal.

0371

Characteristics of glucose intolerance in the Japanese subjects with and without lowering of early-phase insulin responses after glucose load (GTT)

Y. Sakamoto^{1,2}, Y. Inoue², H. Matsumoto², K. Oono², Y. Tokumasa²;

¹Diabetes center, Eastern Japan Medical Center, Ebina-City,

²Ichihara-City Medical Association, Japan.

Background and Aims: The aim of this study was to clarify the characteristics of glucose intolerance after glucose load in the Japanese subjects with and without lowering of early-phase of insulin responses after glucose load.

Materials and Methods: We did a screening test of 22228 general healthy subjects aged over 40 years old. In the 1st. screening test, The subjects were screened for the criteria of glucosuria, FPG levels (110mg/ml) and/or HbA1c levels (5.6%). In the second test (75g OGTT), GTT data from 143 cases applying for a close examination among the positive subjects in the 1st. test were analyzed in detail. Based on the results of Insulinogenic index (30min): (Ins 30min–Ins 0min)/Glu30min–Glu 0min) from 75g OGTT, the subjects were classified into the following 3 groups: Low Responder group (Insulinogenic index: less than 0.4), Moderate Responder group (Insulinogenic index: 0.4–less than 1.0) and High Responder group (Insulinogenic index: not less than 1.0). Normal glucose tolerance (NGT), isolated impaired fasting glucose (IFG: FPG between 110mg/dl and 125mg/dl, 2hPG less than 140mg/dl), isolated IGT (FPG less than 110mg/dl and 2hPG between 140mg/dl and 199mg/dl), isolated IGT with fasting hyperglycemia (IFG/IGT: FPG between 110mg/dl and 125mg/dl, 2hPG between 140mg/dl and 199mg/dl) and DM groups. The DM group is further divided into 2 groups, isolated FPG-DM group (FPG not

less than 126mg/dl and 2hPG less than 200mg/dl, 2hPG-DM group (2hPG not less than 200mg/dl).

Results: 1) In the GTT study, Low Responder subjects was found in 63.6%, Moderate Responder was 24.5% and High Responder was 11.9%. Mean value of Insulinogenic index were as follows: (Low R:0.194, Moderate R:0.588 High R:1.588). 2) The incidence of the 2hPG-DM subjects was found in 26.4% in the Low R group, 5.7% in the Moderate group and no case in the High R group. The incidence of the NGT subjects were as follows: (in the Low R: 34.1%, in the Moderate R: 48.6% and in the High R: 64.7%). The incidence of the isolated FPG-DM subjects were as follows: (in the Low R: 3.3%, in the Moderate R: 5.7% and in the High R: 9.1%). The incidence of the isolated IGT: (in the Low R: 19.8%, in the Moderate R: 22.9% and in the High R: 27.3%). The incidence of the isolated IFG: (in the Low R: 4.4%, in the Moderate R: 2.9% and in the High R: 18.2%). The incidence of the IFG/IGT: (in the Low R: 12.1%, in the Moderate R: 14.3% and in the High R: 0%).

Conclusion: In the Japanese subjects, the incidence of the 2hPG-DM subjects was much lower in the High Responder group compared to that in the Moderate and Low responder groups. And the incidence of the isolated FPG-DM subjects (4.2% in all subjects) was much lower than that of 2hPG-DM subjects (18.2% in all subjects). The pattern of insulin secretion in the Japanese type 2 diabetic subjects is characterized by marked low responses in the early- phase insulin secretion after glucose load.

Which of the criteria is more accurate ADA(IFG100) or IDF(IFG110) for the prediction of IGT1 and IGT2 at high risk group?

The RISK Study Results III

T. Yilmaz¹, M. Sargin², B. Olmez³, S. Karadeniz⁴, B. Oguzhan⁵ & the RISK Study Group,

¹Endocrinology and Metabolism Dept., Istanbul Medical Faculty, Istanbul University, ²Endocrinology and Metabolism Dept., Kartal Educ. and Res.

Hosp., Istanbul, Turkey, ³Novartis Pharma, Istanbul, Turkey,

⁴Medical Faculty, Istanbul Science University,

⁵Diabetes Centers, Turkish Diabetes Foundation, Istanbul, Turkey.

Background and Aim: To compare the prevalence of impaired fasting glycemia (IFG) according to the ADA and IDF criteria for the prediction of impaired glucose tolerance (IGT) 1-h and 2-h glucose values in asymptomatic individuals with high risk characteristics for type 2 diabetes (ADA criteria).

Materials and Method: The population based, cross-sectional RISK study includes 13.140 individuals randomly selected from 191 centers in Turkey. 75-g oral glucose tolerance test (OGTT) and body mass index (BMI) were evaluated. 1.h/2.h postprandial glucose levels between 140–199 mg/dl were considered as IGT1 and IGT2, respectively in individuals with OGTT in nondiabetic range.

Results: The prevalence of IFG according to ADA criteria (FBG \geq 100 mg/dl, IFG100) was higher than IDF criteria (FBG \geq 110 mg/dl, IFG110) in the study population (39.7% versus 18.7%, $p < 0.001$). The prevalence IFG100 and IFG110 were higher in subjects aged \geq 45 yrs than in subjects aged $<$ 45 yrs and with high risk characteristics for type 2 DM according to ADA criteria (39.7% and 18.7% vs 33.8% and 12.1%, $p < 0.001$, $p < 0.001$, respectively). The OGTT revealed IGT1 in 79.1% of subjects with IFG110, 72% with IFG100, 65.8%

with IFG90 and IGT2 in 58.9%, 47.1%, 36%, respectively. The prevalences of IFG110 and IFG100 were %10.8 and 25% in subjects with BMI $<$ 25 kg/m², 12.5% and 34.7% in subjects with BMI 25–30 kg/m², 14.8% and 36.3% in subjects with BMI \geq 30kg/m², respectively.

Conclusion: In our study population consisting of people at risk for type 2 diabetes, the rate of IFG100 was 2.1 times higher than IFG110. On the other hand, the prevalences of either IGT1 or IGT2 were higher in IFG110 group compared to IFG100 group. The concordance between IFG110 and IGT1 or IGT2 is more prominent than IFG100 and IGT1 or IGT2. According to our results, the predictive value of IFG110 is higher than of IFG 100 for glucose intolerance.

Associations between insulin resistance, beta cell function and metabolic markers in a non-diabetic adult population

M. H. Hedman¹, B. Lindahl², S. Söderberg³, G. Hallmans⁴, O. Rolandsson¹;

¹Department of Public Health and Clinical Medicine, Family Medicine,

²Department of Public Health and Clinical Medicine, Behavioural

Medicine, ³Department of Public Health and Clinical Medicine, Cardiology,

⁴Department of Public Health and Clinical Medicine, Nutritional Research, Umeå, Sweden.

Background and Aims: Insulin resistance and beta cell dysfunction are major characteristics of T2DM. We aimed to characterize a non-diabetic population by the associations between different levels of insulin resistance (IR) and beta cell function (B%) and their relation to metabolic markers. We hypothesized that subjects with high IR and low B% would have more metabolic perturbations than other groups.

Fig. 1

Tab. 1 Abstracts 0373

	Group 1 p=1037	Group 2 p=181	Group 3 n=224	Group 4 n=183	p-values
Sex (M/F)	514/523	83/98	104/120	81/102	n.s.
Age	42.0(10.2)	41.7(10.5)	44.7(11.0)	45.6(10.7)	$p < 0.01$
fP-glucose mmol/L	5.2(0.4)	4.6(0.5)	5.2(0.5)	5.7(0.4)	$p < 0.01$
Body Mass Index	24.3(3.0)	25.8(3.9)	28.4(4.6)	26.1(3.8)	$p < 0.01$
Cholesterol mmol/L	5.9(1.3)	5.8(1.4)	6.3(1.2)	6.1(1.2)	$p < 0.01$
Triglycerides mmol/L	1.0(0.1-13.6)	1.2(0.1-4.2)	1.7(0.1-11.0)	1.2(0.3-8.9)	$p < 0.01$
Adiponectin mg/L	8.3(1.1-27.5)	7.7(1.7-22.5)	6.6(1.4-18.9)	7.5(1.8-21.1)	$p < 0.01$
Leptin mg/L	5.0(0.6-32.7)	6.7(0.6-49.1)	10.7(0.8-44.4)	7.5(0.6-74.0)	$p < 0.01$
IGT %	7.3	6.1	9.4	9.3	n.s.
IFG %	2.8	0.0	4.5	12.6	$p < 0.01$

Table 1: Distribution of men and women, mean(SD) for age, fP-glucose, BMI and cholesterol, and median(min-max) for triglycerides, adiponectin and leptin in groups 1-4, respectively. Percentages of subjects with IGT and IFG, respectively. P-values for non-specified differences between the groups.

Materials and Methods: 1625 (M/F 782/843, mean age 42.8 SD10.4) non-diabetic Swedish subjects participated in a health program. Data on fasting plasma glucose (fPG), 2hour plasma glucose (2hPG), cholesterol, triglycerides, BMI and blood pressure were collected. Additional analyses included insulin, C-peptide, adiponectin and leptin. HOMA2 method was used to calculate B% from C-peptide data and IR from insulin data. By dichotomizing IR and B% by their 75th percentiles, four groups with combinations of IR and B% were defined (figure 1).

Results: IR correlated with B% ($r=0.535$, $p<0.01$; figure 1). Women had higher IR ($p<0.01$) and B% ($p<0.05$) than men. IR ($r=0.180$, $p<0.01$), but not B% was correlated with age. Differences between groups 1–4 are presented in table 1. Bonferroni post hoc test showed that subjects in group 3 and 4 were older than in 1 and 2. fPG levels were highest in group 4. BMI, cholesterol, triglycerides and leptin values were highest in group 3, while adiponectin was lowest in the same group. IFG but not IGT was more frequent in group 4.

Conclusion: As found in previous studies the association between IR and B% was hyperbolic. In contrast to our hypothesis, the group with high IR and high B% had more metabolic perturbations than the other groups. This could reflect the natural course of the decreasing beta cell function and increasing insulin resistance towards fulminant T2DM. (Tab. 1)

0374

Heterogeneity of clinically classified type 2 diabetes mellitus: implication to epidemiological studies

F. C. F. Otieno¹, G. Huho², A. Amayo²;

¹Clinical Medicine and Therapeutics, University of Nairobi,

²Clinical Chemistry, University of Nairobi, Kenya.

Background. Diabetes is a heterogeneous disorder broadly classified as type 1 and 2. Type 2 diabetes is equally heterogeneous with obese and non-obese types. Lately, an addition of LADA, that is phenotypically type 2 at onset, is complicating the picture in clinical practice. These clinical varieties of type 2 diabetes vary in their cardiovascular risk loading, therapeutic considerations and consequently their response to the chosen therapies. Primary prevention studies (1,2,3) lend credence to differential response to the various therapeutic interventions on type 2 diabetes, at least, by the weight categories. (4)

Subjects and Methods: Ambulatory patients with clinical type 2 diabetes mellitus (classified by age of onset and BMI only), in equal numbers obese ($BMI>25\text{Kg}/\text{M}^2$) and non-obese ($BMI\leq 25\text{Kg}/\text{M}^2$) were randomly sampled. The patients enrolled were limited to those with ≤ 5 years duration of diabetes. Socio-demographic data and diabetes history were obtained. Clinical examination, laboratory tests of GAD antibody and fasting C-peptide assays, among other tests, were done.

Results: 124 subjects were seen and their fasting C-peptide and GAD antibody status were used to help re-categorise them as types 1A, 1B, LADA or type 2 diabetes.

Table 1. Demographic characteristics of study subjects.

	BMI (Kg/M^2) ≤ 25	>25
Gender %	F-46.6%	54.6%
Mean (SD) age (yrs)	47.2(13.2)	47.6(10.5)
Mean (SD) age at diagnosis (yrs)	45.2(13.2)	45.1(10.3)
Mean (SD) duration of diabetes (months)	25.4(21.7)	29.6(19.9)
Mean (SD) fasting blood glucose (mmol/L)	8.09(4.4)	8.17(4.8)
Current Treatment (%pts)	41.7%	25.4%
Insulin only		
Insulin & OHA	10%	14.3%
OHA only	38.3%	54%
Diet only	10%	6.3%
Family History, 1 st degree relative with diabetes	43.0%	40.6%
Mean BMI Kg/M^2	22.45(2.4)	29.83(3.4)

OHA = Oral hypoglycaemic agents

TABLE 2: AETIOLOGICALLY CLASSIFIED DIABETES IN THE STUDY

AETIOLOGIC TYPES/ CLINICAL		TYPE 1A	TYPE 1B	TYPE 2	LADA
BMI Kg/M^2	Non-obese ≤ 25	4(6.7%)	13(21.6)	39(65%)	4(6.7%)
	Obese >25	0	2(3.1%)	59(91.2%)	3(4.7%)

Figure 1. ROC-Curve to illustrate utility of BMI in identifying aetiologic type 2 diabetes in the study subjects

BMI cut-off of $25\text{Kg}/\text{M}^2$ had sensitivity of 71.4% and specificity of 94.5% for detecting aetiologic type 2 diabetes in study subjects.

Conclusion: Clinical categorisation of the study patients having type 2 diabetes using BMI was useful. However, the patients with $BMI\leq 25\text{Kg}/\text{M}^2$, 17/124 (13.7%) were re-classified as type 1 diabetes and 4/124 (3.2%) as LADA on laboratory testing, suggesting that the lower BMI ($\leq 25\text{Kg}/\text{M}^2$) group was the more heterogeneous group. Both groups had similar proportions of patients with LADA.

BMI appears to be a major indicator of heterogeneity.

Development and validation all-event risk score in patients with type 2 diabetes - Hong Kong Diabetes Registry

X.-L. Yang¹, W.-Y. So¹, A. P. S. Kong¹, G. T. C. Ko³, R. C. W. Ma¹,

C. S. Cockram¹, C.-C. Chow¹, P. C. Y. Tong¹, J. C. N. Chan¹;

¹Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Shatin, ²Hong Kong Institute of Diabetes and Obesity, The Chinese University of Hong Kong, Shatin, Hong Kong.

Background: Patients with Type 2 diabetes are at increased risk of coronary heart disease, heart failure, stroke, peripheral arterial disease, end-stage renal disease and premature death (all-event endpoint). It is unknown whether these events as a whole can be predicted using a single risk score.

Methods: A prospective cohort of 6392 Chinese patients with type 2 diabetes who did not have history of the all-event endpoint at enrolment was used in the analysis. The data were randomly assigned to a training and a test dataset. In the training dataset, stepwise Cox regression ($p=0.05$) was used to select predictors. In the test dataset, calibration was checked using the life table method and discrimination was checked using the area under the receiver's operating characteristic curve (aROC). Risk factors were linear-transformed using spline Cox models before model development.

Results: Age, sex, blood haemoglobin (Hb), spot urinary albumin:creatinine ratio (ACR), estimated glomerular filtration rate (eGFR), HbA_{1c} , current smoking and use of insulin were selected as predictors in the training dataset. The all-event risk score was compiled as follows: $0.0389 \times \text{age (year)} - 0.5295 \times \text{sex (1 if female)} + 0.0620 \times |\text{HbA}_{1c} - 6.5|(\%) - 0.2344 \times \text{blood Hb (g/dL)}$

+ 0.2249 × {Log₁₀(1+ACR)}² - 1.4493 × Log₁₀(eGFR) + 0.3638 × current smoking (1 if yes) + 0.5235 × use of insulin (1 if yes). The 5-year probability of the all-event endpoint was: 0.9019^{EXP(RISK SCORE+3.8424)}. The predicted all-event-free probability was within the 95% confidence intervals of the observed all-event-free rate over a 5-year period. With follow-up time and censoring status considered, the adjusted aROC was 0.803 over the 5-year observation period. At the cutoff point of ≥-3.6024, the sensitivity was 71.1% and the specificity was 71.0%.

Conclusions: All-event endpoint can be predicted and the developed all-event risk score performed well in the Hong Kong Chinese patients with type 2 diabetes. External validation in other Chinese type 2 diabetic populations is needed before clinical use.

PS 16 Diabetes prevalence and incidence

0376

The prevalence of undiagnosed type 2 diabetes mellitus in Ukraine

B. Mankovsky;

Diabetologia, Center for Endocrinology, Kiev, Ukraine.

Background and Aims: Diabetes mellitus represents the world-wide epidemics. However, the prevalence of diabetes mellitus in Ukraine is significantly lower than in neighboring countries. The number of registered patients with diabetes is 1,063 million subjects with the population of the country are 48 million. However, the real prevalence of diabetes in the country remains unknown.

Materials and Methods: To estimate the real prevalence of undiagnosed type 2 diabetes mellitus we performed screening of subjects who have some traditional risk factors for diabetes but who did not have any history of hyperglycemia. We examined 4640 subjects aged from 30 to 80 years old, 1098 men (23,66%) and 3542 women (76,34%) living at 8 different regions of the country. After getting informed consent the plasma glucose was measured either at fasting or random condition. In case of increased plasma glucose level another test was performed at fasting. The statistical analysis was done using the statistical package SPSS-13.

Results: We found that type 2 diabetes mellitus was newly diagnosed in 635 subjects (13.69%), impaired fasting glucose was registered in 1008 persons (21.72%). The risk factors for type 2 diabetes mellitus revealed by regression analysis were age (OR-2.64, p<0.001), history of myocardial infarction (OR-1.73, p<0.001), arterial hypertension (OR-0.71, p<0.001), male gender (PR - 0.52, p<0.001), BMI more than 27 kg/m² (OR-1.47, p<0.001), family history of diabetes (OR-1.23, 0.05) and in women - the history of the birth of the baby with body mass of more than 4 kg (OR-1.2, p<0.1). The prevalence of type 2 diabetes mellitus in subjects younger than 45 year old was 6.53%, in those aged 45-55 year old - 11.67%, in subjects aged 56-65 year - 16.83% and in those older than 65 years was 18.71%. The risk factors for impaired fasting glucose were arterial hypertension (OR-2,5), history of myocardial infarction (OR-2,5) and stroke (OR-2,5), age (OR-1,98), obesity (OR-1,75) and male gender (OR-1,65), p<0.05 for all factors. There were some inter-regional differences in the prevalence of newly-diagnosed diabetes mellitus.

Conclusion: The real prevalence of type 2 diabetes mellitus in Ukraine is significantly higher than registered and active diagnostics of the disease based on an assessment of risk factors is urgently needed to prevent the late diagnostics and complications of the disease.

The prevalence of diabetes in a large representative Hungarian population sample

E. P. Vamos¹, M. Novak², M. Kopp², I. Mucsi^{1,2};

¹First Department of Internal Medicine, Hungary, ²Institute of Behavioral Sciences, Semmelweis University, Budapest, Hungary.

Background and Aims: Although the dramatic effect of diabetes on public health is well-recognized, there is no reliable data concerning the prevalence of diabetes in Hungary. The few studies examining the incidence or prevalence of diabetes in this country focused on specific age groups or certain geographic areas. The aim of our study was to estimate the overall prevalence of diabetes in the Hungarian general population.

Materials and Methods: Hungarostudy 2002 was a cross-sectional survey conducted on a large, nationally representative sample of the Hungarian population over the age of 18. The survey's aim was to extensively examine the mental and physical health status, health behavior and psycho-social risk factors of the Hungarian general population. Study participants were randomly selected from the National Population Register by a clustered, stratified sampling procedure. The identified individuals were home-interviewed by trained nurses. Socio-demographic, lifestyle, health behavior, self-rated health data was obtained during the structured interview. Self-reported information on diabetes and comorbidity was also tabulated.

Results: A total of 12653 patients were enrolled in the survey, refusal rate was 17.7%. The mean age of the population was 47.6±18 with a range of 18-102,

45% were male. The overall crude prevalence of diabetes was 6.6%. There was no gender difference regarding diabetes (6.5% men, 6.7% women, NS). Prevalence increased sharply with age (1.1%, 7.2% and 15.4%, respectively, in age groups 18–39, 40–65 and over 65 years). Forty-eight percent of diabetic subjects vs 29.4% of non-diabetics had less than 10 years in education ($P < 0.0001$). A wide geographic variation in the prevalence of diabetes (3.9% – 9.0%) was observed. Higher BMI was associated with higher prevalence of diabetes (underweight 1.8%, normal 3%, overweight 7.5%, obese 13.9%). Prevalence of comorbid conditions was significantly higher in diabetic individuals compared to non-diabetics; hypertension (59.5 vs. 19.2%), history of stroke (11.2 vs 3.6%), history of myocardial infarct (7 vs 2.1%) and renal failure (5.7 vs 2.2%), $P < 0.0001$ for all comparisons.

Conclusion: Based on this self-reported data the prevalence of diabetes in Hungary is higher than previous estimations and extrapolation from international data predicted. Since up to 50% of the diabetic patients may be undiagnosed, the true burden of diabetes is obviously even larger.

0378

Prevalence of impaired fasting glucose, impaired glucose tolerance and newly-diagnosed diabetes in subjects at risk of developing type 2 diabetes

T. Tankova, N. Chakarova, M. Lazarova, I. Atanassova;
Clinical Center of Endocrinology, Medical University, Sofia, Bulgaria.

Background and Aims: The aim of the present study is to evaluate and compare the prevalence of impaired fasting glucose (IFG), impaired glucose tolerance (IGT) and newly-diagnosed diabetes in subjects at risk of developing diabetes according to 2003 ADA and 2006 WHO criteria.

Materials and Methods: 1029 subjects (467 males and 562 females), of mean age 49.3 ± 18.1 years and mean BMI 29.8 ± 7.9 kg/m², with at least two risk factors for diabetes were enrolled. Subjects' risk was assessed by means of two questionnaires – about main diabetes risk factors and individual risk index FINDRISK. Glucose tolerance was studied during OGTT. Plasma glucose was measured at 0 and 120 minute by a dehydrogenase method (DiaSys; Glucose – GD). Categories of glucose tolerance were defined according to 2003 modified ADA and 2006 WHO criteria.

Results: Using 2003 ADA criteria, 46.6% of subjects demonstrated normal glucose tolerance (NGT), while the rest 53.4% showed different abnormalities – 28.4% appeared to be with IFG, 8.6% – with IGT and 16.4% – with newly-diagnosed diabetes (NDD). The group with NGT demonstrated mean individual risk index FINDRISK 9.98 ± 4.1 , the IFG group -12.21 ± 4.3 ($p < 0.001$ vs NGT), the IGT group -13.22 ± 4.4 ($p < 0.0001$ vs NGT) and the newly-diagnosed diabetes group -14.5 ± 4.07 ($p < 0.0001$ vs NGT; $p < 0.01$ vs IFG and IGT groups). When applying 2006 WHO criteria, 63.8% of subjects appeared to be with NGT, 11.2% – with IFG, 8.6% – with IGT and 16.4% – with newly-diagnosed diabetes. The group with NGT demonstrated mean individual risk index FINDRISK 10.42 ± 4.23 , the IFG group -12.99 ± 4.08 ($p < 0.0001$ vs NGT), the IGT group -13.22 ± 4.4 ($p < 0.0001$ vs NGT) and the diabetes group -14.5 ± 4.07 ($p < 0.0001$ vs NGT; $p < 0.01$ vs IFG and IGT groups). The prevalence of newly-diagnosed diabetes appeared to be higher in males at risk as compared to females (19.0% vs 14.2%); the other forms of glucose intolerance being similar in both sexes. Significant positive correlation was established between the individual risk index FINDRISK and both fasting plasma glucose ($r = 0.73$, $p < 0.001$) and 2-hour plasma glucose ($r = 0.67$, $p < 0.001$).

Conclusions: The prevalence of IFG, IGT and newly-diagnosed diabetes in individuals at risk of developing type 2 diabetes is rather high with either of the criteria being used. When comparing 2003 ADA with 2006 WHO criteria the main difference appears to be in the prevalence of IFG, being 2.5 times higher with ADA criteria. The progression from NGT to IFG, IGT and diabetes correlates well with the number of risk factors and the individual risk index. Therefore, on the basis of the present results we may conclude that screening for diabetes should be performed in subjects with an individual risk index FINDRISK higher than 10.

Fasting plasma glucose, glycated haemoglobin A_{1c} and incidence of diabetes in a Japanese population: the Funagata Diabetes Study

T. Nakagami¹, M. Tominaga², R. Nishimura³, M. Daimon⁴, T. Oizumi⁴, N. Yoshiike⁵, N. Tajima³;

¹Diabetes Center, Tokyo Women's Medical University, Tokyo, ²Department of Laboratory Medicine, Yamagata University School of Medicine, Yamagata, ³Division of Diabetes, Metabolism and Endocrinology, Department of Internal Medicine, Jikei University School of Medicine, Tokyo, ⁴Department of Neurology, Hematology, Metabolism, Endocrinology and Diabetology, Yamagata University School of Medicine, Yamagata, ⁵International University-Business Coordination Center, National Institute of Health and Nutrition, Tokyo, Japan.

Background and Aims: The Ministry of Health, Welfare and Labour, Japan has introduced fasting plasma glucose (FPG) and glycated hemoglobin A_{1c} (HbA_{1c}) measurements to screen undiagnosed diabetes (DM) in the general health check-up system for adults aged 40–75 years old. In this health check-up system, FPG or HbA_{1c} measurement is mandatory. Then, people with FPG of 5.6–6.9 mmol/l or HbA_{1c} of 5.2–6.0% take life-style counseling whereas people with FPG ≥ 7.0 mmol/l or HbA_{1c} ≥ 6.1 % take medical care by physicians. In this study, we assess the predictability of FPG and HbA_{1c} for incident cases of DM and the relevance of the FPG and HbA_{1c} cut-offs to undergo life-style counseling, by using data from Funagata town inhabitants.

Subjects and Methods: In the population-based cohort, HbA_{1c} and fasting and 2-hour plasma glucose on an oral glucose tolerance test (OGTT) were determined in 1995–1997. A total of 1,188 Funagata-town inhabitants aged 35–89 years old and free of DM was confirmed their glycemic status by medical history of DM during 5 years and a repeated OGTT in 2000–2002 if people had no treatment of DM during 5 year period (participation rate: 60.3%). DM was diagnosed according to 1999-World Health Organization criteria when an OGTT would be applied.

Results: During the period, 57 subjects (4.8%) developed DM. The area under the receiver operating characteristic curve for incident of DM was similar between HbA_{1c} (0.785 [95% CI: 0.714–0.855]) and FPG (0.786 [0.719–0.852]). The FPG cut-off point of 5.6 mmol/l gave a sensitivity of 61.4%, a specificity of 82.5%, and a positive predictive value of 15.0%. The corresponding values for HbA_{1c} cut-off point of 5.2% were 73.7%, 71.8%, and 11.7%, respectively. Both FPG and HbA_{1c} were positive, continuous, and independent predictors for incident of DM (both p-values < 0.001). Hazard ratios adjusting for age, sex, and body mass index (95% confidence interval) for incident of DM corresponding to FPG of 5.0–5.5, 5.6–6.0, 6.1–6.9 mmol/l at baseline were: 1.55 (0.63–3.82), 4.61 (1.96–10.85), and 13.12 (5.14–33.48), whereas those corresponding to HbA_{1c} of 4.9–5.99, 5.0–5.19, 5.2–6.0, ≥ 6.1 % at baseline were: 0.33 (0.07–1.66), 1.16 (0.39–3.46), 4.68 (2.05–10.70), 34.27 (9.46–124.08), respectively. Identified cases by FPG 5.6 mmol/l or HbA_{1c} 5.2% at baseline had worse cardiovascular risk profiles than those unidentified, although the difference was not statistically significant.

Conclusion: The cut-off point of FPG and HbA_{1c} for life-style counseling according to the guideline recommended by Ministry of Health, Welfare and Labour, Japan was associated with increased risks of incident of DM. These cut-off points seemed to be effective to identify future DM in the next 5 years, however it seemed to be expensive. Further analyses focusing on mortality and the cost-effectiveness of the screening system will be needed.

High prevalence of abnormal OGTT in patients with chronic hepatitis B or chronic hepatitis C

A. Mavrogiannaki, B. Karamanos, E. Manesis, C. Demponeras, J. Koskinas, G. Papatheodoridis, A. Archimandritis;
2nd Academic Department of Internal Medicine, Diabetes Center, University of Athens, Hippokraton Hospital, Greece.

Background and Aims: The association of glucose intolerance with chronic hepatitis B (CHB) or C (CHC) remains controversial, despite the large number of studies, which however have not used Oral Glucose Tolerance Test (OGTT) as criterion of glucose intolerance and the comparisons were

not done with matched controls. The aim of the present study is to compare the prevalence of glucose intolerance, documented by OGTT, among patients with CHB or CHC and perfectly matched control groups.

Materials and Methods: 187 patients with CHB or CHC, consecutively examined at the outpatient liver clinic, were compared with 187 subjects from the general population, matched for age, sex and Body Mass Index. OGTT was performed in all (except known diabetics).

Results: The prevalence of known diabetes did not differ between the groups of CHB or CHC and their controls (7.2% vs 11.1%, $P=0.389$ and 7.1% vs 7.5%, $P=0.894$, respectively). However, abnormal OGTT was higher in CHB patients compared with their control-group (23.4% vs 8.3%, $P=0.013$). Fasting blood glucose (80.9 ± 2.3 vs 77.3 ± 3.8 mg/dl, $P=0.398$), insulin resistance, by HOMA model, (3.7 ± 0.4 vs 3.3 ± 0.4 , $P=0.144$) and family history of diabetes (29.9% vs 16.7%, $P=0.081$) did not differ between these two groups. CHC patients compared with their controls had higher prevalence of abnormal OGTT (30.5% vs 9.2%, $P=0.000$). Fasting blood glucose was higher in CHC patients than in controls (84.9 ± 1.7 vs 76.8 ± 1.6 mg/dl, $P=0.001$). Insulin resistance (3.4 ± 0.3 vs 3.1 ± 0.2 , $P=0.721$) and family history of diabetes (25.7% vs 16.3%, $P=0.123$) did not differ between these two groups. The majority of patients, both CHB and CHC, with abnormal OGTT had normal fasting blood glucose (69.8% and 54.5%, respectively), thus the diagnosis would have been missed, if only fasting blood glucose had been used.

Conclusion: Increased prevalence of abnormal OGTT is documented not only in chronic hepatitis C, but also in chronic hepatitis B patients, compared with perfectly matched control groups, reported for the first time. In patients with chronic hepatitis B or C the diagnosis of any degree of glucose intolerance requires OGTT, especially if diabetogenic treatments are planned.

Chlamydia pneumoniae and Chlamydia trachomatis antibodies are associated with symptoms of polycystic ovary syndrome: a new aetiology for the syndrome?

L. C. Morin-Papunen¹, A. Torvinen¹, A. Bloigu², S. Franks³, A. Ruokonen⁴, L. Törmäkangas⁵, M.-R. Järvelin⁶, M. Paldanius⁵, M. Leinonen⁵, P. Saikku⁵, A. Pouta²;

¹Department of Obstetrics and gynecology, University Hospital of Oulu, Finland, ²Department of Child and Adolescent Health, National Public Health Institute, Oulu, Finland, ³Institute of Reproductive and Developmental Biology, Imperial College London, United Kingdom,

⁴Department of Clinical Chemistry, University Hospital of Oulu, Finland,

⁵Department of Microbiology, National Public Health Institute, Oulu,

Finland, ⁶Department of Epidemiology and Public Health, Imperial College London, United Kingdom.

Background and Aims: Chronic inflammation has been shown to be involved in the pathogenesis of insulin resistance, type 2 diabetes, and atherosclerosis. All chlamydial species have a tendency to cause persistent infections with subclinical chronic inflammation. *C. pneumoniae* infections have been associated with e.g. atherosclerosis and *C. trachomatis* infections with e.g. infertility and ectopic pregnancies. Polycystic ovary syndrome (PCOS) has been linked to insulin resistance, hyperinsulinemia and low-grade chronic inflammation. Our hypothesis was that the systemic inflammation induced by chlamydial infections might contribute to the development of PCOS. We therefore investigated, if chlamydial antibodies and slightly elevated C-reactive protein (hsCRP) levels are associated with symptoms of PCOS in Northern Finland Birth Cohort 1966 (NFBC)

Materials and Methods: Members of NFBC ($n=5889$) have been studied longitudinally from fetal period, with the most recent assessment occurring at age 31, when a postal questionnaire including questions about hirsutism and oligomenorrhoea was sent to all women. 4523 women returned the questionnaire. Those who reported both symptoms were defined as cases ($n=576$). The presence of *C. pneumoniae* (IgG titers ≥ 32) and for *C. trachomatis* (IgG titers ≥ 8) was measured by microimmunofluorescence (MIF) in 96 cases and 2879 controls, and 96 cases and 853 controls, respectively. Samples for plasma glucose, serum insulin and high-sensitivity C-reactive protein (hsCRP) were collected.

Results: Both *C. pneumoniae* and *C. trachomatis* antibodies were more commonly present in PCOS patients (OR 1.58 with 95% CI 1.05–2.38 and 2.11 with 95% CI 1.19–3.74 respectively) than in the controls. When adjusted for smoking, socioeconomic status, alcohol consumption and BMI, these differences remained significant. Also elevated hsCRP levels (upper quartile)

were a significant risk factor for PCOS (OR 1.53 (1.00–2.35)) without adjustment. The simultaneous presence of *C. pneumoniae* or *C. trachomatis* antibodies with elevated hsCRP levels further strengthened the association (OR 2.25 (1.19–4.24) and 3.96 (1.49–10.55, respectively).

Conclusion: Our findings suggest the association between symptoms of PCOS and chlamydial antibodies. Interestingly, this association was found with both *C. pneumoniae* and *C. trachomatis* antibodies. This association was strengthened by the simultaneous presence of elevated hsCRP as a marker of low grade inflammation. This is a novel finding suggesting that chronic inflammation, associated with chlamydial infections, could contribute to the pathogenetic processes leading to decreased insulin sensitivity and consequently to the metabolic and hormonal disorders of the syndrome.

0382

Prevalence of diabetes mellitus, pre-diabetes and the underlying risk factors in Sri Lanka – Sri Lanka Diabetes and Cardiovascular Study

D. R. Matthews¹, P. Katulanda^{1,2}, G. R. Constantine², M. Wijesuriya³, M. I. McCarthy¹, R. D. Seneviratne⁴, M. H. R. Sheriff²;

¹Oxford Centre for Diabetes Endocrinology and Metabolism, University of Oxford, Oxford, United Kingdom, ²Dept of Clinical Medicine, Faculty of Medicine, Colombo, Sri Lanka, ³Sri Lanka Diabetes Association, National Diabetes Centre, Rajagiriya, Sri Lanka, ⁴Dept of Community Medicine, Faculty of Medicine, Colombo, Sri Lanka.

Background and Aims: South Asian populations are among the worst affected in the current pandemic of diabetes due to the ethnic susceptibility. Impaired fasting glucose (IFG) and impaired glucose tolerance (IGT) increase the risk of diabetes and are termed pre-diabetes. We aimed to determine the prevalence of diabetes and pre-diabetes and the underlying risk factors among different socio-demographic groups in Sri Lanka.

Materials and Methods: In this nationally representative prevalence survey, 5000 subjects above 18 years of age were selected by a multi stage random cluster sampling technique. A structured questionnaire was used to record detailed interview data and physical examination findings. Fasting and post-glucose load plasma glucose was estimated. New cases of diabetes, IGT and IFG were diagnosed according to the ADA criteria. Standardization was performed using UN population estimates 2004. Prevalence and the continuous variables are reported with confidence intervals (CI) and standard deviations (SD) respectively.

Results: Altogether 4464 subjects participated (response 89%); males 40%; mean age 46 years (SD 15). The crude prevalence of diabetes was 11.5% (10.6 – 12.4) and 40% of these were newly diagnosed. The overall age and sex standardized prevalence of diabetes was 10% (9.1–10.9); Male 9.2% (7.9–10.5) and Female 10% (8.9–11.1) ($p=ns$). The prevalence in the urban, rural and plantation sectors were 17.3% (14.7–19.9), 10.6% (9.6–11.6) and 3.8% (0.8–6.8) respectively ($p<0.0001$). The overall prevalence rates of pre-diabetes by sector were urban 13.9% (11.5–16.3); rural 12.3% (11.2–13.4) and plantations 5.1% (1.6–8.6). The prevalence of individual components of pre-diabetes: IFG, IGT and both IFG and IGT were 4.3% (3.7–4.9), 6% (5.3–6.7) and 2% (1.6–2.4) respectively. Mean age in years (54.7 SD12.5 vs 44.7 SD 15), BMI (23.8kg/m³ SD4 vs 21.5 kg/m³ SD4.2), waist circumference (84.7cm SD 10.8 vs 76.3cm SD11.5) and systolic blood pressure (138mmHg SD 24 vs 127mmHg SD20) were significantly higher ($p<0.001$) among diabetic subjects compared to others. The prevalence rates of diabetes among sufficiently active, moderately active and insufficiently active subjects were 8.1% (7.1–9.1), 15.7% (13.8–17.6) and 23.4% (17.1–29.7) respectively. The prevalence among those with and without family history were 21.5% (18.8–24.2) vs 8.2% (7.3–9.1) $p<0.001$; in those with and without acanthosis nigricans were 4.3% (3.7–4.9) vs 14.3% (9.2–19.4) $p<0.001$ and in those who had and hadn't been in overseas were 19% (15.2–22.8) vs 10.7% (9.7–11.7) $p<0.001$.

Conclusion: There is a high prevalence of diabetes and pre-diabetes in urban, rural and plantation sectors in Sri Lanka. Diabetes is positively associated with obesity, hypertension, family history, urban living, overseas stay and acanthosis nigricans. It was negatively associated with physical activity. High prevalence of diabetes indicate the need for urgent primary urgent strategies specifically targeting modifiable risk factors.

Supported by National Science Foundation Sri Lanka, Oxford Centre for Diabetes Endocrinology and Metabolism

0383

Diabetic patients detected in a population screening programme have similar outcomes to clinically diagnosed patients from a matched unscreened populationM. Rahman¹, S. Hennings², N. J. Wareham², S. J. Griffin²;¹Department of Diabetes and Endocrinology, Northwick Park Hospital, London, ²Epidemiology Unit, Medical Research Council, Cambridge, United Kingdom.

Background and Aims: There is continuing uncertainty regarding population screening for type 2 diabetes. Screening may be cost-effective if patients detected and treated early have better outcomes than those detected clinically. We compared outcomes for diabetic patients in a population that had been offered 5-yearly screening by OGTT with clinically diagnosed diabetic patients in a matched population that had not been offered screening.

Materials and Methods: The Ely Study is a population-based, parallel group, cohort study. Individuals aged 40–64 years in 1990 were identified from the register of a single general practice serving the city of Ely. A third of individuals without known diabetes (screened group, SG) were selected at random for offer of 5-yearly screening with OGTT. A further third were randomly selected and invited for OGTT and outcome measurement 10 years later (unscreened group, UG). All diabetic patients from both groups were invited for outcome assessment undertaken by staff unaware of their study group status. Analysis was restricted to those patients still registered at the practice.

Results: Of 220 eligible diabetic patients, 166 (75.5%) attended for testing with no significant difference in attendance between the groups (99 [78.6%] SG vs 67 [71.3%] UG; $p=0.2$); there was no significant difference in age, gender and social deprivation between attenders and non-attenders. The patients were middle-aged (mean age 67 ± 7 years), not deprived (mean Townsend score -1.3 ± 1.9), and 51% were male. Patients in the screened group were slightly older than the unscreened group (mean age in years: 68.4 ± 6.7 vs 66.1 ± 6.2 , respectively; $p=0.02$), but there was no significant difference in duration of diabetes (6.2 ± 5.1 years vs 5.1 ± 6.4 years, respectively; $p=0.2$). Clinical and functional outcomes were not significantly different between groups (see table; values as mean \pm SD, unless stated otherwise).

Conclusion: Differences in health outcomes among diabetic patients in a screened population compared with an unscreened population were small ten years after commencement of screening. This study cannot exclude the possibility that early detection may reduce long term risk of complications, but stronger evidence of net benefit is needed before population screening can be recommended.

Outcome	Screened Group	Unscreened Group	p value
BMI (kg/m ²)	30.2 \pm 5.0	29.5 \pm 4.6	0.4
HbA _{1c} (%)	7.1 \pm 1.9	7.5 \pm 1.6	0.2
Systolic BP (mmHg)	133 \pm 15	132 \pm 14	0.4
Diastolic BP (mmHg)	80 \pm 10	79 \pm 10	0.5
Microalbuminuria % (n)	17.5(22)	17.0(16)	0.9
Neuropathy % (n)	34.9(44)	41.5(39)	0.7
Retinopathy % (n)	45.2(28)	58.5(55)	0.1

Adiponectin and proinflammatory state in type 1 diabetic patients with and without metabolic syndrome

R. Z. Timar, V. Serban, L. Diaconu, A. Vlad, V. Botea, B. Timar, C. Mazilu; Diabetes Clinic, University of Medicine and Pharmacy “Victor Babes”, Timisoara, Romania.

Background and Aims: The metabolic syndrome (MS) is a condition characterized by a clustering of clinical and biochemical proatherogenic abnormalities. MS is an important risk factor for cardiovascular disease and premature mortality in patients with type 1 or type 2 diabetes mellitus (DM) and in nondiabetic persons. Adiponectin is a 30kDa protein hormone secreted almost exclusively by adipocytes with anti-atherogenic, anti-inflammatory and insulin-sensitizing properties.

The aims of our study were to estimate the prevalence of MS in patients with type 1 DM and to assess plasma levels of adiponectin and proinflammatory state in type 1 diabetic patients with and without MS.

Materials and Methods: The study enrolled 72 patients with type 1 DM, 38 men (52.8%) and 34 women (47.2%), with the mean age of 41.3 ± 7.4 years and the mean duration of DM 13.9 ± 4.8 years. The MS was defined according to the IDF criteria. In these patients we assessed plasma levels of adiponectin, leptin, interleukin 6 (IL-6), tumor necrosis factor α (TNF- α), high-sensitive C reactive protein (hs-CRP), fibrinogen. Linear relationships between key variables were tested by Pearson's correlation coefficient.

Results: The MS was present in 21 patients (29.2 %) with type 1 DM. The prevalence of MS was higher in women (32.35 %) than in men (26.31 %). Serum adiponectin levels were markedly higher in type 1 diabetic patients without MS (12.4 ± 1.6 μ g/mL in males, and 14.1 ± 1.3 μ g/mL in females) than in type 1 diabetic patients with MS (6.6 ± 0.5 μ g/mL in males and 8.3 ± 0.8 μ g/mL in females), $p < 0.001$. In patients with MS adiponectin was negatively correlated with body mass index (BMI), waist to hip ratio (WHR), leptin, IL-6, TNF- α , hs-CRP and fibrinogen. We did not find a correlation between adiponectin and proinflammatory state in type 1 diabetic patients without MS.

Table 1. Adiponectin and proinflammatory state in type 1 DM with and without MS

Type 1 DM	MS	Without MS	p
Number (M/F)	10/11	28/23	
Adiponectin (μ g/mL)	7.1 \pm 0.7	13.2 \pm 1.5	$p < 0.001$
Leptin (ng/mL)	12.4 \pm 2.6	7.3 \pm 2.4	$p < 0.001$
TNF- α (pg/mL)	8.3 \pm 1.5	6.2 \pm 1.3	$p < 0.001$
IL-6 (pg/mL)	4.4 \pm 0.7	3.1 \pm 0.6	$p < 0.001$
hs-CRP (mg/L)	7.3 \pm 0.9	5.3 \pm 0.7	$p < 0.001$
Fibrinogen (mg/dL)	342.3 \pm 45.6	231.8 \pm 39.7	$p < 0.001$

Data are mean \pm SD. p was calculated with unpaired Student's t test.

Conclusion: MS is more prevalent in individuals with type 1 DM than in general population and increases the cardiovascular risk of these patients. Hypoadiponectinemia and increased plasma concentrations of acute-phase proteins are present in adult patients with type 1 DM and MS.

Adiponectin may be enhanced in type 1 diabetic patients without MS as a physiological counterregulatory response to mitigate endothelial damage and vascular damage.

0385

Leptin and progression to type 1 diabetes in children with islet autoimmunityM. M. Lamb¹, X. Yin¹, D. Dabelea¹, M. Rewers^{1,2}, J. Norris¹;¹Preventive Medicine and Biometrics, University of Colorado at Denver and Health Sciences Center, Denver, United States,²Barbara Davis Center for Childhood Diabetes, Aurora, United States.

Background and Aims: Increased body fat and insulin resistance in persons with islet autoimmunity (IA) may accelerate β -cell loss and speed progression to type 1 diabetes (T1D). We examined whether levels of leptin (a marker of

fat mass), adiponectin (a marker of insulin sensitivity) and body mass index z-scores (a marker of excess weight relative to others of the same age and gender) differed between children with IA who did or did not progress to T1D.

Materials and Methods: Since 1993, the Diabetes Autoimmunity Study in the Young (DAISY) has prospectively followed children at increased risk for T1D based on HLA-DR,DQ genotype or family history of T1D. IA (insulin, GAD65 or IA-2 autoantibodies present on ≥ 2 consecutive visits) developed in 57 pre-pubertal subjects (21 girls age 1–11 and 36 boys age 1–12). Upon IA development, subjects had clinic visits every 3–6 months, at which height, weight, and non-fasting blood samples were collected. Eighteen subjects progressed to T1D. Leptin and adiponectin were measured in non-fasting plasma, and hemoglobin A1c (HbA1c) was measured in whole blood collected at first IA positive visit (baseline age 3.6 years) and within one year of T1D diagnosis (mean age 6.9 years) for those that progressed to T1D, and at first IA positive visit (baseline age 5.2 years) and most recent visit (mean age 7.8 years) for non-progressors.

Results: At baseline, leptin levels did not differ between those children who progressed to diabetes and those who did not progress. However, leptin was marginally significantly lower in children who progressed to T1D at last follow-up. Adiponectin levels did not differ between progressors and non-progressors at either time point. Body mass index (BMI z-score) at baseline did not differ between progressors and non-progressors, but was significantly lower in progressors than non-progressors at last follow-up. HbA1c was lower in progressors than non-progressors at baseline, but significantly higher in progressors than non-progressors at last follow-up (Table). All analyses were adjusted for age.

Conclusion: These results suggest that progression from IA to overt T1D is not related to decreasing insulin sensitivity, as marked by adiponectin. The lower leptin levels and lower BMI z-scores at last follow-up suggest less excess weight in progressors. The strong rise in HbA1c levels and the decline in leptin levels in children progressing to T1D may reflect insulinopenia preceding diagnosis.

Table

Variable (mean)	Baseline			p-value*	Last Follow-up†			p-value*
	N	Pro-gressors	Non-gressors		N	Pro-gressors	Non-gressors	
Leptin	57	2.4	3.1	0.867	57	1.8	4.2	0.075
Adiponectin	57	17.7	17.1	0.867	57	16.6	17.3	0.497
BMI z-score	40	0.7	0.6	0.839	55	-0.1	0.5	0.048
HbA1c	54	4.8	5.0	0.061	56	6.5	5.1	<0.0001

*p-value adjusted for age

†last follow-up represents the visit just prior to or at diagnosis in progressors, and the most recent visit for non-progressors

The genetic variation in the tenomodulin gene is associated with serum levels of systemic immune mediators – the Finnish Diabetes Prevention Study

A.-M. Tolppanen¹, L. Pulkkinen¹, C. Herder², W. König³, J. Lindström⁴, J. Tuomilehto⁴, M. Uusitupa¹;

¹Department of Public Health and Clinical Nutrition and Food and Health Research Centre, University of Kuopio, Finland, ²German Diabetes Clinic, German Diabetes Center, Leibniz Center at Heinrich Heine University, Düsseldorf, Germany, ³Department of Internal Medicine II-Cardiology, University of Ulm Medical Center, Germany, ⁴Department of Epidemiology and Health Promotion, Diabetes Unit, National Public Health Institute, Helsinki, Finland.

Background and Aims: We have reported that single nucleotide polymorphisms (SNPs) of the X-chromosomal tenomodulin gene (*TNMD*) have gender-specific associations with the risk of type 2 diabetes (T2DM), central obesity and impaired glucose metabolism. The mRNA levels of *TNMD* decrease along with weight reduction and correlate with insulin sensitivity and serum and mRNA levels of inflammatory markers. Our aim was to investigate the associations of *TNMD* SNPs with systemic immune mediators in the Finnish Diabetes Prevention Study (DPS).

Materials and Methods: The baseline concentrations of serum immune mediators of 522 DPS participants (BMI>25, IGT) were analysed. Seven

SNPs were genotyped with Taqman allelic discrimination method. The linkage disequilibrium was calculated by Haploview. Associations of SNPs with immunomarkers were analyzed with general linear model univariate analysis (SPSS 14.0). Data split according to the median 2-hour plasma glucose concentration (2h-pGlu; 8.72 mmol/l) was analyzed to address the genotype effects in different glucose tolerance categories. Q-value was used for multiple corrections (q<0.1 reported).

Results: Rs1155974 and rs2073163, associated with increased T2DM risk in men in our previous study, were associated with serum amyloid A concentrations (SAA) in all men (p=0.01 and 0.016 respectively) and in the group with higher 2h-pGlu (p=0.021 and 0.021 respectively). The same markers were associated with concentrations of soluble intercellular adhesion molecule (p=0.025 and 0.033, respectively). Interestingly, the genotypes associated with higher risk for T2DM also had higher serum concentrations of these mediators. The genotype differences of rs11798018 and rs2073162 regarding IL-6 levels (p=0.049 and 0.035, respectively) and those of rs2073162 and rs4828038 regarding macrophage inflammatory protein 1 α levels (MIP-1 α ; p=0.024 and 0.006, respectively) were statistically significant only in the group with higher 2h-pGlu. Rs4828037 and rs5966709 associated with regulated on activation normal T-cell expressed and secreted concentrations (RANTES) in all men (p=0.02 and 0.023, respectively) and in the group with higher 2h-pGlu (p=0.006 for both markers). In women rs4828037 was associated with SAA (p=0.008, q=0.081) in the group with higher 2h-pGlu while rs11798018 associated with IL-6 levels in all women (p=0.024). In addition, rs4828037 and rs5966709 were associated with MIP-1 α in all women (p=0.045 and 0.022) and in the group with higher 2h-pGlu (p=0.013 and 0.007, q=0.081 for both). rs5966709 was also associated with RANTES (p=0.031) in all women while the genotype effect of rs1155974 and rs2073162 were statistically significant only in the group with higher 2h-pGlu (p=0.018, q=0.081 for both).

Conclusion: These results confirm our previous observation on the connection between *TNMD* and low-grade inflammation. They also suggest that the putative link between *TNMD* and T2DM may be mediated via the effects on systemic immune mediators.

A strong association between serum levels of monocyte chemoattractant protein 1 (MCP-1) and insulin resistant syndrome

A. Fukami, H. Adachi, S.-I. Yamagishi, M. Enomoto, A. Satoh, K. Furuki, Y. Shigetoh, M. Otsuka, S. Kumagai, T. Imaizumi;

Department of Internal Medicine, Division of Cardio-Vascular Medicine, Kurume University School of Medicine, Kurume, Fukuoka, Japan.

Background and Aims: Inflammation plays an essential role in the atherosclerotic process. MCP-1 is a chemokine responsible for the recruitment of monocytes to sites of inflammation. Several human studies suggested that an elevated MCP-1 concentration was associated with a higher prevalence of the atherosclerosis. Recently, MCP-1 has been shown to contribute to macrophage infiltration into adipose tissue and insulin resistance in obesity in animal model. However, data for an epidemiological study of the association between serum levels of MCP-1 and insulin resistance have not been available on a general population. We investigated whether serum levels of MCP-1 are associated with insulin resistance syndrome in a general population.

Materials and Methods: We performed a health examination in a small fishing community in Uku Island, Nagasaki, Japan. A total of 642 Japanese residents (231 men and 411 women, mean age 65.2 \pm 9.8) received the examination. The subjects' medical history, use of alcohol, and smoking habits were ascertained by a questionnaire. Data for fasting blood samples including serum levels of MCP-1 was obtained from 622 subjects (226 men, 396 women).

Results: Uni- and multi-variate analysis were performed to obtain correlates of serum levels of MCP-1. The mean levels of MCP-1 were 189.3 \pm 4.9pg/ml. The serum levels of MCP-1 were higher in men than in women. MCP-1 levels increased with age. Elevated MCP-1 levels were associated with waist circumference (p<.0001), total protein (p=0.009), insulin (p<.0001), and HOMA-R (p<.0001) by multiple linear regression analysis adjusted for age and sex.

Conclusion: The present study reveals that serum levels of MCP-1 are strongly associated with insulin resistance syndrome in a general population.

0388

Association of C-reactive protein with type 2 diabetes: meta-analyses of prospective studiesC.-T. C. Lee¹, S. Erqou², S. J. Sharp³, A. I. Adler^{1,3};¹Diabetes Centre, Addenbrooke's Hospital, Cambridge, United Kingdom,²Department of Public Health and Primary Care, University of Cambridge, United Kingdom,³MRC Epidemiology Unit, University of Cambridge, United Kingdom.

Background and Aims: Epidemiological studies suggest that elevated C-reactive protein (CRP), a circulating marker for acute inflammation produced by the liver, increases the risk of type 2 diabetes. The mechanisms of this association have not been fully established. The heterogeneity (variation in relative risk estimates) among studies is yet to be explored systematically. We aimed to assess the potential associations between CRP and type 2 diabetes in prospective cohort and nested case-control studies.

Material and Methods: We conducted a literature-based meta-analysis of long-term (> 3 years follow-up) prospective studies of the association between CRP and type 2 diabetes published until March 2007. Studies were identified by searching MEDLINE with the terms C-reactive protein and type 2 diabetes, and by scanning relevant reference lists. In addition to information on the association between CRP and type 2 diabetes, information on age, sex, geographic location, study design, follow-up duration, adjustment for potential confounders and CRP assay method, was extracted to enable exploration of potential sources of heterogeneity. Individual studies were combined by using random effect model meta-analysis after appropriate conversion of the relative risk estimates.

Results: We identified 13 publications (8 prospective cohort studies, 5 nested case-control studies). A total of 1300 incident diabetes cases out of 22676 participants in prospective cohort studies and 1769 cases in nested case-control studies (2174 control participants) were reported. Assuming a log-linear association between CRP and risk of diabetes and an approximate normal distribution of CRP in the general population, comparison of individuals in the upper third of baseline CRP distribution with those in the bottom third yielded a combined adjusted relative risk estimate of 1.76 (95% CI 1.56 – 1.99). Substantial heterogeneity between individual studies was found ($\chi^2_{12} = 28.88$, $p = 0.004$), possible reasons were explored.

Conclusion: This meta-analysis suggests that elevated CRP level is associated with an increased risk of type 2 diabetes, independent of age and obesity. The existence of heterogeneity warrants thorough examination of possible reasons for the variability of study results, which would be useful in determining if combined analysis of studies is justified and in further characterization of any association. However, due to the relative small number of studies, further epidemiological data is needed to clarify the role of CRP in increasing the risk for type 2 diabetes and to elucidate the mechanisms of the association.

PS 18 Genetics of beta cell function and insulin resistance

0389

Heritability of beta cell function in Dutch twins and siblingsA. M. C. Simonis-Bik¹, E. M. W. Eekhoff¹, R. J. Heine¹, K. Kroon¹,G. Willemsen², E. de Geus², M. Diamant¹, J. M. Dekker³, D. I. Boomsma²;¹Endocrinology, VU University Medical Center,²Biological Psychology, VU University, ³EMGO Institute, VU University Medical Center, Amsterdam, The Netherlands.

Background and Aims: In type 2 diabetes mellitus two pathogenic factors play a crucial role in the development of hyperglycaemia: impaired insulin secretion and insulin resistance. Remarkably, only a few studies have addressed the heritability of beta-cell function.

Materials and Methods: We recruited 75 twin families from the Netherlands Twin Register to participate in a study of different aspects of beta-cell function. Only healthy monozygotic and dizygotic twins (age 20 – 45 years) with additional siblings of the same sex were eligible. The protocol consisted of a home visit for an Oral Glucose Tolerance Test (OGTT) and the completion of questionnaires about general health and food intake and two visits at the clinic. The first clinic visit involved a standardized mixed-meal test. During the second visit participants underwent a combined euglycaemic / hyperglycaemic clamp test modified with additional GLP-1 and arginine stimulation, to assess several aspects of beta-cell function in relation to the ambient insulin sensitivity.

Results: So far 62 families (29 all male, 33 all female) have completed the OGTT and the meal test and were analysed by Analysis of Variance (ANOVA). Mean age of the 157 participants is 31.2 ± 6.0 years (table 1)

Characteristics

genetic relationship	monozygotic	dizygotic	sibs
total number	82	37	38
sex: male / female	39 / 43	16 / 21	21 / 17
Age mean (±S.D.)	30.6 ± 4.4	28.9 ± 4.8	34.9 ± 8.3
OGTT fasting bg (mmol/l)	4.72 ± .45	4.44 ± .40	4.61 ± .48
OGTT 2 hours bg (mmol/l)	5.63 ± 1.21	4.99 ± .99	5.30 ± 1.15
Before meal FBG (mmol/l)	4.40 ± .41	4.35 ± .37	4.43 ± .42
2 hours after meal BG (mmol/l)	5.39 ± .67	5.15 ± .51	5.41 ± .52
FPG (mmol/l)	4.68 ± .49	4.56 ± .43	4.83 ± .48
HbA1c	5.27 ± .28	5.21 ± .24	5.25 ± .26
BMI (kg/m ²)	23.81 ± 3.37	22.52 ± 2.86	25.23 ± 3.82

bg = capillary blood glucose; FBG = venous Fasting blood glucose;

FPG = venous fasting plasma glucose; BMI = body mass index;

WHR = waist/hip ratio

Table 1. The intra-class correlations for familial resemblance were obtained from the ANOVA and are presented in table 2. If correlations in monozygotic (MZ) twins are larger than in dizygotic (DZ) twins and siblings, is this a first indication that genetic factors are of importance. A first estimate of heritability is obtained by doubling the difference in correlations between MZ twins and first degree relatives.

Table 2: MZ, DZ and sibling correlations and heritability estimates

Intra-class correlation	MZ pairs	DZ twins and sib pairs	heritability
OGTT FBG	0.631	0.397	47%
OGTT 2 hours BG	0.408	0.385	4%
before meal FBG	0.611	0.404	41%
2 hours after meal BG	0.457	0.030	46%
FPG	0.797	0.399	40%
HbA1c	0.803	0.387	83%

Conclusion: These preliminary results confirm the earlier suggested importance of heritability in HbA1c levels. It appears that genes play a less important role in FPG and post-challenge blood glucose.

Screening for -30G>A polymorphism in B-promoter of the GCK gene in the Czech diabetic and non-diabetic populations

P. Lukasova, M. Vankova, J. Vcelak, D. Vejrazkova, H. Kvasnickova, K. Vondra, B. Bendlova;

Laboratory of Molecular Endocrinology, Institute of Endocrinology, Prague, Czech Republic.

Background and Aims: The transition G>A at position -30 of the GCK β -cell-specific promoter (rs1799884) is common within the Caucasian as well as Asian populations. Higher frequency of the minor allele A was detected in subjects with diabetes mellitus type 2 (DM2), gestational diabetes, metabolic syndrome and impaired glucose tolerance (IGT). The minor allele A was associated with elevated fasting and postprandial levels of glucose and with impaired glucose-stimulated insulin secretion (GSIR). Generally the effect of A allele was pronounced under a recessive model of inheritance – the dosage effect was observed. The aim of our study was to determine the genotypic distribution of the -30G>A polymorphism of the GCK gene in the Czech diabetic and nondiabetic populations and to assess possible association of the minor allele A carriership with biochemical and anthropometrical parameters.

Materials and Methods: Detailed biochemical and anthropometrical characteristics of diabetic groups: 338 patients with DM2 (M/F 124/224; age 60.8 \pm 7.95/58.7 \pm 9.27 years; BMI 29.7 \pm 4.44/31.9 \pm 5.59 kg/m²) and 158 gestational diabetics (G) (age 32.3 \pm 4.90 years; BMI 24.9 \pm 4.54 kg/m²); and of nondiabetic groups: 141 healthy offspring of DM2 (HO) (M/F 52/89; age 40.5 \pm 9.62/37.9 \pm 12.59 years; BMI 26.6 \pm 4.29/24.8 \pm 4.02 kg/m²) and 256 control subjects (K) (M/F 81/175; age 29.0 \pm 8.03/30.4 \pm 11.45 years; BMI 23.8 \pm 2.82/23.1 \pm 4.12 kg/m²) were collected. Except DM2 patients the oral glucose tolerance (OGTT) and insulin tolerance tests (ITT) were performed. For screening of -30G>A polymorphism in the B-promoter of the GCK gene the single strand conformation polymorphism (PCR-SSCP) method was used. The positive controls (GG, AG and AA genotypes) were used in every run. Statistical analysis: Chi-square test, Mann-Whitney test and ANCOVA (adjustment for age) (NCSS 2004).

Results: The genotypic distribution (GG/AG/AA) in diabetic and nondiabetic populations was not significantly different: DM2 – 70.9/25.9/3.2; G – 65.2/33.5/1.3; HO – 63.8/31.9/4.3; K – 73.8/24.2/2.0 [%]. In control group the homozygotes for the minor allele A had significantly increased fasting glucose (p = 0.025) and stimulated levels of glycaemia during OGTT (p = 0.001). The homozygotes AA had also increased fasting (NS) and stimulated secretion of C-peptide (p = 0.048) and of insulin (NS). Insulin sensitivity was decreased in AA subjects (HOMA R, p = 0.010; Cederholm index, p = 0.018). The heterozygotes GA did not differ in biochemical and anthropometrical parameters from wild type homozygotes GG. In our study the minor allele A shows a dose effect (recessive model of inheritance). In groups of DM2, gestational diabetics and offspring no association with biochemical and anthropometrical parameters was found.

Conclusion: In control population in homozygous allele A carriers we observed increase of fasting and stimulated glucose levels but conversely to previous studies fasting and stimulated levels of C-peptide and insulin were in these subjects also increased. The impaired insulin sensitivity in AA homozygotes was observed. The occurrence of minor allele A demonstrated the recessive model of inheritance.

Prevalence of glucokinase (GCK) mutations in people with elevated fasting glucose levels: implications for clinical trials

A. L. Gloyn¹, M. van de Bunt¹, I. Stratton², L. Tucker², L. Lonie³, S. Ellard⁴, R. R. Holman²;

¹Diabetes Research Laboratories, Oxford Centre for Diabetes Endocrinology & Metabolism, University of Oxford, ²Diabetes Trials Unit, Oxford Centre for Diabetes Endocrinology & Metabolism, University of Oxford,

³Wellcome Trust Centre for Human Genetics, University of Oxford,

⁴Institute of Biomedical & Clinical Science, Peninsula Medical School, Exeter, United Kingdom.

Background: There is considerable interest in large scale screening programmes and prospective studies to determine which factors influence

whether individuals progress to diabetes. Within these programs there are likely to be individuals with permanent “fixed” defects in glucose sensing who are unlikely to progress to diabetes. Glucokinase (GCK) inactivating mutations cause a subtype of maturity-onset diabetes of the young (GCK-MODY) with elevated fasting plasma glucose (FPG) levels (5.5–8.0 mmol/L) but with normal 2 hour plasma glucose increments (2HPGI) after a 75g oral glucose tolerance test (OGTT) (<4.5 mmol/L). Since the population prevalence of GCK mutations is unknown the number of individuals in these programmes with a “fixed” glucose sensing defect due to a GCK mutation is unknown. The aims of our study were to determine the prevalence of GCK mutations in a cohort selected for impaired glucose tolerance (IGT) and/or impaired fasting glucose (IFG) and to establish if these individuals could be distinguished from non-GCK-MODY subjects on clinical criteria alone.

Methods: We screened 662 people with FPG levels 5.5–7.7 mmol/L inclusive for GCK mutations by DHPLC analysis (98% sensitivity, 4% false-positive rate). Their mean (SD) FPG was 5.9 (0.7) mmol/L, 2HPGI 2.67 (2.3) mmol/L body mass index (BMI) 28.6 (4.5) kg/m² and age 52.1 (9.9) years. The assay was validated by testing 58 different heterozygous GCK mutations. Samples showing an abnormal chromatogram were sequenced on an ABI3700.

Results: Five pathogenic mutations and 11 non-functional polymorphisms were identified. The 5 individuals with GCK mutations were indistinguishable from the rest with mean (SD) FPG 6.2 (0.8) mmol/L, 2HPGI 3.5 (1.5) mmol/L, BMI 29.8 (5.2) kg/m² and age 48.2 (8.9) years.

Conclusion: The prevalence of <1% of GCK mutations in our cohort suggests that FPG screening may not greatly enhance identification of GCK-MODY individuals in this age group. Our data demonstrate that it is not possible to identify patients with GCK-MODY on clinical criteria alone in cohorts selected on the basis of IGT and/or IFG.

Insulin resistance and intrauterine growth retardation due to a novel balanced translocation (46,t(7;19)(p15.2;p13.2)) which disrupts the insulin receptor (INSR) gene

S. G. I. Suliman¹, J. Stanik², N. Misovicova³, D. Gasperikova², N. Wilson⁴, E. Edghill⁵, V. Sandrikova⁶, K. Elliot⁴, L. Barak⁷, S. Ellard⁸, E. Volpi⁴, I. Klimes⁹, A. L. Gloyn¹;

¹Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, United Kingdom, ²Slovak Academy of Sciences, Institute of Experimental Endocrinology, Bratislava, Slovakia, ³Clinical Genetics, Jessenius School of Medicine, Martin, Slovakia, ⁴Wellcome Trust Centre for Human Genetics, University of Oxford, United Kingdom, ⁵Molecular Genetics Laboratory, Peninsula Medical School, Exeter, United Kingdom, ⁶Pediatric Endocrinology, Prievidza Hospital, Prievidza, Slovakia, ⁷Children Diabetes Center at 1st Pediatric Dept., Comenius University School of Medicine, Bratislava, Slovakia, ⁸Molecular Genetics Laboratory, Peninsula Medical School, Exeter, United Kingdom, ⁹Institute of Experimental Endocrinology, Slovak Academy of Sciences, Bratislava, Slovakia.

Background and Aims: Balanced translocations have been pivotal in identifying genes and mutational mechanisms implicated in disease. We describe a family with early-onset diabetes, pre- and post-natal growth retardation, neonatal hypoglycaemia and hyperglycaemia later in life despite elevated insulin levels. The male proband developed hyperglycaemia aged 3 months; his mother developed insulin-treated diabetes aged 15 years. Karyotype analysis identified a balanced translocation [46, t(7;19)(p15.2;p13.2)] co-segregating with the phenotype. We hypothesised that the break point of the balanced translocation disrupts a gene, a regulatory element or the relationship between them resulting in insulin resistance, intra-uterine growth retardation and dysglycaemia. The aim of our study was to identify the gene disrupted by the translocation and to determine whether there was any loss of genetic material (microdeletion).

Materials and Methods: Bio-informatic tools were used to identify genes located within the region of both break points. A gene prioritization tool (genesniffer) was used to prioritise genes in order of biological candidacy. Fluorescence in-situ hybridization (FISH) analysis was performed on patient metaphase arrested chromosomes using labeled bacterial artificial chromosomes (BACs). Multiple ligation probe amplification (MLPA) assay was performed to investigate microdeletions. Detailed biochemical analysis of patient plasma was performed.

Results: Bio-informatics identified 44 genes within the region of the break point on chromosome 19p and 23 genes on 7p. The most plausible biological

candidate was the insulin receptor (*INSR*) gene on 19p. Mutations in *INSR* are implicated in defects of glucose homeostasis and intra-uterine growth retardation. FISH analysis using BACs containing genomic DNA for the entire coding region and known promoter regions of *INSR* demonstrated that the break point disrupts the *INSR*. Fine mapping using fosmids limited the break point to a region of 10.4Kb. MLPA analysis demonstrated a micro-deletion involving exons 15 and 16. Sequencing of *INSR* in genomic DNA from both patients did not identify any mutations. Both patients have elevated insulin and c-peptide levels, an elevated insulin/c-peptide ratio (0.62 and 1.05, normal<0.1) and elevated adiponectin levels (>44ng/ml) supporting the genetic diagnosis of an *INSR* defect.

Conclusion: This is the first demonstration of a cytogenetic defect causing disruption of *INSR* resulting in insulin resistance, pre-and post natal growth retardation.

Associations between insulin promoter factor 1 gene polymorphisms and proinsulin concentrations and type 2 diabetes mellitus

B. Zethelius¹, N. Abrahamsson², L. Berglund¹, A.-C. Syvänen², C. Berne²;

¹Dept. of Public Health and Caring Sciences/Geriatrics,

²Dept. of Medical Sciences, Uppsala University Hospital, Sweden.

Background and Aims: Mutations in the insulin promoter factor 1 (IPF1), a transcription factor involved in the process of insulin gene expression is associated with MODY-4 and may predispose to type 2 diabetes mellitus (T2DM) in recent studies. As diminished early insulin response to oral glucose and fasting proinsulin are significant predictors of T2DM, we hypothesised associations between single nucleotide polymorphisms (SNPs) of the IPF-1 gene, quantitative traits and T2DM. The aim was to examine associations between IPF1 gene SNPs with fasting proinsulin and insulin concentrations, insulin at 30 minutes after oral glucose load and T2DM.

Materials and Methods: Nine SNPs selected from public databases, were determined using multiplex PCR at the Uppsala genotyping platform. Analyses were made in relation to proinsulin and insulin determinations in the ULSAM cohort (<http://www.pubcare.uu.se/ULSAM/>).

Results: In four SNPs, an association with proinsulin concentrations were observed (p for trend 0.003–0.04) and one SNP out of these, rs7331478, was associated with T2DM (p for trend 0.035); GG vs. TT, OR 1.37, 95%CI, 0.71–2.67; GT vs. TT, OR 1.51, 95%CI, 1.10–2.06; and as a recessive model; GG+GT vs. TT, OR 1.49, 95%CI, 1.10–2.01, p=0.010. For rs7331478, an association with proinsulin (8.7 vs 6.5 pmol/l, p=0.016) and an association with insulin at 30 minutes (215 vs 260 pmol/l, p=0.07, borderline significant) was observed in GG-homozygotes as compared to TT-wildtype.

Conclusion: These results suggest that genetic variation in the IPF1 gene is associated with fasting proinsulin concentrations, with low insulin response to oral glucose and is predisposing to T2DM.

Common variants of pancreatic β cell related transcription factor genes are not associated with young onset diabetic subjects of Bangladesh

Z. Hassan¹, M. O. Faruque², K. B. Biswas¹, R. Islam¹, K. Azad³,

A. K. Azad Khan⁴, L. Ali², G. A. Hitman⁵;

¹Physiology and Molecular Biology, BIRDEM, Dhaka, Bangladesh,

²Biochemistry and Cell Biology, BIRDEM, Dhaka, Bangladesh,

³Pediatrics, BIRDEM, Dhaka, Bangladesh, ⁴Gastroenterology, BIRDEM,

Dhaka, Bangladesh, ⁵Centre for Diabetes and Molecular Medicine,

Batrs and the London Queen Mary's School of Med and Dentistry, London, United Kingdom.

Background and Aims: Diabetes in the young Bangladeshis [including fibrocalculus pancreatic diabetes (FCPD)] presents with unique clinical and biochemical characteristics which create special problem in its classification. In an attempt to further characterize the disorders in these patients we have studied the common variants of transcription factors genes involved in pancreatic B cell differentiation and maturation.

Materials and Methods: Young (under 30 years) non-ketotic diabetes mellitus (YDM, n=337), FCPD (n=51) and age-matched healthy Controls (n=332) were studied. Candidate gene markers TCF1 (A98V), NEUROD1 (A45T) and NEUROG3 (G167R and S199F)] were investigated by PCR-RFLP. Serum C-peptide was measured by ELISA.

Results: Mean (\pm SD) BMI of the Controls, YDM and FCPD was 19.7 \pm 3.2, 18.30 \pm 4.9 and 16.1 \pm 3.5 respectively (p<0.001 in YDM and FCPD vs Control). Both YDM and FCPD had significant low fasting C-peptide (nmol/l, median-range) levels compared to Control [0.20 (0.20–1.33) in YDM and 0.12 (0.023–0.84) in FCPD vs 0.39 (0.16–1.44 in Control), pT (A98V): 0.821, 0.168 and 0.011 (homozygous wild, heterozygous variant and homozygous variant respectively) in YDM and 0.834, 0.137 and 0.020 in FCPD and 0.866, 0.142 and 0.003 in the Control; of NEUROD1 G>A (A45T) 0.764, 0.223 and 0.014 in YDM and 0.900, 0.100 and 0 in the FCPD vs 0.764, 0.209 and 0.027 in the controls; NEUROG3 G>A (G167R) 0.906, 0.086 and 0.008 in YDM and 0.941, 0.059 and 0 in FCPD and 0.940 and 0.060 in the Control and NEUROG3 C>T (S199F) 0.167, 0.470 and 0.363 in the YDM and 0.255, 0.451 and 0.294 in FCPD and 0.179, 0.448 and 0.343 in the Control. The genotype frequencies of the candidate gene markers in the YDM and FCPD groups did not show any significant difference compared to the controls. YDM and FCPD subjects with variant (heterozygous and homozygous together) vs wild genotype did not show statistical difference regarding C-peptide level in neither of the candidate gene [TCF1 (A98V), NEUROD1 (A45T) and NEUROG3 (G167R and S199F)] markers.

Conclusion: The data suggest that common variants of transcription factor genes involved in differentiation and maturation of pancreatic B cells are not associated with diabetes in the young Bangladeshi subjects.

Structural requirements for the cytoprotective effects of monounsaturated fatty acids in pancreatic beta cells

S. Dhayal, E. Diakogiannaki, H. J. Welters, N. G. Morgan; Endocrine Pharmacology, Peninsula Medical School, Plymouth, United Kingdom.

Background and Aims: Saturated and monounsaturated fatty acids (FA) exert differential effects on β -cell viability. Long-chain saturated FAs (e.g. palmitate (C16:0)) are cytotoxic but the corresponding monounsaturates (e.g. palmitoleate (*cis*C16:1)) are well tolerated. Furthermore, long-chain monounsaturates are directly cytoprotective to β -cells and can attenuate the loss of viability caused by multiple stimuli (including saturated FAs, pro-inflammatory cytokines and serum withdrawal). However, the structural features required to confer this β -cell cytoprotection remain unknown. It is also unclear whether a cell surface fatty acid receptor (e.g. GPR40) is involved or whether metabolism of the unsaturated fatty acids is required. The present study aimed to investigate these unresolved issues.

Materials and Methods: Clonal rat BRIN-BD11 β -cells were used as a model system and were treated with albumin-bound FAs in tissue culture. Caspase activation, cell viability and intracellular triacylglycerol (TAG) formation were studied in cells exposed to saturated and/or mono-unsaturated FAs.

Results: Palmitoleate dose-dependently (0.05–0.25mM) protected β -cells against cytotoxicity induced by palmitate or serum withdrawal and completely inhibited palmitate-induced caspase3/7 activation over 12h incubation (palmitate: 14972±2793 luminescence units; palmitate+palmitoleate: 596±62). Oleate (*cis*C18:1) also abrogated β -cell cytotoxicity while elaidate (*trans*C18:1) was partially protective but less potent than oleate. Palmitelaidate (*trans*C16:1) failed to attenuate β -cell cytotoxicity at concentrations up to 0.25mM. Monounsaturated FA analogues bearing esterified carboxyl groups (methyl-palmitoleate or methyl-oleate) afforded complete β -cell protection and there was no difference in potency between palmitoleate and methyl-palmitoleate ($EC_{50} \sim 20\mu\text{M}$) suggesting that metabolism of unsaturated fatty acids is not required. In confirmation of this, methyl-palmitoleate failed to alter intracellular TAG formation in β -cells exposed to palmitate (control: $0.9 \pm 0.75 \text{ nmol}/10^6 \text{ cells}$; palmitate: 1.56 ± 0.15 ; palmitate+methyl palmitoleate: 1.50 ± 0.05) under conditions when it exerted complete protection against cytotoxicity. The synthetic GPR40 agonist GW9508 was not cytoprotective in β -cells and it failed to influence the sensitivity of the cells to palmitoleate.

Conclusion: The cytoprotective actions of monounsaturated FAs display clear structural requirements in β -cells, with chain length and the configuration of the double bond particularly important. Metabolism of the FAs is not essential and the results are consistent with the involvement of a specific FA binding site. However, no evidence was obtained to support a role for GPR40 in mediating the protective response.

Proteomic analysis of palmitate-induced changes in insulin secreting INS-1E cells

M. Hovsepian, P. Bergsten; Medical Cell Biology, Uppsala University, Sweden.

Background and Aims: Individuals with type 2 diabetes mellitus have elevated blood levels of glucose and lipids. Such elevated levels of the nutrients have been postulated to cause impairment of insulin secretion from pancreatic β -cells. Chronic exposure to long chain fatty acids, in particular palmitate, has been linked not only to functional impairment of β -cells but also apoptosis. Different mechanisms for the detrimental effects of palmitate have been suggested including alterations in membrane fluidity, mitochondrial function and ceramide generation. Recently, it was suggested that palmitate-induced apoptosis involved the endoplasmic reticulum stress response. Although the latter and the other mechanisms are important contributing factors to explain how the fatty acid induces β -cell deterioration, they account for some aspects of palmitate-induced deterioration of β -cell function and mass. Given the central role of palmitate in β -cell glucose- and lipid-metabolism the aim of

this study was to further explore mechanisms by which the fatty acid acts on the β -cell by identifying proteins exclusively regulated by palmitate.

Materials and Methods: INS-1E cells were cultured in RPMI 1640 medium containing 11 mM glucose in the presence of 1% FCS for 24 hours. In addition, cells were cultured in medium supplemented with 0.5 mM palmitate or oleate (complexed with albumin). After culture, cells were lysed and lysates of 250 μg total protein (corresponding to approximately 1 million cells) were subjected to separation by iso-electric focusing using immobilized pH-gradient strips (11 cm, 3–10NL), followed by size separation with 12.5% SDS-PAGE. Gels were stained by Coomassie and differential protein expression specifically induced by palmitate was analyzed. Proteins of interest separated by 2-DGE were excised from the gel and identified by peptide mass fingerprinting using MALDI-TOF MS.

Results: INS-1E protein patterns obtained from INS-1E cultured in the presence of 11 mM glucose alone or in combination with palmitate or oleate contained more than 600 spots visualized by Coomassie staining. Total correlation between protein patterns derived from lysates of cells cultured under the same conditions was more than 95%. Analysis revealed that 116 spots were significantly different in gels obtained from INS-1E cells cultured in the presence of palmitate or oleate compared to gels obtained from control cells. Further analysis revealed that out of these 116 spots only 9 spots represented proteins that were similarly regulated by palmitate and oleate. The number of spots that were specifically regulated by either oleate or palmitate was 58 and 49, respectively. From the latter 49 spots, which represented proteins either up- or down-regulated by palmitate, 26 were chosen for identification work. Most of the up-regulated proteins were identified as chaperons and ER-related proteins. In contrast, the down-regulated proteins were involved in a broad range of biological processes including structural proteins, glycolytic enzymes, lipid metabolism and protein degradation.

Conclusion: Whereas some β -cell proteins were jointly regulated by oleate and palmitate, most proteins were differentially expressed by either oleate or palmitate. These findings contribute to explain why the effect of palmitate on β -cell function and mass is different from that of oleate. From the identities of proteins specifically regulated by palmitate we have formulated novel hypotheses how palmitate may induce deterioration of β -cell function and mass.

PPAR-alpha controls the crossroad of lipid and glucose metabolism and protects INS-1E beta cells against lipotoxicity

F. Frigerio¹, C. Bartley¹, S. Mandrup², P. Maechler¹;

¹Department of Cell Physiology and Metabolism, University of Geneva, Switzerland, ²Department of Biochemistry and Molecular Biology, University of Southern Denmark, Odense, Denmark.

Background and Aims: Type 2 diabetes is characterized by insulin resistance, impaired insulin secretion, and progressive loss of beta-cell function. Chronic elevation of circulating fatty acids may contribute to the phenomenon named lipotoxicity. Of interest in this context, the three peroxisome-proliferator-activated receptor (PPAR) subtypes, nuclear lipid sensors, are able to react to metabolic changes by regulating gene expression. In particular, PPAR-alpha plays a crucial role in metabolic adaptation by inducing genes responsible for fatty acid oxidation. However, the role of PPARalpha in beta-cells remains poorly characterized. Here, we investigated the effects of PPAR-alpha overexpression in INS-1E beta-cells cultured in the presence of the fatty acid oleate.

Materials and Methods: INS-1E beta-cells were transduced with adenoviruses expressing PPARalpha and RXR before a 3-day culture period in the presence of 0.4mM oleate. Then, we measured key parameters involved in metabolism secretion coupling: mitochondrial membrane potential (rhodamine-123 fluorescence), cytosolic calcium levels (Fura-2 fluorescence), glutamate generation (enzymatic assay), gene expression (quantitative RT-PCR and immunoblotting), insulin secretion (radioimmunoassay), and glucose utilization (3H-glucose) and oxidation (14C-glucose).

Results: INS-1E cells cultured for 3 days in the presence of oleate increased basal insulin release by 80%, while the secretory response to 15mM glucose was blunted compared to control cells (1.68-fold versus 4.56-fold, respectively). PPAR-alpha overexpression partially rescued glucose stimulated insulin secretion (2.14-fold), revealing protection against fatty acid induced toxicity. Investigating metabolism secretion coupling parameters, mitochondrial

membrane potential and cytosolic calcium rise were diminished by oleate treatment ($p < 0.01$), while unchanged by PPAR- α overexpression. Elevation of cellular glutamate levels upon glucose stimulation was blunted in oleate treated INS-1E cells. PPAR- α restored glucose (15mM) induced glutamate rise (+53% $p < 0.002$). This suggested that PPAR- α could promote anaplerotic pathways, necessary for glutamate formation. Such hypothesis was substantiated by the observed augmentation of pyruvate carboxylase expression in PPAR- α overexpressing cells, both at the mRNA (2.8-fold) and protein levels. The enhancement of anaplerotic pathways was corroborated by measurements of glucose utilization and oxidation. In oleate treated INS-1E cells overexpressing PPAR- α , glycolytic flux was increased versus glucose oxidation (1.44-fold versus oleate treatment), showing compensatory mechanisms to cataplerosis (i.e. glutamate generation) by enhanced anaplerosis (pyruvate carboxylase). The effects of PPAR- α on glucose metabolism paralleled increased fatty acids turnover, as demonstrated by enhanced FAT/CD36 expression.

Conclusion: Data show that PPAR- α stimulates both glucose and lipid metabolism in INS-1E beta-cells chronically exposed to oleate. These PPAR- α actions might explain the observed preservation of glucose stimulated insulin secretion in fatty acid treated cells.

The role of G protein-coupled receptor 40 in lipoapoptosis in mouse beta line NIT-1

Y. Zhang, M. Xu, S. Zhang, L. Yan, C. Yang, W. Lu, Y. Li, H. Cheng;
Department of Endocrinology, The Second Affiliated Hospital,
Sun Yat-Sen University, Guangzhou, China.

Background and Aims: Elevated levels of circulating free fatty acids (FFAs) are tightly linked to Type 2 diabetes and FFAs exert divergent effects on β cells, acute exposure to FFAs stimulates insulin secretion, whereas chronic exposure impairs insulin secretion and induces apoptosis (lipoapoptosis). The G protein-coupled receptor 40 (GPR40) is preferentially expressed in β cells and is activated by a wide range of FFAs. GPR40 has been shown to mediate the effects of FFAs on insulin secretion. However, it is uncertain whether GPR40 is implicated in mediating lipoapoptosis of pancreatic β cells. The aim of this study is to determine whether GPR40 is implicated in FFAs mediated lipoapoptosis in NIT-1 cells.

Materials and Methods: We used siRNA approach to inhibit the expression of GPR40 in NIT-1 cells, then examined the effects of long-term incubation with saturated (palmitate) or unsaturated (oleate) fatty acids on apoptosis and function of NIT-1 cells transfected with GPR40 siRNA. Apoptosis was evaluated by TUNEL and flow-cytometry analysis (annexin V/PI staining). And we detected the activation of the phosphatidylinositol 3-kinase (PI3K) and mitogen-activated protein kinases (MAPK) pathway to address the possible mechanisms.

Results: Results showed that palmitate induced β cell apoptosis, which was GPR40 independent; whereas oleate protected NIT-1 cells from palmitate-induced lipoapoptosis, which was mediated at least in part through GPR40. Moreover, by detect the activation of the PI3K and MAPK pathway, we found that oleate promoted the activation of extracellular signal-regulated protein kinase (ERK) MAPK pathway mainly via GPR40, leading to the anti-lipoapoptotic effect on NIT-1 cells.

Conclusion: It was suggested that GPR40 might be implicated in the control of β cell mass plasticity and GPR40 probably provide a link between obesity and Type 2 diabetes.

Analysis of specific arachidonic acid induced changes in gene and protein expression in a clonal rat pancreatic beta cell line

D. Keane, P. Newsholme;

UCD School of Biomolecular and Biomedical Science, Conway Institute,
Dublin, Ireland.

Background and Aims: Diabetes Mellitus is a complex disorder characterized by hyperglycemia and dyslipidaemia. The metabolic abnormalities associated

with type 2 diabetes mellitus can be attributed to failure of the pancreatic beta cells to secrete sufficient insulin. Type 2 diabetes mellitus is often coupled with obesity. Therefore it is possible that increased circulating fatty acid levels are responsible in part for the beta cell dysfunction in type 2 diabetes. It is well established that chronic exposure of cultured beta cells to saturated fatty acids such as palmitic acid (PA) results in a reduction in insulin secretion and an increase in beta cell death. Recent studies have shown that the degree of saturation and chain length are very important when assessing the effects of fatty acids on the beta cell. For example, in contrast to the negative effects of PA, studies from our own lab have demonstrated that chronic exposure of cultured beta cells to the polyunsaturated fatty acid arachidonic acid (AA) does not alter subsequent acute insulin secretion nor does it promote cell death. Other authors have demonstrated protective effects of some mono-unsaturated or polyunsaturated fatty acids against the negative effects of PA. We wished to explore aspects of AA action at the gene and protein level.

Materials and Methods: Clonal BRIN-BD11 beta cells were cultured in the presence or absence of 100 μ M AA for 24hr. Microarray gene expression profiling of BRIN BD11 cells exposed for 24 hours to 100 μ M AA was performed. Protein was also isolated from BRIN-BD11 cells for NADPH oxidase protein expression utilising a specific anti-P47-phox polyclonal antibody in Western blot based analysis. Reactive oxygen species (ROS) generation was measured using flow cytometry.

Results: Culture for 24 hr in 100 μ M AA compared to control resulted in significant (using the Bioconductor software package) changes in 3 genes. Stearoyl-CoA dehydrogenase and ATP-binding cassette, sub-family G (WHITE) member 1 expression were downregulated 3.87 (p value 0.001) and 1.7 fold (p value 0.03) respectively. On the other hand Enoyl Coenzyme A hydratase 1, expression was upregulated 1.73 fold (p value 0.02) relative to control. In contrast to PA, 24 hr exposure of BRIN-BD11 cells to 100 μ M AA led to no significant changes in both P47-phox protein expression and ROS generation.

Conclusion: AA dependent beta cell specific effects appear to be mediated through alteration in signal transduction. We have determined that β -cell ROS production was regulated by type and degree of saturation of the various fatty acids tested.

Glucose signaling via Akt in beta-cells: Rab-GAP AS160 is expressed in pancreatic islets, and is regulated by glucose

K. Bouzakri, K. Rickenbach, P. A. Halban;

Genetic Medicine and Development, University of Geneva Medical Center,
Switzerland.

Background and Aims: PKB/Akt plays a central role in beta-cells but little is known regarding downstream Akt substrates in these cells. Recently a substrate of Akt (Rab-GAP AS160) was shown to be involved in insulin modulation of GLUT4 trafficking in skeletal muscle and adipose tissue. Our aim was to investigate the potential role of AS160 in beta-cells.

Materials and Methods: AS160 mRNA expression was measured in human pancreatic islets. Islets of Langerhans were isolated by collagenase digestion of pancreas from adult male C57BL/6 mice and beta-cells were sorted by fluorescence-activated cell sorter (FACS). Proliferation was measured following BrdU incorporation and apoptosis was assessed by TUNEL assay and detection of active caspase-3. Insulin secretion was quantified by radioimmunoassay (RIA). For knockdown experiments transformed mouse insulin secreting MIN6B1 cells were transfected with pSUPER-GFP plasmid encoding a shRNA against IRS-2, AS160 or a negative control. Cells were cultured for 72 hours before selection of GFP-positive cells by fluorescence-activated cell sorting. Sorted cells were then used to perform the various experiments.

Results: We first establish by RT-PCR that AS160 mRNA is expressed in human pancreatic islets, but due to limited material functional studies were performed using mouse cells. AS160 was phosphorylated after 10 min glucose stimulation (16.7 mM) in primary mouse beta-cells. Using siRNA to knockdown IRS-2 and a specific inhibitor of PI3-Kinase (LY-294002), we demonstrated in MIN6B1 cells that glucose action on Akt and AS160 phosphorylation was IRS-2/PI3-Kinase dependent. Stimulation of cells with 2-deoxyglucose or pretreatment with diazoxide to prevent glucose-stimulated Ca²⁺ influx showed that neither metabolism of glucose nor increased cytosolic Ca²⁺ were required for glucose-stimulated Akt and AS160 phosphorylation.

In MIN6B1 cells, 90% knockdown of AS160 (confirmed by western blot) resulted in a 4-fold increase of basal insulin secretion whereas glucose mediated insulin release was abolished, directly demonstrating a dual role for AS160 in these two components of insulin secretion. Furthermore, glucose increased MIN6B1 cell proliferation by 2.42 ± 0.13 -fold but was no longer able to do so in cells lacking AS160 and/or IRS-2. Apoptosis was increased by 3.5 ± 0.7 -fold in standard culture conditions (25 mM glucose and 15% FCS) and 1.54 ± 0.03 -fold in deprived conditions (5 mM glucose and 1% FCS) in cells lacking IRS-2 and/or AS160 compared to control cells.

Conclusion: Our results demonstrate that Rab-GAP AS160 is expressed in pancreatic beta-cells and phosphorylated after glucose stimulation via IRS-2/PI3-Kinase pathway. Moreover, AS160 silencing demonstrated its implication in beta-cell survival and glucose-mediated proliferation, as well as the regulation of insulin secretion.

Effects of C75, a fatty acid synthase (FAS) inhibitor, on insulin secretion and metabolism in rat pancreatic islets and clonal β cells

S. G. Straub, G. W. G. Sharp;

Molecular Medicine, Cornell University, Ithaca, United States.

Background and Aims: C75, a synthetic compound that potently inhibits fatty acid synthase, has potential clinical use both as an antitumoral agent and in the fight against obesity. Also, it is well known that the level of expression and activity of FAS is markedly different in primary and clonal β -cells, and in rodent models of diabetes. Consequently, the aim of this study was to investigate the effects of FAS inhibition on β -cell function in pancreatic islets from Sprague Dawley (SD) and obese Zucker fa/fa rats, and the clonal INS 832/13 cell line.

Materials and Methods: Pancreatic islets were isolated by collagenase digestion and studied under both static incubation and perfusion conditions. Insulin was assayed by RIA. Glucose (G) oxidation was measured as ^{14}C production from ^{14}C -labeled glucose; FAS activity by incorporation of 3H -acetic acid.

Results: In islets from SD rats, C75 inhibited 16.7 mM G-induced insulin release in a concentration-dependent manner with maximal inhibition at 25 μ g/ml. A time-course study revealed a pronounced reduction of stimulated insulin release by 93% in the presence of the compound, which affected both first and second phases. G oxidation at 16.7 mM was inhibited by 30%. In 2.8 mM G, palmitate oxidation was inhibited by 50% with no further reduction in 16.7 mM G. We next studied the ability of C75 to inhibit FAS in the G-responsive INS 832/13 cell line. 16.7 mM G alone induced a marked enhancement of FAS activity and increased incorporation of label in all of the four lipid subclasses studied. C75 (again 25 μ g/ml) strongly reduced the incorporation in all four. Remarkably, in contrast to the results in rat islets, C75 augmented insulin secretion in the presence of 2.8 mM G, 16.7 mM G, and 20 mM BCH despite inhibition of G oxidation. As in islets from SD rats, C75 inhibited G-stimulated insulin release in islets of lean Zucker rats but enhanced insulin secretion in islets from Zucker fa/fa rats despite a decrease in glucose oxidation.

Conclusion: FAS is the enzyme responsible for the synthesis of long-chain fatty acids through the condensation of malonyl CoA and acetyl CoA using NADPH as a cofactor. Clonal β -cells, like the INS 832/13 cell line, have ample expression of this enzyme. Therefore, it seems likely that the enhanced secretion seen in these cells in response to C75 is due to an accumulation of either malonyl CoA or NADPH or both, as they have been implicated as key players in glucose stimulus-secretion coupling. In contrast, treatment with C75 in SD rats, which show very low levels of FAS activity, is not expected to result in a significant buildup of these signaling molecules. As a result we see inhibition of secretion despite inhibition of palmitate oxidation. Obese Zucker fa/fa rats reportedly show an appreciable increase in anaplerotic input and malonyl CoA generation and therefore inhibition of FAS could augment the levels further and thereby enhance secretion. FAS has an important role in the control of insulin secretion in obese animals.

Prevention of mitochondrial fission protects beta cells from glucolipotoxicity

A. J. A. Molina^{1,2}, G. Twig¹, J. Wikstrom¹, H. Mohamed¹, B. Corkey², O. Shirihai¹;

¹Pharmacology, Tufts University, Boston,

²Obesity Research Center, Boston University, United States.

Long term exposure to high levels of glucose and free fatty acid have been shown to result in impaired mitochondrial function, impaired insulin secretion, and beta cell apoptosis. To date, the mechanism by which increased nutrients lead to mitochondrial dysfunction remains unclear. Using confocal imaging technology, we studied the effect of glucolipotoxicity (20mM glucose+0.4mM palmitate) on mitochondrial architecture in INS1 cells. We found that GLT results in fragmentation of mitochondrial networks that begins as early as 5 hours of exposure. Mitochondrial networks have been shown to be essential for metabolic activity as they allow the sharing of matrix and membrane components across the mitochondrial population. We hypothesized that the GLT induced fragmentation is due to reduced mitochondrial fusion and increased fission. To test this, we used matrix targeted Photoactivatable-GFP, a probe that allows for the photo-labeling and tracking of individual mitochondria within the intact cell. We found that 18 hour treatment of INS1 cells with GLT arrested mitochondrial fusion, a finding that likely explains the resultant fragmentation. In order to determine the functional significance of this finding we inhibited mitochondrial fission by using shRNA. We found that Fis1 knockdown resulted in restoration of mitochondrial networks and also prevented GLT-induced cell death. These findings suggest that a decrease in mitochondrial fusion activity plays a role in the detrimental effects of chronic exposure to high levels of glucose and FFA.

Over-expression of CD36 in insulin producing cells reduces fatty-acid-induced insulin secretion and glucose-regulation of fatty-acid oxidation

T. Wallin¹, Z. Ma¹, H. Wang², M. Iezzi², H. Ogata³, I. Jørgensen³,

C. Wollheim², A. Björklund^{1,2};

¹Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden,

²Cell Physiology and Metabolism, University Medical Center, Geneva,

Switzerland, ³Cancer Research and Molecular Medicine, Norwegian University of Science and Technology, Trondheim, Norway.

Background: CD36 facilitates uptake of fatty acids in muscle and adipose tissues. CD36 is present in beta cells and could potentially play a role for fatty acid metabolism and signalling.

Aim: To investigate the impact of over expressing CD36 on beta cell functioning.

Results and Methods: In INS-1 cells (Tet-On system) doxycyclin (DOX, 75, 250 and 500 ng/ml) increased CD36 protein by respectively 7.5, 13.4 and 27 times (Western blotting). DOX-induced CD36 was localized to the cell membrane (immunofluorescence). In acute experiments 50 μ M palmitate in 30 min final incubations increased glucose-induced insulin both at 2.5 and 21.5 mM glucose (G), $p=0.05$, $n=4$. This effect of palmitate was abolished by DOX. After long term exposure (60 h) to 50 μ M palmitate the DOX-induced cells displayed decreased glucose-induced insulin release ($p<0.05$, $n=9$) during final incubations at 2.5 and 21.5 mM G. Culture with 100 μ M oleate gave similar results. DOX increased 5min uptake of oleate and palmitate. Oxidation of oleate at high glucose was increased: the % oxidized at high glucose compared to low glucose was 9.5 ± 1.9 without DOX and 14.3 ± 2.7 % with DOX, $p=0.022$, $n=7$. DOX did not induce apoptosis (assessed by annexin V and DNA laddering). Neither oil red O staining, nor measurements of total triglycerides, nor thin layer chromatography with C14 oleate or palmitate indicated that CD36 over-expression increased cellular lipids.

Conclusions: Increased access to fatty acids intracellularly by a fatty acid transporter exerts important effects on beta cell function and metabolism.

Palmitate-induced manifestations of the unfolded protein response in pancreatic β cells; dependency on glucose

E. Sargsyan, E. M. Sol, P. Bergsten;

Medical Cell Biology, Uppsala University, Sweden.

Background and Aims: Elevated levels of glucose and lipids are detrimental for β -cell function and mass. The reason for this has been attributed the fact that β -cells preferentially metabolize glucose in the presence of elevated levels of glucose and fatty acids. Inhibition of carnitine-palmitoyl transferase 1 (CPT-1) via glucose-derived elevation of malonyl-CoA has been proposed to be a mechanism of how combined elevated levels of glucose and fatty acids negatively affect the β -cell. Recent studies have demonstrated that endoplasmic reticulum (ER)-stress may also play a role. In the present study, short- and long-term effects of palmitate (PA) on the unfolded protein response (UPR) were studied in the presence of different glucose concentration, i.e. under conditions that direct metabolism towards accumulation or oxidation of PA. The aim of the study was to investigate to what extent PA activates the ER-stress response and if the activation depends on the ambient glucose concentration, i.e. if PA by itself is sufficient to elicit the response or if elevated glucose is required to obtain the full manifestations of the UPR.

Materials and Methods: INS-1E cells were cultured for 3 or 24 hours with 0.5 mM PA at 3, 11 or 20 mM glucose in the presence of 10 % FCS. After culture, cellular protein and mRNA were isolated and used for measurements of transcript and/or protein levels of p-eIF2 α , ATF4, CHOP, GADD34, XBP1, EDEM, ATF6, BiP and CPT1. Total protein level in the wells was used as a measure of β -cell number.

Results: B-cell mass was only reduced in INS-1E cells cultured for 24 hours in the presence of PA and high glucose. In such cells CPT1 transcript as well as protein levels were lower compared to cells cultured in the presence of PA and low glucose. Phosphorylation of eIF2 α is an early manifestation of ER-stress. Indeed, increased levels of p-eIF2 α were already detected in cells cultured for 3 hours in the presence of PA. In addition, p-eIF2 α was higher when the glucose concentration during culture was increased. Transcript levels of ATF4, CHOP, GADD34 and BiP, which are downstream factors of p-eIF2 α , required 24 hours culture in the presence of PA to be up-regulated. Their up-regulation was not glucose-dependent. When corresponding protein levels were measured for CHOP and BiP no changes were observed, however. Enhanced splicing of XBP1 was observed in cells cultured for 24 hours in PA irrespective of the glucose concentration. EDEM, its downstream target involved in protein degradation, was not affected at the transcript level, however. Examination of the ATF6 pathway demonstrated lack of active form of this transcription factor in PA-treated cells at all glucose concentrations.

Conclusion: PA exerts more harmful effects on β -cell mass when combined with high glucose probably due to lowered oxidation of the fatty acid. PA rapidly elicits initial stages of the UPR, which are augmented by high glucose concentrations. It appears that PA causes partial activation of UPR, which does not lead to up-regulation of chaperones and proteins involved in protein degradation and apoptosis. The role of UPR as mediator of apoptosis in INS-1E cells cultured in the presence of PA is therefore unlikely.

The mono-unsaturated fatty acid, palmitoleate, attenuates the expression of the ER stress-associated proteins, ATF4 and CHOP-10, in pancreatic beta cells exposed to palmitate or tunicamycin

E. Diakogiannaki, H. J. Welters, N. G. Morgan;

Biomedical & Clinical Science, Peninsula Medical School, Plymouth, United Kingdom.

Background and Aims: Saturated and mono-unsaturated fatty acids (FA) exert differential effects on β -cell viability with long-chain saturated FAs (e.g. palmitate (C16:0)) causing loss of viability whereas mono-unsaturates (e.g. palmitoleate (*cis*C16:1)) are well tolerated. Furthermore, long-chain monounsaturates are directly cytoprotective to β -cells exposed to saturated

fatty acids. The molecular basis of this differential response is poorly understood but morphological alterations seen in FA-treated cells suggest that changes in the activation state of endoplasmic reticulum (ER) stress pathways may be involved. Therefore, the aim of the present work was to investigate the effects of FA on the signalling cascades associated with ER stress in pancreatic β -cells.

Materials and Methods: The rat pancreatic β -cell line BRIN-BD11 was used and cells were exposed to FAs as their albumin complexes, under serum free conditions. Electron microscopy and Western blot analysis were employed to investigate the morphological changes and altered ER stress pathways respectively, in FA-treated cells.

Results: Palmitate (C16:0; 0.05–0.25mM) reduced beta-cell viability in a time-dependent manner (6–24h) and caused dramatic alterations to the cell morphology, including marked distension of ER membranes. Palmitoleate (C16:1) antagonized the cytotoxicity of palmitate completely such that the cells remained viable and could proliferate but it only partially alleviated the morphological changes seen in the ER. The PERK signalling pathway of ER stress was activated dose-dependently (0.025–0.15mM) in palmitate-treated cells as indicated by increased expression of the transcription factor ATF4. By contrast, ATF4 was not induced in cells exposed to palmitoleate (densitometry for ATF4: control – 1.0 unit; 0.025mM palmitate – 3.7 units; 0.025mM palmitoleate – 1.1 unit). The pro-apoptotic factor CHOP-10/GADD153 was also increased by palmitate but not by palmitoleate. GRP78 expression was not up-regulated in palmitate- or palmitoleate-treated cells. Palmitoleate markedly attenuated the induction of ATF4 and CHOP10 caused by palmitate and it also reduced the induction of these factors in response to tunicamycin, an agent which induces ER stress by inhibiting protein glycosylation. Consistent with these results palmitoleate protected β -cells against the cytotoxicity caused by tunicamycin (1 μ g/ml tunicamycin 22.7% \pm 1.3 dead cells; tunicamycin + palmitoleate: 15.4% \pm 1.4 dead cells; $p < 0.05$).

Conclusion: The mono-unsaturated fatty acid, palmitoleate inhibits the induction of markers of ER-stress in β -cells exposed to either palmitate or tunicamycin. Thus, palmitoleate may exert its protective actions on cell viability by reducing the pro-apoptotic response associated with ER stress although this is not accompanied by complete normalisation of the morphological changes seen in the ER of palmitate-treated cells.

Counteraction of glucolipototoxicity in INS-1E cells by carnitine-palmitoyltransferase 1 over-expression involves reduction in phosphorylation of ER-stress marker eIF2 α

E. M. Sol¹, E. Sargsyan¹, G. Akusjärvi², P. Bergsten¹;¹Department of Medical Cell Biology, ²Department of Medical Biochemistry and Microbiology, Uppsala University, Sweden.

Background and Aims: Chronic exposure of elevated levels of glucose and free fatty acids are correlated with dysfunctional pancreatic β -cells and development of type 2 diabetes. The mitochondrial protein carnitine palmitoyltransferase 1 (CPT1) has an important role in the oxidation of fatty acids by transporting them into the mitochondria. To examine if enhanced fatty acid oxidation is beneficial for β -cells exposed to elevated concentrations of glucose and fatty acids, we performed regulated over-expression of CPT1 in INS-1E cells cultured in the presence of palmitate and 20 mM glucose. After culture, glucose-stimulated insulin secretion (GSIS) and total protein were measured in INS-1E cells with different amounts of CPT1.

Materials and Methods: An adenoviral construct was designed for Tet-ON regulated over-expression of liver type of CPT1 (Ad-Tet-ON-CPT1) and used for infecting INS-1E cells. Subsequently, cells were cultured for 48 hours in the presence of 10% serum, 0.5 mM palmitate and 5.5 or 20 mM glucose. CPT1 expression was induced by adding 0.2 or 1 μ M doxycycline to the culture medium. After culture, INS-1E cells were used for determination of GSIS, which was measured at basal (3 mM) and stimulatory (20 mM) glucose in the presence or absence of palmitate. Total protein levels in the wells were also measured by using DC protein assay. Expression of CPT1 and endoplasmic reticulum (ER)-stress markers phosphorylated eIF2 α , CHOP and BiP, were examined using western blot analysis.

Results: INS-1E cells cultured in the presence of 20 mM glucose and palmitate demonstrated impaired insulin release with elevated basal insulin secretion and perturbed insulin secretion at stimulatory glucose

concentration irrespective of whether palmitate was absent or present during the measurements. In contrast, cells over-expressing CPT1 6-fold demonstrated lowered basal insulin release and improved GSIS when palmitate was present during the release measurements. If palmitate was omitted during release measurements, GSIS was not improved by over-expressing CPT1. Total protein was increased with elevated CPT1-levels. Since total protein rise could reflect decrease in apoptosis, phosphorylation of the early marker of ER-stress eIF2 α was measured. ER-stress is proposed to be one of the underlying mechanisms of fatty acid induced pancreatic β -cell apoptosis and phosphorylation of eIF2 α an initial step in the development of ER-stress response. Phosphorylated eIF2 α was decreased in cells cultured at high glucose concentration and palmitate and over-expressing CPT1. The down-stream ER-stress markers CHOP and BiP were, however, not affected by enhanced levels of CPT1.

Conclusion: The study demonstrates that over-expression of CPT1 is counteracting glucolipotoxicity in INS-1E cells. Enhanced levels of CPT1 improves GSIS, reduces insulin secretion at low glucose, increases total protein content possibly reflecting attenuation of apoptosis, and finally alleviates ER stress by down-regulating p-eIF2 α .

Fatty acid-induced lipid handling and apoptosis in MIN6 cells is determined by fatty acid saturation and chain length

K. Thörn, P. Bergsten;

Medical Cellbiology, Uppsala Universitet, Sweden.

Background and Aims: Prolonged exposure to fatty acids impairs the function of the pancreatic β -cell and causes apoptosis. Most work has been performed using palmitate as a model of saturated fatty acids and oleate as its monounsaturated counterpart. To explain the decline of β -cell function after fatty acid exposure endoplasmic reticulum (ER)-stress was shown to be induced by palmitate but not by oleate. The reason for observed differences between effects on β -cell function and mass of different fatty acids is to a large extent still unclear, however. The aim of the present study was to investigate the regulation of genes involved in intracellular lipid handling and ER-stress when the β -cell is exposed to fatty acids of different chain length and degree of saturation.

Materials and Methods: MIN6 cells were cultured in absence or presence of 0.5 mM palmitate, stearate, palmitoleate or oleate for 48 hours. After culture, glucose-stimulated insulin secretion and apoptosis was measured. RNA was isolated and used to determine transcriptional regulation of genes involved in intracellular fatty acid handling by qPCR. Protein was isolated and separated by SDS-PAGE and immunoblotted with antibodies directed towards proteins involved in ER-stress response.

Results: Insulin secretion at stimulating (20 mM) glucose concentrations from MIN6 cells cultured in presence of saturated fatty acids (SFAs) palmitate or stearate was significantly reduced. On the other hand, stimulated insulin secretion was not affected when cells were cultured in the presence of mono-unsaturated fatty acids (MUFAs) palmitoleate or oleate. Cells treated with either of the MUFAs displayed no difference in apoptosis compared to control cells. In contrast, apoptosis was significantly increased in cells cultured in the presence of either of the SFAs with the effect of palmitate being 45 % higher than stearate. To determine if this difference could be attributed to changes in proteins involved in intracellular lipid handling, mRNA levels of SCD1, SCD2, DGAT1, DGAT2, CPT1 and FAS were determined. SFAs regulated the genes differently compared to MUFAs except for CPT1 which was similarly regulated by all fatty acids. No differences in expression depending on fatty acid chain length were found except for FAS. Palmitate exclusively up-regulated levels of FAS indicating increase in *de novo* synthesis of fatty acids. Since palmitate caused a higher degree of apoptosis than stearate, we examined if this could be attributed to differences of the SFAs to induce ER-stress response. Although both SFAs increased phosphorylated (P) eIF2 α , phosphorylation was more enhanced after palmitate treatment. While palmitate-induced increase of P-eIF2 α translated into increased levels of the pro-apoptotic protein CHOP, stearate-induced increase of P-eIF2 α failed to induce CHOP.

Conclusion: Fatty acids affect the β -cell differently depending both on chain length and saturation. Whereas degree of saturation was important for insulin secretion and in regulating genes involved in lipid handling, chain

length affected apoptosis in cells exposed to SFAs. The difference in apoptosis observed when cells were cultured in the presence of palmitate or stearate may be accounted for by selective palmitate-induction of pro-apoptotic protein CHOP.

Palmitate, but not oleate, induces endoplasmic reticulum (ER) stress and impairs ER to Golgi trafficking independent of de novo ceramide synthesis

A. Preston¹, E. Gurisik¹, A. Busch¹, M. Fuller², P. Meikle², R. Laybutt¹, T. Biden¹;

¹Diabetes and Obesity, Garvan Institute of Medical Research, Sydney,

²Lysosomal Diseases Research Unit, Children Youth and Women's Health Service, Adelaide, Australia.

Background and Aims: Type 2 diabetes (T2D) is characterised by β -cell dysfunction which correlates with increases in plasma lipids and β -cell apoptosis. The ER is a major site of synthesis for protein and complex lipids such as ceramide, a species implicated in β -cell apoptosis. We have previously shown that ER stress occurs in β -cells of human T2D and animal models of the disease. Moreover, we showed that ER stress was necessary for full lipo-apoptosis in vitro. Therefore, we sought to determine the mechanisms whereby fatty acids induce ER stress. As fatty acids are important regulators of vesicular transport, our aim was to investigate links between vesicular trafficking, ER stress and apoptosis in fatty acid treated MIN6 cells.

Materials and Methods: Apoptosis was measured by ELISA. Total ceramide was measured by mass spectrometry and de novo synthesis was determined by incorporation of ³H-serine into ceramide as assessed by thin layer chromatography. To study vesicular trafficking, we transfected MIN6 cells with GFP-tagged vesicular stomatitis virus temperature sensitive mutant ts045 (VSVG-GFP), which is reversibly misfolded and retained in the ER at 40°C and moves out of the ER and into the Golgi complex when temperature is reduced to 32°C. Cells expressing VSVG-GFP were incubated with 0.92% BSA either alone or coupled to 0.4mM palmitate or oleate for 48h. 12h before the end of the incubation, cells were shifted to 40°C and then 32°C for 20 min. VSVG-GFP trafficking was assessed by confocal microscopy. Cells were fixed and immunocytochemistry was performed using markers of the ER and Golgi complex. Trafficking was also measured by resistance of VSVG-GFP to endoglycosidase H (Endo H), a characteristic of secretory products in the Golgi complex. Membranes were isolated following fatty acid treatment, incubated with Endo H and separated by SDS-PAGE. Western blotting for GFP was performed to identify changes in VSVG-GFP mobility and resistance to Endo H.

Results: Confocal microscopy showed that VSVG-GFP was retained in the ER at 40°C. Time course analysis revealed that with lowering the temperature to 32°C, VSVG-GFP in control and oleate treated cells was efficiently transported to the Golgi complex. However in the palmitate treated cells, a proportion of VSVG-GFP exhibited delayed trafficking and was retained in the ER. Endo H treatment of isolated membranes revealed trafficking of VSVG-GFP due to the temperature dependant shift was 90% reduced ($p < 0.05$) in palmitate treated cells compared to control, whereas no significant alteration was observed in oleate treated cells. No change in total ceramide levels was observed with palmitate treatment when compared to control treated cells as assessed by mass spectrometry (8.1 \pm 0.6 vs. 8.3 \pm 0.8 nmol/mg protein respectively). Moreover, concentrations of cycloserine which completely abolished de novo ceramide synthesis did not inhibit lipoapoptosis.

Conclusion: These results indicate that treatment of MIN6 cells with the saturated fatty acid palmitate but not the unsaturated fatty acid oleate causes impairment of vesicular trafficking from ER to Golgi. This defect in trafficking is associated with ER stress and β -cell apoptosis and may contribute to the development of T2D. This blockade in trafficking is not due to increases in de novo ceramide synthesis.

The role of reactive oxygen species (ROS) for lipotoxicity in insulin producing cells

W. Gehrman, M. Elsner, S. Lenzen;

Institute of Clinical Biochemistry, Hannover Medical School, Germany.

Background and Aims: Elevated levels of free fatty acids (FFA) cause β -cell dysfunction and apoptosis in type 2 diabetes, but the molecular mechanisms of lipotoxicity are only partially understood. It is unclear if increased reactive oxygen species (ROS) formation or long chain free fatty acid binding receptors GPR40 and GPR120 are involved in lipotoxicity. The aim of the present study was to analyse the toxicity of different saturated and unsaturated fatty acids in insulin producing cells and the possible molecular mechanisms, particularly with regard to the role of elevated ROS formation and an uncoupling of the respiratory chain.

Materials and Methods: To investigate the cytotoxic effects of different fatty acids upon insulin-producing RINm5F cells *in vitro* viability was measured by MTT assay after exposure to saturated and unsaturated fatty acids for 24h. A FACS-based caspase-3 assay was performed to determine cell death mode of lipotoxicity. To assess the role of ROS formation for lipotoxicity we analysed the cell viability of RINm5F cells overexpressing antioxidative enzymes after palmitic acid treatment. The mitochondrial membrane potential was determined by staining with JC-1. The effect of FFA on the mRNA expression level of uncoupling protein 2 (UCP2) and the expression levels of GPR40 and GPR120 were determined by quantitative RT-PCR. Electron microscopy analyses were performed to detect morphological changes due to FFA treatment.

Results: The saturated fatty acids palmitic (C16:0, $EC_{50} = 113 \mu\text{M} \pm 6$) and stearic acid (C18:0, $EC_{50} = 80 \mu\text{M} \pm 5$) showed toxic effects on insulin producing cells whereas the unsaturated fatty acids oleic (C18:1), palmitoleic (C16:1), linoleic (C18:2), γ -linolenic (C18:3) and arachidonic acid (C20:4) were not toxic up to supraphysiological concentrations. Moreover, unsaturated fatty acids had a significant protective effect against saturated fatty acid induced toxicity at equimolar concentrations. The caspase-3 signal pathway was activated in RINm5F cells due to palmitic acid treatment. Only the cytosolically located antioxidative enzymes catalase and CuZnSOD showed protective effects against palmitic acid induced toxicity, whereas the mitochondrially located antioxidative enzymes mito-catalase and MnSOD had no protective effect. The mitochondrial membrane potential was enhanced by palmitic acid incubation ($31\% \pm 6$ less green fluorescence measured by JC-1) whereas the UCP-2 expression level was unaltered. The FFA binding receptors GPR40 and GPR120 in RINm5F cells were not detectable by quantitative RT-PCR. In electron microscopy analyses we found damage to the endoplasmic reticulum induced by palmitic acid whereas the mitochondria were intact. Incubation with oleic acid led to the formation of lipid droplets in the cytosol.

Conclusion: The presented data indicate that only ROS formation in the cytosol and not in the mitochondria is important for the toxicity of saturated fatty acids. This is in agreement with the morphological changes of the endoplasmic reticulum and not of the mitochondria observed by electron microscopy and the unaltered UCP-2 expression level due to palmitic acid treatment. The FFA binding receptors GPR40 and GPR120 are probably not involved in lipotoxicity.

Insulin secretion defects of human type 2 diabetic islets are corrected by preculture with the radical scavenger IACR. Lupi¹, S. Del Guerra¹, R. Mancarella¹, L. Valgimigli², M. Paolini², A. Soleti³, M. Bugliani¹, M. Martano³, F. Filippini⁴, U. Boggi⁴, S. Del Prato¹, P. Marchetti¹;¹Endocrinology and Metabolism, Metabolic Unit, University of Pisa, Italy,²Pharmacology, University of Bologna, Italy,³Medestea Research, Medestea, Torino, Italy, ⁴Oncology, Transplantation and Advanced Technologies in Medicine, University of Pisa, Italy.

Background and Aims: Oxidative stress is a putative mechanism leading to beta-cell damage in Type 2 diabetes. In the present study, we investigated the effects of the new antioxidant, bis(1-hydroxy-2,2,6,6-tetramethyl-4-piperidinyl)decandioate di-hydrochloride (IAC) on the function of isolated human pancreatic islets from Type 2 diabetic and non-diabetic subjects, matched for age and body mass index.

Materials and Methods: The islets were obtained from 8 non-diabetic and 5 Type 2 diabetic multiorgan donors (age, 49 ± 16 and 65 ± 9.5 years; gender, 4 males/4 females and 3 males/2 females; body mass index, 25.6 ± 2.5 and $27.5 \pm 4.0 \text{ kg/m}^2$), cultured free-floating at 37°C for 24h in M199 culture medium either plain or containing 10 or 100 $\mu\text{mol/l}$ IAC. Oxidative stress was demonstrated by measuring nitrotyrosine concentration (Elisa technique), and by electron paramagnetic resonance (EPR). Functional (glucose-stimulated insulin secretion) and molecular (qualitative and quantitative RT-PCR) studies were also performed.

Results: Nitrotyrosine concentrations were significantly ($p < 0.01$) higher in Type 2 diabetes ($12.4 \pm 0.9 \text{ nmol/l}$) than in control ($6.6 \pm 0.3 \text{ nmol/l}$) islets. In addition, increased oxidative stress in diabetic islets was demonstrated by EPR, which showed a 2-fold increase of nitroxide levels. As expected, glucose-stimulated insulin release from Type 2 diabetic islets was significantly lower than from non-diabetic islets (Stimulation Index, SI 2.0 ± 0.4 and 0.9 ± 0.2 respectively, $p < 0.01$). Pre-culture of Type 2 diabetic islets with 10 or 100 $\mu\text{mol/l}$ IAC caused a significant reduction ($p < 0.01$ by ANOVA) of nitrotyrosine levels (nmol/l), which decreased from 12.4 ± 0.9 to 9.3 ± 0.5 at 10 $\mu\text{mol/l}$ IAC ($p < 0.05$ vs non-treated by the Bonferroni test) or to 10.2 ± 1.4 at 100 $\mu\text{mol/l}$ IAC ($p < 0.05$ vs non-treated by the Bonferroni test). These changes were accompanied by improved glucose-stimulated insulin secretion, with SI values significantly increasing to 1.5 ± 0.4 and 1.6 ± 0.5 with 10 and 100 $\mu\text{mol/l}$ IAC, respectively. Finally, mRNA expression of catalase and glutathione peroxidase was significantly higher in Type 2 diabetic than control islets, and 24h exposure to IAC normalized the expression of the two ROS scavenging enzymes. This was accompanied by a significant increase of the expression of insulin, which was more than 50% lower in diabetic islets as compared to control cells prior to IAC pre-culture, and increased approximately 30% afterwards.

Conclusion: The present study supports the concept that therapy with antioxidants could be an interesting adjunctive pharmacological approach to the treatment of Type 2 diabetes. In this regard, the protection determined by IAC suggests the potential usefulness of this compound.

Evolution with age of antioxidant capacity in rat pancreatic islets.**Early programming by maternal diet**

N. H. Theys, B. Reusens, C. Remacle;

Institute of Life Sciences, Université Catholique de Louvain, Louvain-la-Neuve, Belgium.

Background and Aims: In Type 1 as well as in Type 2 diabetes, β -cell function is progressively disturbed through a complex process during which the cells are exposed to reactive oxygen species (ROS). An increase in ROS production may be a harsh challenge since the level of antioxidant enzymes activities is low in pancreatic islets. We have shown that the vulnerability of the foetal and adult β -cells against ROS can be influenced by the nutritional status of the mother during gestation and lactation. Indeed, islets from foetal and adult progeny of dams fed a low protein diet present a higher rate of apoptosis after cytokines or ROS attacks. In this context, our first aim was to study the evolution of antioxidant capacity during post-natal development. Our second aim was to investigate whether maternal low protein diet may programme the antioxidant activity in islets and liver of the progeny.

Materials and Methods: Wistar rats were fed a control diet containing 20% protein (C group) or an isocaloric low protein diet (LP) containing 8% protein during gestation only (LPR group) or until weaning (LPT group). At birth (LPR group) or after weaning (LPT group), offspring received the control diet. The antioxidant capacity was studied at 5 days, 28 days, 6 weeks, and 3 months in male rats.

Results: In C group, superoxide dismutase (SOD) and catalase (CAT) activities were much lower in islets than in liver at each age. In the liver, SOD activity increased significantly at 6 weeks ($p < 0.05$) compared to younger ages and remained stable thereafter. In contrast, islets showed a higher SOD activity at 5 days ($p < 0.05$) compared to later ages. In the liver, CAT activity was significantly decreased by 50% at 28 days ($p < 0.01$), 6 weeks ($p < 0.05$) and 3 months ($p < 0.05$) compared to 5 days whereas in islets, no significant change was observed with age and this activity was as low as 2% of that in the liver. Plasma lipid hydroperoxide levels were decreased in 3 month-old LPT offspring ($p < 0.05$) whereas the total peroxyl-radical trapping potential tended to be lower. In liver, SOD activity was reduced at

5 days in LPR offspring ($p < 0.05$) compared to C offspring. At 28 days, this difference was no more observed, and at 3 months, LPT animals showed an increased SOD activity compared to C and LPR rats ($p < 0.01$). In islets, SOD activity was lower at 5 days in LPR offspring ($p < 0.001$) compared to C islets but not in LPT progeny. At 3 months, SOD activity in islets from C and LPR animals was similar, whereas it was significantly increased in LPT rats ($p < 0.01$). In comparison to controls, CAT activity was significantly higher in liver ($p < 0.05$) of LPR and LPT offspring already from 28 days. In islets, CAT activity was so low for many samples that it couldn't be detected, particularly in LPT islets.

Conclusion: In C offspring, at all ages studied, antioxidant enzyme activities in islets were much lower than those in liver. Then, already at birth, the endocrine pancreas seems to be particularly vulnerable to oxidative stress. Maternal LP diet modulated the activity of liver and islets antioxidant enzymes. In islets as well as in liver, SOD activity was higher in adult LPT animals and could correspond to a compensatory effect due to early malnutrition. In contrast, CAT activity completely collapsed in islets of LPT offspring. The modulation of antioxidant activities can not explain the increased apoptosis rate observed previously in LP islets but could program antioxidant capacity in ways unfavourable for the future of the progeny.

PS 21 Putative mediators of beta cell damage in type 2 diabetes

0412

High density lipoprotein protects human and mouse pancreatic islets from high glucose and interleukin-1 beta induced apoptosis

S. Rützi¹, J. Ehses¹, L. Rohrer², R. Prazak¹, A. von Eckardstein², M. Y. Donath¹;

¹Endocrinology and Diabetology,

²Institute of Clinical Chemistry, University Hospital, Zürich, Switzerland.

Background and Aims: Increasing evidence indicates that decreased functional insulin-producing β -cell mass is a hallmark of type 2 diabetes. Lipoproteins have been shown to affect rodent β -cell survival. We tested the putative protective role of high density lipoprotein (HDL) on human and mouse β -cell turnover and function.

Materials and Methods: Human islets, obtained from cadaveric organ donors and isolated mouse islets were cultured for 2 or 4 days with varying concentrations of HDL alone as well as in the presence of high glucose or interleukin-1 beta (IL-1 β). Proliferation was assessed by Ki-67 staining and apoptosis by TUNEL staining.

Results: High density lipoprotein, isolated from the plasma of healthy donors by sequential ultracentrifugation, increased 2-fold the basal proliferation of human islet cells ($n=4$, $p < 0.05$) and decreased 2-fold their basal apoptosis ($n=6$, $p < 0.05$). Furthermore, HDL (1mM) protected mouse and human islets from IL-1 β and high glucose induced apoptosis (for IL-1 β , $n=3$, $p < 0.05$). β -cell function, ascertained by glucose stimulated insulin secretion, was not affected by HDL. High density lipoprotein was unable to protect from high glucose or IL-1 β induced functional impairment. Finally, we found that HDL increased islet FLIP mRNA expression ($n=4$, $p < 0.05$) alone as well as in the presence of high glucose or IL-1 β .

Conclusion: These results indicate that HDL induces human islet cell proliferation and protects human and mouse islet cells from glucose and IL-1 β induced apoptosis, possibly via regulation of FLIP expression, without affecting β -cell secretory function.

0413

Molecular mechanism of pioglitazone effect on the pancreatic beta cell preservation in diabetic *db/db* mice: evidence for direct action as PPAR γ agonist

Y. Kanda, F. Kawasaki, M. Hashiramoto, K. Nakashima, M. Matsuki, K. Kaku;

Diabetes and Endocrine Division, Kawasaki Medical School, Kurashiki-shi, Japan.

Background and Aims: We have previously reported that pioglitazone (Pio) preserves the pancreatic beta-cell morphology and function in obese diabetic animal model *db/db* mice. The aim of this study is to clarify the molecular mechanism for preventive effect of Pio on pancreatic beta cell damage in *db/db* mice by directly analysing gene expression in pancreatic beta-cells using Laser Capture Microdissection (LCM) and real-time RT-PCR method.

Materials and Methods: Male BKS.Cg- $+ Lepr^{db}/+ Lepr^{db}/cl$ (*db/db*), BKS.Cg- $m +/+ Lepr^{db}/cl$ (*db/+*) and lean littermate ($+/+$) mice were divided into Pio-treated and -untreated (control) groups ($n=5$). Pio was administered orally for two weeks from 10 weeks of age (30mg/kg BW). BW, fasted plasma glucose (FBG), insulin (FIRI), adiponectin, TG and FFA were measured every week. To analyze gene expression profiles in beta cells, the islet core region was selectively obtained by LCM method at the age of 8 and 12 weeks. Primer pairs encoding genes associated with pancreatic hormones, cell proliferation, cell differentiation, apoptosis, cell cycle, oxidative stress, and organization construction were prepared, and real-time RT-PCR with Sybr Green was applied. Each gene expression was relatively quantified by the comparative Ct method with each result in the 18 SrRNA as a control. Immunoreactions of proliferating cell number antigen (PCNA) and 4-hydroxynonenal modified protein (4-HNE) in islet tissues were also assessed.

Results: BW, FBG, FIRI, HOMA-IR, TG and FFA were significantly increased and adiponectin was decreased in *db/db* mice compared with those in other groups. These deranged metabolic markers were ameliorated by the treatment

with Pio. Gene expression analysis of islet core tissues in *+/+* mice revealed that beta-cells were selectively collected by LCM method. Gene expressions of PPAR γ and insulin in beta-cells were decreased in all three groups of mice treated with Pio. Cyclin E & ERK1 gene expressions related with promotion of cell proliferation were significantly up-regulated in *db/db* mice at 8 week, but down-regulated at 12 weeks of age. CAD gene expression related with promotion of apoptosis was also increased in *db/db* mice with their weeks. In 12 week-old *db/db* mice, treatment with Pio significantly up-regulated ERK1 gene expression (4-fold, $p < 0.05$), and down-regulated CAD gene expression (1/3-fold, $p < 0.05$). On the other hand, anti-apoptotic bcl-2 gene expression was significantly increased by Pio treatment (4.6-fold, $p < 0.05$). NADPH oxidase gene expression related with oxidative stress was markedly decreased ($p < 0.05$), and anti-oxidative stress related GSHPx and SOD2 gene expression was significantly increased by Pio (3 ~4-fold, $p < 0.05$, respectively). Effects of Pio on gene expression demonstrated in *db/db* were also observed in *db/+* and *+/+* mice, but not so much significant compared with those in *db/db*. Morphometric results for cell proliferation (PCNA) and oxidative stress (4-HNE) observed in *db/db* mice corresponded to the data of gene expression analysis.

Conclusion: The present results demonstrated the PPAR γ expression in mouse beta-cells, which is regulated by Pio. Our results strongly suggest the possibility that Pio preserves the beta cell mass directly through a mechanism to modulate cell kinetics as a PPAR γ agonist in addition to amelioration of metabolic disorder.

Beta cells of the diabetic Goto-Kakizaki rat exhibit an unexpected *in vitro* adaptation to oxidative stress- induced apoptosis

G. Lacraz, N. Kassis, F. Homo-Delarche, J. Coulaud, D. Bailbé, B. Portha; CNRS and University Paris Diderot, UMR 7059, Paris, France.

Background and Aims: Prolonged exposure to elevated plasma glucose levels exerts deleterious effects on β -cell function and ultimately leads to β -cell death. Considerable interest has recently been focused on the putative role of reactive oxygen species (ROS) upon deterioration of β -cell function/survival in diabetes. Interestingly, Type 2 diabetic Goto-Kakizaki (GK) rats from a Japanese colony exhibit β -cell oxidative damage and we have reported an islet inflammatory process in our GK colony. We recently showed that insulin exocytosis by GK β cells, when functionally activated (high glucose + acetylcholine 1 mM), exhibits an unexpected resistance to many pro-oxidant agents (50 μ M H₂O₂, 1 mM streptozotocin, 1 mM alloxan or 50 μ M *tert*-butylhydroperoxide) when acutely exposed. Here, we have further examined the delayed effects of a calibrated oxidative stress exposure, upon β -cell apoptosis response *in vitro*.

Materials and Methods: Wistar (W) or GK islets were cultured for 24h or 48h at 10 mM glucose after acute exposure to vehicle, 50 μ M H₂O₂ alone or in combination with the antioxidant N-acetylcysteine (1 mM NAC). Apoptosis within the β -cell population was monitored by DNA fragmentation (TUNEL method and insulin immunostaining). Stress gene expression study was performed by quantitative Real Time PCR.

Results: In the absence of H₂O₂, GK β -cell apoptosis after 24h and 48h-culture period was strongly increased (8.9 and 3.9 fold, respectively) as compared to W β cells. Despite this pattern, H₂O₂ did not further amplify apoptosis in GK β cells, whereas it triggered a major apoptotic wave (12 and 5.6 fold, respectively) in W β cells. Stress gene analysis revealed that pro- (BAX, caspases 3–9) and anti-apoptotic gene (Bcl 2) in GK islets were similarly expressed under basal condition, as compared to W islets. However, several inflammatory responsive genes (cyclooxygenase 2, 12-lipoxygenase, Nuclear Factor κ B, Transforming growth Factor β 1) were overexpressed up to 19 fold in GK islets. In addition, many antioxidant genes were increased (superoxide dismutase 1–2, catalase, thioredoxin 1–2, peroxiredoxin 1–2, haeme-oxygenase 1), at the remarkable exception of glutathione reductase, which was decreased by 10 fold. Interestingly, treatment with the glutathione inductor agent NAC strongly lowered the H₂O₂-induced apoptosis in GK β cells to level similar to W control β cells. Such a protective action of NAC suggests that the weak GK β -cell survival, as detected here under *in vitro* culture conditions, involves ROS production.

Conclusion: In conclusion, even if stressful culture conditions reveal that GK β cells have a decreased survival capacity to adapt *in vitro*, there are still able to defend remarkably against the H₂O₂-induced apoptosis. The pattern of stress gene expression and ROS production that accompanies the β -cell

survival at the end of the 24h-culture period is currently investigated. Since an exaggerated cAMP production is a characteristic of the GK islet, we will also evaluate the putative contribution of the cAMP/PKA pathway to the GK β -cell resistance to the H₂O₂-induced apoptosis.

0415

IL-1 β -MyD88 signaling is central to islet chemokine secretion in response to metabolic stress: evidence from a spontaneous model of type 2 diabetes, the GK rat

J. A. Ehses¹, M.-H. Giroix², J. Coulaud², S. Akira³, F. Homo-Delarche², M. Y. Donath¹;

¹Div of Endocrinology & Diabetes and the Center for Integrated Human Physiology, University Hospital of Zurich, Switzerland, ²Unité mixte de recherches (UMR) 7059, Paris University / D. Diderot, Paris, France,

³Department of Host Defense, Osaka University, Japan.

Background and Aims: Interleukin-1 β (IL-1 β) plays an integral role in the deterioration of β -cell function in type 2 diabetes (T2D). We have recently shown that pancreatic islets in T2D are characterized by macrophage infiltration, and that increased glucose and palmitate concentrations stimulate the secretion of various chemokines from islets. The aim of the present study was to investigate a possible role for IL-1 β in chemokine production by both C57BL/6 (B6) mouse islets and diabetic Goto-Kakizaki (GK) rat islets.

Materials and Methods: Pancreatic islets were isolated from male 8–10 week old B6, MyD88 *+/+*, MyD88 *-/-*, and IL-1 β *-/-* mice and plated on ECM matrix at 5 islets/well. All mice were backcrossed for 10 generations onto the B6 background prior to analysis. Islets from 3-month old male Wistar (the control strain from which the GK line originated) and GK rats were isolated and plated on 3 cm ECM dishes at 20 islets/dish. All islets were stimulated with test conditions for 48h unless otherwise stated, and experiments performed in triplicate.

Results: In mouse islets, 2 ng/mL IL-1 β mimicked the effects of elevated glucose and palmitate on islet KC, G-CSF, and IL-6 secretion; an effect that was completely ablated in MyD88 *-/-* mice ($p < 0.05$, $n = 3–5$). Analysis of the kinetics of these effects indicated significant increases in chemokines already after 6h of treatment ($p < 0.05$, $n = 3–5$). To determine if these effects of glucose and palmitate were partially due to IL-1 β , both B6 and IL-1 β *-/-* islets were treated with the IL-1 receptor antagonist, IL-1Ra. IL-1Ra inhibited the production of KC, G-CSF, and IL-6 by > 50% in B6 islets ($p < 0.05$, $n = 3–10$) with no effect on IL-1 β *-/-* islets ($p > 0.05$, $n = 4–7$). Thus, IL-1 β signalling is required for elevated glucose and palmitate concentrations to stimulate islet chemokine secretion. Next, we evaluated this in 3-month-old GK rat islets. In this spontaneous T2D model, hyperglycemia starts at 1 month of age (weaning) and is then accompanied by progressive inflammatory cell infiltration. Compared to age-matched Wistar islets, GK islets secreted increased amounts of KC, IL-6, MCP-1 and MIP-1 α on a per mg protein basis ($p < 0.05$, $n = 3–6$). Treatment of islets with IL-1Ra significantly decreased the secretion of all these factors *in vitro* ($p < 0.05$, $n = 3$). We also analyzed cytokines and chemokines in Wistar and GK sera from 1 to 32 weeks of age. Certain cytokines (IL-6, IFN- γ , IP-10) spiked similarly in Wistar and GK sera around weaning. Others such as MCP-1 and MIP-1 α , showed a progressive decline with age and, interestingly, their levels were significantly elevated in GK sera at 1 and 2 weeks of age ($p < 0.05$, $n = 4–10$ animal samples).

Conclusion: IL-1 β is a central mediator of islet chemokine secretion induced by elevated glucose and palmitate; an effect that is dependent on MyD88 signalling in mice. Further, diabetic GK rat islets, characterized by progressive macrophage and granulocyte infiltration, secrete elevated levels of KC, IL-6, MCP-1 and MIP-1 α . *In vitro* treatment of these islets with IL-1Ra reduces the secretion of these inflammatory factors. Therefore, we propose that *in vivo* IL-1Ra treatment may prevent macrophage infiltration in islets in type 2 diabetes.

Islet protein expression from type 2 diabetic donors correlating with impaired secretory response

H. K. Nyblom¹, M. Bugliani², P. Marchetti², P. Bergsten¹;

¹Department of Medical Cell Biology, Uppsala University, Sweden,

²Department of Endocrinology and Metabolism – Metabolic Unit, University of Pisa, Italy.

Background and Aims: Islet dysfunction in type 2 diabetes mellitus is caused by alterations in multiple genes. This prompted the use of approaches capable of determining expression profiles rather than single gene products. The first aim was to protein profile islets obtained from type 2 diabetes mellitus and control donors. The second aim was to develop a protocol to discover and identify differentially expressed proteins relevant for the development of islet dysfunction in type 2 diabetes mellitus, by correlating changes in expression patterns to islet function studies.

Materials and Methods: Islets of Langerhans were isolated from five type 2 diabetes mellitus and ten control donors. The two groups were age and weight matched. Insulin release from isolated islets in response to glucose, glibenclamide and arginine was determined. Islet lysates corresponding to approximately 20 islets were applied onto strong anionic protein arrays (Q10) and analyzed by surface-enhanced laser desorption/ionization time-of-flight mass spectrometry (SELDI-TOF MS).

Results: Insulin release from control islets increased 4-fold when the glucose concentration was increased from 3 to 17 mM glucose. Similar rises were observed when glibenclamide or arginine was added. In contrast, insulin release only increased 2-fold from islets isolated from type 2 diabetes mellitus donors when either the glucose concentration was raised or glibenclamide or arginine was added. Protein profiles of islet lysates, from control or type 2 diabetes mellitus donors, showed about 110 peaks ($s/n=4$, peak percentage=15%). Although considerable variability in both insulin release and peak intensity existed within the two groups, 31 differentially expressed peaks ($p<0.05$) were detected. Individual insulin secretory results were plotted against corresponding peak intensities of the differentially expressed proteins. In seven of the differentially expressed proteins there was a correlation between mean peak intensities and the stimulation index for insulin release in the presence of glibenclamide.

Conclusions: Protein profiles of as little as 20 islets can be obtained by SELDI-TOF MS. The limited demand for islets made islet protein profiling from type 2 diabetes individuals possible. Differentially expressed islet proteins were discovered when control and type 2 diabetes mellitus islets were compared. The significance of some of these proteins for islet dysfunction is indicated by the correlation of the expression of these proteins to glibenclamide-induced insulin secretion.

IL-1beta expression in human islets is induced by glucose and auto-stimulation, and increased in beta cells of individuals with type 2 diabetes

M. Boeni-Schnetzler¹, L. Marselli², G. Parnaud³, J. A. Ehses¹, P. A. Halban³, G. C. Weir², M. Y. Donath¹;

¹Endocrinology and Diabetology, University Hospital of Zuerich, Switzerland,

²Joslin Diabetes Center, One Joslin Place, Boston, United States,

³Departement of Genetic Medicine and Development, CMU, Geneva, Switzerland.

Background and Aims: IL-1beta producing beta-cells were previously observed by immunostaining and by *in situ* hybridisation in pancreatic sections of patients with type 2 diabetes (T2D). Further, treatment of patients with T2D with an IL1 receptor antagonist (IL1Ra) improves insulin secretion and blood glucose levels. Exposure of human islets to high glucose levels increased production and release of IL-1beta in most but not all islet cell preparations. The aim of the present study was to substantiate the observations on IL-1beta expression in T2D and to understand the mechanisms of these variable effects of glucose on IL-1beta expression *in vitro*.

Materials and Methods: *In vivo* IL-1beta expression was analysed from gene profiles of near-pure populations of beta-cells obtained by laser capture microdissection (LCM) from frozen pancreatic tissue sections of cadavers from 4 subjects with T2D and 7 normal donors. *In vitro* IL-1beta expression

was analysed in human islets cultured for 4 days with 5.5 or 33.3 mM glucose, 200pg/ml IL-1beta or 1 ug/ml IL1Ra. IL-1beta and IL1Ra mRNA levels were quantified using TaqMan analysis and measuring delta ct values relative to non-treated controls.

Results: Gene array analysis showed that IL-1beta mRNA expression was higher in each of the four samples of beta-cells within pancreas sections from T2D patients when compared to controls ($p=0.014$). RT-PCR confirmed increased IL-1 beta mRNA levels in 3 of the 4 T2D patients while minimal expression of IL-1beta was observed in one out of 4 controls. In cultured human islets 33.3 mM glucose induced IL-1beta mRNA levels in 6 out of 11 islet batches. The mean increase in all preparations was 2.15 ± 0.46 ($n=11$, $p<0.05$) and 3.02 ± 0.49 ($n=6$, $p<0.01$) in those preparations that did respond. Islet preparations where glucose did not increase IL-1beta mRNA displayed higher basal IL-1beta mRNA levels than responsive preparations, and there was a significant negative correlation between basal IL-1beta mRNA levels and glucose-stimulated IL-1beta mRNA ($r^2=0.526$, $p=0.0076$). IL1Ra mRNA levels of human islet preparations were decreased by 33.3 mM glucose to 72.3 ± 10.4 % control ($n=11$, $p<0.05$). Addition of IL1Ra strongly decreased basal and glucose stimulated IL-1beta mRNA levels ($p<0.05$), suggesting that IL-1beta mRNA levels are promoted by auto-stimulation. Confirming this, exogenous IL-1beta increased IL-1beta mRNA levels 6.3 ± 2.18 fold ($p<0.001$) and IL1Ra prevented IL-1beta auto-stimulation. IL-1beta induced auto-stimulation was also observed in sorted human beta-cells. Further, auto-stimulation of IL-1beta was inhibited by the NF-kappaB inhibitor Bay11-07082 to 58.9 ± 12.4 % of the control level ($n=4$).

Conclusion: IL-1beta mRNA levels of cultured human islets are induced by auto-stimulation and reduced by IL1Ra treatment. 33.3 mM glucose increases IL-1beta mRNA levels by promoting auto-stimulation and by decreasing IL1Ra expression. Different islet preparations display variable basal IL-1beta mRNA levels and high basal IL-1beta expression may blunt the effects of glucose-stimulated IL-1beta. In beta-cells of individuals with T2D there is enhanced IL-1beta mRNA expression. This suggests a role for IL-1beta in mediating glucotoxicity in islets of T2D.

Evidence of inflammatory markers in beta cells of type 2 diabetic subjects

L. Marselli¹, D. C. Sgroi², J. Thorne³, S. Dahiya², S. Torri¹, A. Omer³, S. Del Prato⁴, L. Towia⁴, H. H. Otu⁴, A. Sharma³, S. Bonner-Weir³, P. Marchetti¹, G. C. Weir³;

¹Endocrinology and Metabolism, University of Pisa, Pisa, Italy,

²Massachusetts General Hospital, Harvard University, Boston, United States,

³Joslin Diabetes Center, Harvard University, Boston, United States, ⁴Beth Israel Deaconess Medical Center, Harvard University, Boston, United States.

Background and Aims: Type 2 diabetes (T2D) is characterized by beta cell dysfunction associated with reduced beta cell mass. Among various mechanisms that may be responsible of these alterations, inflammation may play a role. To assess this possibility, gene profiling of beta cell enriched samples obtained from T2D donors were evaluated.

Materials and Methods: The samples were obtained using laser capture microdissection (LCM) from frozen pancreatic tissue sections of 4 T2D (age: 67.3 ± 5.0 years; BMI: 28.3 ± 1.9 kg/m² ($n=3$); diabetes duration: 5.7 ± 2.5 years ($n=3$)) and 4 non-diabetic (age: 63.5 ± 3.1 years; BMI: 31.6 ± 7.0 kg/m²) cadaver donors. Extracted RNA was amplified by T7 RNA polymerase and hybridized to Human X3P Arrays (Affymetrix). Data were normalized using the DNA-Chip Analyzer (dChip) software. The program employs standard error to identify differentially expressed genes and uses the lower confidence bound (LCB) to estimate the significance. LCB cutoff of 1.2 was used to assess differentially expressed genes.

Results: In T2D 1532 genes were upregulated and 528 genes were downregulated. Samples from T2D pancreases showed increased expression of C-C and C-X-C inflammatory chemokines and some chemokine receptors. Chemokine genes that were most differentially expressed included: monocyte chemoattractant protein 4 (MCP-4) (LCB 2.8) and GRO beta (LCB 2.3). Other chemokines upregulated in T2D were monocyte chemoattractant protein 1 (MCP-1) (LCB: 2.0), GRO alpha (LCB: 1.5), eotaxin (LCB: 1.5) and stromal cell-derived factor 1 (SDF) (LCB: 1.4). Among the chemokine receptors, chemokine C-X3-C receptor 1 (CX3CR1) (LCB: 3.4), chemokine

binding protein 2 (CCBP2) (LCB: 1.5) and chemokine C-X-C motif receptor 7 (CXCR7) were upregulated.

Conclusion: These results suggest that an inflammatory process is activated in the islets of subjects with T2D and that chemokines may have a fundamental role in its activation.

Human oxidised low density lipoprotein-particles cause a loss of insulin secretion by inducing the transcriptional repressor ICER

D. Favre¹, G. Niederhauser¹, F. Allagnat¹, J.-A. Haefliger¹, R. Regazzi², G. Waeber¹, A. Abderrahmani¹;

¹Service of Internal Medicine, CHUV-Hospital, ²Department of Cellular Biology and Morphology, University of Lausanne, Switzerland.

Background and Aims: Inducible cAMP early repressor (ICER) is a transcriptional repressor that is induced in pancreatic β -cells challenged with a diabetic milieu including hyperglycaemia or non esterified fatty acids (NEFA). The sustained induction of ICER leads to impairment of nutrients-induced insulin secretion. Like hyperglycaemia and NEFA, several studies including ours have shown that the pro-atherogenic oxidised low density lipoprotein-cholesterol (oxLDL) exerts deleterious effects on β -cells by increasing the rate of apoptosis and diminishing insulin synthesis. In this study, we investigated whether oxLDL affects nutrient-induced insulin secretion by increasing expression levels of ICER.

Materials and Methods: Mouse insulin-secreting MIN6 cells and rat isolated islets were exposed to 2 mM of human native LDL or oxLDL-cholesterol for 72hrs. Gene expression and insulin levels were monitored by Real-time PCR (Bio-Rad) and ELISA (SPI-BIO), respectively. Luciferase activities were measured by using an assay system (dual-Luciferase; Promega).

Results: Prolonged exposure of MIN6 or islets cells to oxLDL impaired insulin secretion in response to glucose whereas insulin secretion was preserved in the presence of native LDL. Similar results were obtained in MIN6 cells that were transiently transfected with the plasmid encoding the human Growth Hormone (hGH), a reporter gene monitoring the secretory activity of transfected cells independently of their capacity to produce insulin. In addition, the cells were unable to secrete in response to KCl, a secretagogue that stimulates exocytosis by triggering the calcium influx. This result suggested a defect in the activity of the secretory machinery as observed in cells chronically cultured with elevated concentration in glucose or NEFA. In the latter condition, the secretory defect was in part due to a rise in the

levels of the transcriptional repressor ICER. Real-time PCR experiments performed with total RNAs extracted from MIN6 cells or rat isolated islets cultured with oxLDL showed an increase in ICER mRNA levels. Transient transfection of the luciferase reporter construct under the control of ICER activity confirmed the induction of ICER expression in MIN6 cells incubated with oxLDL. Consistent with an increase in ICER activity, expression of target genes including granuphilin, Rab3a and Rab 27a was diminished in cells exposed to oxLDL. Finally, silencing of ICER with the use of an ICER antisense-encoding plasmid abolished the ICER activity induced by oxidised lipoproteins.

Conclusion: These data show that oxLDL induces a loss of insulin secretion by altering expression of genes of the secretory machinery through induction of ICER.

Green tea extract epigallocatechin gallate preserves pancreatic islet structure, restores insulin secretion and ameliorates diabetes in *db/db* mice

Å. Sjöholm¹, H. Ghanaat-pour¹, N. Kuehn², S. Wolfram³;

¹Department of Internal Medicine, Karolinska Institutet, Stockholm, Sweden, ²Frimorfo, Inc., Fribourg, Switzerland, ³Department of Human Nutrition and Health, DSM Nutritional Products Ltd, Basel, Switzerland.

Background and Aims: Green tea was suggested as a therapeutic agent for the treatment of diabetes more than 70 years ago, but the mechanisms involved in its antidiabetic effect still remain elusive. In this work, we attempted to address this issue by feeding the most abundant green tea catechin epigallocatechin gallate (EGCG), in comparison with the thiazolidinedione PPAR- γ agonist rosiglitazone as positive control, to spontaneously diabetic *db/db* mice.

Materials and Methods: Young (5 weeks old) diabetic *db/db* mice were randomized and assigned into the following groups: Control, EGCG, rosiglitazone. Compounds were administered via the diet for 10 weeks. Glucose and insulin levels were determined during an OGTT after 5 and 10 weeks of treatment. Pancreata were sampled at end of the study for blinded histomorphometric analysis.

Results: In moderately diabetic (5 wk treatment) *db/db* mice, EGCG lowered glucose levels (Fig 1A) and improved insulin sensitivity (Fig 1B).

Fig 1

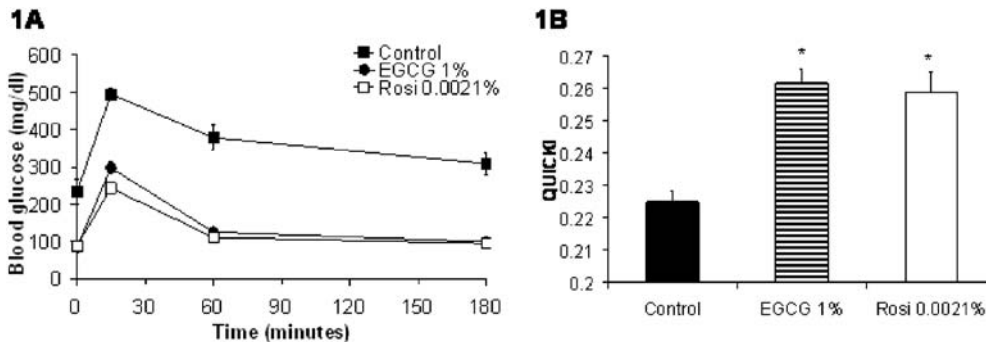

Fig 2

In severely diabetic (10 wk treatment) *db/db* mice, EGCG enhanced glucose tolerance (Fig 2A) but did not any more enhance insulin sensitivity (Fig 2B).

EGCG supplementation reduced the number of pathologically changed islets of Langerhans (Fig 3B), increased the number (Fig 3A) and the size (Fig 3C) of islets, and improved pancreatic endocrine area (Fig 3).

Although EGCG was less potent than rosiglitazone, it exerted changes that were similarly beneficial. Thus, EGCG improved glucose tolerance and glucose-stimulated insulin secretion in *db/db* mice and prevents pathological changes in islets linked to progression of type 2 diabetes.

Conclusion: This study shows that the green tea extract EGCG markedly preserves islet structure and enhances glucose tolerance in genetically diabetic mice. Dietary supplementation with EGCG could potentially contribute to nutritional strategies for the prevention and treatment of type 2 diabetes.

Early mediators and downstream effectors of dsRNA-induced beta cell apoptosis: the role of IRF-3 and ER stress

J. Rasschaert¹, Z. Dogusan¹, M. García¹, D. Flamez¹, L. Alexopoulou², M. Goldman³, C. Gysemans⁴, C. Mathieu⁴, C. Libert⁵, D. L. Eizirik¹; ¹Laboratory of Experimental Medicine, Université Libre de Bruxelles (ULB), Brussels, Belgium, ²Centre d'Immunologie de Marseille-Luminy, CNRS-INSERM-Université de la Méditerranée, Marseille, France, ³Institute of Medical Immunology, Université Libre de Bruxelles (ULB), Charleroi, Belgium, ⁴LEGENDO, Katholieke Universiteit Leuven, Belgium, ⁵Department for Molecular Biomedical Research – VIB, Ghent University, Belgium.

Background and Aims: Viruses, or viral products such as double-stranded RNA (dsRNA), affect beta cell function and survival and trigger autoimmunity in type 1 diabetes by unknown mechanisms. During viral infection beta cells are exposed to both extra- and intracellular dsRNA. We have previously shown that the TLR3 pathway plays a crucial role in exogenous dsRNA-induced beta cell death, but the molecular mechanisms involved in internal-dsRNA-induced beta cell apoptosis are TLR3-independent. We presently characterized the early mediators and downstream effectors of internal-dsRNA-induced apoptosis.

Materials and Methods: FACS-purified rat beta cells and dispersed islet cells from wild type (wt) or IRF-3^{-/-} and type I IFN receptor^{-/-} (IFNAR1^{-/-}) mice were cultured for 5 days with or without transfected synthetic dsRNA (PICin; 10 µg/ml). Viability was determined by the nuclear dyes HO 342 and propidium iodide, while production of IFN-β was measured by ELISA. Gene expression was determined by real-time RT-PCR. Activation of NF-κB and eIF2-α was studied respectively by immunocytochemistry and Western blot using an antibody specific for the phosphorylated forms of STAT-1 and eIF2-α. Protein biosynthesis was determined using tritiated leucine incorporation and TCA precipitation.

Results: Exposure of dispersed islet cells from wt mice to internal PIC for 5 days increased 2-fold apoptosis (50% vs 24% in control wt cells; p<0.005; n=4), while islet cells from IRF-3^{-/-} mice were completely resistant to PICin-induced apoptosis (29% vs 28% in control IRF-3^{-/-} cells; n=4). PICin-induced NF-κB activation was unaffected in IRF-3^{-/-} islet cells when compared to wt cells. These data suggest a key role for IRF-3 in PICin-triggered beta cell apoptosis. IRF-3 signalling regulates type I IFNs production in other cell types, and we observed that PICin induced a 50–2000 fold increase in type I IFNs mRNA expression and a massive production of these cytokines in beta cells. Dispersed islet cells from IFNAR1^{-/-} mice were protected against PICin-

Fig 3

induced apoptosis, indicating that IFNs contribute to cell death in an autocrine manner. In purified beta cells PICin induced eIF-2 α phosphorylation and inhibited protein biosynthesis by 50%, and it up-regulated expression of the ER stress markers ATF-4, CHOP and Bip, suggesting that activation of an ER stress response contributes to beta cell death.

Conclusions: a) The IRF-3 pathway plays a crucial role in internal dsRNA-induced beta cell apoptosis; b) Execution of PICin-mediated apoptosis depends on autocrine effects of type I IFNs and ER stress.

17- β -Estradiol specifically induces apoptosis in cells expressing sulfonylurea receptor 1

S. Ackermann, S. Hiller, H. Osswald, A. Hambrock;
Department of Pharmacology and Toxicology, University of Tuebingen, Germany.

Background and Aims: Apoptosis of pancreatic β -cells is assumed to be involved in the pathophysiology of diabetes type 1 or 2. Previously, we have shown that the insulinotropic sulfonylurea glibenclamide or the natural compound *trans*-resveratrol can induce enhanced β -cell apoptosis and that this effect is specifically linked to the expression of the sulfonylurea receptor isoform SUR1. SUR1 is the regulatory subunit of the pancreatic ATP-sensitive K⁺ channel (K_{ATP} channel) which is essential for triggering insulin secretion in the β -cell. 17- β -Estradiol (E2) induces apoptosis in different experimental systems and is able to decrease K_{ATP} channel activity in β -cells. The aim of the present study was to investigate whether E2 stimulates β -cell apoptosis and whether this effect is mediated via SUR1.

Material and Methods: Cells from the β -cell lines HIT-T15 or RIN-m5F as well as HEK293 cells expressing different forms of SUR or sham-transfected HEK cells (ctr) were treated with E2, estrone (E1), which differs from E2 in lacking one hydroxyl group, or etoposide, a classical inducer of SUR-independent apoptosis. In further experiments, cells were additionally supplemented with the phorbol ester TPA, an activator of protein kinase C. For determination of apoptotic parameters, cell detachment and viability were measured using a CASY Analyser, changes in nuclear morphology were assessed after Hoechst 33258 staining and caspase 3-like activity was quantified by cleavage of fluorescent DEVD-substrate.

Results: E2 treatment (100 μ M, 24 h) resulted in massive cell detachment and intensive nuclear condensation and fragmentation in HIT-T15-cells, RIN-m5F-cells or SUR1-expressing HEK cells, while HEK cells expressing SUR2A (cardiac isoform) or SUR2B (vascular isoform) as well as control-cells were much less affected. Differences between SUR1-cells and control-cells were already observed with lower E2 concentrations after longer treatment intervals (e.g. >1 μ M, 4 days). In the presence of E2 (100 μ M, 24 h), the number of apoptotic nuclei in SUR1-cells was about 3-fold higher compared to SUR2A-, SUR2B- or control-cells (SUR1 vs. SUR2A/SUR2B/ctr: $p < 0.001$; SUR2A/SUR2B vs. ctr: $p > 0.05$). E2-induced cell detachment and nuclear alterations were associated with a significant increase in caspase 3-like activity. The apoptotic potency of E2 was significantly higher than that of glibenclamide, resveratrol or etoposide. E1 induced apoptosis to a much smaller extent than E2. SUR1-specific apoptosis of E2-treated cells was abolished at the mutant SUR1(M1289T), in which a single amino acid in transmembrane helix 17 (TM17) was exchanged by the corresponding amino acid of SUR2B (SUR1(M1289T) vs. SUR1: $p < 0.001$; SUR1(M1289T) vs. SUR2A/SUR2B/ctr: $p > 0.05$). Co-treatment with TPA (100 ng/ml, 24 h) decreased E2-induced apoptosis in SUR1-cells about 1.5-fold (SUR1+E2 vs. SUR1+E2+TPA: $p < 0.01$). This effect of TPA was not observed in respective etoposide-treated cells.

Conclusions: Treatment with E2 specifically induces apoptosis in SUR1-expressing cells (recombinant cells or clonal β -cells). Our results indicate that TM17 of SUR1 is important for E2-induced apoptosis and that protein kinase C may be involved in the respective signalling pathway. As E2 levels are elevated during pregnancy, E2-stimulated apoptosis in pancreatic β -cells might provide an interesting aspect concerning the etiology of gestational diabetes.

Endogenous IRS-2 expression and activation are responsible for β cell survival during glucocorticoid excess

D. Avram¹, F. Ranta¹, S. Hopp¹, A. M. Hennige¹, F. Lang², H.-U. Häring¹, S. Ullrich¹;

¹Internal Medicine IV, University of Tübingen, Germany,

²Institute of Physiology, University of Tübingen, Germany.

Background and Aims: IRS-2 is the main insulin receptor substrate responsible for cell differentiation and survival in insulin secreting cells. Previously we showed that stimulation of insulin secreting INS-1 cells with IGF-1 protects against glucocorticoid-induced cell death. IGF-1 increases IRS-2 tyrosine phosphorylation, an effect antagonized by the glucocorticoid dexamethasone (dex). The reduced IRS-2 phosphorylation is accompanied by reduced PKB phosphorylation and increased apoptosis. Surprisingly, IGF-1 protected against dex-induced cell death even in the presence of PI3 kinase inhibitors. The present study examined the underlying mechanism of protection against glucocorticoid toxicity.

Materials and Methods: INS-1 cells were treated with dex (100 nM) and IGF-1 (50 ng/ml) under standard culture conditions. Apoptosis was quantified by DAPI and TUNEL staining. Proteins and protein phosphorylations were quantified by Western blotting, cellular mRNA concentrations by real time RT-PCR.

Results: During 4 d treatment with dex, IGF-1 inhibited cell death by 75 % after 1 d and by 58 % after 4 d. In parallel, IGF-1 stimulated PKB phosphorylation in control as well as in dex-treated cells. In contrast, ERK phosphorylation induced by IGF-1 was inhibited by dex. When cells were simultaneously incubated with LY294002 (10 μ M), an inhibitor of PI3 kinase, IGF-1 induced phosphorylation of PKB was efficiently abolished while dex-mediated inhibition of ERK phosphorylation was counteracted. LY294002 treatment of the cells increased IRS-2 mRNA 2-fold in the absence and presence of IGF-1 and dex. IRS-2 protein was also increased in LY294002-treated cells. The IGF-1 stimulated tyrosine phosphorylation of IRS-2 was detectable on Western blots only in cells treated with LY294002. When cell death was examined the MAP kinase inhibitor PD98059 (10 μ M) indeed counteracted the protective effect of IGF-1 against dex-induced cell death.

Conclusion: These data suggest that MAP kinase dependent protection against dex-induced cell death depends on sufficient amount of IRS-2 and its stimulation.

0424

Comparison of Quercetin and EGCG (epigallocatechin gallate) for the protection of hydrogen peroxide induced oxidative damage in INS-1 cell line

M. K. Kim¹, H. Chung², C. Yoon², M. Kwon², S. Lee², J. Park²;

¹Division of Endocrinology and Metabolism, Department of Internal Medicine, Maryknoll General Hospital, Busan,

²Division of Endocrinology and Metabolism, Department of Internal Medicine, Pusan Paik Hospital, Paik Memorial Institute for Clinical Research, Inje University, Busan, Republic of Korea.

Background and Aims: Chronic oxidative stress is not only involved in the pathogenesis of diabetic complications, but also play very important role in the development and the progression of type 2 diabetes mellitus via the deleterious effects on the pancreatic β -cells. Insulin resistance and the relative pancreatic β -cell dysfunction are the two main pathophysiologies of type 2 diabetes mellitus. The insulin resistance could be regarded as the prerequisite, while the β -cell dysfunction might be the key pathophysiology that determines the onset and the progression of type 2 diabetes mellitus. Effective protection of pancreatic β -cells from the oxidative stress induced damage in pre-diabetics and type 2 diabetic patients could enable to stop or even reverse the progression of worsening metabolic derangement. Quercetin and EGCG are natural anti-oxidants contained in the plants. Quercetin is very plentiful in grape, and EGCG is the main ingredient of green tea, with proven strong anti-oxidant properties. We wanted to confirm whether these 2 natural substances could protect the oxidative stress induced damage to INS-1 cell line, and verify the detailed mechanisms of protection.

Materials and Methods: We cultured INS-1 cell line in RPMI medium. Hydrogen peroxide was used as an oxidative stressor. Quercetin or EGCG were added to the culture medium. Various kinds of experimental designs

including the time sequences and the concentrations of each substance were employed to verify the possible differences between these 2 substances. The viabilities of the cells were verified by MTT assay. The activity of glutathione peroxidase was assessed by total glutathione quantification kit. Western blot and semi-quantitative RT-PCR for the catalase and SOD (superoxide dismutase) were performed. The phosphorylation status of IRS2 and PI3K was verified also by Western blot and RT-PCR. To confirm the relative contributions of each protecting pathway, we performed knock out experiment using siRNAs. Functional status of INS-1 cell line was tested by GSIS (glucose stimulated insulin secretion).

Results: Both quercetin and EGCG effectively protected hydrogen peroxide induced damage in INS-1 cells verified by MTT assay. The protection by EGCG required pre-incubation of INS-1 cells for at least 24 hours prior to the addition of hydrogen peroxide into the medium, while the protection exerted by quercetin did not. The expression and the activity of SOD and the glutathione peroxidase were significantly increased in quercetin group. The degrees of phosphorylation of IRS2 and PI3K were significantly enhanced in EGCG group. GSIS was well preserved in both groups.

Conclusion: In conclusion, both quercetin and EGCG effectively protected INS-1 cells from the oxidative stress induced by hydrogen peroxide. Quercetin exerted its effect mainly via the activation of anti-oxidant defense, while EGCG via anti-apoptotic pathway rather than anti-oxidant defense system. Further studies will be necessary for the more detailed action mechanisms and the possible clinical implications.

Differential use of calcium stores in reactive oxygen species-dependent pancreatic beta cell death

D. Watson¹, E. Kinsey¹, S. Hazelwood¹, J. Scarpello², A. Loweth¹;

¹School of Life Sciences, Keele University, ²Dept of Diabetes & Endocrinology, University Hospital of North Staffs, United Kingdom.

Background and Aims: Beta cells' susceptibility to oxidant stress contributes to chronic glucose toxicity and beta cell loss in diabetes mellitus. We are currently investigating the mechanism(s) of this oxidant-induced cytotoxicity, particularly how reactive oxidant species (ROS) modulate calcium movements, since intracellular calcium increases promote cell death. The aim of this study was therefore to investigate the functional role of oxidant-induced mitochondrial calcium uptake and intracellular calcium movements in response to both hydrogen peroxide (H₂O₂) and superoxide, the latter generated by the hypoxanthine/xanthine oxidase (HX/XO) system, in the rat pancreatic beta cell line, RINm5F.

Materials and Methods: Cell viability measurements, in response to 40 μM H₂O₂ or 4 mM/0.2 mU HX/XO for 1 hour, were performed using the MTT-formazan reduction assay (results expressed as mean absorbance ± SEM) and counting of detached, dead cell populations by Trypan blue staining and haemocytometry (results expressed as mean cells/ml × 10³ ± SEM).

Results: The dependency of oxidant-induced cell death on intracellular calcium was investigated using the intracellular calcium chelator BAPTA-AM, which completely attenuated cell death in response to both ROS (dead cell numbers: control 1.20 ± 0.2, H₂O₂* 4.30 ± 0.6, H₂O₂ + BAPTA[#] 1.05 ± 0.1, HXXO* 5.30 ± 0.4, HXXO + BAPTA[#] 1.30 ± 0.2; p < 0.001 vs. * control or [#]treatment alone). Blockade of mitochondrial calcium uptake by the mitochondrial calcium uniporter inhibitor, ruthenium red (RR) attenuated H₂O₂'s effect by 34% (MTT results: control 0.862 ± 0.02, RR 0.801 ± 0.02, H₂O₂* 0.096 ± 0.01, H₂O₂+RR[#] 0.354 ± 0.03; p < 0.001 *vs. controls; [#]vs. controls and H₂O₂), suggesting that mitochondrial calcium uptake is a necessary step in H₂O₂-induced cell death. By contrast, superoxide's cytotoxicity was found not to be dependent on mitochondrial calcium uptake and, indeed, inhibition of uptake with RR exaggerated the effect of superoxide (MTT: control 0.996 ± 0.06, RR 0.909 ± 0.03, HXXO* 0.698 ± 0.04, HXXO+RR[#] 0.464 ± 0.02; p < 0.001 *vs. controls; [#]vs. controls and HXXO). We then investigated the effect of extracellular calcium influx on superoxide's effect using the extracellular calcium chelator, EDTA and the L-type calcium channel blocker, nifedipine. Both agents completely attenuated superoxide's effect although no effect was seen on H₂O₂-induced cell death (dead cell numbers: control 1.95 ± 0.2, EDTA 1.30 ± 0.2, nifedipine 2.10 ± 0.1, HXXO* 5.30 ± 0.2, HXXO + EDTA[#] 1.60 ± 0.3, HXXO + nifedipine[#] 1.40 ± 0.05, H₂O₂* 4.10 ± 0.3, H₂O₂ + EDTA 4.40 ± 0.1, H₂O₂ + nifedipine 4.00 ± 0.2, p < 0.001 vs. *controls, [#]HXXO alone).

Conclusion: Our results show that an increase in intracellular calcium levels is necessary for superoxide- and H₂O₂-induced RINm5F cell death, although each species appears to have differential effects on calcium fluxes within the cell, since only H₂O₂-induced cell death was dependent on mitochondrial calcium uptake and superoxide depended only on extracellular calcium influx. It is tempting to speculate that H₂O₂ facilitates store-operated calcium release, generating 'hot-spot' calcium regions allowing uptake through the low affinity mitochondrial uniporter, whereas superoxide participates predominately in calcium influx from the extracellular medium, limiting the potential for mitochondrial uptake.

Oxidative stress is memorized by INS-1E beta cells resulting in mitochondrial dysfunction and impaired glucose stimulated insulin secretion

N. Li, P. Maechler;

Department of Cell Physiology and Metabolism, University of Geneva, Switzerland.

Background and Aims: Mitochondria of pancreatic beta-cells serve as fuel sensors to integrate and generate metabolic signals, thereby coupling glucose recognition to insulin secretion. It has been proposed that mitochondrial defects, such as mutations caused by reactive oxygen species (ROS), might be associated with beta-cell failure in the course of diabetes. We have previously shown (J. Biol. Chem. 1999, 274:27905-27913) that a transient exposure of pancreatic beta-cells to oxidative stress interrupts the transduction of signals normally coupling glucose metabolism to insulin secretion. The aim of this study was to test the hypothesis if such a transient oxidative stress in insulin secreting cells could cause long-term impairment of mitochondrial function that normally couples glucose metabolism to insulin secretion.

Materials and Methods: Using INS-1E beta-cells, we studied the long-term impact of a single transient oxidative stress of 10 min exposure to 200 μM H₂O₂ applied 3 days before analyses. After this recovery period, we tested key parameters involved in metabolism secretion coupling in beta-cells, such as mitochondrial membrane potential (determined by rhodamine-123 fluorescence), cytosolic ATP production (monitored through luciferase bioluminescence), oxygen consumption (performed on isolated mitochondria in an oxymeter), and glucose-stimulated insulin secretion (analysed by radioimmunoassay). In addition, western blot and real-time RT-PCR analyses were performed to detect possible underlying molecular mechanisms.

Results: Three days after one single transient oxidative stress, INS-1E beta-cells exhibited markedly reduced mitochondrial function and responses to glucose. Compared to non-stressed INS-1E beta-cells, we observed impaired mitochondrial membrane potential (-55% upon glucose stimulation), reduced cytosolic ATP production (-59% upon glucose stimulation), decreased oxygen consumption levels (-15% in response to succinate and -60% in response to the combination of succinate and ADP, P < 0.01 in both cases), and blunted glucose-stimulated insulin secretion (-51%, P < 0.01). These parameters correlated with down-regulation of subunits complex I (-28%) and complex IV (-23%) of the respiratory chain and a decrease in expression of genes responsible for mitochondrial biogenesis, such as TFAM (-74%) and PGC-1α (-84%).

Conclusion: INS-1E beta-cells could memorize one single transient oxidative stress as revealed by dysfunction of mitochondrial metabolism and glucose-stimulated insulin secretion. The mechanisms underlying these long-term effects could be due to the alterations of enzyme subunits of the respiratory chain at the protein level, although not primarily at the mRNA level.

Involvement of glucokinase in glucose toxicity in insulin-producing beta cells

H. Schmitt, S. Lenzen, S. Baltrusch;

Institut of Clinical Biochemistry, Hannover Medical School, Germany.

Background and Aims: Metabolic stimulus-secretion coupling in pancreatic beta cells is dependent upon the glucose phosphorylating enzyme glucokinase

(GK). Activation of GK is endogenously provoked by interaction with the bifunctional enzyme 6-phosphofructo-2-kinase/fructose-2,6-bisphosphatase (PFK2) and can be effectively achieved also by a new class of chemical compounds. GK activation as well as GK overexpression resulted in an increase in glucose-induced insulin secretion. Controversially, it was shown that GK overexpression causes a breakdown of glucose metabolism accompanied by glucose toxicity. The aim of this study was to elucidate whether GK mediates glucose toxicity in insulin-producing cells.

Materials and Methods: The recently developed RheoSwitch® Mammalian Inducible Expression System, based on a synthetic inducer, exhibits in contrast to other available systems no cross talk with endogenous transcription factors. This system was adapted to generate stable insulin-producing RINm5F and MIN6 cells. Positive clones with precise regulation of GK or an EYFP-GK fusion construct were selected through resistance against G418 and verified by reporter gene assays. Cells were cultured at different glucose concentrations, GK enzyme activity was measured by a photometric assay, cell viability by MTT assay, mitochondrial membrane potential using JC1 and insulin secretion by a radioimmunoassay.

Results: Insulin-producing RINm5F cells with inducible GK or EYFP-GK overexpression were cultured for 48 h without or in the presence of 0, 0.5, 62.5, 125, 250 and 500 nmol/l of the inductor RSL 1 in medium supplemented with 1, 10 or 30 mmol/l glucose. Independent from the glucose concentration RINm5F-R-GK as well as RINm5F-R-EYFP-GK cells showed an increase in GK activity following the rising inductor concentration. Comparable results were also obtained for MIN6-R-EYFP-GK cells. Furthermore the 3 and 5 fold increase of GK enzyme activity in RINm5F-R-GK and RINm5F-R-EYFP-GK cells after maximal induction correlates with the increase in GK protein determined by Western blot and fluorescence microscopy, respectively. The viability of RINm5F-R-GK and RINm5F-R-EYFP-GK cells after incubation at 1, 10 or 30 mmol/l glucose was not impaired by switching on GK expression through treatment with the inductor RSL 1. Independently from the GK expression a non significant decrease in cell viability after 48 h exposure to high glucose (30 mmol/l) was slightly obvious. RINm5F-R-GK and RINm5F-R-EYFP-GK cells showed after maximal induction of GK expression an increase in insulin secretion by 80%. Interestingly, insulin secretion decreased in the absence of GK expression in RINm5F-R-GK and RINm5F-R-EYFP-GK cells after 48 h exposure to high glucose (30 mmol/l) but not in the presence of GK. To further analyze the intermediary metabolism the mitochondrial membrane potential was measured in RINm5F-R-GK cells using JC1. Thereby a higher mitochondrial membrane potential was observed in the presence of GK after 48 h exposure to high glucose (30 mmol/l).

Conclusion: Our experiments based on a precisely regulated GK expression in insulin-producing cells do not support the hypothesis of GK as a precursor of cellular glucose toxicity. In contrast a beneficial effect on glucose-induced insulin secretion after GK expression was observed. Thus, toxic effects of chronically high glucose are likely not to be mediated by the metabolism of glucose.

Effects of controlled c-MYC activation on mouse pancreatic β cell survival and function

S. M. A. Pascal¹, S. Pelengaris², M. Khan², J.-C. Jonas¹;

¹Endocrinology and Metabolism, University of Louvain, Brussels, Belgium,

²Department of Biological Sciences, University of Warwick, United Kingdom.

Background and Aims: Increased expression of the transcription factor c-MYC may contribute to the alterations of β -cell differentiation, survival and function induced by high glucose concentrations. In support of this hypothesis, c-MYC overexpression in β -cells induces apoptosis more than proliferation and decreases preproinsulin gene expression, thereby reducing glucose-induced insulin secretion. In this study, we compared the effects of c-MYC activation and high glucose concentrations on key glucose stimulus-secretion coupling events in mouse pancreatic islets.

Materials and Methods: pIns-c-MycER^{TAM} mice express, under the control of the insulin promoter, c-MYC fused to the hormone binding domain of 4-OH-tamoxifen (TAM)-responsive mutant estrogen receptor. Islets were isolated from heterozygous pIns-c-MycER^{TAM/+} (Myc⁺) mice and their wild-type littermates (WT) (mixed C57BL/6J x CBA background). They were then cultured for 1wk in RPMI medium containing 5 g/l BSA and 10–30 mmol/l glucose (G10–G30), with eventual addition of 100 nmol/l TAM or DMSO 1/1000 for the last 2–3 days. After culture, glucose-induced changes in mitochondrial membrane potential (rhodamine 123 fluorescence), cytosolic Ca²⁺ concentration ([Ca²⁺]_c) (Fura-PE3 spectrofluorimetry) and insulin secretion (RIA) were measured in perfused islets. Islet caspase activation was measured using FAM-VAD-fluoromethylketone. Results are means \pm SEM for at least 7 islets from 3 experiments. Statistical significance of differences between groups was assessed by unpaired Student's t-test or 2-way ANOVA and a test of Bonferroni.

Results: After culture in G10, acute stimulation of WT islets with increasing glucose concentrations (from 0.5 to 7, 15 and 30 mmol/l) led to a stepwise decrease in rhodamine 123 fluorescence (mitochondrial membrane hyperpolarisation) and a concentration-dependent rise in [Ca²⁺]_c and insulin secretion. These glucose effects were unaffected by TAM treatment for 3 days. Compared with WT islets, the glucose-induced changes in mitochondrial membrane potential, [Ca²⁺]_c and insulin secretion were qualitatively similar in Myc⁺ islets cultured in G10, but the maximal rate of glucose-stimulated insulin secretion was severely reduced (1.0 \pm 0.3 vs 6.9 \pm 1.5 pg/min per ng of islet DNA in WT, $P < 0.01$). These islets also displayed a \sim 1.6 fold increase in caspase activation ($P < 0.05$) and a \sim 60% reduction in insulin/DNA content ratio (1.1 \pm 0.3 vs 2.7 \pm 0.3 ng insulin/ng DNA in WT, $P < 0.01$). TAM treatment of Myc⁺ islets for 2–3 days further increased caspase activation \sim 3.5 fold ($P < 0.001$), reduced their insulin/DNA content ratio by \sim 55% ($P = 0.06$), reduced rhodamine 123 loading, increased resting [Ca²⁺]_c by 44 \pm 7 nmol/l ($P < 0.001$), and reduced the maximal glucose-induced rise in [Ca²⁺]_c (by \sim 40%) and in insulin secretion. Similar [Ca²⁺]_c alterations were observed after overnight culture in the presence of 50 μ mol/l H₂O₂. In contrast, in both Myc⁺ and WT islets, 1wk culture in G30 instead of G10 induced a small increase in islet resting [Ca²⁺]_c and a shift to the left of the glucose-response curve for changes in mitochondrial membrane potential, [Ca²⁺]_c and insulin secretion without changes in maximal glucose effectiveness.

Conclusion: c-MYC activation triggers β -cell apoptosis and alterations of glucose stimulus-secretion coupling events that are better mimicked by H₂O₂ than high glucose concentrations.

Regulation of calcineurin (phosphatase 2B) activity and its role in apoptotic cell death in insulin secreting INS-1 cells

F. Ranta¹, D. Avram¹, F. Lang², H.-U. Häring¹, S. Ullrich¹;

¹Internal Medicine IV,

²Institute of Physiology, University of Tübingen, Germany.

Background and Aim: Calcineurin (PP2B), a Ca²⁺/calmodulin-dependent serine and threonine phosphatase, regulates cellular functions as well as cell

growth and survival. In insulin secreting cells PP2B has been found to increase apoptotic cell death by dephosphorylation of BAD, a pro-apoptotic protein. Previously we described that dexamethasone (dex)-induced apoptosis is partially inhibited by calcineurin inhibitors FK506 and deltamethrin in insulin secreting INS-1 cells. The aim of the present study was to examine whether glucocorticoid treatment activates PP2B. Possible mechanisms of activation are the cleavage of PP2B by calpain that renders the enzyme activity independent of Ca^{2+} or stimulation of PP2B by HSP90 released from the activated glucocorticoid receptor.

Materials and Methods: INS-1 cells were treated with dex (100 nM) for 1 d in standard culture conditions. Apoptosis was quantified by DAPI staining and TUNEL assay. Calcineurin activity was measured in cell homogenates either using pNPP (para-nitrophenylphosphate) or ^{32}P -RII peptide as substrates. Calcineurin and HSP90 were quantified by Western blotting. Protein-protein interactions were examined by co-immunoprecipitation.

Results: FK506- and cyclosporine A-sensitive phosphatase activity was increased in cells treated with dex when measured with pNPP as substrate. Using RII peptide as substrate PP2B activity was significantly higher in homogenates of dex-treated cells at low, submaximal Ca^{2+} concentrations but not at high, 10 μM Ca^{2+} when the enzyme was maximally activated. In control and in dex-treated cells the uncleaved 59 kDa protein but not a calpain-cleaved smaller protein band of 48 kDa was detected by Western blotting. The calpain inhibitor ALLN (1 and 10 μM) did not protect against dex-induced apoptosis. Therefore, we examined whether the release of HSP90 from the stimulated GR might interfere with PP2B and stimulate the enzyme. In immunoprecipitates of INS-1 cell homogenates with calcineurin antibodies, calcineurin and HSP90 were detected indicating an interaction of these proteins.

Conclusion: These data suggest that dex-induced apoptosis in INS-1 cells may involve PP2B activation by HSP90 released from the stimulated GR complex.

The time course and mechanism of hypoxia-induced islet dysfunction

K. Tomotsune¹, Y. Ogawa¹, M. Naraoka¹, T. Kudo¹, N. Hasegawa², Y. Tando¹, J. Matsui¹, N. Tamasawa¹, T. Suda¹;

¹Department of Endocrinology, Metabolism and Infectious Disease, Hirosaki University, ²Department of Internal Medicine, Itayanagi Central Hospital, Aomori, Japan.

Background and Aims: In this study, we aimed to reveal the time course of deterioration of insulin (INS) secretion from the islets cultured in hypoxia (1% O_2), and whether this dysfunction was reversible or not. Furthermore, we investigated if this dysfunction was related with mitochondrial (M) activity or Beta-cell death.

Materials and Methods: The pancreatic islets isolated from SD rats were cultured in 1% O_2 for 0, 6, 12, 24, and 48 hours (h). Then, glucose stimulated INS secretion (GSIS) was examined by either static or perfusion method. As to static GSIS, islets were incubated with 50 mg/dl and 300 mg/dl glucose (glu50 and glu300) for 30 minutes (min) respectively. Then INS secretion ratio (ISR) calculated as the ratio of INS concentration in glu300 to glu50 was compared. As to perfusion, the experiments started with 10 min of perfusion with glu50, followed by 15 min perfusion with glu300, and finally 10 min with glu50, and the area under the curve (AUC) of 1st-phase GSIS and 2nd-phase GSIS was compared. Furthermore, the islets incubated in 1% O_2 for 6h, 12h and 24 h were cultured in normoxia for another 24h to test the reversibility by re-oxygenation and AUC was assessed. To reveal the mechanism of islet dysfunction, we tried to evaluate M activity and islet cell death. M activity of the islets exposed to 1% O_2 was assessed by the alamarBlue assay. The islet cell death was assessed by apoptosis enrichment factor (ApEF) and necrosis enrichment factor (NcEF) determined by sandwich-enzyme immunoassay using antibody binding to DNA and histones.

Results: In static method, ISR significantly declined after 24h in 1% O_2 (0h: 3.11 \pm 3.20, 6h: 1.89 \pm 0.96, 12h: 1.82 \pm 1.20, 24h: 0.94 \pm 0.45, 48h: 0.94 \pm 0.32). In perfusion method, AUC of 1st-phase GSIS significantly declined after 6h 1% O_2 (0h: 12.67 \pm 4.07, 6h: 8.97 \pm 2.02, 12h: 6.28 \pm 1.47, 24h: 5.73 \pm 0.61, 48h: 3.96 \pm 0.55), and AUC of 2nd-phase GSIS significantly declined after 12h 1% O_2 (0h: 23.47 \pm 7.83, 6h: 17.84 \pm 9.73, 12h: 11.60 \pm 3.02, 24h: 10.77 \pm 2.15, 48h: 7.67 \pm 1.74). In the re-oxygenation study, the following normoxia made deteriorated GSIS worse in 6h and 12h (1st-phase, 6h: 4.93 \pm 0.91, 12h: 4.14 \pm 0.33, 24h: 5.06 \pm 0.69 / 2nd-phase, 6h: 10.17 \pm 2.50, 12h: 8.64 \pm 1.07, 24h:

10.50 \pm 1.80). In the alamarBlue assay, alamarBlue absorbance significantly declined after 48h 1% O_2 (0h: 95.52 \pm 12.33, 6h: 99.71 \pm 11.26, 12h: 84.58 \pm 12.52, 24h: 82.78 \pm 7.81, 48h: 74.06 \pm 10.86). In the assay of cell death, there was no significant difference between normoxia (ApEF, 6h: 4.89 \pm 1.95, 12h: 5.84 \pm 2.40, 24h: 6.85 \pm 1.08, 48h: 5.28 \pm 0.56 / NcEF, 6h: 3.75 \pm 1.10, 12h: 5.75 \pm 2.03, 24h: 11.21 \pm 0.57, 48h: 11.24 \pm 0.65) and 1% O_2 (ApEF, 6h: 4.74 \pm 2.17, 12h: 6.72 \pm 3.11, 24h: 8.83 \pm 4.45, 48h: 5.38 \pm 1.37 / NcEF, 6h: 3.90 \pm 1.94, 12h: 5.92 \pm 1.64, 24h: 11.56 \pm 2.91, 48h: 11.24 \pm 0.65). Nevertheless, in the assessment of time course, NcEF but not ApEF was significantly increased after 24h cultured in either normoxia or 1% O_2 .

Conclusion: In this study, the impairment of INS secretion was seen after 6h exposure to 1% O_2 . The declined INS secretion after 24h 1% O_2 seen in static study could be explained by the loss of islet cells due to their necrosis, on the other hand, the diminution of 1st-phase INS exocytosis after 6h culture in hypoxia seen in perfusion study might be caused due to endothelial mechanism from M activity or islet cell death, because they did not decline at 6h.

Mitochondrial uncoupling protein UCP2 influences type 1 diabetes development

Y. Emre¹, C. Hurtaud¹, M. Karaca², T. Nubel¹, F. Zavala³, D. Ricquier¹;

¹Faculte de Medecine Paris 5 – Necker, CNRS UPR 9078, Paris,

²Universite Paris 7, CNRS UMR 7059, Paris,

³Universite Paris 5, Institut Necker, CNRS UMR 8147, Paris, France.

Background and Aims: Uncoupling protein UCP2 is a mitochondrial protein that controls mitochondrial production of reactive oxygen species (ROS). Besides the cells of the immune system, pancreatic beta-cells also exhibit a strong UCP2 expression. In beta-cells, UCP2 is reported to function as a regulator of insulin secretion. In macrophages, UCP2 controls MAPK activation by modulation of mitochondrial ROS. Lipopolysaccharide (LPS)-stimulated Ucp2-KO macrophages exhibit quicker and stronger p38 and ERK activation compared to Ucp2-WT macrophages. Therefore, Ucp2-KO macrophages have increased nitric oxide (NO) and cytokine productions. In this work, we investigated whether UCP2 is implicated in type 1 diabetes.

Materials and Methods: Ucp2-KO and Ucp2-WT male mice were injected with multiple low dose streptozotocin (MLDS). MLDS is an immunemediated murine diabetes model in which hyperglycemia and diabetes are achieved after five daily injections of subdiabetogenic doses of STZ.

Results: Occurrence of diabetes was accelerated in Ucp2-KO mice. Analysis of macrophages from MLDS-treated mice showed that Ucp2-KO macrophages had increased NO and IL-1 β productions compared to Ucp2-WT macrophages. In the same time, mononuclear infiltration of islets was stronger in Ucp2-KO mice. Interestingly, comparison of Ucp2+/+ and Ucp2-/- islets with the same minor degree of lymphocyte infiltration showed an increased number of macrophages in Ucp2-KO islets and was associated with increased NO damage inside Ucp2-/- islets.

Conclusion: We provide relevant data of the implication of UCP2 in MLDS-induced diabetes. It is suggested that increased activity of Ucp2-KO immune system, in terms of cytokine and NO production, leads to an increased inflammation and accelerates the occurrence of type 1 diabetes in Ucp2-KO mice.

Vitamin E homologs improve bioenergetics of porcine islets and INS-1 cells under anoxia

G. Oz¹, G. M. Wildey², S. Kendir³, K. K. Papas²;

¹Department of Radiology, ²Department of Surgery,

³College of Education, Department of Curriculum and Instruction, University of Minnesota, Minneapolis, United States.

Background and Aims: Pancreatic islet transplantation is a highly promising treatment for restoring normoglycemia in a subpopulation of patients with Type1 diabetes. However, islet death induced by hypoxia is a major factor limiting viable islet yield and engraftment and ultimately the success rate of transplantations. We have recently observed that vitamin E homologs (α - and γ -tocopherol) offer substantial protection from anoxia (the most severe

form of hypoxia) induced islet death. The aim of this study was to address the metabolic consequences of islet exposure to anoxia in the presence and absence of vitamin E homologs using ^{31}P and ^{13}C NMR spectroscopy. We utilized highly purified porcine islets that are a promising alternative to human islets that are in short supply, as well as INS-1 cells as a potentially faithful model for β cell metabolism.

Materials and Methods: Porcine islets (30,000 islet equivalents per condition) and INS-1 cells were incubated in RPMI media supplemented with 11 mM [1, 6- $^{13}\text{C}_2$] glucose for 6 hours under 3 conditions: 1. Normoxia (95% Air, 5% CO_2); 2. Anoxia (95% N_2 , 5% CO_2); and 3. Anoxia supplemented with α - and γ -tocopherol (50 μM each). At the end of the incubation cultures were extracted with perchloric acid using standard methods. Extracted metabolites were lyophilized and resuspended in D_2O that contained reference compounds for ^{13}C and ^{31}P NMR. ^{31}P and proton decoupled ^{13}C NMR spectra were acquired using a 500 MHz vertical bore magnet.

Results: ^{13}C label incorporation from glucose into glutamate, which is in exchange with the TCA cycle intermediate α -ketoglutarate, was highly reduced under anoxia due to inhibition of oxidative metabolism in both islets and INS-1 cells. ^{13}C label incorporation into lactate, on the other hand, was increased indicating increased anaerobic glycolysis under anoxia. Although β cells are known to have only low levels of lactate dehydrogenase, these data indicate that the Pasteur effect is operational in porcine islets and INS-1 cells. In addition, under anoxia in the presence of tocopherols, the [3- ^{13}C]lactate-to-[4- ^{13}C]glutamate ratio was closer to the normoxic condition than in their absence for both islet and INS-1 cultures. Similarly, islets and INS-1 cells displayed an improved bioenergetic status in the presence than in the absence of tocopherols by both increased total nucleotide levels and ATP-to-ADP ratios as measured by ^{31}P NMR.

Conclusions: Together with our prior data regarding protection of islets from anoxia induced death by tocopherols, these preliminary data indicate that islets and INS-1 cells are capable of producing enough energy to survive a short (6 h) anoxic insult when supplemented with vitamin E homologs. The antioxidant supplementation likely prevents anoxia induced damage to islets possibly by directly or indirectly modulating the anaerobic and oxidative metabolic rates and preserving ATP levels. The findings implicate vitamin E homologs as promising candidates for islet protection from short and possibly longer exposures to oxygen deprivation.

Calcium elevations in MIN6 cells evoked by cytotoxic concentrations of human IAPP involve activation of the mechanosensitive ion channel *Trpv4*

F. M. Gribble¹, S. Casas^{2,3}, R. Gomis³, F. Reimann¹, A. Novials²;

¹Cambridge Institute for Medical Research and Department of Clinical Biochemistry, University of Cambridge, United Kingdom,

²Sarda Farriol Foundation, Institute of Diabetes, Barcelona, Spain,

³Endocrinology, IDIBAPS, Hospital Clínic, University of Barcelona, Spain.

Background and Aims: Islet amyloid polypeptide (IAPP) is the main component of amyloid deposits found in the islets of most type 2 diabetics. As islet amyloid colocalizes with areas of cell degeneration, the process of amyloidosis has been associated with the progressive loss of β -cell mass. Amyloid peptides elevate intracellular calcium levels ($[\text{Ca}^{2+}]_i$) in neurones, which may play a role in cell apoptosis. The aim of this study was to investigate the effect of human IAPP (hIAPP) on $[\text{Ca}^{2+}]_i$, morphology and apoptosis of pancreatic β -cells.

Materials and Methods: hIAPP aggregation was evaluated by examining the hIAPP peptide conformational state in culture media using transmission electron microscopy (TEM) or by the fluorescence of thioflavine T at 482 nm. $[\text{Ca}^{2+}]_i$ was monitored for 2 h as the 340/380 nm fluorescence ratio in fura-2 loaded MIN6-cells. Cell morphology was evaluated by TEM. Cell viability was assessed by FACS using propidium iodide. Expression of *Trpv4* and *Actb* was analyzed by RT-PCR. Down-expression of *Trpv4* was induced by siRNA for mouse *Trpv4*, using amylase siRNA as a control.

Results: TEM showed spontaneous aggregation of 10 μM hIAPP. Prefibrillar hIAPP structures were first observed after 10 min, with maximum formation by 30–45 min. Fibrils were detected from 30–45 min. Thioflavine T binding confirmed hIAPP fibril formation over time. hIAPP (10 μM) induced an rise in $[\text{Ca}^{2+}]_i$ in 70/328 MIN6-cells, compared with 0/87 in control solution

and 0/128 with 10 μM rat IAPP. Nifedipine (5 μM , NF) added at the start prevented any increase in $[\text{Ca}^{2+}]_i$ (0/198), but its addition after $[\text{Ca}^{2+}]_i$ changes were established only reversed the $[\text{Ca}^{2+}]_i$ rise in 6/16 cells. In Na^+ -free buffer hIAPP increased $[\text{Ca}^{2+}]_i$ in 7/85 cells, but NF could no longer prevent the $[\text{Ca}^{2+}]_i$ rise (13/154 cells, $p < 0.01$). This suggested the involvement of other Ca^{2+} -channels, and we hypothesised that mechanosensitive trp channels might play a role. Trp channel inhibitors, gadolinium (100 μM) or ruthenium red (10 μM , RR), abolished the $[\text{Ca}^{2+}]_i$ rise even in the absence of Na^+ . EM revealed extracellular insoluble hIAPP in close contact with cells. In these regions, the plasma membrane was irregular with deep invaginations at 24 h even with RR. hIAPP reduced cell viability to 63% ($p < 0.05$), and this was partially reversed by inclusion of RR (79% vs 63%, $p < 0.05$). The mechanosensitive trp channel *Trpv4* was found to be expressed in MIN6-cells and mouse pancreas. siRNA against *Trpv4* or amylase reduced the basal cell viability to 91%, but viability was further reduced to 60% by hIAPP in the control group. Cells treated with *Trpv4* siRNA exhibited improved viability in the presence of hIAPP (77%: $p < 0.05$ vs control).

Conclusion: Alterations in $[\text{Ca}^{2+}]_i$ play a role in β -cell cytotoxicity induced by hIAPP aggregation. Both L-type calcium channels and Trp channels play a role in the $[\text{Ca}^{2+}]_i$ rise. The mechanosensitive channel *Trpv4* may sense membrane distortion induced by hIAPP aggregation, enabling Ca^{2+} entry, membrane depolarization and further activation of voltage gated Ca^{2+} channels. Pharmacological inhibition or decreased expression of *Trpv4* prevented hIAPP-induced $[\text{Ca}^{2+}]_i$ changes and protected against its toxic effect on cell viability.

Presence of -132(G/A) mutation in the IAPP promoter gene increase synthesis and secretory granule content of IAPP in pancreatic MIN6-cells

S. Casas^{1,2}, R. Gomis¹, A. Clark³, A. Novials²;

¹Laboratory of Experimental Diabetes, IDIBAPS, Barcelona, Spain,

²Institute of Diabetes, Sardà Farriol Foundation, Barcelona, Spain,

³Oxford Centre for Diabetes, Churchill Hospital, Oxford, United Kingdom.

Background and Aims: Islet amyloid polypeptide (IAPP) is the component peptide of islet amyloid deposits in type 2 diabetic subjects. Increased human IAPP (hIAPP) production could play a role in islet dysfunction in type 2 diabetes. The -132 G/A mutation located within an activator domain of the hIAPP gene promoter was first identified in a cohort of Spanish type 2 diabetic patients. Higher fasting IAPP plasma concentrations were associated with the mutation in diabetic subjects suggesting that this mutation resulted in increased IAPP production. The aims of this study were to determine if pancreatic beta-cells expressing hIAPP under the mutant gene promoter had higher levels of hIAPP production and were less viable compared to those expressing wild type gene promoter.

Methods: Human IAPP cDNA (which includes the full coding sequence for proIAPP) was cloned into a pIRES-EGFP vector. The CMV promoter was replaced by either the wildtype or mutant hIAPP promoter. The plasmid constructs were transfected into MIN6-cells using liposomal lipid reagent. MIN6-cells treated with transfection reagent without DNA were included as control. Transfected cells were cultured for 96 h in 5.5 or 22.7 mM glucose. Transfection efficiency was determined from percentage EGFP-positive cells using FACS. Morphology and hIAPP granule content was evaluated by quantitative morphometry and transmission electron microscopy using immunogold labeling with anti-human N-terminal-pro-IAPP antibody. Cell viability was assessed by FACS using propidium iodide staining. Expression of hIAPP mRNA was quantified by real-time RT-PCR.

Results: Efficiency of transfection with both wildtype or mutant construct was 85±5%. Transfected cells (containing liposomes) showed normal ultrastructural cell morphology. When cultured at 22.7 mM glucose, MIN6-cells expressing hIAPP under mutant compared to wildtype gene promoter had increased gold particles/secretory granule (0.33±0.03 vs. 0.68±0.07 particles/pm² vesicle, $p < 0.001$). No differences were found at 5.5 mM glucose. Increased expression levels of hIAPP mRNA were detected in MIN6-cells carrying mutant compared to wildtype construct. Those differences were higher in cells cultured at 22.7 mM glucose (1.33±0.41 vs. 2.56±0.33 arbitrary units) than at 5.5 mM glucose (1.01±0.23 vs. 1.72±0.45 arbitrary units). No

changes in cell viability were observed in MIN6-cells transfected with mutant compared to wildtype construct at 5.5 or 22.7 mM glucose.

Conclusions: The presence of the -132 (G/A) mutation of the hIAPP promoter induces hyperexpression of hIAPP in pancreatic beta-cells which is increased by glucose but not increased cell death. Increased hIAPP production in patients with the promoter polymorphisms could contribute to amyloidogenesis in type 2 diabetes.

Fasting plasma glucose and haemoglobin A_{1c} predict baboon pancreatic islet amyloidosis: a novel non-human primate model for type 2 diabetes mellitus (t2dm)

R. Guardado-Mendoza¹, A. Davalli², A. O. Chavez¹, E. Bazzigaluppi², C. Belloni², A. G. Comuzzie³, R. Bastarrachea³, A. Monroy¹, E. Bosi², G. Halff³, D. Tripathy¹, E. J. Dick Jr.⁵, G. Hubbard⁵, R. A. DeFronzo¹, F. Folli¹; ¹Diabetes Division, University of Texas Health Science Center, San Antonio, United States, ²Department of Medicine, Istituto Scientifico San Raffaele, Milano, Italy, ³Department of Genetic, Southwest Foundation for Biomedical Research, San Antonio, United States, ⁴Department of Surgery, University of Texas Health Science Center, San Antonio, United States, ⁵Department of Pathology, Southwest Foundation for Biomedical Research, San Antonio, United States.

Background and Aims: T2DM is characterized for insulin resistance (IR) and progressive beta cell dysfunction. Intra-islet accumulation of islet amyloid polypeptide deposits play a major role in the pathogenesis of beta cell dysfunction and death. Baboons share a high degree of genetic (98%) and physiological similarity with humans. Therefore, we hypothesized that pancreatic islet amyloidosis (PIA) would be a major determinant of diabetes in baboons.

Materials and Methods: We analyzed histopathological, clinical and chemistry data in a colony of baboons who were followed over a 12 years period. PIA was diagnosed at necropsy by histological examination, and age/gender/weight matched baboons without PIA were used as controls. Student t test and chi square test were used to compare variables, ROC analysis to evaluate the usefulness of fasting plasma glucose (FPG) and hemoglobin A_{1c} (HbA_{1c}) to predict the presence of PIA. Pearson correlation coefficient was calculated between variables of interest. P values were considered significant when <0.05.

Results: 78 baboons were studied, 30 (24F/6M) with and 48 (33F/15M) without PIA. There were no significant differences in age (22.3±0.6 vs 21.7±0.5, *p* 0.45), gender (M/F ratio 0.25 vs 0.45, *p* 0.205) and weight (26.3±1.2 vs 26.3±1.1kg, *p* 0.97). On the other hand, FPG (158 ± 17mg/dl vs 88 ± 3mg/dl, *p* <0.0001), HbA_{1c} (9.6 ± 2.0% vs 4.5 ± 0.4%, *p* 0.01), frequency of glycosuria (42.8% vs 0%, *p* <0.0001), proteinuria (47.6 vs 16.6%, *p* 0.019) and infectious diseases (43.3 vs 20.8%, *p* 0.032) were significantly higher in baboons with PIA. The extent of PIA was evaluated semiquantitatively by two blinded experienced pathologists using a scale from 0 to 5, where 0 = no amyloid deposits and 5= amyloid involving 100% of the islets. The extent of PIA strongly correlated with FPG (*r* = 0.649, *p* <0.005). Finally, ROC analysis showed that the AUC for FPG to predict the pancreatic amyloidosis was 0.824 (CI 95% 0.718 – 0.931, *p* <0.001), and for FPG levels of 100, 120, and 140mg/dl the sensitivity was 66, 56, and 40%, and the specificity was 85.4, 91.7 and 97.9%, respectively. For HbA_{1c}, the AUC was 0.833 (CI 95% 0.564–1.102, *p* <0.03) and HbA_{1c} levels of 5, 6 and 7% had a sensitivity of 83, 75 and 66% and specificity of 44, 89 and 100%, respectively.

Conclusion: FPG and HbA_{1c} concentrations were strongly associated with the presence of IAPP pancreatic deposits in baboons. Of note, the levels of FPG and HbA_{1c} that predict, with very high specificity, the presence of PIA in this model are within the range of the early metabolic abnormalities associated with T2DM in humans. Furthermore, the extent of PIA was directly correlated with FPG and HbA_{1c}. These data support the concept that the baboon is a novel and pertinent non-human primate model for the study of beta cell dysfunction/apoptosis and therapeutic interventions in T2DM.

PS 24 The role of cytokines and chemokines on pancreatic islet physiology and pathology

IL-1ra increases size and function of islets of Langerhans in vivo

A. Wojtuszczyk, M. Armanet, P. Morel, D. Bosco, T. Berney; Surgery, Geneva University Hospitals, Cell Isolation and Transplantation Center, Switzerland.

Background and Aims: IL-1β is a potent inhibitor of beta-cell function. A receptor antagonist of IL-1 (IL-1ra) has been shown to reverse this effect in vitro. We aimed to demonstrate whether IL-1ra has a beneficial effect on islets in vivo using IL-1ra KO and IL-1ra-overexpressing transgenic (hIL1raTg) mice.

Materials and Methods: Intraperitoneal glucose tolerance test (IPGTT) assay was performed on hIL1raTg, IL1-ra-KO and wild type (DBA1 strain) mice. Islets from these mice were isolated. The mean number of total islets (IT) and islet equivalent (IEQ) was evaluated. Insulin secretion was assessed on isolated islets by static incubation (SI) and on single beta-cells by reverse hemolytic plaque assay (RHPA). Static incubation was performed in absence or presence of cytokines (TNFα 1000UI/ml, IFNγ 1000UI/ml and IL1β 250 UI/ml).

Results: When analysed by IPGTT, hIL1raTg mice presented better response to glucose, with an area under the curve (AUC) significantly lower compared to WT and KO mice (75 ± 91 vs 516 ± 186 and 541 ± 246 mM.min, respectively). The glycemic peak arose earlier and was also lower (4.8 ± 0.7 vs 7.4 ± 2.4 and 9.0 ± 2.4 mM) in hIL1raTg compared to WT and KO mice. After islet isolation, IT, IEQ per pancreas and the mean size of islets was lower in KO mice compared to hIL1raTg and WT mice. Insulin secretion in response to glucose, assessed by SI and RHPA, was lower and more affected by cytokines in IL1-ra KO mice compared to other mice.

Conclusion: IL1-ra improves insulin secretion in vivo and plays a role in preserving islets against deleterious effect of cytokines. IL-1ra has an impact on pancreatic islet mass, suggesting that IL-1ra may be involved in the development and/or regeneration of islets.

Induction of chemokine CXCL1 by extracellular matrix and enhancement by IL-1 in rat pancreatic β cells

P. Ribaux¹, J. A. Ehses², E. B. Hammar¹, J.-C. Irminger¹, M. Donath², P. A. Halban¹;

¹Department of Genetic Medicine and Development, University Medical Center, Geneva, Switzerland, ²Division of Endocrinology and Diabetes, University Hospital of Zürich, Switzerland.

Background and Aims: As we showed previously, the extracellular matrix (ECM) secreted by rat bladder carcinoma cells (804G-ECM) has positive effects on rat primary β-cell function and survival *in vitro*. The aim of this study was to define β-cell genes induced by this ECM with a specific focus on cytokines.

Materials and Methods: Rat primary β-cells were sorted by FACS and cultured in Petri dishes coated with poly-L-lysine (pLL) or 804G-ECM. Analysis of differential gene expression by oligonucleotide microarrays and RT-PCR was performed to identify cytokine mRNA induced by the 804G-ECM. The concentration of cytokines in the conditioned media was quantified by Luminex technology. Data are expressed as mean ± SE for *n* = 3 independent experiments.

Results: Five cytokines were overexpressed by β-cells plated for 4 hours on 804G-ECM compared to pLL: CXCL1, CXCL2, IP10, IL-1α and IL-1β. A time-course experiment indicated that maximal induction by 804G-ECM occurred at 4 hours for CXCL1 (68.3-fold stimulation vs pLL), CXCL2 (14.5-fold) and IP10 (6.7-fold) mRNA. IL-1α and β were expressed at low levels in cells on ECM with no expression detectable on pLL. Stimulation of CXCL1 release by β-cells on 804G-ECM was confirmed at the protein level. Indeed, the concentration of CXCL1 secreted by 600 000 cells/ml after 24 hours of culture was 776 ± 155 pg/ml (vs 35.4 ± 5.6 pg/ml on pLL, *p* <0.001). The absence of macrophages, a major source of cytokines, in the β-cell population

was confirmed by immunofluorescence. Preventing the interaction of $\beta 1$ integrins and laminin-5 (a predominant component of 804G-ECM) with specific antibodies resulted in a 40–50% inhibition ($p < 0.05$) of CXCL1 mRNA expression after 6 hours of culture. NF- κ B activation was shown to be indispensable, since the use of the NF- κ B pathway inhibitor Bay 11-7082 (5 μ M) abolished the increased CXCL1 expression and secretion after 10 hours of culture on 804G-ECM. IL-1 (α and/or β) secreted by cells plated on 804G-ECM was found to be a key soluble mediator, since treatment of cells with 1 μ g/ml of the IL-1 receptor antagonist (IL-1Ra) significantly reduced both CXCL1 gene expression (by 67.8 \pm 5.9 %, $p < 0.001$) and secretion (by 65.4 \pm 6.3 %, $p < 0.001$) after 6 hours of culture.

Conclusion: In the present study, we show that sorted rat primary β -cells express cytokines CXCL1, CXCL2, IP10, IL-1 α and IL-1 β in response to ECM under conditions previously shown to improve function and survival. This effect of ECM is partly due to interaction between laminin-5 and $\beta 1$ integrins. Moreover, the production of CXCL1 is an NF- κ B dependent event with amplification by IL-1 acting via a positive autocrine and/or paracrine feedback loop.

Lack of macrophage migration inhibitory factor (MIF) confers resistance to immunoinflammatory diabetes in mice

I. Stojanovic¹, S. Lazaroski¹, F. Nicoletti², S. Stosic-Grujicic¹;
¹Department of Immunology, Institute for Biological Research, Belgrade, Serbia, ²Department of Biomedical Sciences, University of Catania, Italy.

Background and Aims: Macrophage migration inhibitory factor (MIF) is implicated in the pathogenesis of several inflammatory/autoimmune disorders, including type 1 diabetes. Using a model of immunoinflammatory diabetes induced in susceptible mouse strains by multiple low doses of streptozotocin (MLD-STZ) we have recently shown that *in vivo* abrogation of MIF activity with pharmacological MIF inhibitor (S,R)-3-(4-hydroxyphenyl)-4,5-dihydro-5-isoxasole acetic acid methyl ester, or with neutralizing anti-MIF antibodies, markedly reduced clinical and histopathological features of diabetes. Furthermore, MIF-deficient (MIF-KO) mice were also less susceptible to the MLD-STZ-induced hyperglycemia, insulinitis and apoptosis within the endocrine pancreas than genetically matched wild type (WT) C57BL/6 mice. In all three *in vivo* approaches tested, negating the action of endogenous MIF has induced an immune deviation towards protective type 2/3 response. The aim of this study was to further analyze the role of endogenous MIF in the pathogenesis of diabetes at the level of target tissue (pancreatic islets).

Material and Methods: Pancreatic islets from WT and MIF-KO mice were isolated by collagenase digestion method. β cells were obtained after pancreatic islets digestion with trypsin. Both islets and β cells were cultured 24 to 96 h in the presence or absence of combination of pro-inflammatory cytokines (IL-1+TNF- α +IFN- γ – 10 ng/ml each), or STZ (2 μ g/ml). Evidence of apoptosis induction was indirectly obtained by determination of mitochondrial activity (MTT test). The concentration of phosphorylated form of I- κ B (p-I- κ B) was measured by Western blot. IL-1 β expression was determined by reverse transcription-PCR, while its secretion was measured by ELISA.

Results: MIF-KO β cells or pancreatic islets were more resistant to killing by cytokines (IL-1+TNF- α +IFN- γ) or STZ than WT counterparts. Furthermore, while cytokine-stimulated WT pancreatic islets showed significant NF- κ B activation (judged by p-I- κ B), MIF-KO islets had lower activity of NF- κ B. Finally, in STZ-stimulated MIF-KO islets both IL-1 β mRNA expression and secretion were significantly down-regulated in comparison to the elevation seen in STZ-stimulated WT islets.

Conclusion: Our findings clearly show that the absence of MIF confers β cell protection from the lethal insult of different agents, namely cytokines and STZ. This protection is probably mediated by suppression of NF- κ B and subsequent expression and secretion of IL-1 β , a well-known mediator of β cell death. According to both *in vivo* and *in vitro* observations, it can be hypothesized that MIF inhibition could be beneficial in diabetes treatment. Effects of anti-inflammatory cytokines on insulin-producing cells

E. Gurgul-Convey, K. L. A. Souza, M. Elsner, S. Lenzen;
 Institute of Clinical Biochemistry, Hannover Medical School, Germany.

Background and Aims: The role of pro-inflammatory cytokines, especially IL-1 β , in pancreatic beta cell death is well established. Little is known, however, about the relevance and influence of the so-called anti-inflammatory cytokines IL-4, IL-13 and IL-10 on beta cell survival and death pathways. The aim of this study was to clarify the effects of anti-inflammatory cytokines on pro-inflammatory cytokine-induced beta cell death and to investigate the mechanisms underlying these effects.

Materials and Methods: Insulin-producing RINm5F cells were incubated with pro-inflammatory cytokines (IL-1 β , TNF α and IFN γ) and/or anti-inflammatory cytokines (IL-4, IL-13 and IL-10). Thereafter cell viability (MTT assay), transcription factor NF κ B activation (SEAP-reporter gene assay), caspase-3 activity and inducible nitric oxide synthase (iNOS) expression (Real-Time PCR and Western Blot) were measured.

Results: It was found that the expression levels of anti-inflammatory cytokine receptors (IL-4R α , IL-13R, IL-10R) in insulin-producing cells were 200-fold lower than in the liver. Interestingly, pro-inflammatory cytokines, especially IL-1 β , elevated expression of these receptors (6 h incubation: 2.5-fold IL-4R α , 2-fold IL-13R, 2.2-fold IL-10R induction vs. untreated). Anti-inflammatory cytokines were not toxic to insulin-producing cells (72 h incubation, 60 ng/ml, viability > 98%). Co-incubations of pro- with anti-inflammatory cytokines had a protective effect on beta cell viability (72 h incubation, 60 U/ml IL-1 β 70 % \pm 2 vs. 80 % in cells treated with IL-1 β and anti-inflammatory cytokines; Cytokine Mix 45 % \pm 4 vs. 53 % cells treated with IL-1 β and anti-inflammatory cytokines; n = 4 in triplicates). Incubation with 60 U/ml IL-1 β activated caspase-3 over 5-fold vs. untreated cells. This induction was diminished by all anti-inflammatory cytokines (4-fold reduction). Anti-inflammatory cytokines almost completely prevented an increase of caspase-3 activity induced by a mixture of cytokines (8 h Cytokine Mix 422 % \pm 25, Mix + IL-4 121 % \pm 12, Mix + IL-13 189 % \pm 19, Mix + IL-10 165 % \pm 17; n = 4 in triplicates). All tested anti-inflammatory cytokines significantly diminished IL-1 β -induced activity of NF κ B, a transcription factor that plays a crucial role in the cytokine-induced beta cell death (6 h incubation, IL-1 β 1.8-fold increase \pm 0.2, IL-1 β + IL-4 1.2 \pm 0.1, IL-1 β + IL-13 1.4 \pm 0.1, IL-1 β + IL-10 1.4 \pm 0.1; n = 6 in duplicates). Anti-inflammatory cytokines decreased also IL-1 β -stimulated iNOS gene expression (6 h incubation: 60 U/ml IL-1 β 800-fold \pm 109, IL-1 β + IL-4 61 \pm 7, IL-1 β + IL-13 65 \pm 20, IL-1 β + IL-10 133 \pm 40). Similar effects, although weaker, were observed on the iNOS protein level; anti-inflammatory cytokines tended to prevent a strong iNOS protein expression induced by IL-1 β (ca. 30 % reduction vs. IL-1 β).

Conclusion: Anti-inflammatory cytokines in insulin-producing cells 1. exert a protective effect against pro-inflammatory cytokine-induced toxicity (protection against cell death, decrease of iNOS expression, reduction of caspase-3 activity), and 2. counteract the stimulatory effects of pro-inflammatory cytokines on the NF κ B signal transduction pathway. Interestingly, our results also show a very low expression level of anti-inflammatory cytokine receptors in insulin-producing cells, which can be however increased by pro-inflammatory cytokines thereby enabling protection against cell death.

Peroxiredoxin III prevents stress induced apoptosis in rat insulinoma cells RINm5F

G. Wolf, N. Aumann, M. Michalska, R. Walther;
 Department of Medical Biochemistry and Molecular Biology,
 University of Greifswald, Germany.

Background and Aims: Type 1 diabetes mellitus is characterised by a progressive autoimmune destruction of insulin-producing beta cells in the pancreas. Cytokines induce the synthesis of reactive oxygen and nitrogen species in macrophages and in their target cells. These insulin-producing beta cells are very sensitive to this attack due to their low content of antioxidant enzymes like superoxid dismutase or catalase. In particular the resulting mitochondrial damage gives an important signal to promote beta cell death. For this reason, there is considerable interest in peroxiredoxin III (Prx III, Mer5, SP-22, and AOP-1) and its function in pancreatic islets. Prx

III is localised in mitochondria and belongs to a family of highly conserved thioredoxin-dependent peroxide reductases. The aim of our studies was to elucidate whether the Prx III-thioredoxin-system can contribute to prevent beta cell destruction.

Materials and Methods: Using immunohistochemistry, Northern and Western blot analyses, we determined the expression of Prx III in mouse pancreas and in the rat insulinoma cell line RINm5F. To further examine the role of this antioxidant enzyme in beta cell protection, we established stably transfected RINm5F cells, which can be induced by doxycyclin to overexpress or downregulate Prx III. These cells were treated with TNF- α , IL-1 β , streptozotocin as well as alloxan and caspase activities were measured. After treatment with H₂O₂, we estimated the production of reactive oxygen species (ROS) by flow cytometry using the oxidation-sensitive fluorescent probe 5,6-carboxy-2',7'-dichlorofluorescein-diacetate (DCFH-DA). Activation of iNOS and cleavage of PARP were detected by Western blots.

Results: The detection of Prx III in the pancreas revealed that this enzyme is expressed in the insulin producing β -cells. Our results demonstrate that after treatment with H₂O₂, the accumulation of ROS was reduced in Prx III-overexpressed cells and increased in Prx III-depleted cells. RINm5F cells can be protected against stress-induced apoptosis by enhanced amounts of mitochondrial Prx III. However increased apoptosis as revealed by measurement of caspase-3 and 9-activities, activation of iNOS and cleavage of PARP after treatment with different stressors has been observed if this enzyme is down-regulated.

Conclusion: The results demonstrate that the activation of the mitochondrial Prx III-thioredoxin-system may contribute to protect beta cells against oxidative stress and apoptosis occurring by autoimmune attack during pathogenesis of Type I diabetes.

Do peroxiredoxins reduce the vulnerability of insulin-secreting cells to cytokines?

P. Romanus¹, T. Bouckennooghe¹, B. Vandewalle², C. Remacle¹, B. Knoops¹, B. Reusens¹;

¹Institut of Life Sciences, Université Catholique de Louvain, Louvain-la-Neuve, Belgium,

²U859, Faculté de Médecine Henri Warembourg, Lille, France.

Background and Aims: The autoimmune destruction of the insulin-producing β -cells in Type 1 Diabetes (T1D) is mediated in part by cytokines (IL-1 β , IFN- γ , TNF- α) which are cytotoxic to β -cells via the production of peroxynitrite (ONOO⁻). Both rodent and human islets are highly sensitive to ONOO⁻ because of their low antioxidant enzymes expression. For this reason, there is a considerable interest in a newly discovered peroxidase family composed of six members, the peroxiredoxins (1–6). Moreover, the human Prdx5 which possesses a ONOO⁻ reductase activity and a mitochondrial localisation could play a major protective role against this toxic nitrooxidant. Our goal was to investigate the regulation of the Prdx1, 2, 3, 5 and their cytoprotective function in β -cells exposed to cytokines.

Materials and Methods: Female rat islets, INS-1E and three human islets preparations were exposed during 8h, 24h and 48h to cytokines in usual dosage for rat or human (IL-1 β , IFN- γ , TNF- α). Expression of Prdx1,2,3,5, MnSOD and iNOS were investigated by Western blot analysis and by real-time RT-PCR. To further examine the role of Prdx5, we established transitory transfected INS-1E cells to induce overexpression of Prdx5, which was verified by Western blotting and immunohistochemistry. The viability of INS-1E cells treated by cytokines was determined by a MTT assay.

Results: In rat islets treated by cytokines, the Prdx5 mRNA expression was 10 times overexpressed ($p < 0.01$) after 24h treatment while mRNA levels of the Prdx1,2 and 3 were not modified. Such treated islets featured an increase in MnSOD and iNOS overexpression at the mRNA and protein level with a peak point at 8h. Surprisingly, Prdx5 which was overexpressed at the mRNA level after 24h treatment was the only Prdx significantly underexpressed by 80% ($p < 0.05$) at the protein level. In transfected INS-1E cells, an enhanced amount of mitochondrial Prdx5 reduced the cytotoxicity by 20% ($p < 0.05$), after 24h cytokines incubation. As for MnSOD and iNOS mRNA, in human islets preparation, Prdx5 but not the Prdx3, was overexpressed after 24h cytokines treatment. The protein level of Prdx5 in human islets did not seem to be modified during the time course study contrary to MnSOD which was overexpressed.

Conclusion: Prdx5 overexpression conferred a protection against cytokines to the INS-1E cells. Surprisingly, in rat islets our data established for Prdx5 only, an obvious discrepancy between mRNA level which was markedly increased and protein level that was reduced. Interestingly, this discrepancy was also observed in human islets. Further investigations are therefore necessary to identify an hypothetical post-transcriptional mechanism or to find more evidence for proteasome involvement. Consequently, we propose that modulation of Prdx5 expression by cytokines would be in part implicated in the susceptibility of islets to ONOO⁻-induced β -cells death.

0442

The influence of antioxidative enzyme overexpression on the expression of Bcl-2 members and their modulation through proinflammatory cytokines

I. Mehmeti, S. Lortz, S. Lenzen;

Institute of Clinical Biochemistry, Hannover Medical School, Germany.

Background and Aims: Type 1 diabetes is an autoimmune disease characterized by the selective destruction of pancreatic β -cells. Proinflammatory cytokines are mediators of β -cell death in autoimmune diabetes mainly by the induction of signalling pathways leading finally to apoptosis. Proteins of the Bcl-2 family are important for the regulation of the intrinsic pathway of apoptosis. This family of highly conserved molecules consists of anti-apoptotic (e.g. Bcl-2, Bcl-X_L) and pro-apoptotic proteins (e.g. Bax, Bad, Bim, Bid) and acts primarily on mitochondria. This is mediated by the regulation of mitochondrial homeostasis, integrity and stability. Reactive oxygen species (ROS) generated during cytokine-mediated β -cell destruction are involved as additional mediators of programmed cell death in this intrinsic pathway. Therefore the aim of the present study was to quantify the expression of Bcl-2 family members in insulin-producing cells and to characterize the influence of antioxidative enzymes on the expression of Bcl-2 family members before and after cytokine stimulation.

Materials and Methods: RINm5F control cells and RINm5F cells overexpressing the antioxidative enzymes glutathione peroxidase (GPx), catalase (Cat), mitochondrially located catalase (MitoCat) and Cu/Zn superoxide dismutase (Cu/ZnSOD) were exposed to IL-1 β or a cytokine mix (IL-1 β , TNF- α and IFN- γ) for 24 h. The expression levels of the investigated Bcl-2-related proteins were assessed by RT-PCR and Western blotting.

Results: The expression of the anti-apoptotic proteins Bcl-2 and Bcl-X_L as well as the pro-apoptotic proteins Bax, Bad, Bim and Bid could be detected and quantified in all RINm5F cell clones. Bax showed the highest expression of all investigated Bcl-2 proteins and its expression was around 8-fold higher compared with Bcl-2. These findings could be confirmed in INS-1E cells. Cytokine exposure caused a significant reduction of Bcl-2 expression in control cells. This cytokine-mediated decrease of Bcl-2 expression was also observed in Cu/ZnSOD and Cat transfected cells. In contrast to these findings, GPx and MitoCat cells showed no significant changes of the Bcl-2 expression after cytokine treatment. Bax expression was decreased in all investigated cell clones after cytokine stimulation, except for Cu/ZnSOD and MitoCat cells. Both clones exhibited a significant increase of the Bax expression level after exposure to cytokines. Because of the lower basal Bax expression in unstimulated MitoCat cells compared with controls cells, this cytokine-related increased Bax expression was still lower. The cytokine stimulation of control cells and cells overexpressing cytoprotective enzymes led to a significant increase of Bcl-X_L, Bim and Bid expression. However, Bad mRNA expression and the level of phosphorylated Bad were reduced in all investigated cell clones in the presence of cytokines.

Conclusion: Overexpression of the mitochondrially located H₂O₂-detoxifying enzymes GPx and MitoCat induced an increased expression of anti-apoptotic Bcl-2 and decreased expression of pro-apoptotic Bax after cytokine treatment. This observed shift of the Bcl-2/Bax balance in favour of the anti-apoptotic Bcl-2 can contribute to the observed higher resistance of these insulin-producing cells overexpressing hydrogen peroxide inactivating enzymes against cytokine mediated toxicity and indicates the involvement of mitochondria within the apoptotic process.

0443

Moderate over expression of UCP-2 in beta cells reduces ROS formation and protects against H₂O₂-but not cytokine-induced toxicity and aggravates toxicity due to NO

H. Ogata¹, E. Petersen², I. Jørgensen¹, F. Skorpen², Z. Ma³, A. Björklund³, K. W. Egeberg¹, V. Grill¹;

¹Norwegian University of Science and Technology, Institute of Cancer Research and Molecular Medicine, Trondheim, Norway, ²Norwegian University of Science and Technology, Institute of Laboratory Medicine, Children's and Women's Health, Levanger, Norway, ³Department of Molecular Medicine and Surgery, Karolinska Institute, Stockholm, Sweden.

Background and Aims: Uncoupling protein 2 (UCP-2) exerts diabetogenic influence by decreasing efficiency of glucose metabolism to generate ATP and/or other signaling molecules for insulin secretion. A beneficial role coupled to protection against radical oxygen formation (ROS) may also be operative but is poorly documented.

Materials and Methods: We transfected INS-1 cells to obtain a tet-on UCP-2 inducible cell line. For 48h induction by 0.1 or 1.0 µg/ml doxycyclin (dox) increased UCP-2 protein by respectively 178±29 and 424±113 %. Flow cytometry (FC) and 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) were used to test for functions and viability.

Results: UCP-2 induction by 1.0 µg/ml dox lowered mitochondrial membrane potential (MMP) modestly (5.1+/-2.9%, FC, rhodamine 123, n=4, p<0.02) without affecting mitochondrial mass (FC, MitoTracker Green) and reduced basal ROS production (-26.6% of control fluorescence by 2',7'-dichlorofluorescein diacetate (DCF), n=18, p=0.025). Exposure overnight to a combination of cytokines (TNFα, IL-1β, IFN-γ 10 ng/ml each) increased DCF 2.3 fold (p<0.002). This effect was partially abrogated by UCP-2 induction (p<0.02). The NO donor S-nitroso-N-acetyl penicillamine (SNAP) failed to reproduce the cytokine effect on ROS. In viability testing by MTT, UCP-2 induction protected against toxicity induced by 200 µM H₂O₂ (p<0.01). However, UCP-2 induction did not prevent the decrease of MTT seen after 24 or 48 h exposure to cytokines, whereas induction significantly aggravated (p<0.05) the decrease in MTT seen after SNAP.

Conclusion: Moderate over expression of UCP-2 in beta cells reduces ROS formation and protects against H₂O₂ - but not cytokine-induced toxicity and aggravates toxicity due to NO. Hence UCP-2 is protective only during selected conditions.

PS 25 Immunoregulation and novel interventions in diabetes due to beta cell loss

Prevention of diabetes manifestation by treatment with the immunomodulator FTY720 in the IDDM rat, an animal model of human type 1 diabetes

A. Jörns¹, A. Meyer zu Vilsendorf², T. Taivankhuu³, S. Lenzen³;

¹Institute of Clinical Biochemistry & Center of Anatomy,

²Visceral- and Transplantation Surgery,

³Institute of Clinical Biochemistry, Hannover Medical School, Germany.

Background and Aims: The IDDM (LEW.1AR1-*iddm*) rat is an animal model of type 1 diabetes mellitus with a normal immune system. The aim of the treatment with FTY720 was to prevent in the IDDM rat either the clinical manifestation of diabetes or after onset of the disease to protect the remaining pancreatic beta cells from the autoimmune attack. FTY720 affects by interaction with the sphingosin-1-receptor the resting of all B- und T-lymphocytes in the organ draining lymph nodes and leads to a reduction of the number of lymphocytes in the peripheral blood.

Materials and Methods: For the purpose of primary or secondary prevention the animals were treated with FTY720 (1mg/kg body weight) over 40 days. Gene (*in situ* und *real time* RT-PCR) and proteinexpression (immunohistochemistry and bead-based Multiplex-Assay) of Th1- und Th2-cytokines, of the chemokine MCP-1 and the enzyme iNOS were performed in pancreatic biopsies and the pancreas-draining lymph nodes at the time point of diabetes manifestation, at the end of therapy, and 30 days after the end of treatment.

Results: Primary prevention with FTY720 led to a complete prevention of diabetes manifestation at day 60 in the spontaneously diabetic IDDM rats and also 30 days after the end of the treatment the animals remained normoglycaemic. At the time point of diabetes manifestation the pancreatic islets of the FTY720 treated animals showed no signs of beta cell apoptosis and of immune cell infiltration in contrast to a high rate of beta cell apoptosis accompanied by an immune cell infiltration of T-lymphocytes and macrophages in the spontaneously diabetic IDDM rats. Additionally, in the treated animals, there was no cytokine expression in the pancreatic parenchyma (IL-1β, IFN-γ, TNF-α, IL-4, IL-10). Interestingly, 60 % of the treated animals showed signs of immune cell activation, as documented by an increase of the gene expression of Th1-cytokines and the beta cell apoptosis mediating enzyme iNOS in pancreas-draining lymph nodes as well as an enlarged Th1-cytokine protein expression in the peripheral blood. In the time course after the end of treatment only the pancreases of the animals with signs of immune cell activation showed in 5 % of the pancreatic islets a macrophage dominated immune cell infiltrate which was restricted to the islet periphery. These infiltrated islets expressed the chemokine MCP-1 in the beta cells. In contrast to the results in the primary prevention study, therapy with FTY720 after the clinical manifestation of disease had no preventive effect.

Conclusion: Primary prevention therapy before diabetes manifestation by the immunomodulator FTY720 prevented the disease. Even after the end of the therapy only a few islets showed minor signs of macrophage infiltration, but no lymphocyte infiltration and no loss of beta cell mass.

High-dose pravastatin prevents autoimmune diabetes in non-obese diabetic mice

S. Zhang, Z. Zhou, Y. Sun, P. Zhou, G. Huang, J. Peng, S. Sun, Y. Zhang; Diabetes Center, Institute of Metabolism and Endocrinology, Diabetes Center, Institute of Metabolism and Endocrinology, the Second Xiangya Hospital, Changsha, China.

Background and Aims Statins are inhibitors of 3-Hydroxy-3-methylglutaryl-CoA reductase and widely used as lipid-lowering agents, recently have been reported to possess favorable immunomodulatory properties. Therefore, we hypothesized that type 1 diabetes, which is thought to be a T cell-mediated, organ-specific autoimmune diseases, might benefit from statin treatment.

Methods Female nonobese diabetic (NOD) mice were fed an approximate daily dose of 1mg, 10 mg and 40mg·kg⁻¹·day⁻¹ of pravastatin food admixture starting from 3–4 weeks of age, and the diabetes incidence were monitored up to 30 weeks. And the insulinitis and apoptosis of islets β cell were determined at the age of 12 weeks. Moreover, the secretion and mRNA expression of cytokine IFN- γ , IL-4 and IL-10 in vitro were measured. Furthermore, population of CD4⁺CD25⁺ regulatory T cells were observed.

Results We report in this study that although all doses of pravastatin appeared to decrease the incidence of diabetes at week 30, only the high-dose pravastatin can prevent or delay the development of diabetes ($p < 0.01$, log-rank test). A significant suppression of severe insulinitis was observed in NOD mice treated with high-dose pravastatin ($P < 0.05$). Moreover, the group of mice treated with pravastatin at high but not medium or low doses displayed a significant lower level of IFN- γ but significantly higher level of IL-4 comparing to the untreated group ($P < 0.05$). At transcript level, the high-dose pravastatin treatment significantly increased both IL-4 and IL-10 mRNA while decreasing IFN- γ mRNA ($P < 0.05$). And decreased the apoptosis of islets β cell in mice treated with high-dose pravastatin ($p < 0.01$). However, no significant changes in population of CD4⁺CD25⁺ regulatory T cells were observed.

Conclusion In conclusion, we demonstrated that development of autoimmune diabetes in NOD mice can be arrested by treatment with high-dose pravastatin at the early stage of disease, which is able to induce a Th2 immune response and decrease the apoptosis of islets β cells. These findings suggest that high-dose statins treatment at early time may benefit the prevention of autoimmune diabetes.

Activation of adenosine receptors protects against type 1 diabetes

J. G. Mabley¹, Z. H. Nemeth², D. Bleich², B. Csoka², P. Pacher³, S. Vizi⁴, E. A. Deitch², C. Szabo², B. N. Cronstein⁵, G. Hasko^{2,4};

¹School of Pharmacy and Biomolecular Sciences, University of Brighton, United Kingdom, ²Department of Surgery, University of Medicine and Dentistry of New Jersey, Newark, United States, ³Laboratory of Physiological Studies, NIH, Bethesda, United States, ⁴Hungarian Academy of Sciences, Institute of Experimental Medicine, Budapest, Hungary, ⁵Division of Clinical Pharmacology, New York University School of Medicine, United States.

Background and Aims: There is evidence that adenosine receptors are promising targets in autoimmune disease. Adenosine is a potent endogenous autocrine anti-inflammatory and immunosuppressive molecule which binds to specific adenosine receptors of which there are 4 types; A1, A2a, A2b, and A3. Activation of adenosine receptors decreases the release of pro-inflammatory mediators including cytokines and nitric oxide. The aim of this study was to determine whether adenosine receptor agonists could protect against Type 1 diabetes and the receptor subtype involved.

Materials and Methods: The non-selective adenosine receptor agonist 5'-N-ethylcarboxamidoadenosine (NECA), 0.01 or 0.03 mg/kg/day, was used in these studies. Diabetes was induced in male CD-1 mice using multiple-low-dose-streptozotocin (MLDS) administration (40 mg/kg i.p. on 5 consecutive days). Treatment with vehicle, NECA or the other adenosine receptor agonists commenced on day 1 with blood glucose measured periodically over a 21 day period, with diabetes defined as blood glucose > 200 mg/dL. On day 21 pancreas levels of insulin, chemokines and cytokines were measured using specific ELISA kits. Cyclophosphamide (200 mg/kg) was injected into 8 week old female NOD mice treated with vehicle or NECA; blood glucose levels and diabetes incidence were monitored over the following 21 days, pancreas biopsies taken on day 21 were used for histological analysis.

Results: NECA treatment significantly reduced MLDS-induced hyperglycemia on day 21 from 405 ± 22 to 180 ± 26 mg/dL ($P < 0.05$), as well as diabetes incidence from 100% in the vehicle treated to 30% ($p < 0.05$). NECA treatment attenuated the MLDS-mediated loss of pancreas insulin content (35 ± 2 vs. 72 ± 10 ng/mg protein; $p < 0.05$) as well as reducing pancreatic levels of inflammatory chemokines (MIP-1 from 2.87 ± 0.91 pg/mg protein to 0.5 ± 0.02 ; $p < 0.05$) and cytokines (TNF from 1.5 ± 0.6 pg/mg protein to 0.05 ± 0.02 ; IL-12 from 20 ± 7 to 5 ± 0.1 ; IFN from 0.4 ± 0.1 to 0.09 ± 0.02 ; $p < 0.05$). To determine which receptor subtype was involved we treated mice with the specific A1 receptor agonist CCPA (0.1 mg/kg), A2a receptor agonist CGS21680 (0.1 mg/kg) and A3 receptor agonist IB-MECA (0.1 mg/kg); all

of which proved less effective than NECA at attenuating MLDS-induced hyperglycemia and diabetes incidence. Since no selective A2b receptor agonist was available we used the non-selective agonist NECA with the selective A2b receptor antagonist MRS 1754. MRS 1754 (0.5 mg/kg) administered 30 min prior to the NECA (0.03 mg/kg/day) prevented the protective effect of NECA on MLDS-induced hyperglycemia and diabetes incidence. NECA (0.01 mg/kg/day) also reduced hyperglycemia (320 ± 60 vs. 150 ± 20 mg/dL; $p < 0.05$), diabetes incidence (100% vs. 0%; $p < 0.05$) and insulinitis score (1.3 ± 0.7 vs. 0.8 ± 0.1 ; $p < 0.05$) on day 21 in the cyclophosphamide accelerated NOD mouse model of Type 1 diabetes.

Conclusion: These results demonstrate that activation of adenosine receptors can attenuate Type 1 diabetes and the A2b receptor plays the predominant role in this protective effect.

NK cells in type 1 diabetes

H. Brauner¹, M. Wareing², M. Flodström-Tullberg², K. Kärre¹, P. Höglund¹; ¹IRIS Strategic Research Center, Microbiology, Tumor and Cellbiology, ²Center for Infectious Medicine, Department of Medicine, Karolinska Institutet, Stockholm, Sweden.

Background and Aim: Type 1 diabetes is generally thought to be a T cell-driven autoimmune disease. The Non Obese Diabetic (NOD) mouse develops a disease similar to human type 1 diabetes (T1D). NK cells are part of the early innate immune response and play an important role in fighting certain viruses, tumours and in rejection of bone marrow transplants. A role for NK cells in autoimmune disease has been suggested, but the literature is conflicting. This project aims at elucidating a possible role of NK cells in T1D.

Materials and Methods: 200ug of the antibody to IL-2R β (TM β 1) was given i.p. once weekly to NOD mice and urine glucose measured. NK cells were sorted away from NOD splenocytes on the basis of their high DX5 expression and then transferred i.v. to NOD RAG-/- C γ -/- mice. The influence of NK cells on T cell priming were investigated by transferring T cells labeled with the fluorescent dye CFSE to NOD mice treated with TM β 1 or PBS. CFSE distributes equally in divided cells, and was used to measure proliferation after 3 days. In order to investigate the phenotype of pancreatic NK cells without contamination of lymphocytes from blood or lymph nodes the mice were flushed with PBS via the heart and lymph nodes removed under microscopy.

Results: Most NK cells, but also some T cells express IL-2R β . Depleting NOD mice with an antibody to IL-2R β (TM β 1) protects from T1D, also when administered only close to disease onset. To further address a possible role for NK cells T1D, NOD splenocytes with NK cells sorted away or still present were transferred to NOD recipient mice lacking T, B and NK cells (NOD RAG-/- C γ -/-). Preliminary results show that NK cell removal led to less diabetes in the recipient after transfer, suggesting a pathogenic role for NK cells in this model. We currently address whether NK cells influence T cell priming in the pancreatic lymph node (PLN) or play a pathogenic role in the pancreas itself in the NOD model. Preliminary results suggest that NK cells do not affect the proliferation of T cells in the PLN. The possibility that NK cells may regulate cytokine production by these proliferating T cells is being investigated. Our results show that NK cells are present in the pancreas of NOD mice and that they display a distinct and more activated phenotype compared to spleen NK cells. A kinetic analysis revealed that pancreatic NK cells have acquired this activated phenotype already at 4 weeks of age and that the percent NK cells over T cells are higher in young NOD mice, suggesting an early role in the pathogenesis. Present investigations include the location and the functional properties of the pancreatic NK cells.

Conclusion: The role of NK cells in type 1 diabetes is still controversial. Our results from murine studies suggest that NK cells may play a pathogenic role in this disease, and that the effect of the NK cells may be in the pancreas itself.

Autoaggressiveness and regulatory potential in the LEW.1AR1-iddm rat, an animal model of human T1DM

T. Arndt^{1,2}, A. Joerns³, H. Weiss⁴, M. Tiedge⁴, S. Lenzen¹, H. J. Hedrich², D. Wedekind²;

¹Hannover Medical School, Institute of Clinical Biochemistry,

²Hannover Medical School, Institute of Laboratory Animal Science,

³Hannover Medical School, Centre of Anatomy, ⁴University of Rostock, Institute of Medical Biochemistry and Molecular Biology, Germany.

Background and Aims: The LEW.1AR1-iddm rat – an animal model of human Type 1 diabetes mellitus (T1DM) – originated through a spontaneous mutation within the congenic inbred strain LEW.1AR1. Adoptive transfers of lymphocytes have shown that both autoaggressive and protective cells can be transferred. The aim of this study was to characterise the T-cell subpopulations capable to induce and to prevent T1DM in LEW.1AR1-iddm rats.

Materials and Methods: T-cells were isolated by MACS separation using monoclonal antibodies. CD4+ or CD8+ T-cells from diabetic LEW.1AR1-iddm rats were selectively transferred into athymic LEW.1AR1-Whnru rats. CD4+ and CD8+ T-cells from LEW.1AR1 rats were transferred into pre-diabetic LEW.1AR1-iddm rats. Purity of T-cell populations was verified by flow cytometry using a set of monoclonal antibodies: CD4 (OX-38) FITC and CD3 (G4.18) PE, (BD); CD8 (OX-8) FITC, CD8 (OX-8) PE, G4.18 PE, R73 FITC, CD45RA (OX-33) FITC, NKR (10/78) FITC, ED1 FITC (Serotec).

Results: After adoptive transfer of CD4+ T-cells from diabetic LEW.1AR1-iddm rats into athymic LEW.1AR1-Whnru rats 60 % of the recipients developed diabetes while CD8+ T-cells remained healthy. Only 10 % of the athymic recipients became diabetic after transfer of both CD4+ and CD8+ T-cells. On the other hand, CD8+ T-cells adoptively transferred from T1DM-resistant LEW.1AR1 rats into pre-diabetic LEW.1AR1-iddm rats were able to prevent T1DM development. The transfer of CD4+ T-cells alone as well as a combination of CD4+ and CD8+ T-cells had no effect on diabetes incidence in LEW.1AR1-iddm recipients.

Conclusion: Our results show that T1DM can be provoked by transfer of CD4+ T-cells from LEW.1AR1-iddm rats while T1DM can be prevented by transfer of CD8+ T-cells from LEW.1AR1 rats. These findings indicate that the mutation in the LEW.1AR1 strain leads either to a gain of autoaggressiveness or to a loss of diabetes protection in LEW.1AR1-iddm rats. In diabetic patients both CD4+ and CD8+ T-cell subpopulations have been discussed as lymphocytes bearing autoaggressive potential. But recently, it has been shown that in humans regulatory CD8+CD25+ T-cells are present which have a function similar to CD4+CD25+ T-cells. Thus, the LEW.1AR1-iddm model and its coisogenic LEW.1AR1 control strain provide a valuable experimental tool to characterise the regulatory function of CD8+ T-cells as well as the autoaggressive potential of CD4+ T-cells in T1DM development.

0449

Recent-onset type 1 diabetes: clinical remission is associated with increases both in CD25+ and CD 161+ regulatory subsets of T lymphocytes

T. Milicic¹, N. M. Lalic¹, A. Jotic¹, I. Markovic², B. Djuricic², M. Zamaklar¹, K. Lalic¹, L. Lukic¹, N. Rajkovic¹;

¹Institute for Endocrinology, Clinical Center of Serbia, Belgrade, Serbia,

²Institute for Biochemistry, School of Medicine, Belgrade, Serbia.

Background and Aims: Previous studies have reported an important role of the changes in CD4+ T cell subsets in the initial phase of Type 1 diabetes (T1D). However, the relevance of the changes in CD25+ and CD161+ subsets of the regulatory T cells, potentially exerting suppressive effect on the ongoing autoreactive response during the initial phase of T1D, has not been clarified. Therefore, the aim of this study was to analyze the percentage of regulatory CD25+ and CD161+ subsets of CD4+ T lymphocytes (a) during the first year of the clinical course of the disease comprising (1) insulin-requiring state (IRS) at the onset and (2) the state of clinical remission (CR) in 37 recent-onset T1D patients (group A) as well as (b) in 20 healthy, age-matched control subjects (group B).

Materials and Methods: The CR was defined as optimal metabolic control without insulin lasting >30 days. The percentages of CD3+, total CD4+,

CD4+CD25+ and CD4+CD161+ T cell subsets were analyzed in peripheral blood by using two-color immunofluorescence staining and flowcytometry.

Results: The percentages of CD3+, and total CD4+ T cells did not differ significantly neither between IRS and CR in the group A, nor between the groups A and B. However, when the percentage of CD4+CD25+ T lymphocytes was analyzed, we found that at onset of T1D, in IRS, it was found to be lower in group A vs group B (A/IRS: 2.32±0.31 vs B: 5.10±0.70%, p<0.01). In contrast, in the state of CR, in group A the percentage of CD4+CD25+ T cells increased and it became higher, reaching the values similar to those in group B (A/CR: 4.10±0.12 p=NS). Moreover, the percentage of CD4+CD161+ T cells was found to be lower at IRS in group A vs group B (A/IRS: 3.35±0.68 vs B: 6.08±1.12, p<0.01), while in the state of CR it also increased and became similar to those in the group B (A/CR: 5.87±0.82, p=NS).

Conclusion: Our results have demonstrated that in recent-onset T1D patients, the state of CR was associated with an increase in both CD25+ and CD161+ regulatory CD4+ T cell subsets. The results imply that the appearance of the CR might be strongly influenced on the level of the activity of the suppressive subsets of the regulatory CD4+ T lymphocytes.

0450

Abnormal monocyte-related biomarkers in type 1 diabetes; a study of identical twins

H. Beyan¹, H. J. De Witt², R. D. G. Leslie¹, H. A. Drexhage²;

¹Centre for Diabetes and Metabolic Medicine (DMM), Institute of Cell and Molecular Science, London, United Kingdom,

²Dept Of Immunology, Erasmus MC, Rotterdam, The Netherlands.

Background and Aims: Type 1 diabetes (T1DM) is due to an aggressive adaptive immune response but the innate immune system could be relevant since monocytes infiltrate the islets. Type 1 diabetes is considered to be an autoimmune disease, in which T cells specific for beta cell antigen (e.g. insulin and glutamic acid decarboxylase 65) target the islet, which finally results in the destruction of the beta cells. We have detected changes in monocytes in T1DM patients including a cluster of altered genes expression profiles compared with normal subjects. Our aim was to identify monocyte-related biomarkers in identical twin pairs discordant for T1DM (only one twin with diabetes) to determine which gene clusters were diabetes associated and which were associated with disease-risk.

Materials and Methods: We studied 14 identical twin pairs (all discordant for T1DM) 6 male; mean age of 36.5 (range17–53 years) with mean disease duration 20.5 (7–44 years) and 13 normal identical twin pairs, 7 male; mean age of 37 (23–55 years). Peripheral blood mononuclear cells (PBMC) were isolated using standard procedure on Ficoll. Monocytes CD14+ were isolated from frozen PBMC suspensions by MACS-CD14 separation following manufacture's instructions and RNA extracted by Qiagen (Qiagen, Hilden, Germany). Real-time quantitative RT-PCR was performed using TaqMan 7700 for the following genes previously identified using Affymetrix systems: HSP70, MAPK6, PAC1, PTPN7, CCL2, CCL7, PTX3, COX-2, A20, EMP1, CDC42, STX1a, DHRS, FABP5 plus appropriate controls including Able gene (stable housekeeping gene).

Results: Abnormal expression levels of 11 monocyte genes were identified encompassing changes in monocyte pro-inflammatory features, MAP kinase pathway, cell adhesion/motility and immune regulation. In the diabetic twin a significantly abnormal level of gene expression was detected in the (e.g. FABP5, MAPK6, STX1a), whilst both diabetic and non-diabetic twins had altered expression of a different set of genes compared to controls (e.g.CCL2, CCL7, HSP70, SDR)(all differences <0.02). Gene expression levels were strongly correlated between twins of a pair and were not altered in patients with type 2 diabetes excluding a hyperglycaemic effect. This finding implies monocytes are altered in T1DM and we report for the first time the identification of monocyte molecular signature that may distinguish diabetic from non-diabetic twins.

Conclusion: In summary, these results indicate that there are monocyte signatures of altered gene expression levels which are associated with, on the one hand, familial, probably genetic, susceptibility to T1DM or, on the other hand, with T1DM. These signatures are distinct, reflect potential differences in altered monocyte function, and suggest targets for therapeutic intervention.

0451

Expression of human insulin gene in gastrointestinal tracts

X. Yancheng, N. Li, S. Jiazhong;

Department of Endocrinology, Medical College of Wuhan University, Wuhan China, China.

Background and Aims: Type 1 diabetes mellitus is the result of insulin deficiency caused by the autoimmune destruction of insulin-producing pancreaticβcells. Development of gene therapy has also generated much hope and excitement for a possible “cure” for diabetes since insulin was first cloned and expressed in cultured cells in the late 1970s. The aim is to study the expression of human insulin genes in gastrointestinal tracts of rats with type 1 diabetes.

Materials and Methods: Plasmids isolated with a large-scale alkaline lysis procedure were purified. Experiments were carried out on 45 8-week-old male Wistar rats (180–190g). After an overnight fast, rats were given a single intraperitoneal injection of either 60 mg/kg streptozotocin in 0.01 M citrate buffer. 40 rats with fast serum glucose level > 16.7mmol/L were used in the study. Chitosan-DNA nanoparticles were transfected to diabetes rats by lavage and coloclisis respectively. 2 control groups were treated with Chitosan and normal sodium respectively. Fasting blood glucose and plasma insulin were measured. RT-PCR analysis was performed to confirm the expression of human insulin gene.

Results: Fasting blood glucose levels of the lavage group and coloclisis group decreased significantly compared with control groups ($P<0.01$). And plasma insulin levels of the lavage group and coloclisis group were much higher than those of the control groups accordingly ($P<0.01$). The human insulin gene mRNA was only detected in the lavage group and the coloclisis group.

Conclusion: Human insulin gene embedded with chitosan nanoparticle can be transfected to rats successfully by gastrointestinal tracts, indicating that chitosan is a promising non-viral vector. Compared with other non-viral vectors, chitosan has some merits as followed: (1) It has good biocompatibility, without any toxicity, and can be obtained economically. (2) We can regulate the transfection efficiency of chitosan and intaking of cells by changing molecular weight of chitosan, plasmid concentration, and the ratio of chitosan and plasmid. (3) After the plasmid is embedded in chitosan, it can resist degradation of nucleus.

PS 26 Immunopathogenesis of animal and human diabetes

0452

Lowered expressions of the NF-κB family members in dendritic cells from NOD mice are associated with reduced expression of GATA-2K. Takahashi¹, Y. Oka², J. Satoh¹;¹Department of Diabetes and Metabolism, Iwate Medical University, Morioka, ²Department of Molecular Diabetes and Metabolism, Tohoku University, Sendai, Japan.

Background and Aims: Dendritic cells (DC) are central to the initiation of immune response and maintenance of self-tolerance. In type 1 diabetes, DC display defective phenotype and function in type 1 diabetes, and possibly play crucial roles in the pathogenesis of this disease. To characterise molecular changes in CD11c⁺ bone marrow (BM)-derived DC from NOD mice, a model of type 1 diabetes, we compared transcript profiles of these cells with those from the sister strain, NON mice. In the present study, we analysed our microarray data focusing on the NF-κB/ Rel family members and the related molecules associated with DC development, function, and phenotype.

Materials and Methods: BM cells from 4-week-old female NOD and NON mice were cultivated in the presence of GM-CSF and IL-4 over 5 days, and with LPS for following 2 days. The CD11c⁺ DC were then sorted by magnetic beads-conjugated anti-CD11c⁺ antibodies (MACSTM, Miltenyi Biotech Inc, Bergisch Gladbach, Germany). RNA extracted from the CD11c⁺ DC from 3 independent mice (100 μg/ mouse) was pooled, and used to prepare targets for hybridization to the GeneChip Mouse Genome 430A Arrays (Affymetrix, Santa Clara, CA).

Results: The DC from 4-wk-old NOD displayed reduced mRNA expressions of NF-κB components, p65, p50, p52, and RelB, compared to NON mice: the proportions of the each molecule relative to NON DC were 53.9, 54.1, 54.0, and 37.0%, respectively. As expected, they showed lowered mRNA expressions of immunomodulatory molecules regulated by the NF-κB pathway, including IL-1α (48.8% vs NON DC), IL-1β (49.9%), IL-6 (18.4%), Flt-3L (41.0%), CD80 (29.6%), CD86 (51.1%), 4-1BB (47.2%) and CD40 (46.5%), which is partially consistent with the previous reports indicating defective phenotype and function of NOD DC. The reduced expression of a proteasome subunit, beta type 9 (LMP-2) reportedly leads to defects in the NF-κB pathway in NOD mice, however, our microarray data were not in line with this observation: the expressions of all 26S proteasome subunits, including LMP-2, and related chaperones were identical between NOD and NON DC (data not shown). The transcription factors for the NF-κB members, which showed reduced expressions, such as GATA-2 (45.6% vs NON), heat shock factor 2 (22.6%), and runt related transcription factor 1 (44.3%), were noted as the more likely culprits.

Conclusion: The lowered expressions of NF-κB components, possibly due to defective expression of the upstream transcription factors, underlie the defective phenotype and function of DC from NOD mice, and could predispose to autoimmunity. It is of interest that the GATA-2 gene (Chr6, 38.5cM) locates close to Idd20 (Chr6, 37.7cM).

Suppressed Th1 and induced naive T cell phenotype in type 1 diabetic children

M. Hedman, M. Faresjö, S. Axelsson, J. Ludvigsson, R. Casas;

Department of Molecular and Clinical Medicine, Pediatrics, Linköping, Sweden.

Background and Aims: Type 1 diabetes (T1D) is considered to be caused by an inflammatory process with selective destruction of the insulin producing beta-cells, mediated by CD4⁺ T helper (Th) and CD8⁺ cytotoxic T (Tc) cells. Chemokines play important roles in inflammatory and immunological processes by their capacity to recruit selective subsets of leukocytes expressing their corresponding receptors. However, migration of inflammatory cells into tissues can itself be a cause and inducer of tissue damage. Identifying the signals controlling the recruitment of inflammatory cells into the pancreas might be a novel strategy to inhibit insulinitis. This study aimed to determine the chemokine and chemokine receptor profile of CD4⁺ and CD8⁺ T cells in

T1D children during the first 18 months after diagnosis in relation to healthy children.

Materials and Methods: Peripheral blood mononuclear cells (PBMC) were collected from 44 children (10–18 years of age; 16 boys and 28 girls) within 18 months after diagnosis of T1D and from 12 healthy children (11–15 years of age; 4 boys and 8 girls). The T1D children were grouped according to duration of disease at the time of blood sampling as follows: 0–4 months; 5–9 months, 10–14 months and 15–18 months duration. Expression of chemokine receptors (CCR7, CCR5, CXCR3, CXCR6, IL-18R and CCR4) on CD4⁺ and CD8⁺ lymphocytes were analysed by flow cytometry. Secretion of chemokines (IP-10, MCP-1, MIP-1 α , MIP-1 β and RANTES) in cell supernatants after 72 hours cell culture was detected by multiplex fluorochrome technique (Luminex).

Results: The percentage of CD8⁺ cells expressing CCR7 ($p < 0.0001$) and CD45RA ($p < 0.005$) was high among the T1D children, especially in those with less than nine months disease duration, in comparison to healthy children. There was a steady decline in expression of CCR7 and CD45RA with duration of disease and at 15–18 months duration the expression had decreased to levels almost comparable to healthy children. A positive correlation was observed between these naive receptors ($r = 0.57$; $p < 0.0001$) among the T1D patients. As expected, expression of the maturation marker CD45RO was inversely correlated to CD45RA on CD8⁺ cells ($r = -0.78$, $p < 0.0001$). The percentage of cells expressing CD45RO was lower among T1D children during the first nine months after diagnosis in comparison to healthy children ($p < 0.001$), while the expression increased with longer duration of disease. The percentage of CD4⁺ cells expressing the Th1-associated receptors CXCR3 ($p = 0.001$) and CXCR6 ($p < 0.01$) was low in T1D patients compared to healthy children. CXCR3 correlated with another Th1-like receptor, CCR5 ($r = 0.45$; $p < 0.005$) on CD4⁺ cells. In contrast, CCR7 was inversely correlated to CCR5 ($r = -0.45$; $p < 0.005$) but positively with CXCR6 ($r = 0.46$; $p < 0.005$) on CD4⁺ cells. Secretion of the chemokines IP-10, MIP-1 α and MIP-1 β were low in T1D children compared to healthy controls ($p < 0.001$; $p < 0.01$; $p < 0.01$, respectively).

Conclusion: Low expression of Th1-associated receptors together with an induced naive Tc cell phenotype in the early phase after diagnosis suggests that the inflammatory process in the period close to diagnosis seems to recruit new cytotoxic T cells, which in turn could lead to enhancement of the inflammatory process. Increased knowledge of T cell phenotypes present in the disease process leading to T1D might lead to important clues in developing novel therapeutics for the prevention of disease.

The human insulin B chain is covered with overlapping epitopes binding to protective (HLA-DQ6) and susceptible (HLA-DQ2/8) type 1 diabetes alleles

G. K. Papadopoulos¹, A. K. Moustakas², R. A. Ettinger³,

¹Laboratory of Biochemistry and Biophysics, Epirus Institute of Technology, Arta, Greece, ²Department of Organic Farming, Technological Educational Institute of Ionian Islands, Argostoli, Greece, ³RH Williams Laboratory of Endocrinology, University of Washington, Seattle, United States.

Background and Aims: To scan the insulin B chain, already shown to be highly diabetogenic in NOD mice, for epitopes to the protective HLA-DQ602 allele, besides the already-established InsB6-14 core nonamer.

Materials and Methods: The insulin B chain was scanned for possible core nonamers by testing via energy minimisation other possible nonamers for putative binding to HLA-DQ6. All candidate nonamers were then tested via energy minimisation software Discover (Accelrys, San Diego CA) in a Silicon Graphics Octane II instrument, in order to determine possible fitting of the peptide in the groove.

Results: The scanning of the molecule revealed two possible epitopes, B12-20 (VEALYLVCG) and B15-23 (LYLVCGERG), of which the former fitted much better into the respective groove upon energy minimisation. All five anchor residues satisfy the motif very well in the InsB12-20 epitope, while p6Gly is a very weak anchor in the InsB15-23 epitope. These two HLA-DQ602 epitopes, along with the already identified InsB6-14 core nonamer, are overlapping to the established epitope InsB13-21 of the susceptibility allele HLA-DQ8cis, as well as -DQ8trans and -DQ2trans alleles, and the recently identified InsB8-16 HLA-DQ2cis epitope.

Conclusion: The sum total of the three epitopes that have affinity for the protective and biochemically very stable allele HLA-DQ602, and overlapping epitopes associated with susceptibility to t1d, suggests that epitope stealing is one possible mechanism for protection from t1d, to the extent that the insulin B chain will be shown to be as potentially diabetogenic in man as in NOD mice.

Newly-diagnosed type 1 diabetic patients have distinct differences in the number and cell surface markers (TGF β , InsR) of regulatory T (Tregs) and effector T (Teff) lymphocytes compared to controls

S. A. Paschou¹, G. Vartholomatos², L. Dova², N. Kolaitis³, E. Giotaki⁴, A. Tsatsoulis¹, G. K. Papadopoulos⁵,

¹Endocrinology Clinic, University of Ioannina Regional Hospital, Greece, ²Haematology Laboratory, Molecular Biology Unit, University of Ioannina Regional Hospital, Greece, ³Haematology Laboratory, University of Ioannina Regional Hospital, Greece, ⁴Department of Nursing, Epirus Institute of Technology, Ioannina, Greece, ⁵Laboratory of Biochemistry and Biophysics, Epirus Institute of Technology, Arta, Greece.

Background and Aims: T regulatory lymphocytes (Tregs, CD4⁺CD25^{hi}) play an important role in tolerance and autoimmunity. Our aim was to investigate the expression of key markers on Tregs and T effector cells (Teff, CD4⁺CD25⁺) that may be the targets of Tregs, and to identify differences in the presence and intensity of certain markers between newly diagnosed type 1 diabetes (t1d) patients and controls.

Materials and Methods: Peripheral blood from 7 newly-diagnosed type 1 diabetes patients (ages 16+/-10.7, 5M/2F) and 22 healthy controls having no first or second degree relatives suffering from autoimmune diseases (ages 25.5+/-9.1, 7M/15F), was analysed via triple colour flow cytometry for characteristics of the Treg, and Teff populations. The cut-off line between Tregs and Teff was decided from the dot and contour plots, and confirmed by the higher expression of the transcription factor FoxP3 and the much lower membrane expression of IL-7R (CD127) in Tregs compared to Teff. The markers analysed for were TGF β , TGF β RII, HLA-DR, HLA-DQ, IL-2R β (CD122), and InsR (CD220).

Results: Newly-diagnosed type 1 diabetics had a significantly lower percent of Tregs (as percent of total CD4⁺ T cells) compared to controls: 1.02 +/- 0.27 vs 2.29 +/- 0.56 ($p = 0.01$). Where tested, Teff cells also expressed FoxP3 yet at lower percent and intensity compared to Tregs. Consistently, Treg cells from newly-diagnosed t1d patients exhibit to a lower extent than normals the markers of membrane TGF β (mean +/- SD, p value): 70.2% +/- 12.9 vs 90.9% +/- 4.8 ($p = 0.02$), but at higher Mean Fluorescence Intensity (MFI): 198.2 +/- 53.78 vs 154 +/- 119.1 ($p > 0.05$), and InsR (63.8% +/- 15 vs 83.2% +/- 12.5 ($p < 0.05$) with MFI of 221 +/- 88 vs. 96.5 +/- 22.1 ($p < 0.05$). By contrast, a higher percent of Teff from t1d express InsR compared to controls (24.14 vs. 17.7, $p < 0.05$) with no significant differences in MFI; there is no significant difference in the percent (55.6 +/- 10.5 vs. 61.9 +/- 19.3, $p > 0.05$) or MFI of Teff expressing TGF β RII between patients and controls. The majority of Teff cells from nearly all patients and controls express the activation markers CD122, HLA-DR, HLA-DQ, but with no significant differences between them.

Conclusion: Tregs that participate in the control of autoimmunity are significantly fewer in newly-diagnosed t1d patients compared to controls, and a lower proportion of them express TGF β and InsR. Yet the intensity of expression of InsR in t1d Tregs is much higher, implying a compensatory mechanism for the substantial decrease in Treg numbers. By contrast more Teff cells from newly-diagnosed t1d patients express the InsR, a sign of the increased activity of such cells. If Teff in human t1d are unresponsive to Tregs acting via their membrane TGF β , this cannot be accounted for by lack of TGF β RII in the former cells. The interplay of TGF β and InsR in Tregs and Teff leading to t1d, indicated here for the first time, must be further investigated.

Impaired immune activity is associated with increased expression of glucotransporter 4 (glut4) in natural killer (nk) cells of subjects in the prediabetic stateP. J. Piatkiewicz¹, A. Czech¹, J. Taton¹, M. Kniotek², A. Gorski²;¹Chair and Department of Internal Diseases and Diabetology, Warsaw Medical University,²Department of Clinical Immunology, Warsaw Medical University, Poland.

Background and Aims: Incorrect metabolic conditions (hyperglycemia) influence peripheral blood NK cells that are thought to represent the first line defense in the immune system. This relationship can be particularly expressed by glucose transporter proteins in these cells. The earlier obtained results revealed significant differences in glucose transport between NK cells of healthy subjects and prediabetic patients. The aim of this study was to evaluate the number and activity of NK cells obtained from prediabetic subjects in comparison with healthy control subjects and to determine the quantitative expression of insulin-dependent GLUT4 in these cells.

Materials and Methods: The study group included 6 patients with a diagnosis of the prediabetic state, according to WHO criteria, naive to any hypoglycaemic drugs. As a control group 6 carefully matched healthy subjects were enrolled. Peripheral blood mononuclear cells (PBMC) were isolated by Ficoll gradient centrifugation. The K562 human erythroleukemia cell line was used as the standard target for human NK cytotoxicity assay. K562 were washed in PBS and labelled with DIO (3,3-diiodoacetylcarboxyanine perchlorate) for 20 min at 37°C, 5% CO₂. After two washes in PBS cells were adjusted to 10⁶ cell/ml in medium (RPMI 10%FCS). Target and effector cells were added to reach effector/target ratios: 50:1, 12:1. Dead target cells were stained with PI (propidium iodide). After 4 hours of incubation data were collected for analysis on the Becton-Dickinson FACScalibur flow cytometer. Live target cells (T) were identified with strong green fluorescence, whereas dead target cells (Td) showed strong green and red fluorescence. The percentage of dead target cells (Td%) was calculated as follows: %Td= (Td/T)x100%. Specific lysis was calculated as %Td (cultured with effector cells) -Td (cultured without effector cells). Immunofluorescent phenotyping of NK (CD16⁺) cells in (PBMC) was performed using specific murine anti-human CD16 PE-conjugated monoclonal antibodies. The data was analyzed using Cell Quest software.

Results: We determined the significant differences between the number (P<0.05) and activity of NK cells (P<0.01) obtained from prediabetic subjects and the control group. The prediabetics had an increased number but substantially decreased activity of NK cells when compared to healthy subjects (12,83% and 3,3% respectively vs 9,80% and 9,2%). These abnormalities were associated with the higher level of GLUT4 protein in NK cells of prediabetic patients versus control group (37±3,9% vs 13±2,1%) (P<0.001), as shown in flow cytometry.

Conclusion: Increased number and decreased NK cells activity possibly reflect incorrect metabolic conditions of the prediabetic patients. Overexpression of GLUT4 may profoundly alter the immune response and be the cause of decreased NK cell cytotoxicity. We suggest that NK cell pathology shown in this study is the effect of glucotoxicity and predicts subsequent susceptibility to infections in Type 2 diabetes. NK-cells seem to be a promising model for studies on the impairment of immune activity in the prediabetic state and Type 2 diabetes.

Deficient inducibility of heat shock protein 70 in response to stress at the onset of type 1 diabetes

V. Burkart, L. Germaschewski, N. C. Schloot, K. Bellmann, H. Kolb;

Institute for Clinical Diabetes Research, German Diabetes Center, Düsseldorf, Germany.

Background and Aims: Type 1 diabetes (T1D) is caused by the immune-mediated destruction of autologous pancreatic beta cells. Animal models of the disease demonstrate a defective heat shock protein (hsp) -expression in beta cells resulting in decreased stress-resistance and increased susceptibility to immunological attacks. Furthermore, hsp are involved in the induction and maintenance of self-tolerance, which is severely disturbed in T1D as evident from the immune reactivity evolving against autologous beta cells. These findings strongly implicate that a defective hsp expression contributes

to the progression of T1D. Therefore, our present study was designed to investigate the inducibility of hsp70, a prominent member of the hsp family, during the development of T1D.

Materials and Methods: Peripheral blood mononuclear cells (PBMC) were isolated from 8 T1D patients at the time of diagnosis (before the initiation of insulin therapy) and 8 d after diagnosis and from 8 patients with a disease duration of > 8 months (5.7 ± 2.8 years). Eight healthy controls were assigned to the 2 groups of patients. PBMC were exposed to heat shock conditions (42.5°C, 60 min) followed by a recovery period of 6 or 18 h. Hsp70 protein expression was analyzed by Western Blot; the resulting signals were quantified by chemiluminescence and expressed as Luminescence Units (LU).

Results: Hyperthermia strongly upregulated hsp70 protein expression in PBMC from healthy persons. Already 6 h after termination of the heat shock treatment Western blot analysis revealed high amounts of hsp70 (152 ± 52 LU) which remained stable until 18 h (159 ± 51 LU). In contrast, PBMC from newly diagnosed T1D patients expressed significantly lower hsp70 levels (38 ± 31 LU) 6 h after heat treatment (p<0.05). At 18 h after heat treatment, hsp70 levels increased to 131 ± 40 LU, similar to the range of control PBMC. Eight d after diagnosis of T1D, when appropriate insulin substitution has normalized metabolic control, PBMC still showed depressed hsp70 inducibility. Compared to the control group hsp70 expression levels in PBMC of patients were reduced by about 50 % at 6 and 18 h after heat exposure. After a disease duration of > 8 months hyperthermia-induced hsp70 expression in PBMC of T1D patients was completely normalized. At 6 and 18 h after termination of the heat treatment hsp70 expression of PBMC from control subjects was in a range of 176–179 LU and in PBMC from diabetic patients in a range of 172–180 LU. To examine a potential impact of inflammatory mediators on stress-induced hsp70 expression PBMC of healthy controls were pre-incubated with interferon γ (IFNγ) or transforming growth factor β (TGFβ) for 24 h prior to heat shock exposure. Pretreatment with the Th1-associated cytokine IFNγ significantly diminished heat-induced hsp70 expression to 58 ± 15 % of the level observed in heat-treated PBMC without cytokine exposure (p<0.05). In contrast, the preferentially anti-inflammatory cytokine TGFβ significantly increased heat-induced hsp70 expression to 130 ± 12 % (p<0.05).

Conclusion: Our findings show a deficient hsp70 response to stress in leukocytes of T1D patients at the time of disease manifestation. We conclude that the impaired stress-responsiveness in T1D is largely independent on the quality of the patients' metabolic control but is mediated by the Th1-dominated inflammatory milieu prevailing at the onset of T1D.

Study of haematological parameters in type 1 diabetic patients and associated autoimmunityN. Alonso¹, B. Soldevila¹, E. Colomé¹, M. Granada², J. Juncà³, R. Puig¹,I. Salinas¹, E. Martínez-Cáceres⁴, A. Sanmartí¹;¹Endocrinology and Nutrition, ²Clinical Biochemistry, ³Hematology,⁴Immunology (LIRAD-BST), Hospital Universitari Germans Trias i Pujol, Badalona, Spain.

Background and Aims: Type 1 diabetic patients (DM1) show an increased prevalence of associated organ specific autoimmune aggression against other endocrine and nonendocrine tissues. Anemia of chronic disorders (ACD) is a frequent finding in systemic autoimmune diseases. It is characterized by a relative deficit of erythropoietin and a decrease of bone marrow erythropoietin activity due to an increase of proinflammatory cytokines. The aims of the study were: 1.-To study the hematological parameters of DM1 patients with associated autoimmunity (group A) and compare them with DM1 patients without associated autoimmunity (group B). 2.-To define the type of anemia present in patients with DM1 with associated autoimmunity.

Materials and Methods: Transversal study of 227 DM1 patients (51% male); age: 33.81± 10 years; mean disease evolution time: 13± 6 years; all with normal renal and thyroid function and normoalbuminuria. The following parameters were measured: 1-Immunological: antithyroid peroxidase (aTPO), nuclear (ANA), antigastric parietal cell (CPG) and tissue transglutaminase (tTG) antibodies 2- Hematological: Hemoglobin (Hb), ferritin, cobalamin (RIA), erythropoietin (Epo) (RIA). 3-Inflammatory and biochemical: fibrinogen, C-reactive protein (CRP) and HbA1c.

Results: 1.- *Prevalence of associated autoantibodies:* 63% of DM1 patients tested positive for 1 or more autoantibodies (group A): 21.9% aTPO (17.3% females), 7.8% ANA (5.4% females), 15.2% aCPG (9.8 females) and 6.2% tTG (4.5 females). 2.- *Hematological parameters (group A vs group B):* Hb 13.8 gr/

dL vs 14.8 gr/dL, $p < 0.001$; ferritin 45 (20–73) ng/mL vs 70 (36–115) ng/mL, $p < 0.001$; cobalamin 357 (279–518) pg/mL vs 397 (308–516) pg/mL, NS; Epo 11.3 (8.8–18.3) mU/mL vs 11.2 (8.7–15.6) mU/mL, NS. 3.- *Inflammatory and biochemical parameters (group A vs group B)*: fibrinogen 332±88.21 mg/dL vs 345.6 ± 85.31 mg/dL, NS; CRP 1 (0.94–2.29) mg/L vs 1.2 (0.54–2.99) mg/L, NS; HbA1c 7.53±0.97 vs 7.56±1.38, NS. 4.- *Hematological parameters of anemic patients*: 4.9% of patients presented anemia according to the OMS criteria (Hb<12gr/dL in women and <13 gr/dL in men): 3.1% women and 1.8% men. Of these, 54.3% tested positive for 1 or more autoantibodies (50% aCPG, 33.3% tTG). The results of hematological parameters in this group were: Hb 11.2±1.01 gr/dL; ferritin 15 (7.7–251) ng/mL; cobalamin 323 (197–406) pg/mL; Epo 61.4 (24.4–79.7) mU/mL; fibrinogen 317(245–500) mg/dL; CRP 0.3(0.2–13.9) mg/L.

Conclusion: Patients with type 1 diabetes mellitus and associated autoimmunity, principally of gastric origin, presented anemia most likely due to iron malabsorption and not to the possible proinflammatory state of a second autoimmune disease. This finding could be explained by the fact that the positivity of these autoantibodies responds only to a localized inflammation and not to a systemic inflammatory process.

0459

Enhanced activation of innate immune system in subjects with associated type 1 diabetes mellitus and coeliac disease

S. Brugaletta¹, C. Smaldone¹, C. Fabiano², F. Zaccardi², A. Manto², T. Musella², D. Pitocco², F. Crea¹, G. Ghirlanda²;

¹Cardiology, ²Internal Medicine, Catholic University, Rome, Italy.

Background and Aims: Immune system seems to play a key role in the pathogenesis of type 1 diabetes (T1DM). T1DM is often associated with autoimmune diseases like as coeliac disease (CD). The aim of this study was to assess the effect of associated CD on both innate and adaptive immune system, by measuring serum level of c-reactive protein (CRP) and blood frequency of CD4⁺CD28^{null} T-cells and CD4⁺CD25⁺ T-cells, unusual populations of lymphocytes, involved in autoimmune regulation.

Materials and Methods: We enrolled 30 consecutive patients with T1DM and CD (16 males, mean age 28 ±5,6); CD was diagnosed by intestinal biopsy and every patient with CD was on a gluten-free diet. We also enrolled 19 patients with only T1DM (10 males, mean age 29 ±4,9 yrs) as control group. Demographic and clinical data were collected. Blood samples were taken at time of enrolment. Serum level of CRP was measured using a high sensitivity immuno-nephelometric assay. CD4⁺CD28^{null} T-cells and CD4⁺CD25⁺ T-cells frequency was measured by flow cytometry.

Results: Serum levels of CRP were significantly higher in patients with T1DM and CD than in patients of control group (1,99±3,56 vs 0,98±3,63mg/L) No significant differences in CD4⁺CD28^{null} T-cells (2,195±2,94 vs 2,565±2,05%) and CD4⁺CD25⁺ T-cells (1,56±0,64 vs 1,43±0,73%) frequency and metabolic control (HbA1c 7,1±0,4 vs 7,2±0,3) were found among the two groups.

Conclusion: Our study shows for the first time a higher serum level of CRP, marker of innate immune system activation, in patients with T1DM and CD than in those with only T1DM. This result show a possible enhanced activation of innate immune system in patients with associated T1DM and CD, whereas it seems that cellular-mediated immune system isn't involved.

0460

Residual beta cells and protracted islet autoimmunity after onset of type 1 diabetes in NOD mice: therapeutic opportunities for promoting beta cell regeneration and rescue from recurring immunity

S. Reddy, R. Chai, J. A. Rodrigues, T. H. Hsu, E. Robinson;

School of Biological Sciences, University of Auckland, New Zealand.

Background and Aims: During type 1 diabetes, the precise fate and characteristics of beta cells which remain after onset of disease are unclear. In this study, the extent of beta cell survival was assessed in diabetic NOD mice at various time-points during increasing duration of disease. Results were correlated with the severity of insulinitis, the presence of alpha and delta cells and the expression of glucose transporter-2.

Materials and Methods: Pancreata from adult female non-diabetic NOD mice and diabetic NOD mice at diagnosis and at 1, 2, 3 and 4 weeks thereafter

were obtained (5 mice per group and without insulin treatment). Sections of pancreas were analyzed by dual-label immunohistochemistry for the number and distribution of beta, alpha and delta cells per mm² of islet surface area. The expression of glucose transporter-2 in insulin immunoreactive beta cells was assessed by immunohistochemistry. The degree of insulinitis per group was evaluated on a scale of 0–4 in pancreatic sections stained by H&E. Immunohistochemical and insulinitis analyses were also correlated with the phenotypes of islet immune cell-types in sections of pancreas.

Results: The severity of insulinitis showed considerable inter-islet variation within each study group. At onset of diabetes, there was a marked degree of insulinitis which declined progressively from onset to 4 weeks of disease ($p=0.0031$). Although the mean number of beta cells declined sharply at onset of diabetes and remained low during the 4-week study period, the differences between the various groups did not reach statistical significance ($p=0.21$). The mean number of intra-islet alpha and delta cells showed a significant increase with increasing duration of disease ($p=0.019$ for alpha cells; $p=0.0009$ for delta cells). After diabetes onset, occasional islet cells showed co-expression of insulin and glucagon. Immunolabelling for glucose transporter-2 was undetectable in most insulin-positive cells from 1 week of diabetes. CD4 and CD8 T cells and macrophages were the predominant islet inflammatory cells in the insulinitis lesion and persisted until 4 weeks of diabetes, particularly in islets with residual beta cells or those with extensive insulinitis. Diabetic islets without beta cells or those containing mostly alpha and delta cells showed either an absence or minimum insulinitis.

Conclusion: In diabetic NOD mice, residual beta cells persist for at least 4 weeks after onset, with a concurrent increase in the number of intra-islet alpha and delta cells and a progressive decline in the severity of insulinitis. The predominant phenotypes of the islet immune cells were CD4 and CD8 T lymphocytes and macrophages. The absence of glucose transporter-2 in most insulin-positive beta cells after diabetes onset, suggests that such beta cells may have an impaired response to rising hyperglycaemia. Although the low number of residual beta cells present soon after onset of type 1 diabetes may be amenable to therapeutic regeneration, additional approaches aimed at restoring glucose responsiveness of beta cells and preventing recurrent autoimmunity, may be required.

PS 27 Immunology and prediction of type 1 diabetes

0461

Insulin autoantibody affinity as predictive marker for type 1 diabetes in young children with increased HLA-conferred disease susceptibility

H. T. A. Siljander^{1,2}, S. Simell³, A. Hekkala⁴, T. Salonsaari², T. Simell³, O. Simell³, J. Ilonen^{5,6}, M. Knip^{7,2};

¹University of Helsinki, Hospital for Children and Adolescents/ Research Laboratory, ²Department of Paediatrics, Tampere University Hospital, ³Department of Paediatrics, University of Turku, ⁴Department of Paediatrics, University of Oulu, ⁵Department of Clinical Microbiology, University of Kuopio, ⁶Immunogenetics Laboratory, University of Turku, ⁷Research Laboratory, Hospital for Children and Adolescents, Helsinki, Finland.

Background and Aims: Insulin autoantibodies (IAA) are usually the first or among the first autoantibodies to appear during the prediabetic disease process. As transient and fluctuating positivity for IAA is common, the analysis of IAA affinity may help to differentiate type 1 diabetes (T1D)-related IAA positivity from non-progressive IAA positivity. To test this hypothesis we measured the IAA affinities of the first and last prediabetic IAA-positive samples in young children who progressed to overt T1D and in matched non-progressors.

Materials and Methods: In the Finnish Type 1 Diabetes Prediction and Prevention study (DIPP Study) newborn infants were screened for HLA risk genotypes, and those with high (HLA-DQB1*02/0302) or moderate disease risk (HLA-DQB1*0302 without protective alleles) were observed for the development of diabetes-related autoantibodies (AABs) and clinical T1D. ICA were used for primary AAB screening. If a child tested positive for ICA, all his/her samples were analysed for IAA, GAD and IA-2 antibodies. DIPP children, who progressed to clinical T1D and tested positive for IAA before diagnosis, and IAA-positive non-diabetic control children matched for age, gender, HLA risk genotype and IAA titres were included in the present study. IAA were measured with a competitive radiobinding assay and the affinity assessed with GraphPad Prism 5.0.

Results: 64 IAA-positive children (38 males; 59.4%) presented with T1D at a median age of 3.8 years (0.9–8.8 years). The median IAA affinity of the first IAA-positive sample was 1.35^{10} I/mol (2.4^8 to 2.4^{11} I/mol) among cases compared to that of 1.32^{10} I/mol (1.4^8 to 1.1^{12} I/mol) in controls ($p=0.129$). The IAA affinities were similar in the last samples analysed, the median affinity being 1.15^{10} I/mol (3.8^8 to 5.5^{11} I/mol) among cases and 1.08^{10} I/mol (3.2^7 to 3.4^{12} I/mol) among controls ($p=0.496$). The affinity values did not change over time in either of the groups ($p=0.847$ for cases and $p=0.942$ for controls). The only difference observed was that the IAA titres increased during the observation period in the cases (median values 13.6 vs. 20.5 RU, $p=0.011$), while the titres remained at a similar level among the controls (median value 15.0 vs. 11.9 RU, $p=0.104$).

Conclusion: Although previous studies have suggested that IAA affinity might be useful in the early identification of subjects *en route* to T1D, the present data indicate that IAA affinity is unable to differentiate between rapid progressors and subjects remaining unaffected or progressing slowly to clinical disease among young children from the general population carrying HLA-conferred susceptibility to T1D.

Improved diabetes risk assessment in high risk relatives: role of autoantibodies to IA-2 β

P. Achenbach¹, E. Bonifacio¹, E. A. M. Gale², P. J. Bingley² & the ENDIT Group,

¹Immunology and Prevention, Diabetes Research Institute, Munich, Germany,

²Clinical Science at North Bristol, University of Bristol, United Kingdom.

Background and Aims: Autoantibodies to IA-2 β (IA2 β A) identify a subgroup of antibody positive relatives at increased risk. Our aim was to determine

the role of IA2 β A testing in diabetes prediction in a large, well-characterised cohort of ICA+ relatives followed for 5 years in the multinational intervention trial, ENDIT.

Materials and Methods: IA2 β A, IA2A, GADA and IAA at study entry were measured by radiobinding assay. FPIR and oral glucose tolerance were determined at baseline. Diabetes risk was assessed by survival analysis.

Results: Of 191 ICA+/IA2A+ participants (mean age 14.4 years \pm 0.7, 55% male), 107 developed diabetes and 84 remained non-diabetic during follow-up (5 year cumulative risk of diabetes 61% (95% CI 53–69)). 137 participants were also GADA+/IAA+ (4Ab), 51 positive for one additional marker (3Ab) and 3 GADA-/IAA- (2Ab). IA-2 β A were detected in 135 (71%) ICA+/IA2A+ participants and were associated with increased 5 year diabetes risk (IA2 β A+ 68% (58–78) vs. 44% (30–58) in IA2 β A-, $p=0.0049$). The effect was most marked in 4Ab+ relatives (IA2 β A+ 75% (64–86) vs. 53% (36–70) in IA2 β A-, $p=0.013$). Risk assessment was further refined by metabolic testing. Among 100 4Ab+ relatives with IA2 β A, those with low FPIR ($n=45$) had 5 year risk of 94% (84–100) compared with 55% (35–74) with normal FPIR ($p<0.0001$), and those with IGT ($n=21$) had risk of 95% (86–100) vs. 71% (57–85) with normal glucose tolerance. Median time to diagnosis with 4Ab/IA2 β A and low FPIR was 1.9 years (1.2–2.7). Multivariate analysis confirmed IA2 β A status, antibody number, FPIR and IGT as independent determinants of risk. Of all ENDIT participants who developed diabetes, 75% were IA2A+, 59% were IA2 β A+, 64% had low FPIR and 22% had IGT.

Conclusion: IA2 β A are associated with very high risk in ICA+ relatives with three biochemical antibodies and compare favourably with the IVGTT in identifying a subgroup at increased risk but with similar sensitivity. Combining IA2 β A determination and IVGTT with standard antibody testing allows identification of relatives with >90% 5 year risk. IA2 β A testing should be routinely added to the screening protocols of future intervention trials.

Islet autoantibody development during follow-up of high-risk children from the general Norwegian population from three months of age: design and early results from the MIDIA study

L. C. Stene^{1,2}, E. Witsø¹, P. A. Torjesen³, T. Rasmussen⁴, P. Magnus¹, O. Cinek⁵, T. Wetlesen¹, K. S. Rønningen¹;

¹Division of Epidemiology, Norwegian Institute of Public Health, Oslo, Norway, ²Diabetes Research Centre, Aker and Ullevål University Hospitals, Oslo, Norway, ³Hormone Laboratory, Aker University Hospital, Oslo, Norway, ⁴Division of Administration, Norwegian Institute of Public Health, Oslo, Norway, ⁵Motol University Hospital, 2nd Medical School, Charles University in Prague, Czech Republic.

Background and Aims: Limited data are available on pattern of type 1 diabetes associated autoantibody development from early age in healthy individuals who are not first-degree relatives of persons with type 1 diabetes. The aim was to describe the design of the MIDIA study and present serial islet autoantibody data from three months of age in children from the general population carrying the type 1 diabetes high-risk HLA-DRB1*0401-DQA1*03-DQB1*0302/DRB1*0301-DQA1*05-DQB1*02 genotype.

Materials and Methods: MIDIA is an observational study with blood samples obtained from children at ages 3, 6, 9 and 12 months and annually thereafter. Plasma autoantibodies to insulin, glutamic acid decarboxylase and insulinoma-associated antigen-2 were measured with radiobinding assays.

Results: About 25,000 general population newborns were genotyped (by Oct 2006), and among 526 children with the high-risk HLA genotype, 2104 samples were assayed for autoantibodies (range 1–13 samples per child, median 4). Median age at the most recent sample was 12 months (range 2.9 months to 5.3 years). Fourteen children were positive in at least two consecutive samples, including 12 who were positive for ≥ 2 autoantibodies at least once, of which five developed type 1 diabetes at median age 15.3 months. Seven of 14 persistently positive children seroconverted before nine months, including two before six months of age. The cumulative probabilities of type 1 diabetes and multiple autoantibody positivity at five years estimated using Kaplan-Meier analysis were 2.6% (95% confidence interval: 1.0%–6.4%) and 7.3% (95% confidence interval: 3.5%–12.4%), respectively.

Conclusion: Persistent islet autoimmunity is not uncommon in the first year of life in children from the general population carrying the high-risk *HLA* genotype, and may develop as early as at six or nine months of age.

A novel auto-antibody for diagnosis of autoimmune diabetes mellitus

N. Shehadeh^{1,2}, S. Polak¹, G. Wildbaum², N. Karin²;

¹Pediatric Diabetes Unit, Rambam Medical Center, ²Faculty of Medicine, Technion – Israel Institute of Technology, Haifa, Israel.

Type 1 diabetes Mellitus (T1DM) is the result of organ-specific autoimmune destruction of the insulin secreting β -cells in the pancreatic islets of Langerhans. Although the critical events that trigger the autoreactive process in T1DM are not clear, destruction of insulin-producing β -cells appears to be mediated by the activation of autoreactive T-cells that recognize several islet β -cells antigens, including insulin, glutamic acid decarboxylase (GAD) 65 and 67 isotypes, heat shock protein 60, and some uncharacterized β -cells antigens. The pro-inflammatory mediators in this process include two groups of related proteins: cytokines and chemokines. It had been demonstrated that in attempt to restrain autoimmunity, the immune system can selectively promote auto-antibodies production in a selective manner to eliminate the “harmful” key mediator of the autoimmune process. In the first part of our research, we have evaluated the presence of a selective auto-antibody response to any of the C-C chemokines that are expressed in the inflamed pancreas during the autoimmune process in new onset T1DM patients: 9 out of 10 newly diagnosed patient with T1DM developed a selective auto-antibody response to MIP-1 α (CCL3) and all were negative to other chemokines: MCP-1 (CCL2), MIP-1 β (CCL4) as well as to IL-8 (CXCL8) that is exclusively expressed in humans. The second step was to evaluate the presence of auto-antibodies in blood samples taken from the following group of patients: 30 new onset T1DM patients (within one week of diagnosis), 38 patients with prolonged T1DM (> 5 years), 20 normal controls, 20 prediabetic subjects (first degree relatives of patients with T1DM with positive autoantibodies): Anti MIP1 α antibody was positive in 27/30 (90%) of new onset diabetic patients, 19/20 (95%) of prediabetic subjects and 1/20 (5%) of normal controls (Figure 2). Comparing the presence of anti MIP1 α antibodies with other T1DM related autoantibodies in the new onset group: Anti-Insulin, anti-GAD and ICA were positive in 70%, 60% and 63% respectively compared to 27/30 (90%) positivity to MIP1 α . Moreover, MIP1 α auto-antibody was positive in 27/38 (71%) of patients with prolonged diabetes (more than 5 years duration). The current diagnosis of autoimmune diabetes is based on the presence of β -cell related auto-antibodies (Anti-Insulin., anti-GAD and ICA antibodies). A combined test of all 3 auto-antibodies covers 88% of patients. Therefore, an additional test as anti-MIP1 α will increase accuracy and reliability of the diagnosis of autoimmune diabetes. Moreover, anti-MIP1 α is positive in prediabetic patients and continues to be positive several years after the diagnosis of diabetes. We believe that this important autoantibody could serve as an excellent biomarker for the diagnosis of prediabetic patients, type 1 diabetic patients and autoimmune diabetes in adults and as an important immunological marker in prediction and prevention studies.

Distinct reactivity of cord blood mononuclear cells of newborns with risk of developing type 1 diabetes

K. Stechova¹, K. Flajsmanova¹, K. Bohmova¹, Z. Hladikova¹, M. Durilova¹, I. Spalova², D. Bartaskova³, P. Pithova³, M. Cerna⁴, K. Anelova⁵, D. Chudoba⁶, M. Pechova⁷, M. Faresjo⁸;

¹Paediatric Dpt., 2nd Medical Faculty of Charles University Prague, Czech Republic, ²Gynaecology and Obstetrics, 2nd Medical Faculty of Charles University Prague, Czech Republic, ³Internal Dpt., 2nd Medical Faculty of Charles University Prague, Czech Republic, ⁴NICU, Institute for the Care of Mother and Child, Prague Podoli, Czech Republic, ⁵Internal Dpt., Institute for the Care of Mother and Child, Prague Podoli, Czech Republic, ⁶Dpt. of biology and genetics, 2nd Medical Faculty of Charles University Prague, Czech Republic, ⁷Dpt. of biochemistry, 2nd Medical Faculty of Charles University Prague, Czech Republic, ⁸Div. of Paediatrics and Diabetes Research Centre, Faculty of Health Sciences, Linköping, Sweden.

Background: Incidence of type 1 diabetes (T1D) is increasing worldwide. The highest increase of T1D incidence in the Czech Republic is observed in pre-school age children. For T1D there is still no potent tool to recognise early signs of cellular autoreactivity, which leads to beta cells damage and development of the disease. The naive immune system of the newborn (not yet influenced by external factors) can be used as an important model for studies of the pathogenesis of T1D.

Aim: To study the response of cord blood mononuclear cells to diabetogenic autoantigen stimulation in babies with increased risk of developing T1D by protein microarray.

Methods: Cord blood samples of 22 healthy children (mean gestational age 37+6) born to a diabetic mother (marked as relatives) and 15 newborns with no family history of any autoimmune disease (controls, 38+1) were collected. Diabetes compensation of mothers was without problems (mean of their last GHBC was 5%). Production of 23 cytokines and chemokines (including all important Th1-, Th2- and Th3- cytokines) by cord blood mononuclear cells were detected. Production of cytokines and chemokines, pre- and post stimulation with a mixture of diabetogenic autoantigens (including GAD65, IA2 and proinsulin derived synthetic peptides), were compared by protein microarray and ELISA. Higher basal as well as autoantigen induced production of GM-CSF, GRO, GRO- α , IL-3, -7, -8, -15, MCP-2, MCP-3, MIG and RANTES were observed in the control group (at least $p=0.05$). The most evident differences between risk newborns and controls were observed in secretion of MCP-2 ($p=0.009$) and G-CSF ($p=0.03$) by autoantigen stimulation after subtraction of basal secretion.

Conclusions: Basal as well as stimulated cytokine and chemokine production differed between newborns with and without family history of T1D. Neonates with family history of T1D showed in general a lower overall cytokine and chemokine production. This may indicate a less mature immune responsiveness in neonates with increased risk for T1D.

GAD65 is released into the circulation by injured pancreatic islet β cells and functions as a plasma marker of islet injury

S. D. Chessler¹, M. A. Waldrop¹, A. T. Suckow^{1,2};

¹Department of Medicine, University of California, San Diego, La Jolla,

²Biomedical Sciences Graduate Program, University of California, San Diego, La Jolla, United States.

Background and Aims: GAD65 is a major autoantigen in autoimmune diabetes. The mechanism whereby autoreactivity to GAD65, an intracellular enzyme, is triggered is unknown, and it is possible that GAD65 may be released by injured pancreatic islet β cells. There is a great need for methods by which to detect and monitor ongoing islet injury. While there are no serum markers of islet injury, tests based on the measurement of circulating, discharged enzymes to monitor tissue injury have become an integral part of clinical care and research. If GAD65 is released by injured β cells and is furthermore able to reach the circulation, plasma GAD65 could function as a marker of β -cell injury. The aims of this study were:

1) to determine whether GAD65 is discharged by injured β cells, whether discharged GAD65 reaches the circulation, and whether detection of plasma GAD65 may eventually provide a means by which to monitor β -cell injury.

2) to provide general proof of principle that detection of discharged proteins in the circulation can provide a means by which to monitor islet injury.

3) to test the hypothesis that lethally and sub-lethally injured β cells discharge GAD65 *in vivo* and that therefore such autoantigen release may possibly contribute to the pathogenesis of anti- β cell autoimmunity.

Materials and Methods: A novel immunoassay was employed to determine plasma GAD65 levels in rats and mice treated with the β -cell-specific toxins alloxan and streptozotocin (STZ). Both diabetogenic, β -cell-lethal, and low, non-lethal doses of STZ were employed. Islet injury was assessed by immunohistochemistry and TUNEL staining. The half-life of GAD65 in the rat circulation was determined by measurement of GAD65 levels after injection of recombinant GAD65. Insulin and C-peptide levels were measured by ELISA.

Results: Alloxan and both low-dose and high-dose STZ induced GAD65 release into the circulation in a dose-dependent manner. GAD65 discharge was prolonged after low-dose treatment. Low-dose treatment also differed from high-dose in that it did not cause DNA strand breakage or alter islet morphology. In high-dose-treated rats, GAD65 release preceded hyperglycemia and, unlike insulin or C-peptide discharge, was consistently observed after toxin treatment. The half-time of elimination of GAD65 was ~3 h. In mice, which have very minimal islet GAD65 content, plasma GAD65 was not detected. In STZ-treated, ~90% pancreatectomized rats, after an initial, abrupt period of β -cell injury, plasma GAD65 levels were markedly lower than in control rats.

Conclusion: Taken together, these data demonstrate that GAD65 can be released into the circulation by injured β cells. Such autoantigen shedding may contribute to the pathogenesis of autoimmunity in the multiple low-dose STZ model and perhaps, more generally, in other forms of autoimmune diabetes. These results demonstrate that islet injury – at least in some circumstances – can be monitored by use of discharged, circulating proteins. This approach to the detection of tissue injury has proven to be of great utility with a variety of different pathogenic processes in different tissues. This is cause for optimism that this approach will be successful for detecting islet injury caused by processes such as insulinitis, transplant rejection and virus-induced islet damage. GAD65 is the first confirmed biomarker of ongoing β -cell injury.

Determination of GAD65 in pancreatic islets and its *in vitro* and *in vivo* degradation kinetics in serum using a highly sensitive enzyme immunoassay

M. Schlosser¹, U. Walschus¹, I. Klötting², R. Walther³;

¹Department of Medical Biochemistry and Molecular Biology,

Ernst-Moritz-Arndt University Greifswald, Karlsburg,

²Department of Laboratory Animal Science, Ernst-Moritz-Arndt University Greifswald, Karlsburg,

³Department of Medical Biochemistry and Molecular Biology, Ernst-Moritz-Arndt University Greifswald, Germany.

Background and Aims: Autoantibodies to GAD65 (GADA) are detectable in high prevalence at onset of T1DM but also in probands at risk of the disease. It has recently been proposed that the antigen itself might be useful as a biomarker of beta cell loss in probands following islet transplantation and in subjects at high risk for the disease. The aim of this study was to examine the GAD65 content of pancreatic islets from different species, the *in vitro* and *in vivo* half-life of GAD65 by determination of its degradation kinetics, and its release into circulation after streptozotocin-induced islet destruction.

Materials and Methods: GAD65 was measured using a sandwich ELISA based on two monoclonal GAD65-specific antibodies with different epitope specificities, one of them solid-phase bound for capturing GAD65 and a second biotin-labelled one for detecting bound GAD65. This assay allows the detection of GAD65 with a high sensitivity of 30 pg/ml.

Results: GAD65 was found in quantities of 78 ng (human), 43.7 ng (LEW.1A rat) and 37.4 ng (BB/OK rat) per 1,000 islets, respectively. No GAD65 was detectable in islets of BALB/c and NOD mice. The *in vitro* half-life of porcine GAD65 at 37°C in human serum, plasma and blood was comparable and amounted to 1.27 hours (CI 95%: 1.15–1.41), 1.32 h (1.23–1.41) and 2.16 h (1.75–2.66), respectively. Comparable results were found for human recombinant GAD65 at 37°C with individual serum samples of five healthy

human blood donors (half-life 2.35 h; CI: 2.03–2.72) as well as with a GADA-positive serum from a patient with T1DM (half-life: 1.93 h; CI: 1.55–2.41). These results suggest that the GAD65 degradation kinetics is not affected by the presence of GADA. The recovery rate of GAD65 was 97% in serum of healthy donors and 75% in the serum of the GADA-positive patient. After injecting 2,000 ng recombinant human GAD65 into LEW.1A rats, the *in vivo* half-life was 2.77 h (CI: 1.70–4.52). GAD65 was undetectable after 24 hours in these animals. Following experimental diabetes induction in LEW.1A rats by a single streptozotocin (STZ) application an increase of mean blood glucose levels from 7.7 mmol/l before STZ application to 8.2 mmol/l after 8 h, 20.4 mmol/l after 24 h and 23.9 mmol/l after 48 h indicates a loss of insulin production, however, no GAD65 was detectable in the circulation of animals. Thus, taking the assay's detection limit, the islet GAD65 content as well as the total blood volume into account, at least 13 islets in rat and 1,875 in human must be simultaneously destroyed to detect GAD65 in the circulation.

Conclusion: Therefore, these results should be taken into consideration in further studies aimed at examining the diagnostic relevance of GAD65 to detect graft rejection following islet transplantation. Additionally, studies involving the examination of sera from high-risk prediabetic subjects characterized by a genetic predisposition as well as multiple autoantibodies to islet antigens will help to assess the diagnostic relevance of GAD65 serum levels in the context of autoimmune diabetes.

Detection of free secretory IgA levels in type 1 diabetic patients

G. Nicoloff¹, A. Blazhev¹, A. Nikolov¹, C. Petrova²;

¹Department of Biology & Pathological Physiology,

²Department of Pediatrics, Medical University, Pleven, Bulgaria.

Background and Aims: Secretory IgA (S-IgA) is the main antibody secreted by the mucosa of the airways, gastrointestinal tract, and other mucosal tissues. A high proportion of Ig-producing cells in the mucosal lymphoid tissue is committed to the IgA isotype, and the majority of IgA in mucosa is derived from local synthesis. The importance of IgA in mucosal immunity is further supported by the presence of secretory component (SC) in S-IgA. The SC is a soluble proteolytic cleavage fragment of the extracellular domain of membrane-bound polymeric Ig receptor. Addition of SC to IgA confers increased stability on the resultant S-IgA by helping to hold the IgA monomers together. However the effect of the addition of SC on the biologic activity of IgA is still unknown. The aim of our study was to detect the levels of free S-IgA in patients with Type 1 diabetes mellitus

Materials and Methods: To this end we used a method for detecting immune complexes CIF-ELISA. Isolation of a new glycoprotein complement inhibition factor (CIF) from the parasitic plant *Cuscuta europea* seed, which appears to bind specifically to complement component C3 has been provided an unique tool for the measurement of immune complexes by means of ELISA-type techniques (CIF-ELISA). Free Secretory IgA were detected by using a two-step method consisting of (i) CIF-ELISA to remove immune complexes followed by (ii) a modified ELISA for detection of free S-IgA. The baseline study population consisted of 61 patients with Type 1 diabetes mellitus (mean age 12.3±4 years, diabetes duration 5.2±3.7 years). The control group consisted of 20 healthy children. Thirty-two of 61 diabetics had vascular complications (group 1) and 29 were without vascular complications (group 2).

Results: Diabetics showed significantly higher levels of free S-IgA (0,210±0,101 vs. 0,159±0,036; p=0,029) than controls. Patients without vascular complications did not show significantly higher levels of free S-IgA (0,184±0,076 vs. 0,159±0,036; p>0,05) compared to the control group. Patients with vascular complications showed significantly higher levels of free S-IgA (0,228±0,109 vs. 0,159±0,036; p=0,008) than controls. Significantly higher levels of free S-IgA between both patients groups were not observed (0,228±0,109 vs. 0,184±0,076; p>0,05). Diabetics showed correlation with age (r=0,25; p=0,042); duration (r=0,27; p=0,05); fructose (r=0,26; p=0,045) and puberty (r=0,329; p=0,011). Group 1 showed correlation with age (r=0,33; p=0,023) and puberty (r=0,46; p=0,004) while Group 2 showed correlation with fructose (r=0,379; p=0,036).

Conclusion: These findings show that free serum S-IgA levels are significantly higher in type 1 diabetic children than control group. Further prospective and longer studies of larger populations are needed to identify the role of free serum S-IgA in juvenile diabetes mellitus.

0469

Adiponectin levels decrease before clinical onset of type 1 diabetes but do not improve disease prediction in antibody-positive relatives

J. De Grijse¹, I. Truyen¹, C. Van Schravendijk¹, D. De Smet¹, K. Decochez¹, E. Vandemeulebroucke¹, M. Giri², B. Keymeulen¹, C. Mathieu³, L. Van Gaal⁴, P. De Pauw¹, I. Weets¹, D. Pipeleers¹, F. Gorus¹; Belgian diabetes Registry
¹Diabetes Research Center, Brussels Free University, ²Department of Endocrinology, University Hospital Ghent, ³Department of Endocrinology, University Hospital, Leuven, ⁴Department of Diabetology, Metabolism and Clinical Nutrition, University Hospital, Antwerp, Belgium.

Background and Aims: Insulin resistance has been proposed as risk factor for type 1 diabetes. We investigated whether decreased circulating levels of adiponectin – an abundant insulin sensitizer – can serve as additional predictive marker for type 1 diabetes in first degree relatives of known patients.

Materials and Methods: Adiponectin was measured yearly (ELISA, Linco) in 211 persistently islet antibody-positive (Ab⁺; positive for IAA, ICA, IA-2A and/or GADA at entry and in a repeat sample) first degree relatives (0–39 years) of type 1 diabetic patients and in 211 age- and sex-matched persistently antibody-negative (Ab⁻) relatives. Adiponectin levels were correlated with demographic and anthropometric data, antibody status, random proinsulin/C-peptide (PI/C) ratio and *HLA-DQ* genotype. During follow-up (median [interquartile range]: 81 [59–90] months), 37 Ab⁺ relatives developed type 1 diabetes.

Results: In the group of 422 relatives, baseline adiponectin correlated inversely with age and body mass index and was lower in males than in females especially after age 15 ($p < 0.001$). There was no correlation with antibody status or later development of diabetes. In 24 Ab⁺ relatives sampled fasted, adiponectin levels correlated significantly with homeostasis model assessment of insulin sensitivity (HOMA%*S*; $p = 0.006$). For 28 prediabetic relatives with at least 2 blood samples before clinical onset, adiponectin levels adjusted for age and sex decreased prior to diagnosis ($p = 0.001$) whereas no decrease occurred in 28 age- and sex-matched Ab⁺ non-prediabetic relatives followed over a similar interval. Adiponectin increased again significantly after start of insulin therapy ($p = 0.003$) in those relatives for whom a sample after diagnosis was available ($n = 13$). In Ab⁺ relatives ($n = 211$), a marked decrease in age- and sex-adjusted adiponectin levels during the first year after study entry could not predict type 1 diabetes nor complement risk assessment based on islet antibodies, *HLA-DQ* genotype and pancreatic hormones in Cox regression analysis.

Conclusion: Adiponectin levels decrease shortly before clinical onset of type 1 diabetes, possibly reflecting insulinopenia, but do not contribute to disease prediction in Ab⁺ relatives.

Suppression of rejection for allogeneic islet transplantation in vivo by donor antigen-specific CD4⁺CD25⁺ regulatory T cells

M. Zhang, S. H. Xu, Y. Xu, C. P. Liu, X. D. Mao, C. Liu;
 Department of Endocrinology, First Affiliated Hospital of Nanjing Medical University, Nanjing, Jiangsu, China.

Background and Aims: To investigate the potential effect of allogeneic antigen-specific CD4⁺CD25⁺ regulatory T cells on the suppression of rejection for allogeneic islet transplantation in vivo.

Materials and Methods: Donor antigen-specific CD4⁺CD25⁺ regulatory T cells (Treg cells) were generated by the addition of multiple intravenous injections of ICR mice splenocytes in vivo. Spleen cells were then pooled and enriched for CD4⁺CD25⁺ T cells by negative and positive selection by MACS in vitro, and were injected into diabetic BALB/cByJ mice. Six hundred ICR islets were allogeneically transplanted under the kidney capsule of streptozotocin-induced diabetic BALB/cByJ mice with a single dose of as few as 8×10^5 of donor antigen-specific Treg cells ($n=7$). Islet function was evaluated by in vivo glucose tolerance test. Grafts were harvested for histologic examination when rejection occurred or 30 days after transplantation. Homing and distribution of antigen-specific Treg cells were investigated by CFSE and FACS.

Results: In vivo, the mean survival time of recipients with islets and Treg cells were (34.57±17.15) days, whereas transplanted islets without Treg cells treatment survived a maximum of 13 days in control mice ($p<0.01$). At posttransplant day 30, recipients of islets with Treg cells had similar responses to glucose challenge compared with nondiabetic BALB/cByJ mice. On immunohistochemistry, the kidney capsules displayed higher insulin content and neoplastic microvessels than that in control group. The transferred antigen-specific Treg cells were resident in pancreatic node and mesenteric node.

Conclusion: Donor antigen-specific CD4⁺CD25⁺ regulatory T cells prolong islet graft survival and normoglycemia in transplanted allogeneic diabetic mice. Therefore, donor antigen-specific CD4⁺CD25⁺ regulatory T cells might be used as adjunctive therapy in patients undergoing islet transplantation.

In vitro 1,25-dihydroxyvitamin D₃-modulated dendritic cells: their altered T cell stimulatory capacity is reflected in an islet allotransplantation model

E. Van Etten, G. B. Ferreira, L. Overbergh, C. Mathieu;
 LEGENDO, Katholieke Universiteit Leuven, Belgium.

Background: 1,25-dihydroxyvitamin D₃ (1,25(OH)₂D₃) is a potent immunomodulator with the in vivo capacity to prevent and attenuate the occurrence of autoimmune diabetes in NOD mice and to prolong islet allograft survival. On cellular level, 1,25(OH)₂D₃ exerts its effects mainly through interference with normal dendritic cell (DC) development and behavior. A therapy based on the transfer of DCs that have been treated in vitro with 1,25(OH)₂D₃ could bypass the hypercalcemia observed upon in vivo use of this compound, thus potentiating its clinical immunomodulatory applicability.

Aims: The aim of this study was to investigate in vitro and in vivo the T cell-stimulatory capacity of in vitro 1,25(OH)₂D₃-modulated murine DCs as well as the outcome of DC transfer in murine allogeneic islet transplantation.

Methods and results: Murine bone marrow-derived mature DCs were generated (8 days GM-CSF + IL-4 followed by 48 hours LPS + IFN- γ) in the continuous absence (ctr-DC) or presence of 10^{-8} M 1,25(OH)₂D₃ (1,25D₃-DC). Analysis of surface marker expression (downregulated MHC II, CD80, CD86 and CD54; upregulated CD40, CCR5, F4/80 and DEC205) and cytokine production (inhibited IL-12; enhanced IL-10 and TNF- α) confirmed the modulated phenotype of 1,25D₃-DC. In vitro stimulation of T cells with 1,25D₃-DC inhibited proliferation ($p<0.05$) and shifted cytokine expression towards IL-10 and TGF- β (both $p<0.05$). In islet allotransplantation (BALB/C islets in alloxan-diabetic C57BL/6 mice), triple transfer of alloislet-primed syngeneic 125D₃-DC (days -10, -3 and 0 before transplantation) induced

graft-specific energy of recipient splenocytes. Although no robust tolerance to islet allografts could be induced (graft survival of 11.4 ± 2.2 days in 1,25D₃DC-treated recipients (n=5) versus 9.0 ± 1.0 days in non-treated controls (n=3), NS), primary-non-function of the graft occurring after alloislet-primed syngeneic ctr-DC treatment (n=4) was prevented.

Conclusions: Together, these data provide evidence that in vitro generation of murine DCs in the presence of 1,25(OH)₂D₃ alters their T cell-stimulatory capacity. The in vivo data suggests that with further refinement of the DC transfer regimen possibly a prolonged allograft survival could be achieved, equivalent to or better than in vivo 1,25(OH)₂D₃ treatment without the accompanying calcemic effects.

Long term survival of islet grafts by a novel approach of immunoisolation

B. J. de Haan, J. A. M. Kamps, M. M. Faas, P. de Vos;
Medical Biology, University Medical Center Groningen, The Netherlands.

Backgrounds and aims: The efficacy of immunoisolation in alginate-PLL membranes in order to transplant pancreatic islets in the absence of immunosuppression has been demonstrated by several groups. Unfortunately, large-scale application is hampered by limited longevity of the encapsulated islet tissue. A crucial factor limiting survival is an inflammatory response in the immediate period after transplantation. Directly after implantation the number of macrophages is increased at the transplantation site. In response to islet-derived cytokines (MCP-1) these macrophages secrete high quantities of deleterious cytokines (IL-1 and TNF) which stimulate the islets to produce even more islet-derived cytokines with a harmful circle of activation as a consequence. In the first two weeks post transplantation period 60% of endocrine tissue is destroyed and the remaining cells are not capable to maintain long-term normoglycemia. In the present study we test in a xenograft murine transplantation model the efficacy of a novel encapsulation approach to overcome the tissue response and its consequences in the immediate transplant period.

Methods: We designed a double encapsulation system in which contains islets enclosed in an inner membrane and liposomes containing deoxyspergualin (DSG). Immunoisolated AO-rat islets were encapsulated in this novel system and transplanted into streptozotocin diabetic male BL-6 mice and subsequently transplantation survival was compared with traditional control capsules without DSG.

Results: Since the immediate tissue response after implantation occurs reportedly in the first 14 days after implantation we modulated the liposome composition as such that DSG was released over a period of 14 days. All transplanted animals became normoglycemic within 1 week after implantation. The islet grafts encapsulated in the conventional control capsules survived for 43 (median) days which is much shorter as compared with the novel capsules containing the liposome enclosed DSG. These recipients are 83 (median) days normoglycemic and two are still ongoing and show no signs of graft failure.

Conclusions: Our study shows that inflammatory responses in the immediate post transplant period is crucial for the functional survival of immunoisolated islet graft. It also shows that temporary suppression of this response is a successful approach for prolongation of the graft survival.

Assembly of standardised pancreatic islets by the “Hanging Drop”-technology: improved secretory function of small pseudoislets

G. Cavallari^{1,2}, R. Zuellig¹, R. Lehmann³, M. Weber¹, W. Moritz¹;
¹Clinic for Visceral and Transplantation Surgery, University Hospital, Zurich, Switzerland, ²Department of Surgery Intensive Care and Transplantation, Sant’Orsola-Malpighi University Hospital, Bologna, Italy, ³Division of Endocrinology and Diabetes, University Hospital, Zurich, Switzerland.

Background and Aims: Rejection and hypoxia are the main factors which limit islet engraftment in the recipient liver in the immediate posttransplant period. Recently we reported a negative relationship of graft function and

islets size concluding that small islets are superior to large islets. Islets can be dissociated into single cells and reaggregated into so called “pseudoislets”, which are functionally equivalent to intact islet. The aim of our study was develop a technique that enables to obtain pseudoislets of defined, preferably small dimensions.

Materials and Methods: Islets were harvested from Lewis rats by collagenase digestion and thereafter dissociated into single cells by trypsin treatment. Fractions with defined cell numbers were seeded into single drops onto cell culture dishes which were inverted and incubated for 5–8 days under regular cell culture conditions. Newly formed pseudoislets were analysed for dimensions, morphology, cellular composition and glucose stimulated insulin secretion (GSIS).

Results: The volume of reaggregated pseudoislets strongly correlated with cell number ($r^2=0.995$). Tissue loss could be minimized by performing reaggregation in presence of elevated glucose concentration (11mM) and the GLP-1 analogue Exendin-4 (100 nM). Morphology, cellular composition and architecture of reaggregated islets were comparable to intact islets. GSIS of small pseudoislets, composed of 250 islet cells, was increased by 2.7-fold ($p<0.001$) when compared to a total entity of freshly isolated islets. In small pseudoislets, insulin secretion at high glucose was stimulated by 10.6-fold, while glucose stimulated insulin secretion in regular intact islets was enhanced only by 2.9-fold ($p<0.001$).

Conclusion: With “hanging drop” culture method pseudoislets of standardized size and regular shape can be generated, which do not differ from intact islets in terms of cellular composition and architecture, but exhibit a markedly improved insulin secretory capacity. The concept of small pseudoislet could foster new approaches in islet cell replacement therapy.

Different parameters of islet volume and size as predictors for islet transplantation outcome

P. A. Gerber¹, P. Kugelmeier², R. Zuellig¹, V. Pavlicek¹, M. Weber², G. A. Spinaz¹, R. Lehmann¹;
¹Endocrinology and Diabetes, University Hospital Zurich, Switzerland, ²Transplantation Surgery, University Hospital Zurich, Switzerland.

Background and Aims: It has been previously shown that small islets show better function and survival in vitro as well as in vivo as compared to large islets both in animal models and human islet transplantation. In the last years it became increasingly clear that 5 years after islet transplantation, a majority of patients lose insulin independence. In the present study different parameters of islet transplantation were associated with beta cell function after transplantation to test which quality of transplanted islets best predicts the outcome of islet transplantation.

Materials and Methods: We correlated stimulated C-peptide levels 3 months after transplantation with the volume of transplanted islets (measured as islet equivalents IEQ, total number of transplanted islets, surface of islets, islet mantle volume, volume of islets with a diameter less than 150µm, and the isolation index (IEQ / islet number)). All parameters are corrected by kg of recipient weight.

Results: The volume of transplanted islets did not correlate well with stimulated C-peptide levels after transplantation ($R^2 = 0.22$), nor did the surface of islets ($R^2 = 0.32$) or the mantle volume of islets ($R^2 = 0.23$). The correlation improved by correlation of stimulated C-peptide levels with the volume of islets with a diameter less than 150µm ($R^2 = 0.62$) or the number of transplanted islets ($R^2 = 0.73$, figure 1), and the best prediction was achieved when we used the isolation index ($R^2 = 0.78$).

Conclusion: This study demonstrates that islet size is an important predictor for the outcome of islet transplantation assessed by stimulated C-peptide levels and that the isolation index, and more simple the islet number are the best predictors. The fact that islet surface and islet mantle volume did not predict transplantation outcome in contrast to islet number and the volume of small islets supports the hypothesis that in large islets the whole islet is destroyed by apoptosis/necrosis initiated by central hypoxia and that only the fraction with small islets determine the transplantation outcome. At our institution, the finding of the superiority of small islets led to the use of islet isolations for transplantation which so far have been considered insufficient for a good clinical outcome because of their low volume. The use of the islet number and isolation index for evaluation of islet preparations instead of IEQ increases the percentage of transplantable islet isolations. (Fig. 1)

The deleterious effects of Cytomegalovirus on the functional survival of rat islet isografts

M. J. Smelt, M. M. Faas, A. de Haan, B. J. de Haan, P. de Vos;
Pathology and Laboratory Medicine, University Medical Centre Groningen,
The Netherlands.

Background and Aims: Clinical application of islet transplantation has become a realistic option since the introduction of new immunosuppressive strategies, also known as the Edmonton protocol. However, the long term overall transplantation success rate is still unsatisfactory low. Graft failure is generally thought to be caused by metabolic exhaustion, alloreactivity and recurring autoreactivity. Recently, an association between Cytomegalovirus (CMV) infections and reduced graft function, i.e. allograft rejection, has been found in solid organ transplants, such as heart, lung, liver and kidney transplants. As the deleterious effects of viral infections on beta cells are well recognized, we hypothesize that viral infections, such as Cytomegalovirus, could also play an important role in islet graft failure. In this study, the effect of CMV infection on the survival and function of rat islet isografts was investigated.

Materials and Methods: STZ-diabetic AO rats received a isogenic islet transplant of 5 μ l under the kidney capsule and one day later, the animals received a rCMV infection of 2×10^7 pfu i.p.; non infected recipients of islet isografts served as controls. 4 weeks after transplantation IVGTT (bolus injection of 200 mg D-Glucose) and MTT (2 gr. rat chow (53% carbohydrates, 20% protein and 5% fat) were performed and after 100 days, rats were sacrificed and pancreas, salivary glands and the transplant were retrieved for histological examination.

Results: All islet graft recipients became normoglycaemic after transplantation. Within 14 days after transplantation, the basal blood glucose levels were decreased from $28,26 \pm 5,67$ mM to $5,9 \pm 0,7$ mM in the control group (n=5) and from $27,68 \pm 2,93$ mM to $7,4 \pm 5,2$ mM in the CMV infected animals (n=5). The control animals became normoglycaemic at day 7 ± 4 after transplantation. The time to reach normoglycaemia was somewhat longer in the CMV infected animals, which became normoglycaemic at day 12 ± 9 . Despite the longer period to reach normoglycaemia, no signs of CMV disease were seen, and weight gain was similar in the CMV infected animals compared to the control animals. The CMV infection had a profound effect on the function of the islets. CMV infected recipients showed a reduced glucose tolerance in both the IVGTT and MTT. During the IVGTT, CMV infected animals showed an Insulin Area Under Curve (AUC₀₋₁₂₀) of $192 \pm 7,4$ A.U., which was $197,3 \pm 21$ A.U. in the control animals. Glucose Area Under Curve (AUC₀₋₁₂₀) was 1628 ± 275 A.U. in the CMV infected animals, compared to only $1152 \pm 96,5$ A.U. in the control animals. During the MTT, CMV infected animals showed an AUC₀₋₁₂₀ of $142 \pm 9,4$ A.U., compared to 206 ± 29 A.U. in the control animals. AUC₀₋₁₂₀ was 1118 ± 249 A.U. in the CMV infected animals, compared to $1024 \pm 35,3$ A.U. in the control animals.

Conclusion: These results show that CMV has a direct deleterious effect on islet graft function. Although the graft is able to maintain basal blood glucose levels within the normal range, the graft function is disturbed after CMV infection. Further research will focus on the mechanism by which CMV affects islet graft function and on the effect of CMV on islet allografts.

Immunological profile, choice of immunotherapy and CMV viraemia in pancreas transplant

E. Favaro¹, L. Semperboni¹, S. Pinach¹, F. Giaretta¹, M. Rossetti¹,
R. Romagnoli², I. Miceli¹, M. Cassader¹, P. Cavallo Perin¹, R. Quadri¹,
M. Zanone¹;

¹Dept of Internal Medicine, University of Turin, Italy,

²Liver Transplant, University, Turin, Italy.

Background and Aims: It has been suggested that anti-ATG (anti-thymocyte globuline) induction therapy increases Cytomegalovirus (CMV) infection risk, and newly acquired infection or reactivation from a latent state have been associated with increased rate of allograft rejection and incidence of other opportunistic infections and morbidity. We investigated the occurrence and effect of CMV infection after pancreas transplant, correlation with induction therapy, rejection episodes and autoimmune reactivity.

Materials and Methods: We followed 21 type 1 diabetic patients (mean age 42 years, mean duration of diabetes 29 years) recruited during a 7 year period, for a mean of 39 months after simultaneous pancreas-kidney (SPK), pancreas-liver (1 case) or pancreas alone transplant(1). Induction therapy consisted of ATG in 1 patient and anti-CD25 in the others. All patients received tacrolimus, mycophenolate mofetil and short term steroids. Rejection episodes were treated with ATG and/or steroids. CMV antigenemia, number of positive leucocytes, CMV DNA level in plasma were monitored. Islet autoAbs were monitored before and after transplant in all recipients, and flowcytometric analysis of suppressor function of CD4⁺CD25⁺ T cells was performed.

Results: Transplant was successful at follow up in all but 2 patients (the pancreas alone recipient, with loss of function after 1 year, and 1 SPK with partial loss of function). Overall incidence of CMV infection (all patients on ganciclovir prophylaxis) was 43%, with different distribution between the ATG (induction or rejection treatment) group (75%) and the anti-CD25 group (35%). The rates of CMV infection according to the donor and the recipient serological status were: D-/R-0%, D-/R+0%, D+/R+67% and D+/R-33%. Rejection episodes (43%) had a similar distribution between CMV-infected and non infected patients and CMV viraemia did not occur earlier than in infected patients without rejection episodes. Both patients with partial or total graft loss were treated with ATG and were CMV infected. 14 patients (66%) were anti-GAD Ab +, 2 (9%) anti-IA2 Ab+, 6 (3%) ICA+ (5 also anti-GAD+). The Abs

persisted after transplant, and 2 recipients became anti-GAD+. The pancreas recipient with graft loss became positive for all 3 Abs after transplant, and had several episodes of detection of CMV early antigen and high CMV viraemia, before and after ATG treatment for rejection episodes. In this patient, by flowcytometric analysis, a higher proportion of the CD4⁺ CD25⁺ population coexpressed activation markers and intracellular CTLA-4, as described in recent-onset type 1 diabetic patients, possibly reflecting a disturbance of the balance, and deficiency in function in this population.

Conclusions: Although without statistical significance possibly related to the limited number of cases, ATG induction or rejection treatment increases CMV infection risk, and positive CMV donor status was associated with higher incidence of CMV viraemia. We did not detect more frequent CMV infection in rejection episodes, thus not corroborating the hypothesis of increased incidence of rejection episodes among CMV-infected allograft recipients. This may be related to the anti-CD25 induction therapy and to CMV prophylaxis. CMV infection could however be linked to recurrence of islet autoimmunity in the patient with graft failure.

²Diagnostic Radiology, Fondazione Centro San Raffaele del Monte Tabor,

³Islet Transplant Unit, Fondazione Centro San Raffaele del Monte Tabor,

⁴Vita-Salute San Raffaele University, Milano, Italy.

Background and Aims: Islet transplantation is one of the most promising and effective therapies for restoring normoglycemia in type 1 diabetic patients. Monitoring graft loss, caused either by immunological or non-immunological events, occurring in the first phase after transplantation and at later stages of patient's life is a very important issue. It is therefore of pivotal importance to develop a reliable non-invasive islets imaging modality for the follow-up of the graft fate and for studying the relationships between transplanted islet mass and insulin independence, graft function and diabetes complications. MRI represents an ideal tool for islet imaging because it provides high spatial and high contrast resolution images and can be transferred from animal models to the human clinical setting. Very promising results have been recently shown with islets of Langerhans, imaged using MRI (4.7T) after superparamagnetic iron oxide particles (SPIO) uptake. The aim of the project is to set up a protocol to label human islets in vitro with clinically approved SPIO (Endorem®) and to visualize them in 1.5T clinical and in 7.0T research scanners after transplantation. :

Materials and Methods: Different labeling parameters using Endorem® have been optimized in order to achieve the best-possible uptake preserving islet viability, insulin secretion, expression profile of relevant genes and proinflammatory status of islets. The persistence of Endorem®-labeled islets and their ability to revert diabetes similarly to non-labeled islets is being tested both with mouse islets in syngeneic liver transplantation studies and with human islets transplanted into nude mice, made diabetic by streptozotocin injection. MRI (T2*) protocols, which can be translated into imaging of human islets in transplanted patients, are under development. :

Results: Iron labeled human islets do not show altered viability, reduced glucose induced insulin secretion or higher activation of pro-apoptotic pathways in vitro. Diabetic mice transplanted with 450 islets ± SPIO became normoglycemic and islets incorporating iron could be persistently detected by MRI in mice many days after transplantation while non labeled islets could not be visualized. Monitoring persistence of hypointense islet signals is still ongoing. We have been able to visualize labeled islets in the mouse model both in 7.0T research and in 1.5T clinical scanners.

Conclusion: Our results, according to previous reports, provide the evidence that islets can be labeled with Endorem® and can be imaged with MRI both with a 7.0T research and also using 1.5 T clinical scanners. The future objectives of our research are to better define the behavior of Endorem® labeled islets transplanted in animal models and to transfer the developed islets labeling and MRI protocols to humans.

³Department of Diabetology, University Hospital, Montpellier, France, ⁴Islet isolation laboratory, University Hospital, Geneva, Switzerland, ⁵Department of Urology, University Hospital, Lyon, France, ⁶Department of Diabetology, University Hospital, Besançon, France, ⁷Department of Diabetology, University Hospital, Lyon, France, ⁸Department of Nephrology, University Hospital, Lyon, France, ⁹Department of Nephrology, University Hospital, Grenoble, France, ¹⁰Department of Diabetology, University Hospital, Grenoble, France.

Background and Aims: The aim of this study was to evaluate the health-related quality of life in non uremic brittle type 1 diabetic patients after pancreatic islet transplantation in the Gragil 2 trial

Materials and Methods: From September 2003 to October 2005, 10 type 1 diabetic patients with severe hypoglycaemic events received 11 089±505 IEQ/kg according to the Edmonton protocol. Patients answered to the 36-item Short Form Health Survey (SF-36) and the Diabetes Quality Of Life (DQOL) questionnaires at the inclusion and 6 and 12 months after islet transplantation. SF-36 generic questionnaire assessed global health status while DQOL specific questionnaire analyzed five aspects related to diabetes: satisfaction, impact, social and vocational worry, diabetes worry, and global well-being according to a scoring scale from 0 (worse) to 100 (best).

Results: Twenty seven questionnaires were analysed. At six months post-transplantation, the physical evaluation score of SF-36 increased significantly from 36±9 to 49±10 (p= 0.021) while the psychological evaluation score remained stable. The global perception of health state was improved at 6 and 12 months post-transplantation: 30±16 vs. 78±30 (p=0.01) and 79±17 (p=0.016) respectively. At six months post-transplantation, DQOL revealed a significant decrease of the diabetes impact on the quality of life which was maintained at 12 months: 45±14 vs. 68±13 (p=0.011) and 63±8 (p=0.018). While all patients had functional islets (C peptide > 0.5ng/ml) at 6 months post-transplantation and 8/10 patients at one year, 8/10 patients were insulin-free six months after transplantation and 5/10 one year after islet graft. Severe hypoglycaemic events disappeared in all patients. Severe adverse events requiring or prolonging hospitalization occurred in 3 patients.

Conclusion: Our data show that pancreatic islet transplantation improves quality of life in brittle type 1 diabetic patients despite a need for insulin therapy in 50% of patients. The disappearance of severe hypoglycaemic events could likely contribute to this beneficial aspect of islet transplantation.

PS 29 Regulation of glucagon synthesis and release

0479

Proglucagon processing can be altered to produce GLP-1 in pancreatic alpha cells

N. M. James¹, L. E. Pritchard¹, D. Livesey², D. M. Smith², A. White¹;

¹University of Manchester, United Kingdom,

²Astrazeneca, Macclesfield, United Kingdom.

Background and Aims: The incretin hormone GLP-1 is primarily synthesised in the L-cells of the gut through the posttranslational cleavage of proglucagon by proprotein convertase 1 (PC1). It increases insulin secretion from the pancreas and augments beta cell mass. Pancreatic alpha cells also express proglucagon but it is normally cleaved by PC2, to yield glucagon. Emerging evidence suggests that alpha cells can adapt to produce GLP-1, possibly by upregulation of PC1. The aim of this study is to identify circumstances where processing of proglucagon can be switched to yield pancreatic GLP-1.

Materials and Methods: For regulation of GLP-1 and glucagon secretion, alpha TC1-6 cells were seeded at 1×10^5 cells per well and incubated overnight. After pre-incubation for 30 minutes in Krebs Ringer HEPES (KRH) buffer containing 25mM glucose, the cells were incubated in KCl (40mM) KRH for 30 minutes or with different concentrations of glucose (0–35mM). Islets from PC2 knockout (PC2^{-/-}), heterozygote (PC2^{+/-}), and wild-type (PC2^{+/+}) mice were isolated using collagenase and cultured at 20 islets per well for 2 days in RPMI (11mM glucose). Glucagon was assessed by an enzyme immuno assay (CosmoBio, with a detection limit of 0.02 pmol/ml). Active GLP-1 was measured by ELISA (Linco, with a detection limit of 10 fmol/ml)

Results: GLP-1 was released from alpha TC1-6 cells over 30 minutes (4.2 ± 0.5 fmol/ 10^5 cells; n = 4), but secretion was not stimulated by high or low glucose concentrations. However, glucagon secretion was stimulated from the alpha TC1-6 cells in response to low glucose (0.3 ± 0.07 pmol/well at 0mM glucose vs. 0.1 ± 0.03 pmol/well at 35mM glucose; n = 4, p < 0.05). To determine if GLP-1 was released from secretory vesicles, cells were stimulated with 40mM KCl. GLP-1 levels didn't change, but glucagon release was stimulated (0.1 ± 0.03 pmol/well at basal, vs. 0.2 ± 0.02 pmol/well at 40mM KCl; n = 4, p < 0.05). To establish if proglucagon processing can be changed from glucagon to GLP-1 by decreasing PC2, islets from PC2 knockout mice were studied. Glucagon was virtually absent in PC2^{-/-}, and decreased in PC2^{+/-} (265.5 ± 18.0 fmol/islet; n = 6) vs. PC2^{+/+} (453.3 ± 43.0 fmol/islet; n = 6), with a similar decrease in glucagon secretion from the islets. Conversely GLP-1 levels were increased in PC2^{-/-} (4.7 ± 0.3 fmol/islet; n = 6, p < 0.001) and PC2^{+/-} (0.8 ± 0.2 fmol/islet, n = 6) vs. PC2^{+/+} (0.3 ± 0.1 fmol/islet, n = 6) when measured in total islet lysates, with similar results for its secretion. PC2^{-/-} mice also displayed improved glucose tolerance following an intraperitoneal glucose tolerance test, (AUC 15.7 ± 2.5 mmol/h, n = 6 vs. 22.2 ± 0.8 mmol/h, n = 7; p < 0.01, after a glucose load of 2g/kg).

Conclusion: GLP-1 is released from the pancreatic alpha TC1-6 cell line. However, the GLP-1 does not appear to be in the regulated secretory vesicles, in contrast to glucagon, release of which is stimulated by low glucose and KCl. The loss of PC2 from the alpha cell in PC2^{-/-} mice causes the expected loss of glucagon secretion, but interestingly, there is an increase in GLP-1 in islets. This switch from glucagon to GLP-1 may contribute to the improved glucose tolerance in these animals. Taken together these results indicate that GLP-1 can be released from the pancreatic alpha cell, although how the processing of proglucagon to glucagon and GLP-1 is regulated needs to be determined. The importance of local GLP-1 production in the islet remains unknown, however it may have a role in augmenting beta cell mass.

Targeting the glucagon receptor for glycaemic control and beyond

B. B. Zhang¹, S. Conarello¹, G. Jiang¹, Z. Li¹, C. Li¹, J. Woods¹, E. Zycband¹, R. Bergeron¹, R. Sinha Roy¹, L. Zhu¹, E. Muise¹, J. Thompson¹, K. Wong¹, M. Charron², J. Mu¹;

¹Merck Research Laboratories, Rahway, United States,

²Biochemistry, Albert Einstein College of Medicine, Bronx, United States.

Background and Aims: Glucagon signaling leads to stimulation of hepatic glucose output, providing a major counter regulatory mechanism for insulin. Elevated glucagon levels or altered insulin to glucagon ratios are associated with the development of type 2 diabetes. In contrast to its role in glycemia control, less is known about the importance of glucagon in adiposity and body weight control. It was reported previously that glucagon receptor knockout (KO) mice develop normally and have lower plasma glucose on a normal diet.

Materials and Methods: To further investigate the role of glucagon signaling in metabolic control and glucose homeostasis, wild type (WT) and KO mice were fed with high fat diet (HFD) to induce insulin resistance and injected with low dose streptozotocin (STZ) to induces beta cell damage. The animals were evaluated for changes in their metabolic phenotype as well as pancreatic islet morphology. Effects of deletion of the glucagon receptor gene on the ob/ob background were also assessed in mice. To better understand the role of the glucagon receptor in energy homeostasis, we performed transcriptional profiling using tissues from HFD treated WT or KO mice.

Results: In comparison with the WT mice, KO mice exhibited decreased body weight and food intake, reduced plasma glucose levels, and improved glucose tolerance. Elevated glucagon-like peptide-1 (GLP-1) levels and reduced gastric emptying were also observed in KO mice. KO mice manifested reduced HFD-induced hyperinsulinemia and hyperleptinemia and were resistant to the development of hepatic steatosis. Moreover, STZ induced beta cell damage and hyperglycemia were observed in WT mice, but not in KO mice. Furthermore, glucagon receptor deletion in ob/ob mice led to reduced adiposity, improved glycemic control and increased energy expenditure. Transcriptional profiling of liver and adipose tissue from WT and KO mice on regular diet and HFD highlighted the role of glucagon signaling in the regulation of lipid metabolism and energy homeostasis. In WT mice, HFD feeding induced significant transcriptional changes in liver and white adipose tissue (WAT), most of which were not apparent in KO mice. The largest category of the differentially regulated genes in liver or WAT is related to lipid metabolism, including genes important for lipogenesis, fatty acid oxidation or lipolysis. For example, HFD treatment induced expression of CD-36, PPAR γ , acetyl-CoA dehydrogenase, and endothelial lipase in the liver of WT mice, but not in KO mice. Expression of adiponectin, adiponectin receptor 2, Glut4 and ATGL was suppressed by HFD in the WAT of WT mice only. Furthermore, GCGR deletion resulted in upregulation of FGF21 (a recently identified metabolic regulator) in liver of KO mice; the change in the gene expression also correlated with circulating FGF21 polypeptide levels.

Conclusion: These results imply that differential changes of the identified genes in WT and KO mice likely contribute to the lean phenotype of GCGR KO mice. Antagonizing the glucagon receptor will have beneficial effects that could extend beyond glycemic control to amelioration of multiple defects associated with metabolic syndrome.

0481

Glucose-dependent short-term regulation of glucagon gene transcription in pancreatic alpha-cells

T. Moede, I. B. Leibiger, D. Kaiser, P.-O. Berggren, B. Leibiger;

Department of Molecular Medicine & Surgery, Karolinska Institutet, Stockholm, Sweden.

Background and Aims: The pro-glucagon gene is expressed in alpha-cell, intestinal L-cells and specific neurons, but due to different posttranslational processing only the pancreatic alpha-cell produces and secretes glucagon. The importance of both insulin and glucagon for glucose homeostasis necessitates a strict regulation of release and biosynthesis of both hormones. While a tight connection between insulin release and insulin gene transcription through a positive feedback involving the insulin receptor has been shown, little is known about a similar autocrine feedback mechanism in pancreatic alpha-cells on glucagon gene transcription. The aims of this study are therefore:

- 1.) To study whether there is similar link between glucagon release and transcription.
- 2.) To investigate the signaling pathways involved in this feedback mechanism.

Materials and Methods: We employed mRNA analysis and online monitoring rat glucagon-promoter (–775 to +7 bp) driven DsRed expression to determine glucagon gene transcription. Glucagon release was measured by RIA. Cells were stimulated by treatment with either various glucose concentrations (1 to 16.7 mM glucose) for 15 min or with 200 pmol/ml glucagon at high, non-stimulatory glucose (16.7 mM). To investigate the involvement of the glucagon receptor and various protein kinases, cells were incubated with pharmacological inhibitors or inhibitory peptides 30 min prior to and during the stimulation. All experiments were performed on the alpha-cell line alphaTC1-9.

Results: Stimulation of alphaTC1-9 cells with 1 mM to 3 mM glucose for 15 min resulted in a 2.7 to 3.6-fold increase in glucagon release and in a 1.5 to 1.8-fold increased glucagon promoter activity measured as increase in DsRed-fluorescence. Glucose concentrations that did not elicit glucagon release (5 to 16.7 mM) did not stimulate glucagon gene transcription. Addition of 200 pmol/ml exogenous glucagon at high, non-stimulatory glucose lead to a similar increase in glucagon gene transcription as stimulus-secreted glucagon. The stimulatory effect of either glucagon or low glucose was abolished when the cells were pre-treated with either 1 μM of the glucagon-receptor blocking-peptide des-His1-[Glu9]-glucagon-amide or 20 nM glucagon receptor antagonist II. Furthermore, 100 μM of the protein kinase A inhibitor RpCAMPS also abolished the stimulatory effect of both glucagon and low glucose. These findings were confirmed on the RNA-level.

Conclusion: These results suggest, that glucose-dependent short-term regulation of glucagon gene transcription is dependent on a feedback mechanism involving secreted glucagon, the glucagon receptor and protein kinase A.

Pax6 positively regulates PC2 expression in glucagon expressing cells through the activation of cMaf and Beta2 proteins

L. S. Katz, E. Marthinet, Y. Gosmain, J. Philippe;
Diabetes Unit, Division of Endocrinology, Diabetes and Nutrition,
University Hospital, Geneva, Switzerland.

Background and Aims: Prohormone Convertase 2 (PC2) is the main processing enzyme in pancreatic α cells, where it processes proglucagon to produce glucagon. Pax6 is a master gene in the development of the pancreas, previously shown to regulate glucagon gene transcription. To understand the role of Pax6 in endocrine pancreas development and function we first investigate its target genes in α cells.

Materials and Methods: InR1G9 (hamster glucagon producing cells) clones expressing a dominant negative (DN) allele of Pax6 and control clones were studied by RT-PCR and western blot for expression of genes and proteins, respectively important for α cell differentiation and function. ChIP, EMSA, reporter assays and siRNA experiments were carried in InR1G9 cell culture, and when possible, also in the mouse glucagon producing cell line, α TC1, or in a heterologous cell line, BHK, in order to characterize the interactions between cMaf, MafB, Beta2, and Pax6 transcription factors with the PC2 promoter.

Results: We report that glucagon and PC2 mRNA and protein levels decrease in Pax6-DN cells and cells transfected with siRNA for Pax6 compared to control cells. Pax6 activates glucagon gene transcription through the G1 and G3 promoter elements. However, no binding sites of Pax6 on the PC2 promoter were identified whereas we found MAF and Beta2 putative binding sites on the PC2 promoter. We confirmed the relevance of these sites by ChIP and EMSA assays, and demonstrated transactivation of the PC2 promoter by both cMaf and Beta2. In order to find the mechanisms by which Pax6 might regulate the PC2 gene, we measured cMaf, MafB and Beta2 mRNA in Pax6-DN clones. cMaf and Beta2, but not MafB were found to be decreased by 60 and 50%, respectively and direct targets of Pax6 by ChIP, EMSA and transfection assays. Furthermore, overexpression of cMaf and Beta2 in Pax6-DN clones completely corrected the observed decrease in PC2 gene transcription.

Conclusion: This study establishes Pax6 as critical for glucagon synthesis by activating directly proglucagon gene transcription as well as indirectly

through the activation of cMaf and Beta2, which also activate the glucagon gene and the PC2 promoter.

Postprandial lipaemia is associated with increased glucagon levels and inadequate glucose-induced suppression of glucagon secretion in healthy men

A. Niederwanger, M. Kranebitter, C. Ciardi, T. Tatarczyk, J. R. Patsch, M. T. Pedrini;
General Internal Medicine, University of Innsbruck, Austria.

Background and Aims: A great wealth of studies has been published on the effect of lipids on insulin sensitivity and insulin secretion. The role of plasma lipids in the regulation of glucagon secretion, however, has received much less attention. Previous studies on the effect of lipids on glucagon secretion have led to conflicting results. Abnormalities in glucagon secretion have been implicated in the development of type 2 diabetes for a long time; some thirty years ago, Unger and Orci proposed that in addition to absolute or relative insulin deficiency, an elevated plasma glucagon level plays a key role in the pathogenesis of diabetes. More recent studies revealed that in addition to elevated plasma glucagon levels, reduced glucose-induced suppression of glucagon secretion represents another feature of insulin resistant states. We have recently demonstrated that postprandial lipemia through elevation of triglyceride-rich lipoproteins induces insulin resistance in vitro in cultured skeletal muscle cells and in vivo in healthy male subjects independently of NEFA levels. The aim of the present investigation was to study the effect of postprandial lipemia on plasma glucagon levels as well as on glucose-induced suppression of glucagon secretion in vivo in healthy men. Our study design enabled us to assess the role of plasma NEFA levels in the regulation of glucagon secretion.

Materials and Methods: We performed a randomized crossover study involving 7 healthy volunteers to compare both basal glucagon secretion and glucose-induced suppression of glucagon secretion between the postabsorptive and the postprandial state. For glucose-induced suppression of glucagon secretion, two ivGTTs were performed, one postabsorptively and the other postprandially, i.e. 3h after meal consumption. Two fat-enriched meals were employed with Meal 1 raising plasma levels of both triglycerides and NEFA, and Meal 2 raising triglycerides only.

Results: Basal glucagon levels rose from 80.7±18.2 postabsorptively to 104.2±17.5 μg/l postprandially with Meal 1 (P=0.017) and from 86.1±16.2 to 106.8±30.1 μg/l with Meal 2 (P=0.028).

With glucose injection, glucagon levels immediately decreased with the percent decline not differing between the postabsorptive and the postprandial state. However, taking into account that glucose-induced insulin secretion increased postprandially much more than postabsorptively (by 205.5±145.4 vs. 94.2±41.7 mU/l with Meal 1, P=0.016 and by 174.8±111.5 vs. 68.5±30.3 mU/l with Meal 2, P=0.02), the postprandial suppression of glucagon was inadequate.

Conclusion: Since postprandial lipemia induces a state of insulin resistance, our observations may be interpreted to suggest that either postprandial triglyceride-rich lipoproteins themselves or the acute state of insulin resistance induced by these lipoproteins are responsible for the observed changes in glucagon secretion during postprandial lipemia.

Effect of pioglitazone on glucagon secretion in persons with impaired glucose tolerance

V. Pauvaday¹, G. Dunseath¹, R. Peter¹, R. Chudleigh¹, O. Sawyer², S. Luzio¹, M. Evans², D. R. Owens¹;

¹Diabetes Research Unit, Cardiff University,

²Diabetes, Llandough Hospital, Cardiff, United Kingdom.

Background and Aims: Postabsorptive plasma glucose concentrations are regulated not just by insulin secretion but also glucagon concentrations. Both fasting and postprandial glucagon concentrations are elevated in subjects with impaired glucose tolerance (IGT) compared to subjects with normal glucose

tolerance. The aim of the study was to investigate the effects of pioglitazone on glucagon secretion in subjects with IGT.

Materials and Methods: 15 subjects (9 male) with IGT (WHO criteria) were recruited into this randomised, double-blind, placebo controlled study. All subjects undertook a standard 500kcal meal tolerance (MTT) and intravenous glucose tolerance (FSIVGTT) test on consecutive days following an overnight fast. Plasma glucose (PGs) and glucagon (PGn) were measured following the MTT. Insulin sensitivity (SI) was calculated from the FSIVGTT using the CIBA GEIGY programme. Following 6 months treatment with either placebo or Pioglitazone (Pio 30mg od) all tests were repeated.

Results: In the placebo group, subjects were aged (mean±SEM) 60.3±4.2years, with weight 75.7±7.1kg, BMI 27.4±1.6 kg/m² and HbA_{1c} 5.6±0.2% and in the Pio group age 61.7±3.3years, weight 74.8±3.9kg, BMI 27.8±1.1kg/m² and HbA_{1c} 5.8±0.1%. There were no significant differences between groups or between baseline and follow up. There was a significant decrease in fasting PGs following Pio (5.8±0.2 vs 5.5±0.1 mmol/L; p=0.018) compared to placebo (6.0±0.2 vs 5.6±0.2 mmol/L; p=0.398). However there were no differences in area under the prandial PGs profiles (AUC_(PGs-0-4hr)) after 6 months in either treatment group. There was a significant increase in SI following Pio (0.53±0.26x10⁻⁴ vs. 1.06±0.35 1/min*microU/ml p=0.043) with a significant decrease in the placebo treated group (2.48±0.22 vs. 1.55±0.24 x10⁻⁴ 1/min*microU/ml p=0.043). Compared to the change observed on placebo (82.5±8.7 vs 88.8±6.9), Pio significantly decreased (p=0.046) fasting glucagon concentrations after 6 months (124.8±22.4 vs 113.8±23.0pg/ml). There were no differences in AUC_(PGn-0-4hr) after 6 months in either the placebo (358.9±28.3vs.363.4±19.1pg,h/ml) or Pio (479.3±64.1vs.445.8±64.2pg,h/ml) groups.

Conclusion: In this small cohort of subjects with impaired glucose tolerance, pioglitazone improved insulin sensitivity and thereby lowered both fasting glucagon and glucose concentrations

Liver X receptor activation in the Zucker diabetic fatty rat increases beta cell mass and decreases beta cell apoptosis

B. Blondeau¹, C. Peschard¹, V. Peyrou², J.-M. Luccarini², B. Husson², B. Breaux¹;

¹UMRS 872 Cordeliers Research Center, INSERM, Paris, France,

²Research Center, Fournier Pharma Laboratories, Daix, France.

Background and Aims: Liver X receptors (LXR) are members of the family of nuclear receptors and involved in cholesterol synthesis, lipogenesis and inflammation. Moreover, in vivo, the activation of these receptors by specific ligands also reverses diabetes in mice and rats but their mechanisms of action, particularly on beta cells, is incompletely understood.

Materials and Methods: To gain further knowledge on LXR action, we have treated Zucker Diabetic Fatty (ZDF) rats at 8 weeks of age with the LXR agonist GW3965 and studied these rats during a 4-week treatment.

Results: We found that GW3965 treatment prevented the increase of glycaemia and HbA_{1c} observed in the Vehicle-treated ZDF rats, maintained a high basal insulinemia and slightly increased plasma triglyceride levels. After 4 weeks of treatment with the agonist, the glucose response was greatly improved and insulin secretion dramatically enhanced upon an oral glucose tolerance test. At the end of the treatment, GW3965 significantly induced islet expression of PDX1, SREBP1c and SCD1 mRNA levels and tended to increase the pancreatic GK, MafA, Glut2 and FAS mRNA expressions. Histological and immunostaining studies revealed that islets from Vehicle-treated ZDF rats were disorganized with an irregular shape, obvious fibrosis and abnormal Glut2 staining while GW3965 treatment restored a regular shape and Glut2 staining without modification of fibrosis status. When compared to Lean controls, beta cell mass was increased in ZDF Vehicle-treated animals due to increased islet numbers/cm² without modification of islet size. In GW3965-treated ZDF rats, beta cell mass, islet density and islet size in the head of the pancreas were further enhanced when compared to Vehicle controls. Beta cell proliferation was unchanged between the two ZDF rats groups neither after 4 days nor at the end of the treatment. In contrast, beta cell apoptosis rate that was increased in Vehicle animals compared to Lean controls, was fully restored to basal levels in GW3965-treated ZDF rats.

Conclusion: In conclusion, LXR activation efficiently blocked the spontaneous development of diabetes in ZDF rats. Our thorough analysis of the pancreas reveals that GW3965 treatment is associated with an increased beta cell mass due to an increased islet density, suggesting islet neogenesis. Moreover, beta cell apoptosis is blunted in GW3965-treated ZDF rats, thus helping to maintain a sufficient beta cell mass to protect against diabetes. These data help understanding the mechanisms of action of LXR agonists which represent promising therapeutic targets for the treatment of type 2 diabetes.

PDX-1 interacts with 14-3-3epsilon in pancreatic beta cells

S. Teller, N. Hai Ha, R. Walther;

Department of Medical Biochemistry and Molecular Biology, University Greifswald, Germany.

Background and Aims: 14-3-3epsilon belongs to the 14-3-3 protein family. These proteins are involved in various cellular processes. 14-3-3 proteins are adaptor proteins thought to alter the stability, activity and/or subcellular localisation of their target proteins via protein-protein interaction. PDX-1 is a transcription factor that is mainly expressed in beta and delta cells of the islets of Langerhans in the pancreas. It is required for normal pancreas development and for the proper differentiation of the pancreas. In beta cells, the glucose-induced insulin gene transcription comprises transactivation of PDX-1 via the phosphatidylinositol 3-kinase pathway. However, the detailed mechanism by which PDX-1 becomes activated and changes its localisation is still poorly understood.

Materials and Methods: MIN6 cells were grown to 80% confluence in DMEM containing 25 mM glucose, 10% horse serum and 2.5% FCS. Cells were washed twice and incubated in Krebs-Ringer buffer (118 mM NaCl, 4.75 mM KCl, 1.25 mM CaCl₂, 1.2 mM MgCl₂, 0.05% (w/v) BSA,

25 mM NaHCO₃, 10 mM Hepes pH 7.4). Cells were then stimulated with 16 mM glucose for 30 min. SDS-PAGE, immunoprecipitation, Northern and Western blotting were performed using standard molecular biology protocols. Pull-down experiments were performed using bacterially expressed GST-PDX-1 protein as a bait in lysates of glucose stimulated MIN6 cells. ³⁵S-labeled PDX-1 for GST pull-down experiments was produced by *in vitro* transcription/translation (TNT Quick Coupled Transcription/Translation Systems, Promega, Madison, USA).

Results: The starting point of our studies was the identification of phosphoproteins interacting with PDX-1 after stimulation of starved MIN6 cells with glucose. By *in vitro* GST pull-down assays followed by mass spectrometry, we identified 14-3-3epsilon as a protein binding to GST-PDX-1. This interaction was confirmed by GST pull-down assays using *in vitro* translated PDX-1 and GST-14-3-3epsilon. Furthermore, using deletion mutants of PDX-1, we could show that endogenous 14-3-3epsilon protein binds to the C-terminal part and the N-terminal transactivation domain but not to the homeodomain of PDX-1. PDX-1 was also co-immunoprecipitated with 14-3-3epsilon from MIN6 lysates. The interaction was diminished when the lysates were pre-treated with phosphatase. This indicates that the interaction between PDX-1 and 14-3-3epsilon requires phosphorylation. Experiments with kinase inhibitors showed that neither inhibitors of PKC nor inhibitors of CKII influence the interaction of PDX-1 and 14-3-3epsilon. Atypical PKC's were described as activators of PDX-1, whereas a glucose induced phosphorylation of PDX-1 by CKII was found by our group. Northern blot experiments revealed that overexpression of 14-3-3epsilon increases the insulin-mRNA level in MIN6 cells. For further experiments, a siRNA sequence was determined which is capable to downregulate 14-3-3epsilon in beta cell lines. FRET analysis with YFP- and CFP-coupled fusion proteins were used to detect the localisation of PDX-1 and 14-3-3epsilon in MIN6 cells dependent on starvation or glucose stimulation.

Conclusion: Identification of the phosphorylation dependent interaction between PDX-1 and 14-3-3epsilon in pancreatic beta cells supports the hypothesis that 14-3-3epsilon plays a role in PDX-1 transactivation and the regulation of the insulin gene transcription.

Embryonic lethality and impaired beta cell replication by disruption of Reg receptor gene

S. Takasawa¹, K. Nata¹, I. Takahashi¹, T. Ikeda², N. Noguchi¹, M. Asano³, K. Sugihara³, A. Yamauchi¹, T. Yoshikawa¹, N. J. Shervani¹, A. Uruno¹, M. Unno⁴, A. Sugawara¹, H. Okamoto¹;

¹Advanced Biological Sciences for Regeneration, Tohoku University,

²Innovation Plaza Miyagi, JST,

³Institute for Experimental Animals, Kanazawa University, Kanazawa, Japan,

⁴Surgery, Tohoku University, Sendai, Japan.

Background and Aims: *Reg* (Regenerating gene) gene encodes a 16 kDa secretory protein that induces pancreatic beta-cell proliferation as an autocrine/paracrine growth factor via Reg receptor (RegR). Accumulating *in vitro* and *in vivo* evidence using *Reg* transgenic and *Reg* knockout mice suggests that Reg protein is involved not only in regenerative cell proliferation of pancreatic islet beta-cells but also in the cell proliferation of a variety of tissues such as gastrointestinal cells, neural cells, and cardiovascular cells.

Materials and Methods: We produced mice with a targeted disruption of *RegR* by homologous recombination. Beta-cell replication was induced by partial pancreatectomy and BrdU incorporation and PCNA staining of insulin-positive cells were measured.

Results: The heterozygous mutant mice (*RegR*^{+/-}) had normal fertility and lifespans and maintained similar body weight and blood glucose levels to those of their wild-type cohorts. In addition, there was no difference in the pancreatic beta-cell mass between *RegR*^{+/-} mice and the wild type mice, whereas the mRNA and protein levels of RegR in the tissues of *RegR*^{+/-} mice were about one half of those of the wild type mice. We then intercrossed *RegR*^{+/-} mice and found the total absence of *RegR*^{-/-} pups, indicating that this genotype is embryonic-lethal. Timed pregnancies of heterozygotes revealed that *RegR*^{-/-} mice die between 8.5 and 9.5 days post coitum. As *Reg* knockout mice showed the decreased beta-cell regenerating activity, we induced pancreatic beta-cell replication by partial pancreatectomy in *RegR*^{+/-} mice. Both the BrdU incorporation and the PCNA positive cell numbers in insulin-positive cells of residual pancreas of *RegR*^{+/-} mice were significantly decreased compared to those of *RegR*^{+/+} wild type mice after surgery.

Conclusion: These results indicate that the Reg protein-Reg receptor system is essential for normal mouse development as well as for the replication of pancreatic beta-cells for regeneration.

Antagonism between Hepatocyte Nuclear Factor 4 alpha (HNF4α) and Chicken Ovalbumin Upstream Promoter-Transcription Factor 2 (COUP-TFII) modulates Ped/Pea-15 gene expression

P. Ungaro, R. Teperino, P. Mirra, G. Botta, V. D'Esposito, S. Iovino, G. Lupoli, F. Oriente, C. Romano, R. Valentino, F. Beguinot; Dipartimento di Biologia e Patologia Cellulare e Molecolare & IEOS-CNR, Università di Napoli Federico II, Napoli, Italy.

Background and Aims: Overexpression of the Ped/Pea-15 (Phosphoprotein enriched in diabetes/phosphoprotein enriched in astrocytes) gene has been found in tissues from type 2 diabetic patients and their healthy first degree relatives. In transgenic mouse models, ped/pea-15 overexpression determines insulin-resistance and impairs glucose-stimulated insulin secretion. In order to address the molecular mechanisms responsible for Ped/Pea-15 overexpression, we isolated the promoter of the gene. We identified a cis-acting regulatory element (RE) between -307 and -322 bps upstream from the Ped/Pea-15 gene transcriptional start site (+1). The RE is recognized by both the Hepatocyte Nuclear Factor 4 (HNF4α) and by the Chicken Ovalbumin Upstream Promoter Transcription Factor 2 (COUP-TFII), two orphan members of the steroid/thyroid receptor superfamily both of which are involved in lipid and glucose homeostasis.

Materials and Methods: We have investigated the role of HNF4α and COUP-TFII in the regulation of Ped/Pea-15 expression in cultured HeLa and HepG2 cells.

Results: Based on luciferase assays HNF4α overexpression in HeLa cells reduced Ped/Pea-15 promoter activity in a dose-dependent and site-specific manner. Consistently, both Real Time PCR and Western Blot analysis revealed a decreased PED/PEA-15 expression in HeLa cells transiently transfected with an HNF4α expression vector. In addition, RNA interference (RNAi)-mediated depletion of HNF4α in HepG2 cells increased Ped/Pea-15 mRNA. Similar experiments demonstrated that COUP-TFII acts in the opposite way, as it increases the activity of the Ped/Pea-15 promoter, as well as that of the endogenous Ped/Pea-15 RNA by real time PCR in HeLa cells. Cotransfection of HeLa cells with the reporter construct containing the RE located between -307 and -322 bps and various combinations of HNF4α and COUP-TFII expression vectors indicated that COUP-TFII antagonizes the repression of the Ped/Pea-15 gene by HNF4α. Finally, Chromatin Immuno-Precipitation (ChIP) and Electrophoretic Mobility Shift Assay (EMSA) experiments indicate that both transcription factors directly bind to the responsive element between -307 and -322 bps on Ped/Pea-15 promoter with a similar affinity, indicating that these two proteins compete for the transcriptional control of the Ped/Pea-15 promoter.

Conclusion: Our data demonstrate that the antagonism between HNF4α and COUP-TFII modulates Ped/Pea-15 gene expression. Alterations in the action of HNF4α and COUP-TFII may lead to the dysregulation of Ped/Pea-15 gene expression, thereby contributing to susceptibility to type 2 diabetes.

Shedding light on the controversial role of Tmem27

J. Altirriba¹, R. Gomis¹, M. C. Ruiz de Villa², M. Julià¹, A. Barberà¹; ¹Endocrinology and Diabetes, Hospital Clinic / IDIBAPS, Barcelona, Spain, ²Department of Statistics, UB, Barcelona, Spain.

Background and Aims: Two independent groups have recently identified Tmem27 in the pancreatic β cells as an HNF1a target. However, they have reached different conclusions about Tmem27 role using similar transgenic studies. While one group concludes that an increase of its expression stimulates pancreatic β cell proliferation without modifying insulin secretion, the other states that its rise enhances glucose-stimulated insulin exocytosis without changing the islet mass. To shed light on this controversy, without using a genetically modified model, we aim to assess the changes of Tmem27 in animals treated with tungstate and reconfirm the results obtained in human islets.

Materials and Methods: Wistar rats were treated with tungstate (2 mg/ml drinking water) during 40 days. Insulin sensitivity (ITT) and intraperitoneal glucose tolerance (IGTT) tests were performed. Total pancreas was removed, fixed and islet proliferation was assessed. Islets were isolated from untreated and treated rats in order to study the glucose induced insulin secretion and Tmem27 and insulin expression by qRT-PCR. In order to assess if the changes observed were due to a decrease in food intake induced by the treatment, a pair-fed experiment was conducted. At the end of this experiment, insulinemia and insulin and Tmem27 expression levels in the islets were determined. Finally, the levels of Tmem27, insulin, snapin, cyclin E1 and CDK2 were assessed in human islets by qRT-PCR, establishing its correlation.

Results: Treated (T) rats compared to the untreated (UT) were more glucose tolerant (glycaemia AUC UT 24576 vs T 21324 mg/dL x 120min, $p < 0.01$; insulinemia AUC UT 549 vs T 292 $\mu\text{g/L} \times 120 \text{ min}$, $p < 0.05$), showed an increased insulin sensitivity (AUC UT 6246 vs T 5113 mg/dL x 120 min, $p < 0.01$) and a decreased insulinemia levels (UT 2.28 vs T 1.46 $\mu\text{g/L}$, $p < 0.01$). In isolated islets, glucose induced insulin secretion was decreased (UT 5.85 vs T 2.60 $\mu\text{g/islet} \times 90 \text{ min}$, $p < 0.01$). Morphometric analysis revealed a significantly increased islet proliferation in T rats (T 4.03 vs UT 32.90 nuclei PCNA+/mm² islet, $p < 0.001$). Interestingly, in T animals, a decrease in mRNA levels of insulin (fold change -2.26 , $p < 0.01$) and Tmem27 (fold change -3.08 , $p < 0.01$) was detected. It is worth noting that expression levels of insulin and Tmem27 showed a significant correlation ($\rho = 0.724$, $p < 0.001$). Therefore, tungstate administration to rats led to a decrease in Tmem27 expression similarly to what happened with insulin expression, secretion and insulinemia; whereas the islet proliferation was increased. Furthermore, pair-fed animals showed no differences in insulinemia and insulin and Tmem27 mRNA levels compared to UT animals, discarding the possibility that the changes observed were due to the decrease in food intake induced by tungstate. Finally, in order to check whether the correlation between Tmem27 and insulin expression levels also occurs in human islets, the expression of several key genes of β cell function was assessed. The results showed that Tmem27 strongly correlates with insulin ($\rho = 0.866$, $p < 0.01$) and snapin (component of the SNARE complex) ($\rho = 0.733$, $p < 0.05$) but no significant correlation was found with cyclinE1 and CDK2 (key genes in the progression of the cell cycle).

Conclusion: Our results show that Tmem27 role in β cell function is involved in insulin secretion but not in β cell proliferation.

Affinity binding analysis shows that hnRNP K and hnRNP E, in cytosolic extracts from human islets, binds specifically to the stabilizing segment of insulin mRNA

R. G. Fred¹, C. M. Adams², N. Welsh¹;

¹Medical Cell Biology,

²Biological and Medical Mass Spectrometry, Uppsala University, Sweden.

Background and Aims: The increased production of insulin that occurs in response to a glucose challenge is in part due to an enhanced stability of insulin mRNA. The stability of insulin mRNA is in turn controlled by a pyrimidine-rich sequence located in the 3'-untranslated region (UTR) of the messenger. We have previously shown that the polypyrimidine tract binding protein (PTB1) by binding to this sequence stabilizes the mRNA. Since the exact mechanisms of glucose-induced insulin mRNA stabilization are yet to be determined we presently investigated whether other proteins than PTB1, either directly or in complex with PTB1, specifically bind to the 3'-UTR of insulin mRNA.

Materials and Methods: Biotinylated 27-mer RNA oligonucleotides corresponding to the specific sequences of the rat and human insulin mRNA 3'-UTR were incubated with cytosolic extracts from INS-1 cells or naive human islets. The human islets were obtained from Prof. Olle Korsgren at the Akademiska Hospital, Uppsala, Sweden. Following a 60 min binding reaction, the oligonucleotide/protein complexes were recovered using streptavidin coated ferrite beads. The proteins were eluted from the beads by boiling in SDS-sample buffer and run on 1-D gels together with controls lacking or having mutated oligonucleotides. After commassie staining sequence-specific bands were excised and analyzed by Fourier Transform Mass Spectrometry.

Results: Mass Spectrometry revealed that in addition to the 55 kD band, which contained PTB, specific 40 kD and 70 kD bands contained hnRNP E

and hnRNP K, respectively. Further immunoblot analysis of the RNA-binding proteins, using antibodies recognizing hnRNP E and hnRNP K, showed that the two proteins, bind specifically to the polypyrimidine sequence of insulin mRNA in both human and rodent cell extracts.

Conclusion: Our studies provide ample verification that both hnRNP K and hnRNP E binds specifically to the stabilizing segment of insulin mRNA and that they therefore may be part of the glucose signaling pathway. Further experimentation will provide information on whether the hnRNP proteins bind directly or via protein/protein-interaction to the RNA-oligonucleotide, and whether glucose promotes post-translational modifications to the insulin mRNA-binding proteins.

Glucose and zinc-depletion stimulate beta cell expression of ZnT3, a zinc transporter, whereas ZnT3 KO mice have decreased beta cell capacity

J. B. Jeppesen¹, A. Larsen², N. Jessen³, N. Magnusson¹, L. Egefjord¹, L. Wogensen⁴, B. Brock⁵, O. Schmitz³, K. Smidt¹, M. Stoltenberg², J. Rungby¹;

¹Pharmacology and Endocrinology C, University of Aarhus,

²Dept. Neurobiology, Inst. of Anatomy, University of Aarhus,

³Pharmacology and Endocrinology M, University of Aarhus,

⁴Biochemical Pathology, University of Aarhus,

⁵Pharmacology and Pharmacy, University of Aarhus, Denmark.

Background: Zinc transporter (ZnT)-proteins regulate zinc fluxes into beta-cell vesicles and recently ZnT8 was identified as a major risk factor for developing type 2 diabetes. Contrasting other ZnTs, ZnT3 is upregulated by high glucose levels as well as by zinc depletion in β -cells. We here confirm the glucose dependence of ZnT3 and show by electron microscopy that ZnT3 is located in beta-cell cytoplasm. Further, we report the first results of experiments examining glucose metabolism in ZnT3 KO mice.

Methods: INS1-E rat beta-cells were exposed to 2, 5 or 16 mM glucose for 24 hrs. ZnT3 mRNA was measured by RT-PCR. Measurements were normalized to a mean of three house-keeping genes. Insulin secretion was measured by Elisa. For electron microscopy, INS1-E cells were fixed in paraformaldehyde and examined for the presence of ZnT3 by immunogold staining with a specific goat-rabbit antibody. To determine if knocking out the ZnT3 gene affects whole body glucose metabolism, twelve weeks old ZnT3 KO mice derived from the C57B16 mouse strain were compared to wild type mice after five days of treatment with intraperitoneal streptozotocin 50mg/kg daily or saline. After two weeks of recovery, tail blood glucose levels were measured after a 14 hrs fast with a One Touch Ultra Meter.

Results: We confirmed that, relative to 5 mM glucose, 2 mM glucose caused a significant down-regulation of ZnT-3 and 16 mM an up-regulation ($p < 0.01$). Insulin secretion was increased at 16 mM glucose. By electron microscopy we could identify the presence of ZnT3 in the cytoplasm of INS1-E cells. No significant changes in blood glucose levels were found between ZnT3 KO- and WT mice. However, after treatment with streptozotocin, KO mice had significantly higher blood glucose levels compared with sham-injected KO mice ($p < 0.05$) and streptozotocin-treated WT mice ($p < 0.01$) (Figure).

Conclusion: This study identifies ZnT3 as a pivotal regulator of beta-cell zinc metabolism. Zinc ions have numerous roles in the islets as well as possible roles in the periphery. These include regulation of counter-regulatory hormones and beta-cell apoptosis as well as the formation of insulin crystals.

The fact that ZnT3 gene expression levels can be up-regulated by increasing glucose levels suggest a possible direct function in insulin storage or secretion of ZnT3 controlled zinc fluxes. Furthermore, the increase in glycaemia after moderate beta-cell stress by streptozotocin suggest that other ZnTs are unable to compensate for the lack of ZnT3 in otherwise healthy mice.

High content isoflavone soy protein isolate increases insulin sensitivity and changes the gene expression of key insulin regulatory genes and β cell transcription factors in islets of the diabetic KKAY-mouse

I. Nordentoft, P. B. Jeppesen, J. Hong, R. Abudula, K. Hermansen; Dept. of Endocrinology and Metabolism C., Aarhus University Hospital, Aarhus Sygehus THG, Denmark.

Background and Aims: High content isoflavone soy protein (SBP) have a beneficial effect on the insulin resistance syndrome. The aim of this study was to investigate if SBP possesses beneficial effects on the metabolism in the diabetic KKAY-mouse. Moreover, we investigated the long term *in vivo* effect of SBP on the gene expression profile of key insulin regulatory genes in islets.

Material and Methods: 26 KKAY-mice, age 5 weeks, were divided into 2 groups and treated for 9 weeks with either: A: standard chow diet (control); B: chow + 50% SBP. Blood samples were collected and analysed before and after intervention. As a non diabetic control group (C) twenty normal C57BL-mice were fed with standard chow diet. Gene expression was determined in islets by quantitative real-time RT-PCR and Affymetrix microarray.

Results: We demonstrated that long-term treatment with SBP improves glucose homeostasis, increase insulin sensitivity, lower plasma triglycerides and lower total plasma cholesterol and doubles the islet insulin content in the diabetic KKAY-mice strain. Furthermore, SBP markedly change the gene expression profile of key insulin regulatory genes including *GLUT2*, *Ins1*, *Ins2*, *Beta/Neurod1*, and *11- β -HSD-1*, *Nkx6-1*, *C/EBPalpha* and *Foxa2* in the islets isolated from the KKAY-mice.

Conclusion: The results indicate that SBP improves glucose homeostasis, increases insulin sensitivity, lowers plasma triglycerides and lowers weight in the diabetic KKAY-mice and up-regulates the gene expression of key beta cell insulin regulatory genes.

0493

Gene expression regulated by pioglitazone and exenatide in normal and diabetic rat islets exposed to palmitate

H. Ghanaat-pour¹, N. Welsch², Å. Sjöholm¹;

¹Karolinska Institutet, Department of Internal Medicine, Stockholm South Hospital, Stockholm, Sweden,

²Department of Medical Cell Biology, Uppsala University, Sweden.

Background and Aims: Hyperlipidemia has been suggested to contribute to the loss of β -cell mass (apoptosis), its secretory defects and thereby impaired β -cell function in type 2 diabetes. Treatment of genetically diabetic GK rats and also type 2 diabetic patients with pioglitazone, a PPAR- γ agonist, lowers the fasting levels of plasma glucose and triglycerides. Another recently launched antidiabetic drug, exenatide, an incretin mimetic, has been suggested to stimulate insulin secretion, growth and proliferation of pancreatic β -cells. We aimed to investigate β -cell lipoapoptosis, and the possible protective effect of *in vitro* treatment with pioglitazone and exenatide against this toxicity.

Materials and Methods: Cell viability was examined in pancreatic islets of Wistar rats by utilizing fluorescence microscopy. Global gene expression profiling was applied to characterize genes differently regulated by palmitate, pioglitazone and exenatide in islets from non-diabetic Wistar rats and type 2 diabetic Goto-Kakizaki (GK) rats.

Results: The results from fluorescence microscopy indicated no significant protective effect of pioglitazone on β -cell lipoapoptosis. Gene expression profiling revealed significant changes in islet mRNAs involved in control of β -cell function, e.g. epigenetic regulation of gene expression, cell differentiation and morphogenesis, also metabolism, response to stimulus, transport and signal transduction. Pioglitazone and exenatide appear to significantly impact

epigenetic processes, e.g. stable alterations in gene expression potential that arise during development and cell proliferation. Bcl2 family members may act as anti- or pro-apoptotic regulators and thereby play an important role in the fate of cells. Bcl2-like 1 (Bcl2l1), an anti-apoptotic member of this family, seems to exert a permissive role in cell proliferation and differentiation. Bcl2 modifying factor (Bmf), a pro-apoptotic member of this family, is required for binding to the Bcl2 family members to trigger apoptosis. Bcl2l1 and Bmf were both down-regulated by pioglitazone and exenatide in the presence of palmitate in diabetic GK islets. In contrast, Bmf was down-regulated by pioglitazone in the presence of palmitate in non-diabetic Wistar islets. The activation of PPAR β/δ seems to induce the expression of target genes involved in fatty acid metabolism. In this study, exposure of non-diabetic Wistar islets to palmitate led to a reduction in the expression of PPAR β/δ . This suggests that palmitate may increase the accumulation of triglycerides by reducing PPAR signaling. Moreover, treatment with either pioglitazone or exenatide restored and increased the expression of PPAR β/δ in non-diabetic Wistar islets.

Conclusion: Taking into account that these drugs target different components of the epigenetic machinery, our findings suggest that they might participate in restoring normal gene activity in dysfunctional islets and that additive benefits may occur. Whether such events contribute to the β -cell sparing, proliferative and anti-apoptotic effects of these drugs in diabetes remains to be elucidated.

0494

Pioglitazone modulates lipid metabolism, cell cycle and cell death gene expression profiles in pancreatic islets

R. N. Lamounier^{1,2}, P. White², C. N. Coimbra¹, L. S. Oliveira¹, M. L. Correa-Giannella¹, K. H. Kaestner²;

¹LIM-25, Endocrinology Division, University of Sao Paulo, Brazil,

²Department of Genetics, University of Pennsylvania, Philadelphia, United States.

Background and Aims: Peroxisome proliferator-activator receptor- γ (PPAR- γ) is a target for thiazolidinedione (TZD) antidiabetic drugs and a regulator of adipose tissue differentiation and metabolism. TZD act as an insulin sensitizing agent on peripheral tissues. It has been speculated that TZD could play a role on beta-cell function, preventing loss and improving viability in the long-term. Nevertheless some studies also showed a lack or even a potential deleterious effect of TZD on islets. The role of PPAR- γ target genes in pancreatic islets is still largely unclear. We studied the gene expression profile induced by the treatment with pioglitazone (PIO), an approved TZD for T2DM therapy, on rat pancreatic islets primary culture both at normal and high glucose medium concentrations.

Materials and Methods: Islets were obtained from 2 month-old wistar rats and isolated by the Ficoll gradient method and then cultured in 5.6 mM or 23 mM glucose for 24h, being treated with PIO 10 μ M or DMSO 0.1% (vehicle). Pioglitazone was provided by Takeda Pharmaceuticals, Osaka, Japan. RNA was extracted with Trizol (Sigma) and purified with RNeasy kit (Qiagen). The Ovation™ Aminoallyl RNA Amplification and labeling System was used for sample amplification. Samples were labeled and then hybridized on the Mouse PanChip 13k cDNA microarray, using 5 different biological replicates for each test condition. Statistical Analysis of the microarray data was performed using significance analysis of microarrays (SAM) with a false discovery rate of 10%. Gene expression results were confirmed through Q-PCR. Pathways assessment was performed through Ingenuity Pathway Analysis (www.ingenuity.com).

Results: At 5.6 mM glucose 101 genes were modulated by PIO, 49 upregulated and 52 downregulated. At 23 mM 1235 genes were affected, 612 upregulated and 623 downregulated. Comparison between both conditions revealed 74 genes that were similarly modulated at both glucose concentrations. Pathway analysis of perturbed genes revealed biologically relevant networks related to lipid metabolism at both glucose medium concentrations. At 23mM, cell cycle and cell death pathways were significant modulated as well.

Conclusion: This data demonstrates that in addition to known effect in adipocytes, the insulin sensitizing agent Pioglitazone modulates gene expression in pancreatic islets, especially in the presence of supraphysiological glucose concentrations affecting especially lipid metabolism and mechanisms of cell death and cell cycle.

Regulation of neonatal beta cell growth in rat. Role of Wnt/ beta-catenin signaling pathway

F. Figeyc, B. Portha, J. Movassat;
Physiology, University Paris Diderot, France.

Background and Aims: Wnt signalling pathway plays important roles in normal development of a variety of organs and in the pathogenesis of diseases such as cancer. Wnt signals are secreted glycoproteins which interact with a family of seven-pass transmembrane receptors called Frizzled. This interaction transduces distinct kinds of intracellular signalling pathways. The "canonical" Wnt pathway implicates changes of the intracellular levels of beta-catenin (Wnt/ beta-catenin pathways) and it is thought to be involved in cell fate specification and cell proliferation. The role of beta-catenin dependent Wnt signalling in the development of the normal pancreas has been investigated recently in few studies. However its specific role in the differentiation and growth of the endocrine pancreas remains controversial. In our study we addressed the importance of Wnt/ beta-catenin signalling in the endocrine pancreatic growth during the first post-natal week in Wistar rats. This is an important period during which the endocrine cell mass increases dramatically by both replication of existing cells and differentiation of precursor cells into beta cells.

Materials and Methods: First we assessed the expression of the active hypophosphorylated form of beta-catenin in the pancreas of 2 and 7 days old neonates by Western blot analysis of pancreatic lysates and by immunofluorescence staining of pancreatic sections. Next, in order to address the specific role of beta-catenin stabilization in beta cell proliferation, we established culture of islets of Langerhans isolated from the pancreas of 2 days old pups and assessed the rate of beta cell proliferation following inactivation of Glycogen Synthase Kinase 3 (GSK3 beta) by lithium chloride (LiCl). Cell proliferation was also assessed in culture of insulinoma cell line INS1 treated by LiCl.

Results: Immunostaining of pancreatic sections showed that nuclear beta-catenin can be found in a subset of endocrine cells as well as ductal and acinar cells. Western blot analysis of pancreatic lysates revealed that the active form of beta-catenin is expressed in neonatal pancreases and its expression decreases significantly as a function of age. The greater levels of active beta-catenin in the pancreas at 2 days compared to 7 days of age are correlated with the higher rate of cell proliferation in the pancreas of younger pups. In primary cultures of neonatal islets, the GSK3 beta inhibitor LiCl (10 mM) significantly increased beta cell proliferation after 24, 48 or 72 hours exposure of islets. The proliferation of INS1 cells was also significantly stimulated by LiCl. The inhibition of GSK3 beta led to beta-catenin stabilization as evidenced by increased levels of hypophosphorylated beta-catenin in cells cultured with LiCl. Moreover, we showed that upstream components of the Wnt signalling pathway such as Wnt 5A, Wnt 11 and Frizzled 10 are expressed in insulinoma INS1 cells and in neonatal pancreases.

Conclusion: Overall, our results show that in vivo, the active form of beta-catenin is abundant in the neonatal rat pancreas during the intense phase of cell proliferation, and that stabilization of intracellular beta-catenin leads to the stimulation of beta cell proliferation in both primary culture of neonatal beta cells and in the beta cell line INS1. This suggests that Wnt/ beta-catenin pathway could be important in the regulation of neonatal beta cell growth.

Gastrin treatment stimulates beta cell replication, increases beta cell mass and improves metabolic control in 95% partially pancreatectomized rats

N. Téllez, G. Joanny, J. Escoriza, J. Soler, E. Montanya;
Lab. Diabetes and Experimental Endocrinology, IDIBELL, L'Hospitalet de Llobregat, Spain.

Background and Aims: The administration of the gastrointestinal hormone gastrin has been reported to induce beta cell neogenesis and to increase beta cell mass. These effects were found in particular when gastrin was co-administered with EGF. However, the effects of gastrin alone are less well

defined, and the potential role of gastrin on beta cell replication remains to be established. The aim of the study was to determine the effects of the administration of gastrin to partially pancreatectomized rats, a well established model of beta cell regeneration.

Materials and Methods: SD rats underwent 95% partial pancreatectomy (95%-Px) and were treated with the gastrin analogue [15 leu] gastrin-17 (150 µg/kg · 12h, sc) or with vehicle (n=5) from day 1 (when 95% Px was performed), to day 15 (when pancreatic remnants were harvested). Allocation of pairs of same day pancreatectomized animals to gastrin- and vehicle-treated groups was blinded. Blood glucose and body weight were monitored on days 1, 3, 7, 10 and 15. A group of animals of similar body weight underwent a 95% Px and had the pancreatic remnant harvested immediately after surgery. The pancreas of an additional control group of sham-Px rats (n=6) was harvested after 15 days of follow up. Beta cell mass and cross-sectional individual beta cell size was determined by morphometry, and beta cell replication by BrdU incorporation, in insulin stained sections of harvested pancreatic remnants and pancreases.

Results: 95%- Px rats treated with vehicle developed severe hyperglycemia (day 15: 516 ± 41 mg/dl) that was reduced by gastrin treatment (day 15: 318 ± 85 mg/dl, $p < 0.01$). 50% of animals treated with gastrin, but none of those treated with vehicle, remained normoglycemic after surgery (day 15: 130 ± 20 mg/dl). Beta cell mass immediately after 95% Px was 0.34 ± 0.09 mg, and was 34% higher (0.45 ± 0.13 mg, p : ns) in vehicle-treated rats. Gastrin treatment resulted in a dramatic 364% increment in beta cell mass (1.24 ± 0.24 mg) ($p < 0.05$). Beta cell replication in sham-Px rats was 0.72 ± 0.1%, and was 40% higher in vehicle-treated Px rats (1.02 ± 0.2%; p : ns). Gastrin treatment further increased beta cell replication (1.29 ± 0.23%; $p = 0.07$). The individual beta cell size was similar in gastrin- and vehicle-treated 95%-Px rats (244 ± 13 vs 251 ± 24 µm²) and higher than sham-Px rats (197 ± 16 µm², $p < 0.05$), indicating that gastrin had no effects on beta cell hypertrophy. The number of scattered beta cells (groups of <5 beta cells), considered an indirect marker of islet neogenesis, was similar in gastrin-treated (5.96 ± 0.45) and vehicle-treated (6.16 ± 0.74%) 95%-Px rats.

Conclusion: Exogenous administration of gastrin enhanced beta cell regeneration in 95% partially pancreatectomized rats increasing beta cell replication and beta cell mass and, ameliorated blood glucose control. Gastrin might be potentially useful to stimulate regeneration of beta cells in the treatment of diabetes.

The ob/ob-mouse as a model for studying β cell proliferation

J. Westerlund¹, M. Hovsepian², P. Lindström³, P. Bergsten²;

¹Department of Caring and Public Health Sciences, Mälardalen University, Västerås, Sweden,

²Department of Medical Cell Biology, Uppsala University, Sweden,

³Department of Integrative Medical Biology, Umeå University, Sweden.

Background and Aims: Loss of β-cells is part of the development of not only type 1 diabetes mellitus (T1DM), but also type 2 diabetes mellitus (T2DM). The ability of β-cells to regenerate is very limited, however. The β-cell population in *ob/ob*-mice provides an exception from this rule; as hyperglycaemia develops the β-cells increase. We have observed that whereas some animals are almost normoglycaemic (NG), others are hyperglycaemic (HG) despite a common *ob/ob*-background. We hypothesized that NG animals would show higher β-cell proliferation than HG animals. The first aim of the study was to determine under what conditions *ob/ob*-mice showed accentuated differences in β-cell proliferation. The second aim was to isolate islets from *ob/ob*-mice showing such differences, protein profile the islets and identify differentially expressed islet proteins.

Material and Methods: *ob/ob*-mice were kept on normal laboratory chow with free access to water. Three- and six-months-old animals were recruited to the NG or HG groups on the basis of blood sugar levels lower than 10 mM or higher than 12 mM, respectively. Body weight, food intake and blood sugar levels were monitored for three weeks, after which animals were killed and pancreata were removed and either fixated in formalin or used for islet isolation. Pancreatic sections were used to determine islet area in percentage of total tissue area and β-cell proliferation by Ki67 staining. Isolated islets were used for measuring insulin secretion in the presence of 3 or 20 mM glucose. In addition, isolated islets were lysed and subjected to two-dimensional gel electrophoresis. Separation by iso-electric focusing was done on immobilized

pH-gradient strips, followed by size separation with SDS-PAGE. Gels were stained by silver staining and analyzed for differential protein expression.

Results: Food-intake and weight did not differ between NG and HG animals. In contrast, circulating insulin levels were higher in NG than HG animals, 87 ± 8 and 64 ± 15 ng/ml at 3 months and 126 ± 11 and 90 ± 15 ng/ml at 6 months. Elevated insulin levels were paralleled by increased islet-area in NG compared to HG animals. Islet area (expressed in percentage of total area) in NG and HG animals was 3.9 and 3.2 at 3 months and 11.9 and 6.3 at 6 months. Proliferation of β-cells was measured by counting average number of Ki67-positive cells per islet. Whereas proliferation in 3-month old NG and HG animals was 3.0 ± 1.9 and 0.37 ± 0.21 ($p < 0.01$), it was 2.13 ± 1.39 and 1.10 ± 0.83 (NS) in 6-month old NG and HG animals. Glucose stimulated insulin secretion from isolated islets increased essentially equally by 10-fold in all groups when raising glucose concentration from 3 to 20 mM. Protein profiling of islets isolated from NG and HG revealed approximately 600 spots with approximately 80 differentially expressed proteins.

Conclusion: Findings suggest that animals with a high islet proliferative capacity have higher serum insulin levels and lower blood glucose values than animals with a smaller proliferative capacity. We conclude that *ob/ob*-mice offer an opportunity to explore mechanisms underlying β-cell proliferation. It is expected that identification of differentially expressed islet proteins will yield information that could make β-cells proliferate in individuals with T2DM and potentially T1DM.

Effects of islet transplantation on endogenous β cell regeneration after partial pancreatectomy in rodents

H.-S. Jung¹, J.-Y. Park¹, Y.-R. Ahn², S.-H. Oh², M.-S. Lee¹, M.-K. Lee¹, K.-W. Kim¹;

¹Medicine, Samsung Medical Center,

²Lab251, Samsung Biomedical Reserach Institute, Seoul, Republic of Korea.

Background and Aims: Islet transplantation is one of regimens supplying insulin in diabetes patients, but the effects of islet grafts on the endogenous β-cells are not clear. In the present study, we examined the changes of endogenous β-cell mass after islet transplantation in partially pancreatectomized mice.

Materials and Methods: Balb/c mice were 70% pancreatectomized, transplanted with syngeneic islets (group IV), and were compared with pancreatectomized mice treated with insulin (group III), no insulin (group II), and Sham operation group (I). Remnant pancreas was obtained 6 and 10 days after pancreatectomy, and immunohistochemical staining was done for the evaluation of β-cell mass and cell proliferation. Before sacrifice, plasma blood and insulin levels were measured in each subject.

Results: Hyperglycemia and weight loss were induced after pancreatectomy. After islet transplantation or insulin treatment, blood glucose levels recovered to normal, and body weight started to increase. β-cell mass was larger in group IV than in group II or III until 10 days after pancreatectomy ($p < 0.05$, Fig.1). Cell proliferation evaluated using BrdU staining was increased in all the pancreatectomized groups 6 days after surgery. It was exhausted in group II soon, while it continued in treatment groups (III, IV) although there was a

Fig. 1. Absolute β-cell Mass in the Pancreas

trend to decrease in group IV (Fig. 2). After 10 days, group IV showed larger individual β -cell area than group II or III ($p < 0.05$, Fig. 3). Plasma insulin levels and intensity of insulin staining of islets were also most high in group IV.

Conclusion: These observations suggest that islet transplantation plays a role in enhancing remnant β -cell regeneration and insulin content of islets after partial pancreatectomy in mice. Induction of β -cell proliferation and supplement of adequate amount of insulin might contribute to these phenomena.

The spontaneously decreased beta cell mass and pancreatic IGF2 production in the GK fetal rat are both improved in response to maternal undernutrition

E. Fernández¹, M.-N. Gangnerau², S. Calderari², L. de Miguel¹, P. Serradas², F. Escrivá¹, B. Portha², C. Álvarez¹;

¹Bioquímica y Biología Molecular II, Facultad de Farmacia, Universidad Complutense, Madrid, Spain, ²Lab. Physiopathol. Nutr., CNRS and University Paris Diderot, UMR 7059, Paris, France.

Background and Aims: The Goto-Kakizaki (GK) rat is a spontaneous model of type 2 diabetes with a defective beta-cell mass detectable in late fetal development (21.5 days postcoitum [dpc]) and the diminished IGF-2 production seems to be involved in this effect. Since we have previously shown that early undernutrition increases beta-cell mass in foetuses at term, the aim of the present study was to investigate whether a condition of maternal malnutrition might similarly positively modulate the beta-cell mass in GK foetuses. In addition, the implication of the IGF system, which is highly responsive to nutritional status in these processes was evaluated. To this end, we have measured in 21.5 dpc undernourished GK foetuses

(GK-U) 1) serum GH and IGF levels, 2) beta-cell mass, 3) replication and differentiation of beta-cells, and 4) IGF-1 and -2 protein content in liver and pancreas. All values were compared to those in control GK foetuses.

Materials and Methods: GK rats were obtained from our colony of GK/Par rats. Pregnant GK females were food restricted (65% restriction) during the last week of gestation. Serum concentrations of GH, IGF-1 and -2 were measured by radioimmunoassay. Beta-cell mass, beta-cell differentiation and beta-cell replication were evaluated using quantitative immunohistochemistry methods. The protein content of IGF-1 and -2 was analyzed by western blot in pancreas and liver.

Results: Although in no case the GK-U values reached the levels of control Wistar rats, the results show that beta-cell mass increased by 90% in GK-U foetuses as compared to the GK group and that both beta-cell neogenesis and replication were stimulated as well. On the other hand, similar serum GH, IGF-1 and -2 levels were observed in GK and GK-U foetuses. Malnutrition affected IGF protein content in the various tissues studied. Particularly relevant was a 3-fold increase of pancreatic IGF-2 protein levels in GK-U foetuses.

Conclusion: Our data suggest that 1) maternal malnutrition increased beta-cell mass and pancreatic IGF-2 protein levels in GK-U foetuses at 21.5 dpc, 2) the increased beta-cell mass could be related to the stimulation of both beta-cell neogenesis and beta-cell replication, 3) the locally increased pancreatic IGF-2 may be instrumental in these processes. They also illustrate for the first time that enhanced IGF-2 production in the pancreas can be triggered by a nutritional manipulation of the mother. So far it is not known whether or not undernutrition of the mother is sufficient to delay/decrease the risk of the GK/Par rat for developing overt hyperglycaemia at adult age.

Maternal low protein diet alters the regeneration capacity of the adult β cells after streptozotocin destruction

K. J. R. Goosse, T. Bouckenoghe, B. Reusens, C. Remacle; Institute of Life Sciences, Université Catholique de Louvain, Louvain-La-Neuve, Belgium.

Background and Aims: Maternal Low Protein diet alters the programming of the endocrine pancreas in the progeny. Fetal islets incubated with nitric oxide donor or with cytokines exhibit higher level of apoptosis. Maternal diet has long-term consequences since adult islets of early protein-restricted rats maintained a higher vulnerability toward cytokines. Streptozotocin (STZ) is well-known for its specific destructive action on the β cells. In adult rodents, the endocrine pancreas regenerate after STZ injections. Regenerating protein 1 (Reg1) is expressed during experimental regenerative processes of pancreatic islets such as after 90% pancreatectomy or after STZ injections. Our aim was to determine whether early malnutrition increases the vulnerability of adult β cells toward STZ and impairs their regeneration capacity.

Materials and Methods: Wistar rats were fed a 20% (Control [C group]) or an isocaloric 8% protein diet (Recovery [R group]) during gestation and lactation. After weaning, offspring received the 20% protein diet. Three month-old rats were injected once a week during 5 weeks with 0.5 ml Freund's Adjuvant (FA) injections followed 24h later by injection of 17.5 mg/kg body weight STZ. Blood glucose level was monitored every week. Because we wanted to study the regeneration capacity of the endocrine pancreas, one half of the rats were sacrificed 4 days after the fifth STZ injection (d34), and the other half was maintained for two more weeks without treatment (d48). The pancreas was cut into two pieces, for quantification of insulin content and for morphometry. For that purpose, the piece was fixed with a 2% paraformaldehyde-glutaraldehyde solution and processed for immunohistochemistry. Beta cell surface area, the number of BrdU-positive cells and Reg1 surface area was estimated.

Results: The glycaemia in R group was increased after the second STZ injection, while in C group, rats became hyperglycaemic only after the last injection ($p < 0.05$ vs C). When pancreases were analysed at d34, STZ reduced the pancreatic insulin content (PIC) by 90% and the β cell surface area by 75% in both C and R group. Two weeks later (d48), when compared to the values obtained at d34, the PIC ($p < 0.01$) and the β cell surface area ($p < 0.05$) were increased in C animals. These two parameters remained unchanged in the R group during these two weeks. The number of BrdU positive cells/ β cell surface area was 3-fold higher in STZ animals compared to untreated rats, but

there was no difference between C and R groups as well as between d34 and d48. Reg1 immunostaining was absent in the endocrine pancreases of the FA animals. STZ induced however the expression of the protein in the islets of both groups. Reg1-positive cells were mainly located in the periphery of the islets and co-localized with glucagon. At d34, almost 50% of the islet surface area of the C group was immuno-reactive for Reg1, while in R pancreases only 25% of the islets surface area was Reg1-positive. At d48, 46.1±12.9% of the islets cells were reactive for Reg1 whereas in R group, the Reg1 positive surface area fell to 4.1±1.4% ($p < 0.05$ vs C).

Conclusion: Islets from the progeny that received a low protein diet during gestation and lactation are more prone to the destructive effect of STZ. Such islets have an altered capacity to regenerate new β cells. An inappropriate diet during fetal and neonatal period programs a vulnerability of the adult β -cells toward cytotoxic molecules. This could predispose the progeny to diabetes.

Keratinocyte growth factor stimulates beta cell regeneration in diabetic newborn rats via activation of ductal cell proliferation. Implication of MAP kinase signaling pathway

B. Uzan, B. Portha, J. Movassat; Physiology, University Paris Diderot, Paris, France.

Background and Aims: Keratinocyte Growth factor (KGF) is a potent growth factor with high specificity for epithelial cells. KGF has been shown to promote epithelial growth and tissue homeostasis in various organs. In the pancreas, KGF and its receptor are overexpressed in pancreatic cancer. Organ culture of pancreatic rudiments with KGF promotes proliferation of epithelial cell precursors. We investigated the role of KGF in the compensatory growth of beta cells during the process of regeneration following their destruction by streptozotocin.

Materials and Methods: Wistar rats were injected with streptozotocin (STZ) at the day of birth. A group of STZ treated pups received a daily subcutaneous injection of KGF palifermin (provided by AMGEN, Thousand Oaks, CA, USA) from day 2 to day 6 after birth. Beta cell mass was measured at day 7 after birth. Beta cell replication, apoptosis and neogenesis from precursor cells were assessed in the pancreas of 2, 4 and 7 days old KGF treated and saline treated control neonates. The intracellular mechanism of action of KGF was also investigated using the human pancreatic duct cell line, Panc1.

Results: Daily subcutaneous treatment of STZ diabetic rat neonates with KGF palifermin induced a significant increase of beta cell mass compared to control STZ neonates. We showed that the mitotic index of existing beta cell was similar in both control and KGF treated groups. Moreover there was no difference in the rate of beta cells apoptosis between the two groups. KGF significantly increased ductal cell proliferation which subsequently differentiated into beta cells as evidenced by the increased number of single beta cells incorporated into the epithelium lining the ducts or in the close vicinity of the duct epithelium. KGF also stimulated the proliferation of serum-deprived Panc1 cells. Stimulation of Panc1 cells by KGF induced the activation of MAP kinases ERK 1/2. The MEK inhibitor PD98059 abolished the growth promoting effect of KGF on Panc1 cells, indicating that the mitogenic effect of KGF are mediated mainly by ERK1/2 signalling in pancreatic ductal cells. Moreover, acute in vivo administration of KGF in STZ diabetic neonates stimulated rapid and transient phosphorylation of ERK 1/2 kinases.

Conclusion: We show that KGF stimulates beta cell regeneration in neonatal STZ diabetic rats through the activation of ductal cell proliferation and their subsequent differentiation into beta cell. The mitogenic effect of KGF on ductal cells is mediated mainly by ERK 1/2 signalling.

Ghrelin attenuates insulin release via $G\alpha_{12}$ -mediated modulation of Kv channels and Ca^{2+} signaling in islet β cells

K. Dezaki¹, M. Kakei², T. Yada¹; ¹Physiology, Jichi Medical University, Shimotsuke, ²Internal Medicine, Akita University, Akita, Japan.

Background and Aims: It has been shown that ghrelin is produced in stomach and pancreatic islets and serves as a physiological regulator of insulin release. However, the ghrelin's signaling mechanisms in islet β -cells downstream of its receptor, growth hormone (GH) secretagogue-receptor (GHS-R), are largely unknown. This study aimed to explore signaling mechanisms for insulinostatic ghrelin action in islet β -cells, with special attention to pertussis toxin (PTX)-sensitive heterotrimeric GTP-binding proteins and K^+ channels.

Materials and Methods: Plasma insulin and GH concentrations in rats were measured by ELISA. Islets were isolated from rats, ghrelin-knockout (Ghr-KO) and wild-type mice by collagenase digestion, and insulin release was determined by ELISA. In rat single β -cells, cytosolic Ca^{2+} concentration ($[Ca^{2+}]_i$) was measured by fura-2 microfluorometry, while membrane potentials and whole cell currents were measured by patch-clamp technique.

Results: Systemic ghrelin administration decreased plasma insulin concentrations in rats and this effect was blocked by treatment with PTX, whereas stimulation of GH release was unaffected by PTX. Conversely, counteraction of endogenous ghrelin by specific GHS-R antagonist [D-Lys³]-GHRP-6 markedly increased plasma insulin levels in a PTX-sensitive manner. In rat isolated islets, GHS-R antagonist significantly increased glucose (8.3 mM)-induced insulin release, while exogenous ghrelin suppressed it, both in a PTX-sensitive manner. Glucose (8.3 and 16.7 mM)-induced insulin release in isolated islets from Ghr-KO mice was greater than that from wild-type mice. This augmented secretion in islets of Ghr-KO mice was blunted after treatment with PTX. Ghrelin increased voltage-dependent K^+ (Kv) currents without affecting ATP-sensitive K^+ channel currents in rat β -cells, and this effect was abolished after PTX treatment. Ghrelin also attenuated glucose-induced action potential firing and increase in $[Ca^{2+}]_i$ in β -cells. The effects of ghrelin on glucose-induced $[Ca^{2+}]_i$ increase and insulin release were blunted in the β -cells treated with PTX and with antisense oligonucleotide specific for $G\alpha_{12}$ subunit of heterotrimeric G-proteins.

Conclusion: Ghrelin attenuates glucose-induced insulin release via PTX-sensitive $G\alpha_{12}$ -mediated activation of Kv channels and suppression of Ca^{2+} signaling in β -cells, which represents unique signaling of ghrelin distinct from that for GH release.

0503

Kisspeptin-13 inhibits insulin secretion without affecting glucagon or somatostatin release: study in the perfused rat pancreas

R. A. Silvestre, E. M. Egido, R. Hernández, J. Marco; Experimental Endocrinology and Department of Physiology, Hospital Universitario Puerta de Hierro, Medical School, Universidad Autónoma de Madrid, Spain.

Background and Aims: Kisspeptins are a family of peptides encoded by the KISS1 gene, the most abundant of which is the amidated 54-amino acid form, known as kisspeptin-54 or metastin although shorter forms of 13 and 14 amino acids have also been identified. Kisspeptins have recently been shown to be ligands for an orphan G protein-coupled receptor, GPR54, a receptor structurally related to the galanin receptor. Kisspeptins and GPR54 mRNAs have been detected in both pancreatic B and A cells. GPR54 mRNA expression was also found in MIN6 and alphaTC1 pancreatic cell lines. Kisspeptin-54 has been shown to stimulate the late phase of glucose-induced insulin secretion in mouse islets and to inhibit insulin secretion in MIN6 cells. In vitro, all kisspeptin fragments have a similar affinity and efficacy for GPR54, thus, indicating that the C-terminal part of the kisspeptin molecule is responsible for the activation of GPR54. To gain further insight into the effect of kisspeptin on islet cell secretion, we have investigated the effect of kisspeptin-13 on insulin, glucagon and somatostatin secretion.

Materials and Methods: The study was performed in the perfused rat pancreas. Kisspeptin-13 (Bachem, Switzerland) was infused at 1 μ M, 100 nM,

10 nM, 1 nM or 0.1 nM. Hormone secretion was stimulated by increasing perfusate glucose concentration (from 5.5 to 9 mM), and by infusing arginine (10 mM) or exendin-4 (1 nM). Insulin, glucagon and somatostatin were measured by RIA.

Results: Infusion of kisspeptin-13, at 1 μ M, blocked both phases of the insulin response elicited by glucose (1st phase: -1.7 ± 1.7 [SEM] ng/5 min vs. 21 ± 8 ng/5 min in controls, $p < 0.025$; 2nd phase: -1.8 ± 5.6 ng/15 min vs. 41 ± 14 ng/15 min in controls, $p < 0.025$) and by arginine (1st phase: 14 ± 7 ng/5 min vs. 144 ± 80 ng/5 min in controls, $p < 0.01$, 2nd phase: 9.4 ± 11 ng/15 min vs. 298 ± 58 ng/15 min in controls, $p < 0.01$). Exendin-4-induced insulin release (88 ± 13 ng/15 min) was also reduced by infusion of 10 nM kisspeptin-13 (15 ± 8.7 ng/15 min, $p < 0.05$). The inhibitory effect of kisspeptin-13 on glucose-induced insulin secretion was dose-dependent, fitted a sigmoidal curve ($R^2 = 0.9965$) and the IC_{50} was 1.6 nM. Kisspeptin-13 (1 μ M) failed to significantly modify the glucagon or somatostatin responses to arginine (14 ± 4 ng/20 min vs. 15.7 ± 1.3 ng/20 min in control perfusions, $p = 0.757$, and 397 ± 119 pg/20 min vs. 479 ± 106 pg/20 min in control perfusions, $p = 0.71$, respectively).

Conclusion: In view of the potent insulinostatic effect of kisspeptin-13, it is tempting to speculate that this family of peptides may be implicated in the regulation of B cell secretion. The lack of effect of kisspeptin-13 on both glucagon and somatostatin secretion would indicate that it influences the B cell directly, rather than through an A- or D-cell paracrine effect.

The GLP-1 analogue liraglutide regulates glucose-stimulated insulin granule kinetics

L. Ma¹, A. Kuznetsov¹, C. Labno², V. P. Bindokas², L. H. Philipson¹;
¹Medicine, The University of Chicago, ²BSD Light Microscopy Core Facility, The University of Chicago, United States.

Background and Aims: The glucagon-like peptide 1 (GLP-1) analog liraglutide is currently being investigated for use as a novel therapeutic agent in the treatment of type 2 diabetes. The glucose dependency of the action of GLP-1 has been well established. However, the precise mechanisms of these actions, including downstream changes in insulin granule dynamics, are less well studied.

Materials and Methods: We used total internal reflection fluorescence (TIRF) microscopy to image the motion and exocytosis of insulin granules near the plasma membrane in a MIN6 cell-line stably transfected with green fluorescent protein (GFP)-tagged insulin. We developed a method to photobleach previously docked granules (PDG) using TIRF (TIRF-FRAP) and the appearance of newly docked granules (NDG) at the plasma membrane over the next 5–20 minutes was recorded.

Results: In the first five minutes (first phase of release) fusion events were seen mostly from previously docked granules. The results show a significant increase in disappearance of docked insulin granules from the plasma membrane with t Liraglutide compared to control experiments (8.6 ± 0.93 to 4.6 ± 1.3 %, $P < 0.01$) in 8 mmol/L glucose. In the presence of liraglutide, there was an increase in the rate of appearance NDG, as expressed as a percentage of total PDG (2.37 ± 0.496 per min. compared to 1.52 ± 0.301 per min. for controls, $P < 0.01$). Our data illustrates that liraglutide evoked glucose-dependent exocytosis consistent with a bi-phasic pattern.

Conclusion: These findings indicate that liraglutide both increases insulin granule exocytosis from the pre-docked pool and leads to the mobilization of more insulin secretory granules from the large reservoir pool to then dock at the plasma membrane. Both of these processes are glucose dependent. This new method of using TIRF and TIRF-FRAP can therefore evaluate both exocytosis of docked insulin granules as well as transport of insulin granules to the plasma membrane.

Potential of insulin secretion by obestatin, a peptide derived from preproghrelin

E. M. Egido, R. Hernández, J. Marco, R. A. Silvestre;
 Hospital Puerta de Hierro and Department of Physiology, Universidad Autónoma de Madrid, Spain.

Background and Aims: Obestatin is 23-amino acid peptide derived from preproghrelin. In rats, this ghrelin-associated peptide has been identified and purified from stomach extracts and has also been detected in peripheral plasma. Contrary to ghrelin, obestatin reduces food intake and body-weight gain. Obestatin binds to the orphan G protein-coupled receptor GPR39, which belongs to the ghrelin receptor subfamily and is expressed in several tissues including pancreas. We have previously found that ghrelin inhibits insulin secretion. In the present study we have investigated the effect of obestatin on insulin secretion.

Materials and Methods: The study was performed in the isolated perfused rat pancreas. Obestatin (Peptides International Inc., Louisville, KY, USA) was infused at 3.14 nM, 1 nM or 0.314 nM. Insulin secretion was stimulated by increasing perfusate glucose concentration (from 5.5 to 9 mM), and by infusing arginine (5 mM). Insulin was measured by RIA.

Results: Infusion of obestatin significantly potentiated the insulin response to glucose at 3.14 nM (incremental area: 96 ± 23 , SEM, ng/15 min vs. 41 ± 8 ng/15 min in controls; $p < 0.05$) and at 1 nM (incremental area: 109 ± 23 ng/15 min vs. 34 ± 19 ng/15 min in controls; $p < 0.05$). No effect was observed at 0.314 nM (incremental area: 51 ± 8 ng/15 min vs. 49 ± 12 ng/15 min in controls). Obestatin also potentiated the first phase of arginine-induced insulin secretion (incremental area: 124 ± 35 ng/5 min vs. 42 ± 8 ng/5 min in controls; $p < 0.05$).

Conclusion: The stimulating effect of obestatin on insulin secretion constitutes further evidence that its biological activity is opposite to that of ghrelin. Our results allow us to speculate about a role of obestatin in the control of B-cell secretion. Furthermore, as an insulinotropic agent its potential antidiabetic effect may be worthy of investigation.

Role of the beta cell granulation state in drug-induced desensitization of insulin secretion

K. Hatlapatka¹, A. Wienbergen¹, A. Jörns², I. Rustenbeck¹;
¹Institute of Pharmacology and Toxicology, University of Braunschweig, Braunschweig, ²Institute of Anatomy, Hannover Medical School, Germany.

Background and Aims: The decreased insulin secretion after a prolonged stimulation is often ascribed to an exhaustion of insulin stores. However, the relation between the B-cell granulation state and the secretory responsiveness is only poorly understood.

Methods: Insulin secretion was measured by perfusion and ELISA of the fractionated efflux. K_{ATP} channel activity and membrane potential were measured by patch clamping, the cytosolic calcium concentration $[Ca^{2+}]_i$ by microfluorometry. The granule content was assessed by electron microscopy of islet sections or by time lapse microfluorometry of MIN6 cells transfected with an insulin-EGFP fusion protein.

Results: An overnight culture of NMRI mouse islets in RPMI 1640 (5 mM glucose) containing either 500 μ M tolbutamide or 100 μ M efaroxan led to a strongly diminished secretory response upon re-exposure to either drug. After 4h culture in RPMI alone (5 mM glucose), an overshooting recovery of secretion resulted upon re-exposure to efaroxan, but only a partial recovery upon re-exposure to tolbutamide. After overnight exposure, tolbutamide and efaroxan were still effective to block B-cell K_{ATP} channels and to depolarize the plasma membrane. The resulting pattern of $[Ca^{2+}]_i$ response was not altered during desensitization or recovery. Immunohistochemically, the PDX1 expression was also unchanged. The B-cell granule content in contrast was clearly affected. Tolbutamide desensitization degranulated more strongly than efaroxan desensitization. After 4h recovery, the regranulation of the tolbutamide-exposed islets was more extensive than that of the efaroxan-exposed islets. Use of MIN6 cells expressing EGFP-insulin showed that the tolbutamide-induced degranulation started after 1h of perfusion and was more extensive than that by efaroxan or a strongly

depolarizing K^+ concentration. Similar to B-cells within islets the degree of degranulation varied considerably between single MIN6 cells. Upon withdrawal of tolbutamide, regranulation started after 1h of perfusion in basal glucose.

Conclusion: Drug-induced desensitization of insulin secretion is accompanied by a B-cell degranulation, but the total number of insulin granules does not determine secretory responsiveness. The regranulation is not regulated by transcription nor is the secretion level explained by changes in $[Ca^{2+}]_i$. This leaves translational control and/or metabolic signalling as possible regulators of regranulation and secretion.

0507

Serotonin 2B receptor agonist BW723C86 increases cytosolic Ca^{2+} in β cells via PLC pathway and stimulates insulin and glucagon release at basal glucose in islets

A. Ando^{1,2}, K. Dezaki¹, M. Nakata¹, S. Nagasaka², S. Ishibashi², T. Yada¹; ¹Division of Integrative Physiology, Department of Physiology, Jichi Medical University, Shimotsuke, ²Division of Endocrinology and Metabolism, Department of Internal Medicine, Jichi Medical University, Shimotsuke, Japan.

Background and Aims: Localization of serotonin-containing nerve fibers in pancreas suggests that serotonin possibly has physiological function in pancreatic islets. The effect of serotonin (5-HT) on glucose metabolism has been reported. However, whether it has direct effects on insulin secretion is not evident. We here aimed to study the effect of 5-HT and its receptor agonists, especially 5-HT-2B receptor selective agonist BW723C86 hydrochloride, on insulin secretion in rat islets and cytosolic Ca^{2+} concentration ($[Ca^{2+}]_i$) in β -cells and on glucagon secretion in islets.

Materials and Methods: Expression of 5-HT receptor subtypes in isolated islets from Wistar rats was determined by reverse transcription-PCR and Western-blotting. Localization of 5-HT receptor subtypes in rat pancreas was examined using immunofluorescent staining. Insulin and glucagon release from isolated rat islets under static incubation was determined by EIA. $[Ca^{2+}]_i$ in single islet β -cells of rats was measured by fura-2 microfluorometry.

Results: mRNAs for 5-HT-1A, -2B, -2C, -3, -5B, -6, -7 receptors were expressed in rat islets. Among the 5-HT-2 receptors, western blotting analysis revealed expression of 5-HT-2B and -2C receptor proteins in islets. Double immunofluorescence staining of rat pancreas revealed localization of 5-HT-2B receptor in insulin-containing β -cells. In the presence of 8.3 mM glucose, 5-HT (100 μ M) increased $[Ca^{2+}]_i$ in 44.2% of glucose-responsive β -cells. A 5-HT-2B receptor selective agonist, BW723C86 hydrochloride, at 0.1–100 μ M dose-dependently increased $[Ca^{2+}]_i$ in β -cells at 8.3 mM glucose, and the $[Ca^{2+}]_i$ increase was blocked by 5-HT-2B receptor selective antagonist SB204741 (1 μ M). The 5-HT-2B agonist-induced $[Ca^{2+}]_i$ increase was suppressed by phospholipase C inhibitor U73122 (2 μ M), ER Ca^{2+} pump inhibitor thapsigargin (500 nm), and L-type Ca^{2+} channel blocker nifedipine (1 μ M). Surprisingly, 5-HT-2B receptor agonist BW723C86 had no effect on insulin secretion at 8.3 mM glucose, and 5-HT (100 μ M) suppressed glucose (8.3 mM) induced-insulin release. Under a basal glucose concentration of 2.8 mM, BW723C86 increased $[Ca^{2+}]_i$ in islet β -cells and increased insulin release. On the other hand, immunoreactivities for both 5-HT-2B and -2C receptors were observed in glucagon-containing α -cell. BW723C86 stimulated glucagon secretion at 2.8 mM glucose.

Conclusion: Rat islet β -cells express 5-HT-2B receptor and 5-HT-2B receptor agonist increases $[Ca^{2+}]_i$ in β -cells and stimulates insulin release in islets at 2.8 mM glucose. The 5-HT-2B receptor agonist also enhances 8.3 mM glucose-induced $[Ca^{2+}]_i$ increase in β -cells via PLC pathway but fails to enhance glucose-induced insulin release in islets. The apparent discrepancy between $[Ca^{2+}]_i$ and insulin release suggests that an additional 5-HT-2B receptor signal downstream of $[Ca^{2+}]_i$ could suppress distal processes of insulin secretion, and/or that BW723C86 could react with a yet-unidentified 5-HT receptor subtype other than 2B that influences insulin secretion at 8.3 mM glucose. The latter possibility is supported by the result that 5-HT suppressed insulin secretion at 8.3 mM glucose. Furthermore, 5-HT-2B agonist also stimulates glucagon release from rat islets.

0508

Increased basal insulin secretion from isolated MIN6B1 cells is a consequence of elevated cytosolic calcium

F. Jaques¹, H. Jousset², A. Tomas¹, C. Wollheim², J.-C. Irminger¹, N. Demareux², P. A. Halban¹;

¹Genetic, Medicine and Development, University medical center, Geneva, Switzerland, ²Cell Physiology and Metabolism, University medical center, Geneva, Switzerland.

Background and Aims: Cell-cell interaction is essential for proper function of islet beta-cells. We showed previously that dispersed MIN6B1 cells are poorly responsive to glucose compared with confluent cells with cell-cell contacts, due to the combination of a marked increase in basal and reduction in stimulated secretion. The aim of this study was to understand why basal insulin secretion is elevated in dispersed cells.

Materials and Methods: After 48h in culture, cells were preincubated for 2h in KRB-buffer at 2.8mM glucose and then incubated for 1 h in this same buffer (=basal secretion) followed by 1 h at 16.7 mM glucose or different secretagogues (=stimulated secretion). In order to decrease intracellular calcium, a 15 min period in KRB-buffer without calcium supplemented with 0.1mM EGTA was performed at the beginning of the preincubation. To measure intracellular calcium, cells were loaded with 2 μ M FURA-2/AM and imaged using a frame transfer Micro-Max camera.

Results: The use of different secretagogues showed that stimulation with Ca^{2+} mobilizing agents (glucose, KCl, arginine, leucine and glibenclamide) do not enhanced insulin secretion in dispersed cells (fold-stimulation non-significant). In contrast, dispersed cells were able to respond to secretagogues acting by a mechanism independent of changes in cytosolic Ca^{2+} (fold-stimulation: IBMX 3.41+/-0.27, mastoparan 4.9+/-1.44 and PMA 16+/-3.42, all $p < 0.005$). These results suggested that dispersed cells had a dysregulation in Ca^{2+} homeostasis. Intracellular Ca^{2+} measurements demonstrated that more than 20% of dispersed cells presented spontaneous Ca^{2+} oscillations whilst confluent cells did not. Furthermore, dispersed cells in 2.8mM glucose presented a depolymerized actin cytoskeleton and an activation of the MAPK ERK pathway, two events known to depend on intracellular Ca^{2+} elevation and to be essential for insulin exocytosis. By contrast, confluent cells presented these two characteristics only after glucose stimulation. Finally we showed that short-term deprivation of extracellular Ca^{2+} at the beginning of the preincubation in dispersed cells led to a reduction in the number of cells with Ca^{2+} oscillations at low glucose (10% instead of 22% in normal conditions) as well as a decrease in basal secretion to a level comparable to confluent cells (0.87+/-0.22% vs. 0.73+/-0.23% respectively). This reveals glucose responsiveness in dispersed cells (8-fold stimulation).

Conclusions: Dispersed MIN6B1 cells present spontaneous Ca^{2+} oscillations that trigger cytoskeleton depolymerization and ERK pathway activation, leading to insulin secretion in absence of glucose stimulation. This could be rectified by short-term (15 min) deprivation of extracellular Ca^{2+} . These defects underlie the elevated basal insulin secretion from cells without normal intercellular contacts and emphasise the importance of such contacts in the normal regulation of secretion from beta cells.

Prolonged alanine exposure induces changes in metabolism, Ca^{2+} handling and desensitization of insulin secretion in clonal pancreatic beta cells

L. Brennan¹, S. M. Scullion², B. Mion¹, C. Hewage¹, J. P. G. Malthouse¹, P. Flatt², P. Newsholme¹, N. H. McClenaghan²;

¹UCD School of Biomolecular and Biomedical Science, Dublin, Ireland, ²School of Biomedical Sciences, University of Ulster, Coleraine, United Kingdom.

Background and Aims: Amino acids are an important class of insulinotropic nutrient, playing a key role in regulation of pancreatic beta-cell function. While the acute stimulatory actions of amino acids have been characterised in detail, little is known about the consequences of prolonged beta-cell exposure to elevated concentrations of this class of insulinotropic nutrient. This prompted the present study examining the effects of prolonged beta-cell exposure to the metabolizable amino acid, L-alanine.

Materials and Methods: Clonal pancreatic BRIN-BD11 beta-cells were incubated in culture for 18 h in the presence or absence of 10 mM L-alanine

followed by a 1 h incubation in the presence of [$3\text{-}^{13}\text{C}$]-alanine. Insulin secretion was measured, and cellular metabolites evaluated following perchloric acid extraction. Neutralised cell supernatants were then prepared for NMR analysis with ^{13}C NMR spectra acquired on a Bruker DRX 500 spectrometer. Determination of cellular membrane potential, intracellular Ca^{2+} ($[\text{Ca}^{2+}]_i$) and protein expression was also performed after prolonged alanine exposure.

Results: Prolonged exposure to 10 mM L-alanine in culture did not significantly alter basal insulin release (at 1.1 mM glucose) or cellular insulin content. However, alanine culture markedly suppressed (by 74%, $p < 0.001$) the subsequent acute stimulatory insulinotropic action of alanine. An increase in glutamate labelled at position C4 (by 60%, $p < 0.01$), arising as a result of an increase in the singlet peak was observed after prolonged alanine exposure. This indicates increased flux through pyruvate dehydrogenase (PDH) of alanine derived carbon. Notably, protein expression of pyruvate dehydrogenase kinases (PDK2 and PDK4) was significantly reduced following prolonged alanine exposure, consistent with the observed increased flux through PDH. Interestingly however, prolonged alanine exposure resulted in decreased ATP levels from $5.8 \text{ pmol}/10^4$ cells to $4.2 \text{ pmol}/10^4$ cells ($p < 0.05$). Alanine evoked marked membrane depolarization in cells after control culture (in the absence of alanine). Area-under-the-curve (AUC) analysis revealed that this alanine-induced depolarization response was significantly ($p < 0.01$) suppressed in cells previously cultured with L-alanine. In accordance with this effect, cells cultured in the presence of 10 mM L-alanine exhibited a marked decrease ($p < 0.01$) of $[\text{Ca}^{2+}]_i$ in response to subsequent acute incubation with alanine compared with control culture. This is consistent with the insulin-releasing actions of this amino acid. Intact responses to acute alanine exposure were re-established after 18 h culture of cells in the absence of alanine, demonstrating reversible amino acid-induced desensitization.

Conclusion: The present study extends understanding of nutrient induced beta-cell desensitization to include amino acids, importantly indicating that prolonged exposure to metabolizable L-alanine can induce reversible alterations in metabolic flux, membrane depolarisation, calcium handling and insulin secretion.

PS 33 Intracellular signaling for insulin secretion

AKAPs-mediated subcellular anchoring of PKA plays an essential role in the cAMP-dependent stimulation of pancreatic beta cells and potentiation of insulin secretion

M. O. Faruque^{1,2}, D. Le-Nguyen³, A. D. Lajoix¹, E. Vives⁴, L. Ali², P. Petit¹, D. Bataille¹, E. H. Hani¹;

¹UMR-5230, CNRS, Montpellier, France, ²Dept Biochem & Cell Biology, BIRDEM, Dhaka, Bangladesh, ³FRE-3009, CNRS, Montpellier, France, ⁴EMI0227, INSERM, Montpellier, France.

Background and Aims: Within the endocrine pancreas, hormones like glucagon and glucagon-like peptide-1 are well known to strongly amplify beta-cell mass, function and insulin secretion. Stimulation of their respective receptors leads to elevation of the intracellular concentrations of cAMP, which activates the cAMP-dependent protein kinase (PKA) cascade. The specificity of the PKA signaling module is determined by a sophisticated subcellular compartmentation machinery, which directs the spatio-temporal activation of the kinase. Subcellular localization of PKA pools occurs through high-affinity association with A-kinase anchoring proteins (AKAPs). Recently, a novel peptide, AKAPis, has been proposed to competitively disanchor PKA-AKAPs interactions in vitro. The aim of the present study was to develop a cell-permeable construct of the AKAPis competitor, and use it as a tool-model to characterize the impact of PKA compartmentation by AKAPs on beta-cell responses.

Materials and Methods: AKAPis peptide was chemically synthesized and linked to the HIV1 cell-penetrating TAT peptide to obtain a composite construction "TAT-AKAPis". This construct was used to disrupt endogenous protein-protein interactions between PKA and AKAPs expressed in INS-1. We then evaluated the effects of disrupting PKA-AKAPs complexes on: 1) glucagon-stimulated phosphorylation of key PKA downstream substrates (transcription factor, CREB and p44/p42 MAP kinases); 2) glucagon-stimulated amplification of insulin secretion in intact INS-1 pancreatic beta-cells. PKA-AKAPs interactions were quantitatively determined using co-immunoprecipitation and western immunoblotting. Effects of TAT-AKAPis on PKA localization were also examined using immunofluorescence analysis. The effects of TAT-AKAPis on insulin secretion in response to glucose (with or without glucagon) were quantified using an insulin kit assay. TAT-AKAPis effects on glucagon-stimulated CREB and p44/p42 MAPKs phosphorylations were determined by western immunoblotting.

Results: TAT-AKAPis dose-dependently disrupted the endogenous PKA-AKAPs interactions in INS-1 cells: at 20 μM concentration of the TAT-AKAPis, more than 50% of PKA-AKAP95 complexes were disrupted. This was confirmed by immunofluorescence analysis showing that TAT-AKAPis induced a clear alteration of PKA subcellular localization within INS-1 cells. Moreover, exposure of INS-1 cells to TAT-AKAPis markedly reduced the glucagon-induced phosphorylation of CREB. Likewise, TAT-AKAPis drastically attenuated the glucagon-induced phosphorylation of p44/p42 MAPKs in INS-1 cells, a double phosphorylation event that is dependent on PKA activation. Finally, we found that glucagon-induced potentiation of insulin release from INS-1 cells was considerably reduced in the presence of TAT-AKAPis.

Conclusion: These data demonstrate that subcellular compartmentation of PKA, through interaction with AKAPs, is a key mechanism for PKA-dependent phosphorylation events and potentiation of insulin secretion in pancreatic beta-cells. These PKA-AKAPs interactions represent an additional level of complexity in the regulation of pancreatic beta cells responses to physiological cAMP-elevating agents.

PKC's role in insulin biosynthesis and release in rat islets

N. Warwar, E. Haber, A. Dov, E. Abramovitch, E. Cerasi, R. Neshier; Endocrinology and Metabolism, Hadassah – The Hebrew University Medical Center, Jerusalem, Israel.

Introduction: Glucose metabolism affects most major signal pathways in pancreatic β -cells, including insulin production, storage and exocytosis.

Multiple protein kinases, mediate these effects; however, the role of most kinases is poorly defined. Here we examined the dynamics of glucose dependent activation and translocation of PKC ϵ in β -cells of Wistar rats, and followed its role in the control of insulin secretion and biosynthesis.

Methods: (A) Isolated pancreata from Wistar and GK rats and were stimulated with glucose (16.7 mmol/l) and fixed at time points selected to resolve function in the biphasic dynamics of insulin release. Sections were immunostained with anti-PKC ϵ and anti-insulin antibody and imaged using a three-gun laser-scanning confocal microscope. (B) Adenoviral vectors were used to inhibit PKC ϵ translocation or to inhibit the enzyme's activity, and siRNA constructs were used to diminish PKC ϵ levels. Isolated islets were infected or transfected and used in perfusion studies to study the dynamics of insulin response to glucose or in batch studies to follow total protein and insulin biosynthesis. Insulin precursors and intermediates were identified by HPLC.

Results: Glucose stimulus resulted in the concentration of PKC ϵ near the nucleus, strongly associated with insulin staining and with dynamics resembling that of biphasic insulin response. However the signal persisted for 15 min after cessation of stimulation. Adenovirus or siRNA mediated depletion of PKC ϵ function lead to partial inhibition of insulin secretion in isolated islets. No glucose-induced translocation of PKC ϵ was observed in GK rats pancreas, suggesting a role in the defective insulin response in this model for T2DM. β 'COP-1 was identified as the anchoring protein for PKC ϵ . The fact that β 'COP-1, is a member of the COP complex that controls Golgi protein transport, lead us to examine the role of PKC ϵ in production of β -cell proteins in general and that of insulin, specifically. In isolated islets, diminished PKC ϵ activity by adenovirus or by siRNA, lead to specific inhibition of proinsulin biosynthesis and its conversion to insulin.

Conclusion: Our data suggest a role for PKC ϵ in insulin biosynthesis and in granules exocytosis in pancreatic β -cell. Its diminished activity might be one of the defective signaling in the diabetic islet.

0512

Glucose and dexamethasone regulation of serine/threonine protein phosphatase 5 in normoglycaemic and hyperglycaemic human and rat islets

N. Grankvist¹, H. Ortsäter¹, Q. Zhang¹, R. Honkanen², Å. Sjöholm¹;
¹Department of Clinical Science and Education, Karolinska Institutet, Stockholm, Sweden, ²Department of Biochemistry and Molecular Biology, University of South Alabama, Mobile, United States.

Background and Aims: Serine/threonine Protein Phosphatase 5 (PP5) is a single polypeptide chain containing a catalytic domain near its C-terminus and a regulatory domain at the N-terminus end. The enzyme is present in the cytosol. PP5 is an okadaic acid/microcystin/calyculin A-sensitive phosphatase that belongs to the PPP family of enzymes. Like the other PPP-phosphatases (PP1, PP2A, PP2B/calcineurin, PP4, PP6, and PP7), PP5 is highly conserved among species, and PP5 is expressed in most, if not all, mammalian cells. Its biological function is only beginning to emerge, but PP5 is suggested to be involved in the regulation of glucocorticoid receptor signaling to promote cell growth and to terminate responses to oxidative stress. The influence of PP5 on β -cell function is currently unknown. The aim of the present study was to investigate if the cellular protein level of PP5 is regulated by glucose and dexamethasone.

Materials and Methods: Isolated islets of Langerhans from human donors with or without type 2 diabetes were cultured at 3 or 30 mM glucose in the absence or presence of 500 nM dexamethasone for 48 hours. Islets isolated from normoglycaemic Wistar and age- and sex-matched hyperglycaemic Goto-Kakizaki (GK) rats were cultured for 48 hours in the presence of either 3 or 30 mM glucose. After exposure insulin secretion to the culture media was determined by ELISA. The islets content of PP5 and β -actin proteins were measured by western blot and their insulin content were measured by ELISA.

Results: Human pancreatic islets isolated from healthy donors released 6-fold more insulin when cultured at 30 mM glucose than islets cultured at 3 mM glucose. Dexamethasone did not affect basal insulin secretion at 3 mM glucose but blunted the insulinotropic effect of 30 mM glucose. Human islets isolated from patients with type 2 diabetes showed elevated basal insulin secretion at 3 mM glucose and thus an augmented secretory response to 30 mM glucose. In such islets dexamethasone reduced the secretory rate both at 3 and 30 mM glucose. The islet protein levels of PP5 was positively regulated

both by glucose and dexamethasone in healthy human islets whereas only dexamethasone were able to increase PP5 protein levels in islets isolated from patients with type 2 diabetes. We also investigated the capability of glucose to regulate PP5 protein levels in islets isolated from normoglycaemic Wistar and hyperglycaemic GK rats. As expected 30 mM glucose caused a 5-fold increase in insulin secretory rate in Wistar islets but only a 2-fold increase in GK rat islets. Similar to the finding in human islets glucose caused an elevation (211 \pm 43 %) in islets PP5 protein levels in normoglycaemic rats but failed to do so in islets obtained from hyperglycaemic rats. When comparing Wistar and GK rat islets with regard to their basal PP5 protein levels we observed that GK rats had higher basal PP5 protein levels.

Conclusion: We describe glucose and dexamethasone regulation of PP5 at the translational levels, and show quantitative and qualitative differences between normal and diabetic islets with regard to ability of glucose to regulated PP5 protein levels. PP5 may be a novel regulatory mechanism linking β -cell stimulation to biological responses such as proliferation, apoptosis and insulin exocytosis.

Type III phosphatidylinositol 4-kinases mediate plasma membrane PIP₂ synthesis in insulin-secreting cells

A. Wuttke, J. Säger, N. Welsh, A. Tengholm;
 Medical Cell Biology, Uppsala University, Sweden.

Background and Aims: The membrane phospholipid phosphatidylinositol 4,5-bisphosphate (PIP₂) is important in many types of cells as precursor for second messengers and as regulator of a plethora of cellular processes, including ion channel and transporter activity, cytoskeletal rearrangements and vesicle trafficking. Many of these functions are crucial for insulin secretion from pancreatic β -cells. The first step of PIP₂ synthesis involves formation of phosphatidylinositol 4-phosphate catalyzed by phosphatidylinositol 4-kinases (PI4-kinases). These enzymes may act as metabolic sensors translating changes in the ATP/ADP ratio to phosphoinositide synthesis. This study aimed at identifying the PI4-kinases expressed in pancreatic β -cells and their importance for plasma membrane PIP₂ production.

Materials and Methods: mRNA expression of PI4-kinases was analyzed in MIN6 β -cells with real-time PCR and isoform-specific primers. Plasma membrane PIP₂ concentration was measured in individual cells expressing the PIP₂-binding PH-domain from PLC δ fused to GFP (PHPLC δ -GFP). After plasma membrane permeabilization with α -toxin, ATP-dependent PIP₂ synthesis was recorded as PHPLC δ -GFP translocation with evanescent wave microscopy.

Results: Real-time PCR analysis of MIN6 β -cells demonstrated the presence of mRNA for all four known mammalian isoforms of PI4-kinase (type II α , II β , III α and III β). Individual permeabilized MIN6 cells maintained in intracellular-like medium lacking ATP showed low and stable membrane PHPLC δ -GFP fluorescence. Introduction of ATP resulted in a concentration-dependent rise of fluorescence. This effect reflected membrane translocation of the construct as PIP₂ was synthesized and was prevented by 100 μ M of the PI4-kinase inhibitor phenylarsine oxide. PIP₂ synthesis induced by 0.3–1 mM ATP was unaffected by wortmannin at 100 nM, a concentration sufficient to inhibit PI3-kinase. However, at 10 μ M, a concentration known to inhibit type III PI4-kinases, wortmannin completely prevented ATP-induced PIP₂ synthesis. Such complete inhibition was also obtained with 200 μ M LY294002, which like wortmannin affects only type III, but not type II PI4-kinases. Addition of 0.5 mM adenosine, which preferentially inhibits type II PI4-kinases, did not further affect membrane PIP₂ levels.

Conclusion: MIN6 β -cells express both type II and type III PI4-kinases. Intracellular ATP stimulates plasma membrane PIP₂ synthesis mainly via type III isoforms. The various PI4-kinases may control phosphoinositide synthesis in distinct cellular compartments and thereby contribute to the variety of functions of PIP₂.

Selective insulin signaling in pancreatic beta cells involves different classes of PI3 kinases

B. Leibiger¹, S. Uhles¹, T. Moede¹, J. Domin², P.-O. Berggren¹, I. B. Leibiger¹;
¹Department of Molecular Medicine & Surgery, Karolinska Institutet, Stockholm, Sweden, ²Division of Medicine, Renal Section, Imperial College School of Medicine, London, United Kingdom.

Background and Aims: Pancreatic beta-cells are targets for positive feedback action by secreted insulin. We have shown that insulin activates the transcription of its own gene by signaling through A-type insulin receptor (IR-A) while it activates transcription of the beta-cell glucokinase transcription unit (BGK) via the B-type, IR-B. Because both signaling pathways were differently sensitive towards Wortmannin and LY294002, we studied the PI3K involved.

Materials and Methods: As the readout for signaling via either IR-A or IR-B served insulin promoter-driven DsRed expression and BGK promoter-driven GFP expression, respectively, in co-transfected HIT-T15, MIN6 and primary mouse beta-cells. PI3K activity was measured in IR immunoprecipitates (IPs). By combining the use of pharmacological inhibitors with transient overexpression of insulin receptor variants, phosphatidylinositol phosphatases PTEN and SHIP, and siRNA based knockdown of PI3Ks, we now show that selective activation of insulin and glucokinase gene transcription can be simultaneously achieved by utilizing different classes of PI3K and thereby activating different signaling cascades.

Results: 25 μ M LY294002 or 50 nM Wortmannin in the culture medium blocked insulin-stimulated insulin promoter activity. It needed 100 μ M LY294002 or 150 nM Wortmannin to block insulin-stimulated BGK promoter activity. PI3K activity in IR-A IPs was inhibited by 5–10 nM Wortmannin as described for PI3K classes I, II C2b and III. It needed 100 nM to block PI3K activity associated with IR-B, i.e. concentrations similar to those that inhibit PI3K class II C2a. Overexpression of the dominant-negative acting form of the class Ia adapter protein p85, i.e. Delta-p85, or siRNA against p85, abolished insulin-stimulated insulin promoter activity but not insulin-stimulated BGK promoter activity. Vice versa, siRNA-mediated knockdown of PI3K-C2a abolished insulin-stimulated BGK activation without any effect on insulin promoter activity. The data show that PI3K class Ia is crucial in up-regulating insulin gene transcription, while the class II member PI3K-C2a is required to activate the BGK in the same cell. Moreover, we identified the juxtamembrane NPEY-motif in the insulin receptor B-type as being crucial for PI3K-C2a-mediated up-regulation of the BGK promoter.

Conclusion: Our data suggest that one of the molecular mechanisms involved in the selective signaling via the two IR isoforms in the pancreatic beta-cell is the selective activation of different classes of PI3K.

Insulin release and islet nitric oxide synthase (NOS) activities in type 2 diabetes obese model, the ob/ob mouse. Interaction with regulatory peptides and islet carbon monoxide (CO) production

S. Meidute Abaraviciene¹, J. Jimenez-Felstrom¹, R. Henningsson², I. Lundquist², A. Salehi¹;

¹Clinical Sciences, Malmoe, Lund University, Malmoe,

²Experimental Medical Science, Lund University, Lund, Sweden.

Background and Aims: We investigated the role of islet nitric oxide synthase (NOS) isoforms on insulin secretory mechanisms in the obese *ob/ob* mouse, an animal model of type 2 obese diabetes.

Materials and Methods: Nitric oxide synthase (NOS) activity was determined by HPLC, carbon monoxide (CO) production was detected with a sensitive gas chromatographic method and insulin release with RIA.

Results: In isolated islets nNOS activity was similar in *ob/ob* mice and lean littermates and iNOS expression was negligible. Islets from *ob/ob* or lean mice incubated at high glucose showed increased iNOS activity, while nNOS activity was raised only in lean islets. Glucose injection induced strong expression and activity of islet iNOS in lean, but surprisingly not in obese mice. In *ob/ob* islets the insulinotropic peptides glucagon, GLP-1, and GIP suppressed islet NOS activities and increased insulin release, while the

insulinostatic peptide leptin induced the opposite effects. The production of heme oxygenase (HO)-derived carbon monoxide (CO), a NOS inhibitor, was impressively raised in *ob/ob* islets and the HO inhibitor ZnPP suppressed while the HO activator hemin amplified glucose-stimulated insulin release.

Conclusion: The data suggest that islets from *ob/ob* mice existing in an insulin resistant and hyperglycemic milieu maintain high rate of insulin secretion and protection from glucotoxic effects through being equipped with negligible iNOS activity, which apparently results from a general suppression of islet NOS activities induced by cyclic AMP-generating hormones, high CO production, and leptin deficiency. This beneficial effect on islet function and survival by suppressed iNOS coupled with leptin deficiency might have its clinical counterpart in human leptin-resistant type 2 obese diabetes with hyperinsulinemia.

NN414, a SUR1/Kir6.2-selective potassium channel opener prevents diabetes-induced structural changes of mitochondria: studies in a diabetic transplantation model

A. Björklund¹, T. Wallin¹, Z. Ma¹, H. Borg², J. Bondo Hansen³, V. Grill⁴;
¹Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden, ²Medical Cell Biology, BMC, Uppsala, Sweden, ³Novo Nordisk Research and Development, Novo Nordisk Park, Målöv, Denmark, ⁴Institute of Cancer Research and Molecular Medicine, Norwegian University of Science and Technology, Trondheim, Norway.

Background and Aims: We have previously shown that chronic over-stimulation by moderate hyperglycaemia as commonly found in Type 2 diabetes can irreversibly desensitize beta cells and decrease glucose-induced insulin secretion. In this study we tested for a role of mitochondrial dysfunction.

Materials and Methods: We transplanted islets from Wistar-Furth rats under the kidney capsule to neonatally streptozotocin-diabetic or non-diabetic recipients. Diabetic recipients received daily vehicle, or the selective activator of beta cell type K(+)-ATP channels 6-chloro -3-(1-methylcyclopropyl) amino-4 H-thienol [3,2-e]-1,2,4-thiadiazine 1,1-dioxide (NN414) (3 mg/kg) intragastrically for 8 weeks. Non-diabetic rats received vehicle alone. Transplants were excised exactly 7 days after cessation of treatment (wash-out) and prepared for electron microscopy followed by quantitative morphometric analysis of mitochondria.

Results: Mean blood glucose was 4.6 mmol/l in the non-diabetic rats, 7.7 in vehicle-treated diabetic and 9.5 in NN414-treated animals. Non-diabetic recipients increased weight more markedly than vehicle-treated diabetic rats whereas there was almost no increase in the NN414-treated diabetic rats. The beta cells of islets from grafts from vehicle-treated diabetic rats displayed an extensive rough endoplasmic reticulum with numerous free ribosomes spread through the cytoplasm of the cells. Swollen, pale mitochondria with cristae only seen in the periphery of the organelle were apparent. Volume density of mitochondria (V_{VM}), density of the mitochondrial outer surface area (S_{VM}) and the number of mitochondria per unit volume of tissue (N_{VM}) were measured. From these primary parameters secondary ones were calculated. In vehicle-treated diabetic rats the average mitochondrial volume (V_{VM}/N_{VM}), $p < 0.001$ as well as the average mitochondrial outer surface area (S_{VM}/N_{VM}) $p < 0.001$ was increased vs. non-diabetic rats. NN414-treatment of the diabetic rats partly but significantly normalized these diabetes-induced differences, $p = 0.003$ and $p = 0.001$ for effects on (V_{VM}/N_{VM}) and (S_{VM}/N_{VM}) respectively.

Conclusion: Long-term diabetes with over-stimulation by hyperglycemia leads to pathologically enlarged but fewer mitochondria and these effects are partly counteracted by treatment with NN414. Therapies that prevent over-stimulation may have beneficial effects on beta cell functioning by way of preventing mitochondrial dysfunction.

Ca_v1.2 channels, rather than Ca_v1.3 and Ca_v2.3 channels, permit insulin secretion from INS-1 832/13M. Dekker Nitert¹, A. Wendt², L. Eliasson², H. Mulder¹;¹Diabetes, Metabolism & Endocrinology, Experimental Medical Science, Lund, ²Islet cell exocytosis, Clinical Science, Malmö, Sweden.

Background and Aims: An elevation of intracellular calcium mediated by voltage-gated calcium channels is required for insulin secretion from pancreatic β -cells. However, the voltage-gated calcium channels in the clonal β -cell line INS-1 832/13 have not been characterized. In other clonal β -cell lines and islets from different species, a variety of calcium channels has been found to influence insulin secretion. The aim of this study is to identify the voltage-gated calcium channels that control insulin secretion in INS-1 832/13 cells.

Materials and Methods: Ca_v1.2, Ca_v1.3, and Ca_v2.3 mRNA levels were examined by real time-PCR. Using the calcium-indicator FURA-2AM, intracellular calcium influx into the cells was studied in response to glucose and potassium chloride. The calcium channel blockers isradipine, which blocks Ca_v1.2 and Ca_v1.3, and SNX-482, which blocks Ca_v2.3, were employed. Ca_v1.2 expression was knocked down by RNA interference.

Results: Insulin secretion, which rose 10-fold in response to 16.7 mM glucose (46±14 pg/mg/h), was completely abolished by isradipine (5±2 pg/mg/h). Similarly, the increase in intracellular calcium in response to 15 mM glucose was 61 ± 15 nM but decreased by 21 ± 12 nM in the presence of isradipine, and the frequency of calcium spikes was decreased to the level seen at 2.8 mM glucose. Isradipine also reduced insulin secretion in response to 16.7 mM glucose with 35 mM potassium chloride from 143 ± 10 to 4 ± 2 pg/mg/h. In contrast, inhibition of Ca_v2.3 with SNX-482 did not significantly affect insulin secretion or intracellular calcium. While the cells expressed mRNA for all three calcium channels, the levels of Ca_v1.2 exceeded those of Ca_v1.3 and Ca_v2.3 by two orders of magnitude. Ca_v1.2 mRNA was knocked down by RNA interference to ≈70% of that in control cells, reducing insulin secretion in response to 16.7 mM glucose by ≈50%. The remaining insulin secretion could be reduced to a level equivalent to that at 2.8 mM glucose with isradipine. The calcium influx underlying this remaining insulin secretion could be accounted for by Ca_v1.2 expressed on untransfected cells and/or Ca_v1.3 expression.

Conclusions: INS-1 832/13 cells express Ca_v1.2, Ca_v1.3 and Ca_v2.3. Ca_v1.2 is critical for insulin secretion in these cells although Ca_v1.3 may also play a role. Ca_v2.3 does not appear to play a significant role in insulin secretion in INS-1 832/13 cells, which confirms the previously reported findings in parental INS-1 β -cells. In primary mouse β -cells, however, Ca_v2.3 accounts for 18% of insulin secretion. Taken together, this implies species differences in the role of Ca_v2.3 in insulin secretion.

Loss of extracellular glucose detection by GLUT2 in pancreatic beta cells deeply alters mouse glucose tolerance

E. Stolarczyk, M. Le Gall, E. Brot-Laroche, P. Serradas, A. Leturque; Equipe 9, UMRS 872 INSERM/UPMC/UPD, Paris, France.

Background and Aims: We are investigating the mechanisms by which cells sense and adapt their functions to their nutritional environment, focusing on glucose detection. In hepatic cell line, the expression of a GLUT2 cytoplasmic loop-domain inhibits the stimulation of glucose-sensitive gene expression without modification of glucose metabolism. Our aim is to evaluate *in vivo* the importance of the detection of extracellular glucose triggered by GLUT2 independently of intracellular glucose metabolism on glucose tolerance and pancreatic functions.

Materials and Methods: We created transgenic mice that ubiquitously express the GLUT2 cytoplasmic loop-domain and measured the changes in glucose homeostasis that are resulting from the loss of sugar detection. Glucose tolerance tests (3.6g glucose/kg) were performed in 24h fasted-mice. Insulin and glucagon labelling were performed in pancreas fixed in Bouin's solution and embedded in paraplast according to standard procedures. The number of small beta-cell clusters (<3 insulin positive cells) and islets were quantified in serial pancreas sections.

Results: In the pancreas of GLUT2-loop transgenic mice, the stimulation of sugar-sensitive target genes such ChREBP was reduced in response to a sugar-rich meal. This was not due to decreased GLUT2 protein warranting a preserved glucose metabolism. An oral glucose tolerance test revealed glucose intolerance in transgenic mice. This was correlated with reduced plasma insulin levels. Further investigation of transgenic pancreas showed lower insulin stores (by 30%) but normal proinsulin mRNA expression. Moreover, islet architecture was normal since glucagon cells surrounded insulin positive cells. Total number of islets was similar in transgenic and wild-type mice. However, pancreas weight and ratio of small beta-cell clusters (<3 insulin positive cells) over total number of islets were increased in transgenic compared to wild-type mice.

Conclusion: Taken together these data suggest that invalidation of GLUT2-mediated glucose detection in GLUT2-loop transgenic mice perturbed significantly insulin response to oral glucose in the pancreas. Multiple steps in the process of insulin maturation, formation of insulin stores and islet size are dependent on GLUT2-mediated glucose detection. Thus extracellular glucose detection by GLUT2 controls many aspects of glucose homeostasis. Perturbation of this physiological process may participate in metabolic diseases.

Upregulation of key β cell genes and improvement of function in rodent islets following chronic *in vitro* treatment with a glucokinase activator

D. Gill, D. M. Smith;

AstraZeneca, Macclesfield, United Kingdom.

Background and Aims: Glucokinase (GK) is the glucose sensor in the β -cell and controls the threshold for glucose-stimulated insulin secretion (GSIS). Several small molecule direct activators of GK have been discovered which increase GSIS in β -cells and stimulate hepatic glucose metabolism. We have previously reported the acute effects of a glucokinase activator (GKA50) on the β -cell, demonstrating that GKAs stimulate insulin secretion by a "glucose-like" mechanism. Whether chronic GKA treatment would result in beneficial or "glucotoxic" effects on the islet has not previously been described. The aim here was to determine the chronic effects of one of these compounds, GKA71, on pancreatic β -cell function. Following chronic *in vitro* culture of mouse and rat islets in the presence of GKA71 gene expression was analysed. Perfusion was used to assess the effect of chronic GKA treatment on rat islet GSIS.

Materials and Methods: Islets were prepared from male Wistar rats and C57Bl/6 mice by Liberase digestion. For acute assessment of insulin secretion islets were cultured overnight in 11mM glucose prior to 2h static incubations. For chronic experiments, islets were allowed to recover overnight prior to 72h

incubation in the absence and presence of 10 μ M GKA71 (in 5mM and 25mM glucose), with daily media changes. Taqman low density arrays (TLDA) (mouse islets, only changes >3 fold were considered biologically significant) and single gene Taqman RT-PCR (mouse and rat islets) were performed. All expression data was normalised to HPRT. Islets were perfused using a Brandel SF-12 Superfusion system, using 50 islets per channel. Insulin secretion was assessed at basal (3mM) and stimulated (15mM) glucose concentrations.

Results: In rat islets incubated with 3mM, 5mM and 8mM glucose 1 μ M GKA71 caused a 2.3, 4.6 and 2.6 fold increase in insulin release, respectively (n=4), but at 1mM, 10mM and 20mM glucose there was no effect of GKA71. In mouse islets cultured in 5mM glucose GKA71 (10 μ M) caused a 42 fold (p=0.002) increase in insulin mRNA (n=3). The TLDA results showed that GKA71 caused an increase in amylin (4.6 fold, p=0.0045), insulin (15.9 fold, p=0.0013), PDX1 (4.5 fold, p=0.012), PC1 (6.5 fold, p=0.0014), and GLUT2 (29.3 fold, p<0.001) expression and a decrease in CEBP β (5.0 fold, p=0.04) expression. In rat islets cultured in 5mM glucose (n=6) GKA71 caused an increase in insulin (2.7 fold, p<0.001), GLUT2 (2.3 fold, p<0.001), PC1 (2.5 fold, p<0.001) and amylin (2.2 fold, p<0.001) expression with no significant changes in PDX1 or GK expression. Rat islets treated chronically with GKA71 had an 8.5 fold increase (n=3, p<0.001) in first phase insulin secretion and a 35 fold increase (p=0.001) in second phase insulin secretion compared with control-treated islets. The insulin secretion profile of islets treated with GKA in the presence of 5mM glucose was very similar to that of islets cultured in 25mM glucose for the same period.

Conclusion: GKA71 stimulates insulin release from rat islets in acute experiments. Here we show for the first time that chronic treatment of rodent islets with GKA71 in the presence of 5mM glucose significantly increased the expression of key β -cell genes, including insulin, and significantly increased first and second phase insulin secretion. These results demonstrate that in addition to the reported effects of GKAs on improving blood glucose homeostasis, they may also have an important role in β -cell preservation, and by increasing insulin mRNA be less likely to cause β -cell exhaustion.

Glucose-dependent interaction of glucokinase and PFK-2/FBPase-2 in insulin-producing cells

S. Langer, S. Lenzen, S. Baltrusch;
Institute of Clinical Biochemistry, Hannover Medical School, Germany.

Background and Aims: Glucokinase (GK) plays a pivotal role in the process of glucose-induced insulin secretion in pancreatic beta cells. In previous experiments we elucidated binding between GK and the bifunctional enzyme 6-phosphofructo-2-kinase/fructose-2,6-bisphosphatase (PFK-2/FBPase-2). In pancreatic beta cells expressing the PFK-2/FBPase-2 brain isoform the enzyme acts as an endogenous activator of GK enzyme activity. By immunohistochemistry we demonstrated a glucose-dependent colocalization of GK and PFK-2/FBPase-2 accompanying the increase in GK enzyme activity. The aim of this study was to monitor GK and PFK-2/FBPase-2 complex formation and separation in living cells.

Material and Methods: Interaction between GK and PFK-2/FBPase-2 was analyzed in insulin-producing MIN6 cells using a new fluorescence based mammalian two-hybrid system. Colocalization of GK and PFK-2/FBPase-2 was determined via *in vivo* labeling with the fluorescent proteins ECFP (enhanced cyan fluorescent protein) and EYFP (enhanced yellow fluorescent protein). Association between these labeled proteins was measured via FRET (fluorescence resonance energy transfer).

Results: The mammalian two-hybrid system was established in insulin-producing cells using a new reporter vector containing two fluorescent protein genes. For quantitative analysis one fluorescent protein was necessary for normalization of unavoidable variability in the transfection efficiency while the second one served as the reporter. In contrast to the commonly used mammalian two-hybrid systems that require cell lysis prior to detection our system allows monitoring of the effects of environmental changes on the protein interaction. In medium supplemented with 25 mmol/l glucose a significant interaction between GK and PFK-2/FBPase-2 was measured. Lowering of the glucose concentration in the cell culture medium abolished the interaction between the enzymes. The fluorescent fusion proteins ECFP-GK and EYFP-PFK-2/FBPase-2 were colocalized in a comparable manner as the endogenous proteins, demonstrated by immunohistochemistry. In agreement with the two-hybrid results colocalization between GK and PFK-2/FBPase-2 was significantly higher in cells cultured in medium supplemented

with 25 mmol/l glucose than in medium with 3 mmol/l glucose. Furthermore transfer of fluorescence energy (FRET) from ECFP-GK to EYFP-PFK-2/FBPase-2 was detectable indicating a direct interaction between GK and PFK-2/FBPase-2.

Conclusion: The interaction between GK and PFK-2/FBPase-2 is promoted by glucose. Thus PFK-2/FBPase-2 plays a major role in the glucose-dependent compartmentation and regulation of GK in insulin-producing cells. Our results may open the perspective for a therapeutic targeting of this interaction in type 2 diabetes therapy. Furthermore our established mammalian two-hybrid system offers in insulin-producing cells the possibility to monitor changes in the association of the two key regulatory beta cell proteins in dependence on metabolic conditions as accruing in type 2 diabetes.

Long-chain fatty acyl coenzyme A inhibition of glucokinase in pancreatic islets from rats depleted in long-chain polyunsaturated ω 3 fatty acids

Y. Zhang¹, N. Bulur¹, S. Peltier², Y. A. Carpentier², W. J. Malaisse¹, A. Sener¹;
¹Lab of Experimental Hormonology, Université Libre de Bruxelles,
²Lab of Experimental Surgery, Université Libre de Bruxelles, Belgium.

Background and Aims: The metabolism of D-glucose, but not that of L-glutamine or palmitate, is impaired in pancreatic islets from 2nd generation rats depleted in long-chain polyunsaturated ω 3 fatty acids (ω 3-D rats). The possible participation of altered glucokinase kinetics in such an impairment was investigated in the present study.

Methods: The phosphorylation of D-[U-¹⁴C]glucose by islet homogenates from control animals and ω 3-D rats was measured over 60 min incubation at 37°C in the presence of 5.0 mM ATP.

Results: The apparent activity of glucokinase, as judged from the increase in D-glucose phosphorylation in response to a rise in the concentration of the hexose (e.g. from 1.0 to 20.0 mM), only represented, in ω 3-D rats, 81.8 \pm 4.8 % (n = 11; p < 0.005) of the paired value recorded within the same experiment in control animals. Two series of findings suggest that these results reflect an altered kinetic behaviour of glucokinase, rather than a mere decrease of its islet content. First, the incorporation of exogenous D-glucose 6-phosphate (G6P, 3 mM) and D-fructose 1-phosphate (F1P, 1 mM) into the assay medium decreased the reaction velocity in ω 3-D rats by only 93.2 \pm 2.9 % (n = 8; p < 0.05) of the inhibition found in control animals, as if glucokinase was already partially inhibited by some endogenous factor in the former rats. Second, glucokinase activity, as estimated from the increase in reaction velocity resulting from a rise in D-glucose concentration from 6.0 to 20.0 mM in the presence of exogenous G6P and F1P, was decreased to 62.0 \pm 6.0 % (n = 4; p < 0.01) by palmitoyl CoA (50 μ M) in control animals, whilst failing to be significantly affected (85.9 \pm 12.5 %; n = 5; p > 0.3) by palmitoyl CoA in ω 3-D rats.

Conclusion: Glucokinase activity in islet homogenates from ω 3-D rats is apparently inhibited by endogenous long-chain fatty acyl CoA. This may account, in part at least, for the abnormally low increment in D-glucose utilization in response to a rise in hexose concentration and abnormally low ratio between oxidation and utilization of D-glucose prevailing in intact islets from ω 3-D rats.

Knock-down of pyruvate dehydrogenase kinase 1 in INS-1 832/13 cells increases insulin secretion

O. V. Kotova¹, U. Fransson¹, E. Hallgard¹, M. C. Sugden², H. Mulder¹;
¹Experimental Medical Science, Lund University, Lund, Sweden,
²Centre for Diabetes and Metabolic Medicine, Institute of Cell and Molecular Science, Barts, United Kingdom.

Background and Aims: Hyperglycemia and impaired glucose-stimulated insulin secretion are hallmarks of Type 2 Diabetes. High concentrations of glucose are toxic to pancreatic beta-cells, inducing changes in gene expression. Altered expression of genes encoding enzymes controlling the metabolic pathways involved in stimulus-secretion coupling may underlie impaired insulin secretion in Type 2 Diabetes. Here, we examined which genes coding for metabolic enzymes were affected by elevated glucose, and how they control insulin secretion.

Materials and Methods: We cultured INS-1-derived rat 832/13 clonal beta-cells for 48h at low (2.8 mM) or high (16.7 mM) glucose concentrations. Insulin secretion was measured, and cells were subjected to analysis by a custom-made array of 46 real time-PCR assays for genes involved in glycolysis, TCA cycle, oxidative phosphorylation, and lipid metabolism. A candidate gene was subsequently knocked down by RNA interference, and cellular function was evaluated by determination of insulin secretion, glucose oxidation, and the ATP/ADP ratio.

Results: After 48h culture at 2.8 mM glucose, insulin secretion increased 6.8-fold upon acute (1 h) stimulation with 16.7 mM glucose. In contrast, insulin secretion rose only 3.5-fold, when cells had been cultured for 48 h at 16.7 mM glucose. The pyruvate dehydrogenase kinase (PDK) 1 mRNA level was upregulated (2.4 fold; $P < 0.01$) in cells cultured at 16.7 mM glucose. When PDK1 was knocked down by RNA interference (PDK1 mRNA was reduced by 80%; $P < 0.001$; PDK1 protein expression was decreased, as assessed by Western Blot), insulin secretion in response to 16.7 mM glucose was enhanced by 60% ($P < 0.01$). In contrast, glucose oxidation and the glucose-induced rise in ATP/ADP ratio were unaffected by PDK1 knock down.

Conclusion: We suggest that maintenance of low PDK1 expression, resulting in dephosphorylation of pyruvate dehydrogenase (PDH) and thus, an increase in its activity, is an essential factor for robust glucose-stimulated insulin secretion in pancreatic beta-cells. Based on the observation that PDK1 knock down affected neither glucose oxidation nor the ATP/ADP ratio, we further propose that augmented cycling of citrate to pyruvate may be responsible for the enhancement of insulin secretion.

Ecto-nucleotidase activity in pancreatic islet cells

M.-H. Giroix¹, K. Louchami², E. Hupkens², N. Bulur², Y. Zhang², B. Portha¹, R. Beauwens³, W. J. Malaisse², A. Sener²;

¹Laboratory of Nutrition Physiopathology, CNRS UMR 7059, Université Paris 7 (Denis Diderot), Paris, France, ²Laboratory of Experimental Hormonology, Université Libre de Bruxelles, Belgium, ³Laboratory of Cell and Molecular Physiology, Université Libre de Bruxelles, Belgium.

Background and Aims: The purine nucleotide ATP is released intermittently in pancreatic islets from nerves, and from β -cells themselves together with insulin during exocytosis. This ATP is viewed as both a coordinator of the β -cell rhythmicity, and an autocrine regulator of insulin secretion acting at the intervention of purinoceptors. Such a view led us to investigate whether islet cells display ecto-nucleotidase activity.

Materials and Methods: Pancreatic islets isolated from rat, as well as BRIN-BD 11 and INS-1E cells, were incubated in a salt-balanced medium containing, as required, ATP or other nucleotides. The fall in nucleotide concentration of the incubation medium was monitored by bioluminescent or HPLC procedure. The nucleotide-hydrolyzing activity was also assessed in cell-free incubation media obtained after incubation of islets or islet cells in the absence of any exogenous nucleotide.

Results: After 60 min preincubation of pancreatic islets, BRIN-BD 11 or INS-1E cells in the absence of exogenous ATP, both the islet cells and cell-free medium collected after preincubation demonstrated ATP-hydrolyzing activity, the rate of ATP breakdown being about twice higher in the former than latter case. The release of the hydrolytic activity by the islets occurred at a fairly constant rate over two first preincubation periods of 15 min each and, thereafter, slowly decreased. It was independent of the glucose concentration, and was also detected after a prior 4-day culture of the islets. It apparently failed to differ significantly in islets from normal Wistar (W) rat and Goto-Kakizaki (GK) rat, which represents a model of type 2 diabetes. Thus, the hydrolase activity released over 60 min incubation at 37°C averaged, in W and GK rats respectively, 3.09 ± 0.09 and 3.14 ± 0.15 pmol / islet per 15 min at 1.0 μ M ATP, and 8.88 ± 0.57 and 9.05 ± 0.62 pmol / islet at 3.0 μ M ATP ($n = 8$ in all cases). ADP, AMP and adenosine were generated during ATP breakdown. External ATP, ADP and AMP (10 μ M each) were hydrolyzed at near equal rates. Hydrolysis of GTP, CTP, UTP and ITP (10 μ M each) was also observed. The ATP hydrolytic activity was modulated by the ATP concentration and required the presence of divalent cations (residual activity $< 20\%$ in $\text{Ca}^{2+}/\text{Mg}^{2+}$ -free medium containing 2.5 mM EDTA). It was little affected by classic inhibitors of the P-, F-, and V-type ATPases such as ouabain (1.0 mM), sodium orthovanadate (0.5 mM), sodium azide (1.0 mM) or sodium nitrate (100 mM), but decreased by 50–80 % by the P_2 receptor

antagonists pyridoxalphosphate-6-azophenyl-2',4'-disulfonic acid (PPADS) and suramin (0.1 mM each) reported as inhibitors of ecto-ATPases.

Conclusion: The present study reveals that pancreatic islet cells display ecto-nucleotidase activity, which is apparently expressed at the plasma membrane level and is also released from the cells in the extracellular medium. Such an activity, which could involve several ecto-enzymes, is obviously susceptible to affect the concentration of ATP released by nerve endings and insulin-producing cells in the islet interstitial fluid.

The effect of over-expression of the mitochondrial Aspartate-Glutamate exchanger Aralar1 on insulin secretion and metabolism in the BRIN-BD11 cell line

K. Bender¹, P. Maechler², P. Newsholme¹;

¹Conway Institute, UCD School of Biomolecular and Biomedical Science, Dublin, Ireland, ²Department of Cell Physiology and Metabolism, University Medical Centre, Geneva, Switzerland.

Background and Aims: In the beta cell, mitochondrial Redox- NADH-shuttles are important for coupling glycolysis to mitochondrial energy metabolism. Aralar1, an Aspartate- Glutamate exchanger in the Malate-Aspartate shuttle, has been found to play an important regulatory role in oxidative glucose metabolism and insulin secretion in rat derived INS-1E cells as well as in the clonal BRIN- BD11 cell line. Certain amino acids, in particular L- alanine, L-leucine and L- glutamine, are known to stimulate both insulin secretion and glucose metabolism in the BRIN- BD11 cell line. These effects may have been due to stimulation of anaplerotic metabolism.

Materials and Methods: We have now over- expressed Aralar1 by the means of the recombinant Adenovirus AdCA- Aralar1 in clonal BRIN BD11 cells and have investigated the involvement of Aralar1 in stimulation of glucose and amino acid metabolism plus insulin secretion in the presence or absence of the aminotransferase inhibitor Aminooxyacetate or intracellular Calcium chelator BAPTA-AM. The following parameters were determined; glucose and glutamine consumption, lactate and glutamate generation, mitochondrial membrane potential, NADH and ATP levels, triglyceride and glycogen content and insulin secretion.

Results: Aralar1 over- expression in BRIN-BD11 cells resulted in enhanced glucose consumption ($p < 0.05$), mitochondrial membrane hyperpolarization ($p = 0.03$), NADH levels ($p < 0.05$) and insulin secretion ($p < 0.01$). Insulin secretion and glucose consumption were further enhanced by the presence of 10mM alanine (+30%, $p < 0.01$ and +25%, $p = 0.02$ respectively) whereas both were significantly reduced by the presence of 10mM L- aspartate ($p < 0.05$). However, addition of L- glutamine did not significantly change any of these parameters. The presence of 5mM aminooxyacetate did not significantly inhibit insulin secretion or glucose consumption in Aralar1- over- expressing cells.

Conclusion: The Aspartate- Glutamate exchanger Aralar 1 may be an important site for metabolic control and stimulus-secretion coupling in the pancreatic beta cell.

GAD65 and GABA-transaminase genes are more highly expressed in pancreatic islets than the α -ketoglutarate dehydrogenase gene

I. Hernández-Fisac¹, J. Pizarro-Delgado¹, R. Martín-del-Río², J. Tamarit-Rodriguez;

¹Biochemistry, Complutense University,

²Research Department, Hospital "Ramón y Cajal", Madrid, Spain.

Background and Aims: There is no complete information available in the literature on the expression of all the enzymes responsible of GABA metabolism in pancreatic islets. Direct evidence is missing that GABA can be metabolized either to succinic or to γ -hydroxybutyric acid.

Material and Methods: Semialdehyde succinic acid dehydrogenase and reductase (SSAdh and SSAdh), and α -ketoglutarate dehydrogenase (α KGdh) activities were measured in rat islet homogenates as either NADH production or NADPH consumption in the presence of excess of substrates. Succinic

acid dehydrogenase activity (SUCdh) was measured as the reduction of 2,6-dichloroindophenol by respiratory complex II in the presence of rotenone and excess of succinic acid. Islet RNA isolation and retrotranscription were performed with RNeasy[®] Mini and Quantitect[®] Reverse Transcription kits (Qiagen). Gene expression analysis was performed by real-time RT-PCR, using 18S rRNA as an internal control and pre-designed TaqMan[®] Gene Expressions Assays (Applied Biosystems).

Results: SSAdh and SSAd activities measured in islet homogenates were of a similar magnitude than α KGdh and SUCdh. SSAdh and α KGdh were strongly inhibited by α -ketobutyric acid. SSAd and α KGdh were dose-dependently inhibited by α -ketoisocaproic acid. In proportion to α KGdh (100.0 \pm 24.3 %, n=6), GAD65 and GABA-transaminase (GABA-T) genes showed the highest expression in islets (757.9 \pm 20.4 %, n=6, and 556.3 \pm 22.2 %, n=6, respectively), succinic acid dehydrogenase exhibited intermediate expression levels (259.2 \pm 18.3 %, n=6) whereas SSAdh and SSAd were similarly expressed (131.1 \pm 20.8 %, n=6, and 52.9 \pm 27.6 %, n=6, respectively). This islet gene expression pattern was found different from those observed in cerebellum and liver.

Conclusions: Islets express the enzyme activity responsible for returning "GABA-shunt" metabolic flow into the Krebs cycle (SSA conversion into succinic acid by SSAdh) and another one diverting it out (SSA conversion into γ -hydroxybutyric acid by SSAd). The much higher gene expression of GAD65 and GABA-T than α KGdh suggests that GABA is synthesised at a high rate in β -cells and that its transamination might compete efficiently with α KG decarboxylation in the Krebs cycle. We hypothesize that nutrient secretagogues decrease the intracellular concentration of GABA in β -cells supplying α -KG to feed GABA-T hence facilitating its metabolism to succinic or γ -hydroxybutyric acid. Preliminary experiments seem to indicate that γ -hydroxybutyric acid is produced in pancreatic islets incubated with L-glutamine and glucose.

Background and Aims: Human embryonic stem cells (hES) have been proposed as a potential unlimited source of tissue for transplantation in the treatment of type 1 diabetes. A great deal of research has been conducted on the differentiation of mouse embryonic stem cells into insulin producing cells, much of which is controversial due to the addition of insulin to culture media. There has been new success in the field with a successful differentiation of hES into definitive endoderm.

Materials and Methods: Recently, we have developed a defined protocol to differentiate human embryonic stem cells (hES) into cellular aggregates that are partially composed of pancreatic islet endocrine cells. We have further characterized these islet-like clusters (ILCs), and found them to be immunoreactive for islet markers such as insulin, C-peptide, glucagon, somatostatin, prohormone convertase 1/3 and 2, and PDX-1. We have observed that ILCs contain detectable insulin secretion by responding to a high glucose challenge *in vitro*. We have also transplanted hES derived ILCs under the kidney capsule of streptozotocin induced diabetic immunoincompetent mice, and although blood glucose levels were not normalized, human C-peptide was detected in the serum of these mice. One explanation for not achieving normoglycemia in these mice is that a sub-optimal number of insulin-positive beta cells were transplanted. Nonetheless, the expression of islet endocrine cell markers by immunohistochemistry and RT-PCR (insulin, glucagon, PDX-1) was also maintained even after 70 days *in vivo*.

Conclusion: These results show that ILCs differentiated from hES appear to be immature cells of pancreatic endocrine lineage, and it is possible that further purification, differentiation, and maturation of these cells could lead to the generation of a sufficient source of islets for transplant in patients with Type 1 diabetes.

Isolation, characterisation and prospects of endothelial progenitor cells to aid pancreatic beta cell regeneration

C. P. Khoo^{1,2}, M. G. Valorani^{1,3}, M. Brittan¹, M. R. Alison¹, C. Guglielmi³, G. Warnes⁴, U. Johansson⁵, M. I. Hawa¹, P. Pozzilli^{1,2};

¹Centre for Diabetes and Metabolic Medicine, Queen Mary University, London, United Kingdom, ²Area di Endocrinologia, Università Campus Bio-Medico, Rome, Italy, ³Stem Cell Research, Fondazione Livio Patrizi, Rome, Italy, ⁴Flow Cytometry & Imaging, Queen Mary University, London, United Kingdom, ⁵Centre for Haematology, Queen Mary University, London, United Kingdom.

Background and Aims: Endothelial progenitor cells (EPCs) in the bone marrow and peripheral blood contribute to tissue repair in various pathological conditions, *via* the formation of new blood vessels, and thus have a degree of stem cell potential. It is now established that diabetic patients have reduced EPC number and dysregulated EPC function. Our aim was to isolate, characterise and compare EPCs from pre-diabetic and diabetic non-obese diabetic (NOD) mice, a well-established model of type 1 diabetes to delineate their role in tissue regeneration.

Material and Methods: Whole bone marrow was obtained by flushing femurs, tibias and iliac crests from pre-diabetic and diabetic NOD mice (5–30 weeks) in which the diabetic status was confirmed by measuring blood glucose levels (\geq 11.5 mmol/l); peripheral blood was collected in heparin coated tubes and lysed after incubation with antibodies directed against EPCs. Pancreata from diabetic and pre-diabetic mice were acquired and paraffin embedded for immunohistochemical studies. Slides were stained with endothelial (Factor VIII⁺) and vascular smooth muscle cell (SMA⁺) markers.

Results: Morphological and immunohistochemical studies showed that in pancreata from diabetic mice compared to pre-diabetic mice, blood vessel density was significantly increased with vessels containing elevated numbers of both endothelial (Factor VIII⁺) and vascular smooth muscle cells (SMA⁺). FACS analyses revealed a significant decrease in EPC number (CD31⁺, c-Kit⁺, Sca-1⁺, Lin⁻) in BM from diabetic compared to pre-diabetic mice (P-value: 0.021), which is consistent with human studies. Conversely, EPC number was significantly increased in peripheral blood from diabetic compared to pre-diabetic mice (P-value: 0.015).

Conclusion: These preliminary data suggest that at the onset of diabetes, BM-derived EPCs are stimulated to enter the systemic circulation in response to signals from the pancreas. Our findings of increased EPC-derived lineages and vessel density in the NOD mouse imply that circulating EPCs engraft within the pancreas. This latter observation is supported by many studies of BM-derived stem cell engraftment and contribution to neovascularogenesis in adult tissues, which is enhanced by increasing regenerative demand within a diseased or damaged tissue. The exact signalling pathways and molecular mechanism for this EPC recruitment are as yet unknown. However, our data demonstrates that EPCs could be a prospective source of autologous cells for transplantation with the aim to promote restoration of pancreatic function following the onset of type 1 diabetes by contributing to tissue regeneration via neovascularogenesis.

Transdifferentiation of monocytes derived from healthy and type 1 diabetic donors into insulin-producing cells: development of an optimal and reproducible protocol

D. Chesnel¹, V. Corcelle², B. Boehm³, H. Zulewski⁴, L. Gruaz⁵, R. Schorer¹, D. Burger⁵, C. B. Wollheim¹, B. R. Gauthier¹;

¹Cell Physiology & Metabolism, Geneva University, Switzerland, ²Faculty of Medicine, INSERM U568, Nice, France, ³Clinic of Internal Medicine, Ulm University, Germany, ⁴Division of Endocrinology, University Hospital Basel, Switzerland, ⁵Clin Immunology, GUH, Geneva, Switzerland.

Background and Aims: Although daily insulin injection is the treatment of choice for Type 1 diabetic (T1D) patients, control of glycaemia is problematic and results in long-term complications. The ultimate treatment of T1D would be the replacement of destroyed β -cells by insulin-producing cells. Proof of principle of this concept was shown by normalization of blood glucose of T1D patients subsequent to islets transplantation. However, worldwide use of this approach is hampered by the scarcity of pancreas donors. This has led to efforts into the development of alternative sources of human insulin-producing cells. We have shown that large amount of readily accessible human monocytes can be expanded in the presence of MCSF and partially differentiated into insulin-producing cells, using an islet differentiating medium (IDM) containing 17.5mM glucose. These conditions resulted in low insulin mRNA levels (0.5% as compared to human islets) and cytosolic rather than nuclear localisation of key transcription factors (TFs). The aim of the current study was to improve insulin yields using agents which are known to influence TFs nuclear/cytosolic shuttling: glucose, IBMX/forskolin and Leptomycin B. We also evaluated the capacity of monocytes derived from T1D donors to generate surrogate β -cells.

Material and Methods: Monocytes isolated from healthy and T1D donors were cultured for 9 days in MCSF and subsequently in either RPMI control media or IDM for an additional 11 days. Increasing concentrations of glucose (5, 8.5 or 17.5 mM) were added to culture media. In parallel, 100 μ M IBMX/1 μ M forskolin or 37 nM Leptomycin B was included in IDM for 4 and 9 days. RNA was extracted and insulin transcript levels were determined by QT RT/PCR. Immunocytochemistry was performed to detect insulin, NeuroD, Pdx1 and MafA.

Results: Altering glucose concentrations did not increase nuclear localization of TFs nor improved insulin transcript levels as compared to standard IDM. Exposure to either IBMX/forskolin or Leptomycin B in combination with 17.5mM glucose for 9 days targeted TFs to nuclei resulting in a 2-fold increase in insulin mRNA levels. Lower glucose concentrations failed to improve insulin yields and TFs nuclear localization. Intriguingly, insulin could not be revealed by immunocytochemistry. Reducing exposure time to IBMX/forskolin and Leptomycin B to 4 days did not ameliorate insulin detection. Monocytes maintained in MCSF/IDM for up to 56 days resulted in a 3-fold increase in the insulin transcript. More importantly, monocytes derived from

T1D donors and cultured in MCSF and standard IDM were re-programmed to express the insulin transcript as well as protein.

Conclusions: Nuclear localization of TFs by IBMX/forskolin and Leptomycin B improved insulin transcription yet decreased insulin protein. The latter suggests a potential long-term detrimental effect of the agents on insulin biosynthesis. Furthermore, we established proof of principle on the feasibility of using monocytes derived from T1D donors to generate surrogate β -cells for auto-transplantation.

Pancreatogenesis from embryonic stem cells in streptozocin-injured mice

G. Quinn^{1,2}, T. Ochiya¹, S. Kanegasaki², F. Takeshita¹, M. Kodama¹;

¹Section for Studies on Metastasis, NCCRI,

²Dept of Regenerative Medicine, Effector Cell Institute, Inc., Tokyo, Japan.

Background and Aims: Pancreatic beta cell regeneration is unclear due to poor knowledge of both regenerative stimuli and endogenous responder cells. Previously we demonstrated that streptozocin (STZ)-induced beta cell injury promotes homing and pancreatic morphogenesis of i.p. transplanted ES cells in euglycemic mice. In this study, we demonstrate that similar injury induces pancreatogenesis in renal capsule transplanted embryonic stem cells (ES), in situ, and provide a more detailed analysis of pancreatic cell ontogeny at this site.

Methods: 7 week old female BALB/c nude mice were treated with 175mg/kg STZ, and transplanted with 1×10^5 ES. Immunohistochemistry was performed on ES-derived pancreatic foci at 21 and 28 days following transplantation using antibodies against stage- and lineage-specific markers. Separately, the ability of transplanted ES to modulate blood glucose levels was measured by intraperitoneal glucose tolerance test in euglycemic mice treated with 200mg/kg STZ.

Results: After 21 days, PDX-1+ pancreatic foci in the renal capsule expressed amylase and endocrine hormones. These foci increased in size by day 28 due to acinar and duct proliferation, while endocrine cells remained post-mitotic. PDX-1, Nkx6.1, Ngn3 and ISL-1 were expressed in the endocrine lineage. Unlike embryonic pancreatogenesis, Nkx6.1 was not detected before exocrine/endocrine lineage divergence, and multi-hormone expressing transitional cells were prevalent during endocrine cell ontogeny. Improved glucose tolerance was observed in ES transplanted mice after 4 weeks.

Conclusion: Regenerative stimuli are detectable using renal capsule transplanted ES, and induce both endocrine and exocrine pancreatic lineages resembling embryonic pancreas development.

Generation of insulin-producing islet-like clusters from human embryonic stem cells

A. Sen Majumdar¹, J. Jiang¹, M. Au¹, B. Cooper¹, A. Eshpeter², G. Korbitt², G. Fisk¹, K. Lu¹, J. Lebkowski¹;

¹Cell Therapy Research, Geron Corporation, Menlo Park, United States,

²Department of Surgery, University of Alberta, Edmonton, Canada.

Recent success in pancreatic islet transplantation has energized the field to discover an alternative source of stem cells with differentiation potential to β cells. Generation of glucose-responsive, insulin-producing β cells from self-renewing, pluripotent human embryonic stem cells (hESCs) has immense potential for diabetes treatment. We report here the development of a novel serum-free protocol to generate insulin-producing islet-like clusters (ILCs) from hESCs grown under feeder-free conditions. In this 36-day protocol, hESCs were treated with sodium butyrate (Na-butyrate) and activin A to generate definitive endoderm expressing Sox17 and Foxa2. The endoderm population was then converted into cellular aggregates and further differentiated to Pdx1-expressing pancreatic endoderm in the presence of

EGF, bFGF and noggin. Soon thereafter, expression of Ptf1a and Ngn3 was detected indicative of further pancreatic differentiation. The aggregates were finally matured in the presence of IGFII and nicotinamide. The temporal pattern of pancreas-specific gene expression in the hESC-derived ILCs showed considerable similarity to *in vivo* pancreas development and the final population contained representatives of the ductal, exocrine and endocrine pancreas. The hESC-derived ILCs contained 2–8% human C-peptide positive cells as well as glucagon- and somatostatin-positive cells. We observed as high as 70ng insulin / μ g DNA of ILCs, which is higher than the insulin content of human fetal islets. In addition, the hESC-derived ILCs contained numerous secretory granules as determined by electron microscopy and secreted human C-peptide in a glucose-dependent manner.

Successful *ex vivo* differentiation of c-met and c-kit positive pancreatic precursor cells into insulin positive cells

S. T. Gangaram-Panday, M. M. Faas, P. de Vos;
Pathology and Laboratory Medicine, University Medical Center Groningen, The Netherlands.

Background and Aims: The endocrine pancreas has a high capacity for regeneration. Pancreatic precursor cells are suggested to contribute to this regenerative capacity. A few proteins are described to be markers for pancreatic stem cells of which the c-met and c-kit receptors have already been successfully applied. These c-met and c-kit positive cells can be found in both the endocrine and exocrine pancreas. In the present study we investigated whether c-met or c-kit positive cells have the potential to proliferate and differentiate into insulin producing cells after *ex vivo* manipulation.

Materials and Methods: Single cells of neonatal rat pancreata (collagenase digestion) were used and c-met and c-kit positive cells were sorted and characterised by studying the mRNA levels of c-met, c-kit, insulin, Pdx-1, Pax4, Pax6, Beta2, Islet-1, ngn3, Glut-2, glucagon, amylase. C-met and c-kit sorted cells were also cultured in proliferation (containing EGF and bFGF) (10 and 20 days) or differentiation medium (containing betacellulin, ActivinA, GLP-1, and HGF) (10 days) or 10 days on proliferation medium followed by 10 days on differentiation medium, after which the cells were harvested for protein and mRNA expression of c-met and c-kit, insulin, and Pdx-1.

Results: C-met sorted cells expressed c-met, c-kit, Beta2, Pax6, ngn3, insulin, glucagon, and amylase on mRNA levels. After culture for 10 and 20 days in proliferation medium the cells did not express insulin on mRNA or protein level. The number of cells increased 3 fold and the cells remained positive for c-met. Interestingly, c-met positive cells cultured for 10 days in differentiation medium expressed insulin on mRNA level and protein level. The number of cells did not change during culture. When the 10 days proliferation protocol was followed by a 10 days differentiation protocol c-met positive cells did not express insulin (mRNA or protein), but did express Pdx-1 (mRNA), and c-met (mRNA and protein). C-kit sorted cells expressed c-kit, Beta2, Islet-1, Pax4, insulin, amylase on mRNA levels. C-kit positive cells cultured for 10 days in proliferation medium did not express insulin. The number of cells increased 3 fold and cells became c-kit negative on both protein and mRNA level. When cultured for 10 days on differentiation medium the cells were still weakly positive for c-kit, but did not express insulin or c-met on protein level.

Conclusion: Our data suggest that c-met and c-kit positive cells are pancreatic precursor cells, because they express transcription factors involved in differentiation into endocrine cell types, such as Pdx-1, Pax4, Pax6, Beta2, ngn3, and insulin. Furthermore, our data indicate that c-met positive cells and c-kit positive cells might be distinct populations of pancreatic precursor cells, because they differ in the expression of transcription factors involved in endocrine cell formation. C-met positive cells can be multiplied *ex vivo* and stimulated after proliferation to gain a beta-cell phenotype.

Human pancreatic islet cells interact with their basement membrane laminin through Lutheran glycoprotein

M. Banerjee¹, I. Virtanen², A. Lukinius³, O. Korsgren⁴, M. Hukkanen², Y. Kikkawa⁵, Y. T. Konttinen⁶, T. Otonkoski¹;

¹Biomedicum Stem Cell Center, University of Helsinki, Finland, ²Institute of Biomedicine/Anatomy, University of Helsinki, Finland, ³Department of Genetics and Pathology, University of Uppsala, Sweden, ⁴Department of Clinical Immunology, University of Uppsala, Sweden, ⁵Department of Internal Medicine, Washington University, St. Louis, United States, ⁶Department of Medicine, University of Helsinki, Finland.

Background and Aims: Basement membrane (BM) proteins play an important role in endocrine cell differentiation and function. It has been shown that mouse islets do not have a separate BM but instead interact with endothelial cell BM. The aim of this study was to investigate the BM structure of human islets and experimentally test the adhesion of islet cells to BM proteins.

Materials and Methods: We employed a panel of antibodies against human laminins and their receptors (integrins and Lutheran glycoprotein), as well as other BM components, collagen IV and nidogen, to study their expression by immunofluorescence in surgically obtained human pancreatic samples. Isolated and dissociated human islets were used for short-term *in vitro* adhesion studies.

Results: We found that human islets possess a unique organization pattern of BM components, which structurally resembles to the BM of central nervous system. The peri-islet BM invaginates into islets with vessels forming a duplex pattern of BM of intra-islet vascular channels, distinct from the regular vascular BM. The peri-islet BM mainly consist of laminin α 5, β 1 and γ 1 chains (Lm-511), whereas intra-islet vascular BMs contain laminin chains suggestive of Lms-411/421 and -511/521. This duplex BM organization of the intra-islet vascular channels was further confirmed by collagen IV (α 1/2), nidogen immunostaining and electron microscopy. *In vitro* adhesion experiments demonstrated that insulin-positive beta cells adhered to Lm-511 (5-fold compared to plastic alone). This binding could be inhibited both with an antibody against integrin β 1 (90 % block) or even more effectively by soluble recombinant Lutheran protein (94 % block; mean of five separate experiments).

Conclusions: The present study discloses a hitherto unrecognized islet BM organization in the adult human pancreas, different from the mouse. Furthermore, we demonstrate an important role for a novel laminin receptor, Lutheran, in the adhesion of human beta cells to the laminin isoform of the islet BM.

0533

Extracellular matrix, Rho-ROCK pathway and beta cell function

E. B. Hammar, P. A. Halban;
Genetic Medicine and Development, University Medical Center, Geneva, Switzerland.

Background and Aims: Extracellular matrix secreted by 804G cells (804G-ECM) has been shown previously to increase spreading, induce actin cytoskeleton remodeling and to improve glucose-stimulated insulin secretion (GSIS) of pancreatic beta cells. Actin cytoskeleton dynamics are known to play an important role in beta cell function and three main classes of the small GTPases of the Rho family – Rho, Cdc42 and Rac- are known to play a central role in such dynamics. The function of Rho and its effector ROCK (Rho kinase) in the beta cell has not been studied yet, but there are theoretical reasons for expecting that inhibition of the Rho-ROCK pathway might underlie the beneficial impact of 804G-ECM on beta cells. The aims of this work were to study 1) the impact of 804G-ECM on RhoA activity and 2) the role of Rho and ROCK in the spreading and function of pancreatic beta cells.

Materials and Methods: All experiments were performed with primary rat pancreatic beta cells purified by FACS. Cells were cultured on 804G-ECM-coated dishes or on poly-L-lysine (pLL)-coated dishes (=control) with or without inhibitors: the Rho inhibitor C3 transferase (C3T, 2 μ g/ml) and the ROCK inhibitors Y-27632 (50 μ M) and H-1152 (10 μ M). RhoA activity was analyzed using the RhoA activation assay (G-LISA) from Cytoskeleton, results were normalized to the control (cells on pLL). Insulin secretion was measured

by radioimmunoassay after static insulin secretion test and expressed as percentage of total insulin content. Actin cytoskeleton remodelling was analyzed by confocal immunofluorescence using phalloidin to stain F-actin. Data are means \pm SD (n=3 independent experiments).

Results: There was no significant difference in the RhoA activity in cells cultured on 804G-ECM as compared to control cells (pLL) after 1h of culture. However, after 4h of culture, cells on 804G-ECM displayed a $25 \pm 1\%$ lowering of RhoA activity as compared to cells on pLL ($p < 0.007$). Treatment of cells with Rho or ROCK inhibitors for 24h or more led to a change in morphology, with cells appearing more spread and flatter on both pLL and 804G-ECM. Treatment of cells with the ROCK inhibitor Y-27632 (Y) led to a significant increase of glucose-stimulated insulin secretion (GSIS= % of content secreted at 16.7 mM glucose): pLL control: 6.9 ± 1.5 vs. pLL Y: 14.3 ± 2.4 , $p < 0.003$; 804G-ECM control: 18.8 ± 1.3 vs. 804G-ECM Y: 38.0 ± 8.4 , $p < 0.005$. By contrast, basal insulin secretion was not affected by Y-27632: pLL control: 0.74 ± 0.56 vs. pLL Y: 1.3 ± 0.95 , $p = 0.4$; 804G-ECM control: 0.97 ± 0.71 vs. 804G-ECM Y: 1.91 ± 1.25 , $p = 0.24$. These results were confirmed using H-1152, another ROCK inhibitor. To get insight into mechanisms involved in the positive impact of inhibition of ROCK on GSIS, the impact of ROCK inhibitors on the actin cytoskeleton of cells exposed for 10 minutes to 16.7 mM glucose was visualized by confocal microscopy. The density of the cortical actin cytoskeleton was reduced by the ROCK inhibitors, suggesting that the negative impact of ROCK on GSIS is related to its impact on the state of polymerization of the actin cytoskeleton.

Conclusion: These results indicate that 804G-ECM has a negative impact on the RhoA-ROCK pathway and that inhibition of this pathway leads to increased spreading and improved function of pancreatic beta cells. Taken together, these data suggest that the positive impact of the 804G-ECM on GSIS is related to its negative impact on RhoA activity, thereby providing important insight into the molecular basis of outside-in signaling in beta cells and its impact on their function.

Supported by the Swiss National Science Foundation and JDRF

was significantly inhibited in cells treated with cyclosporin A (804G-ECM control= 2.4 ± 0.5 vs. 804G-ECM+cyclosporin= 1.0 ± 0.2 ($p = 0.03$)) whereas insulin secretion was not affected by this inhibitor.

Conclusion: Rat beta cells can proliferate in vitro and this is increased significantly by ECM in a glucose-dependent manner. Our results suggest that PI3K-Akt/PKB and elevated $[Ca^{2+}]_i$ (possibly acting via activation of calcineurin) might be involved in this stimulation by 804G-ECM whereas the MAP kinase ERK pathway is not.

Supported by the JDRF programme for regeneration of beta cell function

0534

Glucose-dependent stimulation of beta cell proliferation by extracellular-matrix

G. Parnaud, P. A. Halban;

Department of Genetic Medicine and Development,
University Medical Center, Geneva, Switzerland.

Background and Aims: Extracellular matrix derived from 804G cells (804G-ECM) induces spreading, improves glucose-stimulated insulin secretion, and increases survival and proliferation of pancreatic beta cells. The aim of the study was to investigate the mechanisms by which the 804G-ECM increases beta cell proliferation.

Materials and Methods: Autofluorescence FACS-sorted rat pancreatic beta cells were plated on poly-L-lysine (PLL) or on matrix produced by 804G rat bladder carcinoma cell line (804G-ECM). One day later, cells were incubated with BrdU for 24h under control conditions or in the presence of different inhibitors: PD98059 (a specific MAPK ERK pathway inhibitor), LY294002 (a phosphatidylinositol 3-kinase (PI3K) inhibitor), diazoxide (which opens K/ATP channels, thereby preventing depolarization and Ca^{2+} entry) and cyclosporin A (a calcineurin inhibitor). Cell replication was determined by BrdU incorporation and the identity of beta cells confirmed by insulin immunofluorescence. Insulin secretion was measured by radioimmunoassay after static incubation (1h 2.8 mM glucose + 1h 16.7 mM glucose). Data for proliferation are expressed as percentage of BrdU positive beta cells. Data are mean \pm SEM for 3 or more independent experiments.

Results: As expected, rat beta cells spread on 804G-ECM but not on PLL. Rat beta cells proliferated on PLL and 804G-ECM with a significant beneficial effect of the matrix. As previously shown, after 2 days, % of BrdU positive beta cells was 1.8 ± 0.4 vs. 4.6 ± 0.5 ($p = 0.006$) on PLL vs. 804G-ECM respectively. The stimulation of beta-cell proliferation was glucose-dependent (PLL at 2.8 mM glucose= 0.4 ± 0.2 vs. PLL at 11.2 mM glucose= 1.2 ± 0.2 , $p = 0.02$; 804G-ECM at 2.8 mM glucose= 0.6 ± 0.2 vs. 804G-ECM at 11.2 mM glucose= 3.2 ± 0.6 , $p = 0.005$). Treatment of beta-cells with LY294002 (50 μ M) inhibited rat beta-cell proliferation by 90 % on 804G-ECM ($p = 0.0021$ vs. control). By contrast, the MAPK inhibitor PD98059 (50 μ M) had no effect either on cells attached on PLL or on 804G-ECM. Diazoxide inhibited proliferation induced by the matrix (804G-ECM control= 2.8 ± 0.5 vs. 804G-ECM+diazoxide= 0.8 ± 0.2 ($p = 0.01$)). Finally, the 804G-ECM-induced increase of proliferation

PS 36 Structural and functional aspects of beta cell regulation

0535

Characterisation of two β cell subpopulations with different functional activity in normal and 48-h glucose-infused Wistar rats

M. Karaca, J. Castel, C. Magnan, C. Tourrel-Cuzin;
Université Paris 7 Denis Diderot, CNRS UMR France.

Background and Aims: We have previously shown that the sialylated form of the neural cell adhesion molecule (PSA-NCAM) was a good tool to sort β -cell subpopulations according to their functional activity: In high PSA-NCAM-labelled β -cells (β^+ -cells), insulin release in response to glucose was significantly higher than that in low PSA-NCAM-labelled β -cells (β^- -cells). The present study compares some aspects of the intracellular mechanisms that could explain this differential response to glucose in these two β -cell subpopulations in normal rat (control rat) but also in an endocrine pancreas plasticity model: the 48-h glucose-infused rat (HGHI rat) with increased β -cell mass and function. At this end, we examined the handling of intracytoplasmic Ca^{2+} concentrations ($[\text{Ca}^{2+}]_i$), the cAMP content and the response of these cells to various secretagogues.

Materials and Methods: Pancreatic islet β -cells from Wistar rats (control and HGHI) were sorted by flow cytometry either with or without PSA-NCAM labelling. Insulin release was measured in sorted β -cell subpopulations by a perfusion technique in a system allowing concomitant recording of $[\text{Ca}^{2+}]_i$ movements by microfluorimetry. Insulin content was determined by RIA. Using batch-incubated β -cells, cAMP content and/or insulin release in response to glucose (5.5 and 16.7mM) and/or 10nM GLP-1, 19mM arginine, 10mM leucine and 5mM dibutyl cAMP were studied. The effect of 50mM KCl was also assessed in perfusion experiments.

Results: In control β^+ -cells, insulin release in response to 16.7mM glucose was highly increased compared to β^- -cells and was correlated with an increase in $[\text{Ca}^{2+}]_i$ whereas there was almost no increase in β^- -cells. In HGHI β^- -cell subpopulations, the rise of $[\text{Ca}^{2+}]_i$ in response to 16.7mM glucose is not bigger than that described in control β^- -cells despite a clear increase of insulin response to the same stimuli. The impaired functional activity in control or HGHI β^- -cells can't be explained by a decrease in their insulin content. The cAMP accumulation in control β^+ -cells, in response to 5.5 and 16.7mM glucose with GLP-1 was increased compared to that with glucose alone. Insulin release in response to 16.7mM glucose was also potentiated in this population by adding GLP-1. In HGHI rats, glucose infusion increased glucose and/or GLP-1 effects in β^+ -cells. Nevertheless, control or HGHI β^- -cells were not responsive to any glucose or GLP-1 stimulation. In response to 16.7mM glucose with 5mM db-cAMP, insulin release was significantly increased in β^+ -cells and, in part, restored in β^- -cells in both control and HGHI rats. Addition of KCl at the end of perfusion experiments showed that β^- -cells were capable to secrete insulin in the same extent as β^+ -cells. Moreover, arginine elicited same insulin release in both β^+ and β^- populations whereas leucine showed a profile similar to glucose.

Conclusion: Alteration of the functionality of β^- -cells could be explained by a blockage in the steps linking glucose metabolism to the insulin release process. The analysis of glucose-stimulated insulin release characteristics in β -cell subpopulations with a different secretory activity is a prerequisite to identify factors able to ameliorate the functional status of β -cells with low secretory capacities such as in advancing type 2 diabetes.

0536

Effect of low and high glucose concentration on the insulin secretory cell line INS-1

R. D. Fernández, B. Torrejon-Escribano, J. Blasi;
Department of Pathology and Experimental Therapeutics,
University of Barcelona-IDIBELL, Spain.

Background and Aims: Chronic exposure of pancreatic islets to elevated glucose levels has been associated to β -cell dysfunction and the lost the glucose-stimulated insulin secretion. The final steps in insulin secretion are governed by a series of proteins that mediate the correct docking, priming and fusion of insulin containing secretory granules to plasma membrane.

In the present work, the expression of proteins related to insulin secretion was studied in the INS-1 insulin secretory cell line incubated for 1, 3 and 7 days in the presence of 3.3, 11.1 or 20 mM glucose.

Materials and Methods: The protein expression and distribution were analyzed by immunofluorescence and confocal microscopy, ELISA, western blot and Real Time-PCR (RT-PCR).

Results: In addition to insulin, actin and connexin 36 (which has been shown to play a regulatory role in various β -cell functions), the rest of proteins analyzed comprised the SNARE proteins SNAP-25, syntaxin-1, VAMP-2 and cellubrevin and a series of proteins directly or indirectly involved in the regulation of insulin exocytosis: Munc 18, synaptotagmin I, complexin and munc 13. All together, the results show a consistent decrease in the expression of several proteins, in addition to insulin, with the increase of glucose concentration and time of incubation, these proteins include connexin 36, synaptotagmin I, syntaxin 1 and VAMP-2. Exceptionally, western blot analysis showed a slight but significant increase in the expression of SNAP-25 along the time and the increase of glucose concentration in the media. Low glucose concentration produced a consistent increase in the expression of connexin 36 and the formation of cell aggregates. Munc 18, munc 13, complexin and actin did not show any evident change in their expression in the conditions tested. Additionally, the distribution and colocalization of selected pairs of the above proteins were analyzed by confocal microscopy and the results are discussed.

Conclusion: Prolonged exposure of INS-1 cells to high glucose concentration glucose produces evident changes in the expression of proteins directly involved in the secretion of insulin. Low glucose concentrations produce the increase in connexin 36 expression and the formation of cell aggregates, while high glucose concentrations had the opposite effect. These results suggest that elevated concentrations of glucose might disorganize islet cyto-architecture by impairing the formation of both functional cell contacts and cell aggregation.

Background and Aims: Iduronate-2-sulfatase (IDS) is a lysosomal enzyme expressed in pancreatic islets responsible for degradation of proteoglycans, such as perlecan and dermatan sulfate. Previous findings of our group demonstrated the involvement of IDS in the normal pathway of lysosomal degradation of secretory peptides suggesting a role of this enzyme in β -cell secretory functionality. The present work aims to characterise the effect of IDS over-expression on insulin release.

Materials and Methods: INS1E cells were transiently transfected with a pcDNA 3.1 Hygro(-) construct encoding human IDS fused with the 5' end of a c-myc epitope tag. Transfected cells with empty vector were used as controls. Western blot and immunofluorescence assays were performed to verify successful transfection. Total RNA was extracted using a mono-phasic solution of phenol and guanidine isothiocyanate and insulin 1 and 2 (INS1 and INS2) mRNA levels were estimated by quantitative real-time PCR. Release of insulin was measured during static incubation of transfected cells for 30 min, and quantified by ELISA. Exocytosis was analyzed at the single-cell level by monitoring fluorescence changes from INS1-E cells exposed to the cell-impermeable dye FM1-43. The number of vesicles/ μm^2 and the % of vesicles in membrane respect total ones were quantified from fifty cells selected at random from transmission electron microscope images.

Results: Successful transfections were confirmed by western blot and immunofluorescence using an antibody against the c-myc epitope tag. Over-expression of hIDS potentiated the secretory response at 22.7mM glucose compared to controls (+69.15%, $p < 0.01$) leading to a reduction on insulin content (-54.54%, $p < 0.05$). No significant changes were observed at 2.5mM or 0mM glucose. Moreover, hIDS expressing cells showed no changes in insulin mRNA levels (arbitrary units) (INS1: 2.06 vs 1.81, INS2: 1.85 vs 1.70, n.s.) compared to controls. These results indicated that the increase in insulin secretion was not due to an effect of hIDS on insulin expression. Furthermore, ultramorphological analysis suggested a major number of vesicles at the membrane level in hIDS transfected cells compared to controls. Quantitation

of vesicles demonstrated an increase in this value in hIDS transfected cells (68.66% vs 59.97%, $p < 0.01$) as well as a decrease in total vesicles/ μm^2 (0.82 vs 0.62, $p < 0.05$). Preliminary results indicated a higher exocytotic response at the single-cell level in hIDS transfected cells respect to control ones.

Conclusion: Over-expression of hIDS on INS1E cells leads to the enhancement of glucose-stimulated insulin secretion by a mechanism that implies the activation of exocytosis processes.

Expression and functional activity of the putative endogenous imidazol(in)e receptor ligand, imidazole-4-acetic acid ribotide, in the endocrine pancreas

A. R. Oknianska¹, V. L. Fredrich Jr², G. P. Martinelli², G. R. Holstein², G. D. Prell², N. G. Morgan¹;

¹Institute of Biomedical and Clinical Science, Peninsula Medical School, Plymouth, United Kingdom, ²Department of Neurology, Mt Sinai Medical School, New York, United States.

Introduction: A variety of ligands with an imidazoline structure cause the glucose-dependent stimulation of insulin secretion from pancreatic β -cells and this action has been attributed to their binding to I_3 -“imidazol(in)e” receptors. It has been proposed that they may reproduce the actions of a putative endogenous ligand, imidazole-4-acetic acid ribotide (IAA-RP) recently characterised in the central nervous system. In the present study, we have investigated the actions of IAA-RP on insulin secretion from islets of Langerhans and have studied the distribution of this ligand in pancreas to establish whether it might serve as a neuroregulator controlling insulin secretion.

Methods: Isolated rat and human islets were prepared by collagenase digestion of the pancreas and exposed to IAA-RP in vitro. Insulin secretion was measured by radioimmunoassay. The distribution of IAA-RP in normal rat and human pancreas was analysed by immunohistochemistry using a highly specific antiserum raised against synthetic IAA-RP.

Results: IAA-RP and the immediate product of its dephosphorylation, IAA-R, each exerted a dose-dependent stimulation of insulin secretion from both rat and human islets over the range 0.01–10 μM . The response to each agent was biphasic with concentrations of IAA-RP in the range 10–100 nM eliciting a marked rise in insulin secretion from human islets incubated in 6 mM glucose ($140 \pm 15\%$ and $230 \pm 25\%$ vs control, at 10 nM and 100 nM respectively; $p < 0.01$) while stimulation was lost at higher concentrations ($98 \pm 20\%$ vs control at 10 μM IAA-RP). IAA-R increased secretion to maximum of $165 \pm 18\%$ of control ($p < 0.01$) at 100 nM. A highly specific anti-IAA-RP serum (which does not recognise IAA-R) labelled a sub-set of neurons in rat olfactory bulb, confirming the presence of IAA-RP within the CNS. Examination of sections of rat and human pancreas revealed the presence of specific IAA-RP immunoreactivity by both immunohistochemistry and immunofluorescence. The ligand was localised predominantly within islets of Langerhans but not all islets within a given section of pancreas stained positively for IAA-RP. Staining was only rarely seen outside the islets. Antibody binding was completely displaced by pre-incubation with excess ligand, confirming the specificity of labelling.

Conclusions: The putative endogenous imidazol(in)e receptor ligand, IAA-RP, is present in human and rat islets of Langerhans where it may serve as a local neuroregulator involved in the control of insulin secretion.

AMPK activation increases the expression and activity of PPAR α in INS-1 cells

H. Guo^{1,2}, Y. Sun¹, W. Xin³, L. C. Wang³, J. J. Zhao⁴, L. Gao¹;

¹Centre Laboratory, Shandong Provincial Hospital, Shandong University,

²Institute of Pharmacology, School of Medicine, Shandong University,

³Centre Laboratory, Shandong Provincial Hospital,

⁴Endocrinology and Metabolism,, Shandong Provincial Hospital, Shandong University, Jinan, China.

Background and Aims: Peroxisome proliferator-activated receptor alpha (PPAR α) is a ligand-activated transcription factor involved in key metabolic

pathways, such as lipid metabolism. In β cells, PPAR α is reported to major contribute to fatty acid oxidation. Recently, several studies has addressed that AMP-activated protein kinase (AMPK), an cellular energy sensor that is responsible for cellular glucose and lipid metabolism, may affect PPAR α expression in peripheral tissues, such as skeletal muscle. Of these studies, most models were made with transgenic mice or with transfected-gene cells cultured in high-glucose or high-lipid conditions, because PPAR α occurs at relative very small quantities in tissues or cell lines under physiological status, which results in much difficulty to observe the PPAR α change in protein level. Thus, so far, the detection of PPAR α in physiological cells is limited to gene transcriptional levels, while data concerning protein levels and activity of PPAR α are very few. The present study was completed in physiological status, and aimed to investigate effects of AMPK on PPAR α in the levels of transcriptional, protein and binding activity with DNA via AMPK activator and inhibitor, mimicing AMPK activation and inactivation.

Materials and Methods: INS-1 cells were cultured in RPMI 1640 medium, and treated with and without 0.5 mM AICAR (AMPK activator), in the presence and absence of 10 μM Compound C (AMPK inhibitor). Treatment for 8, 12 or 24 hours, total RNA was extracted for determining the levels of PPAR α mRNA by real-time PCR, protein was gained for analysis the expression of PPAR α protein by immunoprecipitation, and nuclear protein was extracted for detecting the PPAR α binding activity with DNA by PPAR α Complete Transcription Factor Assay Kit, respectively.

Results: Compared to control, PPAR α mRNA was increased by 52.25% ($p < 0.05$) in the cells treated with AICAR alone for 8 hours, but this increase was oppressed and reduced by 33.88% in the cells treated with AICAR and Compound C together relative to AICAR alone. However, at 24 hours, we failed to detect any significant change of PPAR α mRNA levels in the observed cells, which could result from the bio-half life of AICAR in our experimental conditions. Consistent with the PPAR α mRNA changes at 8 hours, IP experiment showed a strong stained band ($p < 0.05$) representing PPAR α protein in the cells in the present of AICAR alone, while the weak band ($p < 0.05$) was obtained in the present of AICAR and compound C together. Interestingly, the increase in PPAR α binding activity with PPRE sequence induced by AICAR did not change at 8 hours until 12 hours treatment, which was in agreement with the previous study showing that the change of DNA binding activity occurred later than its protein. AMPK activation enhanced the PPAR α -DNA binding activity by 38.5% relative to control, while compound C -induced AMPK inactivation reduced the binding activity by 17.8% as compared with AICAR alone treatment.

Conclusion: AMPK activation can increase the PPAR α in gene transcriptional level, which leads to the increase in both levels of protein expression and binding activity with DNA in INS-1 cells under physiological conditions.

Influence of glucose and Ca²⁺/Calmodulin-dependent protein Kinase II (CaMKII) on expression and activity of NAD(P)H-Oxidase in INS-1 rat insulinoma cells

M. A. Osterhoff^{1,2}, K. Pütz¹, E. Arslan¹, F. Isken^{1,2}, M. O. Weickert^{1,2}, A. F. H. Pfeiffer^{1,2};

¹Clinical Nutrition, German Institute of Human Nutrition, Nuthetal,

²Endocrinology, Diabetes and Nutrition, Charité – University Medicine Berlin Campus Benjamin Franklin, Berlin, Germany.

Background and Aims: The Incidence of type 2 diabetes mellitus (T2DM) increases world-wide with a trend to reduced age of manifestation. T2DM is characterized by insulin-resistance, an initially relative peripheral insulin deficiency, and a progressive loss of β -cell mass. This finally leads to an absolute lack of insulin. Chronically elevated glucose concentrations cause a damage of β -cells, partially by production of reactive oxygen species (ROS) in mitochondria but also by a NAD(P)H-oxidase subtype expressed in β -cells. Goal of the present work was, to verify the expression of NAD(P)H-oxidase in INS-1 cells and to investigate the glucose- and CaMKII-dependent expression and activation of NAD(P)H-oxidase.

Materials and Methods: RNA from INS-1 rat insulinoma and INS-W12 cells, where the expression of CaMKII is suppressed nearly completely, was extracted with Trizol(R) (Sigma). The expression of α -tubulin (standard) and NAD(P)H-oxidase subunits p65nox and gp91phox were measured by real-time PCR on an ABI 7900HT (“TaqMan”). The cells were stimulated for

4, 24, 48 and 72 hours with 0, 5, 7.5, 11 16.5 and 33 mmol/l glucose. The superoxide-production was measured by lucigenin- or DCF/DA-assays (Molecular Probes).

Results: The investigation of gene expression showed that p65mox but not gp91phox was expressed in INS-1 cells. In INS-W12 cells p65mox was expressed but only 4% of the amount expressed in INS-1 cells. After 48 hours with increased glucose concentrations (16.5 mmol/l) the expression of p65mox tended to higher values in INS-1 cells compared to the expression with glucose concentrations of 2 or 5 mmol/l. After 72 hours the increase in expression was highly significant ($p=0.005$ and $p=0.002$, respectively). Lucigenin- as well as DCF/DA-assays showed that the superoxide-production of NAD(P)H-oxidase (suppression of the mitochondrial fraction by rotenone) increases with the glucose concentration. Up to a glucose concentration of 16.5 mmol/l the production of superoxide by NAD(P)H-oxidase was predominant, while the mitochondrial part (suppression of the NAD(P)H-oxidase fraction by DPI) was elevated using 33 mmol/l glucose. In INS-W12 cells the NAD(P)H-oxidase portion of superoxide production was barely detectable and resembled that of INS-1 cells when suppressed with DPI.

Conclusion: Experiments with CaMKII-suppressed INS-W12 cells demonstrated that the expression of the NAD(P)H-oxidase subtype p65mox depended on the presence of CaMKII. The glucose stimulation experiments point to a predominant superoxide production by NAD(P)H-oxidase in INS-1 β -cells under physiological conditions. Only under super physiological glucose concentrations the mitochondrial superoxide production gained higher importance.

Live imaging of glucose uptake and metabolism in insulin-producing MIN6 cells by a fluorescent sensor

M. T. Kaminski, S. Lenzen, S. Baltrusch;

Institute of Clinical Biochemistry, Hannover Medical School, Germany.

Background and Aims: Glucose plays a key role in pancreatic beta cell signal transduction. After the uptake of the sugar via the low affinity glucose transporter GLUT2 inside the cell, glucose is phosphorylated in the first and rate limiting step of glycolysis by glucokinase. In the subsequent metabolism the stimulus for insulin secretion is generated through an increase in the ATP/ADP ratio. Furthermore, glucose mediates intracellular changes in protein expression and modification and chronically high glucose has been considered to facilitate development of type 2 diabetes. While different indirect techniques have been used to analyze changes in the intracellular glucose concentration, real time measurements in living cells are so far not available. The aim of this study was to monitor the intracellular glucose concentration in dependence upon metabolic changes.

Materials and Methods: Intracellular glucose concentration changes were analyzed using FRET (fluorescence resonance energy transfer) based sensors (FLIPglu) with specificity for glucose by fluorescence microscopy. Insulin-producing MIN6 cells or COS-7 as established control cells were transfected with FLIPglu. Thereafter, cells were incubated at various glucose concentrations either by static incubation or in a perfusion chamber. FRET was calculated as EYFP/ECFP emission intensity ratio.

Results: FLIPglu sensors for intracellular sensing of glucose dynamics were expressed in COS-7 and insulin-producing MIN6 cells. FLIPglu sensors exhibited a correlation between the glucose concentration and EYFP/ECFP ratio. Static incubation at different glucose concentrations revealed a concentration-dependent shift in the EYFP/ECFP ratio. A 3-fold change in the ratio was observed at a physiologically relevant concentration range of 1 to 25 mmol/l glucose in the incubation medium. Thus, the intracellular glucose concentration can be calculated in living insulin-producing cells. In addition, these changes could be resolved temporarily on a single cell level. Upon perfusion of glucose deprived cells with 1, 5, 10 or 25 mmol/l glucose a rapid change in the EYFP/ECFP ratio could be detected, indicating a high capacity of MIN6 cells for glucose uptake via the GLUT2 glucose transporter from the medium. Upon removal of glucose the effects were reversible within 5 min. This opens the possibility to elucidate the regulation of glucose homeostasis in insulin-producing MIN6 cells.

Conclusion: FLIPglu sensors could be successfully established to monitor in real time changes in the intracellular glucose concentration of insulin-producing MIN6 cells. To investigate effects of long-term glucose exposure with respect to glucose toxicity FLIPglu sensors are a promising tool to verify the dependency of the intra- to extracellular glucose concentration.

The effect of pseudoislet formation on insulin production in beta cells *in vitro*

T. Kopska, V. Fürstova, J. Kovar;

Division of Cell and Molecular Biology and Centre for Research of Diabetes, Metabolism and Nutrition, Third Faculty of Medicine, Charles University in Prague, Czech Republic.

Background and Aims: After the dispersion of islet cells the ability of beta cells to produce insulin is impaired. But after reorganisation into pseudoislets beta cells regain cell-to-cell contact important for their function and their ability to secrete insulin improves. Pseudoislets can be formed from isolated beta cells as well as from cells of beta cell lines. The aim of this study was to test the effect of pseudoislet formation and pseudoislet growth on insulin secretion by beta cells *in vitro* in the time course of cultivation.

Materials and Methods: Beta cells of the line MIN6 were cultured in DMEM medium containing 22mM glucose supplemented with 15% FBS. Cell culture plates for suspension cells (Sarstedt, Germany) were used for the induction of pseudoislet formation. The amount of insulin secreted into the culture medium during 1h was determined by Insulin Mouse ELISA kit (DRG Diagnostics).

Results: The number of pseudoislets formed depended on the number of cells seeded. Pseudoislet number to seeded cell number ratio was highest for cell densities ranging 50–100x10³ cells/ml per well. The overall number of cells per well did not increase with time after induction of pseudoislet formation. However, number of cells per pseudoislet grew fast from about 200x10³ cells/pseudoislet on the 2nd day to about 600x10³ cells/pseudoislet on the 6th day after the induction. Then the growth ceased and pseudoislets had about 800x10³ cells/pseudoislet on the 10th day. On the 2nd day after the induction the insulin secretion by the cells in pseudoislets (48.9±20.3 ng/10⁵ cells) was comparable to the secretion by the cells growing in monolayer (57.5 ±5.8 ng/10⁵ cells). On the 4th day the insulin secretion by the cells in pseudoislets increased approximately 2-fold (117.3±13.1 ng/10⁵ cells) compared to 2nd day. The highest insulin secretion (167.1±20.6 ng/10⁵ cells) was found on the 6th day after the induction. After the 6th day, i.e. on the 8th and 10th day the insulin secretion stayed on slightly lower levels (131.0±6.2 and 128.2±5.3 ng/10⁵ cells).

Conclusion: The ability of beta cells (MIN6) to secrete insulin *in vitro* gradually increases with time after the induction of pseudoislet formation and reaches its maximum within six days. The insulin secretion correlates with the growth of pseudoislet cell number. The secretion is near maximum when the pseudoislets have reached their full size. Our knowledge concerning insulin secretion by pseudoislets *in vitro* during the course of cultivation should be useful for the consideration of their involvement in transplantation.

Characterisation of islet morphology in pancreatic tissue from non-diabetic organ donors

C. Reers¹, S. Erbel¹, I. Esposito², B. Schmied³, M. W. Buechler³, P. P. Nawroth¹, R. A. Ritzel¹;

¹Department of Internal Medicine I, University of Heidelberg,

²Institute of Pathology, University of Heidelberg,

³Department of Surgery, University of Heidelberg, Germany.

Background and Aims: Pancreatic beta-cell mass is an important parameter for overall islet function in the context of diabetes mellitus. Since human pancreatic tissue is difficult to obtain analysis of islet morphology is usually performed in autopsy tissue, which prior to fixation might be damaged by ischemia and autolytic processes. In contrast, pancreatic tissue from organ donors is processed directly after explantation with minimal ischemia time. Therefore we characterized islet morphology in human pancreatic tissue from organ donors and compared it to beta-cell volume in autopsy tissue.

Materials and Methods: Paraffin embedded pancreatic tissue (head, body and tail region) from n=14 non-diabetic organ donors was sectioned and stained for insulin, glucagon and the replication marker Ki-67. Beta-cell and alpha-cell volume were determined by morphometric analysis and correlated to age and body-mass index (BMI). Beta-cell volume was compared to

previously established beta-cell volume in autopsy tissue of non-diabetic humans (n=48).

Results: Organ donors were 46.6 ± 17.2 years old (range 7 – 63 years), BMI 25.5 ± 4.3 kg/m² (range 17.1 – 33.1 kg/m²). Islet architecture showed a typical location of beta-cells in the core and alpha-cells in the periphery of the islets. Mean beta-cell volume was 2.3 ± 1.0 % (0.4 – 4.1 %), alpha-cell volume was 0.6 ± 0.6 % (0.1 – 2.0 %). There were no regional differences in alpha- and beta-cell volume (p=n.s. for head vs body vs tail). Beta-cell volume was comparable in donor and autopsy pancreata (2.3 ± 1.0 vs 2.3 ± 0.3 %; p=n.s.). There was no relationship between alpha- or beta-cell volume with age or BMI of organ donors. Beta-cell replication was generally low (0.2 ± 0.2 Ki-67 positive cells/islet), regression analysis showed an age-dependent decrease of beta-cell replication ($r^2=0.63$, $p<0.001$).

Conclusion: In the present group of non-obese and non-diabetic subjects alpha- and beta-cells are evenly distributed throughout the pancreas and overall alpha- and beta-cell volume is not affected by age or BMI. The present data provides evidence that in humans beta-cell replication becomes less important for islet turnover with aging. Finally, pancreatic tissue from donor organs and obtained at autopsy is equally suitable for analysis of beta-cell volume.

Gene modules and networks involved in cytokine-mediated death in human pancreatic islets

B. Kutlu¹, D. Baxter¹, D. Burdick¹, A. K. Cardozo², N. Goodman¹, D. L. Eizirik², N. Welsh³, L. Hood¹;

¹JDRF Center for Bioinformatics, Institute for Systems Biology, Seattle, United States, ²Lab. of Experimental Medicine, Universite Libre de Bruxelles, Belgium, ³University of Uppsala, Dept. of Medical Cell Biology, Sweden.

Background and Aims: Type 1 Diabetes (T1D) is an autoimmune disease that leads to destruction of beta cells of the pancreatic islets of Langerhans. It is well established that cytokines are cytotoxic to pancreatic islets in vitro. With the aim of identifying networks and modules activated in response to cytokines, we performed a detailed transcriptome analysis of IL-1 β and IFN- γ stimulated human islets.

Materials and Methods: High quality human islets (n=2) were exposed to IL-1 β (50 U/ml)+IFN- γ (1000 U/ml) for 48h and gene expression was detected with Massively Parallel Signature Sequencing (MPSS: a signature sequencing technique that is able to detect low abundance transcripts). MPSS analysis of untreated islets was performed previously. A different set of human islet samples (from 3 separate donors, average purity > 90% and beta cell percentage > 58%) were either left untreated or exposed to IL-1 β (50 U/ml)+IFN- γ (1000 U/ml) for 1, 2, 4, 8, 12, 24, 36, 48, 60, 72, 84 and 96h and gene expression was detected at each time point with HGU133 plus 2.0 Affymetrix microarrays. Real Time PCR (RT-PCR) was performed on select transcripts and time points to complement and validate the MPSS and microarray results.

Results: Time series microarray analysis identified 2491 differentially expressed genes in islets in response to cytokine treatment (linear regression model analysis, $p<0.05$ – corrected for multiple testing). In the MPSS dataset, a total of 6893 genes were expressed at a minimum level of 5 transcripts per million (tpm) in human islets after 48h of cytokine treatment. Many of these genes (4624) were detected at less than 50 tpm and 438 are not included on the Affymetrix microarrays. RT-PCR analysis of select transcripts confirm that MPSS-detected genes such as CD99, SAA1 and KREMEN are regulated by cytokines. Model based clustering of time series data resulted in 26 clusters that represent the main trends observed in the data. Two clusters contained most of the 22 significantly regulated chemokines in response to cytokines: all but 2 (CCL26, CXCL12) were up-regulated in an early and robust manner (2–9 fold change on log₂ scale). Gene Ontology (GO) enrichment analysis of cluster members indicate that some strongly induced clusters are enriched in genes involved in apoptosis namely, CASP10, TRAF1, I-FLICE, PUMA etc. All these genes are putative targets of 169 significantly expressed transcription factors that form the backbone of the gene regulatory networks involved in beta cell apoptosis. Screening for a molecular interaction network to identify active subnetworks by integrating protein-protein interactions and gene expression data indicates the presence of a gene module that contains NF- κ B and STAT1 and their interacting partners.

Conclusion: We have identified the early changes in the gene networks active in human islets under cytokine assault. The detailed time course data allows us to refine the existing model of cytokine-induced beta cell death and to increase our understanding of the gene regulatory networks involved in this process.

Characterisation of the pattern of gene expression induced by IL-1 β and TNF- α in insulin-producing INS-1E cells

F. Ortis, N. Naamane, P. Pirot, A. Y. Kreins, D. L. Eizirik;

Laboratory of Experimental Medicine, Université Libre de Bruxelles, Belgium.

Background and Aims: Cytokines such as IL-1 β and TNF- α play an important role in the autoimmune destruction of pancreatic beta-cells in

type 1 diabetes. IL-1 β has a more pronounced pro-apoptotic effect in beta cells and insulin producing INS-1E cells than TNF- α . Both cytokines induce the transcription factor NF- κ B, but recent observations suggest that NF- κ B blocking is more effective in preventing IL-1 β + IFN- γ - than TNF- α + IFN- γ -induced beta-cell apoptosis. We presently compared cell death and the pattern of NF- κ B activation and gene expression induced by IL-1 β and TNF- α in INS-1E cells in order to clarify the reasons behind the different effects of these cytokines on beta-cell apoptosis.

Material and Methods: INS-1E cells were exposed to either IL-1 β (100U/ml) or TNF- α (1000U/ml) in time course experiments. Cell viability was evaluated by Hoechst 342 and propidium iodide, in the presence or absence of cycloheximide (1 μ g/ml – 2h pre-exposure). NF- κ B translocation to the nucleus was measured by immunostaining using an anti-p65 antibody. RNA extracted from these cells was used in real-time RT-PCR and microarray analysis. Microarray analysis was performed using the ApoChip, a targeted oligonucleotide array designed by our group and containing 600 rat genes putatively implicated in beta cell dysfunction and death. Microarray experiments were replicated with dyes swapped in each hybridisation. Results of three independent array experiments were calculated as mean \pm standard error. mRNA expression was considered as modified by cytokines when they had a ≥ 1.2 -fold variation and $p < 0.025$ (t-test) in at least one time point as compared to control cells.

Results: Blocking of proteins synthesis by cycloheximide promoted TNF- α -induced INS-1E cell apoptosis after 24h (apoptotic index of 4.9 ± 1.2 ; $P < 0.05$ vs. control; $n = 6$), while it did not affect IL-1 β -induced apoptosis (apoptotic index of 1.5 ± 0.7 ; N.S.; $n = 6$). IL-1 β induced an earlier translocation of NF- κ B to the nucleus as compared to TNF- α ($77.4 \pm 4.2\%$ vs $37 \pm 8.3\%$ of nuclear positive cells for respectively IL-1 β and TNF- α after 30 min; $n = 7$). Microarray analysis of INS-1E cells exposed to IL-1 β showed an up-regulation and down-regulation of respectively 46 (7.7%) and 7 (1.2%) genes, while in TNF- α -treated cells there was up-regulation of 42 genes (7%) and down regulation of 5 genes (0.8%). 22% of the up-regulated genes, but only 8% of the down-regulated genes, were common for IL-1 β and TNF- α . IL-1 β induced a higher expression of NF- κ B target genes such as MCP-1, Mob-1 and I κ B α , a finding confirmed by real time RT-PCR for some of the genes. Real time RT-PCR for some relevant genes not present and/or not detected in the ApoChip (A20, CD40, etc) also showed a higher induction by IL-1 β as compared to TNF- α .

Conclusions: Our results indicate that *de novo* protein synthesis has a protective role against TNF- α - but not against IL-1 β -induced INS-1E cell death. IL-1 β induces an earlier NF- κ B translocation to the nucleus and an increased expression of some NF- κ B target genes as compared to TNF- α . Interestingly, and in spite of the fact that both cytokines induce the same key transcription factor, there are more similarity regarding up-regulation than down-regulation of genes potentially contributing to beta cell dysfunction and death.

Pro-inflammatory cytokines inhibit insulin secretion but increase glucose consumption, lactate production, triacylglycerol utilisation and AMPK activation in a clonal pancreatic β cell line

A. M. Kiely¹, P. R. Flatt², P. Newsholme¹

¹Biochemistry Department, Conway Institute of Biomolecular and Biomedical Research, Dublin, ²Biochemistry Department, School of Biomedical Sciences, University of Ulster, Ireland.

Background and Aims: Islet associated pro-inflammatory cytokines (IL-1 β , TNF α and IFN γ) are involved in the pathogenesis of type I diabetes via the induction of apoptosis in pancreatic β -cells. The mechanism(s) by which cytokines stimulate apoptosis remain to be elucidated, but gene expression profiling data has determined significant alterations in gene expression related oxidative and endoplasmic reticulum stress and to intermediary metabolism in the β -cell. Our work aimed to elucidate the key metabolic processes that were altered after exposure of a clonal beta cell line to sub-lethal concentrations of pro-inflammatory cytokines.

Materials and Methods: Clonal rat BRIN BD11 beta cells were incubation in the presence of pro-inflammatory cytokines at sub-lethal concentrations for 24 hours (IL-1 β 0.3125U/ml, TNF α 31.25U/ml, IFN γ 15.625U/ml). Glucose consumption, lactate production and intracellular triacylglycerol concentrations were determined by enzymatic assays. Insulin secretion was determined by ELISA. AMPK-P concentration was determined by Western blot.

Results: Glucose consumption after 24 hr treatment with the cytokine cocktail increased from 20.47 ± 5.31 to 44.61 ± 6.67 μ moles glucose/mg protein, an increase of at least 2-fold, $p < 0.0001$. Lactate production increased from 15.87 ± 6.09 to 58.81 ± 13.11 μ moles lactate/mg protein, $p = 0.002$, an increase of almost 4-fold. Intracellular triglyceride levels were reduced from 0.12 ± 0.02 to 0.06 ± 0.04 mg triglyceride/mg protein, a reduction of 49%, $p = 0.008$. The concentration of AMPK-P increased almost 2-fold from 1.0 ± 0.59 to 1.75 ± 0.45 relative units $p = 0.03$. Insulin secretion was reduced from 16.09 ± 2.78 to 6.62 ± 1.04 μ g insulin/mg protein, $p = 0.0002$, a 59% reduction.

Conclusion: Our work clearly demonstrated that sub-lethal concentrations of pro-inflammatory cytokines appear to shift β -cell metabolism away from a primary role of stimulus-secretion coupling, and towards a catabolic state that may be related to cell defence. As each molecule of glucose generates 2 molecules of lactate, these results indicate that 89% of the increased glucose consumed was lost as lactate from the BRIN BD11 cells, indicating that anaerobic glycolytic metabolism was favoured at the expense of oxidative flux. One possible explanation for this is that increased generation of glycolytic intermediates e.g. ATP, triose-phosphates and possibly products of the pentose phosphate pathway, eg NADPH, are essential for cell defence. LDH would be required under these conditions to regenerate NAD⁺ resulting in an increase in export of lactate. Increased intracellular generation of fatty acids from triglyceride would at the same time provide acetyl-CoA for oxidative metabolism in the TCA cycle.

Inhibitory effects of St. John's wort extract and its component hyperforin on cytokine-induced apoptosis and iNOS expression in pancreatic beta cells by down-regulation of STAT-1 and NF- κ B

P. Masiello¹, M. Novelli¹, P. Befy², V. D'Aléo¹, E. Tedeschi³, R. Lupi⁴, R. Zaffini³, P. Marchetti⁴, H. Suzuki³, M. Menegazzi³

¹Dept. of Experimental Pathology, University of Pisa,

²Institute of Clinical Physiology, CNR, Pisa,

³Dept. of Morphological and Biomedical Sciences, University of Verona,

⁴Dept. of Endocrinology and Metabolism, University of Pisa, Italy.

Background and Aims: Type 1 diabetes is believed to result from beta-cell destruction induced by immune and inflammatory cytokines. No low-molecular-weight compounds are known so far to block the cytokine-induced activation of the signal transducers and transcription factors STAT-1 and NF- κ B in pancreatic beta cells, leading to expression of inducible NO synthase (iNOS), beta-cell dysfunction and death. Based on previous results in other cell types, we tested the hypothesis that the extract of *Hypericum perforatum* (St. John's wort, SJW), commonly used as an antidepressant in phytotherapy, and its phloroglucinol component hyperforin (HPF) might interfere with the mechanisms of action of cytokines in beta cells, and consequently protect them from functional impairment and cytotoxicity.

Materials and Methods: Cultured INS-1E cells were exposed to cytokine mixtures (IFN- γ + IL-1 β + TNF- α) for different time periods as appropriate, in the presence or absence of various concentrations of a hydro-alcoholic SJW extract or HPF. Apoptosis was evaluated by caspase-3 activity assay, iNOS expression by Northern blot, STAT-1 and NF- κ B activation by electrophoretic mobility shift assay. Rat and human isolated pancreatic islets were also used to validate the effects of the vegetal compounds on cytokine-induced STAT-1 activation.

Results: Either SJW extract or HPF significantly and dose-dependently protected INS-1E cells against cytokine-induced beta-cell apoptosis (IC50 36 μ g/ml or 2.2 μ mol/l, respectively) and iNOS expression (IC50 7 μ g/ml or 0.5 μ mol/l), and inhibited both STAT-1 (IC50 10 μ g/ml and 0.4 μ mol/l) and NF- κ B (IC50 30 μ g/ml and 1.0 μ mol/l) activation. Constitutively expressed transcription factors such as CBF-1 or SP-1 were unchanged. The inhibitory effect of SJW extract on STAT-1 activation became greater with increasing time of incubation and was also apparent upon preincubation and subsequent removal from the medium during cytokine exposure. Impairment in glucose-stimulated insulin secretion was fully reversed when INS-1E cells were previously exposed to cytokines in the presence of 25 μ g/ml SJW or 1 μ mol/l HPF. The STAT-1 down-regulating effect of the vegetal compounds was confirmed in both rat and human islets. In the latter, SJW and HPF (in the range 50–200 μ g/ml and 2.5–10 μ mol/l, respectively) dose-dependently inhibited cytokine-induced STAT-1 activation.

Conclusions: SJW extract and hyperforin are novel non-peptidyl compounds targeting key mechanisms of cytokine-induced beta-cell injury, thereby improving beta-cell function and survival. Thus, they represent a promising approach to prevent or delay beta-cell destruction elicited by immune and inflammatory cytokines.

***In utero* exposure to the vacuolar-ATPase inhibitor bafilomycin increases susceptibility of pancreatic beta cells to cytokine-induced cell death**

S. Ling¹, M. A. Myers¹, H. E. Thomas²;

¹Biochemistry and Molecular Biology, Monash University,

²Immunology and Diabetes, St. Vincent's Institute of Medical Research, Melbourne, Australia.

Background and Aims: Environmental agents are known to contribute to Type 1 Diabetes development. Bafilomycin, a potent inhibitor of the proton translocating vacuolar ATPase, is found in tuberous vegetables infected with common scab disease. When fed in drinking water to pregnant NOD mice, bafilomycin disrupts beta cell development and accelerates Type 1 diabetes onset in the offspring. Cytokines, in particular IFN gamma, TNF alpha and IL-1 are mediators of the autoimmune beta cell destruction that leads to Type 1 Diabetes. The aim of this study was to test the susceptibility of bafilomycin-exposed beta cells to cytokine-induced cell death.

Materials and Methods: A severe combined immunodeficient mutant derived from NOD (NODscids) was used in these experiments to minimize potential complications due to insulinitis. NODscids breeders were exposed to bafilomycin in drinking water (60 ng/ml) and pancreatic islets were isolated from the offspring at 4 to 6 weeks of age. Pancreatic islets were isolated by intraductal digestion of the pancreas with collagenase P and the separation on a density gradient. The islets were hand-picked to purity and cultured. 100 islets were exposed to IL-1, TNF alpha, IFN gamma, zvad and nmma at different combinations with known concentrations for 4 days at 37°C and apoptosis measured by propidium iodide staining and flow cytometry.

Results: Islet beta cells from control and exposed mice showed similar percentage cell death (7±2 and 11±6 %, mean±sem, n = 3) when untreated. Similar degrees of cell death were observed for both groups when exposed to IL-1 and IFN gamma or TNF alpha alone. Exposure to TNF alpha and IFN gamma in combination showed significant increases in beta cell death in islets from 6 week-old NODscids exposed to bafilomycin *in utero* (58±3 %), as compared to non-bafilomycin exposed mice (37±1 %, p = 0.002, Students t-test). This increased susceptibility to TNF alpha and IFN gamma was inhibited by the caspase inhibitor zvad (26±7 and 29±5 % respectively) and the nitric oxide (NO) synthase inhibitor nmma (21±5 and 23±4 % respectively).

Conclusion: *In utero* exposure to bafilomycin increases susceptibility of pancreatic beta cells to cytokine-induced cell death in an insulinitis-free environment. Increased cytokine susceptibility is mediated by both caspases and NO. This raises the possibility that accelerated diabetes development in NOD mice is caused by an increase in the rate of beta cell destruction leading to more rapid progression to insulin deficiency. Dietary exposure to bafilomycin during pregnancy in early life may be a risk factor for Type 1 Diabetes in those with genetic susceptibility to the disease.

Antiapoptotic action of exendin-4 in ins-1 beta cells: comparative protein-pattern analysis of isolated mitochondria

D. Tews, S. Lehr, S. Hartwig, A. Osmers, W. Paßlack, J. Eckel;

Inst. of Clinical Biochemistry and Pathobiochemistry, German Diabetes Center, Duesseldorf, Germany.

Background and Aims: Besides its numerous physiological functions, Glucagon like peptide-1 (Glp-1) exhibits beneficial effects on the beta-cell mass by both enhancing proliferation and inhibiting apoptosis. However, the precise mechanisms of the antiapoptotic effect have remained elusive. Mitochondria play a key role in the regulation of apoptosis. We performed a comparative protein pattern analysis using two-dimensional difference gel electrophoresis (2D-DIGE) in order to get further insight into the antiapoptotic action of Glp-1 receptor agonists.

Materials and Methods: After a preincubation with the long acting glp-1 receptor agonist exendin-4 for 5 hours, INS-1 cells were cultured overnight with a cytokine cocktail (Interleukin-1β, Interferon-γ). Apoptosis was determined by measuring caspase-3 activity or by Hoechst33342 / propidiumiodide staining. Mitochondria were enriched by sub-cellular fractionation using differential centrifugation monitored by marker enzyme assays. Subsequently, the proteins of the isolated organelles were labeled with Cy-dyes and separated on overlapping zoom 2D gels spanning a pH-range of 4-9. Differences between protein profiles were analyzed by Proteomewave software, and protein spots with significant differences were identified by MALDI mass spectrometry.

Results: Cytokine incubation increased the number of apoptotic cells to 11% and caspase-3 activity to about 300%. Apoptotic events were reduced to 5% of the cells and caspase-3 activity was reduced by 60% by incubation with exendin-4. 2% of the 3300 reproducibly detected protein spots showed significant differences after cytokine treatment, of which we were able to identify 17 proteins via mass spectrometry analysis. Interestingly, several proteins were counter-regulated by exendin-4.

Conclusion: This study allows further insights into the role of mitochondria in cytokine induced apoptosis. Induction of apoptosis by cytokines is regulated by interaction of several metabolic and signalling proteins. Analysis of the counter-regulation of some proteins by exendin-4 may deliver new targets, which could play a role in the antiapoptotic action of Glp-1 receptor agonists.

Protective effects of GLP-1 receptor agonists on TNFα-induced apoptosis in INS-1 beta cells

A. Natalicchio, F. De Stefano, E. Lauranzano, S. Perrini, M. R. Orlando, A. Leonardini, A. Cignarelli, M. Melchiorre, S. Martemucci, C. Caccioppoli, L. Laviola, F. Giorgino;

Endocrinology & Met. Diseases, University of Bari, Italy.

Background and Aims: TNFα represents an important mediator of beta-cell dysfunction and death in diabetes. The objective of this study was to evaluate the mechanisms of TNFα-induced beta-cell damage, and to investigate the potential protective effects of GLP-1 mimetics on beta-cell function and survival.

Materials and Methods: INS-1 beta-cells were stimulated with 20 ng/ml TNFα for several hours. The effects of GLP-1 receptor agonists was evaluated by pre-incubating INS-1 cells with GLP-1 (10 nM) or Exenatide (10 nM) for 18 h. Protein content and phosphorylation of intracellular signaling intermediates were evaluated by immunoprecipitation and immunoblotting techniques. Beta-cell apoptosis was quantified by an ELISA assay evaluating oligosome release into the cytosol.

Results: Treatment with TNFα increased the phosphorylation levels of the serine-kinase JNK 2-fold (p<0.05) and reduced IκBα protein content by 50% (p<0.05). Furthermore, TNFα stimulation resulted in increased serine phosphorylation levels of the IRS-1 protein (p<0.05), and a reduction of IRS-1 mRNA expression by 50%, even though protein levels of both IRS-1 and IRS-2 appeared to be unaffected by the cytokine treatment. Moreover, TNFα reduced basal Akt phosphorylation by 30% and increased beta-cell apoptosis 7-fold (p<0.05). Since the incretin hormone GLP-1 has been shown to promote beta-cell survival, we next investigated potential protective effects of GLP-1 receptor agonists on TNFα-induced beta-cell apoptosis. Pre-incubation of INS-1 cells with GLP-1 (10 nM) or Exenatide (10 nM) for 18 h inhibited TNFα-induced apoptosis by 50% (p<0.05). Furthermore, both GLP-1 and Exenatide prevented TNFα-induced JNK phosphorylation and IRS-1 serine phosphorylation, and restored Akt phosphorylation, without affecting other MAP kinases such as p38. Finally, Exenatide treatment induced a 3-fold increase in IRS-2 protein expression.

Conclusion: TNFα induces apoptosis of INS-1 beta-cells, and this likely occurs by induction of JNK phosphorylation and impairment of IRS-1 and Akt signaling. GLP-1 and Exenatide prevent the signaling abnormalities and cell apoptosis induced by TNFα. Thus, GLP-1 receptor agonists may promote beta-cell survival by directly antagonizing cytokine-dependent signaling reactions mediating beta-cell death.

Factors in serum from type 2 diabetes patients cause cellular insulin resistance

J. W. Eriksson^{1,2}, F. Renstrom³, J. Burén³, M. Svensson³;

¹Lundberg Laboratory for Diabetes Research, Sahlgrenska University Hospital, Gothenburg, ²AstraZeneca R&D, Molndal,

³Medicine, Umea University Hospital, Umea, Sweden.

Objective: This study was designed to investigate whether there are humoral factors, in addition to glucose, insulin and free fatty acids (FFA), in serum from type 2 diabetic patients that can induce or contribute to peripheral insulin resistance with respect to glucose transport.

Methods: Isolated subcutaneous adipocytes from 11 type 2 diabetic subjects and 10 non-diabetic control subjects were incubated for 24 h in medium supplemented with 25% serum obtained from non-diabetic (control) donors or with serum from type 2 diabetic donors. The glucose concentration was adjusted to predefined levels: a low, physiological (5 mM) or a high, 'diabetic' (15 mM) level, respectively. After the incubation period glucose uptake capacity was assessed in intact adipocytes in the presence of 0–1000 mU/L insulin, and Western blots were performed on cellular lysates.

Results: In adipocytes from control subjects, pretreatment with 25% serum from type 2 diabetic donors significantly reduced maximally insulin-stimulated, but not basal, glucose uptake capacity (by ~30%, $p < 0.05$), as compared to control serum. This was seen at 5 mM glucose, but not at 15 mM. There were no differences in insulin and FFA levels, and neither in TNF- α or IL-6, during the incubation that could account for the differences seen between serum from diabetic and control subjects, respectively. A similar impairment of glucose uptake capacity, as that seen with diabetic serum, was exerted by pretreatment with high glucose (15 mM) together with control serum ($p < 0.05$). There was no clear additive effect with high glucose in combination with diabetic serum. No significant alterations were found in cellular content of key proteins in the insulin signaling cascade (IRS-1, IRS-2 and GLUT4) that could explain the impaired insulin-stimulated glucose transport in control adipocytes incubated with serum from type 2 diabetic donors.

In adipocytes isolated from type 2 diabetic subjects, insulin-stimulated glucose uptake capacity was impaired compared to control cells, and this was seen in both fresh cells (reduction by ~50%) and, to a lesser extent, in cells cultured for 24 h ($p < 0.01$). No further changes were observed with different culture conditions, i.e. diabetic or control serum, 5 or 15 mM glucose. The impairment in glucose uptake capacity seen in cultured 'diabetic' adipocytes was very similar to that found in control adipocytes cultured with diabetic serum.

Conclusion: These findings indicate the presence of biomolecules, besides glucose, insulin and FFA, in the circulation of type 2 diabetic patients, that can induce or maintain peripheral insulin resistance. This implies that even if glucose levels are normalised, other circulating factors can impair insulin sensitivity in type 2 diabetic patients.

Insulin signaling in type 2 diabetes – role of the oxidative stress related protein p66shc: preliminary data

E. Pagnin, E. Murphy, E. Iori, S. Schiavo, L. Bertipaglia, L. A. Calo, A. Avogaro;

Dep. Clinical and Experimental Medicine, University of Padova, Italy.

Background and Aims: Oxidative stress plays an important role in endothelial cardiovascular dysfunction and atherogenesis. This is of particular relevance in diabetes, a condition characterized by oxidative stress, and increased prevalence of cardiovascular disease. The major role played by p66shc in oxidative stress-related response has been established by the resistance to and reduction of oxidative stress of p66shc knockout mice. We have demonstrated for the first time in type 2 diabetic patients an increased mononuclear cell p66shc gene expression compared to healthy controls. Abnormal regulation of the phosphatidylinositol 3-kinase (PI3-K)/Akt pathway, which plays an

essential role in the insulin signalling, is another factor known to contribute to diabetic vascular dysfunction. No data are available on the role played by p66shc on insulin signalling. This study evaluates in fibroblasts derived from skin biopsies of three type 2 diabetic patients the effect of p66shc gene silencing on activation of Akt upon insulin stimulation.

Materials and Methods: After incubation (15 min) with insulin (100nM), phospho-Akt (Thr308 and Ser473) were determined by western blot analysis. p66shc gene silencing was performed using siRNA methodology.

Results: Ser473 Akt phosphorylation was significantly lower after incubation with insulin in fibroblasts from type 2 diabetic patients compared to healthy subjects (201,7 D% vs basal \pm 36,2 vs 260,9 \pm 47,9, $p < 0,03$). p66shc silencing not only increased Ser473Akt phosphorylation in cells from type 2 diabetic patients compared to not silenced cells (457,0 D% vs basal \pm 31,5 vs 201,7 \pm 36,2, $p < 0,03$) but also compared to not silenced cells from healthy subjects (457,0 D% \pm 31,5 vs 260,9 \pm 47,9, $p < 0,05$). No significant differences in Thr308Akt phosphorylation were found in cells from type 2 diabetic patients and healthy subjects (118,8 D% \pm 20,2 vs 97,0 \pm 37,9, ns). On the contrary, p66shc silencing caused an increase of Thr308Akt phosphorylation in cells from type 2 diabetic patients compared to not silenced cells from healthy subjects (426,8 D% \pm 124,5 vs 118,8 \pm 20,2, $p < 0,03$).

Conclusion: Our preliminary results demonstrate a role for p66shc in the altered insulin signalling of type 2 diabetic patients due to a p66shc mediated inhibition of PI3-K/Akt pathway which is removed by p66shc gene silencing. This is the first demonstration of a direct involvement of p66shc in insulin signalling in fibroblasts from type 2 diabetes.

Anti-inflammatory effect of insulin on IL-6 signaling in the human hepatoma cell line HepG2

E. Wallerstedt, C. X. Andersson, U. Smith;

Department of Molecular and Clinical Medicine/Diabetes, Medicine, Gothenburg, Sweden.

Background and Aims: It has previously been reported that infusion of insulin leads to anti-inflammatory effects including reduction of plasma concentrations of the acute-phase proteins C-reactive protein (CRP), serum amyloid A (SAA) and plasminogen activator inhibitor-1 (PAI-1). We have recently shown that insulin can antagonize interleukin-6 (IL-6) signaling and exert anti-inflammatory effects in 3T3-L1 adipocytes by significantly reducing the tyrosine phosphorylation of its intracellular signaling molecule STAT3. This is also accompanied by reduced expression of the inflammatory marker genes SAA3 and haptoglobin. To study if the cross-talk between IL-6 and insulin also occurs in other cells, we have used the human hepatoma cell line hepG2.

Materials and Methods: The human hepatoma cell line, HepG2, was cultured and incubated with insulin (100 nM), IL-6 (20 ng/ml) and insulin+IL-6 for 30 minutes up to 24 hours. RNA was extracted and the gene expression was analyzed with real-time RT-PCR (TaqMan) while the proteins were analyzed by immunoblotting.

Results: Insulin exerts an inhibitory effect on IL-6 signaling in HepG2 cells by reducing the tyrosine phosphorylation of STAT3. However, the serine phosphorylation of STAT3 was not affected by insulin. A reduced gene expression of the inflammatory marker genes SAA1, SAA2, haptoglobin, orosomucoid and PAI-1 was observed in cells stimulated with both IL-6 and insulin compared to cells treated with IL-6 alone. IL-6 increased the gene expression of SOCS3 but in contrast to the inflammatory markers, which were reduced by the addition of insulin, a synergistic effect of the combination was found. SOCS3 functions as a feed-back inhibitor of the IL-6 signaling pathway in order to clarify the mechanism for this; insulin could also activate STAT5 another inducer of SOCS3 expression. Importantly, we found that insulin increased the tyrosine phosphorylation of STAT5. Furthermore, co-immunoprecipitation experiments showed that STAT3 and STAT5 were able to heterodimerize when cells had been incubated with insulin. This finding can explain the positive effect of insulin and IL-6 on SOCS3 expression.

Conclusion: Insulin antagonizes IL-6 signaling in the human hepatoma cell line, HepG2, by reducing the tyrosine phosphorylation of STAT3 and, thereby, inhibits the expression of inflammatory marker genes. Our data also suggest that the insulin-induced reduction of the tyrosine phosphorylation of STAT3 is due to an insulin-dependent induction of the feed-back inhibitor of IL-6 signaling, SOCS3.

The inhibition of stress kinases, NF- κ B, and PKC θ by EGB 761 restored palmitate-induced insulin resistance in L6 Myotubes

J. Jung¹, E.-S. Ha¹, H.-J. Jang¹, S.-E. Choi¹, S. Jung², H. Kim², D. Kim², Y. Kang¹, K.-W. Lee²;

¹Institutes for Medical Sciences, ²Endocrinology and Metabolism, Ajou University School of Medicine, Suwon-Si, Republic of Korea.

Background and Aims: EGB 761, a standardized form of Ginkgo biloba leaf extract, was recently reported to increase pancreatic beta-cell function. However, the detailed effect of EGB 761 on insulin resistance has not been examined. We found that EGB 761 prevented palmitate-induced insulin resistance in L6 myotubes. In this study, we investigated the molecular and cellular mechanisms of the protective effect of EGB 761 on palmitate-induced insulin resistance.

Materials and Methods: We used differentiated L6 myotubes as an in vitro skeletal muscle model with glucose deprivation for 3 days. To determine the effect of EGB 761 on insulin resistance, before palmitate treatment, we pretreated differentiated L6 myotubes with EGB 761 and then measured the insulin-stimulated glucose uptake and insulin signaling.

Results: A 12-h exposure of L6 myotubes to palmitate reduced the insulin stimulated glucose uptake by 67%, insulin receptor substrate (IRS)-1 tyrosine phosphorylation by 72%, and protein kinase B phosphorylation by 70%, and increased IRS-1 serine phosphorylation by 169%. EGB 761 prevented the palmitate-induced reduction of insulin-stimulated glucose uptake, IRS-1 tyrosine phosphorylation, and protein kinase B phosphorylation in dose-dependent manners. To elucidate the mechanism of the EGB 761-prevented palmitate-induced reduction of insulin resistance, we monitored the activation of stress kinases, NF- κ B, and PKC θ . Palmitate stimulated the phosphorylation of JNK and p38 by 2- and 1.9-fold, respectively, the degradation of I κ B α and I κ B β by 1.9- and 1.6-fold, respectively, and the translocation of protein kinase c θ by 2.2-fold. Treatment with EGB 761 reduced the activation of stress kinases, NF- κ B, and protein kinase c θ by palmitate, suggesting that EGB 761 prevents palmitate-induced insulin resistance in L6 myotubes via the inhibition of stress kinases, NF- κ B, and PKC θ .

Conclusion: Our data suggest that EGB 761-prevented palmitate-induced insulin resistance is mediated by the inhibition of stress kinases, NF- κ B, and protein kinase c θ and the subsequent restoration of insulin signaling.

The AMPK-induced p70S6K inhibition correlates to the synergistic effect of biguanides and insulin on glucose uptake via the overphosphorylation of the PKB/AS160 axis

L. Bertrand¹, A. Ginion¹, C. Beauloye¹, C. Mouton¹, L. Hue², J.-L. Vanoverschelde¹;

¹Division of Cardiology, ²Hormone and Metabolic Research unit, Université Catholique de Louvain, Brussels, Belgium.

Background and Aims: Biguanides, like metformin and phenformin, are known to lower blood glucose concentration by increasing muscle glucose disposal. Several findings suggest that the effects of biguanides could be mediated by the activation of AMP-activated protein kinase (AMPK). The aim of this work was to study the relationship between AMPK and the biguanide-stimulated glucose uptake in cardiomyocytes.

Materials and Methods: Cultured rat cardiomyocytes were incubated with insulin and phenformin, alone or in combination. Glucose uptake was measured by the detritration rate of [2-3H] glucose. The phosphorylation state of the different signalling elements was measured by immunoblot.

Results: The stimulation of glucose uptake by biguanides (phenformin 0.5mM: 0.77 ± 0.17 vs control: 0.09 ± 0.03 μ moles/mg.h, $p \leq 0.05$) correlated to AMPK phosphorylation (control: 0.03 ± 0.03 vs phenformin: 1.00 ± 0.00 , arbitrary unit, $p \leq 0.05$), whereas that by insulin (1.07 ± 0.14 μ moles/mg.h, $p \leq 0.05$ vs control) correlated with protein kinase B (PKB) phosphorylation (control: 0.0 ± 0.0 vs phenformin: 1.0 ± 0.0 , arbitrary unit, $p \leq 0.05$). When added together, insulin and phenformin induced a concomitant increase in AMPK phosphorylation and PKB overactivation (2.27 ± 0.27 , arbitrary unit, $p \leq 0.05$ vs insulin alone), resulting to a synergistic overstimulation of

glucose uptake (2.24 ± 0.32 μ moles/mg.h, $p \leq 0.05$ vs insulin alone). This phenformin-induced PKB overactivation is accompanied by the inhibition of p70 ribosomal S6 kinase (p70S6K) (control: 0.0 ± 0.0 , insulin: 1.0 ± 0.0 and insulin+phenformin 0.6 ± 0.1 , arbitrary unit, $p \leq 0.05$) and of the phosphorylation of insulin receptor substrate 1 (IRS-1) (control: 0.07 ± 0.03 , insulin: 1.00 ± 0.00 and insulin+phenformin 0.36 ± 0.09 , arbitrary unit, $p \leq 0.05$) on serine, both presumed to be involved in the negative feedback inhibition of the insulin signalling. In all conditions, PKB and AMPK activation fully correlated to the phosphorylation of Akt-substrate 160 (AS160), known to participate in glucose uptake stimulation.

Conclusion: AMPK activators seem to induce overstimulation of glucose uptake in insulin-treated cardiomyocytes via the inhibition of the p70S6K negative feedback loop. This is accompanied by the overphosphorylation of the PKB/AS160 axis. Our results suggest that AMPK activation could be a potential therapeutic approach to treat insulin resistance.

Differential effects of 5'AMP-activated protein kinase (AMPK) activation by metformin and AICAR on glucose uptake and lipolysis in human adipocytes

T. Radimerski¹, D. Seboek¹, B. Kola², P. Linscheid¹, H. Zulewski³, A. Grossman², U. Keller³, B. Müller³, M. Korbonits², M. Christ-Crain^{3,2};

¹Department of Research, University Hospital Basel, Switzerland,

²Department of Endocrinology, Barts and the London Medical School,

London, United Kingdom, ³Department of Endocrinology, Diabetes and Clinical Nutrition, University Hospital Basel, Switzerland.

Background and Aims: Controversy exists regarding the role of 5'AMP activated protein kinase (AMPK) on basal and insulin-mediated glucose uptake and on lipolysis. Data from human adipocytes are lacking.

Here we compared the effects of AMPK stimulator metformin and 5'-phosphoribosyl-5-aminoimidazole-4-carboxamide (AICAR), respectively, on basal and insulin-mediated glucose uptake as well as on lipolysis in human mesenchymal stem cell (MSC)-derived adipocytes.

Materials and Methods: Cells were treated with different doses of metformin, which activates AMPK via reduction of cellular ATP levels or AICAR, an AMP-mimic known to stimulate AMPK, for 3 to 24 hours. mRNA expression was determined by quantitative RT-PCR. Lipolysis was assessed by measuring glycerol release into culture supernatant using a colorimetric method. Uptake of ³H-labelled 2-deoxy-glucose (GU) was assessed in the presence or absence of insulin. AMPK activity was measured using a kinase assay and by immunoblotting for phospho-Acetyl-CoA-Carboxylase (pACC).

Results: As compared to controls, AMPK activity was increased upon AICAR administration to $333 \pm 115\%$ ($n=5$, $p=0.005$) after 24 hours. AMPK activation by AICAR significantly decreased both basal and insulin-stimulated glucose uptake in a time- and dose-dependent manner. In contrast, metformin significantly increased basal and insulin-stimulated glucose uptake, in a time- and dose-dependent manner. Lipolysis was significantly decreased by pre-stimulation with either metformin or AICAR for 24 hours. Insulin responsive glucose transporter 4 (GLUT4) mRNA expression was transiently increased upon 3 hours treatment with AICAR or metformin, in contrast to controls.

Conclusion: The AMPK activating compounds metformin and AICAR exhibit similar effects regarding the inhibition of lipolysis and the stimulation of GLUT4 mRNA expression. Conversely, the different effects on basal and insulin-stimulated glucose uptake by metformin and AICAR suggest that other AMPK activation-independent pathways are involved in their regulatory effects on glucose uptake in adipose tissue.

Resveratrol improves insulin-responsiveness in insulin-resistant models of human primary muscle cells

S. Fröjdö, C. Durand, H. Vidal, L. Pirola;

Inserm u870, INRA U1235, INSA Lyon, HCL, University Claude Bernard, Lyon, France.

Background and Aims: Resveratrol, a polyphenol found in fruits, increases lifespan and protects mice on a high fat diet against the development of metabolic disease. These beneficial effects are mediated by the activation

of the histone deacetylase SIRT1 and its target PCG-1 α , resulting in improved mitochondrial function and insulin sensitivity. Paradoxically, we recently reported that short pre-treatment of cells with resveratrol inhibits insulin-induced PI3K, an observation that argues against a positive effect of resveratrol on insulin action. However, we hypothesize that mild pharmacological inhibition of the PI3K/PKB pathway, which is the major mediator of insulin action in insulin-responsive peripheral tissues, may have a beneficial effect on insulin sensitivity. This hypothesis is supported by ample genetic evidence – in metazoans from yeast to mammals – indicating that mild repression of several components of the insulin-IGF-1 receptor signalling improves insulin action and increases lifespan. Therefore, we evaluated the outcomes of resveratrol treatment of primary human myotubes and muscle-derived L6 cells subjected to treatments leading to insulin resistance.

Results: In starving human primary myotubes, L6 and CCL cells, insulin-induced PI3K activity and PKB/FoxO4 activatory phosphorylation were fully inhibited by a 30 minute pre-treatment with resveratrol. On the contrary, resveratrol only mildly affected the sub-maximal activation of the PI3K/PKB cascade induced by a 24-hour insulin treatment, a treatment that also induced insulin resistance at subsequent insulin stimulation. In this experimental setup, we find that prolonged resveratrol treatments alleviate the insulin-resist status of the cell and thus ameliorate their insulin responsiveness. This improvement was associated with decreased serine-phosphorylation events on IRS-1 and IRS-2, while tyrosine phosphorylation was unchanged after resveratrol treatment.

Conclusion: The improvement of insulin responsiveness induced by prolonged resveratrol treatment is dependent on the capability of resveratrol to inhibit PI3K and the consequential PI3K-induced serine/threonine phosphorylation events in IRS1/2 that impair their signalling potential. These data support the idea that a mild inhibition of the insulin signalling by resveratrol improves insulin action and could partially explain the beneficial effects seen after resveratrol treatment *in vivo*. Further experiments are ongoing to further clarify these effects.

A natural occurring tetrapeptide GHTD-amide increases intracellular free zinc in C2C12 myotubes

R. C. C. Lim, S. G. Paule, B. Nikolovski, R. E. Gray, P. Z. Zimmet, M. A. Myers;
Biochemistry and Molecular Biology, Monash University, Victoria, Australia.

Background and Aims: GHTD-amide is a naturally occurring tetrapeptide hormone first isolated from human urine that improves insulin action in animal models of Type 2 diabetes. GHTD-amide binds zinc ions and disperses hexameric insulin to monomers and this in part accounts for its enhancement of insulin activity *in vivo*. The known insulin-mimetic properties of zinc and deregulated zinc homeostasis in Type 2 diabetes implicate zinc in the processes underlying insulin resistance. The aim of this study was to investigate the effect of GHTD-amide on zinc homeostasis in muscle cells.

Materials and Methods: Detection of intracellular free zinc was by fluoroZin-3 AM ester fluorescence in C2C12 myotubes by live cell imaging. Cells were loaded with 2 μ M of fluoZin-3 then washed and incubated for an additional 30 minutes in media supplemented with physiological concentration of (20 μ M) of ZnCl₂. Time-lapse photography of the cells was performed after the addition of 10 μ M GHTD-amide or relevant positive and negative controls, including the zinc ionophore pyrithione. Zinc uptake and efflux were measured using ⁶⁵Zn. Differentiated C2C12 myotubes were incubated in uptake buffer containing 10 μ M GHTD-amide or 10 μ M of negative control peptide, 10 μ M of ZnCl₂ and 50,000cpm/well of ⁶⁵Zn. Media was collected every 5 minutes for 40minutes and ⁶⁵Zn radioactivity was determined in a gamma-counter. The radioactivity data was normalized for protein content of cell lysates to obtain radioactivity per μ g of protein.

Results: Addition to the culture media of GHTD-amide but not a negative control peptide increased fluoZin-3 fluorescence intensity in C2C12 myotubes over time. Fluorescence intensity stimulated by GHTD-amide decreased after 11 minutes, unlike cells treated with pyrithione where fluorescence continued to increase with time. The increase of intracellular free zinc can be caused by influx of extracellular zinc or by efflux from intracellular compartments. ⁶⁵Zn

uptake assay revealed similar uptake whether the cells were incubated with GHTD-amide or negative control peptides.

Conclusion: GHTD-amide causes a transient increase in intracellular free zinc concentration but does not stimulate the uptake of extracellular zinc. The increase of intracellular free zinc observed in fluoZin-3 live cell imaging is likely to be due to release of zinc from intracellular storage compartments or zinc-binding proteins. Transient increases in intracellular free zinc may activate the insulin signalling pathway and this may be one mechanism by which GHTD-amide enhances insulin activity.

Glucagon causes HISS-dependent insulin resistance

R. S. Patarrao^{1,2}, W. Lauth³, J. Schafer³, M. Macedo^{1,4},

¹Dep. of Physiology, Faculty Medical Sciences – UNL, Lisbon, Portugal,

²Dep. of Biochemistry, Faculty of Medical Sciences – UNL, Lisbon, Portugal,

³Dep. of Pharmacology and Therapeutics, Faculty of Medicine, Winnipeg,

Canada, ⁴Portuguese Diabetes Association, Lisbon, Portugal.

Background and Aims: Insulin action is associated with the release of the Hepatic Insulin Sensitizing Substance (HISS), which enhances peripheral glucose uptake in skeletal muscle. In the immediate postprandial state HISS release is maximal, decreasing with the duration of fasting. The prandial control of HISS action is mediated through hepatic parasympathetic – derived nitric oxide (NO) and hepatic glutathione (GSH). An important regulator of hepatic GSH levels is the cAMP/protein kinase A (PKA) pathway, since a rise in cAMP levels is associated with a decrease in GSH levels. In the liver, glucagon mediates its actions by interacting with specific receptors leading to an increase of the intracellular cAMP levels and PKA activity. We tested the hypothesis that, in fed rats, intraportal (ipv) administration of the cAMP analog, dibutyryl adenosine 3', 5'-cyclic monophosphate (DBcAMP) and glucagon decrease HISS-dependent insulin action, in a dose-dependent manner.

Materials and Methods: Male Sprague-Dawley rats (210–230g) were fasted for 8h, refed for 2h and anesthetized with sodium pentobarbital (65mg/kg, ip). Insulin sensitivity was measured using the Rapid Insulin Sensitivity Test (RIST), with the RIST Index defined as the amount of glucose required to maintain euglycemia following intravenous insulin administration (50mU/kg). Insulin sensitivity was evaluated in the control fed state and after each drug administration. DBcAMP was administered ipv at doses from 0.01 to 1.0mg/kg. Glucagon was also administered ipv at doses from 0.5ng/kg to 20 μ g/kg. In order to evaluate the role of glucagon on the HISS pathway, HISS release was blocked with ipv administration of N-monomethyl-L-arginine (L-NMMA, 0.73mg/kg), a NO synthase competitive antagonist and then insulin sensitivity was evaluated after administration of glucagon, at a dose that produces a maximal inhibition on insulin sensitivity without affecting basal glycemia (200ng/kg, ipv).

Results: In the first group of animals, where DBcAMP was administered ipv (0.01 to 1.0mg/kg), a significant decrease in insulin sensitivity was observed, corresponding to an inhibition ranging from 27.2 \pm 2.1% to 48.8 \pm 7.6% (n=9). In the second group of animals, ipv glucagon (0.5ng/kg – 20 μ g/kg) also decreased insulin sensitivity in a dose-dependent manner, corresponding to an inhibition ranging from 22.1 \pm 8.7% to 66.6 \pm 4.2% (n=14). In the third group of animals, the control RIST Index (177.1 \pm 1.6 mg glucose/kg bw, n=5) was significantly reduced after abolishing HISS action with ipv infusion of L-NMMA (81.0 \pm 8.3 mg glucose/kg bw, n=5, p<0.001), corresponding to an inhibition of 54.2 \pm 4.9%. Further ipv administration of glucagon (200ng/kg) did not change insulin sensitivity (80.4 \pm 5.9 mg glucose/kg bw, n=5).

Conclusion: Our results are in agreement with the proposed hypothesis that increased levels of glucagon results in increased cAMP/PKA pathway activity leading to an impairment of insulin sensitivity, exclusively due to a decrease of HISS release.

Comparison of intracellular signaling properties induced by the long-acting insulin analogues glargine and detemir in cultured cells

T. Sasaoka, H. Tsuneki, T. Wada;

Department of Clinical Pharmacology, University of Toyama, Japan.

Background and Aims: Insulin glargine and detemir are long-acting human insulin analogues. Although their binding affinity to the insulin receptor (IR) has been intensively studied, little is known about the signaling pathways activated after binding. We directly compared intracellular signaling properties of glargine, detemir, and human insulin leading to metabolic and mitogenic actions in cultured cells.

Materials and Methods: 3T3-L1 adipocytes, L6 myocytes, and rat primary hepatocytes were incubated with various concentrations of human insulin, glargine, and detemir with varying concentrations of bovine serum albumin (BSA). Immunoprecipitation was performed and phosphorylation of IR, IRS-1, Akt, GSK3, and MAP kinase (MAPK) was detected by Western blot with anti-phosphospecific antibodies. 2-deoxyglucose uptake was measured in adipocytes and myocytes. Vascular smooth muscle cells (VSMCs) from rat aortas were incubated with insulin analogues, and 5-bromo-2'-deoxyuridine (BrdU) incorporation was measured by enzyme linked immunoassay.

Results: Phosphorylation kinetics were similar among insulins. In 3T3-L1 adipocytes, glargine induced phosphorylation of IR, IRS-1, Akt, GSK3 and MAPK in a dose-dependent manner similar to human insulin, whereas detemir-induced effects were reduced by 30 to 60%. At maximal concentration of 170 nM, detemir-induced glucose uptake was decreased by 65% in 3T3-L1 adipocytes compared with 170 nM human insulin and glargine. In L6 myocytes, the effects of detemir were reduced by 30 to 50% compared to human insulin and glargine. In VSMCs, glargine-induced phosphorylation of IR, IRS-1, and Akt was slightly increased, whereas detemir-induced phosphorylation was 20 to 40% lower versus human insulin. Similarly, detemir-induced phosphorylation of GSK3 and MAPK was less than glargine or human insulin. Consistent results were observed in hepatocytes. BrdU incorporation in VSMCs was similar for all analogues, although for detemir the effect was mildly decreased. The phosphorylation kinetics of detemir was further decreased with increasing concentrations of BSA.

Conclusion: Glargine and human insulin have similar properties in activating intracellular signaling pathways related to metabolic and mitogenic action. In contrast, detemir appears less active in four cell types, and its activity is inhibited by increasing concentrations of albumin.

Overexpression of protein tyrosine phosphatase sigma in mice induces hyperglycaemia

E.-C. Långberg, H. F. Gu, S. Nordman, S. Efendic, C.-G. Östenson;

Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden.

Background and Aims: A number of protein tyrosine phosphatases (PTPs) that are expressed in insulin sensitive tissues are proposed to act as key regulators in insulin signaling. One of these proteins is receptor tyrosine phosphatase sigma (RPTP σ), which is highly expressed in all insulin sensitive tissues. Previously we have demonstrated that overexpression of RPTP σ is linked to impaired glucose-induced insulin secretion in hereditary diabetic Goto-Kakizaki (GK) rats. We have now developed a transgenic (TG) mouse model overexpressing RPTP σ to investigate its role in the development of type 2 diabetes.

Material and Methods: The TG construct consisting of ubiquitin promoter and rat RPTP σ cDNA was used for random insertion on a C57Bl/6 background. Mice were studied regarding body weight, plasma glucose, serum insulin and insulin secretion *in vitro*.

Results: TG mice had significantly increased body weight after 2 months of age compared to wildtype (WT) mice, 23.0 ± 0.6 (n=32) vs. 21.3 ± 0.4 (n=50) g (p<0.05). TG mice showed increased fasting blood glucose levels compared to WT animals already after 2 months of age, 4.5 ± 0.2 (n=32) vs. 3.3 ± 0.1 (n=50) mmol/l (p<0.001) and also at 5 months of age 5.6 ± 0.2 (n=32) vs. 4.8 ± 0.2 (n=49) mmol/l (p<0.01). Serum insulin levels were decreased

in TG mice compared to WT mice, 30.5 ± 2.4 (n=18) vs. 39.9 ± 3.2 (n=17) μ U/ml (p<0.05). RPTP σ TG mice also showed decreased glucose-induced insulin secretion in isolated pancreatic islets compared to wt animals. Thus, islet insulin responses to 16.7 mmol/l glucose were 153 ± 16 (n=7) vs. 220 ± 17 (n=8) μ U/islet/h (p<0.01).

Conclusion: Our results indicate that overexpression of RPTP σ induces increased body weight and hyperglycemia due to impaired glucose-stimulated insulin release. Hence, overexpression of RPTP σ may play a role in the development of type 2 diabetes.

Prevention of diabetes by attenuation of PKC ϵ induced serine phosphorylation of IRS-1 in *Psammomys obesus*

E. Shafrir¹, E. Mack¹, H. Reuveni¹, A. Joerns², S. Lenzen², E. Ziv¹;

¹Diabetes Center, Hadassah University Hospital, Jerusalem, Israel,

²Institute of Clinical Biochemistry, Hannover Medical School, Germany.

Background and Aims: The gerbil *Psammomys obesus* exhibits hyperglycemia and hyperinsulinemia, beta cell lesions and overexpression of muscle PKC ϵ on high energy (HE) diet. Insulin receptor function and tyrosine kinase activity were inhibited due to increased serine phosphorylation, eliciting marked insulin resistance. Our aim is to prevent the diabetes and PKC ϵ induced phosphorylation of signalling proteins by treating with specific peptides.

Material and Methods: Peptides were copied from substrate-binding domain of the PKC ϵ molecule, to prevent serine phosphorylation of IRS-1. The peptides (PCT patent application IL2006/000755) were synthesized and purified to 98% by HPLC. The peptide N terminus was myristoylated to facilitate cell entry. Female *Psammomys* weighing 180–200 g, bred at the Animal Facility on low energy diet were fed high energy diet, then injected with peptide KCE-12 on days 1,8 and 14. Control animals received injections of peptide solvent.

Results: Food consumption and animal weight were unchanged by the treatment. On day 16 non-fasting glucose levels were normalised to 4.8 vs 19.3 mmol/l in controls. Serum insulin was reduced from 584 ± 55 to 180 ± 22 μ U/l. Western blot analyses show that the phosphoserine^{636,639} on IRS-1 in the gastrocnemius muscle of was reduced fourfold and muscle content of GLUT4 rose twofold. PKC ϵ levels were not affected by KCE-12 administration. The damage and loss of insulin in beta-cells were prevented by KC-12 treatment (shown in photomicrographs). The preserved secretion function enabled *Psammomys* to compensate for peripheral insulin resistance and restored glucose homeostasis.

Conclusions: KCE-12 derived from the catalytic region of the PKC ϵ molecule prevents the serine phosphorylation of IRS-1 and abrogates the impediment in insulin signalling, including the translocation of GLUT4, in type 2 diabetes model. Application of specific anti-diabetic peptides may lead to the development of a modality preventing the human over-nutrition induced insulin resistance and diabetes.

Protein kinase C- δ -induced phosphorylation of ser-357 in insulin receptor substrate-1 (IRS-1) attenuates insulin action

R. S. Waraich, C. Weigert, E. D. Schleicher, H. U. Häring, R. Lehmann;

Department of Internal Medicine IV, Eberhard-Karls University, Tuebingen, Germany.

Background and Aims: The function of insulin receptor substrate-1 (IRS-1), a key molecule of insulin signaling, is modulated by phosphorylation at multiple Ser/Thr residues. Recently, we identified Ser357 of rat IRS-1 as an *in vitro* PKC phosphorylation site. The present work was aimed to study the regulation and (patho) physiological function of this phosphorylation site in IRS-1.

Materials and Methods: To monitor phosphorylation of Ser357 in cellular extracts we generated a polyclonal affinity-purified phospho-site specific antibody. Furthermore, Ala357, Ala318, Ala358 and Ala357/358 mutants were made by oligonucleotide mediated site-directed mutagenesis

Results: Using the phospho-Ser357 specific antibody we observed in BHK, C2C12 and HepG2 cells that Ser357 is strongly phosphorylated by phorbol ester (TPA) and insulin stimulation. Cross reactivity with the adjacent Ser358 phosphorylation site was eliminated by affinity-purification of the antiserum using a phospho-Ser358 synthetic peptide. Phosphorylation on Ser357 is mediated, at least partially, by PKC- δ . Other stimuli tested as anisomycin, TNF- α and free fatty acids did not enhance the phosphorylation of Ser357. When we studied insulin signal transduction we found that the activation of Akt/PKB was more pronounced in IRS-1 Ala357 and Ala358 expressing skeletal muscle cells after 10 and 60 min of insulin stimulation, as compared to cells expressing wild type IRS-1. Mutation of both serine sites had no additive effect. Comparable results were obtained in liver cells.

Conclusion: The findings indicate that phosphorylation of Ser357 or Ser358 could lead to down-regulation of insulin action with an interchangeable function of both sites. Interestingly, Ser358 is not conserved between rodents and humans and this putative phosphorylation site is not found in human IRS-1.

JNK and the PI 3-K/mTOR pathway mediate the platelet-derived growth factor-induced IRS-1 phosphorylation at serine residues 307 and 318 in C2C12 myotubes

K. Müssig, H. Lönz, H. Staiger, H.-U. Häring;

Department of Endocrinology, Diabetology, Nephrology, Angiology, and Clinical Chemistry, University Hospital of Internal Medicine, Tübingen, Germany.

Background and Aims: Insulin signaling is negatively regulated by serine/threonine phosphorylation of insulin receptor substrate-1 (IRS-1). Several hormones and cytokines, including platelet-derived growth factor (PDGF), have been shown to impair insulin signaling. The aim of the present study was to investigate whether PDGF induces phosphorylation of IRS-1 at serine 307 (Ser307) and serine 318 (Ser318), two phosphorylation sites that inhibit the interaction between the tyrosine-phosphorylated insulin receptor and IRS-1, and to identify the kinases that are involved in these phosphorylations.

Materials and Methods: C2C12 myotubes were incubated with PDGF for different time periods and with diverse concentrations. When indicated, cells were treated with 50 μ M c-jun N-terminal kinase (JNK) inhibitor SP600125, 25 nM mammalian target of rapamycin (mTOR) inhibitor rapamycin, and 10 μ M phosphatidylinositol 3-kinase (PI 3-K) inhibitor LY294002 prior to PDGF stimulation. Protein expression and phosphorylation of IRS-1, c-jun, Akt, and p70S6 kinase (S6K) were analyzed by Western-Blotting using the appropriate antibodies.

Results: Treatment of C2C12 myotubes with PDGF increased IRS-1 phosphorylation at Ser307 as well as at Ser318. The maximal stimulating effect occurred after 30 min and with a concentration of 5 nM. Inhibition of the PDGF receptor by 5 μ M imatinib decreased time-dependently phosphorylation at Ser307 and Ser318 to the basal levels with the maximal inhibition after 90 min. Preincubation with JNK inhibitor SP600125, PI 3-K inhibitor LY294002, and mTOR inhibitor rapamycin markedly decreased PDGF-induced Ser307 and Ser318 phosphorylation. PDGF treatment increased phosphorylation of c-jun, Akt, and S6K, substrates of JNK, PI 3-K, and mTOR, respectively.

Conclusion: PDGF induces IRS-1 phosphorylation at Ser307 and Ser318 in C2C12 myotubes. JNK, PI 3-K, and mTOR appear to be involved in these phosphorylation processes.

Subcellular localization of PKB/Akt substrate PRAS40

E. B. M. Nascimento¹, M. M. L. Linssen¹, A. B. Jonsdottir¹, M. Fodor², J. Kriek¹, G. C. M. Van der Zon¹, M. Diamant³, J. A. Maassen¹, D. M. Ouwens¹;

¹Molecular Cell Biology, Leiden University Medical Center, ²Anatomy and Embryology/Central Animal Facility, Leiden University Medical Center, ³Endocrinology/Diabetes Center, VU Medical Center, Amsterdam, The Netherlands.

Background and Aims: Insulin resistance is an early clinical hallmark of obesity and type 2 diabetes. This condition is associated with a decreased insulin-mediated activation of the PKB/Akt-pathway. Activation of PKB/Akt has been linked to a variety of cellular responses, including glucose metabolism, cell survival and longevity. The physiological substrates for PKB/Akt regulating these downstream responses are poorly characterized. Recently, we characterized proline-rich PKB/Akt substrate 40 (PRAS40) as a predominant substrate for PKB/Akt in insulin target tissues. Although PRAS40 has been linked to cell survival and nutrient sensing, its exact role in insulin action remains unclear. In the current study we studied the subcellular localization of PRAS40 to further detail the function of this protein.

Materials and Methods: Rat tissues and cultured cells were analyzed for localization and phosphorylation of PRAS40 by immunofluorescence and immunohistochemistry.

Results: Immunohistochemical staining of rat cardiac muscle and liver displayed nuclear localization of phosphorylated PRAS40. Immunofluorescent staining of cultured cells showed nuclear and cytoplasmic localization of total PRAS40 protein. After insulin stimulation, the immunoreactivity for the total PRAS40 antibody was increased for both the nucleus and the cytoplasm. When we used the phosphorylated PRAS40 antibody in immunofluorescent staining of cultured fibroblasts and cardiomyocytes, the antibody showed nuclear localization. Insulin stimulation of cultured cells increased the nuclear localization of phosphorylated PRAS40. Part of the phosphorylated PRAS40 signal was detected in the cytoplasm. The insulin stimulated effects were not detected when cells were pretreated with the PI3K inhibitors LY294002 or wortmannin. The signal for phosphorylated PRAS40 was in proximity of phosphorylated PKB/Akt. The immunoreactivity towards the phosphorylated PKB/Akt antibody was detected at the interface of cytoplasm and nuclear membrane. Interestingly, in the absence of insulin, we also identified a bright spot which was detected between dividing cells i.e. the midbody, using both the antibody against total PRAS40 and the phosphophorylated PRAS40. Double staining with antibodies recognizing aurora-B, which is known to localize to the midbody during cytokinesis, confirmed the midbody localization of PRAS40.

Conclusion: Phosphorylated PRAS40 was detected in the nucleus of the cell. After insulin stimulation an increased amount of phosphorylated PRAS40 was detected in the nucleus and to a small extent in the cytoplasm. Furthermore, the identification of PRAS40 as part of the midbody complex suggests a critical role for PRAS40 in cell cycle regulation.

cAMP-dependent signaling pathways suppress ERK activity but further augmented Akt/PKB activity stimulated by insulin in CHO-IR cells

Z. Cui¹, B. Kim¹, J. Kim², D. Lee¹, G. Koh¹, Y. Lee¹, D. Park¹;

¹Department of Medicine, Cheju National University,

²Jeju Biodiversity Reaech Institute, Jeju, Republic of Korea.

Background and Aims: Although the activation of receptor tyrosine kinase (RTK) is crucial to execute a number of physiological responses by insulin, the roles of signaling pathways derived by G protein-coupled receptors (GPCRs) are unravelled. We previously showed that insulin suppressed apoptotic cell death through signaling pathways including stimulation of PI3 kinase and ERK. The aim of the present study was to examine whether the activation of cAMP-dependent signaling pathways might affect insulin's anti-apoptotic function and RTK-dependent signaling components including ERK and Akt/PKB upon insulin stimulation in CHO-IR cells.

Materials and Methods: cAMP-dependent signaling pathways were stimulated by treatments with cholera toxin (an activator of Gs protein), pertussis toxin (an inhibitor of Gi protein), and 8-bromo-cAMP (a cell

membrane-permeable analogue of cAMP) together with- or without insulin in CHO-IR cells. Activities of ERK and Akt/PKB were analyzed by immunoblotting experiments using specific antibodies against activated ERK and Akt/PKB proteins. Apoptotic cell death was evaluated with fluorescence microscopy after H33342 staining and with cell cycle analysis with flow cytometer after propidium iodide staining.

Results: Addition of cholera toxin as well as pertussis toxin suppressed ERK activity stimulated by insulin treatment. However, insulin-induced Akt/PKB activity was more increased by the addition of pertussis toxin or cholera toxin. 8-bromo-cAMP treatment also led to a suppression of ERK activity and an additional increase in Akt/PKB activity stimulated by insulin. Regardless of an additional increase in Akt/PKB activity, insulin's anti-apoptotic function was blocked by activations of cAMP-dependent signaling pathways.

Conclusion: The present study showed that activation of cAMP-dependent signaling pathways regulated downstream steps of RTK after binding of insulin to its receptor in different manners, down-regulating the ERK activity and up-regulating Akt/PKB activity in CHO-IR cells. From the blockade of insulin's anti-apoptotic function even with the up-regulation of Akt/PKB activity by cAMP pathways, it is suggested that insulin's anti-apoptotic function is not totally dependent on Akt/PKB activity or, at least, is regulated at any downstream signaling steps of Akt/PKB activation.

Overexpression of Sam68 enhances metabolic and mitogenic effects of insulin by potentiating MAPK and PI3K pathways

V. Sanchez-Margalet, S. Najib, C. González-Yanes;

Medical Biochemistry and Molecular Biology, Virgen Macarena University Hospital, Seville, Spain.

Background and Aims: Sam68, is an RNA binding protein with different domains for protein-protein interaction. Thus, a role for Sam68 as an adaptor protein in signal transduction has been proposed. We have previously found that Sam68 is tyrosine phosphorylated by the insulin receptor and recruited to signaling complexes in the PI3K and Ras pathways via interaction with SH2 and SH3 domain containing proteins. In the present study we have investigated the possible contribution of Sam68 in insulin action.

Materials and Methods: We have studied the role of Sam68 on metabolic and mitogenic insulin actions by overexpressing the protein in the cytosol of CHO-WT and CHO-IR cells, by using a construct lacking the C-terminal nuclear localization sequence cloned in pcDNA3.1 expression vector.

Results: Overexpression of a cytosolic Sam68 (lacking the C-terminal nuclear localization sequence) increased both basal and insulin-mediated metabolic (glucose uptake and glycogen synthesis) and mitotic (DNA and protein synthesis) effects in CHO-WT and CHO-IR cells. We also studied the effect of Sam68 overexpression in signaling pathways involved in metabolic and mitogenic effects of insulin: IR, IRS-1, PKB, GSK, MAPK, as well as p70S6K, 4E-BP1 and eIF4E. We found that Sam68 overexpression increased both basal and insulin-stimulated phosphorylation of all these signaling proteins. Moreover, the expression of the glucose transporter 1 (GLUT-1) was increased.

Conclusion: These results provide evidence for a role of Sam68 in insulin-mediated metabolic and mitotic effects, and confirm the possible participation of Sam68 in the signal transduction pathways of the insulin receptor.

Insulin receptor mediates intracellular re-localization of Sam68, an RNA-binding protein that may participate in insulin signaling

C. González-Yanes, S. Najib, V. Sánchez-Margalet;

Medical Biochemistry and Molecular Biology, Virgen Macarena University Hospital, Seville, Spain.

Background and Aims: Sam68, an RNA-binding protein involved in signal transduction, has been previously found to be tyrosine phosphorylated by insulin stimulation and recruited to insulin receptor signaling complexes. Sam68 has a nuclear localization signal, but can also localize in the cytoplasm.

Besides traffic of Sam68 from the nucleus to the cytoplasm and the other way round has been described depending on the Tyr phosphorylation. In the present work we sought to investigate the possible relocalization of Sam68 in response to insulin.

Materials and Methods: We employed Sam68-YFP construct to monitor the localization of Sam68 under basal and insulin-stimulated conditions. The transient transfections were carried out in CHO-WT and CHO-IR cells, and Sam68 localization was investigated by confocal microscopy.

Results: We found that Sam68 was present mainly in the nucleus in the CHO-WT cells, but in CHO cells overexpressing insulin receptor (CHO-IR), Sam68 was found equally in the nucleus and the cytoplasm. In response to insulin, after 10 min stimulation, nuclear localization of Sam68 was lower, and some concentration in the cytoplasm/perinuclear area was observed. After 30 min the localization of Sam68 was the same as basal conditions.

Conclusion: Sam68 is found in both the nucleus and the cytoplasm. Insulin receptor overexpression increased the cytosolic localization, and insulin stimulation mediates a transient relocalization of Sam68 in the cytoplasm/perinuclear area.

Liver-specific knock down of liver X receptor [alpha] in KKAy diabetic mice improves lipid profile but induces organ toxicity

J. Prestle¹, C. Schoelch¹, A. van Marle², H. Pavliska², T. Nolte¹, J. F. Rippmann¹;

¹Boehringer-Ingelheim Pharma GmbH & Co. KG, Biberach a.d.R., Germany, ²A Galapagos company, Biofocus DPI, CN Leiden, The Netherlands.

Background and Aims: Nuclear hormone receptors liver X receptor (LXRalpha and LXRbeta) ligands are attractive approaches for the treatment of dyslipidemia and atherosclerosis. To further elucidate the function of LXRalpha in liver lipid metabolism in a disease relevant animal model, the KKAy mouse, we used different shRNAs in adenoviral vectors (Ad5) to selectively knock down LXRalpha gene expression.

Materials and Methods: Obese KKAy mice were transduced with 1×10^{11} virus genomes per animal via *i.v.* tail vein injection. Quantitative gene expression was analysed by real-time PCR. Metabolic parameters as well as liver histology were assessed at 8 days after virus transduction.

Results: The most effective shRNA reduced LXRalpha mRNA in liver by 66%. LXRalpha-regulated lipogenic genes like SREBP1c, SCD1, and FASN were significantly downregulated, whereas ABCA1 and PCK1 expression was unchanged upon LXRalpha knock down. In addition, we show a LXRalpha gene dosage effect on lipid metabolism with reductions of both plasma and liver triglycerides by about 80% when compared to control virus transduction. Notably, although the animals did not show obvious signs of tolerability problems, LXRalpha knock down induced liver toxicity over time. Strong knock down of LXRalpha drastically increased serum activity of liver specific enzymes. Histological analysis of liver sections revealed hepatocellular degeneration and proliferation of Kupffer and oval cells. None of these changes were seen with control virus transduction.

Conclusion: Liver-specific knock down of LXRalpha *in vivo* by shRNA improved lipid profile of hypertriglyceridemic KKAy mice, but also causes serious liver damage.

Identification of a peroxisome proliferator responsive element (PPRE) in rat glucose 6-phosphatase gene promoter

J.-S. Bae^{1,2}, S.-K. Kwon^{1,3}, S.-S. Im¹, Y.-S. Park^{1,3}, T.-H. Kim^{1,3}, J.-M. Park^{1,3}, Y.-H. Ahn^{1,2};

¹Department of Biochemistry and Molecular Biology, ²Center for Chronic Metabolic Disease Research, ³Brain Korea 21 Project for Medical Sciences, Yonsei University College of Medicine, Seoul, Republic of Korea.

Background and Aims: Glucose-6-phosphatase (G6Pase) is known to play a key role of gluconeogenesis in the fasting liver. Peroxisome proliferators activated receptors (PPARs) are transcription factors involved in the regulation of numerous metabolic processes. The PPAR α isotype is abundant in liver and activated by fasting. However, it is not very clear that the expression of G6Pase gene was related to PPAR α . In this study, we demonstrate that PPAR α /RXR α complex also plays a role in carbohydrate metabolism via regulation of glucose 6-phosphatase gene expression. We have attempted to localize and characterize PPRE (PPAR responsive element) in the promoter regions of rat G6Pase, which plays the important role in the glucose homeostasis in fasting liver.

Materials and Methods: G6Pase mRNA expression was determined in liver tissue of Sprague-Dawley rats by northern blot analysis and RT-PCR. The effect of transiently overexpressed PPAR α /RXR α was studied using G6Pase promoter reporter gene assay in HepG2 cell lines. PPRE was identified in the promoter regions of rat G6Pase by Electrophoretic mobility shift assay (EMSA).

Results: Treatment of HepG2 rat hepatoma cell lines as well as primary rat hepatocytes with PPAR α /RXR α agonists led to stimulation of G6Pase mRNA expression. We examined the physiological significance of PPAR α /RXR α agonist-induced enhancement of G6Pase expression in primary rat hepatocytes. The overexpression of PPAR α by transfection in HepG2 cell

and the treatment of PPAR α agonist, Wy14,643 activated the promoter activity. Serial deletion of the construct revealed that the promoter activity was dramatically decreased when -231 region was deleted. Moreover the promoter activity was decreased by the mutation of PPRE and EMSA study indicated that the putative PPRE is located in the region between bases -109 and -100 of this promoter.

Conclusion: These data suggest that the putative PPRE may be located in the rat G6Pase promoter between -268 and -256. PPAR α /RXR α agonist Wy14,643 is a direct transcriptional mediator of G6Pase gene.

Effect of the Pro12Ala polymorphism of the PPAR γ 2 gene on hepatic glucose uptake

M.-J. Honka^{1,2}, M. Vanttinen^{1,2}, P. Iozzo¹, K. A. Virtanen¹, R. Lautamäki¹, T. Takala¹, A. P. M. Viljanen¹, J. Kemppainen¹, J. Knuuti¹, P. Nuutila¹, M. Laakso²;

¹Turku PET Centre, University of Turku,

²Department of Medicine, University of Kuopio, Finland.

Background and Aims: The Pro12Ala polymorphism of the PPAR γ 2 gene (PPARG2) has been associated with reduced risk of type 2 diabetes. We have previously reported that the skeletal muscle insulin sensitivity is enhanced in lean but not in obese subjects carrying the Ala12 allele. The aim of this study was to investigate the effect of the Pro12Ala polymorphism on hepatic glucose uptake (GU), which is an important determinant of glucose tolerance, and liver fat content in non-diabetic and type 2 diabetic subjects.

Materials and Methods: Study population included 68 healthy and 95 diabetic individuals whose liver GU was measured using fluorine-18-labelled deoxyglucose (¹⁸F]FDG) and positron emission tomography during hyperinsulinemic euglycemic conditions. Liver fat percentage measured by proton spectroscopy was available for 58 diabetic and 16 healthy (obese) subjects. 5% was used as a cut-off point between groups with high (n=50) and low liver fat content (n=24). The Pro12Ala polymorphism of PPARG2 was genotyped with Taqman allelic discrimination assay. Body mass index of 27 kg/m² was used as a cut-off point between non-obese and obese subjects.

Results: In obese subjects with type 2 diabetes, hepatic GU was 39% higher in carriers of the Ala12 allele compared to carriers of the Pro12Pro genotype (21.0±10.6 vs. 15.1±5.1 μ mol/tissue kg/min, p=0.002 adjusted for gender and age), whereas in obese non-diabetic subjects the 28% difference in hepatic GU did not reach statistical significance (25.3±11.5 vs. 19.8±6.6 μ mol/kg/min, p=0.093, adjusted for gender and age, respectively). When subjects with high liver fat content were analysed separately, hepatic GU was 75% higher in subjects carrying the Ala12 allele than in subjects with the Pro12Pro genotype (26.2±11.4 vs. 15.0±8.4 μ mol/kg/min, p<0.0005, adjusted for gender and age). No effect of the Ala12 allele on hepatic GU was observed in non-obese subjects or in subjects with low liver fat content. No differences were found in liver fat percentage between carriers of the Ala12 allele and carriers of the Pro12Pro genotype.

Conclusion: We conclude that the Ala12 allele of PPARG2 is associated with high hepatic GU in obese type 2 diabetic and non-diabetic subjects. Furthermore, this effect is more pronounced in subjects with high liver fat content.

Reciprocal regulation of peroxisome proliferator-activated receptor alpha and glucocorticoid receptor forms a new negative feedback loop

X. Chen, W. Sun, Y. Bi, M. Li, M. Cai, H. liang, Q. Yu, X. He, J. Weng; Department of Endocrinology, The First Affiliated Hospital of Sun-Yat Sen University, Guangzhou, China.

Background and Aims: Peroxisome proliferator-activated receptor alpha (PPAR α) and glucocorticoid receptor (GR) are all pleiotropic nuclear factors. Previous research suggested a negative feedback loop might exist between PPAR α and glucocorticoids. Glucocorticoids are rapid and potent stimulator of hepatic PPAR α expression. On the contrary, PPAR α showed negative

regulation on glucocorticoids at pre-receptor level, inhibiting the expression and activity of the key enzyme type 1 11β -hydroxysteroid dehydrogenase (11β -HSD1) in liver. However, our previous study demonstrated a more direct and important action might exist in this feedback loop. We found PPAR α agonist fenofibrate decreased glucocorticoid receptor (GR) protein expression in liver of SD rats. Therefore, this study was design to further investigate the regulation of fenofibrate on GR.

Materials and Methods: Male SD rats were randomly divided into five groups: normal control rats (NC group), rats treated with fenofibrate (50mg/kg.d for 1 month) (FE1 group), rats treated with fenofibrate (100mg/kg.d for 1 month) (FE2 group), rats treated with fenofibrate (100mg/kg.d for 2 months) (FE3 group), and rats treated with combination of fenofibrate (100mg/kg.d) and PPAR α antagonist MK886 (30mg/kg.d) for 1 month (MK886 group). The GR gene and protein expression levels were detected in liver, visceral fat (VF) and muscle tissues. Circular corticosterone (CORT) level was measured using RIA method.

Results: PPAR α agonist fenofibrate conferred significant tissue-specific downregulation of hepatic GR gene and protein expression of SD rats with increasing CORT level in circulation, and PPAR α antagonist MK886 could block these effects. The downregulation of fenofibrate on GR was dose- and time-dependent on fenofibrate a certain degree.

Conclusion: We further demonstrated a reciprocal regulation between PPAR α and GR, which forms a new negative feedback loop in liver of SD rats.

A change of gluconeogenic gene expression following caloric restriction in liver of OLETF rats

H.-Y. Bae¹, S.-Y. Kim¹, J.-H. Kim²;

¹Internal Medicine, College of Medicine, Chosun university,

²Internal Medicine, Dept. of Internal Medicine, Chosun University Hospital, Gwang-ju, Republic of Korea.

Background and Aims: Traditionally, gluconeogenesis is strongly stimulated during fasting and is aberrantly activated in diabetes mellitus. Carolic restriction(CR) has been shown to improve the glucose control in type 2 diabetes in human and animal models. However, the exact mechanism of CR on gluconeogenesis in the liver has not been well elucidated. In this study, we investigated the effects of CR on gluconeogenesis in the liver of OLETF rats.

Materials and Methods: OLETF rats(male 24 weeks) for diabetic model and LETO rats(male 24 weeks) for control group were used in this study. At 20th week, all OLETF rats underwent an oral glucose tolerance test after an overnight fast. From 24th week, all of these rats received an allotment of food equal to 70% of the food intake measures in the last weeks. The activity of the key gluconeogenic enzymes such as PEPCK, G-6-Pase were measured at 0, 4, 8, 12 weeks in the liver of both groups. At the same time, we measured the mRNA expression levels of PGC-1 and PPAR γ in the liver of both groups by RT-PCR. Also we investigated the mRNA expression of AMPK in the liver of both groups.

Results: The fasting glucose levels and body weights were decreased progressively in OLETF rats. The mRNA expression of the gluconeogenic enzymes such as PEPCK, G-6-Pase were progressively decreased after caloric restriction in both groups and kept a high level in OLETF rats compared to LETO rats during all periods. A expression of PGC-1 were increased to 29% in the liver of non-diabetic LETO rats after 12 weeks, but there was no significant change in OLETF rats. On the other hand, the mRNA expression of PPAR γ were progressively increased in OLETF rats compared to LETO rats. At the same time, we evaluated the mRNA levels of AMPK in both groups. The mRNA expression of AMPK were significantly increased after 12 weeks CR except β 1 subunit in OLETF rats.

Conclusion: The effects of caloric restriction on the expression of gluconeogenic genes in the liver are sufficiently predictable and resonable, but the PGC-1 expression after caloric restriction are altered in the liver of OLETF rats compared to LETO rats. These findings suggest that altered PGC-1 expression may play some role on the aberrantly increased gluconeogenesis in the liver of OLETF rats.

Insulin glargine alleviated fatty liver by down-regulation of *Srebf1* in the liver of high fat diet induced insulin resistant C57BL/6 mice

M. Li, Q. Yu, X. Chen, X. He, Y. Bi, W. Sun, J. Yan, M. Cai, H. Liang, W. Xu, J. Weng;

Department of Endocrinology, The 1st Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

Background and Aims: Insulin resistance in the liver is one of the main defects in the development of type 2 diabetes. Here we investigated the effect of insulin glargine on the liver of high fat diet induced insulin resistant mice.

Materials and Methods: 30 5-week-old C57BL/6 mice were randomized into 3 groups: A, fed with normal diet (9.9% calorie from fat); B and C, fed with high fat diet (60% calorie from fat). After 12 weeks fed, mice in group C were injected with insulin glargine s.c. at 0.5IU. Mice in group A and B were injected with saline s.c. at 0.5ml. The intervention lasted for 4 weeks. After that, the mice were executed and the livers were frozen for mRNA extraction and fat content determination. The mRNA expression of genes involed in insulin signaling pathway and *Srebf1* were determined by gene chip. Fat content of the liver was determined by optical density after Sudan III staining.

Results: The fat content indicated by optical density was 7606 ± 1230 , 11456 ± 786 , 9802 ± 524 in Group A, B and C ($P<0.05$, between any two groups), respectively. If the mRNA expression in Group A was 100%, the expression of genes involved in the insulin signaling pathway of Group B and C was as follow: *Ptpn1* 293% and 143%; *Pik3r2* 241% and 97%; *Akt-2* 26% and 63%; *Akt-3* 17% and 71%, respectively. The expression of *Srebf1*, which stimulated lipid synthesis and uptake in hepatocytes, in Group B and C were 358% and 161% of that in Group A, respectively.

Conclusion: High fat diet induced defects of gene expression in the insulin signaling pathway and increased *Srebf1* expression, caused insulin resistance and fat overload in the liver of C57BL/6 mice. The 4 weeks intervention of insulin glargine partially alleviated the defects and decreased the fat deposition by down-regulation of *Srebf1* in the liver.

Influence of metabolic stimuli on transcriptional regulation by Hepatocyte Nuclear Factor 4 α

A. S. Devonshire, N. J. Plant, A. E. Thumser;

School of Biomedical and Molecular Sciences, University of Surrey, United Kingdom.

Background and Aims: The nuclear receptor Hepatocyte Nuclear Factor 4 α (HNF4 α) (NR2A1) regulates the transcription of many genes involved in both glucose and lipid metabolism. Mutations in the HNF4 α gene are responsible for MODY type 1, and genetic linkage analyses have implicated HNF4 α in the disease processes leading to late-onset type 2 diabetes and dyslipidaemia. HNF4 α -dependent transcriptional activity is known to be modulated by a range of hormones associated with the fasting-fed cycle: glucagon and insulin, as well as their downstream effectors such as protein kinase A (PKA) and AMP-activated protein kinase (AMPK). In this study our aim was to investigate the role of HNF4 α in modulating the effects of physiological mediators on genes involved in carbohydrate and lipid metabolism.

Materials and Methods: Human liver-derived HepG2 cells were serum-starved for 24 h and then incubated for 6 h in the presence or absence of glucagon, dexamethasone, insulin, activators of PKA (8-bromoadenosine 3',5'-cyclic monophosphate (8-Br-cAMP) or 3-isobutyl-1-methylxanthine (IBMX)), or 5-aminoimidazole-4-carboxamide 1- β -D-ribofuranoside (AICAR), an activator of AMPK. In further experiments, HepG2 cells were transfected with a dominant negative (DN) HNF4 α vector (pDGT23.1, a gift of Prof. T. Leff, Wayne State University School of Medicine, Detroit, MI) or an equal amount of control plasmid pcDNA3, 16 h prior to serum-starvation. The relative mRNA expression levels of HNF4 α and selected target genes were quantified using real-time PCR and normalized to the expression of a housekeeping gene, cytochrome c-1.

Results: In testing several hormones and physiological mediators, we found that insulin produced an increase in the expression of fatty acid synthase (74%, $p = 0.05$), and a decrease in apolipoprotein C3 (42%, NS); however HNF4 α gene expression itself was not altered. Glucagon, dexamethasone and the AMPK activator, AICAR, did not produce significant changes in HNF4 α

or target gene expression. In addition, peroxisome proliferator-activated receptor- α and sterol regulatory element-binding protein 1c expression was not significantly altered by any of the conditions after 6 h incubation.

The PKA activators, 8-Br-cAMP and IBMX, stimulated the expression of PEPCK (210%, $p < 0.001$, and 91% respectively, $p < 0.05$) and inhibited the expression of liver-type pyruvate kinase (L-PK) (56% by 8-Br-cAMP, $p < 0.01$; 36% by IBMX, NS). Further investigation of the effect of 8-Br-cAMP on HNF4 α activity in HepG2 cells over-expressing a DN-HNF4 α plasmid showed that 8-Br-cAMP caused a similar increase in PEPCK as in the control, i.e. had no effect, whilst the expression of DN-HNF4 α partially reversed the negative effect of 8-Br-cAMP on L-PK expression, producing only 27% inhibition vs. 56% in the control ($p < 0.05$).

Conclusion: Transfection of HepG2 cells with a DN-HNF4 α expression plasmid, which forms non-functional heterodimers with wild-type HNF4 α and prevents DNA-binding, ameliorated the inhibitory effect of cAMP on L-PK expression, whilst it did not prevent the stimulatory effect of cAMP on PEPCK expression. This real-time PCR data provides evidence for the role of HNF4 α in mediating the inhibitory effects of cAMP on the endogenous expression of the L-PK gene in HepG2 cells. Further work will address the role of co-activators and HNF4 α levels on expression of target genes.

Contrasting actions of sitagliptin and exenatide on food intake, body weight, glucose stimulated insulin secretion and gastric emptying in rodents

B. Gedulin, K. Tatarkiewicz, P. Smith, J. Wilson, D. Bhole, D. Kendall, D. Hargrove, D. Parkes;
Amylin Pharmaceuticals, Inc., San Diego, United States.

Background and Aims: Exenatide (EXN) is an incretin mimetic that shares similar glucoregulatory properties to human GLP-1 including enhancement of glucose-dependent insulin secretion, regulation of gastric emptying (GE), decreased food intake (FI) and decreased postprandial glucagon secretion. Sitagliptin (SGP) is a recently approved DPP-IV inhibitor and acts by increasing the amount of active endogenous GLP-1 in the circulation. The present studies compared the pharmacological effects of acute treatment with EXN vs SGP.

Materials and Methods: To assess duration of action of SGP, C57BL/6J male mice received a single oral dose of 10 or 50 mg/kg, and plasma DPP-IV activity was measured up to 24h. OGTTs were performed in *db/db* mice with EXN (20 μ g/kg IP) and SGP (50 mg/kg PO) administered 15min before a glucose challenge (2g/kg). For measurement of FI and body weight (BW), single housed fed male SD rats received SGP (60mg/kg PO) or water 45 minutes prior to lights out ($n=7$ /group); EXN (5 μ g/kg IP) or 10%DMSO 15 minutes prior to lights out ($n=7$ /group). The food hopper was weighed every 5 seconds for the following 24h. BW was measured 24h post treatment. To assess GE, conscious fasted male SD rats were given an oral gavage of SGP (60mg/kg) or water at $t=-45$; a SC injection of saline or EXN (10nmol/kg) at $t=-5$; and an oral gavage of 33mg acetaminophen (ACET) at $t=0$ ($N=6-12$ per group). GE was measured by appearance of ACET in plasma 30 minutes after ACET gavage.

Results: Three hours after oral administration of SGP (10 or 50mg/kg), DPP-IV activity decreased by 75% and 90% from baseline, respectively, and returned to basal levels after 24h. In the EXN group, after an OGTT, plasma insulin (assessed as $AUC_{0-120 \text{ min}}$) increased by 86% ($P < 0.05$) and plasma glucose ($AUC_{0-120 \text{ min}}$) decreased by 47% ($P < 0.01$) vs control. There was no difference in insulin or glucose AUC between SGP-treated mice and controls. SGP (60 mg/kg PO) did not affect mean cumulative FI (CFI) measured hourly over a 24h period, while EXN (5 μ g/kg IP) significantly decreased CFI at each hour over the 24h period. Mean CFI at 12h and 24h was reduced in the EXN group by 45% and 33% respectively ($P < 0.01$ vs control group). BW gain after 24h was significantly reduced by 2.5% in the EXN group ($P < 0.01$) but not in SGP-treated rats, compared to their respective control groups. Oral administration of SGP (60mg/kg) decreased GE by 39 \pm 4% vs 90 \pm 2% inhibition with EXN (10nmol/kg) administered SC ($P < 0.0001$). In these GE-related studies, DPP-IV activity measured at $t=30$ min was reduced only in SGP-treated rats (91% from control group, $P < 0.001$).

Conclusion: These studies reveal significantly greater in vivo efficacy with exenatide vs sitagliptin for modulating several physiological parameters that contribute to improved glucoregulation.

The insulinotropic effect of GIP is impaired in patients with chronic pancreatitis and secondary diabetes as compared to normal glucose tolerant patients with chronic pancreatitis

E. K. Knop¹, T. Vilssbøll¹, P. V. Højberg¹, S. Larsen², S. Madsbad³, J. J. Holst⁴, T. Krarup¹;

¹Department of Internal Medicine F, Gentofte University Hospital,

²Department of Internal Medicine M, Glostrup University Hospital,

³Department of Endocrinology, Hvidovre University Hospital,

⁴Department of Biomedical Sciences, University of Copenhagen, Denmark.

Background and Aims: The incretin effect is reduced and the insulinotropic effect of the incretin hormone glucose-dependent insulinotropic polypeptide (GIP) is lost in patients with type 2 diabetes mellitus (T2DM). We aimed to evaluate the causality of this deficiency.

Materials and Methods: We investigated 8 patients with chronic pancreatitis (CP) and normal glucose tolerance (NGT) (fasting plasma glucose (FPG):

5.5 (4.5–6.0) mM (mean (range); HbA_{1c}: 5.8 (5.4–6.3) %) and 8 patients with CP and secondary non-insulin dependent diabetes (FPG: 7.1 (6.0–8.8) mM; HbA_{1c}: 7.0 (5.8–10.0) %) during three 15–mM hyperglycaemic clamps with continuous *iv* infusion of saline, glucagon-like peptide-1 (GLP-1) or GIP.

Results: The initial (0–20 minutes) insulin and C-peptide responses were enhanced significantly in both groups by GLP-1 and GIP, respectively, compared to saline ($P<0.05$). In both groups GLP-1 infusion resulted in significantly greater insulin and C-peptide responses from 20–120 minutes compared with saline infusion. During GIP infusion the late-phase insulin response (20–120 minutes) was 3.1 ± 1.0 fold greater than during saline infusion in the group of patients with CP and NGT ($P<0.05$), whereas there was no significant differences in patients with CP and DM.

Conclusion: The lack of GIP amplification of the late insulin response to *iv* glucose develops alongside the deterioration of glucose tolerance in patients with CP, suggesting that the same may be true for the loss of the GIP effect in patients with T2DM.

The long-acting GLP-1 analogue, liraglutide, normalises olanzapine-induced weight gain and glucose tolerance

K. Lykkegaard¹, P. J. Larsen¹, L. B. Knudsen²;

¹Rheoscience, Roedovre, Denmark, ²Novo Nordisk, Maaloev, Denmark.

Background and Aims: Therapeutic use of atypical antipsychotic agents is often associated with weight gain and impaired glucose tolerance. The long-acting GLP-1 analogue liraglutide has been found to reduce weight and improve glycemic control in both preclinical and clinical experiments. In the present experiment, we investigated whether liraglutide could decrease olanzapine induced weight gain and reduce glucose levels in female rats.

Materials and Methods: Female Sprague Dawley rats were implanted with subcutaneous osmotic mini pumps for delivery of olanzapine (1.75 mg/24 hours, n=20) or vehicle (2.5 µl/h, n=20) for 28 days. After 14 days, ten animals from each group received in addition doses of liraglutide (0.2 mg/kg BID) or vehicle (BID) for the remainder of the study. Statistical significance is indicated: ^a $p<0.05$ olan or lira vs. vehicle, ^b $p<0.05$ lira vs. olan.

Results: Liraglutide treatment (lira) during the last two weeks of olanzapine treatment normalized olanzapine-induced (olan) elevation of cumulated food intake to the level of vehicle treated (veh) animals (lira, 601.8 ± 20.4^a ; olan, 667.3 ± 7.0^b ; veh, 593.2 ± 13.2 g). Likewise, liraglutide normalized olanzapine-induced body weight gain (lira, 280.2 ± 5.6^b ; olan 306.6 ± 4.2^a ; veh, 276.4 ± 3.6 g), decreased subcutaneous inguinal fat depot (lira, 2.4 ± 0.2^{ab} ; olan 3.4 ± 0.3^a ; veh, 1.9 ± 0.1 g) and normalized mesenterial (lira, 1.8 ± 0.1^b ; olan 3.1 ± 0.2^a ; veh, 1.7 ± 0.2 g) and retroperitoneal fat depots (lira, 3.5 ± 0.4^b ; olan 6.2 ± 0.6^a ; veh, 2.8 ± 0.3 g). Glucose tolerance was normalized after treatment with liraglutide, measured as the area under the curve of the glucose concentration curve during an OGTT (lira, $1,764\pm 32^b$; olan $1,906\pm 66^a$; veh, $1,770\pm 28$ mM x min).

Conclusion: In conclusion, liraglutide is a promising compound for alleviating the weight gain and glucose intolerance often seen during treatment with atypical antipsychotic agents.

0579

The role of endogenous GLP-1 on insulin secretion during oral glucose tolerance test in healthy subjects and patients with type 2 diabetes mellitus

B. A. Aulinger, T. P. Vahl, D. A. D'Alessio, M. Salehi;

Internal medicine – Endocrinology, University of Cincinnati, United States.

Background and Aims: Glucagon-like peptide-1 (GLP-1) enhances insulin secretion after ingestion of carbohydrates (CHO) glucose-dependently. The effect of endogenous GLP-1 on postprandial insulin secretion has been investigated using the GLP-1 receptor (GLP-1r) antagonist exendin-(9–39) (Ex-9). Although the independent effect of GLP-1 on insulin secretion could not be evaluated given that the blockade of GLP-1r resulted in hyperglycemia, we sought to determine the effect of endogenous GLP-1 on postprandial insulin secretion independent of circulatory glucose concentrations during intravenous-oral hyperglycemic clamp using Ex-9.

Materials and Methods: 8 healthy subjects (5 F and 3 M; age 29–45; BMI 19–31) were studied on two occasions, once with Ex-9 (750 pmol/kg/min) and once with a saline control. This dose of Ex-9 was sufficient to abolish the effects of a supraphysiologic dose of GLP-1 on glucose-stimulated insulin secretion. After an overnight fast, a square wave of hyperglycemia was produced and maintained at a target level. At 90 min, subjects ingested 75g of oral glucose within 5 min. The glucose clamp was maintained for 3 hours after oral glucose by adjustments in the rate of intravenous glucose infusion. The same principle was used in a group of 12 patients (6 female and 6 male; age 40–59 (52 ± 1.8); BMI 26–44 (33.9 ± 1.6) kg/m²) with established T2DM (9 treated with metformin with or without sulfonylurea, 3 treated with diet) and good glycemic control (HbA_{1c} $6.2\pm 0.17\%$) using a 300-kcal mixed meal ingested within 10 min instead of oral glucose solution.

Results: In healthy subjects glucose levels were maintained at 161.9 ± 2.2 mg/dl and 166.4 ± 2.6 (NS) during the 2 studies and diabetic patients were clamped at 215.9 ± 0.9 and 217.5 ± 0.6 (NS), respectively. Glucose levels were not different before and after oral CHO in all studies. Mean insulin levels increased significantly ($p<0.001$) after oral glucose by a factor of 4.4 ± 0.8 and 3.5 ± 0.4 in healthy subjects and about 3-fold in diabetic subjects after ingestion of the mixed meal. Ex-9 decreased mean insulin levels after oral glucose in a healthy subject from 1083 ± 63 to 791 ± 55 ($p<0.05$) in healthy subjects and from 1136 ± 85 to 872 ± 54 ($p<0.05$) in diabetic patients.

Conclusion: Oral administration of CHO significantly enhances insulin secretion during a hyperglycemic clamp in both healthy subjects and patients with well-controlled T2DM. In our healthy and diabetic cohort, endogenous GLP-1 action accounted for 30% of postprandial insulin secretion.

Separate impact of obesity and glucose tolerance on incretin effect in humans

E. Muscelli¹, S. Camastra¹, F. Tesi¹, A. Natali¹, A. Casolaro¹, B. D.

Astiarraga¹, R. Femia¹, F. Santini², J. Holst³, A. Mari⁴, E. Ferrannini¹;

¹Department of Internal Medicine, University of Pisa, Italy, ²Department of Endocrinology, University of Pisa, Italy, ³Department of Medical Physiology, Panum Institute, Copenhagen, Denmark, ⁴Institute of Biomedical Engineering, Consiglio Nazionale delle Ricerche, Padova, Italy.

Background and Aims: The separate impact of obesity and hyperglycemia on incretin effect, i.e. the gain in insulin secretion after oral glucose vs intravenous glucose, has not been investigated.

Materials and Methods: Isoglycemic oral (75 g of glucose, 3 hours) and IV glucose administration was performed – on separate days – in 50 subjects (25 NGT, 16 IGT and 9 type 2 DM, mean age=41±2 years) with a wide range of BMI (19.6 to 61.2 kg.m⁻², mean=35.4±3.6). C-peptide deconvolution was used to reconstruct insulin secretion rates, and β-cell function was evaluated by mathematical modelling. β-cell glucose sensitivity was calculated as the slope of the insulin secretion/glucose concentration dose-response curve. The incretin effect was defined as the ratio of oral to IV secretory responses.

Results: The glucose area-under-curve (AUC_g) during the oral load ranged 965–2624 mmol.l⁻¹.3h (mean=1483±52) and was closely reproduced by intravenous glucose (1504±51 mmol.l⁻¹.3h). Fasting insulin secretion was similar in both studies (95 [57] vs 110 [90] pmol.min⁻¹.m⁻², median [interquartile range], oral vs IV, p=ns), while total post-OGTT insulin secretion was significantly higher with oral than IV glucose (62 [32] vs 46 [36] nmol.m⁻², oral/IV ratio=1.44±0.07, $p<0.0001$). β-cell glucose sensitivity also was higher with oral than IV glucose (100 ± 9 vs 68 ± 6 pmol.min⁻¹.m⁻².mM⁻¹, ratio=1.68±0.12, $p<0.0001$). In the whole group, both the incretin effect on total insulin output and that on glucose sensitivity were inversely related to BMI and AUG_c (all $p\leq 0.01$). In a multiple regression model controlling for sex and age, the incretin effect on total insulin output was reciprocally related to both BMI (standardised $r=-0.58$, $p<0.0001$) and AUG_c (standardised $r=-0.35$, $p=0.01$) independently of one another. Similarly, the incretin effect on glucose sensitivity was independently related to BMI (standardised $r=-0.39$, $p<0.01$) and AUG_c (standardised $r=-0.36$, $p=0.02$).

Conclusion: Incretin-mediated stimulation of insulin secretion and β-cell glucose sensitivity is independently downregulated by both obesity and acute hyperglycemia.

No increased risk of hypoglycaemic episodes during 48 hours of continuous GLP-1 administration in fasting healthy subjectsS. Lerche¹, L. Soendergaard¹, B. Brock¹, J. Rungby¹, N. Moeller², J. J. Holst³, O. Schmitz¹;¹Department of Pharmacology, Aarhus University,²Medical Research Laboratory, Aarhus University Hospital,³Department of Medical Physiology, Copenhagen University, Denmark.

Background and Aims: During fasting the glycaemic level is orchestrated by numerous biochemical processes. The insulinotropic and glucagonostatic effects of glucagon-like-peptide-1 (GLP-1) are glucose dependent. However it is speculative whether the ability to sufficiently compensate hypoglycaemia during fasting is preserved, when pharmacological GLP-1 levels are present. Furthermore, it is uncertain whether an oral glucose stimulus after a 60 hour fasting period would lead to reactive hypoglycaemia during high GLP-1 levels. To date the effect of GLP-1 administration on glycaemia and the counter regulatory response for more than 12 hours of fasting has never been explored. Thus the aim of the study was to assess the safety of a pharmacological relevant dose of native GLP-1 during long term fasting with regard to glycaemia and counter regulation. Our hypothesis was that there was no increased risk of hypoglycaemia with GLP-1 infusion due to glucose dependency and preserved counter regulation and only a minor risk of reactive hypoglycaemia exists in the wake of a subsequent glucose load.

Materials and Methods: We conducted a randomized placebo controlled cross-over study in 8 healthy male subjects (age; 24±2 years (mean±SD), BMI 24.4±0.7kg/m²). After an overnight fast a subcutaneous infusion of GLP-1 (7–36amide) or placebo was started followed by a fasting period of 48 hours and finally a 3-hour oral glucose tolerance test (OGTT) was performed. Using a portable insulin pump GLP-1/placebo was infused continuously in a step wise manner for 6 hours following which 4.8pmol/kg/min was given for the rest of the study. Each subject completed two study periods. At a plasma glucose ≤ 2.8mM and/or neuroglycopenic symptoms the subjects were withdrawn from the study period.

Results: 2 subjects in the GLP-1 group and 1 subject in the placebo group were withdrawn due to the above criteria (after 25, 29 and 25 hours of GLP-1 and placebo infusion, respectively). The average concentration of intact GLP-1 was 30.5±2.0 vs. 5.6±0.9 pmol/l (GLP-1 vs. placebo, mean±SEM), (P=0.004). During the fasting period plasma glucose (PG) declined in a comparable manner from 4.9±0.09 vs. 5.0±0.1 to 3.7±0.2 vs. 3.7±0.1 mmol/l (P=0.003). Levels of insulin (P=0.0006) and C-peptide (P=0.0001) decreased with fasting time, the glucagon level increased (P=0.0001) as did the levels of growth hormone (GH), (P=0.0001) and free fatty acids (FFA) (P=0.0001). No difference between GLP-1 and placebo was observed. Similarly, circulating insulin, C-peptide, FFA, glucagon, GH, cortisol and epinephrine did not differ. During the OGTT, PG was similar to GLP-1 and placebo (P=0.48) whereas circulating insulin (P=0.06) and C-peptide (P=0.05) levels tended to be higher during GLP-1 infusion

Conclusion: The counter regulatory response during 48 hours of subcutaneous GLP-1 infusion was preserved during fasting. There was no increased risk of major hypoglycaemic episodes. No reactive hypoglycaemia was observed after a glucose load following the fasting period. These observations may be of relevance utilizing potential future long acting GLP1 analogues.

The influence of gastric inhibitory polypeptide on ghrelin secretion in different metabolic conditionsA. F. H. Pfeiffer^{1,2}, O. Goegebakan^{1,2}, B. Otto³, M. Mohlig^{1,2}, J. Spranger^{1,2}, M. O. Weickert^{1,2}, N. N. Rudovich^{1,2};¹Clinical Nutrition, DIFE Potsdam-Rehbrücke, Nuthetal,²Endocrinology, Diabetes and Nutrition, Campus B. Franklin, Charite University Medicine, Berlin, ³Internal Medicine and Gastroenterology, Innenstadt University Hospital, Munich, Germany.

Background and Aims: Circulating ghrelin concentrations decrease after meal consumption. The effect incretins on ghrelin secretion in humans remains unclear. We quantified circulating ghrelin concentrations under

different metabolic conditions combined with infusion of gastric inhibitory polypeptide (GIP).

Materials and Methods: 14 health obese men (age: 47.4±8.4 yr.; BMI: 32.5±2.2 kg/m²; mean ± S.E.) participated in two or four of the following procedures: 1. Placebo (0.9 % NaCl) and GIP-infusion for 240 min in cross-over, randomized manner. 2. A hyperinsulinemic, euglycemic clamp (EC) (4.4 mmol/L) combined with placebo or GIP-infusion for 240 min in cross-over, randomized manner. 3. A hyperinsulinemic, hyperglycemic clamp (HC) (7.8 mmol/L) combined with placebo and GIP-infusion for 240 min in cross-over, randomized manner. In all tests GIP was infused at infusion rate of [2.0 · pmol kg⁻¹ · min⁻¹] for 240 min.

Results: Ghrelin levels were unchanged during GIP- and placebo infusion test. In the EC with placebo, ghrelin levels decreased over time to 5.3±9.8 % of baseline, from a mean of 81.96±25.6 pg/ml to 76.96±23.67 pg/ml during the clamp (p = 0.059, NS). In the EC with GIP, ghrelin levels decreased over time to 12.6±8.7 % of baseline, from a mean of 85.16±28.78 pg/ml to 77.09±20.33 pg/ml during the clamp (p = 0.008). Basal and steady-state concentration of ghrelin, blood glucose and insulin were not different between EC with placebo and GIP. In the HC with placebo, ghrelin levels decreased over time to 18.8±12.7 % of baseline, from a mean of 93.76±38.41 pg/ml to 73.01±25.15 pg/ml during the clamp (p = 0.028). In the HC with GIP, ghrelin levels decreased over time to 34.2±17.1 % of baseline, from a mean of 100.45±50.31 pg/ml to 60.55±21.35 pg/ml during the clamp (p = 0.018). Steady-state concentration of ghrelin were lower in the HC with GIP (p = 0.018). Basal and steady-state concentration of blood glucose and insulin were not different in the HC with GIP and placebo.

Conclusion: GIP has an additive suppressed effect on ghrelin secretion under hyperglycemic and hyperinsulinemic condition in uncomplicated obesity.

GLP-1 and Exendin-4 normalise D-glucose uptake in fat and muscle of insulin-resistant rats

P. Moreno, V. Sancho, J. Cancelas, B. Nuche-Berenguer, I. Valverde, M. L. Villanueva-Peñacarrillo;
Metabolims, nutrition, hormones, Fundación Jiménez Díaz, Madrid, Spain.

Background and Aims: GLP-1, incretin with insulin-independent antidiabetic actions, has shown positive effects upon the glucose metabolism of extrapancreatic tissues participating in the hexose homeostasis. Exendin-4 (Ex-4), structurally GLP-1-homologous, shares with GLP-1 some of its *in vitro* stimulating effects such as that upon glucose transport in muscle and fat. Here we have explored the *in vivo* effect of GLP-1 and Ex-4 upon glucose transport (GT) in skeletal muscle and adipocytes from an insulin-resistant rat model.

Materials and Methods: Insulin resistance (IR) was induced in adult Wistar rats by chronic feeding during 8 weeks with standard chow combined with D-fructose (20% in the drinking water). Groups of IR rats (n=5–10 each) were treated (3 days) -through an osmotic pump- with saline solution (control), GLP-1 (0.86 nmol/kg/h) or Ex-4 (0.1 nmol/kg/h). Plasma samples were taken before (basal) and by the end of the treatment, for glucose concentration measurement; then, rats were sacrificed and the epididimal fat pads and soleus muscles were collected. GT was measured as 2-deoxi-D-[1,2-³H]glucose uptake during 18-min incubation period in the case of isolated adipocytes -by enzymatic digestion-, or during 60-min in that of the whole soleus muscle samples. A group of 5 untreated normal rats were also included.

Results: In IR rats, basal plasma glucose (89±3 mg/dl, n=25) was not significantly affected after saline, GLP-1 or Ex-4 treatment. In the muscle samples of IR rats, control GT value (0.192±0.04 nmol/mg/min, n=7) was lower ($p<0.03$) than that in untreated normal rats (0.418±0.09 nmol/mg/min, n=5). After treatment with GLP-1, the GT (0.516±0.025 nmol/mg/min, n=10) was much higher ($p<0.001$) than that in control rats saline-treated; also, after treatment with Ex-4 an increased value was observed (0.753±0.017 nmol/mg/min, n=10, $p<0.001$ vs control) which was even higher ($p<0.04$) than that exerted by GLP-1 treatment. In adipocytes from IR rats treated with GLP-1, the levels of GT (11.9±0.8 fmol/10⁵ cells, n=8) were higher ($p<0.001$) than in those from the control rats (8.1±0.8 fmol/10⁵ cells, n=5), and also an increase of GT was observed after Ex-4 treatment (12.2±0.8 fmol/10⁵ cells, n=6, $p<0.001$ vs control); no difference was detected between the magnitude of the effect of GLP-1 and that of Ex-4.

Conclusion: These findings suggest a beneficial effect of GLP-1 and exendin-4 upon the deleterious glucose transport in muscle and fat in insulin-resistant states, and add support to the therapeutic role of this hormone/peptide in pathological situations running with deficient insulin action.

Effect of the glucagon-like peptide-1 receptor agonist AVE0010 on postprandial hepatic glucose metabolism in the conscious dog

M. C. Moore¹, U. Werner², M. S. Smith¹, T. D. Rodewald¹, A. D. Cherrington¹;

¹Molecular Physiology & Biophysics, Vanderbilt University, Nashville, United States,

²Sanofi-Aventis Deutschland GmbH, Frankfurt am Main, Germany.

Background and Aims: Glucagon-like peptide-1 (GLP-1) receptor agonists are tools for control of hyperglycemia in type 2 diabetes, but little is known about their effects on postprandial hepatic metabolism. The aim was to

determine the effect of acute administration of the synthetic GLP-1 receptor agonist AVE0010 on net hepatic glucose uptake (NHGU) and insulin secretion following a mixed meal.

Materials and Methods: Adult mongrel dogs underwent surgery ≈16 days before study for insertion of femoral artery, hepatic portal vein, and hepatic vein sampling catheters and placement of ultrasonic blood flow probes on the hepatic artery and portal vein. On the study day, overnight-fasted dogs received a subcutaneous injection of AVE0010 (1.5 μg/kg; AVE0010 group; n=5) or vehicle (saline; Control group, n=6) at -30 min. A defined formula diet (93.4 kJ/kg; energy composition 19% protein, 71% CHO, 10% lipid) was given orally at 0 min, and blood samples were collected until 510 min.

Results: Basal arterial and portal blood glucose concentrations were ≈4.6 mmol in both groups. The peak glucose concentrations were 7.7±0.8 vs 5.6±0.6 mM (artery; $p<0.05$) and 9.5±0.8 vs 7.6±0.7 mM (portal vein; $p<0.05$) in Control and AVE0010, respectively. Areas under the curve (AUCs) of blood glucose and plasma insulin excursions were greater in Control than AVE0010 (Table). Glucose absorption was evident by 15 min in Control but was delayed ≈1h in AVE0010. Neither the AUC of net gut glucose output nor that of NHGU differed significantly between control vs AVE0010 (Table). Glucagon concentrations did not differ between groups, remaining near-basal during the study. (Tab. 1)

Conclusion: AVE0010 reduced the postprandial glycemic excursion without increasing insulin concentrations. Slowing the rate of gastric emptying could be one mechanism involved in the effect. The glycemic improvement was achieved without stimulation of NHGU or insulin secretion, suggesting that the drug enhanced glucose clearance by nonhepatic tissues.

Enzyme resistant N-terminally modified cholecystokinin-8 exhibits enhanced satiety and insulinotrophism compared with exendin-4

F. P. M. O'Harte, P. A. Frizelle, P. R. Flatt;
School of Biomedical Sciences, University of Ulster, Coleraine, Northern Ireland, United Kingdom.

Background and Aims: Cholecystokinin octapeptide (CCK-8) is a neuropeptide hormone that regulates short-term feeding and satiety. Like glucagon-like peptide-1(7–36)amide (GLP-1), CCK-8 is also a strong meal-dependent stimulator of insulin secretion. Both peptides have short circulating biological half-lives due to the actions of peptidase enzymes. Here we examine the effects of two stable N-terminally modified CCK-8 analogues, and compare these actions to those of native CCK-8, GLP-1 and its stable mimetic exendin-4(1–39).

Material and Methods: Peptide degradation was examined following incubation (0–240 min, 37°C) with mouse plasma (20 μl) using reversed-phase HPLC and quadrupole time of flight (Q-TOF) mass spectrometry techniques. Food intake was examined using 12 week-old male Swiss TO mice, which were habituated over 3-weeks to 3 h (10.00–13.00 h) of voluntary food intake per day. Mice (29.5±0.1 g) were injected intraperitoneally (10.00 h) with either N-glucitol-CCK-8, pGlu-Gln-CCK-8, native CCK-8, GLP-1, exendin-4(1–39) (100 nmol/kg each) or saline control (10 ml/kg) and immediately allowed to feed. Cumulative food intake was measured at times 30, 60, 90, 120, 150 and 180 min. In another study, fasted (18 h) obese diabetic *ob/ob* mice were acutely treated (100 nmol/kg) with N-glucitol-CCK, native CCK-8 or saline (control) and voluntary food intake monitored at intervals from 30 to 300 min. Acute insulin secretion studies were performed using clonal BRIN-BD11 cells comparing the insulinotropic effects of 10⁻¹² to 10⁻⁶ M CCK-8, pGlu-Gln-CCK and exendin-4(1–39) at 5.6 mM glucose.

Results: Native CCK-8 was rapidly and sequentially degraded by plasma with C-terminal fragment peptides (CCK-7, CCK-6, CCK-5, CCK-4, CCK-3 and CCK-2) identified by *de novo* sequencing software using Q-TOF mass spectrometry. N-glucitol-CCK-8 and pGlu-Gln-CCK-8 were completely resistant to N-terminal plasma degradation. In food intake studies, saline-

Table 1: AUCs (all values are calculated as change from basal over 510 min)

Group	Art Glc (mmol/l)	Por Glc (mmol/l)	Gut Glc Output (mmol/kg)	NHGU (mmol/kg)	Art Ins (nmol/l)	Hepatic Ins (nmol/l)
Control	70±17	151±22	17.5±3.1	11.6±1.4	91±15	398±122
AVE0010	33±11*	103±16*	17.5±2.4	9.0±2.4	63±7*	172±36*

Art, artery; Glc, glucose; Por, portal; Ins, insulin; Hepatic, hepatic sinusoidal; * $P<0.05$ vs Control

treated control Swiss TO mice (n=8) consumed (mean±sem) between 1.5±0.1 g and 3.3±0.2 g per mouse at 30–180 min. N-glucitol-CCK-8 and pGlu-Gln-CCK-8 were more effective than native CCK-8 and reduced cumulative food intake by 65–85% and 72–97%, respectively compared to controls (P<0.001). GLP-1 had no effect on food intake but the stable GLP-1 receptor mimetic exendin-4(1–39) reduced food intake by 36–48% (P<0.001), being significantly less effective at 30–90 min than native CCK-8 (P<0.05 to P<0.001). In *ob/ob* mice, N-glucitol-CCK-8 was more effective than native CCK-8 reducing food intake by 74–93% from 30–300 min compared to saline controls. Concentration-dependent studies in BRIN-BD11 cells revealed that pGlu-Gln-CCK-8 and native CCK-8 (10^{-12} – 10^{-6} M) were highly effective insulinotropic agents evoking 1.6–3.9-fold stimulation of insulin secretion (P<0.05–P<0.001) compared to 5.6 mM glucose alone. In comparison, exendin-4(1–39) stimulated insulin secretion by 1.2–2.3-fold at 10^{-12} – 10^{-8} M (P<0.05–P<0.001).

Conclusion: These data indicate that N-terminal modification of CCK-8 affords resistance to aminopeptidase degradation. Such analogues are potent stimulators of insulin secretion and exhibit significantly enhanced satiety activity. N-terminally modified analogues of CCK-8 are more effective than exendin-4(1–39) in suppressing appetite and stimulating insulin secretion, indicating potential as future agents for treatment of type 2 diabetes.

Exenatide reverses hypertension in a rat model of metabolic syndrome

D. Parkes¹, J. Landry¹, S. Guss¹, T. Coffey¹, K. Laugero²;

¹Amylin Pharmaceuticals, Inc., San Diego, ²Nutrition, Western Human Nutrition Research Center, USDA-ARS, Davis, United States.

Background and Aims: Exenatide (exendin-4) is a 39-amino acid peptide incretin mimetic that has glucoregulatory actions with associated weight reduction. Previous reports demonstrated acute increases in blood pressure after systemic or intracerebroventricular administration of exenatide or GLP-1 in the rat. This acute pressor effect appears to be species-dependent and transient, but might also depend on the animal's physiological state, study conditions, or dosing regimen. To date, there are no reported studies testing the chronic effects of these peptides on blood pressure in the rat. To better understand the chronic hemodynamic effects of peripheral exenatide administration, we examined telemetry-assessed responses in conscious, unrestrained, male, Sprague-Dawley rats under normal conditions and in a model of glucocorticoid-induced hypertension and metabolic syndrome.

Materials and Methods: Rats were subcutaneously implanted with either corticosterone (CORT, n=16) or wax (control) pellets (n=4) and then 14 days later were implanted with subcutaneous osmotic pumps to deliver vehicle (n=8) or exenatide (1 micro g/kg/d, n=8) for 7 days (wax-treated animals received exenatide only).

Results: In control rats implanted with wax pellets, exenatide reduced mean arterial blood pressure by 4.7±0.2 mmHg (P=0.044) below baseline levels by day 7. CORT treatment for 14 days produced hypertriglyceridemia, visceral fat deposition, hyperglycaemia and insulin resistance. CORT significantly (P<0.05) elevated average daily systolic, diastolic and mean arterial pressure by 18±2, 13±2 and 14±2 mmHg above baseline, respectively. Compared to vehicle, exenatide (7d) significantly (P=0.015) reversed all measures of CORT-induced hypertension to levels within 3 mmHg of baseline (95% confidence intervals: systolic (-3, 5), diastolic (-2, 5), MAP (-2, 5)). Exenatide's ability to normalize blood pressure occurred independently of any change in body weight, as no effect was measured on either food intake or body weight at this dose (1 micro g/kg/d, P>0.05) in the present study.

Conclusion: Our results are the first to show a durable anti-hypertensive effect of exenatide in a glucocorticoid-induced model of the metabolic syndrome, and reveal that the acute hypertensive actions of exenatide in rats do not extend to any long-term change in blood pressure.

Effect of Exendin-4 on bone remodelling in normal and type 2 diabetic rats

V. Sancho¹, B. Nuche-Berenguer¹, L. Arnés¹, P. Esbrit², M. L. Villanueva-Peñacarrillo¹;

¹Metabolism, Nutrition and Hormones, ²Laboratory of Bone and Mineral Metabolism, Fundación Jiménez Díaz, Madrid, Spain.

Background and Aims: It has been suggested that incretin hormones could participate in the changes in bone remodelling process occurring after nutrients absorption. Exendin-4 (Ex-4) shows GLP-1-like effects upon glucose metabolism in extrapancreatic tissues where it is agonist of the GLP-1 specific receptors; also, Ex-4 exerts an antidiabetic effect which is even more prolonged than that of GLP-1. Here we have explored the possible *in vivo* effect of Ex-4 on bone turnover markers in normal rats and in a streptozotocin-induced type 2 diabetic model.

Materials and Methods: Type 2 diabetic rat model was developed by streptozotocin injection (100 µg streptozotocin/g body weight dissolved in 25 µl citrate buffer) in neonatal Wistar rats (STZ-T2D). Adult rats, normal (n=5) and STZ-T2D (n=6), were treated (3 days) -through an osmotic pump- with Ex-4 (0.1 nmol/kg/h). In fed conditions, plasma samples were taken before (basal) and by the end of the treatment; then, rats were sacrificed and one tibia from each rat was collected. In plasma, osteocalcin and tartrate-resistant acid phosphatase (TRAP) -by ELISA-, insulin -by RIA- and glucose concentrations, were measured. In the bone, after RNA extraction, the osteocalcin gene expression -by real time-PCR- was determined; untreated rats of both groups (3 rats each) were also included (control).

Results: In normal rats, Ex-4 exerted a reducing effect (-6.4±1.8%Δ, p<0.009) on basal plasma osteocalcin value (438.9±7.4 ng/ml), similar to that on the STZ-T2D group (-12.3±8.8%Δ of basal) which, initially, was showing an apparent lower than normal basal levels (385.1±13.9 ng/ml); basal plasma TRAP (2.64±0.27 U/l) was clearly increased by Ex-4 (36.6±15.3%Δ of basal, p<0.01) in normal rats, while no effect was detected in STZ-T2D; neither plasma glucose nor insulin were significantly affected by Ex-4 in normal or in STZ-T2D rats. As judged from the paired difference between the primary values (cycles) for osteocalcin mRNA and 18S rRNA, and expressing results as a mean fold change from control data (2^{-ΔCT} values), the level of osteocalcin mRNA in the bone of STZ-T2D rats was about 3 times higher (range: 2.45–4.33) than in that of normal controls (range: 0.59–1.71); treatment with Ex-4 in normal rats did not modify (range: 0.63–1.37) the bone control value, and induced in that of STZ-T2D a somewhat lower levels of gene expression (range: 0.57–1.48) respect those in untreated control diabetic rats.

Conclusion: These data show that Ex-4 affects bone remodeling in an insulin-independent manner in normal and type 2 diabetic rats. Although the present data are preliminary, this novel finding suggests that Ex-4 appears to stimulate bone resorption in normal state, effect which does not seem to occur in this diabetic model.

Participation of GLP-1 in the bone remodelling process in normal and type 2 diabetic state

B. Nuche-Berenguer¹, V. Sancho¹, J. Cancelas¹, B. Rodríguez-Frutos¹, P. Esbrit², M. L. Villanueva-Peñacarrillo¹;

¹Metabolism, Nutrition and Hormones, ²Laboratory of Bone and Mineral Metabolism, Fundación Jiménez Díaz, Madrid, Spain.

Background and Aims: The insulin-independent antidiabetic action of GLP-1, is now well documented also its positive effect upon glucose metabolism in liver, muscle and fat, and its neurotrophic and anorectic properties, among others. It has been suggested that hormones with incretin character could participate in the changes in bone turnover occurring after nutrient absorption. Here we have explored the possible *in vivo* modulating effect of GLP-1 on bone turnover markers in normal and streptozotocin-induced type 2 diabetic model

Materials and Methods: type 2 diabetic rat model was developed by streptozotocin injection (100 µg streptozotocin/g body weight, dissolved in 25 µl citrate buffer) in neonatal Wistar rats (STZ-T2D). Adult rats, normal (n=5) and STZ-T2D (n=6), were treated (3 days) -through an osmotic pump- with GLP-1 (0.86 nmol/kg/h). In fed conditions, plasma samples were taken

before (basal) and by the end of the treatment; then, rats were sacrificed and one tibia from each rat was collected. In plasma, osteocalcin and tartrate-resistant acid phosphatase (TRAP) -by ELISA-, insulin -by RIA- and glucose concentrations were measured. In the bone, after RNA extraction, the expression of osteocalcin gene -by real time-PCR- was determined; untreated rats of both groups (3 rats each) were included as controls.

Results: In normal rats, GLP-1 did not modify the basal plasma osteocalcin value (440.5 ± 6.0 ng/ml), while in the STZ-T2D group, initially showing an apparently lower than normal level, GLP-1 induced a clear reduction ($-10.9 \pm 0.9\%$ of basal, $p < 0.001$); basal plasma TRAP (2.64 ± 0.27 U/l) was slightly increased by GLP-1 in normal (2.87 ± 0.24 U/l) and also in STZ-T2D rats (2.88 ± 0.29 U/l vs basal: 2.45 ± 0.27 U/l); plasma glucose and insulin were not significantly affected in normal and in STZ-T2D rats. As judged from the paired difference between the primary values (cycles) for osteocalcin mRNA and 18S rRNA, and expressing results as a mean fold change from control data ($2^{-\Delta CT}$ values), the level of osteocalcin mRNA in the bone of STZ-T2D rats was over 3-times higher (range: 2.45–4.33) than in that of normal controls (range: 0.59–1.71); treatment of normal rats with GLP-1 induced a moderate increase (range: 0.61–2.73) in normal controls, while in the STZ-T2D rats group the level achieved after GLP-1 was somewhat lower (range: 0.38–1.18) than that in its corresponding untreated diabetic rats control.

Conclusion: These findings demonstrate that GLP-1 directly modulates bone turnover markers in both normal and type 2 diabetic states. Moreover, GLP-1 appears to promote an uncoupling of bone resorption and bone function in both conditions.

PS 43 Incretin effects: experimental II

0589

The insulin response to oral glucose is almost entirely dependent on incretins in mice

B. Ahrén¹, M. Sörhede Winzell¹, G. Pacini²;

¹Clinical Sciences, Medicine, Lund University, Lund, Sweden,

²Metabolic Unit, Institute of Biomedical Engineering, Padova, Italy.

Background and Aims: The entero-insular axis is the physiological regulation by the gut of islet function. A key component of this axis is the incretin effect, which is the augmented increase in insulin secretion following oral versus intravenous glucose. This effect is achieved by gastrointestinal hormones, which are released during meal ingestion and which augment glucose-stimulated insulin secretion; the two most important being glucagon-like peptide-1 (GLP-1) and glucose-dependent insulinotropic polypeptide (GIP). In humans, a study with careful matching of glucose levels after oral versus intravenous administration has shown that the incretins contributes to 70–90% of the insulin response to oral glucose. The aim of this study was to estimate insulin secretion after oral and intravenous glucose administration when glucose levels were matched in these two conditions.

Materials and Methods: A variable rate intravenous glucose infusion was used to match glucose levels after oral glucose to estimate the contribution of incretins for insulin secretion after oral glucose through gavage in anesthetized C57BL/6J female mice. Insulin secretion was estimated from C-peptide levels. An initially established dose-response relationship between oral glucose load and plasma insulin revealed that 25mg glucose is a threshold dose whereas 75mg glucose is a maximal dose; these two doses were chosen for the matching studies.

Results: Comparison between oral versus intravenous glucose at low glucose (25mg) showed that insulin secretion (the 15 min C-peptide response) was 1272 ± 138 nmol/l during the oral test versus 655 ± 88 nmol/l during the intravenous test ($P = 0.016$). Furthermore, at high glucose (75mg), the 15 min C-peptide response was 5105 ± 587 nmol/l during the oral test versus 685 ± 101 nmol/l during the intravenous test ($P < 0.001$). This corresponds to an incretin contribution to insulin secretion by 50% after low glucose and more than 85% after high glucose loads. Furthermore, the total hepatic extraction of insulin, calculated from insulin and C-peptide data, was $71.2 \pm 1.2\%$ after oral glucose and $74.4 \pm 1.1\%$ after intravenous glucose at low glucose (NS) and $50.5 \pm 2.3\%$ after oral glucose versus $69.9 \pm 2.8\%$ after intravenous glucose at high glucose ($P < 0.001$).

Conclusion: We conclude that the insulin response to oral glucose at a maximal glucose load is almost entirely explained by incretins, and caused by marked augmentation of the hormone secretion in association with reduced total hepatic insulin extraction of insulin.

0590

Exenatide reduces glycaemia via a mechanism mediated by portal glucagon-like peptide-1 receptors but independent of islet hormones and intestinal motility

V. Ionut, D. Zheng, D. Stefanovski, R. N. Bergman;

Physiology and Biophysics, USC Keck School of Medicine, Los Angeles, United States.

Background and Aims: Exenatide (synthetic exendin-4, EX) is a long acting Glucagon-like peptide-1 (GLP-1) mimetic that is currently used in the treatment of type 2 diabetes. EX lowers fasting and postprandial glucose, decreases HbA1c and reduces body weight. The mechanism by which EX exerts these effects is not completely explained. The aim of our study was to investigate whether in addition to the effects on pancreatic hormones and slowing of gastro-intestinal motility EX lowers glycemia through an islet-independent effect, mirroring the native intestinal hormone GLP-1.

Materials and Methods: Experiments were performed in male mongrel conscious dogs (n=8). In each animal several experiments were performed: 1) mixed (high-fat, high carbohydrate) meal tests, with or without preadministration of EX (20 mcg, s.c. injection, 15 min before the experiment); 2) intraportal glucose infusions, *simulating* the meal test glucose levels, in

matched experiments, with or without EX; 3) intraportal glucose infusion with s.c. EX and intraportal infusion of antagonist exendin 9–39.

Results: 1) **Meal tests:** Administration of EX resulted in lower glycemia (105 ± 5 mg/dl vs. 90 ± 3 mg/dl peak postprandial, $p < 0.01$), without a corresponding increase in insulin (80 ± 21 pM saline vs. 55 ± 13 pM EX, $p = 0.9$), but with significant glucagon suppression (73 ± 10 ng/l vs. 54 ± 9 ng/l, $p < 0.001$) and slowing of gastric emptying. 2) **Intraportal glucose infusion with and without EX:** To assess whether the hypoglycemic effect of exenatide is maintained in the absence of delayed intestinal absorption, in the same animals we infused glucose intraportally with or without EX. With EX we measured lower glycemia (97 ± 3 mg/dl vs. 92 ± 3 mg/dl, $p < 0.001$), without compensatory hyperinsulinemia (60 ± 9 pM saline vs. 53 ± 8 pM EX, $p = 0.9$) or glucagon suppression (57 ± 12 ng/l vs. 61 ± 16 ng/l, $p = 0.1$). Thus EX lowers glucose in the absence of delayed gastric emptying and without a corresponding insulinotropic effect or glucagon suppression. 3) **Intraportal glucose with EX and antagonist:** In a separate experiment we infused intraportally the GLP-1 receptor antagonist exendin 9–39, concomitant with s.c. EX and intraportal glucose infusion. For the period of antagonist infusion glucose levels increased to values that were significantly higher than those in the EX only experiment (95 ± 3 mg/dl vs. 92 ± 3 mg/dl, $p < 0.001$); after the antagonist infusion was stopped at 60 min, glycemic levels reverted to values that were not significantly different from the EX experiment (92 ± 3 mg/dl vs. 91 ± 2 mg/dl, $p = 0.4$). Blockade of GLP-1 receptors with exendin 9–39 indicates that portal GLP-1 receptors might be involved in EX's effect.

Conclusion: Similar to GLP-1, EX has a pancreatic hormone-independent effect on lowering glycemia. This effect appears to be mediated via GLP-1 receptors situated in the porto-hepatic area. Activation of these portal receptors, via a neural mechanism, could increase glucose clearance independent of islet hormones.

Effect of Exendin-4 upon glucotransporter GLUT-4 expression in the adipose tissue of normal and type 2 diabetic states

P. Tornero-Esteban, L. Arnés, V. Sancho, P. Moreno, M. Garcia -Arevalo, I. Valverde, M. L. Villanueva-Peñacarrillo;
Metabolism, Nutrition and Hormones, Fundación Jiménez Díaz, Madrid, Spain.

Background and Aims: Exendin-4 (Ex-4), a peptide of non-mammalian nature, shares with GLP-1 not only a 53% of structural homology but also its antidiabetic action; also, Ex-4 shows GLP-1-like stimulatory effects upon parameters related with glucose and/or lipid metabolism in extrapancreatic tissues involved in glucose homeostasis. In this work, we explored whether Ex-4 modulates *in vivo* the GLUT-4 expression in the fat tissue of a streptozotocin-induced type 2 diabetic rat model as compared to normal.

Materials and Methods: Type 2 diabetic rat model was developed by streptozotocin injection (100 µg streptozotocin/g body weight, dissolved in 25 µl citrate buffer) in neonatal Wistar rats (STZ-T2D). Adult rats, normal and STZ-T2D, were treated during 3 days -through an osmotic pump- with saline solution (control) -5 rats/group- or Ex-4 (0.1 nmol/kg/h) -5 rats/group-. In fed state, plasma samples were taken before (basal) and by the end of the treatment for glucose and insulin -by RIA- concentration measurements; then, rats were sacrificed and the epididimal fat pads were collected for plasma membranes and RNA extraction to determine GLUT-4 protein -by Western blot- and mRNA -by real time PCR-, respectively.

Results: In normal and in STZ-T2D rats, neither basal plasma glucose nor insulin were significantly affected by Ex-4 treatment. As judged from the paired difference between the primary values (cycles) for GLUT-4 mRNA and 18S rRNA, and expressing results as a mean fold change from control data ($2^{-\Delta\Delta CT}$ values), the level of GLUT-4 mRNA in the fat tissue of normal rats treated with Ex-4 was not different from that in the control group. Although in STZ-T2D rats treated with Ex-4, the GLUT-4 mRNA (range 0.66–1.01) showed a tendency toward lower values than those in STZ-T2D control group saline-treated (range 0.77–1.29), the gene expression was not significantly different. In normal rats, GLUT-4-protein value after Ex-4 treatment was indistinct of that found in those saline-treated ($100 \pm 10\%$ of control); yet, in STZ-T2D rats, Ex-4 induced a clear stimulation of GLUT-4-protein in STZ-T2D rats ($151 \pm 13\%$ control, $p = 0.024$), similar in magnitude to that previously detected after GLP-1 treatment.

Conclusion: These present data suggest that Ex-4 could exert a control on the GLUT-4 expression, at least at the translational level, in pathologic situations running with insulin deficiency or action.

Sustained GLP-1R-dependent control of glucose homeostasis by a GLP-1 mimetibody

K. M. Picha¹, S. Adhikarakunnathu¹, M. Cunningham¹, D. Drucker², D. Makropoulos¹, A. Mathur¹, C. McCauley¹, T. Ort¹, M. Scully¹, A. Soderman¹, T. Spinka-Doms¹, J. Sprenkle¹, V. Stojanovic-Susic¹, B. Thomas¹, K. O'Neil¹;

²University of Toronto, Samuel Lunenfeld Research Institute, Canada.

Many biologic processes are regulated by small peptides acting in an endocrine or paracrine manner. Such peptides are generally rapidly metabolized so that although their utility as pharmacologic agents may be well validated, their therapeutic potential is limited. We have developed a novel platform for display and delivery of bioactive peptides that links the biological properties of the peptide to the pharmacokinetic properties of an antibody. Peptides engineered in the Mimetibody™ (MMB) platform have significantly improved biochemical and biophysical properties that are distinct from those of Fc-fusion proteins. CNTO736 is a GLP-1 MMB that retains many of the activities of native GLP-1 but exhibits a significantly enhanced pharmacokinetic profile. In mice, the terminal half-life of CNTO736 is 1000-fold longer relative to GLP-1 peptide. Acute studies in diabetic mice showed that CNTO736 dose-dependently improved glucose tolerance, with a reduction in the AUC during a glucose tolerance test of more than 50% at the highest dose. CNTO736 treatment markedly reduced fasting glucose (FBG) in db/db by 250 mg/dL after six weeks of dosing. Diet-induced obese mice dosed chronically with CNTO736 demonstrated a sustained dose-dependent reduction in FBG and up to a 20% reduction in body weight relative to control mice whereas daily treatment with an equimolar dose of exendin-4 resulted in 2% reduction in body weight loss. The biological activities of CNTO736 were shown to be GLP-1 receptor-dependent as the glucose lowering and food intake effects were not observed in *Glp1r*^{-/-} mice. Although CNTO736 is a 60kDa protein, peripheral administration activated *c-fos* expression in regions of the central nervous system protected by the blood brain barrier. Taken together, our data demonstrate that a GLP-1 MMB mimics a broad spectrum of GLP-1R-dependent actions while exhibiting significantly improved pharmacokinetics relative to the native GLP-1 peptide.

Structural studies of glucose-dependent insulinotropic polypeptide (GIP) in micellar media

C. M. Hewage¹, I. Alana¹, F. P. M. O'Harte²;

¹School of Biomolecular and Biomedical Science, University College Dublin, Ireland, ²School of Biomedical Sciences, University of Ulster, Coleraine, Northern Ireland, United Kingdom.

Background and Aims: GIP (YAEGTFISDYSIAMDKIHQQDFVNWLLAQK GKKNDWKHNI TQ) is an incretin hormone synthesised and secreted in the gut. GIP promotes pro-insulin gene expression, proliferation of β-cells and β-cell survival and mainly glucose lowering action. GIP is believed to play a major role in fat metabolism stimulating the synthesis of fatty acids. We are interested in assessing the importance of the structure of GIP and its analogues in determining their biological activity. Ongoing spectroscopic studies in our laboratory have identified the bioactive conformation of GIP. As a part of drug development program for type 2 diabetes currently running in our laboratory, we have studied the solution structure of GIP in membrane mimicking micellar media using NMR spectroscopy. The results presented here could help in the design of new drugs for diabetes and obesity related disorders.

Materials and Methods: Human GIP was sequentially synthesised on an Applied Biosystems 432A automated peptide synthesiser using standard solid-phase Fmoc procedure. The peptide was purified to homogeneity

by RP-HPLC and structural identity confirmed by MALDI-TOF mass spectrometry. NMR experiments were performed using a 5 mm inverse probe with Bruker DRX 500 and 900 NMR spectrometers operating at a 1H resonance frequency of 500.13 and 900.27 MHz respectively, at 298 K. The peptide samples of GIP (1.5 mM) were dissolved in micellar media (600 µl). One and two dimensional (DQF-COSY, TOCSY and NOESY) proton NMR spectra were acquired with a standard parameter sets. All spectra were referenced internally to the TSP at 0 ppm where necessary. Data were acquired and processed using the Bruker XWINNMR program.

Results: The DQF-COSY and TOCSY spectra provided a basis for the identification of individual residue spin-systems. Discrimination of non-unique residues and identification of all other unidentified spin systems was achieved by direct comparison of the TOCSY and NOESY spectra. The backbone nOe connectivities of were clearly identified using the $\alpha_1H/N_{i+1}H$ and $\beta_1H/N_{i+1}H$ cross-peaks in the fingerprint region of the NOESY spectrum. Strong $\alpha_1H/\beta_{i+3}H$ medium-range connectivities were observed suggesting the presence of an α -helix for residues Ser⁸-Lys³⁰. Clear medium-range $\alpha_1H/N_{i+3}H$ connectivities were also identified for residues between Ser⁸-Lys³⁰. Therefore the NMR data suggest that the structure of GIP in micellar media consists of an α -helical motif between residues Ser⁸-Lys³⁰, unlike the other major incretin hormone, GLP-1, which mainly adopts a random coil conformation, under physiological conditions.

Conclusion: We have shown that GIP adopts an α -helical conformation between residues Ser⁸-Lys³⁰ when dissolved in micellar media using NMR spectroscopic analysis. Molecular modelling studies of GIP in micellar media are currently being investigated. These results may help to gain further insight into the biologically relevant receptor-bound structure of GIP, and so facilitate the design of new analogues and peptidic drugs to treat type 2 diabetes and related diseases.

Supported by the Science Foundation Ireland

for 1h did not significantly affect basal expression of PAI-1, VCAM-1, ICAM-1 or E-Selectin mRNA or protein. Addition of liraglutide (100nM) for 1h did significantly inhibit TNF α -mediated induction of PAI-1 mRNA and protein expression with a reduction to control levels of PAI-1 protein and mRNA expression at the 6hr time point (n=3, P<0.05). Liraglutide treatment (100nM) for 1h also inhibited VCAM-1, ICAM-1 and E-Selectin protein and mRNA expression by between 30 and 40% over TNF α -induced levels with the maximal effect observed at 16hrs post TNF α stimulation (n=3, P<0.05).

Conclusion: Taken together, these observations suggest that liraglutide inhibits TNF α -mediated PAI-1, VCAM-1, ICAM-1 and E-Selectin mRNA expression and protein secretion in an *in vitro* model of vascular endothelial cell dysfunction.

Liraglutide modulates expression of vascular adhesion molecules and PAI-1 in an *in vitro* model of endothelial cell dysfunction

A. E. Dear¹, H. Liu¹, L. B. Knudsen², R. W. Simpson³;

¹Medicine, Monash University, Melbourne, Australia,

²NovoNordiskA/S, Måløv, Denmark,

³Endocrinology, Box Hill Hospital, Melbourne, Australia.

Background and Aims: Endothelial cell dysfunction together with elevated levels of circulating proinflammatory cytokines, including TNF α , and increased expression of endothelial cell adhesion molecules and PAI-1 are among the earliest detectable abnormalities identified in people at risk of atherosclerosis. Accelerated atherosclerosis is a major contributor to morbidity and mortality in type 2 diabetes mellitus. Liraglutide, a novel treatment for diabetes mellitus, is a long-acting human glucagon-like peptide-1 (GLP-1) analogue. Liraglutide improves glycaemic control and lowers body weight in subjects with type 2 diabetes. Previous studies have demonstrated that natural GLP-1 improves endothelial cell dysfunction in diabetic patients and attenuates TNF α -mediated induction of PAI-1 expression in vascular endothelial cells. Our current study aims to explore the *in vitro* effect of liraglutide on expression of vascular endothelial cell adhesion molecules and PAI-1 under conditions of TNF α stimulation in the C11-STH vascular endothelial cell system.

Materials and Methods: PAI-1, VCAM-1, ICAM-1 and E-Selectin protein levels were determined in conditioned medium from C11-STH vascular endothelial cells using ELISA kits for PAI-1 (Biopool), VCAM-1, ICAM-1, and E-Selectin (R&D systems). Northern Blot and Reverse Transcriptase (RT) PCR was used to determine mRNA expression levels for PAI-1, VCAM-1, ICAM-1 and E-Selectin in C11-STH vascular endothelial cells.

Results: PAI-1 protein expression levels increased from 50 to 100IU/ml with TNF α (10ng/ml) stimulation (n=3, P<0.05). VCAM-1, ICAM-1 and E-Selectin protein expression levels were induced from undetectable levels to 8.0 ng/ml, 25.0 ng/ml and 0.60 ng/ml respectively post TNF α treatment (n=3, P<0.05). Maximal response of PAI-1, VCAM-1, ICAM-1 and E-Selectin protein expression to TNF α stimulation was observed at 16h. Basal and TNF α -inducible PAI-1 mRNA expression were observed with maximal response identified at 16h. VCAM-1, ICAM-1 and E-Selectin mRNA expression was undetected in unstimulated cells whilst TNF α stimulation resulted in increased VCAM-1, ICAM-1 and E-Selectin mRNA expression with maximal response identified at 16hrs. Addition of liraglutide (100nM)

An assessment of the effect of high fat diet on pancreatic function in the female Zucker diabetic fatty (ZDF) rat using the hyperglycaemic clamp

R. Potter, J. L. Teague, S. M. Poucher;
AstraZeneca, Alderley Park, United Kingdom.

Background and Aims: Obese female ZDF rats fed with a specific 48% high fat diet develop marked hyperglycaemia, suggested to be due to progressive β -cell dysfunction. The primary aim of these studies was to use the hyperglycaemic clamp (HC) to assess and quantify the effect of 48% high fat diet on glucose stimulated insulin secretion (GSIS) and β -cell function in the female obese ZDF rat compared to chow-fed obese and lean controls. Furthermore we investigate the ability of an acute Exendin-4 infusion to improve β -cell function.

Materials and Methods: Female obese ZDF rats (~7 weeks old) were fed normal chow or 48% high fat diet for ~15 days. Aged matched chow-fed female lean ZDF rats were included as controls. Following an overnight fast, animals were anaesthetised with Inactin® (150–180mg/kg; i.p.). Cannulae were placed in the carotid artery and jugular vein, and a tracheotomy performed. After stabilisation blood samples were taken before a 180-minute HC protocol. Plasma glucose (PG) concentrations were monitored at regular intervals, and maintained ~5.4mM above basal concentrations for 90-minutes using a variable continuous infusion of 25% glucose. Exendin-4 was then administered via i.v infusion (30pmol/kg/min), for a further 90-minutes and clamp re-established. Blood samples were obtained regularly for analysis of insulin and c-peptide concentrations.

Results: Basal fasting PG was higher in the OHF-ZDF (7.95 ± 0.86 mM) and OC-ZDF (7.11 ± 0.36 mM) groups compared to the LC-ZDF (5.25 ± 0.13 mM) controls ($p < 0.05$). In all animals, a steady state HC (5.44 ± 0.02 mM above basal PG) was achieved and maintained. GIR required to maintain hyperglycaemia was lower in the OHF-ZDF compared to the OC-ZDF and LC-ZDF controls ($p < 0.05$). All animals demonstrated a bi-phasic insulin response. The OHF-ZDF and OC-ZDF groups had higher insulin and c-peptide concentrations compared to LC-ZDF controls ($p < 0.05$). DI (a calculated measure of β -cell function related to insulin sensitivity) was reduced in the OHF and OC-ZDF compared to LC-ZDF controls ($p < 0.05$). DI was 50% lower in the OHF-ZDF compared to the OC-ZDF ($p < 0.05$). Exendin-4 caused an increased insulin secretion in the LC-ZDF and OC-ZDF with a parallel increase in GIR ($p < 0.05$). Exendin-4 had no significant effect in the OHF-ZDF.

Conclusions: We have used the HC to demonstrate that the OC-ZDF and OHF-ZDF have a significantly reduced β -cell function following 15-days on respective diets. Furthermore the high fat diet reduced β -cell function by 50% compared to that in the OC-ZDF. This may account for the marked progressive hyperglycaemia observed following high-fat diet administration. Exendin-4 infusion increased both GSIS and glucose disposal in LC-ZDF and OC-ZDF. No effect of Exendin-4 was observed in the OHF-ZDF. This may be due to an increased insulin resistance and reduced β -cell function. Prolonged treatment with Exendin-4 may improve β -cell function and GSIS in the OHF-ZDF.

Glucose intolerance associated to insulin resistance and increased insulin secretion in rats depleted in long-chain ω 3 fatty acids

J. Cancelas¹, P. G. Prieto¹, M. L. Villanueva-Peñacarrillo¹, Y. Zhang², L. Portois³, A. Sener², Y. A. Carpentier³, I. Valverde¹, W. J. Malaisse²;
¹Metabolism, Nutrition and Hormones, Fundación Jiménez Díaz, Madrid, Spain, ²Laboratory of Experimental Hormonology, Brussels Free University, Belgium, ³Laboratory of Experimental Surgery, Brussels Free University, Belgium.

Background and Aims: Second-generation rats depleted in long-chain polyunsaturated ω 3 fatty acids (ω 3D rats) display several features of the metabolic syndrome including visceral obesity, liver steatosis, hypertension and cardiac hypertrophy. Pilot measurements made in fed ω 3D rats also suggest that these animals could display insulin resistance. This work meant to determine the insulinogenic index and HOMA values in ω 3D and normal rats during intragastric D-glucose tolerance test.

Materials and Methods: Female ω 3D rats (11–12 weeks of age) were compared to control rats of same age and gender. After overnight starvation, D-glucose (4 μ l/g body wt. of a 30% (w/v) solution, i.e. 1.2 mg of D-glucose/g body wt.) was administered as an intragastric bolus. Blood was collected from the severed end of the tail in chilled tubes before and up to 120 min after administration of the hexose, for later measurement of plasma D-glucose and insulin concentrations.

Results: The ω 3D rats displayed a higher body weight (230 ± 4 g; $n = 16$; $p < 0.001$) than the control animals (189 ± 8 g; $n = 8$). After overnight starvation, the plasma D-glucose concentration was higher ($p < 0.05$) in ω 3D rats (5.28 ± 0.10 mmol/l; $n = 16$) than in control animals (4.93 ± 0.12 mmol/l; $n = 8$), also, the plasma insulin concentration, insulinogenic index and HOMA were all significantly higher ($p < 0.02$ or less) in ω 3D rats than in control animals. Over the 120 min period following the intragastric administration of D-glucose, the area under the curve of plasma D-glucose concentration was higher ($p < 0.05$) in ω 3D rats (931 ± 24 mmol/l.min; $n = 16$) than in control animals (848 ± 17 mmol/l.min; $n = 8$), although the incremental area was not significantly higher in ω 3D rats (296 ± 29 mmol/l.min; $n = 16$) than in control rats (257 ± 14 mmol/l.min; $n = 8$). A comparable situation prevailed in the case of the plasma insulin concentration and insulinogenic index, which both yielded a higher area under the curve ($p < 0.001$) over 120 min, but no significant difference for the incremental area above basal value. In the case of HOMA, both the area under the curve ($p < 0.001$) and incremental area above basal value ($p < 0.01$) were significantly higher in ω 3D rats than in control animals.

Conclusion: The present study reinforces the view that second generation ω 3D rats represents a suitable animal model for investigating the molecular determinants of obesity and insulin resistance resulting from a depletion in long-chain polyunsaturated ω 3 fatty acids. It indeed emphasizes the lesser peripheral insulin sensitivity and higher secretory responsiveness of pancreatic β cells to D-glucose in these second generation ω 3D rats.

Copper administration prevents and reverses the diabetogenic state and abnormal fat metabolism observed in the Cohen diabetic rat

S. W. Zangen, L. T. Chen, I. Raz;
Diabetes Unit, Hadassah University hospital, Jerusalem, Israel.

Background: Nutrition is an essential element in the manifestation of type 2 diabetes in susceptible individuals. Restricting dietary copper combined with high concentration of dietary sucrose induces lipid peroxidation, atrophy of pancreatic acinar tissue and also reduces mitochondrial function. The CD rats is genetically susceptible to develop impaired glucose stimulated insulin secretion (GSIS) associated with exocrine lesions, lipid deposition and macrophage infiltration when fed a high-sucrose, copper-poor diet (HSD, copper = 1ppm). Resistance of peripheral tissues to insulin and obesity were not observed in the hyperglycemic CD rat :

Aim: To study if the reduced GSIS and exocrine lesions may be reverted and prevented by supplementing the HSD diet with an adequate level of copper (15ppm, HSD-Cu).

Materials and Methods: 3 groups of CD rats were studied: rats fed 30 days HSD (CDs-HSD $n=5$); rats fed 40 days HSD-Cu ($n=6$) and CDs-HSD rats

switched to HSD-Cu diet for an additional 40 days of feeding (HSD-reversal, $n=6$). Blood glucose and insulin levels were assessed during intravenous glucose tolerance test (IVGTT). Fasting serum free fatty acids (FFA) levels, pancreatic triglyceride (TG) content and weight, were assessed in each treatment group. Sensitivity of peripheral tissues to exogenous insulin was assessed by intravenous insulin tolerance test (ITT 0.5U/kg BW).

Results: The high glucose area under the IVGTT curve of CDs-HSD rats was significantly reduced in the HSD-Cu and HSD-reversal rats (1500 ± 158 vs. 724 ± 64 and 659 ± 66 , respectively $\text{mM}/120$ min, $P<0.001$). In contrast, the insulin output was significantly lower in CDs-HSD compared to the HSD-Cu and HSD-reversal rats (87 ± 34 vs. 10603 ± 6250 and 1980 ± 658 $\text{pM}/120$ min, $P<0.01$). Pancreatic exocrine lesions were prevented by HSD-Cu and were milder in the HSD-reversal rats. Pancreatic weight of HSD-Cu and HSD-reversal rats was significantly higher compared to CDs-HSD rats (0.306 ± 003 vs. 0.217 ± 0.01 and 0.133 ± 0.02 g $P<0.001$) while pancreatic TG content and serum FFA were markedly reduced in HSD-Cu compared to CDs-HSD (0.25 ± 0.03 vs. 1.9 ± 0.01 mg/g tissue for the TG and 0.225 ± 0.00 vs. 1.48 ± 0.12 mM for the FFA, $P<0.001$). No fat was found in the gastrocnemius muscle of either group. The high sensitivity to exogenous insulin exhibited by CDs-HSD rats was further augmented by HSD-reversal diet.

Conclusion: The CDs rat is a good model to study the sole effect of reduced copper intake on GSIS and exocrine lesions. The abnormalities induced by the HSD may be prevented and reverted by adequate dietary copper concentration. This may suggest that dietary copper concentration as a key element in the mechanism of insulin secretion and fat metabolism of the CDs-HSD rats.

The diagnostic value of traditional insulin sensitivity and β cell function indices

B. Buday¹, L. Koranyi²;

¹Cardiology, Péterfy Sándor Hospital, Budapest, ²Metabolic Diseases, DRC Ltd, Balatonfüred, Hungary.

Background and Aims: Improving insulin resistance is a powerful tool in prevention of type 2 diabetes, but only the complicated clamp method is sensitive enough for an early diagnosis. We investigated the utility of insulin sensitivity (IS) and beta cell function (BCF) indices derived from fasting blood and oral glucose tolerance test (OGTT).

Materials and Methods: Healthy (NGT, $n=47$), glucose intolerant (GIT, $n=92$, IFG/IGT: $n=67$; type 2 diabetic (2DM) $n=25$) patients were investigated by an OGTT, an iv. glucose tolerance test (IVGTT) and a hyperinsulinemic euglycemic clamp

Results: With the exception of older (age above median) NGT and GIT groups we found moderate ($r=0.4-0.6$, $p<0.001$) correlations in most examined

groups (formed by glucose tolerance, age, gender and BMI) between HOMA indices and whole body glucose utilization measured by clamp (M). The IS OGTT indices (MCRest, ISComp, OGIS) showed strong correlation with the M ($r=0.6-0.8$, $p<0.001$). While their average sensitivity for insulin resistance was low ($50.42 \pm 4.65\%$ for HOMA-S and $60.25 \pm 8.06\%$ for OGTT IS indices), their specificity was fairly good ($83.37 \pm 1.62\%$ for HOMA-S, and $87.29 \pm 1.87\%$ for OGTT indices). Fasting BCF indices (HOMA-B) showed significant correlation only with the AIR of IVGTT in IFG/IGT ($r=0.47$, $p<0.001$) and 2DM ($r=0.54$, $p<0.02$) groups, but not in the NGT groups, while amongst BCF indices derived from the OGTT insulogenic index and ΔI_{30} showed strong correlation with AIR in the NGT ($r=0.63$, 0.73 , $p<0.001$), moderate in IFG/IGT ($r=0.40$, $p<0.01$ and $r=0.57$, $p<0.05$) and moderate or non-significant ($r=0.51$, $p<0.05$, $r=0.12$ n.s.) in the 2DM group. 1st and 2nd phase insulin response of OGTT (Stumvoll indices) correlated weakly with the AIR only in the IFG/IGT ($r=0.33$, 0.36 , $p<0.01$) but not in the NGT and 2DM groups. Their average sensitivity for reduced BCF was very low (36.99 ± 2.72 for HOMA-B and $38.2 \pm 8.19\%$ for OGTT BCF) while their specificity was better (81.75 ± 0.49 for HOMA-B and $79.96 \pm 5.41\%$ for OGTT BCF).

Conclusion: Even though some of the widely used simple IS or BCF indices show good correlation with the indices of more accurate clamp methods, their diagnostic value seems to be insufficient in terms of sensitivity. Therefore we still need to develop a simple but more accurate method, comparable to the clamp and IVGTT techniques.

Acute administration of a sulfonylurea compound restores the insulinotropic effect of glucose-dependent insulinotropic polypeptide in patients with type 2 diabetes

K. Aaboe^{1,2}, F. K. Knop^{1,2}, T. Vilsbøll¹, S. Madsbad³, C. F. Deacon², J. J. Holst², T. Krarup¹;

¹Department of Internal Medicine F, Gentofte University Hospital, Hellerup,

²Department of Medical Physiology, The Panum Institute, University of Copenhagen,

³Department of Endocrinology, Hvidovre University Hospital, Denmark.

Background and Aims: Mutations in the kir 6.2 gene, encoding the pore-forming unit of the ATP-sensitive potassium channels (KATP-channels) of the beta-cell, are part of the genetic polymorphism seen in type 2 diabetes. Defects in the function the kir 6.2 subunit in mice are known to inhibit the insulinotropic effect of glucose-dependent insulinotropic polypeptide (GIP). Our aim with this study was to evaluate a possible role of the KATP-channels in the lost insulinotropic effect of GIP. We hypothesized that closing the KATP-channels in the beta-cell through acute administration of sulfonylurea (SU) would re-establish the insulinotropic effect of GIP.

Material and Methods: Twelve patients (8 men) with type 2 diabetes (Age: $54 [45-70]$ years; BMI: $30 [26-35]$ kg/m^2 ; HbA_{1c} : $7.7 [7-8.6]$ %; values mean

[range]) on mono-therapy with metformin (1 diet) were studied over the course of 4 days. Patients were examined using hyperglycaemic clamps (15 mM, 2 hours) with concomitant infusion of GIP (4 pmol/kg body weight/min), GIP + administration of 10 mg SU (glipizide) as tablets 1 hour before the clamp, saline + administration of 10 mg SU as tablets 1 hour before the clamp or saline alone. During the examinations blood was sampled at intervals of 10 to 15 minutes to measure plasma concentrations of glucose, intact and total GIP, glucagon, insulin, C-peptide, free fatty acids and SU.

Results: Insulin secretion, calculated as the *incremental area under the curve* (iAUC) from time 0 to 120 minutes, was significantly higher during GIP+SU (38 ± 9 nmol/l x 120 min) compared to GIP alone (15 ± 3 nmol/l x 120 min; $p=0.0005$), to SU alone (12 ± 5 nmol/l x 120 min; $p=0.001$) and to infusion with saline alone (6 ± 2 nmol/l x 120 min; $p=0.0005$). The iAUC during examination with GIP+SU was also significantly higher than the sum of SU alone and GIP alone (38 ± 9 vs. 21 ± 5 nmol/l x 120 min; $p=0.02$). There was no significant difference between examinations with GIP alone compared to SU alone (15 ± 3 vs. 12 ± 5 nmol/l x 120 min; $p=NS$).

Conclusion: Our results imply that in patients with type 2 diabetes, treated with metformin as mono-therapy, acute administration of a SU compound seems at least partially to restore the insulinotropic effect of GIP. This effect may be caused by SU closing the K-ATP channels in the beta cell, hereby uncoupling any influence from K-ATP channel malfunction on the effect of GIP. We suggest that K-ATP channel malfunction contributes to the lost insulinotropic effect of GIP observed in patients with type 2 diabetes. (Fig. 1) *Supported by the Danish Diabetes Association*

Suit index is a useful predictor of the beneficial effect of short-period insulin therapy in type 2 diabetic patients

Y. Hamamoto^{1,2}, S. Honjo², H. Ikeda², K. Nabe², K. Nomura², Y. Wada², H. Koshiyama²;

¹Department of Diabetes & Clinical Nutrition, Graduate School of Medicine, Kyoto University, Kyoto,

²Center for Diabetes & Endocrinology, The Tazuke Kofukai Foundation Medical Research Institute Kitano Hospital, Osaka, Japan.

Background and Aims: Type 2 diabetic patients often exhibit decreased insulin secretion after a long-period treatment with Sulfonylurea drugs (SU). Insulin therapy has been reportedly shown to restore β cell function in not only animal models but also humans. Although there have been several reports suggesting beneficial effects of insulin therapy on glycemic control in newly diagnosed type 2 diabetic patients, the effect of insulin on the patients who have taken SU drugs for a long period has not been well examined. Here we report the effects of short-period insulin (SPI) therapy on β cell function assessed by the secretory units of islets in transplantation (SUIT) index in relation with the subsequent glycemic control after the therapy in Japanese diabetic subjects. SUIT index was developed as an index of β cell function for islet transplanted patients but also was shown to be applicable to type 2 diabetic patients by Yamada et al., our colleagues.

Materials and Methods: Sixteen patients who had taken SU more than 5 (8.4 \pm 4.0) years were examined. All the patients were hospitalized and were given insulin therapy 8 to 13 days, and the changes of blood glucose levels, plasma C-peptide (CPR) levels, glucagon-stimulated CPR responses before and after SPI therapy were evaluated in the hospital. HbA1c levels before, 6 months and 12month after hospitalization were also evaluated, and the effect of short-period insulin therapy on glycemic control was examined by comparing HbA1c levels with the patients who were treated without insulin during their hospitalization as a control group. SUIT index was calculated by the formula : $250 \times \text{F-CPR}(\text{nM}) / (\text{F-BG}(\text{mM}) - 3.43)$. It was developed by assuming that normal subjects aged <40 years have 100% β cell function.

Results: HbA1c levels six months after SPI therapy were decreased in all the patients. Although SU doses were reduced after SPI therapy in half of the patients, the average HbA1c level significantly decreased from 8.8 ± 0.9 % to 7.1 ± 1.0 %, while that in the control group showed any statistically significant change (8.6 ± 1.6 % to 7.6 ± 0.8 %). Twelve months after SPI therapy, the average HbA1c level increased to 7.4 ± 1.4 %. The rate of change in HbA1c levels from 6 to 12 months compared with that from before to 6 months after hospitalization could be divided into two groups by the border of 20% increase (preserved group: -333 to 18% vs. worsened group: 23 to 161% increase, n=8 for each). SUIT index before SPI therapy tended to be higher in the preserved group, but was not statistically different between the two

groups (45.7 ± 8.4 vs. 35.1 ± 3.6). However, SUIT index after SPI therapy was significantly higher in the preserved group compared to the worsened group (70.8 ± 14.2 vs. 43.7 ± 4.9). Increase in SUIT index after SPI therapy in the preserved group suggested a recovery of β cell function, which might result in a better glycemic control after SPI therapy.

Conclusion: These results suggest that 1) SPI therapy may be beneficial to recover β cell function in certain subsets of patients with failure of SU drugs, and that 2) SUIT index can be a useful indicator to predict the beneficial effect of SPI therapy on subsequent glycemic control.

0601

Diabetes mellitus and β cell function in patients with cystic fibrosis awaiting lung transplantation

C. Schmid, A. Klarer, M. Hofer, M. Faulenbach, P. Wiesli, A. Boehler; Internal Medicine, University Hospital of Zurich, Switzerland.

Background and Aims: To assess the frequency of diabetes mellitus (DM) and to characterize β -cell function and insulin sensitivity in patients with cystic fibrosis (CF) referred to our centre for lung transplantation (LTx).

Materials and Methods: Over 5 years, consecutive patients were included; they had full evaluation with regard to LTx. Patients not known for previous fasting plasma glucose (FPG) ≥ 7 mM and a control group of healthy subjects underwent an oral (75 g) glucose tolerance test (oGTT). Insulin sensitivity and insulin secretion were assessed by indices proposed by Matsuda and by Wareham, respectively, derived from the oGTT.

Results: 42 CF patients were evaluated. Only one patient was obese, and three did not have exocrine pancreatic insufficiency. 24 (14 female) patients had an established diagnosis of DM (57%), and 18 (13 male) patients and 23 (15 male) healthy controls underwent oGTTs. Patients with known DM and patients undergoing oGTTs did not differ with regard to age (mean \pm SD, 26 ± 6 y) and had comparably reduced BMI (18 ± 2 kg/m²) and FEV₁ (29 ± 6 %) but the former were more often female and had higher HbA1c values (7.2 ± 0.7 vs. 6.1 ± 0.4 %). Among those assessed by oGTT, FPG was similar in CF patients (4.8 ± 0.5 mM) and in healthy controls (4.8 ± 0.4 mM), and so was fasting insulin, fasting proinsulin, and insulin sensitivity. By contrast, HbA1c and peak (>11 mM in 13) and 2 h PG (10.4 ± 3.6 mM vs. 6.1 ± 1.2 mM; >11 mM in 7 patients, 6 male) during oGTTs were higher in the CF patients, and the insulinogenic index was significantly lower in the patients (20.9 ± 11.1) than in the controls (60.4 ± 39.0). Within the patients with CF, the insulinogenic index was highest (>30) in those without exocrine pancreatic insufficiency whereas it was consistently low (<30) in those with exocrine failure, irrespective of whether they met diagnostic criteria for DM or not.

Conclusion: 74% of the CF patients (15 of 19 female, 16 of 23 male) referred for LTx had DM. Increased energy expenditure and insulin-independent glucose clearance may account for completely normal FPG despite severely impaired β -cell function in an important subset (31%) of these patients. FPG is an inappropriate tool to identify patients who might benefit (beyond control of glycaemia) from treatment with insulin, an anabolic hormone.

0602

Is the disposition index law hyperbolic? Importance of the regression methodology

P. Denti¹, M. Campioni¹, G. Toffolo¹, R. Rizza², C. Cobelli¹;

¹Department of Information Engineering, University of Padova, Italy,

²Division of Endocrinology, Diabetes, Metabolism and Nutrition, Mayo Clinic, Rochester, United States.

Background and Aims: Glucose tolerance requires to express beta cell function in relation to insulin action. The most widely used measure is based on the Hyperbolic Law Disposition Index (DI), i.e. $\text{DI} = \text{beta-cell function} \times \text{insulin sensitivity} = \text{constant}$. Recently the validity of this law has been questioned and a different description has been suggested: $\text{DI} = \text{beta-cell function} \times \text{insulin sensitivity}^{\text{alphaha}} = \text{constant}$. Aim of this work is to test the validity of the hyperbolic law.

Materials and Methods: To do so, IVGTT in 145 elderly healthy subjects (age 68.9 ± 0.5 years, BMI 27.5 ± 0.3 kg/m²) was interpreted with glucose and C-peptide minimal models to estimate insulin sensitivity SI_{IVGTT} and 1st and 2nd phase beta-cell responsivity, Phi_i and $\text{Phi}_{i,2}$, with their estimation error. Two

disposition indices, DI_1 and DI_2 , were calculated by multiplying, respectively, Φi_1 and Φi_2 by $SI_{\text{IVGTT}}^{\text{alpha}}$. Four regression models have been compared, L-1V: linear regression on log-data assuming error only on one variable (beta-cell responsivity); NL-1V: nonlinear regression assuming error only on one variable (beta-cell responsivity); L-2V: linear regression on log-data assuming error on both variables; NL-2V nonlinear regression assuming error on both variables.

Results: The table shows the results obtained by the four methods (subscripts 1 and 2 denote 1st and 2nd phase parameters, respectively and, within brackets, confidence intervals are displayed).

	DI_1	Alpha_1	DI_2	Alpha_2
L-1V	94 (66–122)	0.18 (0–0.35)	9 (7–11)	0.20 (0.09–0.3)
NL-1V	135 (107–164)	0.19 (0.06–0.32)	14 (12–16)	0.30 (0.21–0.39)
L-2V	498 (410–585)	0.72 (0.64–0.81)	32 (28–36)	0.67 (0.62–0.73)
NL-2V	333 (273–393)	0.97 (0.85–1.09)	23 (21–26)	0.66 (0.60–0.72)

Conclusion: We conclude that the choice of the regression method is crucial, since neglecting error-in-two-variables, but also performing linear regression on log-data, severely affect the results. When both error in-two-variables and the nonlinearity of the relationship are taken into account (NL-2V), results support the classical hyperbolic law for DI_1 but not for DI_2 .

PS 45 Adiponectin

Peripheral monocyte Adipo-R1 and Adipo-R2 gene and protein expression in patients with CAD and type 2 diabetes

A. Kollias^{1,2}, P. Tsiotra¹, E. Maratou¹, I. Halvatsiotis^{1,2}, E. Kyriazi^{1,2}, E. Boutati², A. Raptis², K. Fountoulaki³, I. Lekakis³, G. Dimitriadis², D. Kremastinos³, S. A. Raptis^{1,2};

¹Molecular Biology Lab., Division of Basic Sciences, Hellenic National Diabetes Center, ²2nd Dept. of Internal Medicine, Research Institute & Diabetes Center, "Attiko" University General Hospital, Medical School, ³2nd Dept. of Cardiology, "Attiko" University General Hospital, Athens, Greece.

Background and Aims: Adiponectin, an adipose tissue produced molecule, has been known to have anti-diabetic and anti-atherogenic properties. Adiponectin levels are decreased in obesity, type 2 diabetes, and patients with coronary artery disease (CAD). Adiponectin receptors 1 (Adipo-R1) and 2 (Adipo-R2) are expressed ubiquitously in most organs and also in human peripheral monocytes and mediate adiponectin's signalling into its target cells. The aim of this study was to examine whether the relative mRNA and protein expression of adipo-R1 and -R2 in human monocytes is altered in patients with CAD with/without type 2 diabetes and whether this might relate to indices of obesity and insulin resistance.

Materials and Methods: We studied 20 subjects (9 with CAD and impaired glucose tolerance (CAD-IGT), 7 with CAD and type 2 diabetes (CAD-DM2), and four (4) without CAD but with impaired glucose tolerance (control-IGT)). We developed a real-time quantitative RT-PCR using fluorescently labelled hybridization probes to detect relative adipo-R1 and adipo-R2 mRNA levels in isolated CD14+ blood monocytes (Light Cyler, Roche). mRNA levels were calculated as the relative ratio of the fluorescence acquisition of adipo-R1 and -R2 mRNA divided by that of β -actin. We also detected adipo-R1 and adipo-R2 protein expression at the same cells using a FACSCalibur Flow Cytometer (BD Biosciences). We also measured fasting and 2 hour post-OGTT plasma insulin (RIA), and plasma glucose levels.

Results: Adipo-R1 mRNA levels tended to be higher in peripheral monocytes from CAD patients (IGT and DM2) compared to controls (Table), while adipo-R2 mRNA levels tended to be lower in CAD compared to controls. Both adipo-R1 and adipo-R2 protein levels tended to be lower in CAD patients compared to controls (Table). The adipo-R1/adipo-R2 protein ratio levels correlated positively with fasting and 2 hour post-OGTT glucose levels ($r=0.587$, $p=0.017$ and $r=0.535$, $p=0.033$, respectively) and HOMA-IR index ($r=0.532$, $p=0.034$), while adipo-R2 protein levels correlated negatively with HOMA-IR ($r=-0.629$, $p=0.009$). (Tab. 1)

Conclusion: The reduced adipo-R2 mRNA and protein levels in CAD- (either IGT or DM2) patients compared to controls-IGT subjects, suggests that adiponectin receptor 2 regulation, possibly, is influenced by the elevated insulin and glucose levels observed in these conditions. This impaired adiponectin signaling which occurs in the peripheral monocytes of the above patients, could possibly contribute to their atherogenicity and their insulin resistance.

Expression of adiponectin receptors in a model of insulin-resistance and type 2 diabetes: the diabetic Zucker ratC. Metais¹, F. Forcheron¹, P. Del Carmine², G. Bricca¹, M. Beylot¹;¹Agressions vasculaires et réponses tissulaires, INSERM ERI 22,²Faculté Rockefeller, ANIPHY, Lyon, France.

Background and Aims: Adiponectin secreted by adipocytes has effects on glucose and lipid metabolism. Its expression is reduced in obesity and diabetes. Adiponectin reverses insulin-resistance in rodent models of type 2 diabetes. Therefore, it improves insulin sensitivity and has protective effects against the development of insulin-resistance and type 2 diabetes. Adiponectin exerts its metabolic effects via two receptors: AdipoR1 and AdipoR2 that have been cloned and characterized. They are expressed in liver, adipose tissue, skeletal muscle, macrophages and pancreatic beta cells. In addition to a decrease in the circulating levels of adiponectin, a decrease in the expression of adipoRs in target tissues could play a role in the development of type 2 diabetes. Actually, the expression of AdipoRs was found reduced in insulin-resistant and type 2 diabetic mice. A therapeutic strategy for the treatment of type 2 diabetes may include the up-regulation of AdipoRs. This could be achieved by metformin, known to improve insulin sensitivity, or fenofibrate, used in the treatment of hyperlipidemia. The aims of this study were 1) to investigate the expression of adipoRs in diabetic Zucker rats in three insulin-dependent tissues: white adipose tissue (WAT), skeletal muscle and liver 2) to test the effect of fenofibrate and metformin on the expression of adipoRs.

Materials and Methods: We studied 4 groups of animals, all receiving a high fat diet: lean Zucker Rats (+/+) n=15, diabetic Zucker Rats (fa/fa) n=15, diabetic Zucker Rats (fa/fa) treated by fenofibrate n=10 and diabetic Zucker Rats (fa/fa) treated by metformin n=10. The expression of adipoRs was studied at 7 weeks of age (insulin-resistance), 14 weeks of age (type 2 diabetes) and 21 weeks of age (type 2 diabetes with insulin deficiency). Liver, skeletal muscle and adipose tissue (peri-renal) samples were collected in anesthetized rats (post-absorptive state). The expression of adipoRs was appreciated by the measurement of their mRNA concentrations (real time PCR).

Results: 1) There was a trend for a decrease in AdipoR1/R2 expression with age in WAT and liver of Lean rats. 2) We found no decrease in the expression of adipoRs in the diabetic Zucker rat in any of the three tissues studied, either in 7 weeks, nor in 14 or 21 weeks old rats. There was on the contrary a trend for higher mRNA concentrations of AdipoR1 and R2 in WAT of diabetic Zucker rats. 3) fenofibrate increased significantly ($p<0,001$) the expression of adipoRs in the liver of the type 2 diabetic Zucker rats (14 weeks), no changes were found in the skeletal muscle and in WAT, 4) metformin increased significantly ($p<0,001$) the expression of adipoRs in the skeletal muscle of the type 2 diabetic Zucker rats (14 weeks) and type 2 diabetic Zucker rats with insulin deficiency (21 weeks); metformin had no action on AdipoRs in the liver and in WAT.

Conclusion: We found no reduction in the expression of adiponectin receptors in this genetic model of type 2 diabetes. Our results do not support a role for decreased expression of adipoRs in the development of insulin-resistance and type 2 diabetes, contrary to what was observed in type 2 diabetic mice. However, fenofibrate and metformin increased the expression of adipoRs in the liver and in the skeletal muscle, respectively, of the diabetic Zucker rats. This could contribute to the beneficial actions of fenofibrate and metformin in the treatment of type 2 diabetes.

0605

Circulating high-molecular weight adiponectin is a strong determinant of ectopic fat in liver and skeletal muscle in humansK. Kantartzis¹, H. Staiger¹, J. Machann², F. Schick², F. Machicao¹, A. Fritsche¹, H.-U. Häring¹, N. Stefan¹;¹Department of Internal Medicine,²Section of Experimental Radiology, University of Tübingen, Germany.

Background and Aims: The adipokine adiponectin increases lipid oxidation in muscle and liver and has insulin-sensitizing and anti-inflammatory properties. Adiponectin circulates in several multimeric forms in human plasma, i.e. trimeric low molecular weight (LMW), hexameric middle molecular weight (MMW) as well as more complex high molecular weight (HMW) structures. Of the higher-ordered structures predominantly the HMW form is considered to have bioactivity. Accordingly, among all

multimeric forms of adiponectin, low circulating HMW adiponectin was found to be the major determinant of insulin resistance, an atherogenic lipoprotein profile, and the metabolic syndrome. However, in a recent study these relationships could not be confirmed. Thus, it is still unsolved whether HMW adiponectin is a more sensitive marker of glucose and lipid metabolism than total adiponectin.

Materials and Methods: In the present study we addressed this issue in 54 subjects without type 2 diabetes applying state of the art measurements. Ectopic fat in liver and skeletal muscle were quantified by localized proton magnetic resonance spectroscopy and insulin sensitivity was determined during a euglycemic hyperinsulinemic clamp. Total-, HMW-, MMW- and LMW adiponectin were quantified using an enzyme immunoassay (ALPCO Diagnostics, Salem, NH, USA).

Results: High-density lipoprotein cholesterol levels, adjusted for age, gender and body fat correlated positively with circulating total- ($r=0.37$, $p=0.006$) and HMW- ($r=0.39$, $p=0.005$) adiponectin, but not with MMW- or LMW adiponectin (both $p>0.08$). Adjusted insulin sensitivity also correlated positively with circulating total- ($r=0.39$, $p=0.004$) and HMW ($r=0.31$, $p=0.02$) adiponectin, while no correlations of insulin sensitivity with MMW- or LMW adiponectin were found (both $p>0.13$). Only adjusted circulating HMW adiponectin ($r=-0.32$, $p=0.03$), but not adjusted total-MMW or LMW adiponectin (all $p>0.12$) correlated with intramyocellular lipids in the tibialis anterior muscle in this group of subjects. In addition, adjusted liver fat significantly correlated with HMW adiponectin ($r=-0.35$, $p=0.01$), while only a non significant relationship of liver fat with total- ($r=-0.26$, $p=0.06$), and no associations with MMW- and LMW adiponectin (both $p>0.70$) were observed. Moreover, when subjects were divided into a group with fatty liver (liver fat>5.5%, n=15) and controls (n=39), HMW adiponectin displayed a larger area under the receiver operating characteristic curve (0.77) than total adiponectin (0.73) to predict fatty liver disease.

Conclusion: We provide novel data showing that HMW adiponectin has a higher predictive power than total adiponectin to determine ectopic fat deposition in liver and skeletal muscle in humans.

Upregulation of HMW adiponectin in visceral adipose tissue by pioglitazone associates with amelioration of insulin resistance syndrome in obese rats

J. Pita, A. Panadero, M. Gonzalo, J. Lara, O. Sanchez-Vilar, A. Rovira; Laboratory of endocrinology, Fundación Jiménez Díaz – Capio, Madrid, Spain.

Background and Aims: Adiponectin is an insulin-sensitizing hormone produced by adipocytes with anti-inflammatory properties which is reduced in insulin resistance states like obesity and type 2 diabetes. Adiponectin exists as truncated form (LMW adiponectin) and as a group of complexes or full-length adiponectin (MMW and HMW adiponectin). Some studies suggest that among the circulating forms, HMW is the best indicator of insulin sensitivity during the treatment with PPAR- γ agonists in human and in mice. Furthermore, they suggest that the HMW form could be the bioactive form of adiponectin responsible for the level of insulin sensitivity. Pioglitazone is a PPAR- γ agonist that improves insulin resistance and upregulates adiponectin levels in plasma and adipose tissue. It has been proposed that adiponectin upregulation could be the mechanism used by PPAR- γ agonists to improve insulin resistance linked to obesity. The aim of this study is to know if there is a different regulation of the adiponectin forms by pioglitazone in fatty Zucker rats, an animal model that associates extreme obesity, insulin resistance and dysregulation of lipidic metabolism.

Materials and Methods: Fatty Zucker rats were treated with pioglitazone (3mg/kg/d, n=10) or placebo (n=10) for 12 weeks. Blood was collected weekly, and at the end of the treatment rats were sacrificed by intraperitoneal injection of sodium penthotal. Blood, visceral (VAT) and subcutaneous (SAT) adipose tissue were collected. Measurements of adiponectin complexes: western-blot analysis were performed in plasma and adipose tissue. Equal amounts of protein, 25 μ g, were subjected to electrophoresis in 4–15% gradient polyacrylamide gels (SDS-PAGE) and immunoblotting-SDS-PAGE under non-reducing and non-denaturising conditions.

Results: Compared to placebo, rats treated with pioglitazone had a significant increase ($p<0.01$) of the HMW form of adiponectin in plasma (1.03 ± 0.06 vs

1.43±0.08 a.u., mean±SE) and in VAT (1.28±0.13 vs 3.06±0.34 a.u.) but not in SAT (2.49±0.36 vs 3.54±0.39 a.u., $p=0.087$).

No changes were found in the MMW adiponectin in plasma or in adipose tissue after the pioglitazone treatment. We studied the correlations between the molecular forms of adiponectin and other features that ameliorated with the pioglitazone treatment, such as, plasma insulin, HOMA, plasma cholesterol and plasma triglycerides. VAT HMW adiponectin significantly correlated with these measurements and plasma HMW adiponectin correlated with plasma insulin and plasma triglycerides. No correlations between the remaining adiponectin forms (HMW form of SAT and MMW form of plasma, VAT and SAT) and the different markers were observed.

Conclusion: HMW adiponectin seems to be upregulated by pioglitazone in visceral adipose tissue from fatty Zucker rats. The increase in the HMW form correlates with the amelioration of metabolic features and insulin resistance observed after the treatment, supporting a role of this form in the insulin sensitivity effects of pioglitazone.

Globular adiponectin activates nuclear factor- κ B and activating protein-1 and enhances angiotensin II-induced proliferation in cardiac fibroblasts

S. Hattori, Y. Hattori, K. Suzuki, K. Kasai;
Endocrinology and Metabolism, Dokkyo University School of Medicine, Mibu, Japan.

Adiponectin is present in the serum as a trimer, hexamer, or high molecular weight form. A proteolytic cleavage product of adiponectin, known as globular adiponectin (gAd), also circulates in human plasma. The biologic activities of these isoforms are not well characterized. Pressure overload in adiponectin-deficient mice results in enhanced concentric cardiac hypertrophy and increased mortality, suggesting that adiponectin inhibits hypertrophic signaling in the myocardium. Therefore, we examined whether gAd exerts the same effects on myocardium signaling. Nuclear factor (NF)- κ B and activating protein (AP)-1 activation were examined using cardiac fibroblasts prepared from the ventricles of 1- to 2-day-old Wistar rats and grown in culture. Globular adiponectin activated NF- κ B and enhanced tumor necrosis factor α -induced NF- κ B activity. Globular adiponectin also activated AP-1 and enhanced angiotensin II-induced AP-1 activity. Globular adiponectin induced mRNA expression of *c-fos* and *c-jun* and activated extracellular signal regulated kinase. Thus, gAd enhanced angiotensin II-induced DNA and collagen synthesis. Antibodies against adiponectin receptors (AdipoR1 and AdipoR2) elicit activation of NF- κ B or AP-1, two redox-sensitive transcription factors. Thus, rather than having an anti-hypertrophic effect, gAd might contribute to the activation of myocardium signalling, leading to myocardial hypertrophy.

Insulin action in adipose tissue and skeletal muscle in obesity

P. I. Mitrou¹, G. Dimitriadis¹, V. Lambadiari¹, E. Boutati¹, E. Maratou², A. Papakonstantinou³, V. Komesidou⁴, T. Economopoulos¹, S. A. Raptis^{1,2};
¹2nd Department of Internal Medicine and Research Institute, Athens University Medical School, ²Hellenic National Diabetes Center, Attikon University Hospital, ³1st Department of Surgery, Evangelismos Hospital, ⁴Department of Nutrition, Evangelismos Hospital, Athens, Greece.

Background and Aims: Although whole body insulin resistance in obesity is well documented, information on insulin action in vivo in peripheral tissues, especially adipose tissue, is limited. This study was undertaken in obese subjects to investigate insulin action on (a) glucose disposal and (b) lipolysis, in skeletal muscle and adipose tissue (AD) after ingestion of a mixed meal.

Materials and Methods: A mixed meal was given to 30 obese (OB, age 34±1yrs, BMI 47±1kg/m²) and 10 non-obese subjects (NOB, age 39±4yrs, BMI 23±1kg/m²). Plasma samples for measurements of glucose (G), insulin (I), triglycerides (TAG) and non-esterified fatty acids (NEFA) were taken for 360min from veins (V) draining the anterior abdominal subcutaneous AD depot and forearm muscle (M) and from the radial artery (A). With each sample blood flow (BF) was measured in AD with ¹³³Xe and in M with strain-gauge plethysmography. Calculations: Glucose flux: [G_(A-V)]x[BF]; Glucose fractional extraction: [G_(A-V)]/[G_(A)]; LPL: [TAG_{(A-V)]x[BF]; Hormone sensitive lipase (HSL): [GLY_{(V-A)]x(BF)]-[LPL].}}

Results: Postprandial changes (area under curve 0–360min) in OB vs NOB: (1) Arterial G was not different (2173±73 vs 2040±40mMmin), but I was increased (23578±2372 vs 10331±608mU/Lmin, $p<0.05$). (2) BF was decreased (1106±78 vs 1589±129ml/100ml tissue in M and 657±48 vs 1345±102ml/100ml tissue in AD, $p<0.05$). (3) Glucose flux was decreased in both tissues (339±54 vs 826±157μmol/100ml tissue in M and 164±45 vs 320±91μmol/100ml tissue in AD, $p<0.05$). (4) Fractional glucose uptake (which is independent of BF) was decreased in M (20±3 vs 33±5%/per min, $p<0.05$), but was not different in AD (12±3 vs 13±5%/per min). (5) Arterial NEFA (166±16 vs 97±11nmol/Lmin, $p<0.05$) and TAG (501±37 vs 260±32nmol/Lmin, $p<0.05$) were increased. (6) In AD, HSL was increased (16±2 vs 7±4pmol_{glycerol}/Lmin, $p<0.05$), and LPL was decreased (5±2 vs 80±31pmol_{glycerol}/Lmin, $p<0.05$).

Conclusion: In obesity: (a) the sensitivity of glucose metabolism to insulin is impaired in both M (because of defects in insulin-stimulated glucose utilization and decreased blood flow) and in AD (because of decreased blood flow); (b) in adipose tissue, impaired suppression of HSL and activation of LPL result in increased lipolysis and impaired TAG clearance, postprandially; this may increase the risk of cardiovascular disease.

0609

Weight loss resulting from bariatric surgery in morbidly obese insulin resistant individuals leads to improvements in insulin signaling

M. Z. Chen¹, C. A. Hudson², E. E. Vincent², C. M. Dayan³, D. DeBerker⁴, J. M. Tavaré², R. C. Andrews¹;

¹Joint Clinical Research Unit, Bristol Royal Infirmary, ²Department of Biochemistry, University of Bristol, ³Henry Wellcome Laboratories for Integrative Neuroscience & Endocrinology, University of Bristol, ⁴Department of Dermatology, Bristol Royal Infirmary, United Kingdom.

Background and Aims: Insulin resistance (IR), worsened by weight gain, plays a major role in the pathogenesis of Type 2 Diabetes. Although the exact mechanism is not known, a likely explanation is that the decreased insulin-stimulated glucose-uptake results from abnormalities in insulin signalling. In this study we have used the hyperinsulinaemic euglycaemic (HE) clamp method to compare in vivo glucose disposal rates (GDR) with insulin signalling in lean (C) and obese (OB) individuals, and within the OB before and after bariatric surgery.

Materials and Methods: Six C and four OB healthy volunteers participated in this study. The C were aged 28.7±3.9 (mean±SE), had a body mass index (BMI) of 19.8±0.4 kg/m² and were on no medication. The OB were aged 48.5±4.6, had BMI of 49.4±2.2 kg/m² with 2 of them having diabetes. Written consent was obtained from all participants.

All attended for a 10-hour HE “long” clamp, where insulin infusion was increased in a stepwise fashion every 2 hours (0.2, 0.5, 1, 2 and 5 mU/kg/min) with blood glucose maintained at 5mmol/l by simultaneous glucose infusion. An insulin response curve was constructed using GDR established in the last 30 minutes, during steady state, of each insulin rate, and used to calculate the insulin concentrations needed to induce half-maximum (ED50) and maximum (ED100) effects on glucose disposal. At the next visit, volunteers attended a 3-hour HE “short” clamp, when muscle biopsies were taken at baseline, and at the ED50 and ED100 insulin doses noted above. All muscle biopsies were examined for insulin-stimulated phosphorylation of PKB and PRAS-40, a potential biomarker of *in vivo* PKB activity. Both long and short clamp visits were repeated for the OB group after surgery.

Results: OB were substantially more IR than C, with their glucose disposal curve shifted to the right; as demonstrated by an increased ED50 (126±43 vs 27±2 mIU/L, $p<0.05$) and reduced ED100 (793±58 vs 384±15 mIU/L, $p<0.05$). Insulin-stimulated phosphorylation of PKB and PRAS40 were not significantly different between the two groups.

Post-surgery, mean weight loss was 34±7.4 kg ($p<0.01$) in the OB and affected subjects were able to reduce their diabetes medication. IR improved with the glucose disposal curve shifted to the left and an improvement in ED50 (75±14 vs 126±43, $p<0.05$). Despite the major weight loss, no significant change in ED100 (709±102 vs 793±58, $p=0.17$) was observed. Surprisingly, we found that there was a significant increase in the sensitivity of both PKB and PRAS40 phosphorylation to insulin, particularly at physiologically relevant serum insulin concentrations.

Conclusion: These findings suggest that the IR seen in OB as compared to C cannot be explained simply by reduced phosphorylation and activation of PKB. However, upon rapid weight loss the fact that improvements in insulin sensitivity occur in parallel with an improvement in PKB signalling, suggests that this pathway may be important in modulating acute responses to weight changes. Thus this signalling pathway may represent a therapeutic target for intervention in morbid obesity.

Intralipid dramatically reduces access of insulin to its target tissue

J. D. Chiu¹, C. Kolka¹, J. M. Richey¹, L. N. Harrison¹, E. Zuniga¹, E. Kirkman¹, M. Ellmerer², R. N. Bergman¹;

¹Physiology and Biophysics, Keck School of Medicine, Los Angeles, United States, ²Internal Medicine, Medical University Graz, Austria.

Background and Aims: Insulin action on skeletal muscle cells includes 1)delivery of insulin to the target tissue via transendothelial transport, 2)diffusion through interstitium, 3)binding to cells, 4)insulin signaling, and 5)transporter mobilization. Several groups have focused on the effect of hyperlipidemia with intralipid to inhibit insulin signaling at the muscle cell, but less on access of insulin to sensitive tissues. The present study was undertaken to determine whether intralipid-induced resistance is a result of limited insulin transport to skeletal muscle.

Materials and Methods: We injected insulin into muscle interstitium directly and examined interstitial insulin levels (lymph) and glucose uptake (GU, a-v difference) w/ or w/o intralipid. Basal insulin euglycemic clamps (0.2mU/min/kg) were done on anesthetized dogs (n=14). The control group (CON, n=10, 31.3±3 kg) received 5 sequential insulin doses (D1 to D5: 0.3, 0.5, 0.7, 1, 3U) with a 30g needle directly into the interstitial space of the v. medialis of one hindleg. The intralipid group (INL, n=4, 31.2±1kg) received the same injections, after 240 min infusion of intralipid/heparin (20% fat emulsion at 1.5mL/min).

Results: Intralipid caused insulin resistance (max. glucose infusion rate, GINF = 2.2±1 v. CON GINF = 5.4±1mg/min/kg; $p<0.05$). Interstitial insulin in CON increased with each insulin injection (D1: +28±6, D2: +139±7, D3: +237±12, D4: +345±13, D5: +389±13pM, $p<0.001$). Surprisingly, systemic infusion of intralipid totally prevented the increase in interstitial insulin after intramuscular injection of insulin: (D1: +0.7±5, D2: -0.5±7, D3: +0.7±7, D4: +1.3±8, D5: +4±14pM, $P<0.001$ compared to CON). That intramuscular insulin was diverted into the capillary circulation was evidenced by elevated hindlimb venous insulin when intralipid was present (CON v. INL; D1: 35±4 v. 86±19; D2: 71±4 v. 255±5; D3: 97±4 v. 260±32; D4: 99±6 v. 290±57; D5: 176±9 v. 460±109pM; $p<0.001$). Average GU across the limb without intralipid was increased with each insulin dose, but we observed little increase

with intralipid (CON: 13±4 v. INL: 6±2mg/min/leg; INL n=2). With systemic intralipid infusion, there was no apparent increase in interstitial (lymph) insulin and no measurable increase in local GU.

Conclusion: Intralipid's acute induction of resistance may relate to decreased availability of insulin in the interstitial space of skeletal muscle. With intralipid, it appears that insulin rapidly exits through the capillaries to the venous system to be redistributed systemically. Shunting of insulin away from insulin sensitive tissues may play a role in insulin resistance during FFA elevations during obesity or diabetes.

Tissue specificity of insulin resistance in humans: fat in the liver rather than in the muscle associates with features of the metabolic syndrome

A. Kotronen^{1,2}, A. Seppala-Lindroos¹, R. Bergholm¹, H. Yki-Jarvinen¹;

¹Department of Medicine, University of Helsinki, ²Department of Medicine, Minerva Medical Research Institute, Helsinki, Finland.

Background and Aims: We determined how intrahepatic as compared to intramyocellular fat are related to features of the metabolic syndrome (MetS) and insulin resistance in the liver and muscle.

Materials and Methods: Hepatic (insulin infusion rate 0.3 mU/kg-min combined with [^{3-³H}]glucose) and muscle (1.0 mU/kg-min) insulin sensitivity were measured in 45 non-diabetic men (age 42±1 yrs, BMI 26.2±0.6 kg/m²) on two separate occasions by euglycemic hyperinsulinemic clamp. Liver fat (LFAT) and intramyocellular lipid (IMCL) were measured by ¹H-MR spectroscopy. In addition, serum FFA concentrations during the 0.3 mU/kg-min insulin clamp, fasting serum insulin and adiponectin, components of the metabolic syndrome, and VO₂max were determined.

Results: Serum triglycerides (1.0±0.1 vs. 1.6±0.2 mmol/l, $p=0.002$) and fS-insulin (5.3±0.4 vs. 9.2±0.7 mU/l, $p<0.0001$) were significantly higher, and S-HDL cholesterol (1.48±0.1 vs. 1.26±0.1 mmol/l, $p=0.02$) and fS-adiponectin (12.2±1.2 vs. 9.5±1.2 ug/ml, $p=0.05$) significantly lower when the subjects were divided into low (median 2.0% [interquartile range 1.0–2.0%]) as compared to high (12.0% [5.7–18.5%]) LFAT groups. When divided into groups with low (5.0% [2.3–7.5%]) as compared to high (19.5% [16.0–26.0%]) IMCL, the groups were comparable with respect to all these parameters. In addition, liver fat content did not differ between the IMCL groups. Liver fat was significantly higher in subjects with (10.9±2.0%) than without (5.3±1.1%, $p=0.017$) the MetS. In contrast, IMCL was similar in subjects with and without the MetS. Insulin suppression of glucose R_a (79% [51–120%] vs. 97% [75–129%]) during 300–360 min, high vs. low LFAT group, $p=0.05$) and of serum FFA were impaired in the high LFAT group, as was muscle insulin sensitivity (4.18±0.38 vs. 6.26±0.39 mg/kg FFM · min; $p=0.0008$). In the IMCL groups, only insulin suppression of serum FFA concentrations was impaired in the high as compared to the low IMCL group.

Conclusion: Fat accumulation in the liver rather than in the skeletal muscle is associated with features of the metabolic syndrome and insulin resistance both in the liver and muscle.

Metabolic MR imaging of human myocardial lipotoxicity

R. W. van der Meer¹, S. Hammer², J. W. A. Smit², M. Frölich³, J. J. Bax⁴, M. Diamant⁵, L. J. Rijzewijk⁵, A. De Roos¹, H. J. Lamb¹, J. A. Romijn²;

¹Radiology, Leiden University Medical Center, ²Endocrinology, Leiden University Medical Center, ³Clinical Chemistry, Leiden University Medical Center, ⁴Cardiology, Leiden University Medical Center, ⁵Endocrinology, VU University Medical Center, Amsterdam, The Netherlands.

Background and Aims: Type 2 diabetes mellitus (DM2) and obesity are associated with increased plasma non-esterified fatty acid (NEFA) levels and

myocardial dysfunction. Using a very low calorie diet (VLCD) to increase plasma NEFA levels we studied the relation between plasma NEFA levels and myocardial lipid and high-energy-phosphate metabolism and cardiac function in healthy subjects.

Materials and Methods: Fourteen healthy non-obese men underwent ^1H -magnetic resonance spectroscopy (MRS) to determine myocardial and hepatic triglyceride content (%TG), ^{31}P -MRS to assess myocardial high-energy-phosphate metabolism (PCr/ATP), and functional MR imaging of the heart at baseline and after a 3-day VLCD.

Results: After the diet-intervention, plasma NEFA levels increased significantly when compared to baseline (from 0.5 ± 0.1 to 1.1 ± 0.1 mmol/l, $p < 0.05$). In addition, myocardial %TG increased significantly when compared to baseline (from 0.38 ± 0.05 to $0.59 \pm 0.06\%$, $p < 0.05$), whereas hepatic %TG decreased significantly during the VLCD as compared to baseline (from 2.2 ± 0.5 to $1.5 \pm 0.4\%$, $p < 0.05$). In addition, the difference in myocardial %TG between the VLCD and baseline in the myocardium was negatively correlated to the difference of the %TG between the VLCD and baseline in the liver (Pearson $r = -0.61$, $p < 0.05$). The VLCD did not change myocardial PCr/ATP (2.33 ± 0.15 vs. 2.33 ± 0.08 , $p > 0.05$) or left ventricular systolic function. Interestingly, deceleration of the early diastolic flow across the mitral valve decreased significantly after the VLCD as compared to baseline (from 3.37 ± 0.20 to 2.91 ± 0.16 ml/s $^2 \times 10^{-3}$, $p < 0.05$). This change in diastolic function was significantly correlated with the increase in myocardial %TG after the VLCD (Pearson $r = -0.55$, $p < 0.05$).

Conclusion: Short-term VLCD induces accumulation of myocardial triglycerides which is associated with altered left ventricular diastolic function, but has no impact on myocardial high-energy-phosphate metabolism. Furthermore, short term caloric restriction exerts differential tissue specific effects on triglyceride contents. These observations stress the physiological flexibility of ectopic triglyceride pools.

Increased epicardial fat and impaired left ventricular energy metabolism in young men with newly found fatty liver

G. Perseghin¹, G. Lattuada², F. De Cobelli³, A. Esposito³, E. Belloni³, F. Ragona², T. Canu³, P. Scifo⁴, A. Del Maschio⁵, L. Luzi¹;

¹Internal Medicine, Università degli Studi di Milano, Faculty of Exercise Sciences, Milano, ²Internal Medicine, Istituto Scientifico H San Raffaele, Milano, ³Diagnostic Radiology, Istituto Scientifico H San Raffaele, Milano, ⁴Nuclear Medicine, Istituto Scientifico H San Raffaele, Milano, ⁵Diagnostic Radiology, Università Vita e Salute San Raffaele, Milano, Italy.

Background and Aims: Fatty liver is characterized by metabolic abnormalities at the liver, but also at the skeletal muscle and adipose tissue sites. It is hypothesized that also the heart may be suffering metabolic alterations and this study was undertaken to ascertain whether individuals with fatty liver have left ventricular (LV) alterations of energy metabolism, structure and function and abnormal amount of epicardial fat as a specific marker of visceral fat accumulation.

Materials and Methods: To this end we studied young, non-diabetic men matched for anthropometric features with (n=21) or without (n=21) fatty liver by means of 1) cardiac magnetic resonance imaging (MRI) 2) cardiac ^{31}P -MR spectroscopy (MRS) and 3) hepatic ^1H -MRS to assess quantitatively the IHF content. Insulin sensitivity was determined by the updated HOMA-2 computer model.

Results: Individuals with fatty liver showed reduced insulin sensitivity, increased serum FFA and E-selectin, abnormal adipokines concentrations and higher blood pressure. LV morphology, systolic and diastolic functions were not different but in the scanned intra-thoracic region, the intrapericardial (7.8 ± 3.1 vs. 5.9 ± 2.5 cm 2 ; $P < 0.05$) and extrapericardial (11.7 ± 6.1 vs. 7.8 ± 3.2 cm 2 ; $P < 0.03$) fat was increased in men with fatty liver compared to those without fatty liver. The phosphocreatine (PCr)/ATP ratio, a recognized *in vivo* marker of myocardial energy metabolism, was reduced in men with fatty liver in comparison with normals (1.85 ± 0.35 vs. 2.11 ± 0.31 ; $P < 0.016$).

Conclusion: In newly found individuals with fatty liver, fat was accumulated in the epicardial area and despite of normal LV morphologic features and systolic and diastolic functions, they had abnormal LV energy metabolism.

Serum soluble E-selectin concentration in relation to the whole-body insulin resistance and carbohydrate and lipid oxidation in lean and obese women

M. Straczkowski, I. Kowalska, A. Adamska, A. Nikolajuk, M. Karczewska-Kupczewska, M. Karolczuk-Zarachowicz, M. Gorska; Department of Endocrinology, Diabetology and Internal Medicine, Medical University of Białystok, Poland.

Background and Aims: Markers of endothelial dysfunction, including soluble E-selectin (sE-selectin), are related to insulin resistance and are independent predictors of type 2 diabetes. The explanation of these associations remains unclear. Insulin resistance might be related to the so-called metabolic inflexibility, i.e. to an impaired stimulation of carbohydrate oxidation and an impaired inhibition of lipid oxidation by insulin. The aim of the present study was to estimate the relationships of serum sE-selectin concentration with carbohydrate and lipid oxidation in the baseline state and during hyperinsulinemia in apparently healthy lean and obese women.

Materials and Methods: The study group consisted of 76 apparently healthy women with NGT: 30 lean and 46 with overweight or obesity. Insulin sensitivity was evaluated with the euglycemic hyperinsulinemic clamp. Carbohydrate and lipid oxidation was studied with indirect calorimetry within two 30-minute periods: in the baseline state and during the last 30 minutes of the clamp.

Results: Obese women had lower insulin sensitivity ($p = 0.0057$) and higher serum sE-selectin concentration ($p = 0.046$). In the obese group, carbohydrate oxidation was increased in the baseline state ($p = 0.022$) and decreased during hyperinsulinemia ($p = 0.032$) in comparison to the lean controls. Lipid oxidation during hyperinsulinemia was higher in the obese in comparison to the lean group ($p = 0.00028$). Obese women had also a lower increase in carbohydrate oxidation ($p = 0.0014$) and a lower decrease in lipid oxidation ($p = 0.021$) in response to hyperinsulinemia. Serum sE-selectin concentration was negatively related to insulin sensitivity ($r = -0.30$, $p = 0.009$). Serum sE-selectin concentration was positively associated with carbohydrate oxidation in the baseline state ($r = 0.31$, $p = 0.007$) and negatively related to carbohydrate oxidation ($r = -0.27$, $p = 0.018$) and positively – to lipid oxidation ($r = 0.29$, $p = 0.011$) during hyperinsulinemia. Additionally, higher serum sE-selectin concentration was associated with a lower increase in carbohydrate oxidation ($r = -0.41$, $p < 0.001$) and a lower decrease in lipid oxidation ($r = 0.30$, $p = 0.008$) in response to hyperinsulinemia.

Conclusion: Serum sE-selectin concentration is associated with both carbohydrate and lipid oxidation. Higher serum sE-selectin concentration might be linked to the metabolic inflexibility of obesity and insulin resistance.

Differential impact of fatness, fitness and physical activity energy expenditure on whole body, liver and fat insulin sensitivity

C. D. T. Byrne¹, H. B. Holt¹, S. H. Wild², N. Wareham³, U. Ekelund³, M. Umpleby⁴, F. Shojaae-Moradie⁴, R. I. G. Holt¹, D. I. Phillips⁵; ¹Endocrinology and Metabolism, University of Southampton, ²Public Health Sciences, University of Edinburgh, ³MRC Epidemiology Unit, MRC Epidemiology Unit, Cambridge, ⁴Diabetes and Endocrinology, Wolfson Centre for Translational Research, University of Surrey, ⁵MRC Resource Centre, MRC Resource Centre, Southampton, United Kingdom.

Background and Aims: The relative contribution of fitness (maximal oxygen uptake, VO₂ max), physical activity energy expenditure (PAEE) and fatness to influence whole body, liver and fat insulin sensitivity is uncertain. The aim of this study was to determine whether fatness, fitness and PAEE were independently associated with whole body, liver and fat insulin sensitivity in men.

Materials and Methods: 25 men (mean [SD] age 53 [6] years) were recruited. With a hyperinsulinaemic, euglycaemic clamp, whole body (M value) and liver (percentage suppression endogenous glucose output) insulin sensitivity were estimated. During an OGTT, insulin sensitivity in fat (insulin sensitivity index for non-esterified fatty acids, [ISI-NEFA]), was estimated. Total and truncal fat were measured by DEXA (dual X-ray absorptiometry), fitness by treadmill and PAEE by three day heart rate monitoring and by Baecke physical activity questionnaire.

Results: In univariate analyses, fitness was associated with whole body, liver and fat insulin sensitivity. PAEE was associated with insulin sensitivity in liver and fat but not whole body insulin sensitivity. Regression models that included PAEE, VO₂ max and fatness as explanatory variables were established to describe associations with the various measures of insulin sensitivity (whole body, fat and liver). Only fatness was independently associated with whole body insulin sensitivity (B coefficient -0.96, p<0.001) and fat insulin sensitivity (B coefficient -1.6 x 10⁻⁵, p=0.004). In contrast only PAEE was independently associated with liver insulin sensitivity (B coefficient 28.4, p=0.03).

Conclusion: These data show for the first time that PAEE, including more vigorous physical activity explains most of the variance in liver insulin sensitivity. In contrast, fatness explains most of the variance in whole body and fat insulin sensitivity.

Evidence that the transaldolase reaction and/or isotope effect at the triose-P-isomerase step occurs in humans: implications for measurement of gluconeogenesis and glucose turnover

G. Bock^{1,2}, R. Basu², S. C. Burgess³, W. C. Schumann⁴, V. Chandramouli⁴, R. A. Rizza², B. R. Landau⁴;

¹Department of Internal Medicine, Division of Diabetes and Metabolism, Medical University Graz, Austria, ²Division of Endocrinology, Metabolism, Diabetes and Nutrition, Mayo Clinic, Rochester, United States, ³Department of Radiology, University of Texas Southwest, Dallas, United States, ⁴Department of Medicine, Case Western Reserve University, Cleveland, United States.

Background: Measurement of gluconeogenesis by the 2H2O method assumes that carbon 5 of glucose becomes labeled with 2H during gluconeogenesis whereas carbon 2 becomes labeled with 2H during both glycogenolysis and gluconeogenesis. Therefore the C5/C2 deuterium enrichment ratio provides the fraction of circulating glucose derived from gluconeogenesis. To the extent that other factors besides gluconeogenesis contribute to C5 enrichment, the 2H2O method would provide an over estimate of gluconeogenesis.

Methods: To determine if C5 enrichment can be influenced by processes other than gluconeogenesis, non-diabetic obese subjects were infused with [3,5-2H₂] glucose and insulin (0.5 mU/kg/min) while glucose was clamped at ~5 mmol/L. Protons on C3 and C5 should exchange with body water at identical rates if the triose-P-isomerase step in gluconeogenesis is the only pathway responsible for this exchange. Deuterium enrichment of C3 and C5 of hepatic

UDP-glucose was measured by NMR analysis of urinary glucuronide under basal and clamp conditions.

Results: The C5/C3 deuterium enrichment ratio in the infusate was confirmed to be 1.0, but the C5/C3 ratio in the UDP glucose pool measured in 4 subjects prior to insulin infusion averaged 0.75±0.07 and in six subjects during insulin infusion averaged 0.67±0.05. This data indicates that the deuterium on C5 of UDP-glucose is lost more rapidly than the deuterium on C3 in all subjects. This divergence might occur by either selective loss of the C5 deuterium, which occurs when carbons of glucose are exchanged with unlabeled three carbon precursors during the transaldolase reaction of the pentose phosphate pathway, and/or slower removal of the C3 deuterium compared to the C5 deuterium (i.e. an isotope effect) at the level of the triose-P-isomerase reaction followed by resynthesis of glucose from the resultant selectively enriched three carbon precursors.

Conclusion: These data are consistent with loss of C5 enrichment by transaldolase activity, a 2H isotope effect in the gluconeogenic pathway or both in humans. The extent to which these processes introduce error in the 2H2O method or whether the magnitude of the error differs in various disease states (e.g. diabetes and obesity) when the 2H2O method is used to measure gluconeogenesis or [3-3H] glucose is used to measure glucose turnover needs to be evaluated.

Direct pathway metabolism of [U-d₇]glucose in healthy humans during an oral glucose tolerance test reveals both G6P-isomerase and transaldolase exchanges

T. J. C. Delgado¹, C. Silva², M. Bastos³, C. Baptista³, A. Faguhla³, L. Barros³, M. Carvalheiro³, A. Mota⁴, M. C. A. Castro¹, C. F. G. Geraldes¹, M. Caldeira⁵, C. Barosa², J. G. Jones¹;

¹NMR Research Unit, Dept of Biochemistry, Faculty of Sciences and Technology, Center for Neurosciences and Cell Biology, University of Coimbra, ²Center for Neurosciences and Cell Biology, University of Coimbra, ³Department of Endocrinology and Diabetes, University Hospital of Coimbra, ⁴Department of Urology and Renal Transplantation, University Hospital of Coimbra, ⁵NMR Research Unit, Dept of Chemistry, Faculty of Sciences and Technology, University of Coimbra, Coimbra, Portugal.

Introduction: Hepatic glycogen is synthesized from ingested glucose by direct and indirect pathways. We developed a simple method for quantifying direct and indirect pathway contributions to glycogen synthesis based on the enrichment of positions 5 and 2 of glucuronide from deuterated water. This analysis assumes that: 1) there is complete exchange of G6P and F6P during metabolism of glucose to glycogen, and 2) that the position 5 hydrogen of hexose metabolized via the direct pathway undergoes no exchange with that of body water via transaldolase. The aim of this work was to examine the validity of these assumptions in healthy subjects during an oral glucose tolerance test.

Methods: Four healthy overnight-fasted subjects were given 75 grams of glucose enriched to 3.33% with [U-d₇]glucose. Peppermint oil (200 mg) was ingested 1 hour before and 1 hour after the glucose load. Urine was collected 2-4 hr after the load. Menthol glucuronide was isolated by solid phase extraction and glucuronide positional ²H-enrichment was analyzed by ²H NMR.

On metabolism of [U-d₇]glucose to glycogen via the direct pathway, ²H in position 2 will be lost due to G6P-F6P exchange while ²H in position 3 is retained. Hence, the ratio of enrichment in position 2 relative to position 3 (H2/H3) reflects the extent of G6P-F6P exchange. Transaldolase will exchange carbons 4, 5 and 6 of F6P with a molecule of glyceraldehyde-3-phosphate. This results in a loss of enrichment in position 5 relative to position 3 hence the ratio of enrichment in position 5 relative to position 3 (H5/H3) of glucuronide reflects the extent of transaldolase exchange.

Results & Conclusions: From the relative ²H-signal intensities of glucuronide hydrogens 2 and 3, H2/H3 was 0.17 ± 0.04 indicating that G6P-F6P exchange was largely complete (83 ± 4 %). Glucuronide H5/H3 was 0.81 ± 0.06 indicating that 19 ± 6% of glucose metabolized via the direct pathway underwent transaldolase exchange. This level of transaldolase activity would result in substantial underestimates of the direct pathway contribution to glycogen synthesis using the deuterated water measurement.

Inhibition of glycogen phosphorylase attenuates hepatic glucose disposal in normal and insulin resistant ratsG. Rakipovski^{1,2}, M. W. Jensen², K. E. Pedersen², H. Andersen², J. Breinholt², K. Fosgerau^{1,2};¹Rheoscience A/S, Roedovre, ²Novo Nordisk A/S, Maaloev, Denmark.

Background and Aims: Type 2 diabetes is characterized by an increased hepatic glucose production as well as a decrease in whole body glucose uptake and disposal, which ultimately may lead to the postprandial hyperglycaemia. Accordingly, inhibition of hepatic glucose production by inhibition of glycogen phosphorylase (GP), the controlling enzyme in glycogen breakdown, has been suggested as a possible therapeutic area of development of new anti-hyperglycaemic drugs. Under normal conditions hepatic glycogenolysis and glycogenesis are tightly regulated to ensure no concurrent glycogen synthesis and breakdown. Thus, the active form of glycogen phosphorylase (GP_a) is known as a powerful inhibitor of glycogen synthase (GS), the controlling enzyme of glycogen synthesis. Here we investigated to what extent pharmacological inhibition of hepatic glycogen phosphorylase might affect hepatic glucose utilization in normal and insulin resistant rats.

Materials and Methods: Rats previously fed a normal chow or a high fat diet (HFD) were acutely treated with or without the glycogen phosphorylase inhibitor, 1,4-dideoxy-1,4-imino-D-arabinitol (DAB, 100 mg/kg), and subsequently subjected to an oral glucose tolerance test (OGTT, 2 g/kg). *De novo* glycogen synthesis was determined by nuclear magnetic resonance technique.

Results: As judged by the oral glucose tolerance test, acute inhibition of the liver GP by DAB significantly reduced the whole body glucose clearance both in chow and HFD fed animals. Interestingly the liver glycogen synthase activity ratio was lowered by 2–3 fold by treatment with DAB both in chow and HFD fed rats, thus giving rise to a concomitant decrease in the rate of *de novo* synthesized liver glycogen in DAB treated animals. (Tab. 1)

The table summarizes the Area Under the Curve for glucose (AUC glucose) of the OGTT, the enzyme activity of glycogen synthase (GS_a: activated form of GS, GS_t: total activity of GS) and the rate of liver glycogen synthesis in HFD or chow rats treated with or without DAB and subsequently subjected to a glucose challenge. Data are given as mean ± SE with n = 7 per group. Statistics: Two-way ANOVA; **p < 0.01 or ***p < 0.001 for treatment with DAB, ^p < 0.05 or ^^p < 0.001 for HFD.

Conclusion: Inhibition of liver GP by DAB leads to a decrease in the liver glycogen synthesis and whole body glucose clearance in normal and insulin resistant rats.

0620

Quantification of hepatic transaldolase exchange activity and its effects on tracer measurements of human hepatic glycogen synthesis by direct and indirect pathwaysJ. Jones¹, C. Barosa¹, P. Garcia², T. Delgado³, M. Caldeira⁴, L. Diogo²;¹Dept of Biochemistry, Center for Neurosciences, ²Dept of Metabolic Diseases, Coimbra Pediatric Hospital, ³Dept of Biochemistry, University of Coimbra, ⁴Dept of Chemistry, University of Coimbra, Coimbra, Portugal.

Background and Aims: Exchange of hepatic glucose-6-phosphate (G6P) and glyceraldehyde-3-phosphate via G6P-isomerase and transaldolase (see Figure 1) modifies hepatic G6P enrichment from gluconeogenic tracers independently of gluconeogenic activity. Consequently, the indirect pathway or gluconeogenic contribution to hepatic glycogen synthesis may be overestimated with some current tracer methodologies. 13C-isotopomer

enrichment of the triose units of G6P from gluconeogenic metabolism of [U-13C]glycerol is sensitive to transaldolase exchange and provides a basis for estimating the extent of this activity. Hepatic G6P can be noninvasively sampled in humans as urinary Paracetamol glucuronide following ingestion of Paracetamol.

Materials and Methods: To determine transaldolase exchange activity in human liver, five healthy fed subjects were given an oral bolus of [U-13C]glycerol (25–30 mg/kg) and Paracetamol (10–12 mg/kg). 13C isotopomers of G6P were quantified by 13C NMR spectroscopy of the monoacetone glucuronolactone derivative of urinary Paracetamol glucuronide.

Results: [1,2,3-13C3]- and [4,5,6-13C3]glucuronide isotopomers, representing the conversion of [1,2,3-13C3]glycerol to G6P via dihydroxyacetone phosphate, were resolved from [1,2-13C2]- and [5,6-13C2]glucuronide 13C-isotopomers, derived from the conversion of [1,2,3-13C3]glycerol to G6P via pyruvate, phosphoenolpyruvate and glyceraldehyde-3-phosphate. Enrichment of [1,2,3-13C3]glucuronide was significantly less than that of [4,5,6-13C3]glucuronide (1.30 ± 0.57 % versus 1.67 ± 0.42 %, p < 0.05). Also, [1,2-13C2]glucuronide enrichment was significantly less than that of [5,6-13C2]glucuronide (0.28 ± 0.08 % versus 0.36 ± 0.03 %, p < 0.05). The contributions of transaldolase and triose phosphate isomerase exchanges to the glucuronide 13C-isotopomer distributions were resolved by applying the 13C-isotopomer data to a model of hepatic G6P metabolism that features transaldolase and triose phosphate isomerase exchanges. Triose phosphate isomerase exchange was ~99 % complete and did not contribute significantly to the unequal 13C-isotopomer distributions of the glucuronide triose halves. Instead, these observations indicate that transaldolase exchange accounted for 25 ± 23 % of hepatic G6P flux. Consequently, the indirect pathway contribution to hepatic glycogen synthesis is overestimated by 25 ± 23 % with tracers such as [5-3H]glucose and deuterated water.

Conclusion: Transaldolase-mediated exchange of hexose and triose phosphates is active in human liver. This results in substantial overestimates of indirect pathway contributions to hepatic glycogen synthesis by some tracer methods in current use.

Divergent relationship between circulating soluble CD36 and markers of liver injury according to glucose toleranceE. Esteve¹, A. Handberg², J. Basols¹, A. López-Bemejo¹, J. Vendrell³, W. Ricart¹, J. Fernandez-Real¹;¹Endocrinology, Hospital of Girona, Spain, ²Department of Clinical Biochemistry, Aarhus University Hospital, Denmark,³Endocrinology, Hospital of Tarragona, Spain.

Background and Aims: CD36-facilitated fatty acid uptake in different tissues has been demonstrated to constitute an important determinant of insulin action in animal models. Liver injury linked to insulin resistance is characterized by mild to moderate increases in aminotransferase activity. A soluble form of CD36 (sCD36) was recently identified in human plasma, and was proposed to reflect altered CD36 expression. The aim of this study was to evaluate the relationships among plasma sCD36, insulin sensitivity and indicators of liver health.

Materials and Methods: A cohort of consecutive middle-aged men from the general population ($n=117$), 73 with normal and 44 with altered glucose tolerance. Insulin sensitivity (S_i , minimal model), circulating sCD36 (ELISA) and serum markers of liver injury were measured.

Results: As expected, serum ALT, AST and γ GT were associated positively with body mass index (BMI), age and negatively with insulin sensitivity. Circulating sCD36 was positively associated with ALT, AST and γ GT in subjects with altered glucose tolerance but not in those with normal glucose tolerance. Multiple regression analysis models were constructed to predict serum ALT activity, with age, BMI, alcohol intake, fasting triglycerides, insulin sensitivity and sCD36 as independent variables. Age, BMI and triglycerides contributed independently to 29% of ALT variance in subjects with normal oral glucose tolerance. In contrast, insulin sensitivity and sCD36 contributed independently to 39% of ALT variance in subjects with altered glucose tolerance.

Conclusion: Circulating sCD36 could represent a marker of liver injury in subjects with altered glucose tolerance independently of insulin resistance.

Evaluation of metabolic and nutritional parameters in cirrhotic patients before, 3 and 6 months after liver transplantation (OLT)F. Donadio¹, M. E. Lunati¹, F. Agnelli², E. Benetti¹, B. Masserini¹, L. Sbrulati¹, F. Donato², M. Colombo², P. Beck-Peccoz¹, E. Orsi¹;¹Department of Medical Sciences, Endocrine and Diabetologic Unit, University of Milan, Fondazione IRCCS Ospedale Maggiore Policlinico, Mangiagalli e Regina Elena, Italy, ²Department of Medical Sciences, Gastroenterologic Unit, University of Milan, Fondazione IRCCS Ospedale Maggiore Policlinico, Mangiagalli e Regina Elena, Italy.

Background and Aims: End-stage liver disease (ESLD) annually affects thousands of people. Cirrhosis is considered to be a catabolic disease that can lead to a profound alteration of metabolic and nutritional state. Furthermore, previous studies shown that after OLT patients may present diabetes, hypertension, obesity and dyslipidemia. The aim of the study was to evaluate changes in metabolic parameters and nutritional habits after OLT.

Materials and Methods: 28 cirrhotic patients (22M/6F, age 52.3±9.4 yrs) were evaluated at baseline and 3 and 6 months after OLT by medical history, anthropometric parameters (BMI, waist and hip circumferences), biochemical parameters (glucose, HbA1C, lipid profile, urate, creatinine, azotemia) and bioelectrical impedance. Moreover nutritional habits were evaluated with 3-day-food records. Differences were analyzed using one-way analysis of variance and values of $P<0.05$ were considered statistically significant.

Results: We reported the onset of de novo diabetes mellitus in 3 patients (16.6%). After 3 and 6 months a change in metabolic parameters (BMI: basal: 25±3.4, 3rd mo.: 24±2.8, 6th mo.: 25.3±3.1 Kg/m²; WC: basal: 93.7±10.6, 3rd mo.: 90.1±8.9, 6th mo.:93.4±10 cm) and in body composition (fat mass: basal:18.6±7.2, 3rd mo.:16.8±6.3, 6th mo.: 19.8±6.4 Kg) was documented; furthermore after OLT we observed a liver function improvement, and a worsening of renal index, the last one due to immunosuppressive therapy. We did not observe significant modification of other biochemical parameters. A change in caloric intake after OLT (basal: 1623±336.3, 3rd mo.: 2410±468.3, 6th mo.:1801±328.3 Kcal/die) was seen, with an increase in lipid assumption

(basal: 32.2±11.6, 3rd mo.: 43.6±5.7, 6th mo.: 37.5±7.1%), despite carbohydrate intake (basal: 52.1±13, 3rd mo.: 42.2±6.5, 6th mo.: 45.6±7.4%).

Conclusion: We reported a significant increase of de novo diabetes mellitus cases after OLT and a worsening of nutritional habits, which could lead to obesity, dyslipidemia and other metabolic diseases. Indeed, a multidisciplinary approach to these patients seems to be necessary in order to prevent the onset of obesity or other metabolic disease that often affects patients after OLT; moreover in non diabetic ESLD patients the improvement of nutritional habits, obtained by therapeutic education, could prevent also the onset of diabetes mellitus.

Arteriovenous concentration difference and carbon 13 NMR measurements reveal that intestinal gluconeogenesis is not demonstrable in diabetic rats

G. Baverel, R. Gadet, R. Nazaret, M. Martin, M. Boghossian, F. Saadé, G. Martin, B. Ferrier, A. Conjard;

Metabolomics and Metabolic Diseases, INSERM U820, Lyon, France.

Background and Aims: Recent studies have reported that the small intestine of diabetic rats substantially contributes to systemic glucose production via gluconeogenesis. Since this would (i) represent a major change in the classical view that only the liver and kidney have a gluconeogenic capacity and (ii) have major consequences in the pathophysiology of diabetes, we have thoroughly re-examined this question.

Materials and Methods: For this, metabolically viable intestinal cells from adult fed and 48h-fasted diabetic ZDF rats, a classical animal model of type 2 diabetes, were incubated in the presence of 5 mM [^{3-¹³C}]glutamine in the absence and the presence of 5 mM unlabelled glucose. Substrate removal and product accumulation were measured at the end of incubation by enzymatic and ¹³C-NMR spectroscopy methods. Arterio-portal concentration difference measurements were also performed in 48h-fasted diabetic ZDF rats.

Results: Despite the removal of ¹³C-glutamine and the formation of glutamate, lactate, alanine, citrulline and ¹³CO₂ at high rates, glucose synthesis by isolated small intestinal cells from both fed and fasted diabetic animals was not demonstrable and this was not due to the re-utilization of glucose synthesized from glutamine. Similarly, no glucose synthesis occurred from 5 mM glycerol or fructose. Arterio-portal concentration difference measurements for glucose, lactate, pyruvate, alanine, glycerol, glutamine, glutamate and ketone bodies in anesthetized 48h-fasted diabetic ZDF rats showed that the intestine neither added nor removed glucose in net amounts. Lactate, pyruvate, glutamate and alanine were released whereas glycerol and β -hydroxybutyrate but not acetoacetate were removed in net amounts by the intestine. Only 32 % of circulating glutamine, which has been reported to be the main if not the exclusive intestinal gluconeogenic precursor in diabetic rats in vivo, was found to be taken up. Assuming that the glutamine plus glycerol taken up were completely converted into glucose, a very unlikely hypothesis, this would have diluted the circulating glucose by only 1.4 %, a percentage that is not measurable in a reliable manner by currently available analytical methods. Similar findings were made in fasted streptozotocin-diabetic Sprague Dawley rats.

Conclusion: The present results, together with our recent demonstration that intestinal gluconeogenesis in 72h-fasted normal Wistar and Sprague Dawley rats remains to be demonstrated, strongly suggest that intestinal gluconeogenesis does not exist in adult diabetic rats.

Identification of adipose tissue secreted proteins as possible therapeutic targets for treatment of obesity

R. Oberauer¹, W. Rust¹, K. Quast¹, W. Patsch², D. Mennerich¹, B. Hamilton¹, H. Neubauer¹;

¹Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, Germany,

²Dept. of Laboratory Medicine, Salzburger Landeskliniken and Paracelsus Private Medical University, Salzburg, Austria.

Background and Aims: With increasing rates of obesity driving the incidence of diabetes to epidemic levels in both developed and developing countries, understanding the role of adipose tissue in the pathogenesis of morbidities is a focus of current research. The identification of adipocytokines such as leptin and adiponectin have confirmed the endocrine role of the fat cell. Identification of novel adipocytokines could provide further insights into the endocrine function of adipose tissue and additional means to therapeutically influence the de-regulated metabolic state of obese persons. Therefore, we compared expression profiles of adipose tissue of obese and lean humans with the aim to identify differentially expressed genes with signal peptide which are currently not associated with obesity. Expression of one candidate gene was further analysed in obese mice to estimate if the murine system could be used for further experiments.

Materials and Methods: Screening for differentially expressed genes in the adipose tissue of humans was performed from several perspectives. Affymetrix HG-U133 DNA Plus 2.0 chip data, accessed via the GeneLogic Gene Express 2.0 database, were used to compare mRNA expression profiles of human adipose tissue obtained from lean (BMI <25 kg m⁻², n =20) and obese (BMI >30 kg m⁻², n =45) individuals. Additionally Affymetrix chips were used for hybridisation of total RNA isolated from human adipose tissue biopsies of 9 obese patients (BMI =42.3 ± 4.25 kg m⁻²) before and after massive weight loss (29.7 ± 5.4 kg) achieved by gastric banding. Confirmation of the chip results was performed by quantitative RT-PCR on adipose tissues of lean (subcutaneous n =4, visceral n =4) and obese humans (subcutaneous n =5, visceral n =6) as well as 16 weeks old lean (C57/Bl6; n =4) and obese mice (ob/ob; n =4 and db/db; n =4).

Results: Several proteins, not linked to obesity in current literature, showing an altered expression in the adipose tissue of obese humans comparing to lean controls were examined in detail (6 with fold change (FC) >+1.8; 6 with FC <-1.8). Leptin, as positive control revealed a median FC of +3.3 (*p* =6.3E-6). Expression of one candidate with enhanced median FC in obese (+16.3, *p* =3.4E-5) was further analysed in more detail. The increased expression in obesity was confirmed by Taqman analysis of another adipose tissue sample set (subcutaneous: mean FC =+24.2, visceral: mean FC =+10). By comparing the expression profile in adipose tissue of humans after weight loss we observed a decreased expression (subcutaneous: -4.2 fold, *p* =1.2E-4; visceral: -1.3 fold, *p* =8.5E-3). The murine homologue was weakly expressed in the adipose tissue of C57/Bl6 lean mice and furthermore hardly detectable in the adipose tissue of the obesity mouse models ob/ob and db/db.

Conclusion: By expression profiling of human adipose tissue, several proteins with altered expression in obesity were identified, which are currently not known to be associated with obesity. For one secreted protein increased expression in obese humans was shown by three independent studies. The investigated mouse models of obesity did not show the observed human profile, therefore further model systems for functional validations will be studied.

Serum amyloid A as a biomarker and a potential contributor to the development of insulin resistance

L. Scheja¹, H. Zitzer¹, B. Heese¹, J. Heeren², U. Beisiegel², K. Seedorf¹;

¹Lilly Research Laboratories,

²IBM II, University Medical Center, Hamburg, Germany.

Background and Aims: Chronic low-grade inflammation is a hallmark of insulin resistance in the context of obesity. It has been reported that circulating levels of acute phase proteins, sensitive indicators of such inflammation, are

elevated in insulin resistant subjects. The purpose of this study was to address the role of the acute phase protein serum amyloid A (SAA) in a mouse model of diet-induced obesity.

Materials and Methods: Blood and tissues were collected from 20 week old, fasted C57Bl/6 mice which were fed either a chow diet (controls) or a high fat diet (59% fat by calories) for 1 week (1w HFD) and 16 weeks (16w HFD), respectively (n=8). An ELISA detecting SAA isoforms SAA1 and SAA2 (Biosource Inc.) was used for quantification in plasma. Gene expression in liver, muscle and adipose tissue was studied using TaqMan[®] real-time PCR assays. Recombinant apoSAA1/2 (Peprtech Ltd.) was used for assessing SAA effects on 3T3.L1 adipocytes.

Results: 1w HFD induced significant hyperinsulinemia and hyperglycemia in the mice compared to controls (*p* < 0.05), indicating mild insulin resistance already after a short period on the obesigenic diet. As expected, 16w HFD led to pronounced overweight and insulin resistance compared to controls (body weight: 44.9 ± 0.7g vs. 23.0 ± 0.5g; plasma insulin: 357 ± 58pM vs. 79 ± 23 pM, plasma glucose: 202 ± 6mg/dl vs. 119 ± 8mg/dl; Mean ± SEM, *p* < 0.01). Plasma SAA was elevated in the 1w HFD group (controls 2.11 ± 0.25ug/ml, 1w HFD 5.06 ± 1.05ug/ml, *p* < 0.05) and further increased in the 16w HFD group (31.4 ± 7.0ug/ml; Mean ± SEM, *p* < 0.01 vs. controls). In order to understand the contribution of tissues to the observed SAA induction in plasma we performed real-time PCR experiments in liver, adipose and muscle. The mRNAs of both SAA1 and SAA2 were expressed almost exclusively in liver, as described previously, and were induced by the HFD (> 3.5 -fold in 1w HFD, *p* < 1.50; > 8-fold in 16w HFD vs. controls; *p* < 0.001). SAA3, although well-expressed in liver, was not significantly induced in this tissue. In contrast, SAA3 was strongly expressed in adipose tissue and markedly induced by the HFD (> 8-fold in 1w HFD and 16w HFD, *p* < 0.05 vs. controls). The strong correlation of SAA1 and SAA2 with insulin resistance in the mouse model prompted us to study a potential causal role of SAA in the development of insulin resistance. To this end, we incubated 3T3.L1 adipocytes with recombinant SAA. Interestingly, we observed a pronounced induction of the proinflammatory markers monocyte chemoattractant protein-1 (MCP-1), inhibitor of kappaB kinase epsilon (IKKε) and SAA3. In contrast, the genes of several proteins involved in insulin signaling, glucose transport and mitochondriogenesis (adiponectin, IRS1, Glut4, PGC1α, PGC1β) were significantly downregulated by SAA. The alterations in 3T3.L1 gene expression were very similar to the changes observed in adipose tissue in vivo after feeding HFD.

Conclusions: In C57Bl/6 mice serum amyloid A is elevated after induction of insulin resistance and obesity by a high fat diet and correlates well with the severity of the metabolic condition. The effects of recombinant SAA on gene expression in 3T3.L1 adipocytes suggest that SAA produced in liver has the potential to promote inflammation in adipose tissue thereby worsening insulin resistance.

Serum components mediate glucose-induced immune gene expression in leukocytes from patients with the metabolic syndrome

K. Kempf, R. Rütter, B. Rose, C. Herder, S. Martin;

Institute for Clinical Diabetes Research, German Diabetes Center, Düsseldorf, Germany.

Background and Aims: Type 2 diabetes mellitus (T2DM) and the Metabolic Syndrome (MetS) are associated with chronic, subclinical inflammation. Recently we could demonstrate that an oral glucose challenge significantly increased immune gene expression in leukocytes from MetS patients and that this increase in expression and secretion of immune mediators also occurred after glucose stimulation in vitro. Therefore, the aim of the study was to analyze if components in the serum of MetS patients mediate glucose-induced immune gene expression.

Materials and Methods: Peripheral blood from subjects with (n=10) and without MetS (n=10) was cultured in low-glucose medium (100mg/dl D-glucose), high-glucose medium (500mg/dl D-glucose) and an osmotic control medium (100mg/dl D-glucose + 400mg/dl L-glucose) for 72 hours. The capacity of serum factors to prime leukocytes for glucose-induced immune gene expression was tested by incubation of leukocytes from MetS patients with serum from non-MetS subjects and vice versa (n=5 each). Expression of tumor necrosis factor alpha (TNF-α), intercellular adhesion molecule 1 (ICAM-1) and interleukin 6 (IL-6) was determined by quantitative RT-PCR. For statistical analysis Wilcoxon rank sum test was used.

Results: As shown before glucose significantly increased mean expression of ICAM-1 ($p<0.0001$), TNF- α ($p<0.0001$) and IL-6 ($p=0.014$) during the OGTT as well as after in vitro glucose stimulation with autologous serum in the MetS group only. Serum factors from MetS patients were able to increase immune gene expression in leukocytes from non-MetS subjects (+30% for TNF- α , +25% for ICAM-1 and +35% for IL-6), whereas incubation of leukocytes from MetS patients with serum from non-MetS subjects reduced glucose-induced immune gene expression compared with incubation with MetS serum (–15% for TNF- α , –25% for ICAM-1 and –130% for IL-6).

Conclusion: Presence of the MetS sensitizes leukocytes to up-regulate pro-inflammatory markers in response to glucose, and serum factors seem to be important mediators for this effect.

0627

Macrophage migration inhibitory factor (MIF), adipocytokines and insulin sensitivity in severe obese women with normal and impaired glucose tolerance

M. S. Sumarac-Dumanovic¹, D. D. Micić¹, V. Trajković², D. Stevanović³, J. Jorgić⁴, M. Georgiev¹, D. Stamenković-Pejković¹, A. Kendereski¹, G. Cvijović¹, S. Zorić¹;

¹Dept for Endocrinology, Institute of endocrinology, ²Department for immunology, School of Medicine, Institute of immunology, ³Dept for Physiology, School of Medicine, Institute of Physiology, ⁴Dept for Eating Disorders, School of Medicine, Institute of Eating Disorders, Belgrade, Serbia.

Background and Aims: There are data that hyperglycemia causes an increase in plasma visfatin levels in people with T2DM. This increase gets more prominent as the glucose intolerance worsens. Macrophage Migration Inhibitory Factor (MIF) is elevated in obesity and it was shown that metformin suppresses plasma MIF in the obese. The aim of the study was to determine level of plasma MIF and adipocytokine and insulin sensitivity in severely obese women with normal and impaired glucose tolerance.

Materials and Methods: Sixteen obese women (age: 34.56±2.24yrs; BMI 34.06±0.66 kg/m²) with normal glucose tolerance (NGT) and 10 age and BMI matched obese women (age: 35.80±2.54 yrs; BMI 36.98±1.66 kg/m²) with normal fasting and impaired glucose tolerance during oral glucose tolerance test (OGTT) (IGT) were included in the study. Fasting plasma visfatin (EIA Phoenix, ng/ml), adiponectin (Linco RIA, ng/ml), leptin (Linco RIA, ng/ml) and insulin (RIA Inep, mU/l), MIF (ELISA, ng/l) were measured. OGTT (75 gr of glucose) were performed in all obese women. Insulin sensitivity (M index: mg/kgBW/min) was determined using euglycemic 2hr clamp.

Results: There was no difference in fasting visfatin between NGT and IGT (74.85±4.40 vs. 69.80±5.55, $p>0.05$), fasting leptin (32.63±3.52 vs. 30.70±3.88, $p>0.05$) fasting adiponectin (7.84±1.61 vs. 9.65±4.59, $p>0.05$) and plasma MIF (2252.75±420.01 vs. 2344.80±481.80, $p>0.05$). Insulin sensitivity was reduced in obese women with IGT (6.02±0.56 vs. 2.74±0.38, $p<0.05$). There were no significant correlation among investigated parameters neither with insulin sensitivity index.

Conclusion: In conclusion, decreased insulin sensitivity is confirmed in severely obese women with IGT. Our data suggest that impairment in insulin sensitivity precede change in adipocytokines and MIF during development of type 2 diabetes in obesity.

Glycaemic variability (measured by 48h continuous glucose monitoring) in subjects with metabolic syndrome, with or without diabetes, is independently associated with IL-6 blood concentrations

S. Buscemi, S. Verga, S. Cottone, V. Azzolina, B. Buscemi, D. Gioia, M. R. Tranchina, G. Cerasola;

Internal medicine, cardiovascular and kidney diseases, University of Palermo, Italy.

Background and Aims: Subjects who develop diabetes have an increased cardiovascular risk even before the appearance of diabetes. It cannot be excluded that both fasting and postprandial plasma glucose and glycated haemoglobin do not describe adequately the glycaemic control and its impact on endothelial dysfunction and cardiovascular risk in diabetic

subjects. Glycaemic variability is an interesting measurement concerning the frequency and duration of hyperglycaemic and hypoglycaemic excursions, another factor that is potentially able to induce endothelial dysfunction. Furthermore, adipose tissue is known to release adipokines that are able to influence both insulin sensitivity and endothelial dysfunction. The aim of this study was to investigate the glycaemic variability measured by continuous glucose monitoring (CGM CV%) in subjects affected by metabolic syndrome (MS) and to explore if glycaemic variability was associated with circulating levels of IL-6, a proinflammatory cytokine, or with an anti-inflammatory factor like adiponectin. **Materials and Methods:** Three groups of obese subjects with (MS+: 6m, 8f; BMI 33.1 ± 1.4 mean ± sem) or without metabolic syndrome (MS-: 2m, 4f; BMI 29.2 ± 2.2) and with MS associated with type 2 diabetes (MS/T2D: 3m, 5f; BMI 32.9 ± 1.4) were investigated. The glycaemic variability was measured in all subjects in terms of CV% of the glycaemic values obtained every 3 minutes during the course of a 48h CGM performed using a subcutaneous glucose sensor (Glucoday; Menarini Diagnostics, Italy). The circulating levels of both IL-6 and adiponectin were measured in a subgroup of 18 subjects (n= 5 in SM-; n= 8 in SM+; n= 5 in SM+/T2D group).

Results: The average CGM CV% increased from MS- group (21.1%) to the MS+ group (23.9%) and to the MS+/T2D group (27.4%) but it was not correlated to the CGM mean glycaemia ($r= 0.20$; p ns). In some instances CGM CV% was found higher in MS+ subjects than in some MS+T2D subjects. As expected, IL-6 blood concentrations increased across the three groups (MS-: 50.0 ± 4.2; MS+: 88.2 ± 10.4; MS+/T2D: 115.3 ± 9.6 pg/ml) while adiponectin concentrations decreased (MS-: 7.6 ± 0.6; MS+: 6.1 ± 0.3; MS+/T2D: 5.2 ± 0.8 µg/ml); IL-6 and adiponectin were inversely correlated ($r= -0.63$; $p< 0.01$). According to stepwise multiple correlation analysis, IL-6 was a predictor of CGM CV% ($R^2= 0.35$, $\beta= 0.13$; $p< 0.05$) independent from BMI, waist circumference, adiponectin and insulin concentrations; adiponectin concentrations predicted CGM mean glycaemia ($R^2= 0.63$, $\beta= 29.7$; $p< 0.05$) independently from BMI, waist circumference, IL-6 and insulin concentrations.

Conclusions: These results are in agreement with the hypothesis that micro-inflammation may have a central role in the pathogenesis of metabolic and cardiovascular complications of MS. The CGM CV% may contribute to better describe the individual metabolic state and to understand the pathogenesis of endothelial dysfunction in subjects with MS.

The effect of telmisartan on selected insulin-stimulated plasma and subcutaneous adipocytokines in patients with metabolic syndrome

P. Wohl¹, E. Krušinová¹, S. Kratochvilová¹, L. Kazdová¹, M. Hill², P. Mlejnek³, M. Pravenec³, T. Pelikánová¹;

¹Diabetes center, IKEM, ²Institute of Endocrinology, Institute of Endocrinology, ³Academy of Science, Academy of Science, Prague, Czech Republic.

Background and Aims: Telmisartan exerts a beneficial effect on lipid and glucose metabolism and improves insulin sensitivity, but mechanisms are still unclear. The aim of our study was to test the effect of telmisartan on selected plasma and subcutaneous adipocytokines and their insulin-stimulated changes.

Materials and Methods: 12 patients with impaired glucose tolerance or impaired fasting glucose were enrolled in randomized, placebo-controlled, cross-over study of 3 weeks treatment with telmisartan (160 mg/d) or placebo. The glucose disposal rate (M) was estimated by one-step hyperinsulinemic euglycemic clamp (120 minutes; 1 mU.kg⁻¹.min⁻¹ 5 mmol/l) conducted at the end of each treatment period. Before and during the clamp (0,30,120 minutes) plasma levels of adiponectin, resistin, tumor necrosis factor- α (TNF), leptin were measured and needle biopsy of abdominal subcutaneous adipose tissue (0,30 minutes) was performed to evaluate the expression of adipocytokines by the real-time PCR method.

Results: Despite fasting plasma glucose was lower after telmisartan compared to placebo (5.1±0.6 vs 5.6±0.4 mmol/l, $p<0.02$), there were no significant differences in M and in basal plasma adiponectin, resistin, TNF, leptin levels after telmisartan as compared to placebo. However, telmisartan significantly increased plasma adiponectin ($p<0.05$), leptin ($p<0.001$) and resistin ($p<0.001$) during the clamp, while the decrease in insulin-stimulated TNF ($p<0.05$) was found. Subcutaneous expressions of adiponectin, TNF and

leptin were not affected by insulin or telmisartan. Expressions of resistin were higher after telmisartan compared to placebo ($p < 0.05$).

Conclusion: We conclude that 3 weeks intervention with telmisartan has significant effect on insulin-stimulated increase in plasma adiponectin, leptin, resistin and decrease in plasma TNF during the clamp. These changes cannot be explained by their subcutaneous adipose tissue expressions. Interestingly, higher expression of resistin was observed after telmisartan treatment. The results support the hypothesis, that the changes in selected plasma adipocytokines might be involved in the beneficial metabolic effects of telmisartan in patients with metabolic syndrome. The anti-inflammatory effects of rosiglitazone in patients with type 2 diabetes mellitus

N. P. Kadoglou¹, F. Iliadis¹, C. D. Liapis², D. Perrea³, T. P. Didangelos¹, H. Tsanikidis⁴, M. Alevizos¹;

¹1st Propedeutic Department of Internal Medicine, AHEPA University Hospital of Thessaloniki, Greece, ²Department of Vascular Surgery, University of Athens, Greece, ³Laboratory of Experimental Surgery and Surgical Research, University of Athens, Greece, ⁴Diabetic outpatients' department, General Hospital of Katerini, Greece.

Background and Aims: Growing evidence indicates that adipokines, interleukins, matrix metalloproteinases (MMPs) and their inhibitors (TIMPs) have all been implicated in atherosclerotic plaque development and vulnerability. The aim of our study was to evaluate the pharmacological effects of the addition of rosiglitazone to oral anti-diabetic regimen on the above variables in patients with type 2 diabetes mellitus.

Material and Methods: Seventy individuals with type 2 diabetes mellitus were randomized to either rosiglitazone group (8mg/day – RSG) or control group (CG) for 6 months. All participants were already on stable anti-diabetic regimen (gliclazide 160mg plus metformin 1700mg), but with inadequate glycemic control (HbA1c > 7%). Patients receiving lipid lowering medications or with diabetic vascular complications were excluded. Anthropometric parameters, glycemic indexes, lipid profile, insulin resistance, adiponectin, IL-6, IL-10, IL-18, MMP-9, TIMP-1 and TIMP-2 were measured at baseline and after 6 months. We used Student's independent t-test and paired-samples t-test for statistical analysis ($p < 0.05$).

Results: Improvements in glycemic control (HbA1c: $-0.88 \pm 0.23\%$, fasting plasma glucose: -30.93 ± 17.36 mg/dl), HDL (3.28 ± 1.08 mg/dl), fasting insulin (-2.46 ± 0.94 mU/L) and HOMA-IR (-1.92 ± 0.96) levels were noted only in RSG ($p < 0.05$). The rest of lipid parameters remained unaltered in both groups. In comparison to baseline values and control group, rosiglitazone treatment increased adiponectin (from 7.19 ± 2.77 μ g/ml to 14.085 ± 2.44 μ g/ml), IL-10 (from 4.38 pg/ml to 5.45 pg/ml) and TIMP-2 (from 132.83 ± 9.39 ng/ml to 140 ± 10.98 ng/ml) concentrations significantly ($p < 0.05$) after 6 months. Considerable decreases in IL-6, IL-18 and MMP-9 ($p < 0.01$) were observed in the rosiglitazone-treated patients, while the latter variables slightly increased in CG. Plasma levels of TIMP-1 decreased in both groups, but its difference between groups was marginal ($p = 0.063$). Finally rosiglitazone therapy elicited a pronounced increase of body weight in comparison to control group ($+2.6 \pm 1.08$ kg vs $+0.3 \pm 1.06$ kg; $p < 0.001$).

Conclusion: Despite significant weight gain adjunctive treatment with rosiglitazone exerted beneficial effects on glycemic control, insulin sensitivity and plasma concentrations of cytokines, MMP-9 and TIMPs. Totally rosiglitazone suppressed inflammatory milieu, along with increments of

anti-inflammatory markers indicating novel cardioprotective mechanisms in patients with type 2 diabetes mellitus.

Synergistic effects of n-3 polyunsaturated fatty acids and rosiglitazone in the amelioration of insulin resistance and adipose tissue inflammation

O. Kuda¹, Z. Jilkova¹, M. Rossmesl¹, P. Flachs¹, N. C. Ogston², V. Mohamed-Ali², S. Cinti³, J. Kopecky¹;

¹Department of Adipose Tissue Biology, Institute of Physiology, Prague, Czech Republic, ²Adipokines and Metabolism Research Group, Centre for Clinical Pharmacology, University College London, United Kingdom, ³Institute of Normal Human Morphology, University of Ancona, Italy.

Background and Aims: Effective therapeutic strategies for the prevention and treatment of metabolic syndrome are being sought. Polyunsaturated fatty acids of n-3 series (n-3 PUFA), especially eicosapentaenoic (EPA; 20:5 n-3) and docosahexaenoic (DHA; 22:6 n-3) acids, act as natural hypolipidemics and reduce risk of cardiovascular disease. In rodents, n-3 PUFA can prevent, but not reverse, obesity and insulin resistance induced by a high-fat diet. We investigated the combined effects of n-3 PUFA and rosiglitazone in the prevention of obesity and glucose intolerance in mice.

Materials and Methods: Experiments were conducted in C57BL/6 mice fed for 20 weeks either a corn oil-based high fat (HF) diet or HF diet containing: (i) 15 % of its lipids replaced by n-3 PUFA concentrate – EPAX 1050TG (60% EPA/DHA; Pronova Biocare a.s.); (ii) rosiglitazone (ROSI; 10 mg/kg diet); and (iii) EPA/DHA and rosiglitazone at doses as above (EPA/DHA-ROSI).

Results: Beneficial synergistic effects of EPA/DHA and ROSI on plasma triglycerides (HF: 2.09 ± 0.13 mmol/l; EPA/DHA: 1.75 ± 0.20 ; ROSI: 1.49 ± 0.10 ; EPA/DHA-ROSI: 1.14 ± 0.08 ; $p < 0.01$), glucose tolerance and plasma levels of adiponectin were observed. The systemic effects of the treatment correlated with the significant reduction of low-grade inflammation of adipose tissue, namely accumulation of macrophages, which was nearly abolished by the EPA/DHA-ROSI combination. Additive impact of EPA/DHA and ROSI in the prevention of hypertrophy of adipocytes was obvious and was in accord with the changes in the DNA tissue content.

Conclusions: The combination of n-3 PUFA and thiazolidinediones thus represents a promising strategy for the treatment of metabolic syndrome.

Chronic ethanol feeding induces visceral fat accumulation and GLUT4 impairment in rat adipose tissue via AMPK α , MEF2, and PPAR γ

L. Feng¹, J. Zhang², L. Gao², X. L. Hou¹, J. J. Zhao³;

¹Endo., Shandong Provincial Hospital, Shandong University,

²Central Laboratory, SPH, Jinan, China,

³Endo., Shandong Provincial Hospital, Jinan, China.

Background and Aims: Visceral fat accumulation and GLUT4 impairment are two major contributors to insulin resistance. The mechanism by which ethanol feeding influences them remains obscure. AMP-activated protein kinase α (AMPK α) regulates lipid oxidation and GLUT4 expression via peroxisome proliferator activated receptor γ (PPAR γ) and myocyte enhancer factor 2 (MEF2). To observe effect of chronic ethanol feeding on visceral fat accumulation and GLUT4 expression in rat adipose tissue and explore

possible underlying mechanism, we measured AMPK α , MEF2A, and PPAR γ in both mRNA and protein levels.

Materials and Methods: Thirty-six male Wistar rats were randomly divided into three groups, receiving either distilled water (group C) or ethanol with a single daily dose of 0.5 (group L), 5 g/kg (group H). Body weights were monitored weekly and treatment lasted for 22 weeks. After anaesthetic, fasting blood samples were obtained for determining the concentration of blood glucose and serum insulin. Epididymal, perirenal and retroperitoneal fat pads were rapidly removed, weighed and saved. HOMA-IR index and the ratio of visceral fat weight to body weight were calculated. Gene transcription and protein expression were tested by RT-PCR (normalized against GAPDH) and western blotting, respectively.

Results: In the present study, body weights of ethanol-treated rats showed a slight decrease, but no significant differences were found. However, visceral adipose tissue was increased by 13.43- and 22.5% in group L and H when normalized for body weight. Accumulation of visceral adipose tissue is considered to be a positive contributor to insulin resistance, and we further calculated HOMA-IR index. As expected, group L and H had a higher HOMA-IR index compared with group C and increased by 5.11- and 9.56%, respectively. Correlation analysis showed a positive relationship between the ratio of visceral adipose tissue to body weight and HOMA-IR index ($r=0.7$, $P<0.05$), indicating ethanol feeding induced visceral fat accumulation, and hence insulin resistance. We subsequently measured AMPK α , MEF2A, PPAR γ , and GLUT4 expression in epididymal adipose tissue. Results showed no significant effect of ethanol on AMPK α 1, α 2 isoform mRNA, and total-AMPK α protein, but phosphorylated-AMPK α (P-AMPK α) protein was reduced in ethanol feeding groups, indicating ethanol feeding impairs AMPK α activation. It is reported that activated-AMPK up-regulates GLUT4 expression via MEF2. In this study, we found the changes of MEF2A in rat adipose tissue after ethanol exposure was indeed consistent with that of P-AMPK, it was decreased in mRNA level by 7.29–14.77%, and decline of MEF2A protein was also observed. Recently, several studies revealed activated-AMPK could also lessen the inhibition of GLUT4 via depressing PPAR γ expression. Concurrent to these findings, we tested that ethanol exposure increased the expression of PPAR γ in mRNA level by 7.67-, 46.54% and in protein level by 6.43-, 21.86% in group L, H, respectively. Co-regulated by MEF2A isoform and PPAR γ , GLUT4 was significantly declined in mRNA level by 6.1–27.23% and in protein level by 20.69–26.13% in the ethanol-treated group.

Conclusion: Chronic ethanol feeding induces visceral fat accumulation and GLUT4 impairment via P-AMPK α , MEF2A, and PPAR γ , and hence contributes to insulin resistance.

PS 49 Adipokines: effects of weight loss

0633

Bariatric surgery and regional adiposity; the relevance of insulin sensitivity

C. H. Thompson^{1,2}, M. L. Heath³, J. P. Slavotinek³, R. Valentine³, L. Kow⁴, J. Toouli^{1,2};

¹General Medicine, Flinders Medical Centre, Bedford Park,

²Medicine, Flinders University, Adelaide,

³Radiology, Flinders Medical Centre, Bedford Park, ⁴General and Digestive Surgery, Flinders Medical Centre, Bedford Park, Australia.

Background and Aims: Weight loss following bariatric surgery is usually less in the diabetic than in the non-diabetic subject. Studies including both diabetic and non-diabetic subjects indicate that relative visceral fat (VAT) loss exceeds abdominal subcutaneous fat (SAT) loss over 12 months. During significant weight loss, few studies have evaluated the relevance of insulin sensitivity to regional adiposity including hepatic steatosis. This study evaluates and relates regional adiposity and insulin sensitivity before and after laparoscopic adjustable gastric banding surgery (LAGB) in a non-diabetic population.

Materials and Methods: Eighteen obese women underwent anthropometry, proton magnetic resonance (MR) spectroscopy to assess liver fat (LFAT) and MR imaging to assess VAT and SAT volume. Fasting blood was taken for NEFA and for homeostasis model assessment (HOMA-R). Measurements were repeated 3 and 12 months after LAGB.

Results:

Table 1: Descriptive characteristics

	Baseline	3 months after LAGB	12 months after LAGB
Body weight (kg)	104.3 \pm 12.5	94.5 \pm 10.6 [†]	85.0 \pm 12.3 [†]
BMI (kg/m ²)	39 \pm 5	3.5 \pm 4 [†]	32 \pm 5 [†]
Waist circumference (cm)	112.2 \pm 11.9	102.8 \pm 8.3 [†]	96 \pm 10.3 [†]
LFAT (%)	12 \pm 13	7.5 \pm 7.5	9.3 \pm 14.9
VAT (ml)	175 \pm 89	142 \pm 71 [†]	111 \pm 54 [†]
SAT (ml)	596 \pm 127	506 \pm 108 [†]	421 \pm 124 [†]
NEFA (mM)	0.77 \pm 0.021	0.57 \pm 0.27 [†]	0.48 \pm 0.23
HOMA-R	3.6 \pm 3.5	2.7 \pm 1.5	1.8 \pm 1.3 [†]

Data presented are mean \pm SD; LFAT, liver fat; VAT, abdominal visceral adipose tissue; SAT, abdominal subcutaneous adipose tissue; HOMA-R, homeostasis model assessment insulin resistance index; [†] $p<0.05$ cf baseline; [†] $p<0.01$ cf 3 months after LAGB.

Descriptive characteristics of subjects before and after LAGB are shown in Table 1. Three months after LAGB, reductions had occurred in body weight, BMI, waist circumference, VAT, SAT (all $p<0.01$) and NEFA ($p<0.05$). 12 months after LAGB, further reductions ($p<0.01$) occurred in these variables, except for NEFA. No significant reduction occurred in LFAT at either time point in the group as a whole. In those with pre-operative hepatic steatosis (LFAT $>5\%$, $n=8$), LFAT fell from 12% to 8% ($p=0.015$) 3 months after LAGB with no further reduction occurring by 12 months. There was an improvement in HOMA-R at 12 ($p=0.04$) but not 3 months.

Though there was progressive fat loss ($p<0.01$) from both VAT (-11% at 3 months, -29% at 12 months) and SAT (-13% at 3 months, -28% at 12 months) sites, the relative changes were similar at each timepoint ($p>0.05$). At baseline, LFAT correlated both with VAT volume ($r=0.68$, $p<0.01$) and HOMA-R ($r=0.48$, $p<0.05$), as well as with the change in HOMA-R at 3 ($r=0.48$, $p<0.05$) and 12 months ($r=0.47$, $p<0.05$) and with the change in VAT volume at 12 months ($r=0.51$, $p<0.05$). Relative to VAT loss, SAT loss at 12 months was greatest in the most insulin sensitive patients ($r=0.70$; $p<0.01$).

Conclusions: After LAGB in the non-diabetic population, relative VAT and SAT loss were similar and progressive over 12 months. The ability to mobilise SAT relative to VAT related to insulin sensitivity postoperatively. Excess LFAT was lost in the first 3 months postoperatively. The pre-operative degree of hepatic steatosis may predict the post-operative loss of visceral adiposity and improvement in insulin resistance.

0634

Insulin secretion, β -cell glucose sensitivity and insulin resistance in severe obesity: effect of massive weight loss after gastric bypass

D. M. Marin¹, S. Monte Alegre¹, J. N. M. Ortiz¹, J. C. Pareja¹, C. A. Silva¹, A. Souza¹, A. Gastaldelli², E. Muscelli³;

¹Department of Internal Medicine, Faculdade de Ciências Médicas, UNICAMP, Campinas, S. Paulo, Brazil,

²Istituto di Fisiologia Clinica, Consiglio Nazionale delle Ricerche, Pisa, Italy,

³Department of Internal Medicine, Università di Pisa, Italy.

Background and Aims: The aims of this study were to evaluate the contribution of insulin resistance and impaired β -cell function to glucose tolerance in severely obese subjects and to evaluate the effect of massive weight loss by Roux-en-Y Gastric bypass, RGB-Y, on the adaptation of insulin secretion to insulin resistance (IR).

Materials and Methods: 34 obese (17 OB-NGT, 11 OB-IGT and 6 type 2 diabetic – OB-T2D; age 37.3±1.4y; BMI 50.0±1.5kg/m²) and 10 healthy lean CT (BMI 22.3±0.6kg/m²; 35±4y). Protocol: euglycemic hyperinsulinemic clamp (3h-insulin infusion at 240pmol/min·m⁻²) with indirect calorimetry, IVGTT and OGTT was used. 14 patients (11OB-NGT and 3OB-IGT) were re-evaluated post-surgery after weight stabilization ~18 months. Total (T-ISR) and fasting insulin secretion (f-ISR) were evaluated by C-peptide deconvolution and β -cell glucose sensitivity (β -GS) as the slope of the insulin secretion/glucose concentration dose-response curve. The disposition index was calculated as ISRxMvalue of the clamp.

Results: Obese subjects were insulin resistant for oxidative, nonoxidative and whole body glucose disposal (OB-T2D, OB-IGT and OB-NGT were ~30%, 60% and 43% of CT). During IVGTT the acute insulin response (AIR_{0-10min}) was significantly higher in OB-NGT than in CT and in the other obese groups (CT 5378±590; OB-NGT 9363±895; OB-IGT 6544±558 and OB-T2D 3893±622 pmol·min⁻¹·m⁻²), T-ISR was elevated in all obese groups (CT 20.2±1.9; OB-NGT 39.2±3.6; OB-IGT 39.2±2.5 and OB-T2D 37.1±4.5 nmol·min⁻¹·m⁻²·x60min) while β -GS was decreased in OB-IGT and -T2D but not in -NGT as compared to CT (OB-T2D -4±3; OB-IGT 31±4; OB-NGT 56±6 and CT 43±6 pmol·min⁻¹·m⁻²·mM⁻¹). The disposition index was reduced in OB-IGT and -T2D but not in -NGT.

After weight loss BMI was 30.2±1.2kg·m⁻², f-ISR (from 148±12 to 83±12, p<0.05 vs. pre; p=ns vs. CT 76±8 pmol·min⁻¹·m⁻²) and insulin sensitivity (from 30±3 to 55±4, p<0.05 vs. pre; p=ns vs CT 62±4 μ mol·kg⁻¹·min⁻¹) changed to normal values. The time-course evidenced a significant decrease in T-ISR, and an unchanged AIR. β -GS increased to levels higher than CT (from 49±7 to 78±12 pmol·min⁻¹·m⁻²·mM⁻¹). Before surgery the disposition index was similar to the CT group, but after weight loss increased to values higher than in CT.

Conclusion: T2D and IGT severe obese subjects show a progressive deterioration of glucose homeostasis, despite increased insulin secretion. This can be explained as an impairment of β -cell function for the prevailing IR. RGB-Y weight loss normalized IR and improved β -cell function in IGT and NGT obese to levels higher than in lean CT.

Expression of adipocytokines in adipose tissue of obese type 2 diabetic subjects before and after major weight reduction

M. Nannipieri¹, E. Mancini¹, M. Anselmino², F. Cecchetti¹, B. Solito², F. Santini³, A. Bonotti¹, D. Gandini⁴, A. Pinchera³, E. Ferrannini¹;

¹Internal Medicine, University of Pisa, ²Unit of Bariatric Surgery,

S. Chiara Hospital of Pisa, ³Endocrinology, University of Pisa,

⁴Plastic Surgery, Cisanello Hospital of Pisa, Italy.

Background and Aims: Adiponectin (APM1) and visfatin have been linked with obesity and atherosclerosis in opposite manner, negatively the former, positively the latter. We examined the effect of weight loss (by gastric by-pass surgery) on the expression of APM1, its receptors (AdipoR1 and AdipoR2) and visfatin in abdominal subcutaneous adipose tissue (SAT) of morbidly obese subjects with or without diabetes.

Materials and Methods: In 10 obese non-diabetic subjects (NGT) (39±9 years, BMI 45.1±5.4 kg/m²) and 10 obese diabetic patients (DM2) (45±5 years, BMI 47.2±3.0 kg/m²), SAT tissue was obtained during bariatric surgery and

again one year after surgery (by biopsy). cDNA was synthesised and relative quantifications of APM1, AdipoR1, AdipoR2 and visfatin mRNA (target gene) were performed by RT-PCR. Results were expressed as the target to reference (hypoxanthine-phosphorybosyl-transferase) ratio for each sample.

Results: After surgery, BMI was similarly reduced in NGT and DM2 subjects (-15.9±3.6 and -15.9±6.1 kg/m², respectively, p<0.0001 for both). Likewise, fasting plasma insulin was reduced in both groups (-15.3±11.3 and -13.1±9.4 μ U/ml, p<0.01). Fasting plasma glucose was reduced in DM2 (-2.9±1.6 mmol/l, p=0.001), but not in NGT (-0.1±0.6 mmol/l, p=ns). Following weight loss, APM1 did not change in NGT, (3.83±1.25 vs. 4.08±2.01, p=ns), whereas it increased in DM2 (2.69±1.32 vs. 4.77±1.26, p=0.0035). AdipoR1 was not significantly changed by weight loss in either group (3.49±1.18 vs. 2.83±0.98 in NGT and 2.73±1.29 vs. 2.89±2.89 in DM2, p=ns); this was also true of AdipoR2 (4.92±2.84 vs. 3.88±1.7 in NGT and 4.18±3.02 vs. 3.76±1.3 in DM2, p=ns). In contrast, visfatin expression decreased both in NGT (2.12±1.15 vs. 1.02±0.27, p=0.008) and DM2 (3.09±2.56 vs 1.02±0.24, p=0.028) after weight loss.

Conclusion: We conclude that, whereas adiponectin receptor expression is not altered following weight loss, visfatin expression in subcutaneous fat falls markedly with weight reduction. In addition, adiponectin expression increases in weight-reduced diabetic subjects, possibly contributing to their improved insulin sensitivity.

0636

Effect on plasma visfatin concentrations after bariatric surgery in morbidly obese patients

J. Garcia-Aleman¹, J. M. Garcia-Almeida¹, E. Garcia-Fuentes², J. Garcia-Arnes³, F. Vilches¹, S. Garcia-Serrano², J. Pinzon¹, D. Fernandez¹, M. Picon¹, I. Mancha¹, F. Tinahones¹;

¹Endocrinology, H. Virgen de la Victoria, Malaga, ²Endocrinology, Ciber Fisiopatología Obesidad y Nutrición (CB06/03), Instituto de Salud Carlos III, Malaga, ³Endocrinology, H. Carlos Haya, Malaga, Spain.

Background and Aims: Adipose tissue has recently been shown to secrete a peptide, visfatin, which is high in obese persons and in persons with type 2 diabetes mellitus (DM2). The aim of this study was to determine the course of plasma visfatin in morbidly obese persons following weight loss after bariatric surgery in relation with the glycemia concentration.

Materials and Methods: Plasma levels of visfatin and leptin were studied in 53 morbidly obese persons (MO) before and seven months after bariatric surgery, and in 28 healthy persons. All the patients underwent bariatric surgery

Results: The basal levels of visfatin in the MO were greater than in the controls (55.9±39.9 vs. 42.9±16.6 ng/mL, P=0.024). This increase was due to the MO with impaired fasting glucose (IFG) (63.4±36.6 ng/mL) and with diabetes (60.0±46.0 ng/mL). The MO with normal fasting glucose had similar levels of visfatin (32.1±17.6 ng/mL) to the controls. Seven months after surgery, visfatin levels were significantly increased (84.8±32.8 ng/mL, P<0.001). This increase was independent of the presurgical glucose levels. The type of bariatric surgery had no influence on visfatin levels. Post-surgical visfatin was significantly correlated with the percentage reduction in hip measurement, leptin and the change in plasma leptin concentrations (presurgery – post-surgery leptin).

Conclusion: Plasma visfatin in MO were increased, but only when accompanied by high glucose levels, even in the range of IFG. Bariatric surgery causes an increase in visfatin that is not wholly independent of the changes in the distribution of body fat.

Circulating levels of preadipocyte factor-1 (PREF-1/FA1) decreased after massive weight lost and have a modulatory effect on pro-inflammatory cytokines

M. R. Chacón¹, M. Miranda¹, C. J. Jensen², J. Fernández-Real³, N. Vilarrosa⁴, A. García-España¹, W. Ricart³, S. Näf¹, J. Gómez⁴, J. J. Vendrell¹;

¹Research Unit, University Hospital Joan XXIII, Tarragona, Spain,

²Department of Immunology and Microbiology, University of Southern Denmark, Odense C, Denmark, ³Diabetes Unit, University Hospital “Dr. Josep Trueta”, Girona, Spain, ⁴Endocrinology Unit, University Hospital of Bellvitge, Barcelona, Spain.

Background: *PREF-1* gene is highly expressed in mouse preadipocyte cells and it has been proposed to be a negative regulator of adipogenesis. Transgenic mice showed substantial but not complete loss of adipose tissue, hypertriglyceridemia, impaired glucose tolerance and decreased insulin sensitivity. However, in human subcutaneous adipose tissue this gene is scarcely expressed. On the other hand, the soluble circulating form of this protein named “foetal antigen 1” (FA1) has been associated in obese subjects and in patients with type 2 diabetes with a worse cardiovascular profile.

Aim: We aimed to search for the cell type responsible for its scarce gene expression in adipose tissue. We also evaluated FA-1 circulating plasma levels in severely obese patients before and 6 months after bariatric surgery and related them to lipidic, glycaemic and inflammatory profile. Biological function was also assessed in vitro on THP-1 human monocytic/macrophage cells.

Materials and Methods: FA1 plasma levels were measured by ELISA technique on n=61 severely obese women. Gene expression levels were measured in several human samples: placenta, subcutaneous and visceral adipose tissue, human monocytes and lymphocytes, mature adipocytes, stromovascular fraction and preadipocytes. Real Time PCR was used to evaluate *PREF-1* gene expression. THP-1 human monocytic cell line was stimulated in vitro with 1, 3 and 5 µg/ml of FA1. Cytokine protein and gene expression for TNFα, IL-6, MCP-1 and TNFR2 were evaluated.

Results: *PREF-1* gene expression on human preadipocytes was quantifiable but the low levels detected were not considered to have any biological activity. Plasma levels of FA1 in the severely obese cohort decreased significantly ($p<0.001$) with the lost of weight after 6 months of surgery (before: 27.13 ± 10.53 ng/ml and 6 months after surgery: 19.98 ± 9.34 ng/ml). A multivariate regression model was constructed with FA1 at basal state as dependent variable and hsCRP, IL-6, glucose, insulin, triglycerides as independent variables; FA1 levels at basal state were strongly related to triglyceride levels ($\beta=0.587$, $p=0.008$). A similar model was constructed for FA1 levels after 6 months and we found that age and triglycerides were the independent determinants of FA1 levels ($\beta=0.499$, $p=0.001$ and $\beta=0.457$, $p=0.002$ respectively). The biological effect of FA1 protein on THP-1 human monocytic cells observed in our study were a clear up-regulation of TNF-α, MCP-1 and IL-6 pro-inflammatory cytokines.

Conclusion: *PREF-1* gene is not a relevant gene in human preadipocytes. FA-1 circulating levels may be a marker of a worse metabolic profile in severely obese patients with a possible modulatory effect on pro-inflammatory cytokines derived from monocyte/macrophage cells.

New mouse models of impaired glucose tolerance generated using N-ethyl-N-nitrosourea mutagenesis

L. Bentley, W. Wang, C. Church, P.-S. S. Muller, R. D. Cox; Mammalian Genetics Unit, MRC HARWELL, Oxfordshire, United Kingdom.

Background and Aims: N-ethyl-N-nitrosourea (ENU) is a powerful chemical mutagen that induces point mutations at a per locus rate of approximately 1/1000 and has been used effectively in a number of phenotype-driven screens in the mouse to produce new mouse mutants. Both dominant (F1) and recessive (G3) offspring of mutagenised males from the new Harwell ENU mutagenesis programme were assayed for impaired glucose tolerance and plasma and urine biochemistry with the aim of identifying new mouse models of metabolism and associated kidney disease.
