General Internal Medicine, Radboud University Nijmegen Medical Centre, Netherlands.

Background and aims: Subjects with type 2 diabetes mellitus (T2DM) are characterized by the presence of a chronic low grade inflammation mainly originating from expanding adipose tissue. Obesity-induced enlargement of adipose tissue promotes the infiltration of monocytes and lymphocytes, leading to an increased production of pro-inflammatory cytokines. Hyperglycaemia plays a central role in the progression of T2DM and is known to induce an inflammatory response and a disturbed redox balance. Thioredoxin-interacting protein (Txnip) controls the cellular redox state and appears to be an important regulator of glucose homeostasis. In this study we investigate the role of Txnip in the production of pro-inflammatory cytokines in human adipocytes and peripheral blood mononuclear cells (PBMCs) under normo- and hyperglycaemic conditions.
Material and methods: Differentiated primary adipocytes, total adipose tissue, PBMCs and isolated monocytes of human origin were cultured for 48 hours under normoglycaemic (5mM) or hyperglycaemic (25mM) conditions. Medium, RNA, and protein lysates were collected to determine the expression level of Txnip and pro-inflammatory cytokines.
Results: Txnip mRNA and protein levels were abundantly expressed in adipose tissue and were elevated 3-fold after exposure to high glucose. Fractioning of adipose tissue into mature adipocytes and stromal vascular cells

revealed that Txnip expression was mainly originating from adipocytes. Differentiation of primary human pre-adipocytes towards mature adipocytes under hyperglycaemic conditions led to a 3-fold higher expression of Txnip protein and mRNA as compared to normoglycaemic treatment. Furthermore, exposure of primary human mature adipocytes to high glucose also increased Txnip protein and mRNA levels. In line with the effects observed in adipocytes, also incubation of isolated human PBMCs and monocytes under high glucose conditions induced Txnip mRNA and protein expression levels, with Txnip protein being elevated more than two fold under hyperglycaemic compared to normoglycaemic conditions. In both adipose tissue and PBMCs, Txnip expression completely disappeared when cultivated in the absence of glucose.
Concurrent with the induction of Txnip, hyperglycaemia showed clear increases in mRNA expression of the pro-inflammatory cytokines tumor necrosis factor-α (TNF-α), interleukin-6 (IL-6) and interleukin-8 (IL-8) by mature adipocytes. In PBMCs and monocytes, hyperglycaemia resulted in a 2-fold increase in the intracellular level of interleukin-1β (IL-1β), and a 5-fold induction of IL-1β mRNA as compared to normoglycaemic conditions. Secretion levels of TNF-α and IL-8 were also elevated by high glucose.
Conclusion: Our results show that Txnip is present in human adipose tissue and PBMCs and that its activation strongly dependents on glucose exposure. Hyperglycaemic conditions induce a strong pro-inflammatory response in both adipocytes and peripheral blood cells, and this is associated with a strong increase in Txnip levels. Our results suggest that Txnip may be involved in the hyperglycaemia-induced production of pro-inflammatory cytokines.

Fas (CD95) induces lipolysis through down-regulation of lipin-1 and subsequent activation of the MAPK pathway in 3T3-L1 adipocytes
R.A. Rapold[1,2], S. Wueest[1,2], E.J. Schoenle[1], D. Konrad[1,2];
[1]Division of Pediatric Endocrinology and Diabetology, University Children's Hospital, Zurich, [2]Zurich Center for Integrative Human Physiology, University of Zurich, Switzerland.

Background and aims: Fas (CD95) is a member of the tumour necrosis receptor superfamily that plays a crucial role in the induction of apoptosis. In addition, activation of Fas can also induce non-apoptotic signalling pathways including cell proliferation. We previously found that Fas-deficient and adipocyte-specific Fas knockout mice are partly protected from high fat diet induced insulin resistance. The aim of this study was to elucidate the molecular mechanisms behind this protective effect; in particular the impact of Fas activation in adipocytes on lipolysis.
Materials and methods: Fully differentiated 3T3-L1 adipocytes were treated with 2 ng/ml Fas ligand (FasL) in the presence or absence of the MEK inhibitor U0126, or with various concentrations (1 - 100 μM) of phosphatidic acid. Protein and mRNA was collected for western blot and real-time PCR analysis. Lipolysis was assessed by measuring free glycerol release.
Results: Treatment of adipocytes with FasL influenced lipolysis in a time dependent fashion with an initial decrease after 2 hours and an approximately 2-fold increase after 12 hours. Fas activation induced phosphorylation of the p44/42 MAP kinases (ERK1/2) with a peak after 6 hours and FasL-induced lipolysis was completely blocked by ERK-inhibition. Interestingly, FasL reduced mRNA-expression and protein levels of lipin-1, a phosphatase involved in the generation of triacylglycerols.This effect was independent of ERK1/2 activation. It was previously shown that down-regulation of lipin-1 leads to accumulation of its substrate phosphatidic acid (PA) in adipose tissue. We show here that administration of PA to adipocytes increases phosphorylation of ERK1/2 and induces lipolysis.
Conclusion: These results suggest that Fas activation induces lipolysis in a lipin and ERK1/2-dependent manner and, thus, might have an important impact on adipocyte and whole-body metabolism.

AMP-activated protein kinase (AMPK) modulates lipopolysaccharide (LPS)-induced cytokine expression and lipolysis in human adipocytes
J. Grisouard[1], D. Seboek Kinter[1], T. Radimerski[1], K. Timper[1], D.M. Frey[2], B. Kola[3], M. Korbonits[3], H. Zulewski[1], U. Keller[1], B. Müller[4], M. Christ-Crain[1];
[1]Dept. of Biomedicine, Metabolism Group, University Hospital Basel, Switzerland, [2]Dept. of Surgery, Div. of General Surgery and Surgical Research, University Hospital Basel, Switzerland, [3]Centre for Endocrinology, Barts and the London Medical School, University of London, United Kingdom, [4]Dept. of Internal Medicine, Kantonsspital Aarau, Switzerland.

Background and aims: In adipose tissue of obese patients, low-grade chronic inflammation is mirrored by elevated levels of pro-inflammatory cytokines which enhance lipolysis. This contributes to the elevation of circulating triglyceride and non-esterified fatty acid concentrations in type 2 diabetic individuals. It also correlates with deposition of fat in liver and skeletal muscles, promoting insulin resistance. Therefore, we investigated modulators of inflammation and lipolysis in adipose tissue using a human adipocyte model and inducing inflammation with endotoxin (lipopolysaccharide, LPS).
Materials and methods: Human mesenchymal stem cells and human pre-adipocyte-derived adipocytes obtained from surgical biopsies were differentiated *in vitro* into adipocytes, and the effects of 24 h stimulation with LPS (100 ng/ml), metformin (1mM), AICAR, compound C (5μM) and their respective combinations on inflammatory cytokine (IL-6, IL-1beta and IL-8) mRNA expression and glycerol release (readout of lipolysis) were determined.
Results: LPS increased mRNA expression of IL-6 to 1269±184% of control (P<0.001), IL-8 to 32780±6437% of control (P<0.001) and IL-1beta to 1027±91% of control (P<0.001). Induction of IL-6 mRNA by LPS was significantly reduced by pre-incubation with metformin and AICAR, 5'AMP-activated protein kinase (AMPK) activators, and increased by compound C, an AMPK inhibitor. In contrast, induction of IL-1beta and IL-8 mRNA by LPS was significantly increased by metformin and AICAR. Glycerol release increased from 41.6±2.5μg/ml in basal state to 82.1±2.2μg/ml in LPS-treated cells (P<0.001). LPS-induced lipolysis was significantly inhibited by metformin and AICAR and slightly increased by compound C.
Conclusion: Compound C increased and both, metformin and AICAR inhibited LPS-induced IL-6 expression and lipolysis. This indicates that AMPK modulates the inflammatory and lipolytic effects of LPS in human adipocytes.

Involvement of receptor-mediated processes in proinflammatory adipocyte activation by heat shock protein 60
V. Burkart, T. Märker, S. Mollérus, U. Wohlrab, C. Habich;
Institute for Clinical Diabetology, German Diabetes Center, Düsseldorf, Germany.

Background and aims: Adipocytes are a source of a variety of inflammatory mediators which allow the cells to exert immunoregulatory activities resembling those of innate immune cells. Adipocyte-derived proinflammatory mediators contribute to the development of chronic inflammation, thereby promoting the induction and progression of insulin resistance/metabolic-syndrome and diabetes. Currently, the physiological signals inducing the release of inflammatory mediators by adipocytes are largely unknown. As heat shock proteins (Hsp) have been identified as potent regulators of the inflammatory activities of innate immune cells, our present study was designed to investigate the interaction of adipocytes with Hsp60 as the decisive initial event in the induction of proinflammatory adipocyte mediators.
Material and methods: Adipocytes of the murine line 3T3-L1 were incubated with recombinant Hsp60 and the release of interleukin (IL)-6, CXCL1 and monocyte chemoattractant protein (MCP)-1 from these cells was determined by multiplex beads system. Analyses of Hsp60-signalling was performed by immunoblotting and by the application of inhibitors against specific signalling proteins. Characterization of Hsp60-binding to adipocytes and identification of responsible binding epitopes was studied by FACS analyses with fluorescent-labelled Hsp60 and with specific antibodies.
Results: Our experiments demonstrate that Hsp60 stimulates the release of the proinflammatory cytokines IL-6, CXCL1 and MCP-1 in a time- and con-

centration-dependent manner from 3T3-L1 adipocytes. Analyses of Hsp60-signalling in these adipocytes revealed that members of the MAPK-family (ERK1/2, p38) and the transcription factor NFκB are involved in Hsp60-mediated induction of the mediators IL-6, CXCL1 and MCP-1. Binding-studies with fluorescence-labelled Hsp60 demonstrated that the interaction of Hsp60 with adipocytes exhibits basic features of receptor-mediated interactions. Hsp60-binding to adipocytes was saturable and reached its maximum at 3.5 μM. Binding was inhibitable only by the unlabelled ligand (52%), but not by unrelated proteins, thereby proving the specificity of Hsp60-binding. Further approaches to characterize Hsp60-receptor structures on adipocytes revealed the presence of Toll-like receptor (TLR)4 on adipocytes. TLR4 has been found to be expressed on macrophages and to interact with Hsp60, therefore suggesting TLR4 as a potential receptor candidate for Hsp60 on adipocytes. In order to identify the Hsp60-epitope involved in binding, we investigated the effect of specific antibodies directed against defined epitopes of the Hsp60-molecule. Incubation of Hsp60 with antibodies directed against the N-terminus of the Hsp60-molecule (amino acids 1-200; 5-25 μg/ml) inhibited Hsp60-binding to adipocytes (47-80%) indicating that the N-terminal region of Hsp60 is involved in receptor binding.
Conclusion: Our experiments demonstrate that the Hsp60 stimulated release of proinflammatory mediators from adipocytes involves a receptor-mediated interaction of the heat shock protein with the cells. These findings implicate that Hsp60-receptor interactions could serve as a target to modulate the proinflammatory activity of adipocytes and to develop therapeutic strategies for patients suffering from chronic, diabetes-associated inflammatory diseases.

NF-κB dependent regulation of IP-10 in 3T3-L1 and human primary preadipocytes and adipocytes
P. Dietl[1], C. Brunner[2], P.A. Ruiz[3], D. Haller[3], H. Hauner[1], H. Laumen[1];
[1]Else Kröner-Fresenius-Center for Nutritional Medicine, Technische Universität München, Freising, [2]Physiologische Chemie, Universität Ulm, [3]Biofunctionality, Nutrition and Food Research Center, Technische Universität München, Freising, Germany.

Background and aims: Chemokine secretion by adipocytes and preadipocytes has been postulated to initiate leukocyte infiltration and might mediate the establishment of obesity-related low-grade inflammation. In this context, interferon-γ-inducible protein 10 (IP-10/CXCL10) is a novel interesting candidate, as increased levels of IP-10 expression have been associated with obesity and type 2 diabetes in humans and it is expressed in primary human adipocytes. The aim of this work was to study the role of NF-κB in the regulation of IP-10 in murine 3T3-L1, primary human preadipocytes and adipocytes and and to characterize its functional role in adipose tissue.
Materials and methods: Cell culture of *in vitro* differentiated murine 3T3-L1, primary human preadipocytes, adipocytes and primary mouse splenocytes; retroviral infection, transfection, luciferase-assay, ELISA, western-blot, qRT-PCR, migration-assays.
Results: In order to specifically inhibit the NF-κB activity, we stably expressed a transdominant mutant of IκBα in 3T3-L1 cells. This mutant completely suppressed the basal and induced IP-10 secretion and expression. In primary mature adipocytes IL-1β stimulated IP-10 mRNA expression was completely blocked by a chemical NF-κB-inhibitor. Moreover, adipocytes secrete and express significantly higher levels of IP-10 compared with preadipocytes. In addition, we could demonstrate that induction of T cell migration by conditioned medium from IL-1β-induced adipocytes was inhibited by overexpression of IκBα-mut as well as by neutralization of IP-10.
Conclusion: This study demonstrates that the NF-κB pathway is essential for the regulation of IP-10 in 3T3-L1 and primary human adipocytes. Adipocytes rather than preadipocytes contribute to obesity-associated elevated IP-10 levels. Furthermore, IP-10 release from adipocytes may act as a potent chemoattractant for lymphocyte migration towards adipose tissue.

Interleukin-1F6 is expressed in adipose tissue and inhibits adipocyte differentiation
E.J.P. van Asseldonk, R. Stienstra, T.B. Koenen, L.J.H. van Tits, C.J. Tack, M.G. Netea;
General Internal Medicine, UMC St Radboud, Nijmegen, Netherlands.

Background and aims: Inflammation appears to be an important link between obesity and insulin resistance. Nutrient excess and subsequent storage in adipose tissue result in expansion of the adipose tissue mass and adipocyte size, which is positively correlated with the number of infiltrating macrophages. Adipose tissue macrophages (ATMs) in obese individuals express many genes characteristic for M1 macrophages, which have a pro-inflammatory cytokine profile, while most ATMs in lean individuals are M2 macrophages (anti-inflammatory). ATMs can release proinflammatory cytokines such as the Interleukin (IL)-1family members IL-1 and IL-18, and an increasing amount of evidence shows that these cytokines are involved in the interplay between obesity and insulin sensitivity. IL-1 family of cytokines consists of several members in addition to Il-1 and IL-18, among which IL-1F6 has known pro-inflammatory properties. However, little is known about the potential metabolic effects of IL-1F6 in adipose tissue. The aim of this study was to assess whether IL-1F6 is expressed in adipose tissue and whether IL-1F6 influences adipocyte differentiation.
Materials and methods: Human abdominal subcutaneous tissue and primary human MI or type MII differentiated macrophages were used to determine the expression of IL-1F6. MI or MII differentiation of Macrophage was induced using either GM-CSF or M-CSF (100 ng/ml). Because obesity is associated with a chronic low-state inflammatory reaction, we tested whether IL-1F6 gene expression is induced by inflammation, using LPS. To determine the effects of IL-1F6 on adipocyte differentiation, primary human pre-adipocytes were differentiated towards adipocytes in the presence or absence of recombinant IL-1F6 (100 ng/ml). Adipocyte differentiation was analyzed by real-time PCR gene expression levels of adipogenic genes including AP2, PPARgamma, adiponectin and GLUT4, as well as by oil red O staining of lipid uptake.
Results: IL-1F6 is expressed in human adipose tissue. Fractioning of human adipose tissue revealed that IL-1F6 is primarily expressed in the stromal vascular fraction containing the ATMs. Although the stromal vascular fraction showed to be the primary source of IL-1F6, IL-1F6 was also present in adipocytes, be it at low levels. Treatment with endotoxin significant increased the expression of IL-1F6 in both MI and MII macrophages, as well as in SGBS preadipocytes. Recombinant IL-1F6 inhibited adipocyte differentiation, as showed by significantly reduced expression of AP2, PPARgamma and adiponectin, but not of GLUT4. Reduced differentiation was confirmed using microscopy and oil red o staining.
Conclusion: The proinflammatory IL-1 family member IL-1F6 is expressed in human adipose tissue. Although the primary source of IL-1F6 in adipose tissue is the stromal vascular fractions, both adipocytes and macrophages are able to produce IL-1F6. The presence of IL-1F6 inhibits human adipocyte differentiation, and future studies aimed to evaluate its effects on insulin sensitivity are warranted.

Remodeling of adipose tissue from lipodystrophic patients with LMNA mutations: presence of fibrosis and mitochondrial alterations but no inflammation
V. Béréziat[1], P. Cervera[1], M.-C. Verpont[2], C. Le Dour[1], B. Antuna-Puente[1], S. Dumont[3], M.-C. Vanthyghem[4], L.-M. Somja-Azzi[5], J. Capeau[1], C. Vigouroux[1];
[1]UPMC Inserm UMR_S938, Paris, [2]Institut Fédératif de Recherche en Santé Saint Antoine IFR65, Paris, [3]AP-HP Hôpital St Antoine, Paris, [4]Service d'Endocrinologie et Maladies Métaboliques- CHU de Lille, [5]Unité d'Endocrinologie, Clinique du Vert Galant, Tremblay-En-France, France.

Context: A low-grade inflammation of adipose tissue has been reported in obesity, associated with metabolic complications of obesity. However, in genetic lipodystrophies, the histological features of adipose tissue have not been described up to now. We then performed the histological characterization of adipose tissue from lipodystrophic patients bearing *LMNA* mutations.
Objective, design and patients: We comparatively studied the histological, ultrastructural and protein expression features of subcutaneous fat obtained during plastic surgery in three patients with *LMNA*-linked lipodystrophy, in

a patient with mitochondrial (mt)DNA-linked lipomatosis, in three patients with HIV antiretroviral-linked lipodystrophy and in eight healthy non-diabetic non-obese controls.
Results: *LMNA*-mutated, mtDNA-mutated and HIV-infected lipodystrophic fat was characterized by decreased adipocyte size, increased intercellular fibrosis and mitochondria density as compared to control samples. An ultrastructural analysis revealed irregular cell outlines with thickened peripheral rims of cytoplasm and interstitial edema with compact and thick fibrils invading the intercellular area in fat from patients bearing *LMNA* mutations. However, *LMNA*-mutated fat was not infiltrated with macrophages and did not show inflammatory alterations, in contrast to adipose tissue from mtDNA-mutated or HIV-infected patients. We also showed abnormal prelamin A accumulation, the precursor protein of lamin A, and altered protein expression of adipogenic transcription factors and mitochondrial respiratory chain proteins.
Conclusion: Lipodystrophic adipose tissue from patients with *LMNA* mutations presents a unique pattern of structural alterations with small adipocytes, intercellular fibrosis and mitochondrial disturbances in the absence of inflammation. We suggest that lamin mutation and/or prelamin A accumulation could impair adipocyte differentiation and lead to adipose tissue fibrosis.

Clinical impact of inflammatory cytokines produced in adipose tissue of septic patients
D. Ikeoka[1], S. Korsatko[1], C. Pachler[1], J.K. Mader[1], M. Bodenlenz[2], J. Plank[1], M. Ellmerer[1], T.R. Pieber[1,2];
[1]Department of Internal Medicine, Medical University Graz, [2]Joanneum Research, Graz, Austria.

Background and aims: Cytokines produced in adipose tissue were recently implicated in the generation of insulin resistance and diabetes. High levels of circulating inflammatory cytokines in circulation might also contribute to the genesis of glucose intolerance as observed in septic patients. However, the role of cytokines produced in adipose tissue was not studied in sepsis. The aim of this study was to investigate possible interactions between blood glucose and cytokines produced in adipose tissue in patients with severe sepsis. Other clinical variables were analyzed in parallel.
Materials and methods: Nine patients with severe sepsis from a medical intensive care unit were investigated over 26 hours. Informed consent was provided from the closest relative. A standard open-flow microperfusion catheter inserted in the subcutaneous adipose tissue (SAT) of the abdominal wall was used for continuous sampling of interstitial fluid effluent. Arterial blood samples were obtained simultaneously at two-hour intervals, along with clinical variables as part of the intensive care monitoring. Blood glucose was measured in a standard point-of-care device. Cytokines (TNF-alpha, IL-1beta, IL-6 and IL-8) present in SAT effluent samples and serum were measured using a multiplexed ELISA system.
Results: Distinct time profiles were registered for each cytokine in SAT effluent samples. Cytokine concentrations were higher in SAT than in serum for IL-1beta (10.0 [3.5; 13.9] vs. 0.7 [0.6; 1.4] pg/ml; median [25; 75 percentile]; $p<0.05$), IL-6 (1.66 [1.17; 2.33] vs. 0.06 [0.05; 0.08] ng/ml; $p<0.01$) and IL-8 (0.83 [0.51; 1.40] vs. 0.08 [0.02; 0.12] ng/ml; $p<0.01$). No important correlation was found for any of the measured cytokines and blood glucose. A weak negative correlation was observed between blood glucose and diastolic blood pressure (DBP; Pearson -0.21, $p=0.03$). Significant negative correlations were observed between SAT inflammatory cytokines and mean DBP (IL-1beta: Pearson -081, $p=0.008$; IL-6: Pearson -084, $p=0.005$; IL-8: Pearson -073, $p=0.025$). Regression analysis uncovered a strong interaction between DBP and IL-6 produced in SAT (B= -0.01; $p=0.002$; R-square=0.78). No other significant correlation between clinical variables and cytokines were observed.
Conclusion: Cytokines measured in SAT effluent from septic patients using OFM technique are probably locally produced, as suggested by the serum-SAT gradients, and seem to exert no major influence on blood glucose levels. Nonetheless, IL-6 might be implicated in the regulation of blood pressure in the studied population.

PS 47 "Metabolic syndrome" - clinical and experimental

644

APOE*3Leiden.CETP transgenic mice as model for the metabolic syndrome
A.M. van den Hoek[1], J.W.A. van der Hoorn[1], C. van den Hoogen[1], A. van Nieuwkoop[1], E. Offerman[1], E.J. Pieterman[1], A. Maas[1], L.M. Havekes[1,2], H.M. Princen[1];
[1]Biosciences, TNO, Leiden, [2]Department of Endocrinology and Metabolic Diseases, Leiden University Medical Center, Netherlands.

Background and aims: Metabolic syndrome is characterized by the co-occurrence of several risk factors i.e. increased body weight (bw) and insulin resistance (IR) with increased plasma glucose and insulin levels and at the same time adverse changes in plasma lipids as observed in diabetic dyslipidemia, with increased triglycerides and apoB-containing lipoproteins and decreased HDL.
We evaluated whether the APOE*3Leiden.CETP (E3L.CETP) mouse is a useful animal model to study the metabolic syndrome.
Materials and methods: E3L.CETP mice, a well-established model for hyperlipidemia and atherosclerosis, responding to all clinically used hypolipidemics, were put on a high fat diet and fructose in drinking water for 12 weeks to induce diet-induced obesity and IR and were subsequently treated with either rosiglitazone (10 mg/kg bw/d) or resveratrol (75 mg/kg/bw/d) for 5 weeks. Effects on bw, plasma parameters and insulin sensitivity (via hyperinsulinemic euglycemic clamps) were assessed.
Results: Dietary treatment resulted in a human-like lipoprotein profile with a TC/ HDL-C ratio of 3. Rosiglitazone significantly decreased triglycerides (-49%), cholesterol (-55%), glucose (-22%) and insulin (-82%) and increased insulin sensitivity (3.5-fold increase in glucose infusion rate). Resveratrol significantly reduced plasma triglycerides (-24%) and cholesterol (-44%) and increased HDL (+25%). All $p< 0.05$.
Conclusion: The data indicate that the E3L.CETP mouse is a good translational animal model that combines all important features that underlie the metabolic syndrome and mimic the human response to clinically used treatments. We conclude that this mouse is a promising model to investigate the effects of new drugs that affect insulin resistance and dyslipidemia.

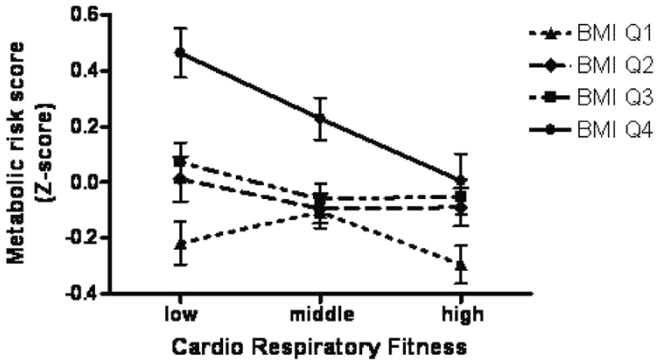
645

The role of body mass index and cardio respiratory fitness in predicting metabolic risk factors in adolescents: a longitudinal study
S.I. Brouwer[1,2], E. Corpeleijn[2], K.A.P. Lemmink[3,1], R.P. Stolk[2];
[1]Institute for Sport Studies, Hanze University, Groningen, [2]Epidemiology, University Medical Centre, Groningen, [3]Movement Sciences, University, Groningen, Netherlands.

Background and aims: The aim of this study was to examine whether Body Mass Index (BMI) is predictive for a clustering of metabolic risk factors in adolescents and whether this association is influenced by cardio respiratory fitness (CRF).
Materials and methods: Data on BMI were collected at age 11 (march 2001-july 2002) and repeated at age 16 (September 2005-dec 2007). At age 16 fasting blood samples were taken and CRF was estimated using the Shuttle Run Test. All participants from the 'Tracking Adolescents' Individuals Lives Survey' (TRAILS) with measures for metabolic risk and CRF at age 16 were included in this analysis (n=567). A clustered metabolic risk score was calculated as the mean of waist circumference, triglycerides, HDL-cholesterol and mean arterial pressure.
Results: At age 16 clustered metabolic risk score for females was lower than for males ($p<.001$). Clustered metabolic risk score at age 16 was higher for the upper quartiles of BMI measured at age 11 ($p<0.001$) compared to the lower quartiles. After adjustment for pubertal stage, sex, school and wearing HR-monitoring during SRT, CRF was associated with clustered metabolic risk score in the highest BMI quartile at age 11 (standardized β=-3.54; 95%CI: -.045- -.013) but not in the lower BMI quartiles. This is graphically depicted in the figure. For males CRF is negatively correlated to waist circumference (Pearson's $r=0.25$, $p<.01$), triglycerides ($r=0.121$, $p<.05$) and glucose ($r=0.14$, $p<.05$). For females CRF is negatively correlated to waist circumference ($r=0.226$, $p<0.01$) and positively related to HDL-cholesterol ($r=0.155$, $p<.01$).

Figure. A high CRF is related to reduced clustered metabolic risk score at age 16 in those with increased BMI at age 11. Differences on the clustered metabolic risk score was only significantly reduced between the low and high CRF tertiles for those with increased BMI.

Conclusion: A higher BMI at age 11 is associated with higher clustered metabolic risk scores at age 16. CRF has a positive influence on metabolic risk in adolescents with a higher BMI. The positive effect of CRF on males on clustered metabolic risk score is due to lower waist circumference, triglycerides and glucose. In females the positive effect of CRF on clustered metabolic risk score is due to lower waist and a higher HDL-cholesterol.



646

Significant decrease of fetuin-a after dramatic weight loss in morbidly obese women

J.-M. Brix[1], F. Höllerl[2], V. Eger[2], H.-P. Kopp[1], S. Kriwanek[3], G.-H. Schernthaner[2], G. Schernthaner[1];
[1]Medicine I, Rudolfstiftung Hospital, Vienna, [2]Medicine II, Medical University of Vienna, [3]Department of Surgery, Rudolfstiftung Hospital, Vienna, Austria.

Background and aims: Patients with morbid obesity have a high risk for cardiovascular morbidity, mortality and diabetes. The only effective method to reduce weight and to lower the high cardiovascular risk is bariatric surgery. Recent studies demonstrated that the liver-secreted protein fetuin-A is elevated in insulin resistance, is an independent predictor of type 2 diabetes and is associated with atherosclerosis. Thus it was of interest for us to evaluate Fetuin-A levels in patients with morbid obesity versus control subjects as well as before and after weight loss induced by gastric bypass.

Materials and methods: We included 47 morbid obese patients (MO, 40 women, BMI 46.6±7.3 kg/m²) and 28 healthy controls (13 women, BMI 26.1±3.3 kg/m²) in a cross sectional study. 31 women were investigated before and one year after gastric bypass surgery. Apart from weight and cardiovascular risk-markers (blood pressure, lipids), a glucose tolerance test (75g oGTT) was performed and renal, liver as well as inflammation parameters were assessed. Insulin resistance (IR) was calculated by using HOMA.Fetuin-A levels were determined in serum samples by a commercial ELISA.

Results: Fetuin-A levels were significantly increased in MO: 795.0±191.5 vs healthy controls: 393.2±146.5µg/ml; p <0.001. In the longitudinal study Fetuin-A (827.2± 181.8 vs 753.9 µg/ml; p= 0.033) BMI (46.6±7.3 vs 31.6±6.8 kg/m²; p < 0.001), weight (133.5± 20.8 vs.90.6±20.3kg;p<0.001) and HOMA (6.6±6.3 vs. 2.0±1.2 p<0.001) decreased significantly 1 year after gastric bypass. Correlation analysis of pre-surgery Fetuin-A values revealed that Fetuin-A was associated with HOMA-IR (R=-0.413; p=0.029), diastolic blood pressure (R=-0.392; p=0.036) and 1hour postprandial blood glucose (R=-0.385; p=0.047). In a multivariate model HOMA-IR (beta=-0.408; p=0.024) and diastolic blood pressure(beta=-0.382; p=0.033mmHg) predicted independently from each other Fetuin-A.Correlation analysis of post-surgery Fetuin-A showed that Fetuin-A levels were associated with bilirubin (R=0.390; p =0.040) and 2 hour postprandial Insulin levels (R=-.479; p=0.028). In a regression analysis Insulin 2 hour postprandial levels remained the only significant predictor for post-surgery Fetuin-A (beta=-0.479; p= 0.028).

Conclusion: This is the first study demonstrating a significant increase in Fetuin-A values in patients with morbid obestity compared to nonobese control subjects. Fetuin-A levels were reduced after bariatric surgery. Since Fetuin-A was shown to be associated with the future development of type 2 diabetes and atherosclerosis, the observed significant decrease in Fetuin A after dramatic weight loss might help to understand the beneficial effects of gastric bypass surgery.

Background and aims: Obesity, especially visceral has been shown to be associated with abnormal postprandial lipid response. "Hypertrigliceridemic waist" (HW) phenotype is suggested to be a reliable marker of visceral obesity (waist girth ≥90cm in men and ≥85cm in women, with plasma triglycerides (TG) concentration ≥2mmol/l). Type 2 diabetes (T2D) represents frequent comorbidity in obesity and is closely associated with abnormalities in postprandial lipid metabolism mostly through insulin resistance. The aim of our study was to analyze the influence of presence of HW phenotype and postprandial lipemia in obese patients with T2D. The following groups of patients were included in the study: obese T2D patients with HW phenotype (Group A, n=30), obese T2D without HW phenotype (Group B, n= 25) and nonobese T2D without HW phenotype (group C, n=30). Patients were aged 40-70 years, matched by gender, duration of diabetes with optimal glycemic control.

Materials and methods: Postprandial lipids, apolipoproteins (Apo), NEFA and insulin response were measured after mixed meal (51g fat) at 2-h intervals during 8hrs. Results were expressed as AUCs determined by the trapezoid method. Total cholesterol (TC), HDL, LDL and TG were determined by enzymatic methods. Apolipoproteins (Apo A1, ApoA2,ApoB,ApoE) were determined by nephelometric and NEFA by colorimetric methods. Insulin levels were measured by RIA and insulin resistance was evaluated in all groups in fasting state using HOMA method.

Results: We found that the postprandial TG increase were the highest in group A, being significantly higher in group A than in B and in group B than in C (AUC A: 2020.4±133, B:1575.6±100.4, C:1263±100.2mmol/l/min, A vs B p<0.01 and B vs C p<0.05). Simultaneously, postprandial response of TC were the highest in group A, being significantly higher in group A than in group B, but without significant difference beetwen groups B and C (AUC A:3088.9±213, B:2879±150, C:2682±145mmol/l/min; A vs B p<0.01 and B vs C p=NS). There was no differences in postprandial response of HDL, LDL and NEFA between groups. However, significantly higher postprandial increased of Apo B and Apo E was found in group A than in groups B and C (ApoB AUC: A:633.9 ± 52, B:591.5± 45, C: 514 ± 50 g/l/min; A vs B vs C p<0.05; ApoE AUC: A:30662±538, B:26232±999, C:20460±538mg/l/min; A vs B vs C p<0.01) without differences regarding levels of ApoA1 i ApoA2. Insulin response was significantly higher in group A compare to group B, but there was no difference among groups B and C (AUC: A:31400±254; B:22900,±129; C:19800±117mI/ml/h;A vs B<0.01, B vs C p=NS). Regarding the insulin resistance, we found the highest HOMA-IR in group A but, there was no differences beetwen groups B and C (A: 11.9±2.3, B: 5.65±1.8, C: 5.2±1.2Avs B p<0.01, AvsC p<0.01, B vs C p=NS). Moreover, amplified postprandial TG response ccorrelated with HOMA-IR and postprandial insulin response (r=0.44, p<0.05 and r=0.42 p<0,05) respectively, only in group A. We did not find that correlation in the other groups.

Conclusion: Our results have demonstrated that in obese T2D patients presence of hypertrigliceridemic waist phenotype was associated with enhancement of abnormal postprandial lipid, especially TG, response. The data imply that this enhancement was strongly influenced by increased of postprandial insulin response and insulin resistance in these T2D patients.

The association of serum fatty acid-binding protein 4 with progression of metabolic syndrome status in apparently healthy Korean adults

S.-E. Park, E.-J. Rhee, S.-H. Yoo, W.-J. Kim, E.-S. Choi, J.-C. Pae, C.-Y. Park, W.-Y. Lee, K.-W. Oh, S.-W. Park, S.-W. Kim;
Endocrinology, Kangbuk Samsung Hospital, Sungkyunkwan University, Seoul, Republic of Korea.

Background and aims: Adipocyte fatty acid-binding protein (A-FABP), also known as aP2 or FABP4, is abundantly expressed in adipocytes and plays a role in glucose homeostasis. We analyzed the relationship of serum FABP4 level with the progression of metabolic syndrome in apparently healthy Korean adults.

Materials and methods: In 494 Korean adults (mean age 40.8 years, male 65.8%), selected among the participants in a medical check-up program in

a health promotion in 2003, serum FABP4 levels were measured by ELISA. Anthropometric measurements were performed in all subjects and in fasting status, fasting glucose, insulin and lipid profiles were measured. Insulin resistance was assessed by HOMA-IR and the presence of metabolic syndrome was assessed according to AHA/NHLBI criteria with BMI substituted for waist circumference. After 4 years, the metabolic syndrome status was assessed in association with baseline serum FABP4 level in the same subjects.
Results: In 4 years, 395 subjects (80%) maintained their initial status (normal to normal, or metabolic syndrome present to metabolic syndrome present; non-progressor), 81 subjects (16.4%) progressed to more serious stage (normal to metabolic syndrome; progressors) and 18 subjects (3.6%) regressed to metabolic syndrome to normal (regressors). When baseline serum FABP4 levels were compared among the three groups, progressors showed significantly higher baseline mean value of logarithmically transformed (log) FABP4 compared with the non-progressors in 4 years of follow-up (2.42±0.45 vs. 2.16±0.45 ng/mL, p<0.001), and these significant differences were consistent even after adjustment for age and BMI (p=0.029). When logistic regression analysis with the progression to metabolic syndrome as the dependent variable, was performed after excluding regressors (n=18), with age, high baseline log FABP4 level, male gender, high BMI and low SBP were the significant determinants for the development of metabolic syndrome (odds ratio for log FABP4 levels, 2.549, p<0.001).
Conclusion: Baseline serum FABP4 level is assumed to be the significant predictor for future progression of metabolic syndrome in apparently healthy adults even after adjusting confounding factors in 4 years of follow-up in this ethnic groups.

Intestinal triglyceride concentration of morbidly obese persons is lower in those with type 2 diabetes mellitus
F. Soriguer[1], S. Garcia-Serrano[2], L. Garrido-Sanchez[3], G. Rojo-Martinez[4], J. Garcia-Arnes[5], J.L. Gallego-Perales[5], V. Delgado[5], E. Garcia-Fuentes[4]; [1]Servicio de Endocrinología y Nutrición, Hospital Carlos Haya, [2]CIBERDEM, [3]CIBER Fisiopatología Obesidad y Nutrición (CB06/03), [4]Fundación IMABIS, [5]Hospital Carlos Haya, Málaga, Spain.

Background and aims: High levels of apolipoprotein B-48-containing lipoproteins in the fasting state seem to be associated with increased cardiovascular disease risk. We studied the association between insulin resistance and the lipid content in plasma and the small intestine of morbidly obese persons with or without diabetes.
Materials and methods: The study was undertaken in 17 morbidly obese persons, 8 of whom had type 2 diabetes. The HOMA-IR was calculated to determine insulin resistance and measurements were made of the plasma apolipoprotein B-48 and chylomicrons. Jejunum samples were obtained during gastric bypass in order to quantify their content of triglycerides (biochemical techniques and Oil Red-O staining) and apolipoprotein B (immunohistochemistry).
Results: The morbidly obese persons with diabetes had greater plasma concentrations of triglycerides (P=0.003), chylomicron triglycerides (P<0.001) and apolipoprotein B-48 (P=0.012). The samples of jejunum obtained from the morbidly obese persons with diabetes had a lower jejunal triglyceride content (P=0.012) and a lower apolipoprotein B signal (P=0.008). The HOMA-IR correlated positively with the plasma levels of apolipoprotein B-48 (r=0.688, P=0.003) and chylomicron triglycerides (r=0.700, P=0.003), and negatively with the jejunal triglyceride content (r=-0.774, P=0.001) and the jejunal apolipoprotein B signal intensity (r=-0.747, P=0.001). The jejunal triglyceride content also correlated positively with the jejunal apolipoprotein B signal intensity (r=0.776, P<0.001) and negatively with the plasma apolipoprotein B-48 (r=-0.674, P=0.004).
Conclusion: The lipid content of the jejunum was significantly reduced in morbidly obese persons with diabetes and was inversely related with the plasma levels of chylomicrons, apolipoprotein B-48 and the HOMA-IR.

Associations between components of the metabolic syndrome and fatty liver are mediated by insulin resistance and endothelial dysfunction, but not by inflammation (the CODAM study)
M.M.J. van Greevenbroek[1], C.J.H. van der Kallen[1], M. Jacobs[1], I. Ferreira[1], C.G. Schalkwijk[1], E.E. Blaak[2], E.J.M. Feskens[3], C.D.A. Stehouwer[1]; [1]Internal Medicine, Maastricht University, [2]Human Biology, Maastricht University, [3]Division of Human Nutrition, Wageningen University, Netherlands.

Background and aims: The metabolic syndrome (MetS) is associated with presence of fatty liver and this association may be related to insulin resistance and inflammation and possibly also to endothelial dysfunction, e.g. via effects on liver metabolism. We have therefore investigated whether plasma alanine aminotransferase (ALT), a surrogate marker of fatty liver, is associated with individual components of the MetS and, if so, the extent to which these associations are mediated by insulin resistance, inflammation and/or endothelial dysfunction.
Methods: Analyses were done in the CODAM (cohort study on diabetes and atherosclerosis Maastricht) population with only subjects who consumed < 2 units of alcohol/day and included 397 subjects (53.1% male, age 59.2 ± 7.2 yrs). All independent variables were transformed into Zscores (log-transformed when appropriate). An inflammation score, i.e. average of the Z-scores of the inflammation markers CRP, IL6, ceruloplasmin, haptoglobin, serum amyloid A and ICAM, was calculated. Likewise, a score for endothelial dysfunction (E-selectin, vWF and VCAM) was calculated. HOMA2*ir* was used as a measure of insulin resistance.We used linear regression analyses to determine the associations of components of the MetS, and the inflammation, insulin resistance and endothelial dysfunction scores, with ALT (dependent, all adjusted for age, sex and presence of type 2 diabetes). Next, we investigated whether the associations of the MetS components with ALT were mediated by insulin resistance, inflammation and/or endothelial dysfunction.
Results: Prevalence of MetS (NCEP-ATP 2005) and type 2 diabetes was 56.7% and 26.2%, respectively. All components of the MetS (beta [95%CI] for waist was 0.057 [0.041; 0.074], BP; 0.038 [0.020; 0.055], HDL; -0.034 [-0.051; 0.016], TG; 0.048 [0.032; 0.094], glucose 0.046 [0.023; 0.070]) as well as scores for insulin resistance (0.086 [0.070; 0.102]), inflammation (0.036 [0.013; 0.060]) and endothelial dysfunction (0.081 [0.054; 0.109]) were associated with logALT. The associations between MetS components and ALT were strongly attenuated by insulin resistance, with the strongest effect on glucose, followed by HDL, waist, TG and BP (decrease in beta of the MetS components was 89.1, 76.5, 73.7, 58.3, and 47.4%, respectively). They were somewhat attenuated by endothelial dysfunction, with the strongest effect on HDL followed by glucose, waist, BP and TG (decrease in beta was 29.3, 21.7,15.6, 13.2 and 12.5%, respectively) and hardly by inflammation (decrease in beta was 14.7 to 2.1%, respectively). Total attenuation with insulin resistance, endothelial dysfunction *and* inflammation added to the model was strongest for glucose followed by HDL, waist, TG and BP (decrease in beta was 92.3, 82.4, 73.7, 58.3, 47.4%).
Conclusion: The associations between fatty liver, when measured as plasma ALT, and all components of the metabolic syndrome were for a very large part explained by insulin resistance with a small additional effect of endothelial dysfunction but, unexpectedly, not by systemic inflammation.

Prevalence of features of the metabolic syndrome in healthy white-collar employees with or without fatty liver disease: role of plasma glucose levels of ≥ 100mg/dl versus ≥ 110mg/dl
J. Haas[1], S. Teufel-Sies[2], S. Mack[1], E. Becker[2], B. Knebel[3], J. Kotzka[3], A. Burchard[1], M. Merkel[1], T. Stein[2], D. Muller-Wieland[1]; [1]Institute for Diabetes Research and I. Med. Dep, Asklepios Klinik St. Georg, Hamburg, [2]Diagnostic-Center Fleet-Insel, Hamburg, [3]Institut for Clinical Biochemistry and Pathobiochemistry, German Diabetes Center, Duesseldorf, Germany.

Background and aims: Non alcoholic fatty liver (NAFL) is the most common chronically liver disease and often associated with the features of the metabolic syndrome. But, there is little knowledge about the prevalence of single components of the metabolic syndrome in healthy individuals with or without fatty liver disease.
Materials and methods: In this study data of more than 1500 healthy, male white-collar employees (30 to 60 year old) participating in a regional prevention program were collected.

Results: Sonographic analysis indicated a fatty liver in 32% of all cases investigated. Approximately 50% of these individuals showed triglycerides levels >150 mg/dl and in 12% of cases had HDL-levels below 40 mg/dl. More than 67% of probands showed hypertension with values above 130/85 mmHg and fasting blood glucose levels exceeding 110 mg/dl were detected in 13% of individuals investigated. These data indicated a more than twofold increase of pathologically levels for triglycerides, HDL-cholesterol and hypertension in patients with fatty liver disease. Interestingly, pathologically increased fasting blood glucose values were detected in only 2.5% of individuals without fatty liver, but occurred with a 7-fold higher prevalence in patients with fatty liver disease. Focusing on the three prominent parameters crucial for the metabolic syndrome i.e. increased triglyceride levels, hypertension and increased fasting blood glucose >110 mg/dl, the criteria were fulfilled in 14% of individuals with fatty livers, but only in 2% of the non fatty liver group. Reducing the critical value for impaired fasting glucose from >110 mg/dl to >100 mg/dl even doubles the prevalence of this risk factor pattern in the fatty liver group investigated, indicating the importance of this parameter in respect to the metabolic syndrome.
Conclusion: The data indicate that reducing the pathological value of impaired fasting glucose to >100 mg/dl might be valuable for screening of patients also in respect for other components of the metabolic syndrome. Furthermore all individuals with fatty livers should also be routinely screened for criteria of the metabolic syndrome.

Cerebrovascular effects of endocannabinoids
É. Ruisanchez[1], R. Benkő[1], M. Leszl-Ishiguro[1], Z. Lacza[1], Z. Járai[2], P. Sándor[1], Z. Benyó[1];
[1]Institute of Human Physiology and Clinical Experimental Research, [2]1st Department of Internal Medicine, Semmelweis University, Budapest, Hungary.

Background and aims: Antagonists and inverse agonists of the CB1 cannabinoid receptors have been recently developed by several pharmaceutical companies as adjuvants to lifestyle modification for weight reduction, glycemic control and dyslipidemia in obese and type 2 diabetes patients. Since endocannabinoids have been implicated as important mediators in the cardiovascular system pharmacological manipulation of the CB1 mediated signaling pathway may have marked circulatory consequences. Obesity and diabetes are often associated with cerebrovascular dysfunction which can be influenced by inhibition of the CB1 pathway. In the present study we aimed to investigate the effects of endocannabinoids on the resting blood flow and on hypoxia/hypercapnia (H/H)-induced hyperemia of the cerebral cortex.
Materials and methods: Adult male Wistar rats were anesthetized with intraperitoneal injection of 1.3 g/kg Urethane. Cerebrocortical blood flow (CBF) was measured simultaneously in the parietal cortex of both hemispheres by laser-Doppler (LD) flowmetry. H/H was induced by inhalation of different gas mixtures. In the first step, during mild H/H, animals inhaled a gas mixture of $10\%O_2$-$10\%CO_2$-$80\%N_2$, which produced arterial pO_2 of 75-85 mmHg and pCO_2 of 50-60 mmHg. In the second step, during moderate H/H, animals inhaled a gas mixture of $5\%O_2$-$20\%CO_2$-$75\%N_2$, which produced arterial pO_2 of 55-65 mmHg and pCO_2 of 80-90 mmHg. In the third step, during severe H/H, animals inhaled a gas mixture of $0\%O_2$-$20\%CO_2$-$80\%N_2$, which produced arterial pO_2 of 45-50 mmHg and pCO_2 of 90-100 mmHg.
Results: Inhibition of endocannabinoid reuptake by AM-404 (10 mg/kg iv.) resulted in a transient increase of the resting CBF, which had a peak (+65±16 %) at 5.2±0.6 minutes and disappeared within 10 minutes. The CBF changes were accompanied by reduction of the ventilation rate as well as by increased arterial pCO_2 and decreased pO_2. Application of the CB1 receptor antagonist AM-251 (10 mg/kg iv.) did not alter baseline CBF but was able to prevent the effects of AM-404. The VR1 vanilloid receptor antagonist capsazepine (20 mg/kg iv.) influenced neither the resting CBF nor the effects of AM-404. Furthermore, AM-251 significantly increased the H/H-induced hyperemia: by 30 % during mild H/H, by 22 % during moderate H/H, and by 14 % during severe H/H. In contrast, the vehicle of AM-251 had no significant effect. H/H did not change mean arterial pressure in untreated or vehicle-treated animals, although following AM-251 treatment it induced slight hypertension (+11 ± 6 mmHg).
Conclusion: Our results indicate that endocannabinoids may increase the resting CBF either by a CB1-mediated direct vasodilator mechanism or indirectly via respiratory depression and the consequent changes of the blood gas tensions. Interestingly, activation of CB1 receptors attenuates the H/H induced cerebrocortical hyperemia by a yet undefined mechanism. Therefore, the cerebrovascular and systemic circulatory actions of CB1 antagonists have to be considered as potential side effects during management of obesity and diabetes.

Phthalate metabolites are associated with insulin resistance in 3T3-L1 cells *in vitro*
N. Kloeting[1], R. Chakaroun[1], M. Illes[1], M. Fasshauer[1], P. Kovacs[1,2], M. Stumvoll[1], M. Blüher[1];
[1]University of Leipzig, [2]IZKF, Leipzig, Germany.

Background and aims: The metabolites of di-(2-ethylhexyl)-phthalate (DEHP), a ubiquitous environmental contaminant, might influence glucose homeostasis and insulin sensitivity of adipose tissue. We therefore investigated the effects of DEHP treatment on insulin stimulated glucose uptake, palmitate uptake into 3T3L1 adipocytes as well as on mRNA expression of key adipocyte genes *in vitro*.
Materials and methods: Mouse 3T3-L1 preadipocytes (American Type Culture Collection, Rockville, MD) were cultured with 0.01% DEHP for two days and differentiated into mature adipocytes. In fully differentiated 3T3L1 adipocytes, basal and insulin-stimulated glucose transport was measured using 2-deoxyglucose. In addition, uptake of palmitic acid into 3T3-L1 cells was estimated by a [1-^{14}C] palmitic acid based assay (Perkin Elmer, Massachusetts, USA). Triglyceride content was determined using the LabAssay Triglyceride (WAKO Pure Chemicals). The mRNA expression of key genes in adipose tissue function was performed using RT-PCR.
Results: Treatment with DEHP resulted both in increased basal and insulin stimulated glucose uptake. Palmitic acid uptake was not affected by DEHP treatment *in vitro*. DEHP treatment of 3T3L1 adipocytes significantly increased adipocyte proliferation rate. In parallel to that, expression of *IGF1R, PI3K, VAMP4* mRNA was up-regulated, whereas adiponectin mRNA expression was down-regulated in response to DEHP treatment.
Conclusion: The environmental contaminant DEHP has significant effects on adipocyte proliferation, gene expression and *in vitro* glucose uptake into adipocytes which may contribute to adipose tissue dysfunction in obesity.

Identification and characterisation of candidate genes in diet-induced non-alcoholic fatty liver disease in inbred mice

H.E. Waller-Evans[1], J. Fearnside[1], K. Argoud[1], A. Burt[2], S.P. Wilder[1,3], I. Gut[4], J. Scott[5], D. Gauguier[1];
[1]Wellcome Trust Centre for Human Genetics, University of Oxford, United Kingdom, [2]Institute of Cellular Medicine, University of Newcastle, Newcastle upon Tyne, United Kingdom, [3]Embl-ebi, Wellcome Trust Genome Campus, Cambridge, United Kingdom, [4]Equipe Genotypage Plante, Centre National de Génotypage, Paris, France, [5]National Heart and Lung Institute, Imperial College London, United Kingdom.

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is associated with the metabolic syndrome, which comprises several disorders including obesity and type 2 diabetes mellitus, and is influenced by both genes and environmental factors. Mouse models are important tools in the dissection of the genetics of these complex diseases. The aim of this research is to identify susceptibility genes for obesity and NAFLD in inbred mice susceptible (129S6) and resistant (BALB/c) to high-fat diet induced obesity and NAFLD.
Materials and methods: 129S6 and BALB/c mice were intercrossed to generate a cohort of 180 F2 hybrids. Male F2 mice were fed high-fat diet (40% fat) for 15 weeks and scored for body weight, adiposity (obesity), NAFLD and liver inflammation phenotypes. Genome-wide scans were performed with 400 Single Nucleotide Polymorphism markers showing evidence of allele variation between 129S6 and BALB/c. Genetic maps were constructed using JoinMap. Linkage analyses between genotypes and quantitative phenotypes were performed using R/qtl.
Results: Statistically significant Quantitative Trait Loci (QTLs) linked to body weight were identified on chromosomes 3 (logarithm of the odds (LOD) 4.7) and 4 (LOD 5.1). The chromosome 4 QTL was also strongly linked to adiposity (LOD 5.6) and NAFLD (LOD 3.8). A region of chromosome 18 was significantly linked to NAFLD phenotypes including macrovesicular and microvesicular steatosis (LOD 5.1 and 8.4 respectively) and inflammation (LOD 4.2), but did not show evidence of linkage to adiposity. At the QTLs identified, 129S6 alleles contribute to increased body weight and adiposity, and increased incidence of NAFLD and inflammation phenotypes.
Conclusion: These data demonstrate the polygenic control of both obesity and NAFLD induced by high fat diet feeding. QTL data suggest that NAFLD and obesity underlie the effect of the same gene(s) on chromosome 4, which does not cause inflammation. In contrast, NAFLD can also develop through a different mechanism controlled by a gene on chromosome 18 which leads to liver inflammation without influencing adiposity. Genome annotations of NAFLD QTLs and sequence analysis have provided information for strong positional and functional NAFLD candidate genes which we are currently investigating.

Hepatocyte-specific inflammation enhances VLDL production in mice

J.A. van Diepen[1], M.-C. Wong[2], S.E. Shoelson[3], L.M. Havekes[4], J.A. Romijn[1], P.J. Voshol[1];
[1]Endocrinology and Metabolic Diseases, Leiden University Medical Center, Netherlands, [2]Pulmonology, Leiden University Medical Center, Netherlands, [3]Joslin Diabetes Center and Department of Medicine, Harvard Medical School, Boston, United States, [4]Department of Biomedical Research, TNO-Quality of Life, Leiden, Netherlands.

Background and aims: The low-grade inflammation that is associated with Type 2 Diabetes (DM2) and Cardiovascular Diseases (CVD) plays an important role in their pathophysiology. Shoelson et al have shown that activation of the inflammatory Nf-κB pathway in the hepatocyte induces severe metabolic changes. We questioned whether hepatocyte-specific activation of Nf-κB affects triglyceride and cholesterol metabolism directly.
Materials and methods: The LIKK-mouse has a transgenic hepatocyte expression of constitutive active IkB kinase, IKKβ. We crossbred this LIKK-mouse with the APOE*3Leiden mouse for its human-like lipid metabolism and investigated the effects of this continuous activation of liver Nf-κB on fasted plasma cholesterol, triglycerides and lipoproteins in 12 week old male LIKK.APOE*3Leiden and APOE*3Leiden mouse fed a chow diet (n=6). Livers were collected to determine hepatic steatosis. Furthermore, hepatic VLDL production was measured using Triton WR1339 to block peripheral VLDL lipolysis, in overnight fasted mice (n=8).
Results: Constitutive active IKKβ expression in the hepatocyte induced an increase in basal triglycerides ($p<0.05$) in APOE*3Leiden mice, which was confirmed by elevated levels of VLDL-triglycerides (0.576 vs 0.382 mM). Liver lipid content was not different between both mice. By blocking the VLDL lipolysis with Triton1339, VLDL-triglycerides were accumulating faster in LIKK.APOE*3Leiden mice than APOE*3Leiden mice (0.065±0.017 vs 0.044±0.013 mM min^{-1}, $p<0.05$), thereby showing an increased hepatic VLDL production.
Conclusion: These data show that hepatocyte-specific low grade inflammation directly increased VLDL-TG levels in plasma by upregulation of hepatic VLDL production. We can conclude that chronic low-grade inflammation plays an important role in the pathophysiology of dyslipidemia associated with Cardiometabolic risk.

Influence of lipodystropy on gene expression in liver

B. Knebel[1], J. Haas[2], S. Jacob[1], U. Nitzgen[1], D. Muller-Wieland[2], J. Kotzka[1];
[1]Clinical Biochemistry and Pathobiochemistry, German Diabetes Center, Duesseldorf, [2]Institut for Diabetes Research and I. Med. Dep. Asklepios Clinic St. Georg, Hamburg, Germany.

Background and aims: Sterol regulatory element binding protein (SREBP)-1c is a key transcription factor that mediates the gene regulatory effects of hormones, cytokines, metabolites as lipids or glucose as well as cholesterol. The systemic impact of this central regulator of lipid metabolism in vivo was analyzed by tissue specific overexeression of SREBP-1c in adipose tissue and liver.
Materials and methods: We generated transgenic mouse models that express the N-terminal transcriptional active domain of SREBP-1c adipose tissue specific under control of the aP2 promoter. The second model SREBP-1c is expressed liver specific under control of the albumin promoter and a liver specific enhancer. Animals were kept under standardized conditions with unrestricted access to water and chow until the age of 24 or 48 weeks, respectively. Following liver resection histological and gene expression studies (Mouse 430 2.0, (Affymetrix)) were performed. RNA-data were analyzed on statistical relevance and significant expression variation of at least 2-fold ($p=0.01$) over the complete experimental series (Genespring, Agilent).
Results: Overexpression of SREBP1c in adipose tissue results in a complete loss of adipose tissue i.e. features of lipodstropy with the parallel development of massive fatty livers. In contrast, the liverspecific overexpression of SREBP-1c results in hepatic lipid accumulation, featuring a fatty liver with massively increased of visceral adipose tissue. The direct comparison of the different gene regulation in the livers shows in the lipodystrophic mouse model the differential regulation of approximal 1000 transcripts. Here genes for lipid peroxidation, transport and degradation of oxidized lipids being essential in neutralization of oxidative metabolic products i.e. ATP-transporter as ABCA1 but also key signaling molecules as PPAR-gamma or apolipopoteines are differentially regulated. The increased expression of genes from stress- and apoptosis signaling pathways as heat shock proteins or caspases might indicate the declining compensation of hepatic lipid intoxication. In the fatty liver model approximately 2500 genes, including genes for lipid and energy- metabolism like mitochondrial NADH-dehydrogenase, aldehyd-dehydrogenases, various sterol carrier proteins or cytochrome subunits next to intra- and extra- cellular transporters, were regulated.
Conclusion: These mouse models allow the elucidation of the pathogenetic role of the transcription factor SREBP-1c, but also the investigation of a pathophysiology of primary lipid accumulation in liver as well as the long term effects of chronic fatty liver.

657

Liver metabolic fluxes in response to high fat diet

G. Vial[1], H. Dubouchaud[1], K. Couturier[1], N. Taleux[1], A. Athias[2], A. Galinier[3], X. Leverve[1];
[1]INSERM U884, Grenoble, [2]Université de Bourgogne, INSERM UMR866, Dijon, [3]UMR 5241 CNRS-UPS, IFR 31, C.H.U. Rangueil, Toulouse, France.

Aim: To determine adaptations of metabolic fluxes in liver of adult rats fed with a high fat (HF) diet.

Methods: Hepatocytes isolated from rats fed either a standard (carbohydrate diet: CHO) or a HF diet were perifused with increasing concentrations of glycerol in the absence or presence of octanoate (0.4mM).Glucose, lactate, pyruvate, hydroxybutyric acid and oxaloacetic acid production were measured at each substrate concentration. Oxygen consumption and major enzymatic activities were measured in isolated hepatocytes and isolated liver mitochondria. Analysis of gene expression involved in major metabolic pathways was assayed in liver using RT-PCR.
Results: Gluconeogenesis from glycerol is increased in HF group in the presence of octanoate (+30%) but is decreased in the absence of fatty acid. This effect was associated with an increase in glycerol metabolism without effect on glycolysis. In both conditions, cytosol was more oxidized whereas mitochondrial compartment was more reduced. Cellular and mitochondrial oxidative capacities were reduced by HF diet (-40%). As glycerol metabolism requires a stoechiometric utilization of ATP and NAD+, control of this pathway is either at the dehydrogenase level, (at low rate of glycerol metabolism), or at the phosphorylation level (at high rate of metabolism) depending on the redox condition. Hence, the lower glycerol metabolism observed with HF at high flux is due to diminished oxidative phosphorylation capacity and to an inability to maintain ATP content in the cytosol. By contrast, when flux through the pathway is reduced by high redox pressure generated by fatty acid metabolism, the ability of HF rats to maintain an oxidized cytosolic compartment allow then to metabolize more glycerol. In addition, RT-PCR revealed an enhanced expression of glycerol kinase mRNA and phosphoenolpyruvate carboxykinase mRNA in HF rats supporting an elevation of gluconeogenesis pathway in presence of fatty acid.
Conclusion: Metabolic fluxes were highly altered by HF diet. These changes were attributed to oxidative phosphorylation adaptation and to genomic regulation of key enzymes of carbohydrate and fatty acid metabolic pathways.

Prominent role of liver in elevated plasma palmitoleate levels in response to a low-dose rosiglitazone

T. Jelenik[1], O. Kuda[1], B. Stankova[2], E. Tvrzicka[2], M. Hensler[1], M. Rossmeisl[1], P. Flachs[1], J. Kopecky[1];
[1]Dept. of Adipose Tissue Biology, Institute of Physiology, Academy of Sciences, [2]4th Department of Internal Medicine, Charles University, 1st Faculty of Medicine, Prague, Czech Republic.

Background and aims: Thiazolidinediones, such as rosiglitazone, are insulin-sensitizing drugs, which exert their benefits as agonists of peroxisome proliferator-activated receptor-γ. Recently, palmitoleate (C16:1n-7) has been identified as adipose tissue-derived lipokine that stimulates muscle insulin action. In this study, tissue expression of stearoyl-CoA desaturase-1 (SCD-1), an enzyme driving the formation of palmitoleate, as well as complex changes of fatty acid (FA) composition induced by a low-dose rosiglitazone were analyzed in mice fed a high-fat diet.
Materials and methods: C57BL/6 mice were fed a corn oil-based high fat (lipids ~35% weight/weight) diet or high-fat diet supplemented with rosiglitazone (10 mg/kg diet) for 8 weeks. Insulin sensitivity was assessed by hyperinsulinemic-euglycemic clamps, while FA composition in various lipid fractions in plasma, liver, and adipose tissue was analyzed using gas chromatography and evaluated by principal component analysis (PCA). Gene expression was assessed by real-time quantitative RT-PCR.
Results: Low-dose rosiglitazone increased whole-body glucose turnover during clamp (41 ± 3 vs. 30 ± 5 mg/kg/min, rosiglitazone vs. high-fat, respectively; $p<0.05$) without significantly affecting hepatic glucose production, suggesting improved muscle glucose metabolism. After rosiglitazone treatment, *Scd-1* expression increased ~2-fold in adipose tissue and skeletal muscle, however in the liver it increased >5-fold. In general, rosiglitazone induced a shift towards monounsaturated FAs in the liver, adipose tissue and plasma, with palmitoleate being the most up-regulated FA (3-, 1.5-, and 2-fold, respectively). Specifically in the liver, enrichment of cholesteryl esters and phosphatidyl cholines with palmitoleate and vaccenate was found, and strong correlations between the changes of various lipid fractions in the liver and total plasma lipids were observed ($r = 0.74$-0.88).
Conclusion: Changes in plasma lipid profile favouring monounsaturated FAs, mainly palmitoleate due to induction of *Scd-1* in the liver, could be involved in the stimulatory effect of rosiglitazone on muscle insulin sensitivity in mice fed a high-fat diet.

IL-1β in conditioned medium from TNFα pre-treated 3T3-L1 adipocytes mediates insulin resistance in Fao hepatoma cells

O. Nov, A. Kohl, E. Lewis, N. Bashan, A. Rudich;
Department of Clinical Biochemistry, Ben Gurion University, Beer Sheva, Israel.

Introduction: Central obesity is frequently associated with adipose tissue inflammation and hepatic insulin resistance. We hypothesized that an *in-vitro* system to assess if insulin resistance in liver cells could be induced by secreted products from adipocytes pre-exposed to an inflammatory stimulus could assist in identifying individual mediators in this process.
Methods: 3T3-L1 adipocytes were exposed to TNFα for 18 hours in the absence and presence of Rosiglitazone or YVAD (caspase I inhibitor II). Cells were washed thoroughly, and conditioned medium from control adipocytes (CM) or from TNF-pre-treated adipocytes (TNF-CM) was collected during the subsequent 24h. CM and TNF-CM were used to treat Fao hepatoma cells in the absence or presence of interleukin 1 receptor antagonist (IL-1Ra), after which insulin action was studied. Cytokines levels in CM or CM-TNF were analyzed by ELISA and LUMINEX technology.
Results: As compared to CM -treated Fao cells, TNF-CM induced a decrease in insulin-stimulated IR ($p<0.05$) and IRSs tyrosine phosphorylation ($p<0.05$), and in PKB ($p<0.01$) and GSK3 serine phosphorylation ($p=0.01$), with no effect on the total amount of either of these proteins. Moreover insulin stimulated glycogen synthesis by 2-fold in CM treated Fao, an effect nearly fully blunted in TNF-CM treated cells. Rosiglitazone added prior to and during TNFα treatment of adipocytes partly prevented ($p<0.05$) insulin resistance in Fao cells induced by TNF-CM. Screening of possible inflammatory cytokines elevated in TNF-CM showed a 10-fold increase in IL-1β ($p<0.01$) and 4-fold in IL-6 ($p<0.05$), whereas TNFα levels were without change and IL-1α decreased compared to CM. Direct exposure of Fao to IL-1β or to IL-6 impaired insulin signaling, which in the case of IL-1β could be prevented by IL1-Ra. Similarly, IL-1Ra prevented the insulin resistance induced in Fao cells by TNF-CM. Moreover, treatment of adipocytes with YVAD (during preparation of TNF-CM) decreased IL-1β levels in TNF-CM by 70% ($p<0.05$), and prevented insulin resistance in the Fao cells. Intriguingly, IL-6 levels in TNF-CM were also diminished by YVAD (an inhibitor of the production of IL-1β and IL-18).
Conclusion: We conclude that IL-1β is a central mediator of disturbed crosstalk between adipocytes and Fao cells that is induced by exposure of adipocytes to the prototypic pro-inflammatory cytokine TNFα. This effect can be attenuated using rosiglitazone and YVAD (on the adipocytes), or IL-1Ra (on the liver cells). Although other cytokines may also contribute to the disturbed adipocyte-hepatocyte crosstalk, it seems that in this system IL-1β plays a central role, potentially also acting in an autocrine fashion to induce IL-6 secretion from adipocytes.

Association of fatty liver increases small, dense LDL in metabolic syndrome

I. Sugino[1], K. Kuboki[1], T. Matsumoto[1], S. Nakano[1], C. Nishimura[2], G. Yoshino[1];
[1]Division of Diabetes, Metabolism and Endocrinology, Department of Internal Medicine (Omori), [2]Department of Medical Informatics, Toho University School of Medicine, Tokyo, Japan.

Background and aims: Small,dense LDL (sLDL)is known as an atherogenic lipoprotein and is often associated with metabolic syndrome (MS). High frequency of sLDL is found in hypertriglyceridemic subjects. Also, fatty liver (FL) is often associated with MS. Therefore,the present study was conducted to examine if association of FL increases sLDL-cholesterol (sLDL-C) in the subjects with MS.
Materials and methods: Two hundred and seven patients were enrolled in this study. Fatty liver was estimated by echogram. Presense of MS was diagnosed according to the Japanese Guidelines for the Definition of Metabolic Syndrome. Plasma sLDL-C was measured by the 2-step (precipitation and homogeneous) assay system established by Hirano et al. Plasma triglyceride and LDL-C were measured by a standard autoanalizer method. One- and two-way analyses of variance (ANOVA) were used to compare mean values among groups. All values were expressed as mean ± SD. A significant difference was defined as $p<0.05$.

Results: sLDL-C of MS group was higher than that of non-MS group(45.4±24.2 vs. 36.5±18.9). sLDL/LDL-C of MS group was also higher than that of non-MS group(0.34±0.15 vs. 0.28±0.12). Also sLDL-C and sLDL/LDL of FL groups were both higher than those of non-FL groups(46.5 ±24.1 vs. 35.9±19.1 , 0.35±0.14 vs. 0.28±0.12). Correlation coefficients between plasma triglyceride and sLDL-C and between plasma triglyceride and sLDL/LDL were 0.36 and 0.51, respectively. Furthermore, in MS group, those correlation coefficients were 0.32 and 0.52, respectively. While in non-MS group, they were 0.36 and 0.40, respectively. In FL group, they were 0.32 and 0.52, and in non-FL group, 0.32 and 0.38, respectively. Two-way ANOVA revealed that FL was more powerful determinant of plasma sLDL-C (p=0.010) or sLDL/LDL (p=0.008) , but not MS. When we divided all subjects into four groups such as MS(-)FL(-), MS(-)FL(+), MS(+)FL(-) and MS(+)FL(+) groups, sLDL/LDL of MS(+)FL(+) group was significantly higher than all other groups.
Conclusion: In this study, we found that if both MS and FL are present, sLDL/LDL is significantly higher than that in all other groups. The liver may produce triglyceride from exess circulating glucose, free fatty acid and triglyceride,which may result in development of fatty liver. In order to avoid further triglyceride deposition, fatty liver may secrete triglyceride-enriched VLDL particles, which is recognized as a precursor of sLDL particles. In the present study, we found a significant relationship between sLDL-C and plasma trigryceride. Furthermore, this became stronger in fatty liver group, indicating that fatty liver may produce triglyceride-rich VLDL, thereby contributing to an appearance of sLDL particles in plasma of MS patients with fatty liver. Together with the result that sLDL/LDL ratio was the highest in MS(+)FL(+) group, our present findings may support above hypothesis.

661

Independent relationship between decrease of liver triglyceride content and increase of plasma adiponectin levels after pioglitazone treatment in patients with type 2 diabetes

K. Nagasawa, Y. Kaneko, H. Taneichi, M. Masaya, T. Takahashi, S. Kakino, H. Honma, M. Yamashina, M. Ishii, F. Fujiwara, T. Kajiwara, N. Takebe, K. Takahashi, J. Satoh;
Division of Diabetes and Metabolism, Iwate Medical University, Morioka, Japan.

Background and aims: Pioglitazone, an insulin-sensitising thiazolidinedione, has multiple clinical effects including improvement of insulin sensitivity, decrease of liver fat content, increase of plasma adiponectin levels, and improvement of serum lipid profiles. However, a correlation and causal relationship between these effects are not fully understood clinically. Therefore, we analyzed these in patients with type 2 diabetes treated with pioglitazone.
Materials and methods: Fifteen Japanese patients with type 2 diabetes were treated with piopglitazone (15 mg/day) for 24 weeks. Before and after the pioglitazone treatment, BMI (kg/m^2), liver triglyceride (TG) content (% out of water), fasting plasma glucose (mg/dl), fasting plasma insulin (U/ml), HbA1c (%), plasma adiponectin (μg/ml), plasma NEFA (mEq/l), serum lipids [total cholesterol (mg/dl), TG (mg/dl), LDL-cholesterol (mg/dl), HDL-cholesterol (mg/dl), RLP-cholesterol (mg/dl), and midband (%)], AST (IU/l), ALT (IU/l), and gamma-GTP (IU/l) were measured. Liver TG content was measured by magnetic resonance spectroscopy (MRS) at 3.0 tesla.
Results: Liver TG content (26.1±25.2 vs. 7.3±4.5, p<0.05), HOMA-R (5.1±3.6 vs. 2.6±1.5, p=0.07), HbA1c (8.1±1.5 vs. 7.1±1.6, p<0.01), plasma adiponectin (4.8 vs. 10.9, p<0.01), and serum levels of TG (181 vs. 118, p<0.01), HDL-cholesterol (60 vs. 67, p=0.07), RLP-cholesterol (5.9 vs. 4.9, p<0.01), midband (15 vs. 10, p<0.01), AST (32±15 vs. 21±5, p<0.05), ALT (45±38 vs. 25±9, p<0.05), and gamma-GTP (66±42 vs. 43±19, p=0.06) were significantly (or tendency of significance) decreased or increased, whereas BMI (26.9±4.7 vs. 27.0±4.3), and serum total cholesterol (223 vs. 216), LDL-cholesterol (137 vs. 128), and NEFA (0.42 vs. 0.39) were not significantly changed. There was a significant correlation between decrease of liver TG content and increase of plasma adiponectin levels after the pioglitazone treatment (R=-0.7, p<0.05). Stepwise multiple regression analysis adjusted for the all variables described above showed that decrease of liver TG content was independently and significantly associated with increase of serum adiponectin levels (β=-0.98, R^2=0.95, P<0.001).
Conclusion: These results indicate that the pioglitazone treatment increased plasma adiponectin levels and resulted in decrease of the liver TG content via activation of AMP-activated protein kinase (AMPK), because it has already been reported that adiponectin activates AMPK, which stimulates fatty acid oxidation in the liver.

Glucose intolerance in patients with chronic hepatitis B or chronic hepatitis C is related with different factors

A.N. Mavrogiannaki, B.G. Karamanos, E.K. Manesis, J.S. Koskinas, G.V. Papatheodoridis, A.J. Archimandritis;
Diabetes Center, 2nd Academic Department, Athens, Greece.

Background and aims: The prevalence of glucose intolerance in patients with chronic hepatitis B (CHB) or C (CHC) is higher than in the general population and moreover it is higher in CHC than CHB. Aim of the present study was to explore possible associations of glucose intolerance with different factors in CHB or CHC.
Materials and methods: We studied 83 consecutive CHB patients and 113 CHC patients examined at the outpatient liver clinic. Blood samples were obtained for laboratory investigations and OGTT was performed in all (except in known diabetics). A liver biopsy was performed in 80% of patients according to clinical indications and evaluated blindly. As glucose intolerance (GI) we considered abnormal OGTT or known diabetes. We compared biochemical and histological abnormalities and the use of interferon between CHB patients with GI (N=24) and CHC with GI (N=40). All comparisons were done after adjustment for age and BMI.
Results: CHB-GI patients, compared with those with CHC-GI had more frequent family history of diabetes (58.3% vs 27.5%, P=0.019), while CHC-GI compared with CHB-GI had higher systolic blood pressure (127.7 ± 2.2 mm Hg vs 115.6 ± 3.0 mm Hg, P=0.002), higher insulin resistance, by HOMA model (5.1 ± 0.6 vs 3.8 ± 0.3, P=0.044), c-peptide (1.2 ± 0.2 ng/ml vs 0.6 ± 0.2 ng/ml, P=0.039), Apo A (135.5 ± 6.6 mg% vs 102.1 ± 9.4 mg%, P=0.007) and lower HDL (42.0 ± 2.6 mg% vs 53.5 ± 3.6 mg%, P=0.015). The prevalence of cryoglobulinemia was higher in CHC-GI group (58.3% vs 10.5%, P=0.001). Insulin/c-peptide molar ratio (index of insulin uptake by the liver), and aminotrasferase level were not different. The majority of patients in both groups had mild histological alterations of fibrosis, but the grade of necroinflamatory activity, the stage of fibrosis, the presence of cirrhosis, the grade of steatosis and the use of interferon were not different between CHB-GI and CHC-GI patients.
Conclusion: a) The type and the grade of histological alterations of the liver are similar in patients with chronic hepatitis B or C and cannot explain the higher prevalence of Glucose Intolerance in C, while b) glucose intolerance is related with genetic factors (family history of diabetes) in B and epigenetic factors in C (insulin resistance, cryoglobulinemia), which may explain its higher prevalence in C.

663

Adipocytokines, insulin resistance and hepatitis C

E.D. Rusu[1,2], G. Radulian[2], I. Ancuta[2], F. Rusu[3], M. Jinga[4], A. Dragomir[3], D. Cheta[1];
[1]Nutrition, diabetes, Healthy Nutrition Foundation, [2]University of Medicine "Carol Davila, [3]Healthy Nutrition Foundation, [4]Emergency Military Hospital "Carol Davila", Bucharest, Romania.

Background and aims: The aim of this study was to analysis if adipocytokines levels correlate with parameters exploring insulin resistance (IR) and indices of chronic liver disease.
Materials and methods: We selected 110 patients who are divided in 2 groups: group A - 65 patients with chronic hepatitis C (CHC); and group B - 45 healthy volunteers (without CHC or diabetes - control group). IR was determinated used Homeostasis model assessment (HOMA-IR). All patients with CHC underwent liver biopsy and the liver specimens were evaluated with the Ishak scoring system for viral liver disease. Body weight, BMI, lipid profile, alanin aminotransferase, aspartat aminotransferase, gamma glutamil transpeptidase, proinflammatory state and adipocyokines were measured.
Results: The average age was 55.45±11.63 in group A and 54.27±15 years in group B. HOMA-IR (3.35 versus 1.65), adiponectin (6.21 versus 3.12 μg/ml), TNF alpha (1.99 versus 0.54 pg/ml), IL-6 (3.45 versus 1.33 pg/ml) was significantly higher in CHC patients (all p < 0.05). By multiple linear regression, independent predictors of HOMA-IR included the body mass index, apparent liver disease duration, and the serum levels of leptin, TNF alpha, IL-6 (positive correlation) and adiponectin (negative correlation). TNF alpha and IL-6 levels was correlated with the extent of histological injury (portal/periportal inflammation, p = 0.001).
Conclusion: Several pathogenic mechanisms may be involved in the effect of CHC on insulin resistance and adipocytokines and inflammatory cytokines play an important part.

Search for low-frequency variants associated with overall and central adiposity

C.M. Lindgren[1,2], S. Ripatti[3], E. Zeggini[1,4], L. Peltonen[4], M.I. McCarthy[1,2], A.P. Morris[1];
[1]Wellcome Trust Centre for Human Genetics, University of Oxford, United Kingdom, [2]Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, United Kingdom, [3]FIMM Institute for Molecular Medicine Finland, University of Helsinki, Finland, [4]Wellcome Trust Sanger Institute, Hinxton, United Kingdom.

Background: Recent genome-wide association studies have identified more than 20 common variants that are associated robustly to overall and central adiposity. However, with these associations we can explain only ~2% of the variance of adiposity. Available sample-sizes and traditional statistical association analysis techniques are well-powered for searches for common variants but are likely to be under-powered to identify low frequency variants (LFV) with moderate effect sizes.
Methods: We have developed a method for detecting association of quantitative phenotypes with accumulations of minor alleles at LFV within gene coding regions (± 50kb to incorporate additional functional elements and the promoter region). With our approach, the phenotype is modelled in a regression framework as a function of the proportion of LFV at which an individual carries minor alleles, heterozygous or homozygous, and can be adjusted for necessary covariates. Using this method we have screened 6,686 samples from the Type 2 Diabetes(T2D)-WTCCC cohort (genotyped using the Affymetrix GeneChip Human Mapping 500K Array) and the Northern Finnish Birth cohort (NFBC) 1966 (genotyped using the Illumina HumanHap 370 BeadChip). We tested for association of accumulations of variants with a minor allele frequency <5% to overall (body mass index, BMI) and central adiposity (waist-circumference [WC] and waist-hip ratio [WHR], both adjusted for BMI). All three phenotypes were log transformed, with analyses adjusted for age and gender. Analyses were performed separately, within each cohort, and combined through meta-analysis for each gene containing rare variants on both genotyping platforms.
Results: The strongest signal of association with BMI was observed through meta-analysis on chromosome 4p13 ($p=9.3x10^{-6}$, effect size (beta)=0.033, standard error (se)=0.0075), with consistent effects in both cohorts, despite differences in the SNPs genotyped in each. Strong signals of association with WC were observed in the T2D-WTCCC cohort on chromosomes 17q12 ($p=4.4x10^{-5}$, beta=-0.014, se=0.0034) and 12p13 ($p=6.2x10^{-5}$, beta=-0.020, se=0.0051), and with WHR in the NFBC on chromosome 9q34 ($p=8.7x10^{-5}$, beta=-0.010, se=0.0026).
Conclusion: None of these loci have been previously associated with adiposity in studies of common variants but at least two of them are plausible biological candidates (i.e. one putative phospholipase and one neuronal sodium channel). We are currently following up these regions, together with a few weaker signals of association with strong candidacy for adiposity, with deep re-sequencing of samples in the tails of the adiposity distribution.

Regulatory mechanisms for adipose tissue M1 and M2 macrophages in diet-induced obese mice

K. Tobe, I. Usui, Y. Kanatani, S. Fujisaka, S. Senda, B. Agussalim, Y. Yamazaki, H. Suzuki, M. Iwata, M. Ishiki, M. Urakaze;
First Department of Internal Medicine, University of Toyama, Japan.

Background and aims: Obesity and insulin resistance are closely associated with a state of low-grade inflammation in adipose tissue. Adipose tissue macrophages (ATMs) consist of at least two different phenotypes, i.e., classically activated M1 macrophages secreting pro-inflammatory cytokines and alternatively activated M2 macrophages that secrete anti-inflammatory cytokines, including IL-10.
Materials and methods: After the mice had been subjected to a high-fat diet and pioglitazone (an insulin sensitizer) treatment (Pio), ATMs were analyzed by flow cytometry using CD206 as an M2 marker and CD11c as an M1 marker.
Results: Not only the numbers of M1 ATMs and the expression of M1 marker genes, such as TNFa and MCP-1, but also the M1/M2 ratio were increased by a high-fat diet (HFD) and decreased by subsequent pioglitazone treatment. We also found that the increased number of M2 ATMs after an HFD was associated with the increased expression of IL-10, an anti-inflammatory cytokine, in the adipocyte fraction as well as in adipose tissue. The systemic overexpression of IL-10 by an adenovirus vector increased the expression of M2 markers in adipose tissue. In addition, overexpression of IL-10 improved insulin sensitivity and insulin signaling both in lean and high fat-induced obese mice. Interestingly, the expression of genes involved in mitochondrial OXPHOS and b-oxidation was increased in the skeletal muscle, which may be mediated by IL-10's effect on hypothalamus. These results suggest that IL-10 improved whole body insulin sensitivity by suppression of hepatic gluconeogenesis and an increase in genes involved in fatty acid oxidation and mitochondrial OXPHOS in the skeletal muscle.
Conclusion: M1 and M2 ATMs constitute different subsets of macrophages. Insulin resistance is associated with both the number of M1 macrophages and the M1/M2 ratio. IL-10 secreted from M2 ATMs may contribute to the improvement of insulin resistance.

666

Fat depot-specific differences in inflammatory markers in lean and obese insulin resistant pregnant rats

J. Marciniak, J. de Castro, J. Sevillano, A. Acevedo, E. Herrera, M.P. Ramos Alvarez;
Biochemistry, Molecular and Cellular Biology, Faculties of Pharmacy and Medicine, University CEU San Pablo, Madrid, Spain.

Background and aims: In healthy pregnancy, several components of the metabolic syndrome, such as insulin resistance, hypertrygliceridemia and up-regulation of inflammatory markers, are present. Furthermore, obesity before pregnancy is becoming a common issue in obstetric management. We have shown that lumbar adipose tissue (AT) exhibits a low grade inflammation during pregnancy that correlates with insulin resistance in the mother. Fat depots vary in size, function, and their potential contribution to disease. It is not known, however, whether in pregnancy there are regional differences in AT inflammation. Thus, the present study was aimed at characterizing the contribution of different fat depots to the inflammatory state associated with late pregnancy, and at determining whether obesity before pregnancy impairs this inflammatory condition of the mother.
Materials and methods: 2 months old rats were fed ad libitum a standard chow diet (control) or a palatable cafeteria diet (CF-diet). After 30 days, all animals were mated and the respective control or CF-diet was maintained during pregnancy. On day 20 of gestation (late pregnancy), animals were sacrificed, and lumbar and mesenteric AT were removed. BMI, insulin sensitivity indexes (HOMA and FGIR), and biochemical parameters were estimated before and at late pregnancy. We also assessed plasma and tissular markers of inflammation (including TNF-alpha/IL-6 ratio as an index of Th1/Th2 response).
Results: Animals fed on CF-diet showed a significant increase of body weight. In fact, 70% of the CF-diet rats were obese (BMI>95th). These animals had a significant increase in plasma triglycerides (TG), insulin, leptin, and IL-1. CF-diet also provoked a deterioration of insulin sensitivity as compared to controls. Pregnancy was followed by an elevation of both TG and insulin in the control group but not in the obese animals. Furthermore, insulin resistance associated with late pregnancy was not further enhanced in the CF rats. Circulating levels of MCP-1 and PAI-1 were increased by pregnancy in both control and CF animals. Analysis of cytokines in various fat depots revealed that leptin, IL-1, TNF-alpha, and MCP-1 were higher in lumbar than in mesenteric AT, whereas PAI-1 was increased in the mesenteric AT. In both fat tissues, no change of IL-6 was observed. Thus, lumbar AT of pregnant animals had a significantly higher index of type 1/type 2 inflammatory response as compared to mesenteric AT. Leptin was the only adipokine that was increased in both fat depots of animals that were obese before pregnancy. Finally, adiponectin, an adipokine associated with insulin sensitivity and vascular relaxation, was significantly higher in mesenteric than in lumbar AT, and was significantly decreased in the mesenteric fat of the obese pregnant rats.
Conclusion: Our results show that insulin resistance during late gestation is an inflammatory state irrespective of body fat mass and that this inflammatory state could have a fat depot-specific physiological function. At one hand, lumbar AT exhibits a predominantly Th1 response, with increasing pro-inflamatory markers, such as TNF-alpha and IL-1, which may be implicated in the insulin resistance state of adipose tissue during pregnancy. At the other

hand, mesenteric adipose tissue shows an increase of PAI-1 and adiponectin, which may be involved in the changes of vascular function associated with pregnancy.

The gene expression of the main lipogenic enzymes is down-regulated in visceral adipose tissue of obese subjects

W. Ricart[1], J.M. Fernandez-Real[1], D. Mayas[2], J.M. Moreno-Navarrete[1], V. Catalan[3], J. Gómez-Ambrosi[4], E. Esteve[1], J.I. Rodriguez-Hermosa[5], B. Ruiz[5], B. Peral[6], G. Fruhbeck[7], F.J. Tinahones[2], F.J. Ortega[1];
[1]Service of Diabetes, Endocrinology and Nutrition, Institut de Recerca Biomèdica de Girona (IdIBGi), [2]Service of Endocrinology and Nutrition, Hospital Clinico Universitario Virgen de Victoria de Malaga, [3]Department of Endocrinology & Metabolic Research Laboratory, Clínica Universitaria de Navarra, Girona, [4]Department of Surgery, Institut de Recerca Biomedica de Girona (IdIBGi), [5]Department of Surgery, Institut de Recerca Biomèdica de Girona (IdIBGi), [6]Service of Diabetes, Endocrinology and Nutrition, Instituto de Investigaciones Biomédicas Alberto Sols (IIB), Madrid, [7]Department of Endocrinology & Metabolic Research Laboratory, Clínica Universitaria de Navarra, Spain.

Background and aims: Contradictory findings regarding the gene expression of the main lipogenic enzymes in human adipose tissue depots have been reported. In this cross-sectional study, we aimed to evaluate the mRNA expression of fatty acid synthase (FAS) and acetyl-CoA carboxilase (ACC) in omental fat depots from subjects who varied widely in terms of body fat mass.
Materials and methods: Fatty acid synthase and acetyl-CoA carboxilase gene expression were evaluated by RT-PCR in 188 samples of visceral adipose tissue which were obtained during elective surgical procedures in 119 women and 69 men.
Results: Decreased sex-adjusted FAS (-59%) and ACC (-49%) mRNA were found in visceral adipose tissue from obese subjects, with and without DM-2, compared with lean subjects (both $p<0.0001$). FAS mRNA was also decreased (-40%) in fat depots from overweight subjects ($p<0.05$). Indeed, FAS mRNA was significantly and positively associated with ACC gene expression ($r=0.316$, $p<0.0001$) and negatively with BMI ($r=-0.274$), waist circumference ($r=-0.437$), systolic blood pressure ($r=-0.310$), serum glucose ($r=-0.277$) and fasting triglycerides ($r=-0.226$), within others (all $p<0.0001$). Similar associations were observed for ACC gene expression levels. In a representative subgroup of non-obese (n=4) and obese women (n=6), relative FAS gene expression levels significantly correlated ($r=0.657$, $p=0.034$; n=10) with FAS protein presence. FAS protein levels were also inversely correlated with blood glucose ($r=-0.640$, $p=0.046$) and fasting triglycerides ($r=-0.832$, $p=0.010$).
Conclusion: The gene expression of the main lipogenic enzymes is down-regulated in visceral adipose tissue from obese subjects.

Insulin sensitivity correlates with visceral adipose tissue heme oxygenase-1 expression that is determined by hip to waist ratio

M. Zeyda[1], S. Shakeri-Manesch[2], J. Huber[1], B. Ludvik[1], G. Prager[2], T.M. Stulnig[1];
[1]Dept. of Internal Medicine III, Clin. Div. of Endocrinology and Metabolism, Medical University of Vienna, [2]Dept. of Surgery, Medical University of Vienna, Austria.

Background and aims: Insulin resistance in visceral obesity is substantially driven by adipose tissue inflammation, in particular macrophages accumulating in obese adipose tissue. On the other hand, adipose tissue macrophages express the hemoglobin scavenger receptor (CD163) and heme oxygenase-1 (gene: *HMOX1*) that together protect from oxidative stress. Aim of this study was to evaluate the expression of *CD163* and *HMOX1* in intra-abdominal visceral (omental) and subcutaneous adipose tissue as well as circulating soluble CD163 concentrations in human obesity and its association with adipose tissue inflammation, body fat distribution, and insulin resistance.
Materials and methods: *CD163, HMOX1* and *CD68* mRNA expression in visceral and subcutaneous adipose tissue, serum concentration of soluble CD163 in morbidly obese patients (BMI>40 kg/m^2) who underwent laparoscopic surgery for gastric banding (n=20), matched for age and sex to lean control subjects (BMI<30 kg/m^2; n=20) was analyzed.
Results: *CD163* expression was highly upregulated in human adipose tissue and soluble CD163 serum concentration was elevated in obese vs. lean subjects. *HMOX1* was upregulated in adipose tissue by obesity as well and expressed predominantly in macrophages. While *CD163* expression strictly correlated with macrophage abundance, *HMOX1* was additionally upregulated within macrophages, and this upregulation was significantly lower in visceral compared to subcutaneous adipose tissue. Strikingly, relative visceral adipose tissue expression of *HMOX1* negatively correlated with waist to hip ratio and HOMA-IR (both $p=0.024$).
Conclusion: Our data suggest visceral obesity to promote insulin resistance by defective upregulation of heme oxygenase-1 in visceral adipose tissue thereby abrogating its anti-oxidative and anti-inflammatory action.

Gene expression of glucagon-like peptide 1 receptor in visceral and subcutaneous adipose tissue. Decreased expression in obesity

A. Megia[1], E. Caubet[2], S. Näf[1], E. Solano[1], M. Alcaide[1], F. Tinahones[3], M. Miranda[1], V. Vicente[1], J.M. Fernandez-Real[4], J. Vendrell[1];
[1]University HospitalJoan XXIII. CIBERDEM, Tarragona, [2]Hospital Sant Pau i Santa Tecla, Tarragona, [3]Clinic Hopital. CIBEROBN, Malaga, [4]University Hospital Josep Trueta. CIBEROBN, Girona, Spain.

Background and aims: It has been observed a dual effect of Glucagon-like peptide 1 (GLP1) in human adipocytes stimulating lipogenesis and lipolysis. These effects are exerted through a GLP1 specific receptor (GLP1R). It has been observed a reduced lipogenic action of GLP1 in subcutaneous adipose tissue (SAT) from morbidly obese patients compared with normal weight. A down regulation in the expression of GLP1R in adipose tissue of obese patients could be the mechanism implicated in this modulation. The aim of the study was to test the hypothesis that GLP-1R gene expression levels in adipose tissue may be affected by the presence of obesity.
Materials and methods: SAT and Visceral adipose tissue (VAT) was obtained from 61 non-diabetic subjects (aged 55,90±14,61 years; 37 men and 24 women) who underwent an elective abdominal surgery. There were 19 lean, 27 overweight, and 15 non-severely obese subjects. Anthropometrics, biochemical and metabolic parameters including glucose, lipidic profile, HbA1c and high-sensitivity C-reactive protein (hsCRP) were recorded or quantified by routine biochemical techniques. Gene expression of GLP1R and a profile of enzymes and adipokines involved in adipogenesis and inflammation were measured by Real-time quantitative PCR on a 7900HT Fast Real-Time PCR System using commercial Taqman Assays.
Results: In VAT: Lean patients showed significantly higher GLP1R expression levels compared with overweight and obese patients ($p<0,05$) and a negative correlation was observed between GLP1R expression and BMI ($r=-0.273$; $p<0,05$). GLP1R was negatively correlated with the lipogenic enzyme Acetyl-CoA-sythetase (ACoAS) (r: -0,349; p=0,006) and Visfatin (r: -0.350; p=0,006) gene expression. A positive correlation was observed with serum triglycerids levels (r:0,266; p=0,045). To select which of the variables explain better GLP1R expression levels a stepwise linear regression model was developed including sex, BMI, triglycerids, ACoAS and visfatin as independent variables. ACoAS (B: -0.519; $p<0.0001$) and Visfatin (B: -0.414; $p<0.0001$) were the unique variables included in the model. In SAT: No differences were observed in GLP1R mRNA expression according to the degree of obesity. However, a negative correlation was observed with abdominal circumference (AC) (r: -0,462; p=0.000) and HOMA index (r: -0,340; p=0.021). Likewise, a negative correlation was observed with GLUT1 expression levels (r:-0.376; p=0,003) and a positive one with Omentin (0,309; p=0,015) and Retinoid orphan receptor (ROR) expression levels (0,356; p=0,015). In order to strengthen the independence of these associations in SAT, a stepwise linear regression analysis was developed including sex, HOMA index, AC, GLUT1, Omentin and ROR expression levels. AC was the only parameter independently associated with GLP1R expression in SAT (B: -0.015; p=0,003).
Conclusion: GLP1R gene is expressed both in SAT and VAT depots and seems to be down regulated in obesity. Expression in SAT seems to be inversely determined by parameters of visceral fat content. In VAT, expression of GLP1R is inversely associated with gene expression of the insulin-mimetic adipokine, Visfatin and possibly with a decrease in fatty acid synthesis.

Neck fat area is strongly associated with insulin resistance

C. Thamer[1], J. Machann[2], H. Staiger[1], N. Stefan[1], F. Schick[2], A. Fritsche[1], H.-U. Haring[1];
[1]Medical Clinic IV, [2]Section on Experimental Radiology, Department of Diagnostic Radiology, University of Tuebingen, Germany.

Background and aims: Obesity is known to be strongly associated with insulin sensitivity (IS) and type 2 diabetes. The distribution of the deposited fat harbors unique information about the individual metabolic impact of obesity. Subcutaneous abdominal adipose tissue (SCAT), visceral adipose tissue (VAT) and fat in the neck area (NF) have previously been described to be metabolically relevant fat depots of the upper body. Whole body magnetic resonance imaging (MRI) offers a unique approach to quantify these different fat depots in lager cohorts. The present analysis was designed to study i) the impact of the three afore mentioned fat depots of the upper body on insulin sensitivity in a cross sectional design and ii) changes in these fat depots and their effect on changes in IS during lifestyle intervention (LI).
Materials and methods: A total of 187 subjects at an increased risk for type 2 diabetes were included in the cross-sectional study. Follow-up data after participation in the LI program were available in 174 subjects. Body fat depots were quantified in single reference slices at the umbical level (SCAT, VAT) and at the level of the shoulder joint (NF) using whole body magnetic resonance imaging.
Results: Cross-sectionally SCAT, VAT and NF were all negatively associated with IS (all p<0.0001). In multivariate linear regression analyses, insulin sensitivity adjusted for gender and age was significantly associated with NF (p<0.01) and VAT (p<0.001) but not with SCAT (p=0.97). The change in IS during LI adjusted for gender, age and, all fat depots at baseline was associated with change in NF (p<0.01) but not with change in SCAT (p=0.3) or VAT (p=0.3).
Conclusion: We conclude that NF represents a subcutaneous fat depot of particular importance for whole body IS, both cross sectionally and during LI. Further studies are needed to clarify the metabolic properties of NF.

Diabetes mellitus type 2 is associated with a redistribution of fat mass in postmenopausal women

D.J. Hadjidakis[1], A. Mylonakis[1], I.I. Androulakis[1], M. Peppa[1], A.E. Raptis[1], A. Papaefstathiou[1], E. Garoflos[1], C. Koliaki[1], T. Economopoulos[1], S.A. Raptis[1,2];
[1]Endocrine Unit, 2nd Department of Internal Medicine, Research Institute and Diabetes Centre, «Attikon» University Hospital, Athens University, [2]Hellenic National Diabetes Centre, Athens, Greece.

Background and aims: Diabetes mellitus type 2 is characterized by impaired glucose metabolism mainly due to obesity and insulin resistance. The aim of the study was to investigate any alterations caused by diabetes mellitus type 2 either in the distribution of fat mass in the whole body or in the correlation between whole body fat mass and the whole body bone mineral density.
Materials and methods: Eighty-six diabetic and 96 healthy postmenopausal women, matched for age and BMI, were studied [age 60.1±.4.7 and 59.5±4.4 yrs (mean±1SD), BMI 32.1±4.2 and 31.7±3.8 kg/m2 respectively, HbA1c 7.9±1.1% for the diabetic women]. None of the women had ever received either any medication known to affect bone metabolism (except from sulphonylureas when appropriate) or insulin treatment. The estimations of either the distribution of fat mass in the extremities and the abdomen or the WBMD were performed by dual-energy X-ray absorptiometry (DXA). They included the average proportions of fat mass (PF, %) in the upper and lower extremities (ARMPF and LEGPF), the average PF of the four extremities (EXTPF), the PF in the abdomen (ABPF),as well as the whole body PF (WBPF) and whole body BMD (WBBMD).
Results: No significant differences were observed between the groups regarding age, WBBMD and WBPF. The diabetic women exhibited significantly higher ARMPF (p<0.005) and significantly lower LEGPF (p<0.01), while the EXTPFs and WBPF did not differ significantly between the groups. The ABPF was significantly higher in the diabetic women (p<0.05). No significant correlation was observed between WBBMD and any PF. In both groups the correlation of BMI to LEGPF was not significant (r=0.23 and 0.14, NS), in contrast to its correlations with any other PF. The ABPF was stronger correlated to ARMPF [r=0.73 in diabetic and 0.71 in healthy women (p<0.001)] than LEGPF [r=0.43 and 0.31(p<0.05), respectively). Age was significantly correlated to all PFs only in the healthy group.
Conclusion: Diabetes mellitus type 2 seems to be accompanied by a redistribution of fat mass which is shifted from the lower extremities to the upper ones and to the abdomen. Whole body bone mineral density does not seem to be affected by the diabetic status. In both diabetic and obese non-diabetic postmenopausal women bone mineral density does not seem to significantly correlate to the proportion of fat mass in total body mass.

672

Low relative skeletal muscle mass is independently associated with insulin resistance in Korean diabetic patients

Y. Choi[1], S. Choi[2], S. Park[3], D. Kim[4], C. Kim[5], S.-H. Jee[6], E.-J. Lee[6], S. Lee[1], B. Huh[1], K. Huh[1];
[1]Huh's Diabetes Center, Seoul, [2]Seoul National University Bundang Hospital, Sungnam, [3]Pochon Cha University, Sungnam, [4]Aju University, Suwon, [5]Hallym University, Anyang, [6]Yonsei University, Seoul, Republic of Korea.

Low relative skeletal muscle mass (sarcopenia) is associated with an increased risk of adverse health outcomes. Insulin resistance could be involved in age-related muscle protein loss, progressively leading to sarcopenia. Only few studies has examined the association between skeletal muscle mass and insulin resistance in diabetic patients. In this study, we investigated whether skeletal muscle mass was associated with insulin resistance in type 2 diabetic subjects. We enrolled 3034 patients (mean age 57±10 yr, men 50%) with type 2 diabetes, who visited our Diabetes Center from 2004 to 2008. The skeletal muscle mass was estimated from bioimpedance analysis measurements and expressed as skeletal muscle mass index (SMI = skeletal muscle mass/body mass x 100). Insulin resistance was directly assessed by short insulin tolerance test as a rate constant for plasma glucose disappearance (*kitt*, %/min) after intravenous injection of regular insulin (0.1U/kg). The SMI was negatively correlated with total cholesterol (r=-0.084, p<0.01), triglyceride (-r=0.089, p<0.01), systolic blood pressure (r=-0.063, p<0.05) and diastolic blood pressure (r=-0.108, p<0.001), and positively correlated with HDL-cholesterol (r=0.074, p<0.01) and *kitt* (r=0.100, p<0.001). In multiple regression model, the SMI was independently associated with *kitt* after adjusting for age, glucose, triglyceride, HDL cholesterol, systolic blood pressure and fat mass in both sexes (men: β=0.083, p<0.01, women: β=0.050, p<0.05). The odds ratio for severe insulin resistance (those with lowest quartile of *kitt*) was 1.41 (95% CI: 1.03, 1.91) in men and 1.50 (95% CI: 1.04, 2.17) in women with lowest quartile of the SMI compared with men and women with highest quartile of the SMI.
In conclusion, the low relative skeletal mass indicative of sarcopenia is associated with insulin resistance in type 2 diabetes. Interventions leading to skeletal muscle hypertrophy such as resistance training and/or amino acid supplementation may need to be tested in diabetic patients with severe insulin resistance.

Body composition in type 1 and type 2 diabetes patients with similar body mass index

R. Lichiardopol, A. Florentiu, C. Pencea, R. Nafornita, A. Nicoara;
Clinic of Diabetes, Nutrition and Metabolic Diseases, "N.C. Paulescu" Institute, Bucharest, Romania.

Background and aims: Increased body fat is associated with type 2 diabetes while this association with type 1 diabetes is weak or nonsignificant. The objective of this study was to evaluate differences regarding body composition and fat distribution in type 1 and type 2 diabetic people with similar body weight.
Materials and methods: Anthropometric and body composition measurements [body fat mass (BFM), percent body fat (PBF), estimated visceral fat area (eVFA) and skeletal muscle mass (SMM)] were performed using a multifrequency bioelectric impedance analyzer (InBody 720) in diabetic patients with BMI<25 Kg/m^2 (Group A: 30 type 1 and 36 type 2 diabetes patients) or BMI>25 Kg/m^2 (Group B: 35 type 1 and 72 type 2 diabetes patients).
Results: In both groups, type 2 diabetes patients had significantly greater mean (SD) values for age [Group A: 65.5 (9.1) vs 45.6 (12.4) years; p<0.0001, Group B:59.0 (11.9) vs 40.4 (15.1) years; p< 0.0001] and eVFA [Group A: 114.0 (17.3) vs 84.0 (21.0) cm^2 ; p<0.0001, Group B: 145.6 (24.4) vs 114.9 (28.9) cm^2 ; p<0.0001]. No significant differences in BMI, waist circumfer-

ence (WC), BFM, PBF and SMM, between groups, were observed. In a larger group of T2DM patients,in simple linear regression analysis, BFM (r=-0.283; n=172; p<0.0002), SMM (r=-0.458; n=172; p<0.0001) and WC (r=-0.332; n=146; p<0.0001) were inversely correlated with age, while in T1DM patients WC (r= 0.656; n=51; p<0.0001) and eVFA (r= 0.520; n=62; p<0.0001) were directly correlated with age. We calculated the eVFA/BFM ratio to estimate the relationship between eVFA and BFM with increasing weight. As expected, the ratio eVFA/BFM decreased with increasing weight both in T1DM and T2DM patients, but remained comparatively greater, inside every group [Group A: 7.5 (2.8) vs 5.8 (2.1) cm^2/Kg; p<0.007, Group B: 5.6 (0.9) vs 4.5 (1.0) cm^2/Kg; p<0.0001] in T2DM patients. In 30 from 88 T2DM (34%) but only in one from 32 (3.1%; p<0.001) T1DM patients abdominal ultrasound examination disclosed liver steatosis. In logistic regression analysis, liver steatosis was significantly correlated to BFM and eVFA.
Conclusion: Our data suggest that, at similar levels of body fatness, T2DM (as compared to T1DM) patients have a different body composition with significantly more ectopic fat accumulation in visceral area and liver steatosis.

Insulin promotes fatty acid storage in white adipose tissue by a CNS-mediated and CD36-dependent mechanism
B. Guigas[1], C.P. Coomans[2], J.J. Geerling[2], A.M. van den Hoek[3], E.T. Parlevliet[2], D.M. Ouwens[1], H. Pijl[2], P.J. Voshol[2], P.C.N. Rensen[2], L.M. Havekes[3], J.A. Romijn[2];
[1]Dept. of Molecular Cell Biology, Leiden University Medical Center, [2]Dept. of Endocrinology and Metabolic Diseases, Leiden University Medical Center, [3]Gaubius Laboratory, TNO-Biosciences, Leiden, Netherlands.

Background and aims: Central insulin administration has been shown to increase mass and cell size of white adipose tissue (WAT). The aim of this study was to determine to what extent the effects of insulin on fatty acid (FA) metabolism in WAT are mediated through the central nervous system (CNS).
Materials and methods: The effects of central (intracerebroventricular administration) or peripheral (during hyperinsulinemic-euglycemic clamp) insulin on tissue-specific partitioning of plasma triglycerides (TG) and FA were assessed in male C57Bl/6 mice using continuous i.v. infusion of glycerol tri[^{3}H]oleate-labeled VLDL-like particles and albumin-bound [^{14}C]oleate as tracers.
Results: Intracerebroventricular (i.c.v.) administration of insulin does not affect plasma parameters (insulin, glucose, FA and TG) but selectively increased the retention of both TG-derived FA (+69%; p<0.05) and albumin-bound FA (+86%; p<0.05) in WAT. This effect is abolished in diet-induced insulin resistant mice and is also completely blocked by co-administration of the K_{ATP} channels inhibitor tolbutamide, indicating the involvement of central insulin signaling pathway(s). In addition, the i.c.v.-induced retention of FA in WAT was totally abrogated in CD36-/- mice, demonstrating that the long chain FA transporter CD36 plays a crucial role in this effect. In order to investigate its physiological relevance, we next studied to what extent insulin signaling in the CNS is involved in the tissue-specific partitioning of plasma TG and FA induced by circulating insulin. Very interestingly, the rise in peripheral insulin level during hyperinsulinemic-euglycemic clamp increased retention of both TG-derived FA (+72%; p<0.01) and albumin-bound FA (+265%; p<0.01) in WAT, an effect which is abrogated by concomitant i.c.v. administration of tolbutamide.
Conclusion: Insulin promotes FA retention in WAT by a CD36-dependent mechanism involving activation of K_{ATP} channels in the brain. These findings highlight a paradigm where circulating hormones can act directly on target tissues as well as indirectly through the CNS.

Insulin in the brain promotes locomotor activity in lean
A.M. Hennige[1], T. Sartorius[1], O. Tschritter[1], A. Fritsche[1], H. Preissl[2], P. Ruth[3], H.-U. Häring[1];
[1]Internal Medicine IV, [2]Institute of Medical Psychology and Behavioural Neurobiology, [3]Department of Pharmacology and Toxicology, University of Tuebingen, Germany.

Background and aims: The insulin signaling pathway coordinates multiple cellular responses in the periphery and the brain, and when insulin action fails a diabetic phenotype occurs. In the presence of cerebral insulin resistance, neuronal activity is diminished and followed by alterations in glucose and energy homeostasis, however, the impact of insulin in the brain with regard to behavioural aspects like locomotion is unknown.
Materials and methods: To address insulin action in the brain with regard to cortical activity in and its behavioural consequences, the insulin signaling pathway was followed from the receptor up to electrical activity, and locomotion. Western Blot analysis, electrocorticogram recordings with intracerebroventicular (icv) application of insulin, and measurements of locomotor activity were performed in lean and obese mice and correlated to magnetoencephalography measurements in humans.
Results: Here, we show that insulin application icv into mice was accompanied by a profound increase in locomotor activity, whereas a PI 3-kinase inhibitor or adiposity-related factors abolished insulin-induced locomotion. In diet-induced obesity, insulin delivery to the brain was not able to enhance both, cerebrocortical activity and locomotion. A potential candidate that links insulin signaling to locomotion is the insulin-sensitive potassium channel Kv1.3. In accordance with this concept, selective pharmacological inhibi-

tion of Kv1.3 channels promoted locomotor activity in lean and obese mice. In addition, human subjects carrying a single-nucleotide polymorphism in the promoter region of the Kv1.3 gene displayed significantly impaired aerobic capacity, and the insulin-mediated desire to move was tightly correlated with spontaneous cortical activity in human subjects that underwent a hyperinsulinemic-euglycemic clamp.
Conclusion: Thus, our data provide functional evidence for a direct effect of insulin on brain activation patterns associated with locomotor activity and show that adequate insulin action in the brain is the basis for the maintenance of locomotion, while in obese, insulin-mediated locomotor activity is blunted and further aggravates physical inactivity.

IL-6 links exercise to hypothalamic insulin and leptin sensitivity through IKKβ and ER stress in DIO rats
E.R. Ropelle, M.B. Flores, D.E. Cintra, J.R. Pauli, G.Z. Rocha, J. Morari, C.T. Souza, J.C. Moraes, L.A. Velloso, M.J.A. Saad, J.B.C. Carvalheira;
Internal medicine, UNICAMP, Campinas, Brazil.

Background and aims: Recent studies provide an intriguing link between metabolic inflammation and dysfunction of the hypothalamic insulin and leptin signaling through activation of IKKβ and endoplasmatic reticulum (ER) stress. It has been proposed that physical exercise improves insulin and leptin signaling in the hypothalamus and induced appetite suppressive actions, but the mechanism by which exercise increases the insulin and leptin response in obese rats remains uncertain. Here we investigated the central role of interleukin-6 (IL-6) on hypothalamic IKKβ activation and ER stress in diet-induced obese (DIO) rats after physical exercise.
Materials and methods: Immunohistochemistry, Western blot, RT-PCR and ELISA assays were combined to evaluate the effects of acute swimming exercise in the hypothalamus of DIO rats and C3H/Hej mice.
Results: High-fat diet atypically activated the hypothalamic IKKβ and ER stress and induced central insulin and leptin resistance and orexigenic response in rats. A single bout of exercise was sufficient to reduce IKKβ phosphorylation and ER stress, restored central insulin and leptin sensitivity and reduced food intake in DIO rats. Interestingly, the pretreatment with intracerebroventricular (icv) infusion of IL-6 antibody blocked these effects of exercise. The icv infusion of recombinant IL-6 reduced IKKβ phosphorylation and ER stress and restored central insulin and leptin signaling in DIO rats at rest. In addition, exercise and the icv infusion of recombinant IL-6 reduced ER stress induced by icv infusion of Tapsigargin in lean animals. However, in contrast to control mice, in IL-6-deficient mice (C3H/Hej) injected with icv Tapsigargin, exercise failed to reduced ER stress.
Conclusion: Our results show that exercise reduced the aberrant IKKβ activation and ER stress in the hypothalamus and prevented hyperphagic response in an IL-6 dependent-manner in rodents. Hence, IL-6 is an important physiological contributor to the central insulin and leptin action mediated by exercise, linking it to hypothalamic ER stress and inflammation.

Changes in cerebrospinal fluid insulin during non-neurological surgery
S. Bromander[1], R. Anckarsäter[2], B. Ahrén[3], M. Kristiansson[1], L. Träskman-Bendz[4], E. Wennberg[5], K. Blennow[6], H. Anckarsäter[6], H. Zetterberg[6], C. Wass[6];
[1]Department of Forensic Psychiatry, Karolinska Institutet, Huddinge, [2]Department of Anaesthesiology and Intensive Care, Kungälv Hospital, [3]Faculty of Medicine, Lund University, Lund, [4]Department of Psychiatry, Lund University, Lund, [5]Department of Anaesthesiology and Intensive care, Kungälv Hospital, [6]Department of Psychiatry and Neurochemistry, Göteborg University, Sweden.

Background and aims: Recently, insulin has been found to play an important role in central nervous system (CNS) signalling, and is thought to influence cognition, the regulation of body weight and other metabolic parameters. The CNS is dependent on an active uptake of insulin over the blood-brain barrier (BBB) as no insulin seems to be synthesized de novo in the CNS. However, very few studies regarding the different factors affecting insulin uptake in the CNS have been published, especially in humans. In this study, the Surgical Stress Study, the aim was to study how the levels of different substances and their metabolites in cerebrospinal fluid (CSF) were affected by major stress in the form of non-neurological surgery.
Materials and methods: Thirty-five patients undergoing non-neurological major surgery (knee arthroplastics) had serum and CSF samples drawn before, three hours after and on the morning after surgery (point A, B and C). Serum and CSF samples were analyzed for concentrations of insulin and albumin. Statistical calculations were performed in order to assess correlations between the different outcome measures at the three different points, and with body mass index (BMI).
Results: The CSF insulin concentration was compared with the serum concentration as well as with albumin and other CSF proteins. Preliminary results demonstrate that the concentrations of insulin in CSF and serum were strongly correlated at all three points. The changes in CSF insulin were considerably smaller than the changes in serum insulin at all time points. The albumin levels in CSF and serum and the CSF/ serum albumin ratios showed no correlation with CSF insulin before surgery, but a strong correlation was seen between CSF albumin and insulin at both points after the operation. BMI was negatively correlated with the CSF/serum insulin quota before and directly after surgery.
Conclusion: In this study, we replicated in humans animal findings showing that serum and CSF insulin levels are correlated and that the changes in CSF insulin mirror those in serum insulin under stress, although at a much lower absolute level. It seems like the central nervous system is protected from strong fluctuations in peripheral insulin levels. CSF insulin levels decreased (though not significantly) during the operation, but increased again, although not to the level at point A, after the following night. An interesting observation is that CSF insulin and albumin are correlated during the operation. This could be a sign of BBB permeability being influenced by the operative stress, so that at least a subgroup of subjects experience a drastic decrease in permeability and transport of both proteins. A high BMI impaired the transport of insulin into the CNS. The effect of insulin in the CNS is opposite that of peripheral insulin, decreasing food intake and promoting weight loss, so this could indicate a possible mechanism by which stress promotes obesity.

Human primary astrocytes represent a novel insulin-responsive cell type
M. Heni, H. Staiger, M. Guthoff, A.M. Hennige, H.-U. Häring;
Department of Internal Medicine IV, Tübingen, Germany.

Background and aims: After systemic or intranasal application of insulin, we recently showed modulation of the activity of very specific brain regions using MEG and fMRI techniques.
Since insulin receptors are thought to be nearly ubiquitously expressed throughout the brain, insulin's effects on specific regions may be mediated by additional processes. One hypothesis that could explain this observation is a modulation of neuronal activity by other insulin-sensitive cell types. Due to the fact that astrocytes constitute the predominant cell type in the brain and can influence neurons in several ways, they are therefore potential candidates. Astrocytes can (i) store glycogen and supply neurons with lactate as energy source; (ii) take up and release neurotransmitters, and (iii) form the blood-brain barrier in cooperation with endothelial cells and pericytes. In this study, we asked whether primary human astrocytes are insulin-responsive at the molecular level.
Materials and methods: Commercially available Normal Human Astrocytes (Lonza) were grown in the recommended media. Before each experiment, they were starved in media containing 0.5 % FCS for 48h. After insulin stimulation, cells were lysed and the protein content of the lysates was determined using the Bradford method. Proteins were separated by SDS-PAGE. Major players in the insulin signaling pathway were detected by Western blotting using specific antibodies. Protein phosphorylation levels were investigated with phospho-specific antibodies. Glucose uptake was determined using 3H-Deoxy-D-Glucose. Lactate levels were measured enzymatically.
Results: We could demonstrate relevant expression of key proteins of the insulin signal cascade, such as insulin receptor β-subunit, insulin receptor substrat-1, Akt / protein kinase B and glycogen synthase kinase 3, in Normal Human Astrocytes. After stimulation with increasing concentrations of insulin (0 - 50 nM) for 15 minutes, activating phosphorylation of these proteins was detected. We could neither detect significantly increased glucose uptake after insulin treatment for 15 minutes (0-100 nM) nor lactate secretion after insulin stimulation for 6-8 hours (0-100 nM).
Conclusion: This study demonstrated the expression of key signaling molecules of insulin signal transduction in primary human astrocytes. Detection

of phosphorylation proved the functional activity of this signaling pathway. Nevertheless, we could not detect the ultimate endpoint of insulin signaling in astrocytes, yet. While insulin increases glucose uptake in many cell, it does not so in commercially available Normal Human Astrocytes. Another important function of astrocytes, the secretion of lactate, is also unchanged by insulin in these cells. Thus, astrocytes are a candidate insulin-responsive cell type for the modulation of neuronal activity after insulin stimulation, but the interaction pathway is still unknown.

Feeding modulates human brain responses to food cues

Y. Nathan[1], S. Lee[2], S. Brookes[3], P. Choudhary[1], M. Brammer[2], L. Reed[2], S.A. Amiel[1], F. Zelaya[2];
[1]King's College Hospital, [2]Institute of Psychiatry, [3]Institute of Psychiatry, London, United Kingdom.

Background and aims: The central responses to food ingestion are important in maintaining normal energy balance and dysregulation may result in overeating , leading to obesity and Type 2 diabetes. We studied modulation by food ingestion of regional brain activation at rest and in response to food cues in health using functional Magnetic Resonance Imaging (fMRI).
Materials and methods: Ten healthy volunteers were studied using fMRI (1.5T MRI scanner) in a random order after an eight hour fast or a 400Kcal mixed meal. Changes in regional brain perfusion were measured during rest using continous arterial spin labelling imaging (CASL) and during food and non food imaging viewing in a block design paradigm using blood oxygen level dependant (BOLD) imaging. Time series were extracted from brain regions which showed statistically significant differences between food and non food, fed and fasted conditions .Satiety responses were recorded using a visual analogue scale. Analysis for the BOLD data was made using XBAM, and for CASL using SPM-5 FIL London.
Results: Food ingestion increased satiety scores ($p<0.0001$), while hunger and desire to eat scored more highly in the fasted state($p<0.001$ $p<0.0004$) Preliminary analysis of CASL analysis showed increase perfusion in the fed state in thalamus (sensory relay betweeen subthalamic areas andsesory cortex), hypothalamus (energy sensing) , precuneus (responsible for self processing), cerebellum, gustatory cortex and the visual and auditory cortices. We also observed significant reduction in perfusion in the orbito-frontal cortex. Food ingestion enhanced BOLD responses to food image viewing in dorsolateral prefrontal cortex, insula, anterior cingulate, while responses in visual cortex were not different between food and non food images in either the fed or fasted state.
Conclusion: Food ingestion alters neuronal activation at rest and in response to furtherfood cues in classicalcue response network and brain regions known known to be involved in appetite control and satiety sensing.The modulation of cerebral perfusion and food cue-induced response by feeding provides a measure of the normal response to feedingwhich may be exploited in the study of groups at risk of overeating, obesity and Type 2 diabetes and possible treatments that work through modulating appetite and food ingestion.

Evidence of a regulation in peripheral glucose metabolism by central nervous system in humans: from Parkinson to diabetes

M. Batisse[1], C. Guillet[1], I. Rieu[2], F. Durif[2], Y. Boirie[1];
[1]Human Nutrition Unit, University Hospital, [2]Neurology, University Hospital, Clermont Ferrand, France.

Background and aims: Recent animal studies have demonstrated an important link between central sensing of substrates and endogenous glucose production, suggesting that specific neurons in the hypothalamus and second order neurons might control peripheral glucose metabolism. Subthalamic nucleus-deep brain stimulation (STN-DBS) is an alternative treatment for patients with uncontrolled symptoms of Parkinson disease. As subthalamic nucleus are located close to hypothalamus, we hypothesized that DBS may induce changes in the hypothalamus activity and modify hepatic glucose production in humans.
Materials and methods: To this aim, endogenous glucose production (EGP) was measured during 5h infusion of D-[6,6-$^2H_2$]-Glucose in 8 STN-DBS treated patients after DBS interruption (Stim OFF) and under DBS (Stim ON) conditions. EGP was then compared to EPG of matched healthy subjects (control group) as well as plasma insulin, glucagon and free fatty acids.
Results: In Stim OFF conditions, EGP was higher in patients than in the control group (2.62 ± 0.09 vs 2,27 ± 0.10 mg/kg/min, $p<0.01$). Despite no significant change in plasma glucose (p=NS), a significant and consistent decrease of EGP was observed in the patients between Stim OFF and Stim ON (2.04± 0.07 mg/kg.min, $P<0.05$), and there was no more difference between control group EPG (2.09 ± 0.03 mg/kg.min) and Parkinson patients in Stim ON (p=NS). No difference in insulin, glucagon or FFA levels was observed between the patients in Stim OFF and Stim ON and with the control group.
Conclusion: These results demonstrate for the first time an effect of deep brain stimulation on endogenous glucose production and suggest a role of central nervous system on peripheral glucose regulation in human. In addition, these data indicate that non-diabetic patients with Parkinson disease may have impaired glucose metabolism likely secondary to dysfunction of autonomous nervous system.

Alfa linolenic (w-3) and oleic (w-9) fatty acids revert inflammation and apoptosis in the hypothalamus of diet-induced obese rats

D.E. Cintra, E.R. Ropelle, J.R. Pauli, J.C. Moraes, C.T. De Souza, M.J.A. Saad, M. Milanski, L.A. Veloso;
Department of Clinic Medicine, State University of Campinas, Brazil.

Background and aims: In obesity, the adequate hypothalamic function is disrupted by local inflammation and apoptosis of neurons involved in the control of feeding and thermogenesis. Recent studies have revealed that long-chain saturated fatty acids present in western diets are involved in the induction of the pro-inflammatory and apoptotic response. Here, we evaluate the properties of w-3 and w-9 fatty acids as candidate protective factors against diet-induced inflammation and apoptosis of the hypothalamus.
Materials and methods: Obese and diabetic male Wistar rats were separated into three groups and submitted to stereotaxic implantation of a cannula to receive either w-3, w-9 or BSA via icv administration into the 3rd ventricule, for 5 days. Feeding behavior was measured daily. Molecular, histological and biochemical parameters were analyzed at the end of the experimental period. The pro- and anti-inflammatory proteins IL6, IL10, TNFa, iNOS, and JNK; the insulin and leptin pathways proteins IR, IRS1/2, AKT, FOXO, JAK, and STAT; and the pro- and anti-apoptotic proteins BAX and Bcl were evaluated by Western Blot and RT-PCR. For the immunohistochemical (IH) analysis, the specific antibody F4/80 was utilized to detect activated microglia.
Results: Control group consumed 15±2 g/d diet as compared with w-3 and w-9 groups, which consumed 3±1 and 4±1 g/d, respectively. Blood glucose levels were lower in w-3 and w-9 groups (113 mg/dL±5 and 125 mg/dL±7 vs. 198±3mg/dL, Control). The IH images of the hypothalamus showed a distinct reduction in the pro-inflammatory process mediated by macrophages in both FA groups, in comparison with Control. The molecular analysis revealed the potential activity of w-3 and w-9 to decrease pro-inflammatory proteins, as well as the pro-apoptotic protein. The most important proteins involved in the insulin and leptin pathways showed an increase in their activity on the hypothalamus. In both groups, w-3 and w-9, an important increase in IL-10 and Bcl-2 expression was observed in the respective anti-inflammatory and anti-apoptotic responses.
Conclusion: In conclusion, w-3 and w-9 re-established the correct hypothalamic signaling of te insulin and leptin. The hypothalamic cell survival was increased by w-3 and w-9, and all the effects together resulted in the control of the hyperphagic state, reducing the body weight and glycemic levels.

Combination of mitochondrial targeting nutrients for the management of brain failures associated with type 1 diabetes

T. Kuchmerovska, I. Shymanskyy, G. Donchenko, A. Klimenko;
Coenzymes, O.V. Palladin Institute of Biochemistry, Kyiv, Ukraine.

Background and aims: The brain is known to be abnormally susceptible to oxidative damage from high ambient oxidant levels associated with diabetes. Much attention has been recently focused on the important role of mitochondria in the interplay between energetic failure and oxidative stress within nerve cells. If such a mechanism is indeed relevant to the pathogenesis of diabetes-associated brain disorders, the agents that can both attenuate mitochondrial dysfunction and directly or non-directly scavenge free radicals might prove to be efficacious. The study was performed to evaluate neuro-

protective efficacy of a combined supplementation of mitochondria-specific antioxidants (acetyl-L-carnitine (ALC) and alpha-lipoic acid, ALA) and nicotinamide (NAm), as a multiple-action drug.

Materials and methods: All studies were carried out after 4 weeks of STZ-induced diabetes (60 mg/kg of body weight, i.p.) in rats treated for 14 days with or without combination of ALC, ALA and NAm (respectively 100, 50 and 100 mg/kg b.w., i.p.). Reactive oxygen species (ROS) were analysed using 2',7'-dichlorodihydrofluorescein diacetate, converted to fluorescent 2',7'-dichlorofluorescein (DCF) upon oxidation. Mitochondrial membrane potential ($_{\Delta}\Psi_{m}$) was assayed spectrofluorimetrically with rhodamine123 (Rh123). NAD^{+} and sorbitol levels were assayed enzymatically.

Results: Diabetes was shown to be associated with 23.0±1.7% elevation of Rh123 fluorescence under self-quenching conditions and decreased response to protonophore FCCP that is indicative of mitochondrial membrane depolarization. Research into brain energetic revealed that compared with the ATP and NAD^{+} contents in control, those in diabetic brain were respectively 28.3±1.9 and 30.4±2.0% decreased, p<0.05. Combined treatment of diabetic rats with ALC, ALA and NAm countered loss of $_{\Delta}\Psi_{m}$, restored NAD^{+} and partially reversed ATP towards control levels most likely due to normalization of the efficiency of mitochondrial function. Dysfunctional mitochondria appear to account for increased formation of ROS, since DCF fluorescence level in diabetic mitochondria was 37.2±2.8% higher than in control, p<0.05. Combined therapy diminished the diabetes-associated DCF-sensitive mitochondrial ROS production by 29.3±2.0%, p<0.05. In keeping with cellular respiration defects and oxidative stress Na^{+},K^{+}-ATPase activity was found to be reduced to 153±10 in diabetes vs. 249±15 nmol Pi/min per mg protein in control, p<0.05. The enzyme activity was significantly increased (by 19.5±1.2 % vs. diabetes, p<0.05) after the treatment. Following administration of the drugs to diabetic rats, hyperglycaemia was reduced to 15.2±1.0 vs. 20.3±1.2 mmol/l in diabetes and two-fold elevated brain sorbitol level was markedly normalized, p<0.05. It is also notably that the combination of therapies in this study can ameliorate brain lesions induced by diabetes more effectively than each nutrient alone as was previously shown.

Conclusion: The findings suggest that neuroprotective therapy in diabetes should proceed towards the simultaneous protections of nerve cells against impairments of mitochondrial energy transformations and enhanced endogenous oxidant burden by using combination of multiple naturally occurring compounds with various mechanisms of action. Beneficial effects of combined supplement of ALC, ALA and NAm offer a non-toxic, well tolerated and rational option for diabetes-associated brain disorders.

Alterations of PED/PEA-15 gene at the interface of diabetes and Parkinson disease

G. Perruolo[1], F. Fiory[1], D. Viggiano[2], A. Cassese[1], A. Scorziello[2], A.P.M. Barbagallo[1], A. Sadile[3], L. Annunziato[2], F. Beguinot[1], P. Formisano[1]; [1]IEOS-CNR, [2]Division of Pharmacology Dept. of Neuroscience, Federico II, [3]University of Naples and Dept of Experimental Medicine, Second University, Naples, Italy.

Background and aims: Recent studies show that an increased risk of neurodegenerative disorders including Parkinson's disease (PD) is associated with type 2 diabetes. PD results from the loss of dopaminergic cells in the substantia nigra. Studies in animal models have shown also that chronic hyperglycemia impairs striatal dopaminergic transmission. However the molecular mechanisms underlying the abnormal dopaminergic function in individuals with T2D are still unknown. PED/PEA-15 is a 15 kDa cytosolic protein overexpressed in peripheral tissues of T2D patients. Transgenic mice ubiquitously overexpressing PED/PEA15 (PED-TG) feature insulin resistance and impaired pancreatic beta-cell function. Moreover, PED/PEA-15 is highly expressed in brain, in particular in the prefrontal cortex and substantia nigra. We have therefore investigated whether PED/PEA-15 may affect dopaminergic function.

Materials and methods: Motor-behavioural, immuhistochemical and biochemical studies were performed.

Results: Motor function in PED-TG mice was investigated by measuring the time to climb an inclined platform and the time to rotate 180 degrees after placed nose down on an incline (negative geotaxis). The experiments showed a two-fold increased time of climbing (P<0.02) and impaired negative geotaxis (P<0.05) of PED-TG, compared to their wild-type littermates. Moreover, grip strength testing, hanging wire test and pole test excluded significant differences in muscular force. Footprint analysis excluded locomotor ataxia, whereas the presence of air righting reflex excluded abnormalities in vestibular functions. Learning rate for motor ability tasks, measured with four consecutive trials on a rotarod, and for spatial tasks, measured with Barnes Maze (ability to find and remember the shortest path to an exit on a round board) was also significantly slower (P<0.02). Moreover, PED-TG mice suspended by the tail present foot-clasping reflex; an aberrant behaviour linked to deranged dopaminergic function. No impairment of cerebral structures, including striatum size, was noticed by morphological examination. Nevertheless, tyrosine hydroxylase (TH) content was 60% lower in caudate-putamen protein extracts from PED-TG compared to controls (P<0.02), as assessed by Western blot analysis. Immunostaining of brain slides from PED-TG mice also revealed a reduced content of TH and of dopamine, compared to controls.

Overexpression of PED/PEA-15 in PC12 cells leads to 40% reduction of TH levels. In particular insulin increase TH expression in parental PC12, while not in those overexpressing PED/PEA-15.

Conclusion: Our data support the hypothesis that PED/PEA-15 overexpression in mice reduces dopamine levels inducing a Parkinson-like syndrome and modifies neuronal response to insulin.

Subjects with early-onset type 2 diabetes show defective activation of the skeletal muscle PGC-1α/mitofusin-2 regulatory pathway in response to physical activity

H. Thabit[1], M.I. Hernandez[2], N. Burns[1], S. Shah[1], I. Brema[1], M. Hatunic[1], F. Finucane[1], M. Liesa[2], C. Chiellini[2], D. Naon[2], M. Palacin[2], A. Zorzano[2], J.J. Nolan[1];
[1]Metabolic Research Unit, Dublin, Ireland, [2]Institute for Research in Biomedicine, Barcelona, Spain.

Background and aims: Type 2 diabetes is associated with insulin resistance and skeletal muscle mitochondrial dysfunction. Recent studies have indicated that subjects with early-onset type 2 diabetes show an incapacity to increase VO2max in response to chronic exercise. This suggests a defect in muscle mitochondrial response to exercise. Here, we have explored the nature of the mechanisms involved.
Material and methods: Muscle biopsies were collected from young type 2 diabetes subjects and obese controls before and after acute or chronic exercise protocols and the expression of genes and/or proteins relevant to mitochondrial function was measured. In particular, the regulatory pathway PGC-1a/mitofusin-2 (Mfn2) was analyzed.
Results: At baseline, subjects with diabetes showed reduced expression (by 26%) of the mitochondrial fusion protein, Mfn2 and a 39% reduction of the a-subunit of ATP synthase. Porin expression was unchanged consistent with normal mitochondrial mass. Chronic exercise led to a 2.8-fold increase in Mfn2, as well as increases in porin, and the a-subunit of ATP synthase in muscle from control subjects. However, Mfn2 was unchanged following chronic exercise in those with diabetes while porin and a subunit of ATP synthase were increased. Acute exercise caused a 4-fold increase in PGC-1a expression in muscle from control subjects but not in those with diabetes.
Conclusion: Our results demonstrate alterations in the regulatory pathway that controls PGC-1a expression, and induction of Mfn2 in muscle from patients with early onset type 2 diabetes. Patients with early-onset type 2 diabetes display abnormalities in the exercise-dependent pathway that regulates the expression of PGC-1a and Mfn2.

685

The effects of suppression of endogenous insulin on hepatic and quadriceps glycogen stores after 60 min of submaximal exercise in healthy adult males

W.D. Strain[1], K.L. Gilbert[2], K.M. Macleod[1], J. Fulford[1], A.C. Shore[1], K.A. Stokes[2];
[1]Peninsula Medical School, Exeter, [2]School for Health, University of Bath, United Kingdom.

Background and aims: Hypoglycaemic episodes are more common and more severe within 24 hours of exercise in patients with type 1 diabetes. This may in part be due to depleted hepatic glycogen stores. Physiologically at least 50% of insulin is subject to hepatic first-pass metabolism, exposing the liver to higher concentrations of insulin than the peripheral circulation. Management of type 1 diabetes using peripherally administered insulin is associated with a relative hepatic hypoinsulinaemia. We aimed to explore whether relative hepatic hypoinsulinaemia is associated with impaired hepatic glycogen replenishment after exercise.
Materials and methods: Four men, aged 18-25, attended after an overnight fast and cycled for 60 min at 70% of their VO2 max, after which they underwent a hyperinsulinaemic euglycaemic clamp (HEC) for 300 min, in order to suppress endogenous insulin secretion. Measures of liver and quadriceps glycogen stores were taken pre-exercise, 0-80 mins (early) post-exercise and 220-300 min (late) post-exercise using 13C magnetic resonance spectroscopy (MRS - 40 minute protocol per tissue). The protocol was repeated after no less than 1 month without endogenous insulin suppression, by administration of glucose alone in the same quantities as received during the HEC.
Results: Exercise approximately halved the glycogen stores in the quadriceps in both the HEC and glucose alone studies (Proportion of baseline glycogen present ± SD = 0.54±0.16 and 0.44±0.36 respectively). There was no difference in the recovery of glycogen in the quadriceps in the late phase between the groups (Figure 1). In the early post exercise phase there was a trend towards a difference in hepatic glycogen store in the two groups with lower values in the HEC group compared to the endogenous Insulin group (Proportion of baseline ± SD = 0.81±0.2 and 2.0 ± 1.2 respectively). In the late post exercise phase (figure 1) hepatic glycogen stores remained depleted in those on the HEC whereas those treated with glucose alone had replenished their hepatic glycogen stores (p for difference = 0.02).
Conclusion: A HEC, simulating the effects of a deficiency in endogenous insulin replaced by peripherally administered insulin, in healthy males after 60 min of exercise at 70% VO2 max impaired glycogen replenishment in the liver over at least 6 hours. If this is representative of patients with type 1 diabetes, it may account for the increased risk and severity of delayed hypoglycaemia observed after exercise.

Figure 1: Proportion of baseline glycogen stores in the quadriceps and liver 220-300 min. after 60 min. exercise at 70% VO_2 Max(1=baseline)

The effect of exercise on intrahepatocellular (IHCL) and intramyocellular lipids (IMCL)

A. Egger[1], C. Boesch[2], R. Kreis[3], J.-M. Nuoffer[4], I. Krull[1], P. Diem[1], C. Stettler[1], E.R. Christ[1];
[1]Division of Endocrinology, Diabetes and Clinical Nutrition, Inselspital, Bern University Hospital, [2]Department of Clinical Research, Bern University, [3]Clinical Research, Department of Clinical Research, Bern University, [4]Department of Clinical Chemistry, Bern University, Switzerland
.

Background and aims: Intramyocellular (IMCL) and intrahepatocellular lipids (IHCL) are both related to insulin sensitivity and thus of crucial importance for the epidemic "metabolic syndrome". While it is well known that IMCL are metabolically active and the concentration in skeletal muscle can be changed within several hours with diet and exercise, short-term variations of IHCL in liver tissue are much less recognized. 1H-MR spectroscopy allows to assess changes of IMCL and IHCL repeatedly. This study aims at short-term variations of IMCL and in particular IHCL due to exercise.
Materials and methods: Nine healthy volunteers (age 35 +/- 12 years; BMI 22.6 +/- 2.7 kg/m2; VO2peak 56.1 +/- 10.7 ml/kg/min) were enrolled in this sub-study. Three days prior to the study, the volunteers did not perform exercise and increased the daily fat intake by additional fat snacks (0.75 g/kg/d). Following a first MR examination with determination of IMCL and IHCL, the volunteers exercised on a treadmill at 50-55% of VO2peak for two hours, followed by a second MR examination.
Results: IMCL decreased significantly during exercise (reduction in %, mean±SD: -25±5, p =0.006), which contrasts to a significant increase of IHCL (increase in % mean±SD:32±11, p = 0.026). During exercise, serum free fatty acids (FFA) increased significantly (p << 0.001, two-way ANOVA).
Conclusion: The reduction of IMCL during exercise has been expected from several reports in literature. However, an increase of IHCL as a consequence of 2 hours exercise has not been reported to the best of our knowledge. Obviously, during exercise the skeletal muscle uses IMCL; in parallel, adipose tissue releases FFA, which may result in an increase of IHCL.

Effects of six months of moderate resistance-versus endurance-training on muscle ATP synthesis in first-degree relatives of patients with type 2 diabetes

G. Kacerovsky-Bielesz[1,2], M. Chmelik[2,3], C. Ling[4], R. Pokan[5], J. Szendroedi[1,2], M. Farukuoye[2], M. Kacerovsky[2], A.I. Schmid[2,3], S. Gruber[3], M. Wolzt[6], E. Moser[3], G. Pacini[7], G. Smekal[5], L. Groop[4], M. Roden[8,2]; [1]First Medical Department, Hanusch Hospital, Vienna, Austria, [2]Karl-Landsteiner Institute for Endocrinology and Metabolism, Vienna, Austria, [3]MR Center of Excellence, Medical University of Vienna, Austria, [4]Department of Clinical Sciences, Lund University, Malmo, Sweden, [5]Department of Sports and Exercise Physiology, University of Vienna, Austria, [6]Department of Clinical Pharmacology, Medical University of Vienna, Austria, [7]Metabolic Unit, Institute of Biomedical Engineering, CNR, Padova, Italy, [8]Department of Medicine/Metabolic Diseases, Heinrich Heine University Dusseldorf, Germany.

Insulin resistant first-degree relatives of type 2 diabetic patients (REL) feature reduced flux through myocellular ATP synthase (fATPase) and increased myocellular (IMCL) and hepatocellular (HCL) lipids. As exercise training can improve insulin sensitivity, we compared effects of moderate resistance (RE) vs. endurance (EN) training on fATPase. Glucose tolerant REL (RE: 3f/5m, age: 37±13a, BMI: 25±5kg/m2; EN 5f/3m, age: 43±11a, BMI: 26±2kg/m2) with comparable O2 uptake at the respiratory compensation point (VO2rcp) underwent OGTT to measure insulin sensitivity (OGIS) and 1H/31P magnetic resonance spectroscopy to assess fATPase, IMCL in soleus muscle and HCL before and after 26 weeks of exercise training (twice weekly at 90% of VO2rcp, duration was individually adjusted and increased). OGIS was similar at baseline (RE: 380±73 vs. EN: 381±70 ml.min-1.m-2) and after exercise training (389±40 vs.382±90 ml.min-1.m-2). fATPase was also comparable at baseline (12±5 vs.12± 3 µmol.ml-1.min-1) and after exercise training (13±3 vs. 11±2 µmol.ml-1.min-1). Likewise, IMCL were comparable at baseline and did not change by exercise training (basal: RE: 1.08±0.20 vs EN: 1.13± 0.46, after training RE: 1.06± 0.53, EN: 1.11±0.08) and HCL were similar at baseline (5.0±6.1 vs. 6.7±9.8% water) and tended to decrease in both groups.
VO2rcp remained unchanged in RE, but rose by 30% in EN (RE: 24.3±6.4 vs. 24.8±6.9 ml.kg-1.min-1, ns; EN: 20.3±4.7 vs. 26.4±6.4 ml.kg-1.min-1, p=0.001). Evaluating maximal strength of knee extensors and flexors using isokinetic dynamometer (30°.s-1 and 60°.s-1) torque (Nm) (as sum of both knees and both measures) increased in RE (flexors: 294±88 vs. 412±132; extensors: 586±171 vs. 720±203) and did not significantly change in EN (flexors: 319±135 vs. 337±12,1, ns; extensors: 606±250 vs. 637±231, ns). Moderate exercise training does not affect insulin sensitivity and mitochondrial ATP turnover in nonobese, glucose tolerant and insulin sensitive relatives of type-2 diabetic patients.

Change in expression levels of lipid droplet coat protein in human skeletal muscle during strength training

I.M.F. Gjelstad[1,2], F. Norheim[2], T. Raastad[3], K.I. Birkeland[1,4], C.A. Drevon[2]; [1]Oslo University Hospital Aker, [2]Department of Nutrition, University of Oslo, [3]Norwegian School of Sport Sciences, Oslo, [4]Faculty of Medicine, University of Oslo, Norway.

Background and aims: Depositions of fat in non-adipose tissues like skeletal muscle and liver are associated with insulin resistance and type 2 diabetes. Excess fat is stored as triacylglycerol in intracellular lipid droplets. The perilipin family of lipid droplet coat proteins (perilipin, adipophilin, S3-12, TIP47 and LSDP5/OxPAT/MLDP) are essential for this cellular lipid storage. The aim of the present study was to study the effect of physical exercise on gene expression of these lipid droplet coat proteins.
Materials and methods: Ten healthy men (26.7 ± 4.6 years of age) with no regular strength training during the last year participated in an eleven weeks strength training study with three workouts per week. Each workout included leg and upper-body exercises. Skeletal muscle biopsies from a thigh muscle (*m. vasus lateralis*) were obtained at baseline and after two and eleven weeks of training. mRNA expression was analyzed with TaqMan® Gene Expression Assays.
Results: In eight of ten subjects, the expression of markers of muscle fiber type I (MYH7) and IIx (MYH1) decreased from baseline to two weeks and was increased again after further nine weeks of exercise training. The expression of LSDP5, S3-12 and adipophilin followed a similar pattern, and the expression at week two was reduced as compared to baseline for LSDP5 (-0.011, 95%CI: -0.019, -0.0036), S3-12 (-0.030, 95%CI: -0.044, -0.016) and adipophilin (-0.016, 95%CI: -0.032, 0.00). At week eleven the expression of the same genes were increased again (LSDP5: 0.011, 95%CI: 0.00, 0.021; S3-12: 0.021, 95%CI: 0.00, 0.040; adipophilin: 0.021, 95%CI: 0.010, 0.036), and did not differ from baseline. The expression of TIP47 increased marginally during the intervention whereas perilipin expression did not change.
Conclusion: These are the first results indicating a possible important role of exercise in the regulation of the perilipin family of lipid droplet coat proteins in skeletal muscle. Two weeks of strength training changed gene expression of several genes, including the lipid droplet coat proteins LSDP5, S3-12 and adipophilin. After further nine weeks of exercise the muscles seem to be adapted to the intervention and the expression levels are comparable to baseline levels.

Effect of resistance exercise on muscular subfascial adipose tissue and retinol-binding protein-4 concentration in individuals with diabetes

Y. Ku[1], H.-R. Kwon[2], H.-G. Seok[2], H.-J. Ahn[2], J. Kim[1], E.-K. Park[1], B.-K. Koo[1], H.-J. Kim[1], K.-S. Pak[1], K.-A. Han[1], K.-W. Min[1]; [1]Internal Medicine, Eulji University School of Medicine, [2]Diabetes Center, Eulji Hospital, Seoul, Republic of Korea.

Introduction: Mounting evidence indicates that elevated muscular lipid accumulation is associated with diminished insulin sensitivity in skeletal muscle. It is reasonable to hypothesize that resistance exercise decreases muscular adipose tissue and have favorable effects on retinol-binding protein-4 (RBP4), which is linked to adipose tissue, and insulin sensitivity in women with diabetes.
Methods: Forty four overweight women with type 2 diabetes (55.7±6.5 yr) were randomly assigned to control (C, N=16), resistance exercise (RG, N=13), using

elastic band three times per week at about 40-50% of maximal exercise capacity under supervision and aerobic exercise group by walking (AG, N=15), which was monitored with accelerometer. We assessed anthropometric parameters, subcutaneous (ASAT) and visceral adipose tissue (AVAT) at abdomen, subcutaneous (SCAT), subfascial (SFAT), and intramuscular adipose tissue (IMAT) at mid-thigh level using computed tomography, plasma level of RBP4 and insulin sensitivity by insulin tolerance test (KITT), before and after 12-week exercise program.
Results: After 12-wk training program, changes of SCAT, SFAT, IMAT, RBP4, and KITT were not different across three groups, although change of BMI and ASAT in AG was greater than that in C. Within group analysis using paired T test, BMI, ASAT, and SCAT was decreased from baseline in both exercise groups, and plasma RBP4 concentration was significantly decreased only in RG. The change of RBP4 concentration had positive correlation with that of SFAT (r=0.664, p=0.013) in RG, but not in AG (r=-0.405, p=0.151).
Conclusion: Resistance exercise didn't alter intramuscular adipose tissue but reduced plasma RBP4 level without improvement of insulin sensitivity.

Severity of obstructive sleep apnea syndrome (OSAS) is highly correlated with a decreased ability to oxidize lipids during exercise
M. Desplan[1], M. Outters[1], C. Fedou[1], J. Pochic[2], J. Brun[1], M. Sardinoux[1], A. Avignon[2], J. Mercier[1];
[1]Dept of Clinical Physiology, [2]Dept. of Metabolic Diseases, CHU & University of Montpellier, Montpellier, France.

Background and aims: To determine if OSAS in the metabolic syndrome is associated with an impaired skeletal muscle ability to oxidize lipids during exercise.
Materials and methods: Thirteen patients with metabolic syndrome (3 women/10men; age: 55.5 ± 9.6 years; BMI: 37.5 ± 6.22 $kg.m^{-2}$; Waist Circumference: 125.4 ± 21.8 cm; body fat %: 40.8 ± 11.5 %, free fat mass (FFM): 65.3 ±15.8 kg; mean ± SD) were evaluated by overnight polygraphy to assess OSAS status (airflow, thoracoabdominal effort and oxymetry), which was quantified with the apnea/hypoapnea index (AHI). The balance of substrates oxidized during exercise was studied with exercise calorimetry, with determination of the maximal lipid oxidation rate (lipoxmax).
Results: During polygraphy, the AHI was 35.31 ± 21.7 with mild (AHI 5-15), moderate (AHI 15-30), and severe (AHI >30) OSAS in respectively 4, 1, and 8 patients. The lipoxmax occurred at 23.1 ± 13.7 % of the theoretical maximal power. At this level 2.7 ± 1.39 $mg.kg^{-1}.min^{-1}$ of lipids were oxidized. The lipoxmax was highly correlated with AHI (R=0.799; p=0.0018) and body fat% (R=0.794; p= 0.0021), while no correlation was found between AHI and Body fat% (R=0.48, p=0.35). A partial regression analysis showed that if the variable Body fat% is kept constant, the correlation between AHI and lipoxmax remains highly significant (R=0.778; p=0.002). Maximal lipid oxidation at exercise was significantly decreased in severe compared to mild and/or moderate OSAS (1.85 ±0.533 vs 3.91 ± 0.164; p= 0.0081).
Conclusion: The severity of OSAS is an independant determinant of the ability to oxidize lipids during exercise, regardless % body fat. Although the mechanism of this relationship remains to be determined, it could be a mechanism of resistance to weight reduction. This suggests to investigate the efficiency of exercise training targeted at the LIPOXmax in OSAS patients.

Exercise during pregnancy reduces high fat induced macrosomia
K.B. Rooney[1], P. Ruell[1], C. Caillaud[1], C. Thompson[2], S. Ozanne[3];
[1]Exercise and Sport Science, University of Sydney, Lidcombe, Australia, [2]Flinders Medical Centre, Bedford Park, Australia, [3]Department of Clinical Biochemistry, University of Cambridge, United Kingdom.

Background and aims: Dietary insults on the intrauterine environment are associated with altered fetal development and subsequent progressive metabolic disorders in adulthood. Evidence of the fetal origins of adult diseases in humans has been identified in epidemiological studies linking birth weight to subsequent risk of type 2 diabetes, obesity and cardiovascular disease. We have previously reported elevated abdominal adiposity together with reduced hepatic insulin signalling proteins in 15 week old offspring of dams fed a high fat diet during gestation. Physical activity is recognised as a positive intervention for the metabolic related disorders of high fat feeding. Potentially, specific exercise training during pregnancy could present as a method for obesity and diabetes prevention in offspring of high fat fed mothers. We aim to investigate the effect of exercise training during pregnancy on offspring development of high fat fed pregnant dams.
Materials and methods: 8 female (160g) and 8 male Wistar rats (215g) were fed a high fat diet (34% omega-6 PUFA, 26% Protein, 22.3 kJ/g). An oral glucose tolerance test (OGTT) (3g glucose / kg) was performed on day 24 with blood collected at fasting as well as 15, 30, 60 and 120 minutes post gavage. Glucose and insulin response was assessed as the total area under the curve (TAUC) for the 2 hour period. On day 28, mating pairs were established. Dietary intervention proceeded for a further 3 weeks. After 7 days of co-habitation, mating pairs were separated. Four females were randomly allocated to a training intervention. Training consisted of 30min of treadmill running at a moderate intensity for 10 days of the 16 between separation from males and spontaneous delivery. An OGTT was performed on all females on the 12th day following separation. Following delivery, all pups were weighed and litter sizes standardised to 8 (4 male, 4 female) per dam. During lactation all mothers were fed standard laboratory chow (11% Fat, 23% Protein, 13.9kJ/g).
Results: Exercise training did not significantly affect total body weight of mothers prior to delivery (Sedentary 312.2 ± 28.5g versus Trained 326.6 ± 23.8g). While insulin and glucose TAUC were similar between groups, plasma glucose 15 minutes following gavage was significantly lower in trained mothers (Trained 4.4 ± 0.7 versus Sedentary 5.8 ± 0.7 mM p = 0.05). Fasting plasma Leptin was lower following training but this was not significant. Six of eight mothers successfully delivered, 2 sedentary litters (31 pups, 6.4 ± 0.6g) and 4 trained litters (56 pups, 6.1 ± 0.9g). Pup weights showed significantly reduced birth weight in litters from trained mothers (p = 0.03). Pup blood glucose at day 1, was similar between groups (Trained 5.2 ± 0.9 versus Sedentary 5.0 ± 0.9 mM). Pups are currently being weaned for tissue collection at 15 weeks of age.
Conclusion: Exercise training during pregnancy reduced pup birth weight compared to pups from sedentary mothers. This was independent of changes in glucose TAUC, however improved insulin sensitivity may be inferred from the reduced glucose levels observed acutely following oral gavage for comparative insulin levels. This data suggests that exercise during pregnancy reduces if not prevents macrosomia observed in offspring of high fat fed mothers. The overarching effect this reduced birth weight may have on offspring metabolic development is yet to be determined.

A single bout of low-intensity exercise strongly reduces the prevalence of hyperglycaemia throughout the day in type 2 diabetes patients
R.J.F. Manders[1], J.-W.M. van Dijk[1], F. Hartgens[2], L.J.C. van Loon[1];
[1]Human Movement Sciences, [2]Epidemiology, Maastricht University Medical Center, Netherlands.

Introduction: Glycemic instability is a severely underestimated problem in type 2 diabetes treatment. Therapeutic targets should aim to reduce postprandial blood glucose excursions. Exercise prescription can effectively improve blood glucose homeostasis and reduce the risk of cardiovascular complications.
Aim: To asses the impact of a single bout of either low- vs high-intensity exercise on the prevalence of hyperglycemia throughout the subsequent 24 h period in longstanding type 2 diabetes patients.
Methods: Nine sedentary, male type 2 diabetes patients (age: 57±2 y, BMI: 29.0±1.0 kg/m^2, Wmax: 2.2±0.2 W/kg body weight) were selected to partici-

pate in a randomized cross-over study. Subjects performed either an equicaloric bout of exercise for 60 min at 35%Wmax (LI) or 30 min at 70%Wmax (HI) or no exercise at all (NE). Thereafter, blood glucose homeostasis was assessed over the subsequent 24 h post-exercise period by continuous glucose monitoring under strict dietary standardization but otherwise free-living conditions.
Results: Average 24 h glucose concentrations were reduced following the low-intensity exercise bout (7.8±0.9 mmol/L) when compared with the control experiment (9.4±0.8 mmol/L; P<0.05). The high-intensity exercise bout did not significantly lower mean glucose concentrations (8.7±0.7 mmol/L; P=0.14). Hyperglycemia was prevalent for as much as 35±9% (8:17±2:04 h) throughout the day (NE). A single bout of exercise reduced the prevalence of hyperglycemia with 49.7±4.4% (P<0.05) and 18.6±8.8% (P=0.13) in the LI and HI exercise experiment, respectively.
Conclusion: A single bout of low-intensity exercise substantially reduces the prevalence of hyperglycemia throughout the subsequent 24 h period in long-standing, type 2 diabetes patients.

Dynamic response of growth hormone secretion to aerobic exercise in subjects with type 1 diabetes mellitus under eu- and hyperglycaemic clamp conditions
S. Jenni[1], S. Allemann[1,2], C. Oetliker[1,3], L. Tappy[4], M. Ith[5], S. Wuerth[6], A. Egger[1], C. Boesch[5], P. Schneiter[4], P. Diem[1], E. Christ[1], C. Stettler[1,2]; [1]Division of Endocrinology, Diabetes and Clinical Nutrition, University of Bern, [2]Institute of Social and Preventive Medicine, Bern, [3]Institute of Anaesthesia, Basel, [4]Department of Physiology, University of Lausanne, Bern, [5]Department for Clinical Research, Magnetic Resonance Spectroscopy and Methodology, University of Bern, [6]Institute for Sport Science, University of Basel, Switzerland.

Background and aims: Individuals with type 1 diabetes mellitus (T1DM) exhibit an exaggerated growth hormone (GH) response to a variety of stimuli including exercise. While physical exercise is known to stimulate GH secretion, GH is alleviated by hyperglycaemia both at rest and during exercise in healthy individuals. Data on the impact of exercise under differing glycaemic levels in T1DM is scarce and controversial. We aimed, therefore, at comparing exercise stimulated GH secretion under eu- and hyperglycaemia in individuals with T1DM.
Materials and methods: In this randomized single-blinded cross-over trial 7 men with T1DM were examined twice in the fasting state after overnight euglycaemia. Blood glucose clamp was started at 08:15 a.m. to a target of either 5 mmol/l or 11 mmol/l for eu- and hyperglycaemia, respectively. Cycling over 120 min at 55-60% VO_{2peak} was initiated at 10:00 a.m. Serum GH was measured before clamp and before exercise (in duplicate), then every 15 min throughout exercise and 120 min thereafter. Areas under the curve (AUC) over 120 min of exercise were calculated. Log-transformed GH data were analysed data using paired Student's t-test and geometrical means with 95% confidence intervals (CI) are presented.
Results: The subjects' (mean±standard error) age was 33.5±2.4 years, diabetes duration 20.1±3.6 years, HbA_{1c} 6.7±0.2% and IGF-1 103.4±7.8 ng/ml. Until the start of exercise GH had modestly increased from baseline under both euglycaemia (from 0.60 ng/ml, CI 0.46-0.76, to 1.06 ng/ml, CI 0.58-1.92) and hyperglycaemia (from 0.70 ng/ml, CI 0.53-0.92, to 1.14 ng/ml, CI 0.68-1.91). Exercise led to a more than 10 fold increase in both groups. But 41% higher GH peaks were reached in euglycaemia with 18.9 ng/ml, CI 9.6-37.2, compared to 13.2 ng/ml, CI 7.2-24.5, in hyperglycaemia (p<0.01). AUC_{GH} during exercise were 1430 ng/ml*min, CI 703-2910, and 1061 ng/ml*min, CI 538-2091, in eu- and hyperglycaemia, respectively (p=0.02). In both groups GH returned to baseline two hours after exercise.
Conclusion: Departing from similar basal levels before exercise, GH response to prolonged exercise diverged according to glycaemic levels with lower values observed in hyperglycaemia. These data are consistent with a glycaemic regulation of GH secretion under exercise conditions in T1DM which is comparable to healthy individuals.

Metabolic and adipogenic properties of insulin detemir in human subcutaneous and visceral adipocytes differentiated *in vitro* from precursor stromal cells
A. Cignarelli, S. Perrini, R. Ficarella, A. Peschechera, A. Conserva, M. Barbaro, M.C. Carreira, A. Natalicchio, L. Laviola, F. Giorgino; Endocrinology & Metabolic Diseases, University of Bari, Italy.

Background and aims: In clinical trials, insulin Detemir (D) is associated with no or lesser body weight gain as compared to human insulin (HI), particularly in individuals with high BMI. The objective of this study was to compare the metabolic and adipogenic properties of D and HI in human subcutaneous (SC) and visceral (V) adipocytes differentiated in vitro from precursor stromal cells.
Materials and methods: Human fat precursors were isolated from paired SC and V fat biopsies of 7 subjects (3F/4M, age 63±1 yrs, BMI 25.9±1.4) with normal glucose tolerance. Preadipocytes were isolated from the stromal fraction of the SC and V biopsies, respectively, and differentiated in vitro with dexamethasone, IBMX, insulin and rosiglitazone. Terminal differentiation of the adipocyte cultures was verified through morphological evaluation, Oil-O-Red staining, and assessment of gene expression of fat-specific molecules (PPARgamma2, adiponectin, GLUT4, and FAS) by real-time RT-PCR. Glucose uptake was assessed through evaluation of [^{3}H]1,2-deoxy-D-glucose uptake rates. Erk-1/2 expression and phosphorylation were evaluated by immunoblotting of total cell lysates with specific antibodies.
Results: In SC adipocytes, 100 nM D and 100 nM HI stimulated [^{3}H]2-deoxy-D-glucose uptake by 1.8- and 1.5-fold, respectively (p<0.05 vs. basal). In contrast, in V adipocytes, 100 nM HI induced a 3-fold increase in glucose transport (p<0.05), whereas 100 nM D appeared to be much more active, leading to 5- and 8-fold increases in glucose uptake at 10 and 100 nM, respectively (p<0.05 vs basal and HI). However, D and HI induced activation of Erk-1/2 proteins to a similar extent. Regression analysis showed an inverse correlation between D-stimulated glucose uptake in V adipocytes and BMI (β =-20.7, R^2 =0.87, p<0.05) and HOMA-IR (β =-70.7, R^2 0.92, p<0.05) of the donor subjects, whereas no correlation was found for HI. Then, precursors were differentiated in the presence of 500 nM D or HI. mRNA levels of PPARgamma2, GLUT4, adiponectin and FAS, which were undetectable in SC and V precursors, were increased by 10- to 50-fold in adipocytes differentated with HI (p<0.005). By contrast, they were lower by 10-fold in SC and V adipocytes differentiated with D (p<0.005 vs HI). In addition, triglyceride accumulated as large lipid droplets in about 90% of cells differentiated with HI and as minute lipid droplets in only 40% of adipocytes exposed to D.
Conclusion: In comparison with HI, D stimulates glucose uptake more efficiently in V adipocytes, and induces adipogenesis to a lesser extent in both SC and V precursors. Moreover, the metabolic effect of D is profoundly influenced by the degrees of adiposity and insulin resistance of the donor subject. The differential properties of D compared to HI may contribute to the weight gain-sparing effect of this insulin analog.

6-year baros of 1890 primary bariatric operations. Decrease in mortality and similar resolution of comorbidities, especially type 2 diabetes independent of primary bariatric operation used
F. Horber, R. Steffen;
Klinik Lindberg, Winterthur, Switzerland.

Background: Comparative long-term results with high follow-up rates after primary bariatric operations are scarce.
Methods: We analyzed and compared our 6 years BAROS after 57 vertical gastroplasties (VBG), 152 biliopancreatic diversions (BPD), 1245 adjustable gastric bandings (AGB) and 441 standard RY gastric bypasses (RY). Standard techniques were used for VBG, AGB and RY. BPDs are heterogeneous, but have a common channel of 100cm or less. VBGs and BPDs were operated mainly through laparotomy, RYs and AGBs were mostly laparoscopic operations.
Eye-to-eye follow up was more than 91 %. All data were recorded prospectively. Reoperations were done for technical problems, weight regain, late

dumping as clinically necessary and defined for gastric banding by an algorhytm (Surgery 2005). An intention to treat analyses was performed.

Results:

Group	VBG	BPD	AGB	RY
N	57	152	1245	441

* p<0.05 using ANOVA vs all other groups; **p<0.05: ANOVA vs BPD and RY. *** p <0.05: ANOVA GB or RY vs VBG or BDP. ****p<0.05 using non-parametric comparisons by Kruskall-Wallis.

EWL was lowest in GB patients. Total QoL was similar in all groups, but eating behaviour was significantly better in BPD and RY compared to VBG and GB- patients. Moreover rate of reoperation during the 6 years of follow up was similar in GB and RY patients, but more than twice as high in VBG and BPD subjects. Interestingly improvement in comorbidities was similar in all groups. According to total BAROS, overall 10.1% were considered as failures. Failure rate was highest in VBG and lowest in RY. In contrast rating of good or better by BAROS was highest in BPD patients. Overall procedural and nonprocedural mortality was 19 per 10000 personyears as was resolution of Type 2 Diabetes. In conclusion 6 years after bariatric surgery only 10% of subjects were considered as failures, whereas about two third of patients were considered as good or better with the exception of VBG. Overall mortality was 3 times lower as that reported for non operated morbid obese subjects (>50 per 10'000 person years)

Weight loss induced by bariatric surgery improves the ability to oxidize lipids at exercise but shifts the power of maximal lipid oxidation (LIPOXmax) to the left

D. Nocca[1], J.-F. Brun[2], M. Sardinoux[2], V. Salsano[3], G. Fabre[3], J. Bringer[4], P. Lefebvre[4], J. Mercier[2];

[1]Visceral Surgery, Hospital Saint Eloi, [2]Inserm eri25, CERAMM, [3]Hospital Saint Eloi, Visceral Surgery, [4]Hospital Lapeyronie, Endocrinology, Montpellier, France.

Background and aims: It is attractive to develop combined strategies in which exercise will be employed to improve the effects of bariatric surgery and provide to patient the possibility to become less sedentary on the long term, as has been successfully done in other chronic diseases. In the case of obesity after bariatric surgery, the question arises of which kind of exercise should be proposed. Recent studies propose in metabolic diseases (obesity, diabetes mellitus) to target exercise training at the intensity level where lipid oxidation is maximal (LIPOXmax). Thus, the purpose of this study was to determine LIPOXmax in obese patients that had lost weight after bariatric surgery, compared to obese subjects matched for body mass index (BMI) before and after surgery, and nonobese subjects.

Materials and methods: Evaluation by indirect exercise calorimetry of the LIPOXmax, as well as the Crossover point (exercise level at which carbohydrates become the predominant fuel) in 28 obese patients after bariatric surgery (17 by sleeve gastrectomy, 7 by Roux-en-Y gastric by-pass and 4 by gastric ring; BMI before surgery: 45,5 ± 1,3 Kg/m²; BMI after surgery: 32,7 ± 1,2 Kg/m²; average weight loss 41.7 ± 4.3 kg; age: 39 ± 2 years; average ± SEM), compared to two groups of obese, 33 matched with the preoperative BMI (45,2 ± 0,8 Kg/m²) and 87 matched for the actual BMI (32.4 ± 0.14 Kg/m²), and one group of 322 nonobese subjects (BMI: 24,8 ± 0,2 Kg/m²), all being matched for age and gender.

Results: The LIPOXmax occurs at a lower exercise intensity in obese patients treated by bariatric surgery compared to all the other groups, although the maximal lipid oxidation rate is quite the same in all groups.

Table 1: * p<0.05 Vs A; ** p<0.01 Vs A; *** p<0.001 Vs A;

		A Post surgery obese subjects	B Matched on post slimming BMI	C Matched on initial BMI	D Non obese controls
Crossover point	Watts	51 ± 4	62 ± 4	51,2 ± 7	60 ± 2,4
	%Pmax	27 ± 2	34.6 ± 0.02	36 ± 6	37,7 ± 1,2
LIPOXmax	Watts	43 ± 3	56 ± 3 *	52 ± 3 *	55 ± 2 *
	%Pmax	23 ± 1,7	30 ± 0.01 **	34 ± 2***	33 ± 0.01***
maximal lipid oxidation point (Mg/min)		216 ± 13	213 ± 12	186 ± 15	207,5 ± 7

Conclusion: Compared to matched obese and nonobese subjects, the patients of group A, who have lost an average of 42 kg after bariatric surgery, exhibit a peak oxidation of lipids shifted to lower exercise intensities. This mechanism may contribute to resistance to slimming, suggesting that targeted training with the aim of increasing lipid oxidation at exercise may be interesting to evaluate in this context.

697

Electronic health technology for assessment of physical activity and eating habits in children and adolescents with overweight and obesity

A. Kaps[1], G. Bieber[2], R. Schiel[1];

[1]MEDIGREIF Inselklinik Heringsdorf, Ostseebad Heringsdorf, [2]Fraunhofer Institut IGD Rostock, Germany.

Background and aims: During the last decades overweight/obesity has increased markedly. They are associated with a high risk for diabetes and death. Effective intervention is mandatory. Following participation in treatment programmes children/adolescents often fail to reach sufficient long-term weight reduction. The present trial aims to integrate telemedical support in therapy to improve long term outcome.

Materials and methods: All children/adolescents with overweight/obesity were included (n=66, age 13.9±2.6 years, BMI 31.2±5.4 kg/m2, BMI-SDS 2.41±0.6) admitted to our hospital 04-03/2009. To asses physical activity and eating habits electronic health technology was used (Fraunhofer-Institute, IGD, Rostock, Germany). The system consists in a mobile motion sensor board (MoSeBo) or a motion sensor integrated in a mobile phone (DiaTrace). The system analyses kind, intensity and duration of physical activity and eating habits.

Results: Follow-up period was 182 days. Total physical activity measured with MoSeBo/DiaTrace was 310.4±;122.3 min/d (15.6±;12.3 units/d). Patients spent 44.6 (3-173.3) min/d with walking, 7.5 (0-42.3) min/d with running, 17.2 (0-52.0) min/d with cycling and 24.7 (0-88.7) min/d with car driving. In contrast, in most domains activity documented by patients was significantly higher: Walking 298.7 min/d (p=0.001 vs MoSeBo/DiaTrace)and running 94.7 min/d (p=0.001). In respect of cycling patients' estimation (21.4 min/d) and objective documentation were comparable.Similar differences were seen concerning eating habits. Multivariate analysis: There was an association between weight reduction (R-square=0.590) and intrinsic motivation (ß=0.732, p< 0.001), intrafamilial conflicts (ß=0.461, p=0.002), duration of physical activity measured with MoSeBo/DiaTrace (ß=-0.438, p=0.002) and body fat mass (ß=-0.393, p=0.005).

Conclusion: 1. There are differences between patients´ self-assessment and objective perception of physical activity and eating habits. Discrepancies in perception are maybe important determinats of poor long-term outcome. **2.** Using modern electronic health technology allows the objective assessment of kind, intensity and quantity of physical activity and eating habits. This could be an important new advanced method to improve the therapy of obesity and diabetes.

Diabetic patients' response to clopidogrel is independently related to fibrinogen plasma level but not to glycaemic control

P. Darmon[1], B. Gaborit[1], C. Frere[2], O. Romieu[3], T. Cuisset[4], P. Morange[2], L. Camoin[5], M.-C. Alessi[2], A. Dutour[1];
[1]Department of Endocrinology, Metabolic Diseases, and Nutrition, CHU Nord, Inserm U626, [2]Inserm U626, Faculty of Medicine, Laboratory of Haematology, CHU Timone, [3]Department of Endocrinology, Metabolic Diseases, and Nutrition, CHU Nord, [4]Inserm U626, Department of Cardiology, CHU Timone, [5]Laboratory of Haematology, Hôpital Conception, Marseille, France.

Background and aims: There is a higher prevalence of stent thrombosis and of inadequate platelet response to clopidogrel in diabetics. However, whether or not glycemic control is implicated in this suboptimal response remains unknown. The aim of this study was to determine the clinical and biological factors implicated in clopidogrel platelet response in diabetic patients.
Materials and methods: ADP-induced platelet aggregation (ADP-Ag) and Platelet Reactivity Index of Vasodilatator-Stimulated Phosphoprotein (PRI VASP) were analysed in 124 diabetic patients treated with clopidogrel. Platelet tests were repeated for 15 poorly controlled patients after glycemic optimization with the use of continuous subcutaneous insulin infusion.
Results: No correlation between platelet tests and glycemic control (fasting blood glucose, HbA1c) was observed. ADP-Ag and PRI VASP did not differ before and after glycemic optimization (53.5 ± 25 versus 52.8 ± 21 % and 64.5 ± 18 versus 66.9 ± 18 %). No relationship was found between ADP-Ag or PRI VASP and gender, duration of the disease, BMI, hypertension, lipid profile, creatinine, microalbuminuria, high sensitive CRP, or adiponectin. However, type 2 diabetic patients had higher ADP-Ag and PRI VASP than type 1 diabetic patients (49±19 vs 33±19 %, p= 0.008; 62±16 vs 48±27 %, p= 0.02, respectively). After adjustment for potential confounders (age, time since diagnosis, BMI, triglycerides, fibrinogen), only ADP-Ag remained statistically different between the two types of diabetes (p= 0.007; p=0.11 respectively). Remarkably, a positive independent correlation was found between ADP-Ag and fibrinogen (r=0.38, p= 0.0005). Fibrinogen was an independent predictor of ADP-Ag, and clopidogrel non responders had elevated plasma fibrinogen, compared with clopidogrel responders: 8.2 ± 0.5 versus 3.8 ± 0.1 g/L ($p<10^{-4}$). ROC curve analysis showed that a threshold value of 3.57 g/L gave a negative predictive value of 94.7%. The addition of purified fibrinogen to platelet rich plasma obtained from diabetic patients with an adequate response to clopidogrel (final concentration 11g/L) did not lead to a significant increase in ADP-Ag (41 ± 19 vs 40 ± 18 %, p = 0.69), eliminating a direct effect of fibrinogen on ADP-Ag.
Conclusion: High post treatment platelet reactivity assessed by ADP-Ag is not related to glycemic control but to the type of diabetes. Fibrinogen is a strong predicting factor of ADP-Ag in diabetics treated with clopidogrel. Evaluation of inflammation and treatment of infection in diabetics could improve clopidogrel platelet response and reduce the risk of stent thrombosis.

The inhibitory effect of metformin on nitric oxide production via MyD88-independent pathway in macrophages

Y. Kato, K. Kato, C. Inagaki, Y. Adachi, K. Otake;
Internal Medicine, Division of Endocrinology, Metabolism and Diabetes, Aichi Medical University, Japan.

Background and aims: The United Kingdom Prospective Diabetes Study 34 (UKPDS 34) demonstrated that administration of metformin reduced all-cause mortality, myocardial infarction, and stroke more than insulin or sulfonylureas, although its glucose-lowering effect was similar to them. UKPDS 34 suggested that metformin confers vascular benefits beyond its hypoglycemic action. Recent clinical studies further suggested that metformin may alter inflammation as determined by decreased inflammatory markers in plasma. Nitric oxide (NO) is a free radical molecule known to play an important role in the pathogenesis of inflammation. Recent studies suggested that plasma levels of NO metabolites correlate with body mass index and body fat mass, that plasma nitrite levels are elevated modestly in diabetic patients, and that inducible nitric oxide synthase may be involved in the pathogenesis of metabolic disorders associated with a low-grade chronic inflammatory state, such as atherosclerosis and obesity-linked Type 2 diabetes. However, the effects of metformin on nitric oxide production are not known yet. In the present study we investigated the effects of metformin on nitric oxide production and the molecular mechanism of its effect in macrophages to evaluate the anti-inflammatory effects of metformin.
Materials and methods: The murine macrophage cell line, RAW264.7 cells were maintained in RPMI 1640 medium containing 5% heat-inactivated fetal calf serum. RAW264.7 cells were stimulated by lipopolysaccharide (LPS) from Escherichia coli O55:B5 or poly(I:C). Nitric oxide was measured as its end product, nitrite, using Griess reagent. TNF-α or interferon-β (IFN-β) was measured by ELISA.
Results: We examined the effects of metformin on LPS or poly(I:C)-induced nitric oxide production, LPS-induced IFN-β production, and LPS-induced TNF-α production. Previous studies indicate that NO production by LPS is induced via Toll-like receptor 4 (TLR4) and NO production by poly(I:C) is via Toll-like receptor 3 (TLR3). LPS/TLR4 signaling is divided into MyD88-dependent and MyD88-independent pathways, but poly(I:C)/TLR3 signaling has only MyD88-independent pathway. NO production by LPS is induced via MyD88-independent pathway which mediates IFN-β production. TNF-α production by LPS is induced via MyD88-dependent pathway. Metformin inhibited LPS-induced nitric oxide production in RAW264.7 cells (6.6±0.2 μM vs. 3.4±0.3 μM, p<0.005). Metformin inhibited poly(I:C)-induced nitric oxide production (8.8±1.2 μM vs. 2.9±0.4 μM, p<0.005). Metformin inhibited LPS-induced IFN-β production (349.5±7.7 pg/mL vs. 178.9±1.8 pg/mL, p<0.05). Metformin did not inhibit LPS-induced TNF-α production.
Conclusion: Metformin inhibited nitric oxide production via MyD88-independent pathway in macrophages. Our data indicates that metformin has beneficial effects on diabetic complications through its anti-inflammatory effects via MyD88-independent pathway.

Miglitol decreases gene expressions of inflammatory cytokines/cytokine-like factors in peripheral leukocytes in parallel with the reduction in blood glucose fluctuations in type 2 diabetes

K. Mochizuki[1], T. Osonoi[2], M. Saito[2], N. Fukaya[1], T. Muramatsu[1], T. Goda[1];
[1]Laboratory of Nutritional Physiology, The University of Shizuoka, [2]Naka Kinen Clinic, Ibaraki, Japan.

Background and aims: Many patients with type 2 diabetes are treated with α-glucosidase inhibitors, which have beneficial effects in improving postprandial hyperglycemia. Miglitol, an α-glucosidase inhibitors, is more potent in reducing early postprandial blood glucose than other α-glucosidase inhibitor, such as acarbose and voglibose, and delays the peak of postprandial blood glucose. In this study, we focused the daily blood glucose fluctuations and gene expressions of inflammatory cytokines/cytokine-like factors in patients with type 2 diabetes and examined the effects of the switch from acarbose or voglibose to miglitol on them.

Materials and methods: The subjects comprised 43 patients with type 2 diabetes (22 men and 21 women) aged 26-81 years with HbA_{1c} levels from 6.5% to 7.9%. They had received combination therapy with acarbose (100 mg/meal) or voglibose (0.3 mg/meal) and insulin or sulfonylurea for more than six months. At the start of the study, all α-glucosidase inhibitors were switched to miglitol (50 mg/meal) and the new treatments were continued for three months. At each end of the study period, basic clinical parameters, such as HbA_{1c}, fasting glucose, triglyceride, total-cholesterol and C-reactive protein, were measured, and the severity of adverse events, such as hypoglycemia, fecal disturbance (diarrhea/constipation), flatulence and abdominal distention, were monitored. Blood glucose was determined just before and one hour after meals by self-monitoring. Gene expressions of inflammatory cytokines/cytokine-like factors in peripheral leukocytes were determined by real-time RT-PCR.
Results: The levels of HbA_{1c} and fasting blood glucose were maintained even after acarbose or voglibose was switched over to miglitol. Meanwhile, hypoglycemic events were significantly reduced by 58% ($p<0.001$) after the change of treatments. Blood glucose fluctuations were ameliorated and the M-value was decreased by 24% ($p<0.001$). In peripheral leukocytes, the gene expression levels of IL-1β, TNF-α, S100a4, S100a6, S100a9, S100a10, S100a11 and S100a12 were significantly decreased by 25% ($p<0.01$), 24% ($p<0.001$), 17% ($p<0.05$), 20% ($p<0.05$), 23% ($p<0.05$), 19% ($p<0.01$), 25% ($p<0.01$) and 24% ($p<0.05$), respectively.
Conclusion: After the switching from other α-glucosidase inhibitors, miglitol improved blood glucose fluctuations without changes in both HbA_{1c} and fasting blood glucose in patients with type 2 diabetes. On the other hand, miglitol also decreased the gene expressions of inflammatory cytokines/cytokine-like factors in peripheral leukocytes. These results suggest that the blood glucose fluctuation may affect the gene expressions of inflammatory cytokines/cytokine-like factors in peripheral leukocytes in type 2 diabetes.

701

The effects of decreased gastric secretion on treatment of obesity
G.S. Pudar[1], B. Dapcevic[2], M. Andjelic[1], P. Svorcan[2], A. Brankovic[1];
[1]Endocrinology and Diabetology, [2]Gastroenterology, University Clinical Hospital Zvezdara, Belgrade, Serbia.

Background and aims: Over many years of our medical practice we noticed that patients with gastric troubles who were treated with ranitidine hydrochloride (selective H2 receptor antagonists) have been maintaining their restricted diets more easily and successfully. The aim of this study was to examine the effects of using ranitidine in the treatment of obesity.
Materials and methods: We examined 26 healthy obese persons (BMI >30 kg/m^2), mean age 42.1 ± 10.1 years. All patients came to endocrinologist only because of their problem with obesity. Three months before this study all patients have already been on therapy with the low calories diet and physical activity, but they didn't succeed to reduce their body weight. In this study the patients continued with the same diet and physical activity and in addition they were given to take daily two tablets of 150 mg ranitidine (morning and evening) for the next eight weeks. At baseline and after 8 weeks period we determined body weight, waist circumference (WC) and BMI (kg/m^2), lipid status (total cholesterol, triglycerides, HDL cholesterol and LDL cholesterol). Also a 2 hours 75-g oral glucose tolerance test (oGTT) was done during which we followed plasma insulin concentration (by radioimmunoassay) at the beginning and after one hour of the test (60').
Results: At the end this study has shown that all patients have significantly reduced their body weight from 2 to 23 kg, mean 7.2±4.6 kg (103.1±14.1 vs 95.9±13.5 kg, $p<0.01$), BMI (36.8±4.9 vs 34.2±5.1 kg/ m^2, $p<0.01$) and WC (108.4±9.3 vs 99.6±10.2 cm, $p<0.01$). Also, they had better lipid status with significantly reduced triglycerides (2.2±0.9 vs 1.7±0.7mmol/l, $p<0.05$) and increased HDL cholesterol (1.1±0.3 vs 1.3±0.3 mmol/l, $p<0.01$). Fasting plasma insulin was improved (10.1±5.2 vs 10.3±4.9, NS) and insulin secretion after 60'of oGTT was significantly reduced (76.2±41.5 vs 58.1±37.6, $p<0.05$).
Conclusion: Potential explanation for our findings is that ranitidine has effects like gastric bypass surgery on gut hormones that control insulin secretion (GLP-1, YYP, Ghrelin). All patients also affirmed that they were feeling good during this therapy and they could maintain the advised dietary programme with pleasure and without being hungry, nervous or depressed.

Effects of immunosuppressive agents on insulin stimulated glucose transport in primary rat adipocytes
M.J.R. Pereira[1,2], P. Nunes[3], J. Palming[1], J. Eriksson[1,4], M.A. Aureliano[5], E. Carvalho[3];
[1]Department of Medicine, Lundberg Laboratory for Diabetes Research, Goteborg, Sweden, [2]FCT - University of Algarve, CCMAR, Faro, Portugal, [3]University of Coimbra, Center for Neuroscience and Cell Biology, Portugal, [4]AstraZeneca R&D, Molndal, Sweden, [5]University of Algarve, CCMAR, Faro, Portugal.

Background and aims: Glucocorticoids (GC) and immunosuppressive agents (IA) used in transplant recipients and patients with autoimmune diseases can cause insulin resistance. However the mechanism behind the development of insulin resistance needs to be further investigated. One hypothesis is that GC and IA cause metabolic changes in adipocytes leading to impaired insulin sensitivity. If IA induce changes in whole body glucose and lipid metabolism leading to abnormal insulin signaling and the accumulation of lipid in skeletal muscle, this is likely to contribute to the development of whole-body insulin resistance, glucose intolerance and fasting hyperglycemia. The aim of this study was to elucidate the direct effects of IA and GC on insulin stimulated glucose uptake in rat adipocytes.
Materials and methods: Rat adipocytes isolated from epidydimal fat pads, where incubated with different IA and GC: Cyclosporine A (CsA: 0.5-30 μM), n=9; Tacrolimus (FK 1-50 μM), n=9; Sirolimus (Sir: 5-250 μM), n=9, Dexamethasone (D 0.01-10 μM), n=15; and Prednilosone (P: 0.01-10 μM), n=12, for an initial 5 min. Thereafter adipocytes were further incubated with or without insulin (10 nM) for 10 min before glucose uptake was measured by adding 14C-glucose (0.86 μM) for 30 min. After incubation the reaction was stopped by centrifugation in silicon oil. The cellular uptake of labeled glucose was analyzed by scintillation measurement.
Results: Insulin stimulated glucose uptake was reduced after incubation with the different IA; CsA (0.5-30 μM) by 27-39% ($p<0.05$), with FK (10-50 μM) by 30% ($p<0.05$) and Sir (5-250 μM) up to 67% ($p<0.05$). D (0.01-10 μM) caused a reduction in insulin stimulated glucose uptake by 26% ($p<0.05$), whereas P had no statistically significant effect on basal or insulin stimulated glucose uptake. Basal glucose uptake was left intact with all IAs and GCs.
Conclusion: These results demonstrate that the IAs, Cyclosporine A, Tacrolimus, and Sirolimus, as well as, the GC Dexamethasone inhibit insulin stimulated glucose uptake in rat adipocytes after short-time incubations. Further elucidations of the mechanisms underlying adipose tissue insulin resistance caused by IA and GC, will help to optimize treatments, in order to prevent post-transplant diabetes.

Acute rhabdomyolysis after fucidic acid and atorvastatin therapy
M. Francois;
CHU Robert Debré - Service de Diabétologie et Maladies Métaboliques, Reims, France.

We report the case of a 58-year-old patient who was admitted with progressive and generalised muscle pains and weakness. The patient had a history of type 2 diabetes mellitus combined with hypertension, lower limb arteriopathy and recent myocardial infarction. He had been taking atorvastatin (80 mg daily) for 6 months. He was also treated for rheumatoid arthritis. In October 2008, he underwent surgery for osteoarthritis of the foot and oral antimicrobial therapy (fucidic acid 1500 mg per day, and cotrimoxazole 1600 mg per day) was prescribed. Three weeks later, he developed symptoms consistent with severe rhabdomyolysis, confirmed by high serum creatine kinase level (56000 UI/L) (normal limit < 350 UI/L). He could not move his legs and arms, and rapidly developed dysarthria, swallowing disorders and dyspnea. Extensive investigations ruled out other known causes of polymyositis : absence of muscle antibodies and histological analysis of muscle biopsy confirm toxicity mechanism. Atorvastatin and fucidic acid were discontinued. Eight days after discontinuation, his serum creatine kinase concentration fell to 320 UI/L and the patient was again able to walk.
Less than ten cases involving an interaction between an HMG CoA-reductase inhibitor and fusidic acid have been reported. We presume that the most likely cause was hepatic inhibition of the CYP3A4 isoenzyme by fucidic acid, resulting in a dramatic rise in plasma statin levels and then increase the risk of rhabdomyolysis.
Conclusion: Clinical should be aware of this potential adverse effect between acid fucid and statin therapy. The extensive use of statin therapy in patients with vascular disease and the frequency of MRSA infections may increase the incidence of this presumed drug interaction.

PS 53 Lipid effects and metabolism

Opposite changes in enzyme expression of "the sphingolipid rheostat" by palmitate and oleate

L. Manukyan, K. Thorn, P. Bergsten;
Department of Medical Cell Biology, Uppsala University, Sweden.

Background and aims: Development of obesity-induced type 2 diabetes mellitus is characterized by rising blood glucose and lipid levels. Long-term exposure of β-cells to free fatty acids has negative effects on both function and mass especially when combined with elevated levels of glucose. In this context, saturated fatty acid palmitate (PA) causes more severe effects and rates of apoptosis compared to mono-unsaturated fatty acid oleate (OA). When OA is administered together with PA, attenuation or even reversal of the negative effects of PA on b-cell function has been observed. One of the proposed mechanisms for the negative effects of PA in b-cells exposed to elevated levels of glucose is inhibition of fatty acid oxidation causing elevated generation of ceramide. Ceramide is a sphingolipid formed either by de novo synthesis from palmitate and serine, cleavage of the sphingolipid metabolite sphingomyelin or conversion from sphingosine, which is another sphingolipid metabolite. The contribution of ceramide from conversion from sphingosine is the result of the dynamic balance between sphingosine-1-phosphate (S1P) and sphingosine. Indeed, the balance between anti-apoptotic S1P and pro-apoptotic ceramide/sphingosine ("the sphingolipid rheostat") is an important factor determining cell fate. To define how these three different ceramide generation pathways are affected in b-cells exposed to PA, OA or the combination of the two, the expression levels of key enzymes of sphingolipid pathways were measured.
Materials and methods: Insulin-secreting mouse insulinoma (MIN6) cells were cultured for 48 hours in the absence or presence of 0.25 mM palmitate (PA), oleate (OA) or PA plus OA (0.25mM each). After culture, expression levels of enzymes of sphingolipid metabolism were measured by RT-qPCR.
Results: Prolonged exposure of β-cells to PA resulted in limited rise in expression levels of some enzymes of ceramide de novo synthesis. With regard to expression levels of sphingomyelin cleavage enzymes they were not significantly affected in comparison with those measured in control cells. When PA was replaced by OA, expression levels of enzymes of ceramide de novo synthesis were slightly lower than in control cells. Such reversal of metabolic flux towards reduced ceramide production was also observed in the sphingomyelin cleavage pathway of cells exposed to OA. In cells treated with the combination of PA and OA, ceramide de novo synthesis was decreased as compared to cells exposed to PA alone. Synthesis was still slightly increased in comparison with control cells, however. Enzymes catalyzing sphingomyelin cleavage were not altered in cells exposed to PA and OA in comparison with cells exposed to PA alone. With regard to "the sphingolipid rheostat" PA altered the expression of enzymes consistent with shifting the equilibrium towards synthesis of pro-apoptotic sphingosine and ceramide. In contrast, treatment with OA enhanced expression of enzymes promoting formation of anti-apoptotic S1P. After treatment with PA and OA, the equilibrium was shifted towards sphingosine formation rather than ceramide as observed in the presence of PA alone.
Conclusion: Shifts induced by PA, OA or the combination of the two fatty acids primarily in "the sphingolipid rheostat" and to a lesser extent ceramide de novo synthesis and ceramide formation from sphingomyelin cleavage are proposed to contribute to explain the different effects of the fatty acids on the b-cell.

TBC1D1-dependent regulation of glucose and lipid metabolism in cultured C2C12 myotubes

A. Chadt[1], F. Carlotti[2], R.C. Hoeben[2], H.-G. Joost[1], H. Al-Hasani[1];
[1]Department of Pharmacology, German Institute of Human Nutrition, Potsdam-Rehbruecke, Nuthetal, Germany, [2]Department of Molecular Cell Biology, Leiden University Medical Center, Netherlands.

Background: We have recently identified *Tbc1d1* as a novel susceptibility gene for high-fat diet-induced obesity and diabetes in mice. TBC1D1, a Rab-GTPase-activating protein (GAP) is homologous to the insulin signalling protein AS160 (TBC1D4) and has been linked to familial forms of human obesity. Recombinant congenic mice lacking *Tbc1d1* show reduced body weight, decreased respiratory quotient, increased fatty acid oxidation and reduced glucose uptake in isolated skeletal muscle. Our results indicate that TBC1D1 controls whole body energy homeostasis by reciprocally regulating fatty acid oxidation and glucose use in skeletal muscle. However, the molecular mechanism by which TBC1D1 controls fuel metabolism in muscle remains unknown. We have therefore investigated the role of TBC1D1 in glucose and lipid metabolism oxidation in cultured C2C12 muscle cells.
Methods: For expression experiments, C2C12 myotubes were either electroporated with siRNA or subjected to lentiviral gene transfer. Uptake and oxidation of glucose and palmitate was determined by tracer techniques. Gene expression was analyzed by Western Blot and TaqMan-Realtime-PCR.
Results: *Tbc1d1* is predominantly expressed in skeletal muscle of mice and humans. Consistent with the tissue expression profile, differentiation of C2C12 myoblasts into myotubes induces TBC1D1 protein expression ~3-fold. SiRNA-mediated knockdown of *Tbc1d1* significantly increased palmitate uptake and oxidation in C2C12 myotubes by ~25%. Conversely, lentiviral overexpression of wildtype *Tbc1d1* in C2C12 myotubes led to a concomitant reduction of palmitate uptake and oxidation. Interestingly, knockdown of *Tbc1d1* also significantly increased 2-deoxyglucose uptake by ~40% whereas overexpression of *Tbc1d1* had the opposite effect. However, overexpression of the GAP-inactive mutant, R941K, had no effect on glucose uptake or palmitate uptake and oxidation, respectively, indicating that an intact GAP domain is required for the metabolic actions of *Tbc1d1*. Expression of GLUT1, the main glucose transporter in C2C12 cells, was not changed on both mRNA and protein levels after overexpression or knockdown of *Tbc1d1*. In contrast, the increased fatty acid combustion in *Tbc1d1*-depleted myotubes was accompanied by substantially increased levels of mRNA for fatty acid translocase (*Cd36*) and long-chain acyl-CoA dehydrogenase (*Acadl*), and elevated expression of genes involved in lipid metabolism including *Fabp3, Pgc1a*, *Pdk4, Ucp2 and Ucp3*. Importantly, additional knockdown of *Cd36* in *Tbc1d1*-depleted C2C12 myotubes completely abrogated the increase in palmitate uptake.
Conclusion: Our data demonstrate that CD36 is responsible for TBC1D1-mediated fatty acid uptake in C2C12 cells. Moreover, TBC1D1 exerts control on fuel selection and energy metabolism in skeletal muscle at least in part through regulating gene expression of key enzymes for lipid uptake and oxidation, including targets for peroxisome proliferator-activated receptor delta (*Ppard*). In contrast to skeletal muscle, lipid and glucose use are not reciprocally regulated by TBC1D1 in C2C12 cells. This implicates that TBC1D1 controls the flux of glucose and lipid through two independent pathways.

Beneficial effects of phytosterols isolated from Aloe vera on obesity-associated metabolic disorders in Zucker diabetic fatty (ZDF) rats

M. Eriko[1], M. Tanaka[1], K. Nomaguchi[1], M. Yamada[1], T. Toida[1], K. Iwatsuki[1], T. Kawada[2];
[1]Morinaga MIlk Industry Co.,Ltd., Zama City [2]Kyoto University, Uji City, Japan.

Introduction: We have confirmed the hypoglycemic effects of Aloe vera gel in db/db mice, an animal model of type II diabetes. We also identified five phytosterols (lophenol, 24-methyl-lophenol, 24-ethyl-lophenol, cycloartanol, and 24-methylene-cycloartanol) as anti-diabetic compounds from Aloe vera gel. In this study, we administered two kinds of the aloe phytosterols, lophenol (Lo) and cycloartanol (Cy) to an obese animal model of type II diabetes, Zucker diabetic fatty (ZDF) rats, in order to assess the effects of Aloe phytosterols on hyperglycemia and hyperlipidemia.
Methods: Male ZDF rats (9 weeks old) were orally administered Lo and Cy (25 μg/kg/day) once a day everyday for 6 weeks. During treatment, body weights, random and fasting blood glucose levels were monitored. After 6 weeks of treatment, fasted rats were sacrificed, and blood was collected by cardiac puncture. Abdominal adipose tissues (epididymal fat, mesenteric fat and retroperitoneal fat) were excised and weighed. The biochemical parameters of serum were also investigated. Additionally, we analyzed the mRNA levels of genes involved in lipid and glucose metabolisms in liver by real-time RT-PCR.
Results: ZDF rats exhibit marked obesity, hyperglycemia, hyperlipidemia and hyperinsulinemia compared with their lean littermates. In the Lo and Cy treatment groups, random and fasting blood glucose levels were lower

than the ZDF-control. Consistent with the blood glucose level, hemoglobin A1c (HbA1c) percentages were also reduced in aloe phytosterol-treated rats. These findings indicated that administration of aloe phytosterols suppressed hyperglycemia in ZDF rats. Interestingly, body weights were not affected by aloe phytosterol treatments, however the weights of total abdominal fat tissues were significantly lower in ZDF rats with Cy (26.3%) and Lo (27.7%) administration compared to those in controls. Additionally, the serum triglyceride level was significantly reduced and adiponectin concentration was elevated in aloe phytosterol-treated ZDF rats compared with those in ZDF controls. Furthermore, the expression levels of genes involved in lipid and glucose metabolisms in liver were changed in the aloe phytosterol-treated group compared with those in ZDF controls. Especially, the expression levels of lipogenic enzymes (Fasn, SCD1) and gluconeogenic enzymes (PEPCK and G6Pase) were significantly decreased, and the expression of β-oxidation enzyme (ACOX) was increased in the aloe phytosterol-treated groups compared with those in ZDF control groups.
Conclusion: Our study showed that aloe phytosterols ameliorated hyperglycemia, hyperlipidemia and visceral fat obesity in ZDF rats. In addition, the quantitative gene expression analysis of ZDF rats indicated that aloe phytosterols might improve lipid and glucose metabolism in the liver. These findings suggested oral ingestion of aloe phytosterols could be beneficial in preventing and improving metabolic disorders associated with obesity.

Acyl CoA-profiling in biological tissues using online SPE-LC-FTMS (Orbitrap)

C. Magnes[1], M. Suppan[1], T.R. Pieber[2,3], F.M. Sinner[1];
[1]Inst. of Med. Technologies and Healthmanagement, Joanneum Research, Graz, [2]Dep. of Int. Medicine, Medical University of Graz, [3]Institute of Medical Technologies and Healthmanagement, Joanneum Research, Graz, Austria.

Background and aims: Coenzyme A (CoA) activated compounds (e.g. malonyl CoA, medium- and long chain acyl CoAs) play a pivotal role in energy and lipid metabolism. The aim was to develop a robust online-SPE-LC/FTMS-based method for the quantification of acyl CoAs in a wide range of biological tissues. The method should require minimal sample preparation and should enable structural analysis to be performed by accurate mass determination in MS and MSn.
Materials and methods: All experiments were carried out on an Ultimate 3000 (Dionex) comprising an autosampler with cooled tray and a column oven with switching unit coupled to an Orbitrap (ThermoScientific). The sample extraction procedure comprises three steps: (1) addition of buffer and internal standards, (2) homogenization and (3) centrifugation. The supernatant is injected directly into the SPE-LC-FTMS system (Online-SPE-cartridge: Oasis HLB, analytical column: Zorbax C18 Extend). Samples were loaded onto the SPE-column using 0.1% aqueous formic acid. For washing, the acetonitrile content of the SPE-eluent was increased. After online-SPE, separation was performed on the analytical column using acetonitrile and water containing 100 mM ammonium hydroxide as solvents. Data acquisition was performed in full scan mode using a resolution of 60.000 FWHM.
Results: A combination of online SPE/LC and high resolution mass spectrometry (LTQ Orbitrap XL) was used to identify and to determine the relative levels of multiple CoA-activated compounds in samples of mouse liver and muscle without prior sample extraction and solvent evaporation steps. Reproducible ionization efficiency for quantification issues was still achieved despite this minimal sample pre-treatment. The selectivity and sensitivity provided by the Orbitrap system in full MS-scan mode was moreover comparable to that obtained using triple quadropol SRM-Scans and enabled the generation of profiles of CoA-activated compounds from less than 10mg of tissue. The use of non-targeted, full MS data acquisition and automated peak detection, integration, alignment and grouping using the open source software XCMS provided data about every detectable metabolite eluted from the LC-system: hundreds of features in the LC-MS data including the CoA-activated compounds were detected in this manner. Identifications were confirmed by accurate mass data, data dependent MS/MS scans and retention times. As well as the above, nine CoA activated compounds (malonyl-, acetyl-, C6:0-, C16:0-, C16:1-, C18:0-, C18:1-, C18:2, C20-4) were absolutely quantified using calibration standards. Accuracies between 85 and 115% for quality control samples (CoAs spiked in tissue homogenates) were achieved using internal standards (isotopically labelled for malonyl-CoA and acetyl CoA and C17-0 CoA for medium and long chain acyl CoAs).
Conclusion: The developed online SPE/LC-FTMS method enables accurate quantification and profiling of acylCoAs in a broad range of different biological tissues.

Muscular lipid droplet dynamics: ADRP and OXPAT protein expression upon lipid loading in cultured myocytes

M. Bosma[1], R. Minnaard[2], S. Kersten[3], M.K. Hesselink[2], P. Schrauwen[1];
[1]Department of Human Biology, Nutrition and Toxicology Research Institute Maastricht (NUTRIM), Maastricht University, [2]Department of Human Movement Sciences, Nutrition and Toxicology Research Institute Maastricht (NUTRIM), Maastricht University, [3]Nutrition, Metabolism and Genomics group, Division of Human Nutrition, Wageningen University, Netherlands.

Background and aims: Type 2 diabetes is associated with elevated intramyocellular lipid levels. Intracellular lipids are stored in lipid droplets (LDs) covered with a protein coat comprising of a range of different proteins, dependent on the maturation and metabolic fate of the LD. These LD-coating proteins have been mainly studied in adipose tissue; less is known about their role in skeletal muscle. Here we aimed to examine the role of LD-coating proteins in muscular fat accumulation. To that end, we investigated the effect of fatty acid (FA) incubation on adipose differentiation-related protein (ADRP) and OXPAT protein content in skeletal myotubes. As it is known that different types of FAs differentially affect myocellular fat accumulation, we investigated the effects of FA-induced myocellular lipid accumulation on ADRP and OXPAT protein content.
Materials and methods: C2C12 mouse muscle cells were differentiated into myotubes and incubated for 24h with 200 uM oleate, palmitate, eicosapentaenoate, or octanoate, in the presence or absence of 1 mM carnitine. Lipids were extracted for triglyceride (TG) measurements and ADRP and OXPAT protein contents were measured using Western blotting.
Results: As shown in Figure 1, FA incubation led to marked accumulation of myocellular TG, which was more pronounced in the absence of carnitine. Octanoate did not increase TG and ADRP protein levels and the presence of carnitine did not influence TG accumulation and ADRP protein content upon eicosapentaenoate incubation. With most FAs, relative ADRP protein levels paralleled changes in myocellular TG content. However, oleate incubation in the absence of carnitine resulted in a two-fold larger increase in ADRP protein content compared to the increase in TG content. OXPAT protein content was not increased upon lipid loading, though a small increase was observed upon octanoate incubation.
Conclusion: The present study demonstrated parallel changes in TG and ADRP upon lipid loading in muscle cells, suggesting a role for ADRP in lipid storage in muscle. Only after oleate incubation the induction of ADRP protein content was discordant with TG storage. In contrast, OXPAT protein levels did not match changes in TG content. Our experiments suggest that the roles of ADRP and OXPAT in muscular lipid storage are complex. The discrepancies in TG, ADRP, and OXPAT levels might be explained by differences in the metabolic fate of the type of FA entering the cell. Experiments investigating the effects of siRNA-mediated ADRP knockdown on myocellular lipid accumulation and its metabolic consequences (insulin signaling) are in progress.

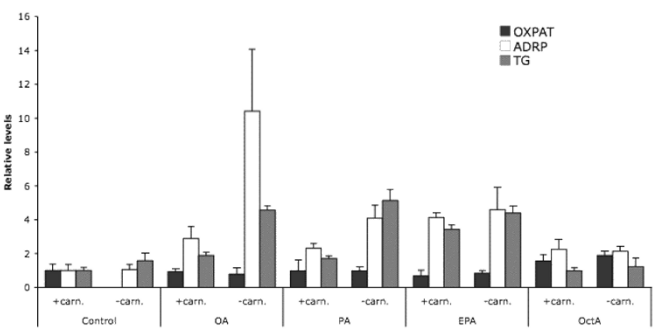

Figure 1: Relative triglyceride and ADRP levels upon incubation with 80 μM BSA complexed to 200 μM oleate (OA), palmitate (PA), eicosapentaenoate (EPA), octanoate (OctA), or control (solely 80 μM BSA) (n=3) in the presence or absence of 1 mM carnitine (carn.). ADRP and OXPAT protein contents were normalized to β-actin content and TG levels were normalized to total cellular protein content. The control treatment with carnitine addition was set at 1.0 (reference treatment). Data are expressed as mean +/- SEM.

***LPIN1* mRNA levels are more associated with lipogenic/lipolytic genes in subcutaneous than in visceral adipose tissue. *In vitro* lipogenic/lipolytic effects on human SGBS adipocytes**

M. Miranda[1], A. Megía[1], E. Caubet[2], I. Simón[1], M. Wabitsch[3], J.M. Fernández-Real[4], J.M. Gómez[5], J. Vendrell[1];
[1]CIBERDEM. Hospital Universitari Joan XXIII. IISPV, Tarragona, Spain, [2]Hospital Sta Tecla i San Pau, Tarragona, Spain, [3]Sektion Pädiatrische Endokrinologie u. Diabetologie. Interdisziplinäre Adipositasambulanz., Univ. Klinik für Kinder- und Jugendmedizin. Universität Ulm, Germany, [4]CIBEROBN. Hospital Trueta, Girona, Spain, [5]Hospital de Bellvitge, L'Hospitalet de Llobregat, Spain.

Background and aims: Adipose tissue dysfunction implies the appearance of insulin resistance, partly due to the increased plasma free fatty acids and to the lipid accumulation in not fat tissues. Human subcutaneous adipose tissue (SAT) *LPIN1* mRNA expression is positively associated with insulin sensitivity and a negative association with the body mass index (BMI) has been described. We have analysed the visceral (VAT) and SAT *LPIN1* transcription in the adipose tissue of a cohort of subjects that includes a wide range of obesity, and its relationship with genes involved in lipogenesis and lipolysis. We also aimed to analyse *LPIN1* mRNA expression in human adipocytes in response to lipogenic and lipolytic stimuli.
Materials and methods: Adipose tissue samples were collected from 62 apparently healthy subjects (38 men and 24 women; mean age 55.5±14.8). Anthropometric and metabolic parameters were recorded. Gene expression (*LPIN1, ACSS2, DGAT1, ACC1, CD36, FABP4, PCK1, ATGL, HSL, PLIN, PDE3B, PPIA*) was assessed by quantitative real time PCR. SGBS human preadipocytes were differentiated to adipocytes and stimulated with insulin/isoproterenol/TNFα and *LPIN1* mRNA levels were quantified.
Results: *LPIN1* levels were positively correlated between adipose depots (R=0.615, p<0.001) and no differences between SAT and VAT depots was observed. Overweight and obese subjects had significant reduced *LPIN1* levels in both adipose depots (p<0.01 in SAT and p<0.05 in VAT) and it was also decreased in subjects with metabolic syndrome with significant differences in SAT (p<0.001 in SAT and p=0.052 in VAT). *LPIN1* levels negatively correlated with waist circumference (p<0.001); BMI, fasting triglycerides and insulin levels, HOMA and SBP (p<0.01); and glucose (p<0.05) in SAT, whereas in VAT we found negative correlations only with waist (p<0.01), BMI and insulin (p<0.05). We found positive correlations between *LPIN1* mRNA levels lipogenic and lipolytic genes. In SGBS adipocites, *LPIN1* was up- regulated by insulin, whereas lipolytic stimuli (isoproterenol) had no effect on LPIN1 mRNA levels. On the contrary, TNFα (a pro-inflammatory stimuli that is known to induce lipolysis) significantly down-regulated *LPIN1* transcript levels.
Conclusion: Unlike other adipogenic genes that are higher epressed in SAT, *LPIN1* mRNA levels are comparable between SAT and VAT. Whereas SAT showed strong and positive associations with insulin sensitivity and with lipogenic/lipolytic genes, VAT only showed moderately association. *In vitro* experiments showed that *LPIN1* transcription levels are up-regulated by insulin and down-regulated by TNFα. Insulin resistance and the inflammatory milieu that characterize obesity could explain the decreased levels of LPIN1 mRNA in adipose tissue of obese patients.

Effect of 24-hour lipid infusion on adipocyte fatty acid binding protein (A-FABP) in patients with type 2 diabetes and healthy subjects

J. Kopecký jr.[1], E. Krušinová[1], P. Wohl[1], L. Kazdová[1], P. Mlejnek[2], M. Pravenec[2], T. Pelikánová[1];
[1]Diabetes Center, Institute for Clinical and Experimental Medicine, [2]Institute of Physiology, Prague, Czech Republic.

Background and aims: Intracellular transporter adipocyte fatty acid binding protein (A-FABP) is a) involved in a regulation of lipid metabolism, b) considered as a marker of the metabolic syndrome and c) thought be involved in the development if insulin resistance (IR). Our aim was to evaluate its plasma concentrations and expressions in abdominal subcutaneous adipose tissue during lipid infusion and consequent hyperlipidemia.
Materials and methods: 11 patients with type 2 diabetes (D) and 9 age-matched healthy control subjects (C) underwent 24-hour infusion of lipid emulsion (Intralipid 20%; 3 g of fat/kg/day; HTG). At 0, 4, and 24 hours A-FABP plasma concentrations and its mRNA expressions in abdominal subcutaneous adipose tissue were assessed. Adipose tissue sample was obtained by needle biopsy and mRNA measured by real-time PCR.
Results: In group D vs. C, both higher plasma concentrations (p<0.01) and expressions in abdominal subcutaneous adipose tissue (p<0.001) of A-FABP were found. During the lipid infusion plasma concentrations of A-FABP decreased significantly (p<0.001), with difference in between groups (p<0.01): significant decrease in C, only a trend to decrease in D. mRNA expressions in abdominal subcutaneous adipose tissue did not change in time in both groups.
Conclusion: In patients with type 2 diabetes, both higher plasma concentrations and adipose tissue mRNA expressions of A-FABP were found. During lipid infusion induced hyperlipidemia A-FABP plasma concentrations significantly decreased in healthy subjects, whereas only a non-significant trend was observed in patients with type 2 diabetes.

Hyperlipidaemic conditions induce 'metabolic memory' within human abdominal subcutaneous adipose tissue and isolated adipocytes, *in vivo*

A.L. Harte, E.M. Youssef, E.A. Wahba, A.A. Hussen, A. Cerellio, P. O'Hare, S. Kumar, P.G. McTernan;
Unit for Diabetes and Metabolism, University of Warwick, Coventry, United Kingdom.

Background and aims: Both chronic hyperlipidemia and hyperglycemia are established as key factors in the pathogenesis of obesity mediated diabetes. Chronic elevation of free fatty acids (FFAs) and glucose (Glc) appears to activate an inflammatory response in multiple cell types; which may be compounded by continual feeding. Restoration of physiological FFA and Glc levels may not attenuate the original insult on the cell; a finding that has been termed 'metabolic memory' in other systems. Therefore we investigated (1) the effect of FFAs and Glc on the inflammatory signaling pathway in adipose tissue (AT) and adipocytes (Ads) (2) whether Ads are subject to 'metabolic memory'.
Materials and methods: Abdominal (Abd) subcutaneous (Sc) AT was collected from patients undergoing elective liposuction surgery (age 45±3.3 yrs; BMI: 21.9±2.4 kg/m^2; n=6). AbdSc AT explants and Ads were treated with chronic low glucose (L-Glc): 5.6mM and high glucose (H-Glc): 7.5mM, with low (0.2 mM) and high (2 mM) doses of a palmitate:stearic tri-mix for 48 hrs. Further, AbdSc AT explants and Ads were also exposed to the aforementioned treatment regimen for 12hr periods, with alternating rest periods of 12hrs in L-Glc. Conditioned media were collected and pro-inflammatory cytokine secretions were assessed by ELISA. Western blot was utilized to examine components of the NFκB pathway.
Results: Chronic treatment with L-Glc and high FFAs, H-Glc and high FFAs up-regulated key factors of the NFκB pathway in both AbdSc AT explants and Ads (AbdSc AT explants TLR4, Control: 1.09±0.02, H-Glc & FFA (2 mM) 2.00±0.47*; Ads TLR4, Control: 1.04±0.02, H-Glc & FFA (2 mM) 1.32±0.13*; AbdSc AT explants NFκB, Control: 1.06±0.03, H-Glc & FFA (2 mM) 1.44±0.02*; Ads NFκB, Control: 1.04±0.03, H-Glc & FFA (2 mM) 1.95±0.01*; *p<0.05) whilst MyD88 protein levels remained unchanged. Similarly, intermittent treatment with Glc and FFAs increased TLR4 (p<0.05), NFκB (p<0.05) and IKKβ (p<0.05) in explants and Ads. However, in contrast to chronic treatment, MyD88 protein expression was significantly increased (AbdSc AT MyD88, Control: 1.03±0.01, H-Glc & FFA (2 mM) 1.30±0.13*; Ads MyD88, Control: 1.04±0.01, H-Glc & FFA (2 mM) 1.67±0.2*). No change in JNK2 or JNK1 protein expression was observed across all treatments. Downstream both TNF-α (p<0.05), resistin (p<0.05) and IL-6 (p<0.05) secretion were markedly increased in chronically treated AbdSc AT explants and Ads

whilst, in intermittently treated cells, a metabolic memory effect was noted in absence of treatment.
Conclusion: Hyperlipidemia upregulated the innate immune response in human AbdSc AT explants and Ads with chronic and intermittent exposure. AbdSc explants and Ads were subject to 'metabolic memory', differentially activated by the MyD88 dependent pathway, in contrast to the chronically treated cells. This study implicates elevated FFAs as a key instigator of the inflammatory response in both AT and Ads, via NFκB, which suggests that short-term exposure of cells to uncontrolled levels of FFAs and Glc lead to a longer-term inflammatory insult within the Ad. These findings indicate the importance of maintaining a low fat diet in order to reduce inflammatory risk in patients with obesity and type 2 diabetes.
We would like to acknowledge the BHF for funding Dr. Harte's intermediate fellowship

Lipid-altering efficacy of ezetimibe/simvastatin 10/20 mg compared to rosuvastatin 10 mg in high-risk patients with and without type 2 diabetes mellitus

H. Vaverkova[1], M. Farnier[2], M. Averna[3], L. Missault[4], M. Viigimaa[5], Q. Dong[6], A. Shah[6], A.O. Johnson-Levonas[6], P. Brudi[7];
[1]3rd Department of Internal Medicine, Medical Faculty and University Hospital Olomouc, Czech Republic, [2]Point Medical - Rond Point de la Nation, Dijon, France, [3]2Dipartimento di Medicina Clinica e delle Patologie Emergenti-Policlinico "Paolo Giaccone", Palermo, Italy, [4]St Jan Hospital, Department of Cardiology, Bruge, Belgium, [5]Tallinn University of Technology North-Estonia Regional Hospital, Tallinn, Estonia, [6]Merck Research Labs, Rahway, United States, [7]Merck/Schering-Plough, North Wales, United States.

Background and aims: This post-hoc exploratory analysis compared the lipid-altering effects of switching to ezetimibe/simvastatin (EZE/SIMVA) 10/20 mg or rosuvastatin (ROSUVA) 10 mg in high-risk hypercholesterolemic patients (pts) with and without type 2 diabetes mellitus (T2DM).
Materials and methods: In this randomized, double-blind study, 618 high-risk pts with elevated LDL-C ≥2.59 and ≤4.92 mmol/L despite prior use of statins entered a 6-wk open-label stabilization/screening period during which they continued on the same statin dose prior to enrollment. Pts were randomized 1:1 to EZE/SIMVA 10/20 mg or ROSUVA 10 mg for 6 wk. Pts were classified as having T2DM based on ≥1 of the following: prior diagnosis of T2DM, use of antihyperglycemic medication or baseline fasting plasma glucose ≥7 mmol/L. The primary endpoint was % change from baseline in LDL-C at study endpoint in the overall study population. This post-hoc analysis evaluated % change from baseline in lipids and % of pts attaining LDL-C, non-HDL-C and apo B goals at study endpoint in pts with (n=182) and without T2DM (n=434). Consistency of the treatment effect across subgroups was evaluated by testing for treatment × subgroup interaction. No multiplicity adjustments were made.
Results: EZE/SIMVA 10/20 mg was more effective than ROSUVA 10 mg at lowering LDL-C, TC, non-HDL-C and apo B in the overall population and across the subgroups (Table 1). Numerically greater between-treatment reductions in LDL-C, TC, non-HDL-C and apo B were seen in pts with T2DM vs those without T2DM. A significant treatment × subgroup interaction was observed for LDL-C (p=0.015) suggesting that pts with T2DM achieved larger between-treatment reductions vs. those without T2DM. More pts with and without T2DM achieved LDL-C levels < 2.59, < 2.00 and < 1.81 mmol/L, non-HDL-C < 2.59 mmol/l and apoB < 0.8 g/L with EZE/SIMVA vs ROSUVA.
Conclusion: In this post-hoc analysis of high-risk patients with elevated LDL-C despite prior use of statin therapy, switching to EZE/SIMVA 10/20 mg vs ROSUVA 10 mg provided superior reductions in LDL-C, TC, non-HDL-C and apo B in pts with and without T2DM.

Serum vaspin concentration is associated with metabolic syndrome in male subjects

S. Choi[1], S. Kwak[2], S. Lim[1], H. Jang[1], I. Lee[3], E. Koh[4], K. Lee[4], K. Park[2];
[1]Seoul National University College of Medicine, Seongnam, [2]Seoul National University College of Medicine, [3]Kyungpook University School of Medicine, Daegu, [4]Ulsan University College of Medicine, Seoul, Republic of Korea.

Background and aims: Vaspin (visceral adipose tissue derived serpin) is a newly indentified adipokine, serine protease inhibitor family with insulin sensitizing effect in animal study. It was expressed in visceral adipose depots in OLEF rats and the mRNA expression of vaspin was found in adipose tissue only in obese, insulin-resistant human. There were few studies to show the clinical impact of vaspin but some suggested its possible role in obesity and insulin sensitivity. Thus, we want to investigate which clinical conditions are related to serum vaspin concentrations in humans.
Methods: We finally analyzed 403 (male: 202, female: 201) subjects from NGT to DM and measured the correlation between various metabolic parameters and serum vaspin concentrations (by ELISA kit, Adipogen, Seoul, Korea). Multidetector coronary computed tomography (MDCT) was performed for estimating coronary atherosclerosis in our subjects.
Results: Serum vaspin concentrations is significantly elevated in female compared to male subjects (0.53 (0.04-5.45) vs. 0.44 (0.05-2.51), $p<0.05$). Over age of 50, this difference of serum Vaspin level disappeared between male and female. Comparing serum vaspin levels of subjects with NGT vs. IGT&DM showed trends of decrement in subjects with IGT&DM in male. Serum vaspin concentrations are significantly high in subjects with metabolic syndrome (MS) in male (0.40 (0.05-2.51) vs. 0.60 (0.12-2.44, $p<0.001$) but not in female. Serum vaspin concentration is significantly associated with the numbers of MS in male. Body mass index, waist circumference, triglyceride showed independent predictors for serum vaspin concentration in male, only HbA1c showed negative correlation to vaspin levels in female. Serum vaspin concentration did not show any association with the status of atherosclerosis (coronary calcium score, degree of coronary stenosis, plaque burdens by MDCT) in our subjects.
Conclusion: Serum vaspin concentration showed sexual difference, higher in female. BMI, waist circumference, triglyceride showed significant correlation to vaspin level. Subjects with MS showed higher vaspin concentration than subject without MS in male. Paradoxical increase of vaspin concentration is associated with MS and glucose intolerance in male subjects, suggests its possible role in obesity and insulin sensitivity in human.

714

Association of serum visfatin with insulin secretion and sensitivity among prediabetic and type 2 diabetic subjects

Z. Hassan[1], F. Kabir[2,3], I. Khan[1], F.A. Jahan[2], M.O. Faruque[2], L. Ali[2];
[1]Dept Physiology and Molecular Biology, BIRDEM, [2]Dept of Biochemistry and Cell Biology, BIRDEM, [3]Dept of Biochemisty, Shahabuddin Medical College, Dhaka, Bangladesh.

Background and aims: Insulin resistance in IGT and T2DM subjects have been shown to be associated with Visfatin, a cytokine of visceral fat origin. The association, however, has been studied only in obese subjects. Since BMI is a major confounder of both subclinical chronic inflammation and insulin resistance we have explored the association of serum Visfatin with insulinemic status in normal to moderately overweight prediabetic and diabetic subjects.
Materials and methods: A group of 75 subjects with impaired glucose regulation (IGR) [mean (±) age 43±7 and BMI 25.3±4.5] and 43 T2DM [43±6 and 24.9±3.9 respectively] subjects were included in this study and 51 healthy subjects [42±5 and BMI 24.5±4.1 respectively] served as control. The three groups were matched for age and BMI. Anthropometric features and total body fat mass were determined following standard procedure. Glucose and lipids were measured by standard methods. Insulin and visfatin were determined by enzyme linked immunosorbent assay (ELISA). Insulin secretory capacity (HOMA%B) and insulin sensitivity (HOMA%S) were calculated by homeostasis model assessment (HOMA) using HOMA-Sigma Software. Data were analyzed by appropriate univariate as well as multivariate tools.
Results: Mean (±SD) age was, and in the Control, IGR and T2DM groups respectively and BMI was, and respectively. Fasting insulin (μU/ml) was significantly higher in the IGR and T2DM group compared to the Controls ($p=0.002$ and $p<0.001$ respectively) but between the IGR and T2DM group no significant difference was observed. HOMA%B was significantly lower in T2DM compared to the Control ($p=0.004$) and IGR ($p=0.008$) groups. HOMA%S was significantly lower in the IGR and T2DM groups compared to Controls ($p<0.001$). Fasting visfatin (ng/ml) was 3.1±3.0, 5.6±4.3 and 5.5±4.2 in the Control, IGR and T2DM respectively. Mean (±SD) visfatin in the IGR and T2DM was significantly higher compared to the Control ($p=0.002$ and $p=0.006$ respectively), but the value was almost similar in the two groups. Visfatin did not show any significant correlation with fasting glucose, insulin, HOMA%S and HOMA%B. But multinomial logistic regression revealed association of serum visfatin with both IGR and T2DM groups ($p=0.027$ and 0.033 respectively) when age, BMI and TG were adjusted. On multiple linear regression analysis Visfatin was found to be significantly associated with insulin when fasting glucose, age, BMI and TG were adjusted in T2DM ($p=0.035$) but the association was not significant in the Control and IGR groups. Visfatin, however, did not show any association with HOMA%S and HOMA%B in any of the three groups when the effect of age, BMI and TG was adjusted.
Conclusion: Visfatin may be associated with prediabetic and diabetic conditions, but it does not seem to be a direct mediator of B cell secretory capacity and insulin sensitivity.

A novel quantitative flow cytometric method for the determination of a new adipocytokine, omentin, in human plasma

E. Maratou[1], E. Boutati[2], M. Peppa[2], V. Lambadiari[2], T. Economopoulos[2], G. Dimitriadis[2], S.A. Raptis[1,2];
[1]Hellenic National Center for Research, Prevention and Treatment of Diabetes Mellitus and its Complications (HNDC), Athens, [2]2nd Department of Internal Medicine, Research Institute and Diabetes Center, Athens University, Greece.

Background and aims: Omentin is a recently described adipocytokine, selectively expressed and secreted from visceral, but not from subcutaneous adipose tissue. *In vitro* studies have shown that omentin increases insulin signal transduction by activating Akt/protein kinase B and enhancing insulin stimulated glucose transport. Preliminary studies have indicated a possible implication of omentin in metabolism. It is of major importance to determine whether there is any correlation between the plasma levels of circulating omentin and metabolic disorders such as obesity or type 2 diabetes and whether omentin exerts a protective action. The aim of this study was the development of a flow cytometric technique that would allow the quantitative determination of the circulating omentin.
Materials and methods: Blood (5ml) was withdrawn from 17 healthy women (BMI 22.2±4, age 34±9). The levels of circulating omentin in human plasma were detected by a novel technique based on the immunological transaction of a monoclonal anti-omentin (Ab) antibody (conjugated on the surface of capture beads) with omentin. A monoclonal biotin-conjugated Ab (detection Ab) was incubated with the capture beads, the test samples/standards and streptavidin-phycoeryhtrin reagent to form a sandwich complex. The samples were then analyzed by flow cytometry (FACS Calibur, BD Biosciences, SJ, California USA). The results were quantified by the usage of a standard curve. The Mean Fluorescence Intensity of the standards was plotted against the concentrations of the standards and the standard curve fitting was performed by the GraphPad Prism software (GraphPad Software Inc, San Diego, USA). Omentin plasma levels were interpolated from the standard curve. The omentin plasma levels versus waist circumference, HOMA, BMI, waist to hip ratio (w/h) were statistically tested for linear correlation (Pearson r) by GraphPad Instat.
Results: The introduced method has allowed the measurement of the plasma omentin in 17 women (average level 106±59ng/ml, range 20-250ng/ml). The omentin levels were negatively correlated with BMI ($r=-0.56$, $P=0.019$), HOMA ($r=-0.55$, $P=0.019$), waist circumference ($r=-0.55$, $P=0.021$) and w/h ratio ($r=-0.55$, $P=0.021$). These parameters are indicators of the metabolic status and reflect the distribution of the adipose tissue.
Conclusion: Our results lead to the conclusion that omentin plasma levels decline as deposition of fat in the waist line increases. This decrease may contribute to the insulin resistance observed in obesity, diabetes and generally in metabolic syndrome. Additionally, the measurements prove that the intro-

duced flow cytometric technique produces results similar to those produced by the classical method of quantitative western blotting assay. The advantages of the flow cytometric technique are the easiness of handling, the small amount of required blood, and the fact that the results are rapidly produced without compromising specificity and accuracy. This experimental approach permits the determination of this newly discovered adipokine in a large sample size of humans, in order to clarify the physiological role of omentin.

716

Association of plasma retinol binding protein 4 with insulin secretion and sensitivity among prediabetic subjects

F. Kabir[1,2], M.O. Faruque[1], I. Khan[3], F.A. Jahan[1], Z. Hassan[3], L. Ali[1];
[1]Dept of Biochemistry and Cell Biology, BIRDEM, [2]Dept of Biochemisty, Shahabuddin Medical College, [3]Dept of Physiology and Molecular Biology, BIRDEM, Dhaka, Bangladesh.

Background and aims: Retinol binding protein 4 (RBP4) is now thought to be an important molecule in the pathogenesis of insulin resistance in T2DM, but the causal association of the adepocytokine with the basic defects of T2DM (insulin secreatory defect and insulin resistance) are still not settled. An investigation of this molecule in prediabetic subjects can help in better understanding of this association. We have studied a group of IGR (IFG, IGT and IFG-IGT) cases for the relationship of RBP4 with glycemic and insulinemic status.
Materials and methods: A total 75 IGR subjects [17 IFG, 44 IGT and 14 IFG-IGT] were recruited purposively and 51 healthy subjects served as control. Anthropometric measures and total body fat mass were determined. Glucose and lipids were measured by standard biochemical methods. Insulin and RBP4 were estimated by using enzyme linked immunosorbent assay (ELISA). Insulin secretory capacity (HOMA%B) and insulin sensitivity (HOMA%S) were determined by homeostasis model assessment (HOMA) using HOMA-Sigma software. Data were analyzed by appropriate univariate as well as multivariate tools.
Results: The study subjects in the four groups were age- and BMI- matched. Waist to hip ratio and total body fat mass among the groups did not show statistical difference between groups. Fasting triglyceride was significantly higher in the IFG, IGT and IFG-IGT groups compared to Controls (p=0.002, <0.001 and 0.013 respectively). Mean HDL was significantly lower in IGT group compared to the Controls (p=0.009). Fasting insulin (μU/ml) in the IGT and IFG-IGT groups was significantly higher compared to the Controls (p=0.002 and 0.017 respectively). HOMA%B was 107±25, 76.5±18, 126±44 and 78.9±17 in Control, IFG, IGT and IFG-IGT- respectively; the value was significantly lower in IFG and IFG-IGT groups (p<0.001 for both) and higher in IGT (p=0.019) compared to the Control. HOMA%S was 81.9±18, 72.3±23, 67.7±18 and 62.3±17 in Control, IFG, IGT and IFG-IGT-respectively; which was significantly lower in the IGT and IFG-IGT groups compared to Controls (p<0.001 and p=0.001 respectively). Fasting RBP4 (μg/ml) was 30.4±6.1, 32.2±10.9, 36.7±9.0 and 35.5±7.6 in Control, IFG, IGT and IFG-IGT- respectively; it was significantly higher in IGT and IFG-IGT groups compared to the Controls (p<0.001 and p=0.011 respectively). RBP4 levels did not show any significant difference between the IFG and the Control groups. When the study subjects were categorized on the basis of 75th percentile of plasma RBP4, insulin level was found significantly higher (p=0.028) and HOMA%S lower (p=0.008) in the group with higher RBP4 compare to lower RBP4 group. HOMA%B, however, did not show any difference between the groups. In binary logistic regression analyses RBP4 showed association with IGR (IFG, IGT and IFG-IGT pooled together) group (p=0.001) after adjusting the confounding factors (age, BMI and WHR). Multiple linear regression analyses showed that RBP4 affected both HOMA%B (β=0.308, p=0.012) and HOMA%S ((β=-0.283, p=0.020) when the effect adjusted for age, BMI and WHR.
Conclusion: The present data indicate that RBP4 may have a causal association with type 2 diabetes mellitus.

Relationship of Retinol binding protein-4 with insulin sensitivity and intima media thickness in women with untreated essential hypertension

E. Muscelli, E. Santini, S. Madec, C. Rossi, A. Solini;
Department of Internal Medicine, University of Pisa, Italy.

Background and aims: Retinol binding protein-4 (RBP4) is a novel adipokine able to modulate the action of insulin in several tissues. A variable degree of insulin resistance characterizes the vast majority of hypertensive patients. Aim of the present study was to evaluate the relationship between RBP4 and essential hypertension, exploring potential links between RBP4, other adipokines and insulin sensitivity with some proxies of early vascular damage in female, naïve for treatment, hypertensive patients.
Materials and methods: Serum RBP4, leptin, adiponectin and resistin levels were determined in 35 normotensive (CT - 46.9 ± 6.3 years; BMI 25.7 ± 1.4 kg/m^2) and in 35 hypertensive (HYP - 47.4 ± 5.0 years; BMI 25.0 ± 1.6 kg/m^2) women with normal glucose tolerance by OGTT. Carotid intima-media thickness (IMT) was measured using high-resolution B-mode ultrasound. Insulin sensitivity was estimated from the plasma glucose and insulin responses by the Oral Glucose Insulin Sensitivity (OGIS) index.
Results: All participants had normal glucose tolerance. Mean IMT was 0.499 ± 0.127 mm in CT and 0.543 ± 0.148 mm in HYP (p=ns). In HYP, RBP4 levels were markedly higher than in CT (37.1 ± 1.6 vs. 11.1 ± 0.77 μg/ml; p<0.0001), and adiponectin levels were slightly but significantly lower (5.6 ± 0.2 vs. 6.2 ± 0.2 μg/ml, p<0.05). No differences were observed in resistin and leptin concentrations. Fasting glucose was similar (4.7 ± 0.6 vs. 4.7 ± 0.4 mmol/l) as well 2-h glucose (6.2 ± 0.7 vs. 6.0 ± 0.8 mmol/l), insulin (108 ± 38 vs. 98 ± 40 pmol/l) and OGIS (492 ± 49 vs. 492 ± 45ml/min/m^2). In the whole study group, a strong linear relationship was observed between IMT value and both RBP4 (Rho 0.32, p=0.008) and resistin (Rho 0.34, p=0.005); there was a trend to correlate with OGIS (Rho 0.22, p=0.07), but not with fasting glucose and insulin or adiponectin. RBP4, resistin, mean blood pressure and triglycerides were, actually, the only variables independently related to IMT (r^2=0.30; p=0.0002) by multiple regression analysis.
Conclusion: In non-obese, non-diabetic naïve hypertensive women, RBP4 levels are increased and correlate with the degree of intima-media thickness, suggesting a participation of this adipocytokine in the modulation of the atherosclerotic process exerted by the adipose tissue as endocrine organ.

718

Apelin regulates luminal intestinal glucose absorption through AMPK dependent mechanisms

R. Ducroc[1], C. Dray[2], Y. Sakar[1], D. Daviaud[2], P. Valet[2], I. Castan-Laurell[2];
[1]Neuroendocrinologie et Physiologie Digestive, Inserm U773, Paris, [2]Institut de Médecine Moléculaire de Rangueil, I2MR, Inserm U858, Toulouse, France.

Background and aims: Intestinal absorption of carbohydrate-digested products by the small intestine constitutes one highly regulated way to deliver glucose to the blood. Glucose absorption is mainly driven by sodium glucose transporter 1 (SGLT-1) in preprandial and interprandial states, and requires further assistance of GLUT2 transporter in brush-border membrane (BBM) upon ingestion of sugar-rich meal. This process is highly regulated by peptides and hormones. As other adipokines/gut peptides (ie leptin, resistin β) apelin is produced by proximal digestive cells and secreted in the lumen where it is believed to bind specific receptor APJ in apical membrane of enterocyte. Here we examined whether apelin can act from luminal side of intestine to regulate glucose absorption and which are the intracellular mechanisms involved in this regulation.
Materials and methods: Male C57Bl6J mice were used. Specimen of jejunal mucosa were prepared for immunohistochemical analysis of AJP. Proximal intestine from fasted mice was isolated in Ussing chamber and glucose absorption was measured after 10 mM glucose challenge as Na^+-induced short-circuit current (Isc) that sustains glucose entry through SGLT-1. Apelin (0.01 nM-1 μM) was added into luminal reservoir 3 min before glucose challenge. Jejunal loops were also prepared to quantify *in vitro* transepithelial transport of ^{14}C glucose in absence and presence of luminal apelin (1 nM). The GLUT2 and SGLT-1 proteins abundance in BBM and phosphorylation status of AMPK were studied by western blot after *in vivo* incubation of jejunal loops with apelin and/or 30 mM glucose.
Results: Mice proximal mucosa was immunohistochemically reactive for APJ. Apelin receptor was found expressed predominantly in villi. In Ussing

chamber, luminal apelin dose-dependently inhibited glucose-induced Isc (IC50 ~1 nM). This inhibition of SGLT-1 activity was maximal at 100 nM, and blocked by preincubation with a monoclonal antibody to the peptide. Accordingly, glucose-induced abundance of SGLT-1 in BBM was blunted after rapid incubation of jejunal loops with 1 nM apelin. At the same time, apelin enhanced glucose-induced abundance of GLUT2 in BBM that is a hallmark of AMPK stimulation. Thus we further examined the effect of apelin on AMPK. Total proteins from the same cells indicated this was associated with a rapid phosphorylation of AMPK. The result of this dual effect of apelin on transporters resulted in a 15% increased of the glucose transepithelial transport without change in mannitol permeability.
Conclusion: Apelin was previously shown to restore glucose tolerance and increase glucose utilization. Here we demonstrate that apelin, as a gut peptide, may bind APJ receptors at enterocyte BBM to rapidly balance glucose transport in response to alimentary sugars. As SGLT-1 cotransports water, apelin-induced regulation of glucose transport could ameliorate osmotic balance when luminal glucose increases. These data give new insight on apelin role, as a strong physiological regulator of glucose homeostasis in peripheral tissues.

719

The human adiponectin receptor R2 is expressed predominantly in adipose tissue and linked to the adipose tissue expression of MMIF-1

K.T. Kos[1], S. Wong[1], M. Jernas[2], D. Kerrigan[3], L. Carlsson[2], J.P.H. Wilding[1], J.H. Pinkney[4,1];
[1]Diabetes and Endocrinology, Clinical Sciences Aintree, Liverpool, United Kingdom, [2]Department of Molecular and Clinical Medicine, Sahlgrenska Academy, Gothenburg, Sweden, [3]Surgery, Clinical Sciences Aintree, Liverpool, United Kingdom, [4]Diabetes Research, Royal Cornwall Hospital, Truro, United Kingdom.

Background and aims: Expression of adiponectin (ADN) receptors in human adipose tissue (AT) in relation to inflammatory cytokines is poorly understood. The aim of this study was to describe the regional AT-ADN and ADN receptor R1 and R2 expression and their relation with metabolic parameters, circulating and AT-derived cytokines and chemoattractants.
Materials and methods: Paired subcutaneous (SCAT) and visceral AT (VAT) was taken from 18 lean and 39 obese humans, mRNA expression of adipokines and cytokines analysed by rt-PCR and corresponding serum levels by ELISA. R1 and R2 adipose expression was compared with the distribution in 17 other human tissues.
Results: ADN gene expression was lower in VAT than SCAT (mean (SD) 1.54(1.1) vs 2.84(0.87); p<0.001), and lower in obese subjects (VAT:p=0.01;SCAT: p<0.001). SCAT-ADN correlated positively with serum ADN (r=0.33; p=0.036) but not VAT. There were inverse correlations between AT-expression of ADN and MMIF, IL18 and CD14 in both depots. R1 and R2 genes were expressed ubiquitously and R2 expression was highest in AT and this in adipocytes. Both receptors were expressed in VAT and SCAT, but R2 was the predominant receptor (X10); levels were similar in lean and obese subjects and unrelated to the metabolic syndrome, however, receptors correlated with expression of VAT-MMIF (R1:r=0.4;p=0.008; R2:r=0.35,p=0.02) and SCAT-MMIF (R2: r=0.43;p=0.004)and SCAT-R2 correlated with TNFα (r=0.30, p=0.05).
Conclusion: Unlike the protein adiponectin, its receptors R1 and R2 are ubiquitously expressed and R2 expression is highest in AT and not in the liver like in rodents. R2 expression in adipose tissue is associated with MMIF and TNF-alpha expression and may thus be under the influence of local inflammation in adipose tissue. This may potentially be mediated by obesity-induced hypoxia in AT which is known to reduce ADN and may also increase adiponectin receptor expression and which requires further investigation.

HMW-adiponectin associates with triglyceride concentrations in type 1 diabetic patients

C. Maruyama[1], R. Ishibashi[1], R. Araki[1], H. Hirose[2], T. Maruyama[3];
[1]Food and Nutrition, Japan Women's University, Tokyo, [2]Internal medicine, Keio University, Tokyo, [3]Internal Medicine, Saitama Social Insurance Hospital, Japan.

Background and aims: Recent studies have observed higher adiponectin concentrations in patients with type 1 diabetes, compared with healthy subjects, but no correlation with plasma glycemic parameters.The objective of this study was to investigate relation between serum high molecular weight (HMW)-adiponectin concentration and fasting and postprandial blood glycemic and lipid parameters in type 1 diabetic patients.
Materials and methods: Type 1 diabetic patients treated with short-acting insulin analogs and healthy volunteers were recruited. The subjects were divided into two groups based on the mean HMW-adiponectin value of 12.2 mg/L: low HMW-adiponectin (men/women=7/2) and high HMW-adiponectin (men/women=3/8). Blood samples were collected after an overnight fast, and 30-180 min after consuming white bread (B) or white bread with butter (BB).The insulin dose injected for the BB meal should have been the same as that for the B meal.
Results: Mean HbA1c in patients with low and high HMW-adiponectin were 6.8 ± 0.8 % and 6.8 ± 0.9 %, respectively, and C-peptide concentrations also showed similar low levels in the two groups. Onset age and duration of diabetes did not differ between the two diabetic groups. BMI did not differ among the three groups. Type 1 diabetic patients with high HMW-adiponectin had lower triglyceride and remnant like particle (RLP)-triglyceride concentrations compared with those with low HMW-adiponectin (p<0.01), and had higher lipoprotein lipase mass (p<0.01) than healthy subjects (men/women =8/6). After the B and BB meals, type 1 diabetic patients with high HMW-adiponectin consistently had lower triglyceride and RLP-triglyceride concentrations up to 180 min than those with low HMW-adiponectin and healthy subjects (p<0.01) (Figure). However, apoB48 did not differ between these two groups. Fasting and postprandial plasma glucose were higher in both diabetic groups than in healthy subjects (p<0.001), with no significant difference between the patient groups.Multiple regression analysis resulted, log HMW-adiponectin was an independent negative predictor of fasting plasma glucose (beta coefficient -0.487, p=0.036) but not of fasting triglyceride and postprandial log areas under the curve (AUC) triglyceride in healthy subjects. However, in the diabetic patients, no independent predictor of any fasting glucose or AUC plasma glucose was observed, but log HMW-adiponectin was an independent negative predictor of log fasting triglyceride (beta coefficient -0.563, p=0.012), and log AUC triglyceride after both B (beta coefficient -0.584, p=0.009) and BB meal consumption (beta coefficient -0.666, p=0.002).
Conclusion: HMW-adiponectin is more strongly associated with very low density lipoprotein remnant metabolism than glucose utilization in type 1 diabetic patients receiving short-acting insulin analogs.

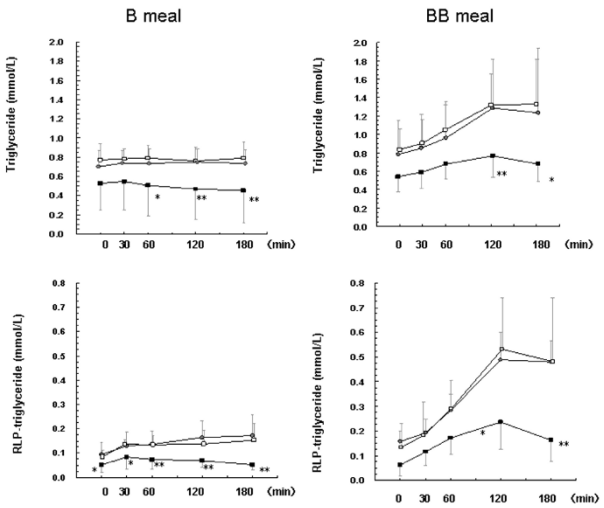

Figure. Postprandial serum triglyceride and RLP-triglyceride changes after B and BB meals in healthy subjects (●), patients with low HMW-adiponectin (□), and patients with high HMW-adiponectin (■). Data are mean ± SD. *: p<0.05, **: p<0.01; statistically significant differences compared with healthy subjects.

PS 55 Secretory function of adipose tissue

721

Profiling of adipokine secretion by adipose tissue in transgenic mice with homotopic overexpression of adiponectin

Q. Ge, L. Noel, E. Maury, L. Rycken, S. Brichard;
Unité d'Endocrinologie et Métabolisme, l'Université Catholique de Louvain, Bruxelles, Belgium.

Background and aims: We have generated a transgenic (Tg) mouse model allowing persistent and moderate overexpression of native adiponectin (ApN) targeted to white adipose tissue [the transgene being placed under control of aP2 (fatty-acid binding protein) promoter]. Adiposity was reduced in aging mice fed a high-sucrose diet and this anti-obesity effect favored enhanced insulin sensitivity and improved lipid profile. APN appears to be a potent regulator of other adipokines. We took advantage of this unique *in vivo* model to study the influence of APN on adipokine secretion profiling. In order to investigate the early and specific effects of APN, mice were studied before any significant decrease of fat mass or glycemia and circulating lipids occurred.
Materials and methods: 10-wk-old Tg mice receiving a high-sucrose-diet were compared to wild-type (WT) littermates. Subcutaneous adipose tissue was fractionated into adipocytes (A) and stromal-vascular (SV) cells (i.e. non-fat cells that contain macrophages), which were then cultured for 8 h. Medium was screened by medium-scale protein arrays allowing the simultaneous detection of 144 cytokines. Gene expression of some adipokines was measured by RTQ-PCR.
Results: As expected, ApN expression was much higher (30-fold) in A than in SV cells of WT mice, while leptin was virtually undetectable in the SV fraction. ApN was overexpressed in both cellular fractions of Tg mice, in line with the fact that aP2 is co-expressed in adipocytes and macrophages (but at a much lower extent in the latter cells). By using cytokine antibody arrays, we detected more than 40 cytokines secreted by each cellular fraction of WT and Tg mice. Profiling of adipocyte secretory products showed that 9 adipokines were less secreted by Tg than WT mice: one chemokine (regulated upon activation normal T-cell expressed and secreted, RANTES), three pro-inflammatory cytokines (IL-6, IL-17B, IL-21), two extracellular matrix remodeling-/growth arrest-factors and three hematopoietic growth factors (one for megakaryocytes, thrombopoietin; the other two for granulocytes and/or macrophages, GM-CSF/ G-CSF). Profiling of SV cell products showed that 13 peptides were differentially secreted between Tg and WT mice, with usually stronger genotype differences than those observed in adipocytes. Thus, secretion of 12 peptides was downregulated, while one was upregulated in Tg mice. Hyposecreted factors include five adipokines that were also reduced in adipocytes (RANTES, IL-6 and the 3 hematopoietic growth factors) together with another chemokine, four other pro-inflammatory cytokines/ factors (comprising two adhesion molecules), one receptor for an angiogenic factor (VEGF R1), and one factor involved in lipid metabolism (fatty acid translocase). We also found that the secretion of one anti-inflammatory factor (IL-R4, which is an IL1-receptor family member) was increased by SV cells of Tg mice.
Conclusion: At the onset of overexpression, ApN reduced the secretion of 9 to 12 inflammatory adipokines in each cellular fraction of adipose tissue in Tg mice, while upregulating the secretion of one anti-inflammatory factor. Thus, ApN induced a shift of the immune balance in both adipocytes and SV cells toward a less inflammatory phenotype, with a greater effect on SV cells. These adipokines, which are newly identified as downstream targets of ApN *ex vivo*, may have therapeutic potential for the management of the metabolic syndrome.

Regulation of the expression of angiopoietin-like protein 4 mRNA in diabetic mice

N. Mizutani, N. Ozaki, Y. Seino, T. Fukuyama, E. Sakamoto, Y. Oiso;
Nagoya University Graduate School of Medicine, Japan.

Background and aims: Angiopoietin-like protein 4 (Angptl4) is mainly secreted from the liver and adipose tissue. It inhibits lipoprotein lipase activity, thereby causing an increase in the serum triglyceride level. The expression and plasma levels of Angptl4 are increased by fasting and decreased by feeding. We have recently shown that insulin negatively regulates Angptl4 mRNA expression in 3T3-L1 adipocytes, suggesting that insulin plays an important role in the regulation of Angptl4 expression. In this study, we aim to elucidate the regulation of Angptl4 expression in diabetic states.
Material and methods: Type 1 diabetes was induced in C57BL/6 mice by treating with streptozotocin (STZ). As a model of type 2 diabetes, the mice were fed with a high-fat diet (HFD) for 18 weeks. We determined Angptl4 mRNA expression by using a quantitative real-time PCR method and compared it with 36B4 mRNA expression.
Results: When compared with the normal mice, the STZ diabetic mice showed significantly higher serum glucose and triglyceride levels. The level of Angptl4 mRNA expression in the STZ diabetic mice had increased by 2.23 ± 0.47 fold in the liver ($p < 0.05$), 2.00 ± 0.37 fold in white adipose tissue (WAT) ($p < 0.05$), and 1.79 ± 0.26 fold in brown adipose tissue (BAT) ($p < 0.05$) when compared with the corresponding values in normal mice. Furthermore, this effect was attenuated by the administration of insulin. In the HFD diabetic mice, a significant increase in insulin resistance and triglyceride level was observed at 18 weeks. The level of Angptl4 mRNA expression in the HFD diabetic mice was increased by 2.15 ± 0.30 fold in the liver ($p < 0.005$), 1.68 ± 0.27 fold in WAT ($p < 0.05$), and 1.77 ± 0.31 fold in BAT ($p < 0.05$) when compared with the corresponding values in the normal chow-fed mice.
Conclusion: Thus, the level of Angptl4 mRNA expression was increased in both the insulin-deficient and insulin-resistant diabetic states, thus indicating that insulin negatively regulates Angptl4 mRNA expression in the liver and adipose tissue of diabetic mice.

723

N^{ε}-(Carboxymethyl)lysine trapping in adipose tissue in obesity: implications for obesity-associated changes in adipokine expression

K. Gaens[1], M.P.H. van de Waarenburg[1], J.L.J. Scheijen[1], H.W.M. Niessen[2], M.C.G. Brouwers[1], S.S.M. Rensen[3], W.A. Buurman[3], J.M. Greve[3], M.A.M. van Zandvoort[4], C.D.A. Stehouwer[1], C.G. Schalkwijk[1];
[1]Internal Medicine, Maastricht University Medical Center, [2]Pathology, VU Medical Center, Amsterdam, [3]General Surgery, Maastricht University Medical Center, [4]Biomedical Engineering, Maastricht University Medical Center, Netherlands.

Background and aims: Obesity is linked to a wide variety of pathophysiological conditions. Dysregulated production of adipokines is associated with obesity and provides a link between obesity and obesity-related complications. Factors that lead to a dysregulated production of adipokines remain unknown. We hypothesize that accumulation of the advanced lipoxidation endproduct N^{ε}-(carboxymethyl)lysine (CML) in adipose tissue contributes to the altered expression of adipokines in obesity.
Materials and methods: Accumulation and localization of CML in adipose tissue of obese patients was assessed by immunohistochemistry using a CML specific antibody. Colocalization studies of CML with macrophages (CD68) and endothelial cells (CD31) were performed. Plasma levels of protein-bound CML were measured by UPLC-tandem MS in controls (n=77), familial combined hyperlipidaemia (FCHL, n=42) and obese patients (n=44). Blood clearance of fluorescently labeled CML-albumin was compared with unmodified-albumin in Db/Db mice at different time periods. Uptake of fluorescently labeled CML-albumin and unmodified albumin in adipose tissue was assessed with two-photon microscopy. To examine the biological effects of CML in adipose tissue, preadipocytes were incubated with CML-albumin, and changes in gene expression of plasminogen activator inhibitor-1 (PAI-1), IL-6 and the receptor for AGE (RAGE) were analyzed by Real Time PCR.
Results: Immunohistochemistry showed the presence of CML in adipocytes, macrophages and endothelial cells of adipose tissue of obese patients. CML staining was significantly higher in visceral (VAT) than in subcutaneous adipose tissue (SAT) (IH score 1.50±0.21 and 1.26±0.20, resp, $p<0.001$). Plasma CML levels were lower in obese (1.3±0.2 μM, $p<0.001$) and FCHL patients (1.3±0.3 μM, $p<0.001$) as compared with controls (1.9±0.5 μM). Weight reduction in obese patients led to an increase of plasma CML levels ($p=0.01$). CML plasma levels were negatively correlated with BMI (r=-0.475, $p<0.001$), and VAT (r=-0.548, $p<0.001$), but not with SAT (r=-0.148, $p=0.238$). This suggested an accumulation and trapping of plasma CML in VAT of obese patients. Experiments in Db/Db mice showed higher clearance of CML-albumin than unmodified albumin, and preliminary results of two-photon microscopy showed accumulation of CML-albumin, but not albumin, in VAT of Db/Db mice. Incubation of human preadipocytes with CML-albumin during 24h and 48h had no effect on gene expression of IL-6, PAI-1 and RAGE, while an incubation of 72h increased their expression by 2.4-, 1.8- and 4.9-fold, respectively.

Conclusion: We demonstrated the accumulation of CML in VAT of obese patients. Plasma CML levels are lower in obese patients as compared with controls. The inverse relation between CML plasma levels and VAT suggests trapping of CML in VAT, which was shown in Db/Db mice. The increased pro-inflammatory gene expression after incubation of preadipocytes with CML-albumin supports our hypothesis that CML has biological effects regarding the dysregulation of adipokines.

AQP7 gene expression profile in context of obesity and type 2 diabetes mellitus. Relationship with lipogenic and lipolytic genes in subcutaneous and visceral fat

V. Ceperuelo-Mallafré[1,2], M. Miranda[1,2], M.R. Chacón[1,2], E. Caubet[3], E. Solano[1], I. Simón[1,2], J. Fernandez-Real[4,5], J. Vendrell[1,2];
[1]Research Department, University Hospital Joan XXIII, Tarragona, , [2]CIBERDEM, Tarragona, [3]Surgery Service. Hospital de Sta. Tecla. Tarragona, [4]Diabetes Unit. University Hospital "Dr. Josep Trueta", [5]CIBEROBN, Girona, Spain.

Background: Adipose tissue is a dynamic organ in which a balanced activity between lipogenesis and lipolysis is crucial for adequate energy equilibrium. Lipolysis results in the hydrolysis of triglycerides to free fatty acids and glycerol, which is specifically transported outside the cell by the Aquaporin-7 (AQP7) channel. Modulation of *AQP7* expression has been suggested to play a role in the development of obesity and insulin resistance in rodents. No data about the relationship between lipogenic, lipolytic and inflammatory gene markers in the setting of obesity and tpe 2 diabetes has been reported in humans.
Aims: We have studied *AQP7* mRNA expression in adipose tissue from obese and type 2 diabetic patients and its relationship with lipogenic, lipolytic and adipokine gene expression, both in subcutaneous (SAT) and visceral (VAT) fat depots. Likewise, regulation on *AQP7* expression by lipolytic and lipogenic stimuli were analysed in a human preadipocyte cell line (SGBS).
Materials and methods: 73 subjects were included in the study (19 lean, 28 overweight, and 15 obese subjects). We also included 11 patients with type 2 diabetes. Clinical and anthropometrical variables were measured in all subjects. Biochemical and metabolic parameters were quantified. Gene expression of *AQP7*, *ACC1*, *ACSS2*, *DGAT1*, *PEPCK*, *FABP4*, *PLIN*, *ATGL*, *HSL*, *APM*, *PPAR (α,δ,γ)* and *PPIA* were quantified by Real-time PCR. Human SGBS preadipocytes were differentiated and cultured overnight in serum-free medium. Cells were stimulated with several doses of insulin and isoproterenol (0 up to 100 nM) for 24h and *AQP7* gene expression was measured.
Results: Obese subjects shown higher VAT *AQP7* mRNA expression than overweight patients (p=0.006). No differences in SAT *AQP7* gene expression were found according BMI. In patients with type 2 diabetes, higher VAT *AQP7* expression was observed when comparing with their BMI-matched non-diabetic counterparts (p=0.018). *AQP7* both in SAT and VAT depots correlated positively with *APM*, genes related with lipogenesis, lipolysis, FFA transport and with the three members of the *PPAR family*. The independence of the associations was evaluated by linear regression analysis, including sex and presence of type 2 diabetes as confounding variables: In SAT, *AQP7* mRNA expression was positively associated with *APM* (B=0.380, p=0.000), *PPARγ* (B=0.768, p=0.000), *ACC1* (B=0.162, p=0.004) and negatively with *PEPCK* mRNA (B=-0.055, p=0.017). In VAT *AQP7* mRNA expression was determined by BMI (B=0.298, p=0.043), *PLIN* (B=0.283, p=0.038), *FABP4* (B=0.413, p=0.000) and *ATGL* mRNA expression (B=0.298, p=0.043). Treatment of SGBS adipocytes with 100 nM insulin and 100 nM isoporterenol for 24 h inhibited significantly AQP7 gene expression by 60% and 40%, respectively.
Conclusion: AQP7 shows a different pattern of gene expression in SAT than in VAT depots. VAT from obese and type 2 diabetic patients show higher AQP7 mRNA expression levels. A strong interdependence with lipogenic and lipolytic genes was observed. A paradoxical inhibitory response in adipocytes is observed both with lipogenic and lipolytic stimulus.

Circulating and adipose tissue gene expression of zinc-alpha2-glycoprotein in obesity. Its relationship with adipokyne and lypolitic gene markers in subcutaneous and visceral fat

S. Näf[1], V. Ceperuelo-Mallafré[1], X. Escoté[1], E. Caubet[2], J.M. Gómez[3], M. Miranda[1], M.R. Chacón[1], J.M. González-Clemente[4], J.M. Fernández-Real[5], L. Gallart[1], C. Gutierrez[1], J. Vendrell[1];
[1]Endocrinology and Diabetes Unit, University Hospital of Tarragona Joan XXIII, CIBERDEM, Tarragona, [2]Diabetes Surgery Service, Santa Tecla Hospital, Tarragona, [3]Endocrinology and Diabetes Unit, University Hospital of Bellvitge, CIBERDEM, Barcelona, [4]Diabetes Endocrinology and Nutrition Department, University Hospital of Sabadell Parc Taulí, [5]Department of Endocrinology, Diabetes and Nutrition, University Hospital of Girona Dr. Josep Trueta, CIBEROBN, Girona, Spain.

Background and aims: Zinc-alpha2-glycoprotein (ZAG) is a soluble protein similar in structure to the class I major histocompatibility complex (MHC) heavy chain, which has been implicated in lipid catabolism. However the clinical significance of this lipolytic activity remains scarcely explored. The aim of this study was to analyze ZAG gene expression in human adipose tissue from lean and obese subjects in parallel with several lipolytic and adipokine genes. ZAG circulating plasma levels and its relationship with cardiometabolic risk factors were also studied.
Materials and methods: Clinical and anthropometrical variables were assessed in 73 Caucasian (43 male and 30 female) subjects. Plasma and adipose tissue [subcutaneous (SAT) and visceral (VAT)] from the same patient were studied. Real-time quantification of PPARγ, Hormone sensitive lipase (HSL), Adipose triglyceride lipase (ATGL), Adiponectin, Omentin, Visfatin and ZAG was performed. Plasma concentrations of ZAG were determined with ELISA.
Results: ZAG plasma levels showed a negative correlation with insulin (r= -0.39; p=0.008) and with the HOMA index (r= -0.36; p=0.016). *ZAG* expression in SAT was significantly reduced in overweight and obese individuals compared to lean subjects (p<0.001 and p=0.007 respectively). *ZAG* mRNA expression both in SAT and VAT depots were negatively correlated with many clinical and metabolic cardiovascular risk factors (Table 1). A positive correlation between *ZAG* mRNA expression and circulating adiponectin levels was observed (r=0.404; p<0.001 and r=0.337; p=0.007 for SAT and VAT *ZAG* mRNA expression, respectively). After multiple linear regression analysis, SAT *ZAG* was mainly predicted by *Adiponectin* mRNA expression (B=1.068; p<0.0001) and triglyceride plasma levels (B=-0.572; p=0.006). VAT *ZAG* expression was predicted by *Adiponectin* expression (B=0.539; p<0.0001), and *HSL* VAT expression (B=0.123; p=0.036).
Conclusion: The present study provides evidence of a role of *ZAG* gene in adipose tissue metabolism, with a close association with A*diponectin* gene expression in subcutaneous and visceral fat.

Insulin resistance in hyperthyroidism: the role of cytokines

E.G. Tsegka[1], P. Mitrou[2], G. Dimitriadis[1], V. Lambadiari[1], E. Maratou[2], E. Boutati[1], T. Economopoulos[1], S.A. Raptis[1,2];
[1]2nd Department of Internal Medicine and Research Institute, Athens University Medical School, "Attikon" University Hospital, [2]Hellenic National Center for Research, Prevention and Treatment of Diabetes Mellitus and its Complications (H.N.D.C), Athens, Greece.

Background and aims: Although insulin resistance is a common finding in hyperthyroidism, the implicated mechanisms are obscure. In muscle and adipocytes of euthyroid subjects, adiponectin has been found to stimulate glucose disposal by activating AMP-activated protein kinase, whereas leptin to reduce insulin stimulated glucose uptake. Tumor necrosis factor-α (TNF-α) and interleukin-6 (IL6) are cytokines with metabolic and weight-regulating effects. In euthyroid subjects both TNF-α and IL6 inhibit lipoprotein lipase activity and increase lipolysis. The aim of this study was to investigate whether cytokines plasma levels are altered in hyperthyroidism and if these changes could be related to the development of insulin resistance.
Materials and methods: A mixed meal was given to ten female hyperthyroid subjects (HR: age 37±4 years, BMI 24±1kg/m^2, Total fat mass (TFM)17±2.9kg T3 334±44ng/dl, TSH 0.03±0.003μU/ml) and eight female euthyroid subjects (EU: age 34±4 years, BMI 24±0.6 kg/m^2 , TFM 15.7±2kg, T3 112±8ng/dl, TSH 1.1±0.07 μU/ml). Plasma samples were taken every 30-60 min for 360 min from a vein draining the abdominal subcutaneous adipose tissue (AD) and from the radial artery for measurements of glucose, insulin, non-esterified fatty acids (NEFA), leptin, TNF-a, IL-6 and adiponectin.
Results: (1) In HR vs EU: (a) arterial glucose was similar ($AUC_{0\text{-}360}$2212±43 vs 2089±41mM*min), but insulin was increased (16333±2804 vs 10087±548mU/l*min, p=0.03) (b) HOMA was increased (2.17±0.47 vs 0.9±0.1 kg/m2, p=0.03) suggesting the development of insulin resistance in hyperthyroidism (c) plasma NEFA levels were increased ($AUC_{0\text{-}360}$138381±16488 vs 89265±7851μmol/l*min, p=0.02), suggesting increased lipolysis (d) fasting plasma levels of IL-6 (2±0.3 vs 0.9±0.1ng/ml, p=0.01), TNF-a (4±0.9 vs 1.4±0.2ng/ml, p=0.04) and leptin (12.3±2 vs EU 5.3±0.8 ng/ml, p=0.03) were increased, whereas adiponectin plasma levels were decreased (10.2±1.7 vs EU 20.8±3.5ng/ml, p=0.01). **(2)** (a) IL-6 was increased in the abdominal vein compared to the radial artery, both in HR (4.9±1.2 vs 2±0.3ng/ml, p=0.01) and in EU (5.6±1.7 vs 0.9±0.1ng/ml, p=0.01), suggesting that IL-6 is produced by the subcutaneous adipose tissue (b) IL-6 levels ($AUC_{0\text{-}360}$) were positively correlated with HOMA index (r=0.66, p=0.03) (c) TNF-α was positively correlated with arterial NEFA levels ($AUC_{0\text{-}360}$) (r=0.86, p=0.006).
Conclusion: In hyperthyroidism: **(1)** glucose and lipid metabolism are resistant to insulin **(2)** IL-6, TNF-a and leptin are increased and adiponectin is decreased supporting the development of insulin resistance **(3)** subcutaneous adipose tissue releases IL-6 which could then act as an endocrine mediator of insulin resistance **(4)** although there is no net secretion of TNF-α by the subcutaneous adipose tissue in vivo, increased systematic TNF-α levels could be part of the mechanism explaining the resistance of lipolysis to insulin.

The weight sparing effect of insulin detemir is associated with increased adiponectin levels and decreased adiposity in the diabetic ZDF rat

C. Fledelius, G.S. Olsen, A.B. Jensen, J. Damgaard, A. Vinterby, M. Schiødt, E. Nishimura, U. Ribel, J. Sturis;
Novo Nordisk, Måløv, Denmark.

Background and aims: It is currently unclear how changes in body weight (BW) are associated with changes in fat mass and adiponectin levels, which are reduced in conditions associated with increased risk of cardiovascular disease (CVD), such as diabetes. This study compared the effects of NPH insulin (NPH) and insulin detemir (IDet) on glycemic control (HbA_{1c}), BW, fat mass, and adiponectin levels in the ZDF rat model of type 2 diabetes.
Materials and methods: Diabetic ZDF rats were treated subcutaneously with vehicle, NPH or IDet for 4 weeks. Fat was determined non invasively using quantitative magnetic resonance.
Results: At baseline, HbA_{1c}, BW, and fat mass did not differ significantly between groups, with HbA_{1c} averaging 8.0±0.3% (mean±SD). NPH and IDet both decreased HbA_{1c} significantly (6.2±0.3%, p<0.01; 6.2±0.4%, p<0.01) compared with vehicle (9.1±0.3%). Despite comparable changes in glycemic control, IDet significantly reduced gain in BW and fat mass vs NPH. The reduction in fat mass with IDet accounted for 62% of the reduced BW gain. Four-week relative weight reduction in the IDet group was 2.1%. NPH and IDet increased adiponectin levels 48% (p<0.01) and 90% (p<0.001) respectively vs vehicle, and IDet increased adiponectin levels 28% (p<0.001) vs NPH.
Conclusion: Four weeks of basal insulin therapy (NPH or IDet) resulted in increased adiponectin levels. IDet reduced gain in BW and fat mass and resulted in a greater increase of circulating adiponectin levels in the ZDF rat than NPH, suggesting that IDet may improve the CVD risk profile compared with NPH.

Human adipocyte-secreted factors and vascular smooth muscle cell proliferation: an integrated proteome analysis

S. Lehr, S. Hartwig, D. Lamers, H. Sell, W. Paßlack, J. Eckel;
Institute of Clinical Biochemistry and Pathobiochemistry, German Diabetes Center, Duesseldorf, Germany.

Background and aims: Adipose tissue as an endocrine organ secretes a variety of proteins and peptides. In the context of obesity, especially the perivascular fat may induce inflammation and proliferation in the vascular wall and therefore play a major role in development of atherosclerosis. In this study we examined the influence of adipocyte secretion products on vascular smooth muscle cells (SMC) combining different protein profiling techniques.
Materials and methods: SMCs were incubated with conditioned media (CM) derived from isolated and *in vitro* differentiated pre-adipocytes, which comprises a complex mixture of secretion products. Performing proliferation assays revealed an increase of three-fold in response to CM. In order to examine the cellular mechanism, we performed combined protein profiling by Kinex™ Antibody Microarray and 2D-gel based Difference in Gel Electrophoresis (DIGE). Protein samples achieved under standardized conditions were either analyzed using the array approach screening by 650 different antibodies specific for several hundred distinct proteins including diverse phosphorylation states or by explorative 2D-DIGE multiplex analysis.
Results: Dependent on CM incubation, array analysis revealed 145 alterations in protein abundance or protein phosphorylation status. Investigating the proteome of these SMC by comparing more than 1800 different protein spots, indicated significant alterations for 62 different protein spots. Subsequently these protein spots were identified by MALDI-TOF-TOF analysis. Assigning identified proteins to their cellular functions and combining the results from array and gel based profiling indicates that several cellular key proteins e.g. mTOR, Rac1, STAT, FAK, Caldesmon and Zyxin are influenced through CM incubation and can be assigned to cellular signaling pathways playing a decisive role for regulation of cell cycle.
Conclusion: Factors released by human adipocytes have the potential to induce proliferation of smooth muscle cells. Therefore, integrated proteome analysis of SMCs provide new insights into intra-cellular networking and may lead to new hints for identification of atherogenic or anti-atherogenic factors and their pathways.

Effects of exenatide plus rosiglitazone on measures of beta cell function and insulin sensitivity in subjects with type 2 diabetes previously treated with metformin

L.C. Glass[1], C. Triplitt[2], M.S. Lewis[3], Y. Qu[4], Y. Guo[3], D. Maggs[5], R.A. DeFronzo[2];
[1]Cardiovascular/Metabolism, Lilly Research Laboratories, Indianapolis, [2]Division of Diabetes, Department of Medicine, University of Texas Health Science Center at San Antonio, [3]Lilly USA, LLC, Indianapolis, [4]Eli Lilly and Company, Indianapolis, [5]Amylin Pharmaceuticals, San Diego, United States.

Background and aims: This 20 week study was designed to study the effects of exenatide (EXE) plus rosiglitazone (ROSI) on β-cell function and insulin sensitivity in subjects with type 2 diabetes (T2D) using the hyperglycaemic and euglycaemic insulin clamp techniques.
Materials and methods: A total of 137 subjects (mean age 55.7 years, weight 92.9 kg, and HbA1c 7.8%) were randomized to either EXE (10μg twice daily [BID]), ROSI (4mg BID), or EXE (10μg BID) + ROSI (4mg BID). A subgroup (n=50) completed the clamp procedures at baseline and after 20 weeks to allow estimation of insulin secretion, insulin action, and the disposition index (*AUC*M÷I*, where AUC=insulin area under the curve [hyperglycaemic clamp], *M*=insulin sensitivity and *I*=insulin value [steady state of euglycaemic clamp]).
Results: HbA1c decreased significantly in all groups, with the greatest decrease observed for EXE+ROSI (see Table). Subjects treated with ROSI had significant weight gain, while those on EXE or EXE+ROSI had significant weight loss. At 20 weeks, total insulin secretion was significantly higher in EXE and EXE+ROSI than ROSI, and insulin sensitivity (M value) was significantly higher in EXE+ROSI and ROSI than EXE.
Conclusion: Combination therapy elicited an additive effect on glycaemia, and the combination of EXE with ROSI offset the known weight gain effects of ROSI. We confirmed the insulin sensitizing effects of ROSI with a negligible effect on the β-cell while EXE exerted a robust effect on the β-cell and also a modest insulin sensitizing effect. Combination therapy resulted in significant improvements in insulin secretion and insulin sensitivity with reductions in body weight, thus targeting the major pathophysiologic defects of T2D.

Exenatide once-weekly treatment elicits sustained glycaemic control and weight loss over 2 years

M. Trautmann[1], K. Wilhelm[2], K. Taylor[2], T. Kim[2], D. Zhuang[2], L. Porter[2];
[1]Eli Lilly & Company, Indianapolis, [2]Amylin Pharmaceuticals, Inc., San Diego, United States.

Background and aims: Treatment with the GLP-1 receptor agonist exenatide once weekly (QW) resulted in sustained improvements in HbA_{1c}, fasting plasma glucose (FPG), body weight, serum lipid profiles, and blood pressure through 52 weeks of treatment in patients with type 2 diabetes. Here we describe interim results in a cohort of these patients (on a variety of background antihyperglycaemic agents) who completed the 30-week, controlled, open-label trial in which they received either exenatide QW or exenatide BID, followed by 70 weeks of treatment with 2 mg exenatide QW during a subsequent open-ended assessment period.
Materials and methods: Of the 181 patients in this cohort who entered the trial, 75% (n=135) completed 2 years of treatment. Baseline characteristics (mean±SD) for these patients were: HbA_{1c} 8.3±1.0%, FPG 9.26±0.21 mmol/L, body weight 100±19 kg, BMI 34.7±5.0 kg/m^2, diabetes duration 8±6 y.
Results: Significant improvements (LS mean±SE) in both HbA_{1c} (-1.8±0.1%; 95% CI: -2.0 to -1.6%) and FPG (-2.04±0.22 mmol/L; 95% CI: -2.48 to -1.59 mmol/L) were maintained after 2 years of treatment, with 66% and 42% of patients achieving an HbA_{1c} ≤7.0% and ≤6.5%, respectively. Body weight was significantly reduced (-3.6±0.6kg; 95% CI: -4.8 to -2.3 kg) from baseline following 2 years of treatment. Serum lipid profiles also were significantly improved during 2 years of treatment (triglycerides: -18%, 95% CI: -24% to -12%; total cholesterol: -0.25±0.09 mmol/L, 95% CI: -0.42 to -0.07 mmol/L). Furthermore, a clinically significant reduction in systolic blood pressure (-3.2±1.2 mmHg; 95% CI: -5.5 to -0.8 mmHg) was maintained through 2 years of treatment. Nausea (predominantly mild in intensity) was the most common adverse event during the 30-week treatment period and decreased over time, occurring in 8% of patients during the open-ended treatment period. No severe hypoglycaemia was observed.

	EXE (n=45)	ROSI (n=47)	EXE+ROSI (n=45)	P EXE vs. ROSI	P EXE vs. EXE+ROSI	P ROSI vs. EXE+ROSI
ΔHbA1c (%)	-0.9±0.1	-1.0±0.1	-1.3±0.1	0.720	0.016	0.039
ΔWeight (kg)	-2.8±0.5	1.5±0.5	-1.2±0.5	<0.001	0.038	<0.001
Hyperglycaemic Clamp	(n=17)	(n=15)	(n=18)			
Insulin Incremental AUC (% increase)	372±83	3±19	286±66	<0.001	0.414	<0.001
Insulin clamp (M value) (% increase)	27±11	61±15	69±15	0.061	0.032	0.728
Disposition Index (mg/kg, Change from Baseline)	80.1±15.1	10.6±15.4	100.3±14.4	0.003	0.344	<0.001

Data presented as LS mean±standard error

Conclusion: Exenatide QW was well tolerated during the treatment period. This study demonstrated sustained glucose control and weight loss over 2 years of treatment with exenatide QW.

731

Reductions in glycaemia and weight with once-weekly dosing of LY2189265, a long-acting glucagon-like peptide 1 (GLP-1) analogue in patients with type 2 diabetes mellitus

T.A. Hardy[1], P. Barrington[2], J. Chien[1], H. Showalter[1], K. Schneck[1], S. Cui[3], F. Tibaldi[4], B. Ellis[1];
[1]Eli Lilly and Company, Indianapolis, United States, [2]Eli Lilly and Company, Windlesham, United Kingdom, [3]i3 Statprobe, Austin, United States, [4]GSK Biologicals, Rixensart, Belgium.

Background and aims: LY2189265 is a novel, long-acting glucagon-like peptide 1 (GLP-1) analog, being developed for treatment of type-2 diabetes (T2DM). LY2189265 consists of a dipeptidyl peptidase-IV (DPP-IV)-protected GLP-1 analog covalently linked to an Fc fragment of human IgG4, thereby increasing its duration of pharmacological activity. Safety, tolerability, pharmacokinetics (PK), glycemic and weight effects, and immunogenicity of weekly subcutaneous doses of LY2189265 were evaluated in a 5-week, placebo-controlled, parallel-group, patient- and investigator-blinded study of 43 patients with T2DM.
Materials and methods: Patients inadequately controlled by diet and exercise or metformin were enrolled and received 0.05 mg to 8 mg of LY2189265 or placebo. Evaluations included glucose, insulin, glucagon, C-peptide during test-meals and oral glucose tests, changes in weight, gastric emptying rate, hemoglobin A1C, and antibodies to LY2189265.
Results: The half-life of LY2189265 was ~95 hours in T2DM patients. LY2189265 at ≥1 mg significantly reduced fasting and postprandial glucose area under the concentration-time curve (AUC) and 2-hour glucose after a test meal. Glycemic reductions observed following the first dose were maintained through weekly dosing. An insulinotropic effect of LY2189265 was demonstrated by increased insulin and C-peptide AUC normalized to glucose AUC. Statistically significant reductions in A1C (-0.69% to -1.34%, p<.01) were observed across doses. Statistically significant effects on gastric emptying after the first dose and weight loss after the last dose were observed at ≥5 mg. LY2189265 was well tolerated at doses producing significant reductions in glycemia. The most commonly reported adverse events were nausea, vomiting, headache, and diarrhea. A statistically significant increase in heart rate was noted at the 5-mg dose. No patient developed antibodies to LY2189265.
Conclusion: Once-weekly administration of LY2189265 demonstrated sustained glycemic and GLP-1 effects in T2DM patients. Side effects were consistent with expected GLP-1 pharmacology. These results support further investigation of this novel long-acting GLP-1 analog.

732

Differences in baseline characteristics between patients prescribed sitagliptin versus exenatide based on a US electronic medical record database

L. Radican[1], S. Rajagopalan[2], P. Mavros[1], S. Engel[3], D. Yin[1], Q. Zhang[1];
[1]Global Outcomes Research and Reimbursement, Merck & Co., Inc, Whitehouse Station, [2]MedData Analytics, Inc, Williamsville, [3]Clinical and Quantitative Science, Merck & Co., Inc, Rahway, United States.

Background and aims: Sitagliptin (SITA) is the first once-daily oral dipeptidyl peptidase-4 inhibitor and exenatide (EX) is the first twice-daily injectable glucagon-like peptide-1 receptor agonist available for the treatment of type 2 diabetes (T2DM). This study examined differences in baseline characteristics

between patients with T2DM initiating SITA vs. EX in real-world practice in the US, where SITA and EX are both indicated for use in dual and triple combination therapy with other oral antihyperglycemic agents (AHA) and SITA is also indicated as monotherapy.
Materials and methods: The General Electric Centricity electronic medical record database, covering 9 million U.S. patients of all ages from 49 states, was used to select patients with T2DM, aged ≥30 years, who received their first SITA or EX prescription between Oct 2006 and June 2008. Included patients were new to monotherapy, dual or triple combination therapy. Although EX is not indicated as monotherapy, real world EX monotherapy use was observed and included. Patient's medical records, including demographics, diagnoses, prescriptions, and lab results were extracted for the one year period (baseline) prior to the date of the first prescription of SITA or EX. Patient baseline profiles were stratified by mono-, dual, or triple therapy and compared between regimens with SITA vs. EX.
Results: Among patients new to AHA, 1091 initiated SITA and 759 initiated EX monotherapy. Compared to patients initiating EX, at baseline, patients on SITA were older (63.8 vs. 56.9 years), and had a lower obesity rate (61.5% vs. 87.6%), higher serum creatinine (106 μmol/L vs. 88 μmol/L), higher proportion of males (46.1% vs. 35.6%), and higher prevalence rates of macrovascular conditions (18.1% vs. 10%) (all p<0.0001). Among patients started on dual combination regimens, 2261 were prescribed SITA, and 1901 were prescribed EX. Similar to the pattern seen with initial monotherapy, patients on SITA at baseline were older, and had a lower obesity rate, higher serum creatinine, higher proportion of males, and higher rate of macrovascular conditions; additionally, patients started on SITA had a higher rate of renal insufficiency (based on diagnosis of renal disease or elevated serum creatinine level >132 μmol/L for male and >106 μmol/L for female) (all p<0.0001). Among those new to triple combination therapy, patients with SITA (n=3194) compared to EX (n=2661) at baseline were also older, and had a lower obesity rate, higher serum creatinine, higher proportion of males, and higher rates of macrovascular conditions (all p<0.0001). Observed patient profile differences were consistent across all the three regimen types.
Conclusion: This study demonstrates that patients with T2DM who received SITA compared to EX in a real-world setting were generally older, more likely to be male, had higher rates of preexisting macrovascular conditions and renal insufficiency and had a lower rate of obesity than patients who received EX. This has important implications for future observational studies using electronic medical record or claims databases, in that estimated outcome measures may be biased by the channeling of sicker, higher-risk patients to SITA.

Investigation of features of type 2 diabetic patients with secondary failure to oral hypoglycaemic agents associated with blood glucose response to exenatide
M. Sardinoux, G. Baptista, A. Wojtusciszyn, J. Bringer, E. Renard;
Endocrinology Dept, CHU & University of Montpellier, France.

Background and aims: Exenatide is a GLP-1 receptor agonist that may improve insulin secretion in T2D patients. We investigated the features of T2D patients with secondary failure to oral hypoglycemic agents (OHA), either never treated by insulin or using insulin combined with OHA for less than 12 months, which were associated with blood glucose response to exenatide.
Materials and methods: Blood glucose response to exenatide was prospectively followed-up for 6 months in 21 T2D patients with secondary failure to OHA (A1c > 7.5 %). Group A (N or mean ± SEM) included 7 women/3 men; age: 55.8 ± 3.5 years, BMI: 33.1 ± 2.6 kg/m²; waist circumference (WC): 107.5 ± 8 cm; diabetes duration (DD): 14.8 ± 1.6 years; A1c: 9.97 ± 0.42 % who never used insulin. Group B included 6 women/5 men; age: 56 ± 2.3 years; BMI: 34.1 ± 1.7 kg/m²; WC: 119.2 ± 4.7 cm; DD: 18.2 ± 3.2 years; A1c: 9.14 ± 0.36 % who had been using insulin combined with OHA for less than 12 months at baseline. Before initiation of exenatide, blood glucose levels were brought close to normal by a 48-hour IV insulin infusion after withdrawal of SC insulin (if applicable) and OHA but metformin. Insulin sensitivity (S*i*) was assessed by the amount of insulin in IU/kg/day needed during the last 24 hours of IV insulin infusion to keep blood glucose in the normal range and insulin secretion was investigated by **Δ** plasma C peptide before and 6 min after 1 mg glucagon IV. Exenatide was then initiated at 5 μg bid for at least one month and increased to 10 μg bid according to blood glucose monitoring, while OHA were restored as before IV insulin. A1c was followed-up at 2, 4, and 6 months. Responders to exenatide were defined as patients whose A1c change was greater or equal to median A1c variation after 2 months (i. e. ≥ -1.5%). Statistical analysis was performed using ANOVA for repeated measurements.
Results: Baseline characteristics of patients were not significantly different in groups A and B, in terms of S*i* : 0.56 ± 0.05 vs. 0.50 ± 0.09 IU/kg/day; *p*=0.58, and **Δ** plasma C peptide:1.04 ± 0.25 vs. 0.6 ± 0.34 ng/ml; *p*=0.15, respectively. Maximal change in A1c levels was obtained between baseline and month 2, and remained stable for 6 months in both groups. Among patient features at baseline, only **Δ** plasma C peptide was significantly higher in responders to exenatide (R; n=9) than in non-responders (NR; n=12) as shown in the table below. Moreover, previous insulin use was associated with a significantly higher non-response rate to exenatide: 10/11 vs. 2/10 (Fisher exact test, *p*=0.0019).

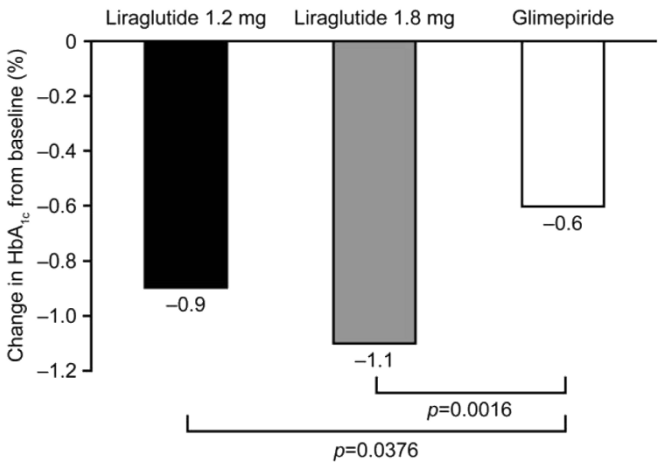
	Responders	Non Responders	
Age (years)	55 ± 1.74	56.6 ± 3.4	*p*=0.71
Diabetes duration (years)	15.7 ± 2.14	17.3 ±2.83	*p*=0.68
Baseline A1c (%)	9.98 ± 0.53	9.26 ± 0.31	*p*=0.22
BMI (kg/m²)	32.3 ± 2.8	34.6 ± 1.5	*p*=0.46
Waist Circumference (cm)	106 ± 9	118 ± 4	*p*= 0.17
S*i* (IU/kg/day)	0.55 ± 0.7	0.51 ± 0.6	*p*=0.68
Δ plasma C peptide (ng/ml	1.16 ± 0.26	0.55 ± 0.12	*p*=0.04

Conclusion: From our data, remaining capacity of insulin secretion appears as a significant factor associated with response to exenatide on blood glucose control in T2D patients showing secondary failure to OHA. Previous insulin use is also associated with a poor response to exenatide therapy.

734

Liraglutide, a human GLP-1 analogue, maintains greater reductions in HbA_{1c}, FPG and weight than glimepiride over 2 years in patients with type 2 diabetes: LEAD-3 extension study
A.J. Garber[1], R. Henry[2], R. Ratner[3], P. Hale[4], C.T. Chang[4], B. Bode[5];
[1]Depts. of Medicine, Biochemistry and Molecular Biology, and Molecular and Cellular Biology, Baylor College of Medicine, Houston, [2]University of California, San Diego, [3]MedStar Research Institute, Hyattsville, [4]Novo Nordisk Inc, Princeton, [5]Atlanta Diabetes Associates, Atlanta, United States.

Background and aims: The human GLP-1 analogue liraglutide (1.8 and 1.2 mg QD) achieved greater reductions in HbA_{1c}, FPG, weight, hypoglycaemia and systolic blood pressure than glimepiride (8 mg QD) when used as monotherapy for one year in patients with type 2 diabetes in the randomised, double-blind, LEAD-3 study (n = 746). This open-label extension study analysed the continued efficacy and tolerability of liraglutide, as compared with glimepiride, during a further year of treatment (2 year extension).
Materials and methods: The extension period was an open-label continuation of the one-year, randomised, double-blind, parallel-group LEAD-3 study. A total of 90% (n=440) of one-year completers entered the extension study for a further one year, of whom 321 (73%) completed a further year of treatment (2-year completers: mean age = 54yrs, HbA_{1c} = 8.2%; median diabetes duration = 3.3yrs; BMI = 33kg/m²; diet/exercise only at LEAD 3 study entry = 36%; 1 OAD = 64%) Data presented are for 2-year completers.
Results: Compared with subjects taking glimepiride, after 2 years liraglutide (1.8 and 1.2mg) subjects experienced greater reductions in HbA1c (-1.1 and -0.9%, respectively, versus -0.6%; ANCOVA; p = 0.0016 and p = 0.0376, respectively) (Figure); had lower final HbA1c (6.9 ± 1.2 and 7.1 ± 1.2% versus 7.5 ± 1.2%); and a greater proportion reached HbA1c < 7.0% (58 and 53% vs. 37%; p = 0.0054 and p = 0.0269, respectively). Liraglutide also achieved greater reductions in FPG (1.5 and 1.3 versus 0.3 mmol/L , respectively). Weight loss at one year associated with liraglutide and weight gain observed with glimepiride were maintained (-2.7 and -2.1kg versus + 1.1kg; p < 0.0001), Hypoglycaemia (BG < 3.1 mmol/L) was reduced by at least 85% with the use of liraglutide 1.8 mg/day compared to glimepiride (0.28 and 0.16 vs. 1.82 events/subject/yr; p = 0.0001 and p < 0.0001). Differences in HbA1c between completers and the ITT (LOCF) population were comparable; ITT (LOCF) analyses also showed significantly greater reductions in FPG, weight and hypoglycaemia with liraglutide vs. glimepiride.
Conclusion: The clinically and statistically significant reductions in HbA_{1c}, FPG, weight and hypoglycaemia achieved after one year of liraglutide treatment are maintained after 2 years, showing benefit over glimepiride, with lower hypoglycaemic risk.



Data are for 2-year completers; n=321

Background and aims: Albiglutide (ALB) consists of a DPP-4-resistant human GLP-1 dimer fused to human albumin resulting in a pharmacokinetic half-life of ~5 days that allows the potential for weekly or less-frequent dosing. This study was conducted to establish optimal ALB dose and schedule for Phase 3 trials and to assess glycemic responses and adverse events (AEs). Open-label exenatide (Ex) was used as a reference arm. The overall population is reported, and an exploratory analysis examined efficacy and tolerability of ALB in subjects previously treated with only metformin (MET), to compare treatment effects vs Ex used per label.
Materials and methods: In this randomized, multicenter, double-blind, parallel-group, Phase 2 study, 356 subjects (mean age 54 years, BMI 32.1 kg/m^2) with type 2 diabetes inadequately controlled (mean HbA_{1c} 8.0%) on diet/exercise or MET received subcutaneous placebo (PBO), ALB [weekly (4, 15 or 30 mg), biweekly (15, 30 or 50 mg) or monthly (50 or 100 mg)] or open-label Ex twice daily (on MET background, per label) for 16 weeks.
Results: Across ALB groups and PBO, 65.6-74.3% received background MET. After 16 weeks, background MET subjects experienced fasting plasma glucose (FPG) reductions of -1.26, -2.10, -1.80 and -0.07 mmol/L for the 30 mg weekly, 50 mg biweekly and 100 mg monthly doses of ALB and PBO, respectively, vs -1.44, -1.32, -1.22 and -0.10 mmol/L, respectively, for the overall population. Ex decreased FPG by -0.80 mmol/L.
In MET subjects, the highest ALB doses in each dose schedule significantly reduced HbA_{1c} similarly over 16 weeks: ALB 30 mg weekly, 0.78%; ALB 50 mg biweekly -0.83%; and ALB 100 mg monthly -0.77% vs PBO (-0.05%, $p < 0.05$); Ex reduced HbA_{1c} by -0.54%. In the overall population, HbA_{1c} was reduced -0.87, -0.79 and -0.87% by ALB 30 mg weekly, 50 mg biweekly and 100 mg monthly dosing, respectively, vs PBO (-0.17%, $p < 0.005$).
Among MET patients, HbA_{1c} <7% was achieved by 43%, 50% and 46% of subjects receiving ALB 30 mg weekly, 50 mg biweekly and 100 mg monthly, respectively, vs 15% with PBO and 35% in the Ex group. Weight loss with ALB was observed in both the MET group (-0.4 to -2.1 kg) and in the overall population (-0.9 to -1.8 kg). Documented hypoglycemia was not increased with ALB, and most commonly reported AEs were gastrointestinal events. Rates of nausea or vomiting in MET subjects were 18.2%, 47.8% and 56.5% of patients receiving 30 mg weekly, 50 mg biweekly and 100 mg monthly doses of ALB, respectively, vs 29.0%, 54.3% and 55.9% in the overall study population. Nausea or vomiting was experienced by 45.7% in the Ex group.
Conclusion: Albiglutide was effective in patients receiving background MET and provided numerically greater HbA_{1c} and FPG reductions than did exenatide. Tolerability was most favourable with the 30 mg weekly ALB group.

Improvement in glycaemic control when adding liraglutide to existing therapy: results from a meta-analysis of six large randomised clinical trials

J.J. Holst[1], M. Nauck[2], J. Brett[3], A. Falahati[4], R. Pratley[5];
[1]Panum Institutet, Copenhagen, Denmark, [2]Diabeteszentrum, Bad Lauterberg im Harz, Germany, [3]Novo Nordisk, Princeton, United States, [4]Novo Nordisk, Copenhagen, Denmark, [5]University of Vermont College of Medicine, Burlington, United States.

Background and aims: In modern clinical practice, worsening glycaemic control associated with the progression of type 2 diabetes is usually addressed by adding additional drugs to existing therapy. Liraglutide is a once-daily human glucagon-like peptide-1 (GLP-1) analogue for the treatment of type 2 diabetes. Liraglutide was tested as monotherapy or in combination with various therapies, including lifestyle, in six randomised, controlled phase 3 trials in 4442 patients.
Materials and methods: Meta-analysis using logistic regression of the subset of patients who maintained their pre-trial regimen of oral antidiabetic drugs during these trials (n=1683) examined the efficacy of combining liraglutide with existing therapy. Only those patients who maintained their pre-trial regimen, and added liraglutide, were included. Existing therapy was diet and exercise in one trial, metformin in one trial, SU in one trial, metformin+SU in two trials and metformin+TZD in one trial. Impact on glycaemic control, body weight (BW) and systolic blood pressure (SBP) was assessed for liraglutide 1.8 mg, liraglutide 1.2 mg, and placebo.
Results: ANCOVA analysis of the improvements in HbA_{1c} from baseline for liraglutide 1.8 and 1.2 mg as add-on to prior treatment showed reductions of 1.5% and 1.3%, respectively ($p<0.0001$ for both). In the placebo group, HbA_{1c} was reduced from baseline by 0.3% ($p=0.0008$). As add-on therapy compared to placebo, liraglutide 1.8 mg and 1.2 mg reduced HbA_{1c} by 1.2% and 1.0%, respectively ($p<0.0001$ for both). The proportion of subjects (with 95% CIs) reaching target HbA_{1c}<7% with add-on therapy was 71% [65%; 75%] for liraglutide 1.8 mg; 59% [51%; 67%] for liraglutide 1.2 mg; and 18% [12%; 26%] for placebo. The odds-ratios of reaching target HbA_{1c} <7% with add-on therapy for liraglutide 1.2 mg vs placebo was 6.6 ($p<0.0001$), and for liraglutide 1.8 mg vs placebo was 11.1 ($p<0.0001$). The odds ratio of reaching target HbA_{1c} <7% for liraglutide 1.8 mg vs liraglutide 1.2 mg was 1.7 ($p=0.0202$). FPG was improved by 1.8 mmol/L with liraglutide 1.8 mg, and 1.7 mmol/L with liraglutide 1.2 mg, while an increase of 0.5 mmol/L was observed for placebo. Body weight was reduced by 2.2 kg for liraglutide 1.8 mg, 1.4 kg for liraglutide 1.2 mg, and 0.4 kg for placebo. SBP improved by 2.9 mmHg with liraglutide 1.8 mg, by 1.4 mmHg with liraglutide 1.2 mg, and by 0.4 mmHg with placebo.
Conclusion: When added to existing treatment as per clinical practice, greater improvement in glycaemic control was achieved for liraglutide than previously reported from individual trials where background medication was changed for many subjects.

Comparison of liraglutide with placebo, as add-on therapy (summary statistics)

		HbA_{1c} (%)	FPG (mmol/L)	BW (kg)	SBP (mmHg)
Liraglutide 1.8 mg	Baseline	8.3	9.6	90.0	132.0
	End of trial	7.0	7.7	88.0	129.0
	Change	-1.4	-1.8	-2.2	-2.9
Liraglutide 1.2 mg	Baseline	8.3	9.5	89.3	128.6
	End of trial	7.1	7.7	88.1	127.0
	Change	-1.3	-1.7	-1.4	-1.4
Placebo	Baseline	8.3	9.3	89.1	132.4
	End of trial	8.0	9.8	88.7	131.8
	Change	-0.3	0.5	-0.4	-0.4

Add-on group includes subjects on prior SU in LEAD 1, prior met in LEAD 2, prior diet/exercise in LEAD 3, prior met and TZD in LEAD 4, prior met and SU in LEAD 5, and all subjects in LEAD 6. Data are ITT LOCF.

Liraglutide, a human GLP-1 analogue, lowers HbA_{1c} independent of weight loss

W.E. Schmidt[1], S. Gough[2], S. Madsbad[3], B. Zinman[4], A. Falahati[5], A.D. Toft[5], G. Sesti[6];
[1]Dept. of Medicine I, St. Josef-Hospital, Bochum, Germany, [2]University of Birmingham, United Kingdom, [3]University Hospital, Hvidovre, Denmark, [4]University of Toronto, Canada, [5]Novo Nordisk, Bagsvaerd, Denmark, [6]University Magna Graecia of Catanzaro, Italy.

Background and aims: GLP-1 receptor agonists offer the potential to both improve glycaemic control and promote weight loss. Weight loss is known to improve glycaemic control in people with type 2 diabetes. The objective of this meta-analysis comparing reductions in HbA_{1c} with liraglutide 1.8 mg daily and placebo was to investigate whether improvements in HbA_{1c} induced by liraglutide were independent or dependent on concomitant weight loss.
Materials and methods: A meta-analysis of six phase 3 randomised controlled trials (RCT) including 2739 patients with type 2 diabetes compared HbA_{1c} reductions among patients in different categories of weight change from baseline (weight gain, weight loss ≥0 to ≤3%, weight loss >3 to ≤5%, and weight loss >5%), following treatment with liraglutide 1.8 mg once daily or placebo. HbA_{1c} reductions and weight changes were assessed at 26 weeks in all trials.
Results: Seventy-six per cent of patients treated with liraglutide lost weight from baseline compared with 60% in the placebo group. Greater than 5% weight loss occurred in 24% of patients in the liraglutide group and 10% of patients in the placebo group. Weight loss of >3% to ≤5% occurred in 17% and 13% of patients in the liraglutide and placebo groups, respectively. A similar percentage of patients in both groups had weight change from baseline of 0 to 3% (35% with liraglutide and 37% with placebo). Liraglutide induced statistically and clinically significant reductions in least-squared (LS)-mean HbA_{1c} from baseline of between 1.29% and 1.65% in all weight change groups compared with reductions of 0.16% to 0.70% in the placebo group ($p < 0.0001$) (Figure 1). The effect of liraglutide on change in HbA_{1c} was independent of weight loss category ($p = 0.71$).
Conclusion: A greater percentage of patients treated with liraglutide lost weight from baseline compared with placebo and almost a quarter of patients treated with liraglutide experienced >5% weight loss. Liraglutide treatment also induced significantly greater reductions in HbA_{1c} compared with placebo across all weight loss categories. HbA_{1c} change with liraglutide was independent of weight loss category.

Exenatide compared with long acting insulin to achieve glycaemic control with minimal weight gain in patients with type 2 diabetes mellitus: results of the Helping Evaluate Exenatide in patients with diabetes compared to Long-Acting insulin (HEELA) study

M.J. Davies[1], R. Donnelly[2], A.H. Barnett[3], S. Jones[4], C. Nicolay[5], A. Kilcoyne[6];
[1]Department of Cardiovascular Sciences, University of Leicester, United Kingdom, [2]School of Graduate-Entry Medicine & Health, University of Nottingham, United Kingdom, [3]Division of Medical Sciences, University of Birmingham and Heart of England NHS Foundation Trust, United Kingdom, [4]The Academic Centre, James Cook University Hospital, Middlesbrough, United Kingdom, [5]European Medical Department, Eli Lilly GmbH, Bad Homburg, Germany, [6]Medical Department, Eli Lilly & Co. Ltd., Basingstoke, United Kingdom.

Many add-on therapies for glycaemic control in patients with T2DM are associated with weight gain. The HEELA study was designed to examine whether the GLP-1 receptor agonist, exenatide, could provide better control of HbA1c and weight than basal insulin glargine for 26 weeks. Overweight patients with at least one other cardiovascular risk factor (previous cardiovascular event, peripheral vascular disease, abnormal lipids or blood pressure) and T2DM inadequately controlled with 2 or 3 OADs were randomised to add-on exenatide 10 µg b.i.d. (n=118) or insulin glargine o.d. (n=117; median final dose 34.0 IU/day). Patients had overall mean (SD) age 56.5 (9.1) years, HbA1c 8.57 (0.67)% and BMI 34.1 (5.3) kg/m^2 at baseline, and 58.5% were taking 2 OADs. The proportion of patients achieving HbA1c ≤7.4% with weight gain ≤1 kg was greater in the exenatide group (53.4%) than the insulin glargine group (19.8%, P<0.001). Improvements in LS mean [SEM] HbA1c following treatment with exenatide (-1.25 [0.09]%) and insulin glargine (-1.26 [0.09]%, P=0.924) were similar. In contrast, mean body weight decreased with exenatide but increased during insulin glargine treatment. The between-group difference in weight changes was significant after 4 weeks (P<0.001) and was maintained to 26 weeks (-5.71 [0.44] kg, 95%CI: -6.58 to -4.84 kg, P<0.001). Treatments did not differ in overall or severe hypoglycaemia, but nocturnal hypoglycaemia incidence was lower with exenatide. In overweight patients with T2DM and cardiovascular risk factors, additional exenatide treatment resulted in significantly more patients achieving better glycaemic control with minimal weight gain compared with insulin glargine.

DURATION-2: exenatide once weekly demonstrated superior glycaemic control and weight reduction compared to sitagliptin or pioglitazone after 26 weeks of treatment

C. Wysham[1], R. Bergenstal[2], P. Yan[3], L. MacConell[3], J. Malloy[3], L. Porter[3];
[1]Rockwood Clinic, Spokane, [2]International Diabetes Center, Minneapolis, [3]Amylin Pharmaceuticals, Inc., San Diego, United States.

Background and aims: The once weekly GLP-1 receptor agonist exenatide (EQW) has demonstrated sustained improvements in glycaemic control and body weight through 2 years of treatment.
Materials and methods: DURATION-2, a randomised, double-blind, double-dummy, 26-week study, compared the efficacy, safety, and tolerability of weekly treatment with EQW (2 mg; n=160) to maximum daily doses of a DPP-4 inhibitor (sitagliptin 100 mg; n=166) or a TZD (pioglitazone 45 mg; n=165) in patients with type 2 diabetes on a stable metformin background (ITT N=491; A1C 8.5±1.1%, FPG 9.1±2.6 mmol/L, weight 88.0±20.1 kg).
Results: EQW produced a clinically and statistically superior reduction in HbA_{1c} compared to both sitagliptin and pioglitazone that was first evident at Week 6. A significantly greater proportion of EQW patients achieved HbA_{1c} targets of ≤7.0% and ≤6.5%. EQW resulted in significantly greater weight loss versus sitagliptin from Week 4 through Week 26; patients on pioglitazone gained weight (+5.1 kg weight difference vs. EQW at Week 26). Significant improvements from baseline in systolic BP, albumin:creatinine, hsCRP, BNP, and adiponectin were observed with EQW; improvements in hsCRP and adiponectin also occurred with sitagliptin and pioglitazone. All treatments were generally well tolerated, with over 80% of patients completing the trial. Nausea was transient and predominantly mild (24% EQW; 10% sitagliptin; 5% pioglitazone; 1 withdrawal due to nausea in each treatment arm). No major hypoglycaemia was observed. Pancreatitis, including one case of necrotising pancreatitis, occurred in 2 patients treated with pioglitazone; no EQW patients experienced pancreatitis.
Conclusion: Once weekly treatment with exenatide was well tolerated and elicited superior improvements in glucose control and body weight compared to maximum daily doses of sitagliptin and pioglitazone on a background of metformin.

Week 26	Exenatide QW	Sitagliptin	Pioglitazone
Δ HbA_{1c} (%)	-1.55±0.10	-0.92±0.10*	-1.23±0.10*
% to HbA_{1c} ≤7.0 / ≤6.5%	66 / 43	42*/ 18*	56*/ 33*
Δ FPG (mmol/L)	-1.8±0.2	-0.9±0.2*	-1.5±0.2
Δ Body Weight (%)	-2.7±0.4	-0.9±0.4*	+3.2±0.4*

Can the glycaemic effect of incretin mimetics be predicted prior to therapeutic application?

E. Salzsieder[1], L. Vogt[2], K.-D. Kohnert[1], P. Heinke[1], G. Fritsche[1], P. Augstein[1];
[1]Institute of Diabetes Karlsburg, [2]Diabetes Service Center Karlsburg, Germany.

Background and aims: Incretin mimetics are a new class of antihyperglycaemic agents that have the possibility to improve glycaemic control similar to natural incretin hormones. Exenatide, the first incretin mimetic on the market, mediates the re-establishment of glucose-dependent insulin secretion, suppression of elevated postprandial glucagon secretion, and slowing of gastric emptying. Initial application of Exenatide has also demonstrated that some patients meet the expected effects on glycaemic control but others failed. At present, no pre-clinical method is available to predict low or high Exenatide responders. It was therefore the aim of this project to develop and to verify a method allowing identification of low or high responders prior to the therapeutic application of incretin mimetics.
Materials and methods: The Karlsburg Diabetes-Management System KADIS® was used to develop an *in silico* method for outcome prediction of therapeutic application of the incretin mimetic Exenatide. For this purpose, KADIS® was adapted to the special requirements needed to meet the aim of this study. The modified KADIS®-supported program comprises: (1) continuous glucose monitoring (CGM) which was performed first in each study patient; (2) KADIS®-based identification of the current individual metabolic situation of each patient; (3) *in silico* testing of the metabolic effect of the application of 20µg Exenatide on the 24-h glycaemic pattern; (4) estimation of an Exenatide equivalence factor by replacing *in silico* Exenatide by a long acting insulin and titration of the insulin dose required to achieve the same blood glucose lowering effect as Exenatide; (5) relating the patients to high or low responders according to the estimated Exenatide equivalence factor of insulin action. To verify the proposed procedure, 58 non-insulin treated type 2 diabetic patients were involved into the study.
Results: The overall glycaemic lowering effect of 20µg Exenatide was estimated to be 0.81± 0.50 mmol/l and equals an insulin dose of 12.6 ±4.8 IU. 41% of the study patients could be identified to be high responders (equivalence factor of insulin action >12.6 IU) to an Exenatide therapy and 59% were low responders (equivalence factor of insulin action <12.6 IU). In the group of high responders the mean daily glucose pattern (MBG) dropped down by 1.15 ±0.57 mmol/l which equals an insulin dose of 17.2 ±3.2 IU, whereas in the group of low responders the MBG dropped down by 0.57 ±0.23 mmol/l which equals an insulin effect of 9.3 ±2.6 IU. In the group of high responders to an Exenatide therapy a higher BMI (31.4 vs. 28.5 kg/m^2), an enhanced endogenous insulin supply (62.2 vs. 49.7 IU/day), and a higher HbA1c (6.7 vs. 6.2%) was observed at baseline.
Conclusion: The metabolic effect of an Exenatide therapy can be predicted prior to therapeutic application by using CGM in combination with KADIS®-based *in silico* simulation strategy.

Association of British Clinical Diabetologists (ABCD) nationwide exenatide audit

R.E.J. Ryder[1], C. Walton[2], P.H. Winocour[3], ABCD nationwide exenatide audit contributors;
[1]City Hospital, Birmingham, [2]Hull Royal Infirmary, [3]Queen Elizabeth II Hospital, Welwyn Garden City, United Kingdom.

Background and aims: In December 2008, 18 months after the launch of exenatide in the UK, ABCD launched a 9 month project to accelerate understanding of the new agent, through a nationwide audit of its use in real clinical practise.
Materials and methods: A password protected on-line questionnaire for collection of anonymised patient data. Diabetes specialists in the UK were given persistent email encouragement to submit their data.
Results: There has been a dramatic response such that already we have data promised on 7559, data submitted on 5313 and data available for analysis on 3913 patients (mean (+/- SD) age 54.6 (+/-10.4) years, 2167/3913 (55.4%) male), with all these numbers rising relentlessly. First analysis of the data thus far showed that in response to exenatide mean (+/- SD) HbA1c, weight and body mass index fell as follows: HbA1c by 0.75 from 9.42 (+/- 1.19) to 8.65 (+/- 1.22)% ($p<10^{-126}$), weight by 4.9 from 114 (+/- 23.3) to 109.1 (+/- 22.6) kg ($p<10^{-15}$), BMI by 1.74 from 39.89 (+/- 7.5) to 38.15 (+/-7.24) kg/m^2 ($p<10^{-16}$). The weight reduction was variable with some patients showing dramatic response (see figure). A similar wide variability in HbA1c response was observed. Factors accounting for variability in weight response included: patients with osmotic symptoms who increased weight as exenatide controlled glycaemia; patients in whom discontinuation or reduction of insulin, glitazones and/or sulphonylureas contributed to weight loss. Factors accounting for variability in HbA1c response included: patients in whom discontinuation or reduction of other antidiabetic drugs led to worsening glycaemic control; patients with dramatic weight loss and concurrent dramatic reduction in HbA1c. Other reported benefits included return of ovulation in polycystic ovary syndrome and improvement in obstructive sleep apnoea. Gastrointestinal side effects were reported in 1122/3913 (28.7%) (transient in 773/3913 (19.7%), stopped exenatide temporarily in 67/3913 (1.7%), stopped exenatide permanently in 282/3913 (7.2%)). 1763/3913 (45%) patients were on insulin prior to exenatide. Hypoglycaemia rate increased from 104/3913 (2.7%) prior to 177/3913 (4.5%) after exenatide. 7/3913 (0.18%) cases of pancreatitis were reported.
Conclusion: The ABCD nationwide exenatide audit has already generated a very substantial clinical database which is expanding rapidly. First analysis has revealed responders and non responders and that the responses are very varied but sometimes dramatic. The 9 month project is scheduled to finish by September 2009. Further detailed analysis of the expanding database will be undertaken to define the factors associated with different degrees of response, and the extent to which factors such as change in medication, initial weight, BMI and HbA1c, and duration of diabetes contribute to response. Detailed analsis of the response against time and cases of pancreatitis will also be performed.

Difference between last weight after exenatide and weight before exenatide in 2977 patients

A phase I/II study of the safety, pharmacokinetics and pharmacodynamics of albiglutide in Japanese subjects with type 2 diabetes

M.A. Bush[1], H. Nakajima[2], H. Miyahara[2], T. Kurita[2], F. Yang[3], M.W. Stewart[3], Y. Seino[4];
[1]GlaxoSmithKline, Research Triangle Park, United States, [2]GlaxoSmithKline, Tokyo, Japan, [3]GlaxoSmithKline, King Of Prussia, United States, [4]Kansai Electric Hospital, Osaka, Japan.

Background and aims: Albiglutide is a long-acting GLP-1-receptor agonist shown to improve indices of glycemia in white and Hispanic populations when dosed weekly, once every other week (biweekly) and monthly. The aim of this study was to assess the pharmacokinetics, pharmacodynamics, and safety and tolerability of albiglutide in Japanese subjects with type 2 diabetes.
Materials and methods: A 28-day, single-blind, randomized, placebo-controlled study was conducted. A total of 40 subjects (mean age 54.5 years, BMI 24.5 kg/m^2, HbA_{1c} range 6.3-10.3%) were given (subcutaneous, to the abdomen) placebo or albiglutide in the following doses: 15 mg or 30 mg once weekly; 50 mg biweekly; or 100 mg monthly.
Results: Albiglutide had a plasma half life of 5.3 d, systemic clearance (CL/F) of 68.7 mL/hr and volume of distribution (V/F) of 12.6 L. Albiglutide was generally well-tolerated; GI events were comparable with placebo in all doses except 100 mg monthly and were numerically lowest in the 30 mg weekly group. In the 100 mg monthly group, the most common adverse events (AEs) were flatulence (n=3, 38%), vomiting (n=3, 38%) and nausea (n=2, 25%). No serious AEs were reported. Fasting plasma glucose (FPG) and weighted mean glucose AUC_{0-4} were improved as early as day 3. At day 29, all doses of albiglutide except 100 mg monthly significantly reduced FPG and weighted mean glucose AUC_{0-4} from baseline, compared with placebo; all doses significantly reduced HbA_{1c}. At the day 43 follow-up visit, albiglutide also significantly reduced FPG (all doses except 100 mg monthly) and HbA_{1c} (all doses) compared with placebo.

	Albiglutide Dose			
Placebo-adjusted change from baseline (LS Means Difference)	15mg Weekly (n=8)	30mg Weekly (n=8)	50mg Biweekly (n=8)	100mg Monthly (n=8)
FPG (day 3), mmol/L	-0.85	-0.98*	-1.33*	-0.97
FPG (day 29), mmol/L	-1.91*	-1.98*	-1.74*	-0.73
FPG (day 43), mmol/L	-1.43*	-1.16*	-1.18*	-0.29
AUC_{0-4} glucose, mmol/L (day 29)	-2.86*	-3.58*	-2.51*	-1.44
HbA_{1c}, % (day 29/43)	-0.58*/ -0.87*	-0.57*/ -0.78*	-0.63*/ -0.79*	-0.51*/ -0.59*

*p < 0.05 vs placebo

Conclusion: Weekly or biweekly doses of albiglutide significantly improved glycemic control, with a favorable safety and tolerability profile, in Japanese subjects with type 2 diabetes.

Attaining a clinically relevant endpoint of HbA_{1c}<7.0%, no weight gain and no hypoglycaemia with liraglutide as compared to other therapies in type 2 diabetes mellitus: meta-analysis of the LEAD studies

B. Zinman[1], J. Buse[2], A. Falahati[3], A. Moses[4];
[1]Mount Sinai Hospital, Toronto, Canada, [2]University of North Carolina Medical School, Chapel Hill, United States, [3]Novo Nordisk A/S, Bagsvaerd, Denmark, [4]Novo Nordisk Inc, Princeton, United States.

Background and aims: Therapies for type 2 diabetes mellitus (T2DM) commonly are associated with undesirable hypoglycaemia and weight gain, limiting success in achieving HbA_{1c} clinical practice recommendations. In this context we conducted a post-hoc meta-analysis of 6 large randomised controlled trials of liraglutide, a human GLP-1 receptor agonist, versus other diabetes therapies to determine the proportions of subjects achieving a composite endpoint: HbA_{1c} <7.0% with no major or minor hypoglycaemia and no weight gain.
Materials and methods: The meta-analysis was performed on 26-week data from the six LEAD (Liraglutide Effect and Action in Diabetes) trials

(n=3967), which compared liraglutide as follows: liraglutide vs glimepiride (GLM) as monotherapy; liraglutide +metformin (MET) vs GLM+MET; liraglutide + GLM vs rosiglitazone (ROS)+GLM; liraglutide +ROS + MET vs placebo + ROS + MET; liraglutide + MET + GLM vs insulin glargine + MET + GLM; liraglutide + MET and/or GLM vs exenatide + MET and/or GLM. Analyses were ITT and LOCF, and results were adjusted for baseline HbA1c and weight.

Results: At 26 weeks, the composite target was achieved by 42% of the liraglutide 1.8 mg group, 35% of the liraglutide 1.2 mg and 6-27% of those treated with comparators (Figure). Odds ratios (p values) for reaching the composite endpoint with liraglutide 1.8 mg vs comparators were as follows: vs liraglutide 1.2 mg, 1.38 (0.0047); ROS, 11.15 (<0.0001); GLM, 6.05 (<0.0001); glargine, 4.22 (<0.0001); exenatide, 1.96 (0.0067); and placebo, 7.87 (<0.0001). For liraglutide 1.2 mg, odds ratios (p values) for reaching the composite endpoint were as follows vs competitors: vs ROS, 8.06 (<0.0001); GLM, 4.37 (<0.0001); and placebo, 5.68 (p<0.0001).

Conclusion: The composite endpoint reflects three clinically relevant outcomes in T2DM (HbA1c, weight control and hypoglycaemia). The odds of reaching this composite endpoint were significantly increased with the GLP-1 receptor agonist liraglutide. These observations provide clinically relevant information for selecting pharmacotherapies for T2DM.

The human GLP-1 analogue liraglutide given once daily provides excellent metabolic control in Japanese patients either as monotherapy or in combination with SU during 52 weeks of treatment

Y. Seino[1], M.F. Rasmussen[2], Y. Katayama[3], K. Kaku[4];
[1]Kansai-Denryoku Hospital, Osaka, Japan, [2]Novo Nordisk, Bagsvaerd, Denmark, [3]Novo Nordisk Pharma, Tokyo, Japan, [4]Kawasaki Medical School, Okayama, Japan.

Background and aims: Liraglutide is a once daily human GLP-1 analogue. To investigate its safety and efficacy in Japanese subjects with type 2 diabetes, two large phase 3 trials were performed.

Materials and methods: The first trial (trial A) compared liraglutide 0.9 mg (n=268) vs. glibenclamide 1.25-2.5 mg (n=139), both as monotherapy. The second trial (trial B) compared liraglutide 0.6 mg or 0.9 mg in combination with sulphonylurea (SU) vs SU monotherapy (n=88 all groups). The trials consisted of a 24-week double blind part followed by a 28-week unblinded part.

Results: In trial A HbA_{1c} decreased from baseline by 1.48±1.12% in the liraglutide group vs. 0.95±1.06% in the glibenclamide group, the difference being -0.49% [-0.71, -0.27] after 52 weeks of treatment. The percentage of patients reaching HbA_{1c} <7.0% was significantly greater for liraglutide (36.9%) compared to glibenclamide (18.2%). In trial B the corresponding decrease from baseline was 1.09±0.84 (liraglutide 0.6 mg); 1.30±0.91 (liraglutide 0.9 mg) and 0.06±1.29 (SU); the difference (liraglutide vs SU) being -0.96% [-1.25, -0.67] and -1.33% [-1.62, -1.04], respectively. More patients reached HbA_{1C} <7.0% with liraglutide (0.6 mg: 46.5%, 0.9 mg: 70.5%) vs SU (14.8%) Fasting plasma glucose (PG) and 7-point profiles showed that mean PG and mean PG increments were lower with liraglutide in both trials. Beta-cell function measured as pro-insulin/insulin and pro-insulin/C-peptide was improved in both trials for patients treated with liraglutide. The liraglutide safety profiles in the two trials did not raise any concerns. In both trials more subjects reported AEs from the GI tract during the first 4 weeks of the trials; however after 4 weeks the GI-related AEs were at comparator level. No major hypoglycaemic events were reported in the two trials. In trial A patients on liraglutide experienced 0.7 hypoglycaemic episodes per patient year, vs 3.8 in the glibenclamide group. In combination with SU (trial B) the rates were similar in the groups (3.1 vs 3.7 vs 3.0 episodes/patient year); however in the period from 24 to 52 weeks the rates in the liraglutide groups were lower than those in the SU group. Despite markedly improved glycaemic control, liraglutide in both trials was weight-neutral. Approximately 15% of patients treated with liraglutide developed liraglutide antibodies in the two trials. Antibodies did not have an influence on HbA_{1c} and the mean decrease in HbA_{1c} in both trials was similar in patients with antibodies as in the entire group.

Conclusion: Once-daily administration of liraglutide as monotherapy provided safe and sustained metabolic control superior to glibenclamide without causing weight gain and low frequency of hypoglycaemia. Addition of liraglutide in people poorly controlled with SU further improves and sustains glycaemic control in a dose-dependent manner. Both trials demonstrate improved beta-cell function with liraglutide and significant long-term clinical benefit in typical Japanese patients with type 2 diabetes.

DURATION 2: weight-related quality of life, psychological well-being, and satisfaction with exenatide once weekly compared to sitagliptin or piaglitazone after 26 weeks of treatment

J.H. Best, P. Yan, J. Malloy;
Medical Affairs, Amylin Pharmaceuticals, San Diego, United States.

Background and aims: In this 26-week randomised, double-blind, double-dummy study, patients (ITT N=491) with type 2 diabetes on a stable metformin background received once weekly exenatide (exenatide QW 2 mg; n=160), or maximum daily doses of sitagliptin (100 mg; n=166) or pioglitazone (45 mg; n=165). Weight-related quality of life (QOL), psychological general well being, diabetes treatment satisfaction, and general health status were assessed using the Impact of Weight on Quality of Life Questionnaire-Lite (IWQOL), Psychological General Well-being (PGWB) index, Diabetes Treatment Satisfaction (DTSQ), and EQ-5D at Baseline (BL) and Week 26.

Materials and methods: The ANCOVA model was used to estimate least squares (LS) mean group changes in IWQOL, PGWB, DTSQ, or EQ-5D from BL to Week 26 and compare the treatment effects between groups. The model included factors for treatment group, country, HbA_{1c} stratum (<9% vs. ≥9%), and baseline score for IWQOL, PGWB, DTSQ, or EQ-5D as a covariate.

Results: Exenatide QW produced a statistically superior reduction (%±SE) in HbA_{1c} (-1.55±0.10) versus sitagliptin (-0.92±0.10) and pioglitazone (-1.23±0.10). Exenatide QW resulted in significantly greater weight loss (-2.7%±0.4) versus sitagliptin (-0.9%±0.4) and pioglitazone (+3.2%±0.4). Exenatide QW and sitagliptin groups experienced significant improvement in all five domains of weight-related QOL (physical function, self-esteem, sexual life, public distress, work) and IWQOL total score, with no significant differences between exenatide QW and sitagliptin. The pioglitazone group significantly improved only on self-esteem. The exenatide QW group experienced significantly greater improvement in physical function, public distress, work, and total IWQOL score versus pioglitazone. All groups experienced significant improvements in all six domains of the PGWB (anxiety, depressed mood, positive well-being, self-control, general health, and vitality) and on the PGWB global scale, as well as in overall treatment satisfaction. The exenatide QW group experienced significantly greater improvement in overall treatment satisfaction versus sitagliptin. Patients in the exenatide QW and sitagliptin groups experienced significant improvements in overall health status.

Conclusion: Exenatide QW resulted in superior improvements in glucose control and body weight compared to sitagliptin and pioglitazone on a background of metformin. Patients on exenatide QW and sitagliptin experienced significant improvement on all domains of weight-related QOL. Significant improvements in weight-related QOL were observed for exenatide QW versus pioglitazone, consistent with differences in body weight change. All

groups experienced significant improvement in all domains of psychological general well-being and overall treatment satisfaction; greater improvement in overall treatment satisfaction was observed with exenatide QW versus sitagliptin.

Parameter	Exenatide QW	Sitagliptin	Pioglitazone
Baseline IWQOL total score	80.67 ± 1.51	80.74 ± 1.49	79.32 ± 1.50
Δ IWQOL total score	5.15 ± 1.04*	4.56 ± 1.02*	1.20 ± 1.06†
Δ Physical function	6.78 ± 1.35*	5.81 ± 1.33*	2.00 ± 1.38†
Δ Self-esteem	5.88 ± 1.39*	5.79 ± 1.36*	3.11 ± 1.41*
Δ Sexual life	5.80 ± 1.61*	5.02 ± 1.61*	2.41 ± 1.63
Δ Public distress	3.86 ± 1.17*	2.40 ± 1.14*	-0.63 ± 1.18†
Δ Work	2.79 ± 1.28*	3.02 ± 1.25*	-1.28 ± 1.29†
Baseline PGWB global score	67.54 ± 1.38	69.96 ± 1.30	71.60 ± 1.16
Δ PGWB global score	6.82 ± 1.00*	6.97 ± 0.98*	4.78 ± 1.02*

ITT LS mean change ± SE; positive scores indicate improvement on all domains and items of the PGWB and IWQOL.
*P<0.05 for Baseline to Week 26.
†P<0.05 vs. Exenatide QW.

Glycaemic outcomes following initiation of insulin glargine or exenatide in type 2 diabetes patients treated with oral agents in US

R. Bhushan[1], J. Rosenstock[2], M.-P. Dain[3], M. Bhushan[1], P. Home[4]; [1]Metabolic Center of Louisiana, Baton Rouge, United States, [2]Dallas Diabetes and Endocrine Center, Dallas, United States, [3]sanofi-aventis, La Garenne Colombes, France, [4]Newcastle University, Newcastle upon Tyne, United Kingdom.

Background and aims: Randomized controlled trials can demonstrate the safety and efficacy of glucose-lowering agents in specific populations under well-defined circumstances for regulatory purposes, but assessing these agents in general clinical practice remains challenging.
Materials and methods: We analyzed US managed care databases of 47 health plans from May 2005 to September 2007 to evaluate therapeutic outcomes after initiating insulin glargine (GLAR, n=15,695) or exenatide (EX, n=21,516) in patients previously treated with only oral antidiabetic drugs (OADs).
Results: Baseline characteristics (6 months prior to study initiation) for GLAR vs EX, respectively, were as follows: mean age, 54 vs 53 years; female, 43% vs 54%; glycated hemoglobin A1C (A1C), 9.5% vs 7.9%; and rate of hypoglycemia on OAD only, 4.8% vs 2.7%. Of note, 16% on GLAR vs 31% on EX visited an endocrinologist at baseline. The unadjusted change in A1C 1 year after initiation was -1.22% for GLAR vs -0.41% for EX (P<0.001). The medication discontinuation rate at any time following initiation was 37% for GLAR and 50% for EX (P<0.001). One year after initiation, 11% of EX patients started insulin and 5% of GLAR patients started EX. In patients without (n=35,877) and with (n=1,334) hypoglycemia at baseline, respectively, the 1-year incidence of hypoglycemia was 6% vs 3% (odds ratio [OR] = 1.97, P<0.001) and 35% vs 43% (OR=0.71, P=0.003) for GLAR vs EX. The 1-year adjusted A1C was 7.2% vs 7.8% (Δ=0.6%, P<0.001) for GLAR (n=2,117) vs EX (n=3,450), after multivariable adjustment for age, sex, baseline A1C, hypoglycemia, hospitalization, Charlson comorbidity score, statin use, concomitant medications and timing of A1C measurement. The Figure shows increased glycemic benefits with higher baseline A1C in patients initiated GLAR instead of EX. Specifically, the higher the baseline A1C the greater the difference in adjusted A1C between the groups during the period of 1 year follow-up.
Conclusion: Although a seemingly apparent choice of therapy as a function of baseline A1C level, this study suggests that initiation of GLAR relative to EX was associated with a lower and better adjusted 1-year A1C after controlling for the baseline A1C and additional confounding factors. However, these results should be interpreted with caution, as GLAR or EX appeared to be used in different populations.

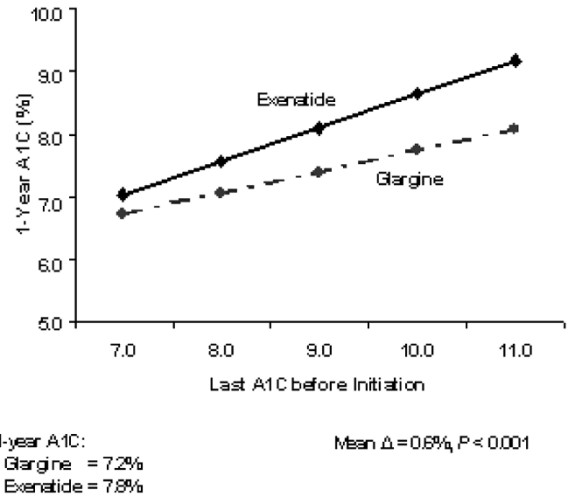

Figure 1: Adjusted 1-year A1C after Initiation of Glargine or Exenatide

Initial combination therapy with sitagliptin and pioglitazone improves glycaemic control and measures of beta cell function compared with pioglitazone alone in patients with type 2 diabetes

K. Yoon[1], G. Shockey[2], R. Teng[3], G. Golm[3], P. Thakkar[3], A. Meehan[3], D. Williams-Herman[3], K. Kaufman[3], J. Amatruda[3], H. Steinberg[3];
[1]Catholic Univ of Korea, Seoul, Republic of Korea, [2]Desert Clinical Research LLC, Mesa, United States, [3]Merck, Rahway, United States.

Background and aims: Initial combination therapy with sitagliptin (SITA) + pioglitazone (PIO) was compared with PIO alone in drug-naïve patients (pts) (HbA1c 8-12%) with type 2 diabetes.
Materials and methods: After a 2-week single-blind placebo run-in, 520 pts (mean baseline HbA1c=9.5%) were randomized (1:1) to SITA 100 mg q.d.+ PIO 30 mg q.d. or PIO 30 mg q.d. monotherapy for 24 weeks.
Results: Initial treatment with SITA+PIO led to a reduction from baseline in HbA1c of -2.4% compared with -1.5% with PIO monotherapy (between-group difference for SITA+PIO vs. PIO -0.9%;p<0.001). A greater HbA1c reduction was observed in pts with a baseline HbA1c ≥10% (change from baseline with SITA+PIO -3.0% vs. -2.1% with PIO). Significantly more pts in the SITA+PIO group vs. PIO group had an HbA1c of <7% at Wk 24 (60% vs. 28%, respectively;p<0.001). Fasting plasma glucose was reduced by -63.0 mg/dL with SITA+PIO compared to -40.2 mg/dL with PIO monotherapy (between-group difference SITA+PIO vs. PIO -22.8 mg/dL;p<0.001), and 2-hr post meal glucose was reduced by -113.6 mg/dL with SITA+PIO compared to -68.9 mg/dL with PIO (between-group difference SITA+PIO vs. PIO -44.7 mg/dL;p<0.001). Regarding measures related to β-cell function, the insulinogenic index and the postprandial proinsulin/insulin ratio were significantly improved with SITA+PIO vs. PIO (p≤0.001). Additionally, in response to a meal challenge, the areas under the curves for glucose, insulin, and C-peptide were significantly improved with SITA+PIO vs. PIO monotherapy (p<0.05 for all parameters). SITA+PIO was generally well tolerated compared with PIO monotherapy, with similar incidences of hypoglycemia (1.1% vs. 0.8%, respectively), gastrointestinal adverse events (5.7% vs. 6.9%, respectively), and edema (2.7% vs. 3.5%, respectively).
Conclusion: In summary, initial combination therapy with sitagliptin and pioglitazone substantially improved glycemic control and was generally well tolerated compared with pioglitazone monotherapy.

748

Twelve weeks treatment with the DPP-4 inhibitor sitagliptin improves glycaemic control, but does not improve GLP-1 secretion, in patients with type 2 diabetes - a randomised trial

K. Aaboe[1], F.K. Knop[1], T. Vilsbøll[1], C.F. Deacon[2], J.J. Holst[2], S. Madsbad[3], T. Krarup[1];
[1]Department of Internal Medicine F, Gentofte Hospital, University of Copenhagen, Hellerup, [2]Department of Biomedical Sciences, The Panum Institute, University of Copenhagen, [3]Department of Endocrinology, Hvidovre Hospital, University of Copenhagen, Hvidovre, Denmark.

Background and aims: Subjects with type 2 diabetes (T2DM) have been shown to display reduced postprandial secretion of glucagon-like peptide 1 (GLP-1), possibly as a consequence of the diabetic state. We examined whether 12 weeks treatment with the dipeptidyl peptidase-4 (DPP-4) inhibitor sitagliptin would improve glycemic control and increase the postprandial response of total GLP-1. Furthermore, intact GLP-1 and total and intact glucose-dependent insulinotropic polypeptide (GIP) were examined.
Materials and methods: A double-blinded, placebo-controlled study was performed over 12 weeks, in which 24 patients with T2DM were randomized to receive either sitagliptin (Januvia®) 100 mg qd or placebo as add-on therapy to ongoing treatment with metformin (≥1000mg). In week 0, 1, and 12, subjects were examined with a 240 min standardized meal test (2,370 KJ). HbA_{1c} was measured before and after the treatment period. Intact and total (the intact hormone and the metabolite) GLP-1 and GIP responses were calculated as the area under the meal test response curves (AUC).
Results: 22 subjects (sitagliptin n=12, mean age 60 years, mean HbA_{1c} 8.3%; placebo n=10, mean age 61 years, mean HbA_{1c} 7.6%) were included in the post-study analysis. Two subjects originally randomised to placebo were excluded due to a deliberate 12% body weight loss. From week 0 to 12, sitagliptin induced a placebo-corrected reduction in HbA_{1c} of 0.9% (p=0.005). From week 0 to week 1, sitagliptin increased the levels of intact GIP 2-fold (p=0.002) and intact GLP-1 3-fold (p=0.003). In week 12, levels of intact GIP remained elevated, whereas intact GLP-1 did not (p=0.6, week 0 *vs* week 12). Sitagliptin had no effect on the levels of total GLP-1 (p=0.2) or total GIP (p=0.3) from week 0 to 12. The increases in intact GLP-1 and GIP in week 1 were significantly different from the changes in the placebo group (both p<0.001). There were no significant changes in the placebo group.
Conclusion: 12 weeks treatment with sitagliptin in subjects with T2DM significantly improved glycemic control. However, this improvement did not increase the postprandial response of total GLP-1. Sitagliptin efficacy was retained despite the fact that the plasma level of intact GLP-1 was not increased in week 12. This would suggest that factors in addition to an increase in the peripheral concentration of intact GLP-1 may contribute to the therapeutic efficacy of DPP-4 inhibitor treatment.

Initial therapy with combination alogliptin plus pioglitazone in type 2 diabetes patients inadequately controlled with diet and exercise

P. Fleck[1], S. Inzucchi[2], J. Seufert[3], C. Wilson[1], Q. Mekki[1], J. Rosenstock[4];
[1]Takeda Global Research & Development Center, Inc., Lake Forest, United States, [2]Yale University School of Medicine, New Haven, United States, [3]Schwerpunkt Endokrinologie und Diabetologie Abteilung Innere Medizin II, Freiburg, Germany, [4]Dallas Diabetes and Endocrine Center, Dallas, United States.

Background and aims: Initial combination therapy is an emerging strategy to address the multifactorial nature of T2DM from the outset. This study investigated the efficacy and tolerability of initial combination therapy with the DPP-4 inhibitor alogliptin (ALO), which improves islet cell function, and the TZD pioglitazone (PIO), which reduces insulin resistance.
Materials and methods: This randomized, double-blind study compared the effects of two doses of ALO in combination with PIO vs ALO alone and PIO alone in T2DM inadequately controlled with diet and exercise (A1C 7.5%-11%). Subjects were randomized (1:1:1:1) to ALO 25 mg/d (n=164), PIO 30 mg/d (n=163), ALO 12.5 + PIO 30 mg/d (n=164) and ALO 25 + PIO 30 mg/d (n=164). Sequential efficacy analysis on the intent-to-treat population using ANCOVA compared first ALO 25 + PIO 30 vs ALO and PIO alone and, if significant, then ALO 12.5 + PIO vs PIO alone.
Results: Mean baseline characteristics (N=655; age 53 yrs; diabetes duration 3.2 yrs; A1C 8.8%; fasting plasma glucose (FPG) 191 mg/dL; BMI 31 kg/m^2) were similar between groups. Greater improvements in the least-squares (LS) mean change from a baseline A1C 8.8% were observed in the ALO 25 + PIO (-1.71%) vs either ALO (-0.96%) or PIO (-1.15%) (P<0.001) and for ALO 12.5 + PIO (-1.56%) vs PIO (P<0.001). The decreases in A1C for both combination treatment groups vs PIO monotherapy reached statistical significance at week 4 and remained through week 26. Percentages of subjects with A1C ≤7% at study end were: 24, 34, 53 and 63% for ALO, PIO, ALO 12.5 + PIO and ALO 25 + PIO; respectively. The LS mean FPG change from baseline at Week 26 was -25.8, -37.3, -48.5, and -50.2mg/dL, for ALO, PIO, ALO 12.5 + PIO, and ALO 25 + PIO, respectively. Weight changes were -0.3kg, +2.2kg, +2.5kg and +3.1kg, respectively; edema was not increased in the ALO + PIO groups (1.2- 2.4%) compared to PIO alone (5.5%). Hypoglycemia was rare, occurring in 0.6%, 1.8%, 1.8%, and 3.0% of subjects in the four groups, respectively.
Conclusion: In conclusion, this study demonstrates the potential for initial combination therapy with ALO + PIO to significantly improve glycemic parameters beyond either monotherapy component.

Vildagliptin added to basal insulin glargine improves glycaemic control and reduces glycaemic excursions in type 2 diabetes

J. Brooks[1], V. Bravis[1,2], S. Morgenstern[1], E. Hui[1], B. Gohel[1], T. Savarananthan[1], M. Carrolls[1], D. Devendra[1,2];
[1]Diabetes and Endocrinology, Jeffrey Kelson Diabetes Centre, Central Middlesex Hospital, London, [2]Department of Investigative sciences, Imperial College, London, United Kingdom.

Background and aims: The majority of patients with Type 2 diabetes who fail to achieve adequate glycaemic control on once daily basal insulin tend to be given the option of trying twice daily mix insulins or other more inten-

sive insulin regimes. The introduction of the new class of oral hypoglycaemic agents, dipeptidyl peptidase-IV inhibitors (DPP-IV inhibitors), provides clinicians with more choices to treat patients with Type 2 diabetes, particularly in those who are obese. The aim of our audit was to evaluate the efficacy and safety of adding vildagliptin 50mg bd to patients inadequately controlled (HbA1c >8.0%) on once daily insulin glargine.
Materials and Methods: We observed 14 patients with type 2 diabetes, who were on at least 25 units of insulin glargine per day and who took at least 1g/day of metformin. Hypoglycaemic events (capillary blood glucose < 4 mmol l^{-1} and/or symptoms) were recorded 4 weeks prior to the initiation of vildagliptin. Before the addition of vildagliptin, all patients underwent 48 hours of continuous subcutaneous glucose monitoring (CSGM). Two days after the initiation of vildagliptin, patients underwent a further 48 hours of CGSM. Weight and HbA1c were recorded prior to treatment and repeated again 8 weeks after initiation of vildagliptin.
Results: Mean HbA1c prior to and 8 weeks after initiation of vildagliptin was 8.4% and 7.3% respectively. Fasting glucose reduced by 11% and post-prandial glucose reduced by 29%. The total of hypoglycaemic events was 6 in the previous 8 weeks prior to the addition of vildagliptin and a total of 7 events for 8 weeks on vildagliptin. Mean weight before and 8 weeks after initiation of vildagliptin was 83.7kg and 83.3kg respectively.
Discussion: We have demonstrated that the addition of vildagliptin to insulin glargine improves HbA1c and does not induce any significant increase in hypoglycaemia. More importantly it did not induce weight gain associated with increasing insulin dosage. The addition of vildagliptin to basal insulin therapy is an attractive option to current treatment options in people with type 2 diabetes.

751

Initial therapy with the Fixed-Dose Combination (FDC) of sitagliptin and metformin (JANUMET™) in patients with type 2 diabetes mellitus provides superior glycaemic control and HbA_{1c} goal attainment with lower rates of abdominal pain and diarrhea vs metformin alone

C.A. Reasner[1], L. Olansky[2], T. Seck[3], D. Williams-Herman[3], E. Luo[3], M. Chen[3], L. Reigle[3], Y. Ling[3], A. Levonas[3], K. Kaufman[3], B. Goldstein[3]; [1]University of Texas, San Antonio, [2]Cleveland Clinic, Cleveland, [3]Merck, Rahway, United States.

Background and aims: Initiating oral therapy with the combination of 2 agents is a potential approach to achieve earlier and more effective glycemic goal attainment.
Materials and methods: This large, multicenter, double-blind study evaluated the efficacy and safety of initial therapy with the combination of sitagliptin and metformin [SITA/MET] (administered as a FDC tablet) compared with metformin (MET) alone in drug-naïve pts with type 2 diabetes mellitus (HbA1c≥7.5%). After a 1-wk screening period, 1250 pts (mean baseline HbA1c=9.9%) were randomized 1:1 to twice-daily (BID) SITA/MET or MET for 18 wks. SITA/MET 50/500 mg BID and MET 500 mg BID was uptitrated over 4 wks to 50/1000 mg BID and 1000 mg BID, respectively.
Results: At Wk 18, mean HbA1c reductions from baseline were -2.4% (95% CI:-2.5,-2.2) for SITA/MET and -1.8% (95% CI:-1.9,-1.6) for MET alone, resulting in a significant between-group difference of -0.6% favoring SITA/MET (p<0.001). More pts in the SITA/MET group achieved an HbA1c goal of <7% vs. MET alone (49% vs. 34%; p<0.001). Reductions in fasting plasma glucose were significantly greater with SITA/MET (-69.5 mg/dL) compared with MET alone (-53.5 mg/dL) (p<0.001). A reduction from baseline in body weight of -1.6 kg (95% CI:-2.1,-1.1) was seen in each group. The incidences of overall clinical adverse experiences were similar in both groups. The incidences of hypoglycemia were low and not significantly different between the 2 groups (2.1% for SITA/MET; 1.8% for MET; p=0.686). The incidences of abdominal pain (1.1% and 3.8%, respectively; p=0.002) and diarrhea (12.0% and 16.8%, respectively; p=0.015) were significantly lower with SITA/MET vs. MET alone, while the incidences of nausea and vomiting were similar in both groups.
Conclusion: In summary, initial treatment with the combination of SITA/MET provided superior glycemic improvements, resulted in more pts achieving HbA1c goals, similar weight loss and lower incidences of abdominal pain and diarrhea vs. MET alone over 18 wks.

752

Effect of alogliptin combined with pioglitazone on glycaemic control in metformin-treated patients with type 2 diabetes

R. DeFronzo[1], C. Burant[2], P. Fleck[3], C. Wilson[3], Q. Mekki[3], R. Pratley[4]; [1]University of Texas Health Sciences Center, San Antonio, [2]University of Michigan School of Medicine, Ann Arbor, [3]Takeda Global Research & Development Center, Inc., Lake Forest, [4]University of Vermont School of Medicine, Burlington, United States.

Background and aims: The efficacy and safety of alogliptin (ALO) combined with pioglitazone (PIO) in patients with type 2 diabetes inadequately controlled on metformin monotherapy was assessed in a randomized, double-blind, placebo-controlled, 26-week study.
Materials and methods: Individual treatment arms were placebo, ALO alone (12.5 or 25 mg qd), PIO alone (15, 30, or 45 mg qd), and the combinations of each ALO dose with each PIO dose. The primary analyses compared PIO monotherapy (all doses pooled; n = 387) with ALO 12.5mg plus any dose of PIO (n = 390) or ALO 25mg plus any dose of PIO (n = 390).
Results: There were statistically significant (P<0.001) decreases from baseline in the mean HbA1c levels at Week 26 in subjects treated with ALO12.5 + PIO or ALO25 + PIO vs PIO alone. These decreases were seen as early as Week 4 and were sustained through Week 26. The least squares (LS) mean change from baseline was -0.89%, -1.43%, and -1.42%, for PIO alone, ALO12.5 + PIO, and ALO25 + PIO groups, respectively (Figure A). Each of the individual combination therapy arms had significantly greater efficacy at lowering HbA_{1c} than either component monotherapy (Figure B). For fasting plasma glucose (FPG), the LS mean change from baseline at Week 26 was -28, -45, and -44mg/dL for the PIO alone, ALO12.5 + PIO, and ALO25 + PIO groups, respectively. Weight gain in the ALO + PIO groups was within the expected range previously reported for PIO. Also, weight gain was not associated with peripheral edema, and a parallel increase in edema-related adverse events was not observed.
Conclusion: In conclusion, ALO combined with PIO was well tolerated and produced statistically significant reductions in HbA_{1c} and FPG. The combinations of ALO (12.5 or 25mg qd) plus PIO (15, 30, or 45mg qd) were significantly more effective than either component monotherapy.

Reaching HbA_{1c} goals with saxagliptin in combination with metformin or sulfonylurea

R. Chen, Z. Xu, Y. Duan, A. Apanovitch;
Bristol-Myers Squibb, Princeton, United States.

Background and aims: Saxagliptin (SAXA) is a potent, selective dipeptidyl peptidase-4 (DPP-4) inhibitor, specifically designed for extended inhibition of the DPP-4 enzyme. Metformin (MET) and sulfonylurea (SU) are two of the most commonly used agents to treat type 2 diabetes (T2D). Three multicenter, randomized, double-blind, 24-wk phase 3 trials (CV181-) assessed the efficacy and safety of SAXA as add-on to background MET (-014), as initial combination therapy with MET (-039), or as add-on to the SU glyburide (GLY) (-040) in patients (pts) with T2D and inadequate glycemic control. Previously-treated pts with inadequate glycemic control (-014, -040) and treatment-naïve pts with high mean baseline (BL) HbA_{1c} (-039) were studied; data for SAXA 5 mg (the proposed usual clinical dose) vs control are presented with a focus on the proportion of pts reaching predefined HbA_{1c} goals of <7.0% and ≤6.5%.
Materials and methods: In the add-on to MET study, 743 pts inadequately controlled on MET alone (HbA_{1c} 7.0%-10.0%; mean BL HbA_{1c} 8.0%; mean T2D duration 6.5 yrs) were randomized to SAXA or placebo (PBO) in addition to each pt's ongoing dose of MET. In the initial combination study, 1306 drug-naïve pts (HbA_{1c} 8.0%-12.0%; mean BL HbA_{1c} 9.5%; mean T2D duration 1.7 yrs) were randomized to SAXA + MET, SAXA + PBO, or MET + PBO. In the add-on to SU study, 768 pts inadequately controlled on SU alone (HbA_{1c} 7.5%-10.0%; mean BL HbA_{1c} 8.4%; mean T2D duration 6.9 yrs) were randomized to SAXA or uptitrated GLY + PBO in addition to open-label GLY. Blinded uptitration was allowed in the uptitrated GLY + PBO arm to a maximum total daily dose of GLY 15 mg. Efficacy analyses for continuous variables were performed using an ANCOVA model with last-observation-carried-forward methodology; the proportion of pts reaching HbA_{1c} goals were examined using the Fisher exact test. HbA_{1c} goals were predefined for each study.
Results: At 24 wks, pts treated with SAXA + MET as add-on or initial combination therapy or with SAXA + GLY demonstrated statistically significantly greater decreases from BL in HbA_{1c} vs control. In all three studies, statistically significantly greater proportions of SAXA-treated pts achieved HbA_{1c} goals of <7.0% and ≤6.5% vs control at 24 wks (Table). More than twice as many pts treated with SAXA added to MET (-014) or GLY (-040) achieved the HbA_{1c} goal of <7% and ≤6.5% relative to control at 24 wks. For all three studies, the frequency of adverse events (AEs) was generally similar for SAXA vs control (Table).
Conclusion: Saxagliptin 5 mg + MET, as either add-on or initial combination therapy, and saxagliptin 5 mg + SU, significantly improved glycemic control and more patients achieved predefined HbA_{1c} goals vs control. Saxagliptin in combination with MET or SU was generally well tolerated and may be a suitable combination partner in a broad range of patients with T2D.

Efficacy & Safety Variables at Wk 24	Add-on MET		Initial Combination With MET		Add-on SU

Long-term efficacy with sitagliptin as monotherapy or add-on therapy to metformin: improvement in glycaemic control over 2 years in patients with type 2 diabetes

D. Williams-Herman, T. Seck, G. Golm, H. Wang, J. Johnson, K. Kaufman, B.J. Goldstein;
Merck Research Laboratories, Rahway, United States.

Background and aims: The long-term efficacy of sitagliptin as monotherapy or as add-on therapy to metformin was evaluated over 2 years in 2 pooled populations of patients with type 2 diabetes (T2DM).
Materials and methods: For the monotherapy analysis, data from 2 clinical trials were pooled, and the HbA_{1c} response over time was examined in the cohort of 147 patients not on an antihyperglycemic agent at screening and with a common baseline HbA_{1c} of 7.5%-10%. For the add-on therapy to metformin analysis, data from 2 other clinical trials were pooled for this cohort of 852 patients on ≥1500 mg/day and with a common baseline HbA_{1c} of 7%-10%. Data following initiation of an additional antihyperglycemic agent (used as glycemic rescue therapy in some studies) were treated as missing. Missing data were not imputed.
Results: Mean baseline values for the pooled monotherapy cohort included: age 53 years, HbA_{1c} 8.5%, fasting plasma glucose (FPG) 187 mg/dL, and duration of T2DM 4.9 years. Sitagliptin monotherapy decreased mean HbA_{1c} from 8.5% at baseline to 6.9% at 2 years (Figure A). Mean baseline values for the pooled add-on to metformin cohort included: age 56 years, HbA_{1c} 8.0%, FPG 173 mg/dL, and duration of T2DM 6.5 years. The addition of sitagliptin to ongoing metformin therapy decreased mean HbA_{1c} from 8.0% at baseline to 6.9% at 2 years (Figure B). Treatment with sitagliptin was generally well tolerated over 2 years in each of the 4 clinical trials from which the pooled populations were drawn.
Conclusion: Sitagliptin as monotherapy or as add-on therapy to metformin in patients with T2DM provided substantial improvement in glycemic control over 2 years.

Weight loss and associated changes in glycaemic control and cardiovascular biomarkers in patients with type 2 diabetes mellitus receiving incretin therapies in a large cohort database

R. Berria[1], J. Rosenstock[2], C. Silberman[1], K.L. Davis[3], E.S. Horton[4];
[1]Diabetes Franchise, Roche Laboratories, Inc, Nutley, [2]Dallas Diabetes and Endocrine Center, Dallas, [3]RTI Health Solutions, Nutley, [4]Joslin Diabetes Center, Boston, United States.

Background and aims: In clinical trials, incretin therapies improve glycemic control and cardiovascular (CV) risk factors such as blood pressure (BP) and lipids. GLP-1 agonists also produce weight loss (WL), and DPP-IV inhibitors are weight neutral. However, the effect of GLP-1 agonist-induced WL on glycemic control and CV biomarkers has not been examined in a large cohort database.
Materials and methods: We analyzed retrospectively the GE Centricity electronic medical records database to explore the association between WL and glycemic control, changes in BP, and changes in lipids in patients with type 2 diabetes (T2DM) who initiated exenatide (EXN), sitagliptin (SIT), or insulin (INS) in 2005-2007 in the United States. Patients had baseline and 1 yr follow-up data for body weight, A1C, fasting glucose (FPG), BP, total cholesterol (TC), LDL-C, HDL-C, and triglycerides (TG). Multivariate regression and correlation analyses were conducted, adjusting for baseline factors and outcome measures.
Results: A total of 6280, 5861, and 32,398 patients on EXN, SIT, and INS, respectively, were studied (baseline factors shown in the Table). Patients on EXN and SIT had WL (mean± SE) of 3.0±0.09 and 1.1±0.07 kg, respectively, whereas INS was associated with a slight weight gain (0.6±0.05 kg). WL was associated with reductions in BP in all groups ($p<0.0001$) and reductions of TG in the EXN and SIT groups ($p<0.05$). Moreover, EXN showed improvements in A1C, FPG ($p<0.0001$ both), TC ($p<0.0001$), and LDL-C ($p=0.004$), which were correlated with WL after multivariate adjustment. There was no correlation with WL and A1C and FPG for SIT, and correlations were negative with INS ($p<0.0001$). EXN patients who lost ≥4.5 kg were more likely to achieve A1C<7% with an adjusted odds ratio [OR] of 2.01[95% CI 1.52, 2.67] compared with those who lost no weight; where this OR was 1.39 [1.00,1.93] and 1.50 [1.25,1.80] for SIT and INS; respectively.
Conclusion: Thus, in a large cohort of patients with T2DM, even a small degree of WL was associated with significant improvement of BP. Furthermore, GLP-1 agonists provided additional benefits on lipids when WL was ≥4.5 kg, and significant incremental benefits in glycemic control were associated with WL. Therefore, the greater WL associated with GLP-1 agonists and its associated improvement in glycemic control, BP, and lipids may convey long-term CV benefits in T2D.

Mean±SD	EXN	SIT	INS
HbA1c (%)	7.7±1.54	7.7±1.53	8.8±2.28

Exenatide once weekly reduced HbA_{1c}, weight, and cardiovascular risk factors across a wide BMI range

J. Ruggles, K. Taylor, T. Okerson, P. Yan, S. Miller, T. Kim, M. Wintle;
Amylin Pharmaceuticals, Inc., San Diego, United States.

Background and aims: Type 2 diabetes (T2DM) is often accompanied by cardiometabolic complications including obesity, hypertension, and dyslipidemia that elevate patients' risk of cardiovascular (CV) disease. In a 30-week open-label phase 3 study, exenatide once weekly (QW 2 mg) improved glycaemic control with associated weight reduction and improvement in CV risk factors in patients with T2DM (N = 148, HbA_{1c} 8.3 ± 1.0%, weight 102 ± 19 kg, BMI 35 ± 5 kg/m^2, diabetes duration 7 ± 5 y, mean ± SD). HbA_{1c} and weight reductions from baseline to Week 30 were -1.9 ± 0.1% and -3.7 ± 0.5 kg, respectively (LS mean ± SE). Because higher BMI has been associated with an increased risk of diabetes complications, we examined the relationship between baseline BMI and changes in CV risk factors with exenatide QW treatment.
Materials and methods: The association between BMI at baseline and HbA_{1c} reduction at Week 30 in the overall ITT population was examined using the Pearson correlation coefficient. We also examined the cardiometabolic profile in subgroups of the population stratified by baseline BMI (<30 [n = 24], 30 to <35 [n = 58], 35 to <40 [n = 44], ≥40 kg/m^2 [n = 22]). Comparisons across the BMI subgroups for each parameter were made using an ANCOVA model with baseline BMI stratum as the factor and baseline value of the parameter as a covariate.
Results: The analysis indicated that HbA_{1c} reduction was not significantly correlated with baseline BMI (Pearson r = 0.02) and that improvements in HbA_{1c} and CV risk factors were apparent in all BMI subgroups (Table). Further, comparison across the BMI subgroups demonstrated no statistically significant differences between subgroups in change from baseline for HbA_{1c}, weight, blood pressure, total cholesterol, LDL, or triglycerides. Exenatide QW was generally well tolerated. Nausea was reported in 26% of patients and was predominantly mild in intensity and transient. No major hypoglycaemia was observed.
Conclusion: In this study, exenatide QW improved glycaemic control, weight, blood pressure, and lipids for patients with T2DM across a wide range of BMI, from mildly overweight to morbidly obese.

Endpoint Δ from Baseline	Baseline BMI Subgroup (kg/m^2)				ANCOVA P-value[†]

Effects of exenatide vs insulin glargine on central haemodynamics in subjects with type 2 diabetes

A. Cohen[1,2], E. Horton[1,2], H. Gibson[3], B. Lamparello[1], S. Herzlinger Botein[1,2], L. McFarland[1];
[1]Joslin Diabetes Center, [2]Harvard Medical School, [3]Harvard School of Public Health, Boston, United States.

Background and aims: Exenatide (EXN), a GLP-1 agonist, is an effective glucose lowering therapy, primarily resulting in the reduction of postprandial glycemia. Data are emerging that GLP-1 may have beneficial effects on the cardiovascular system, including reduction in peripheral blood pressure and improvement in endothelial function. It is not known whether EXN has any effects on central hemodynamic parameters, which may be better markers for cardiovascular risk than peripheral blood pressure. We assessed the effects of EXN compared to insulin glargine (IG) on central hemodynamics and endothelial function in subjects with DM2.
Materials and methods: 56 subjects with DM2 (HbA_{1c} 8.15 ± 1.14%) were randomized to 3 months of treatment with either EXN or IG to obtain similar reductions in HbA_{1c}. A liquid mixed meal test (MMT) using Boost [360 kcal, 61.5g Carbohydrate, 15g Protein, and 6g Fat] was performed before and after 3 months of therapy. Flow mediated dilation (FMD) of the brachial artery

and pulse wave analysis (PWA) were performed fasting, 2 hours, and 4 hours after the MMT before and after 3 months of therapy. Measurements of central hemodynamics by PWA included central pulse pressure (CPP), augmentation pressure (AP), and augmentation index (AI).
Results: 28 subjects were randomized to treatment with EXN and 28 to treatment with IG. The EXN and IG groups had similar reductions in HbA_{1c} [-1.37 ± 1.16 vs. -0.85 ± 0.71%, respectively (p=.NS)]. The EXN group had a significant reduction in the systolic blood pressure (SBP) (-8.1 ± 12 (p=.002)] and diastolic blood pressure (DBP) [-4.9 ± 7.3 (p=.002)], while the IG group did not have a significant decrease in SBP or DBP. The EXN group had a significant reduction in CPP and AP at all time points, and in AI 4 hours after the MMT (Table 1). The IG group had no improvement in any parameters of central hemodynamics. There was no effect of either treatment on FMD (Table 1) or response to nitroglycerin (data not shown).
Conclusion: In subjects with DM2, treatment with EXN, compared to IG, resulted in a reduction in SBP and DBP, as has been previously reported. Treatment with EXN also resulted in a reduction in CPP and AP, which has not been previously described. Reduction in CPP may more strongly predict a reduction in cardiovascular risk than the reduction in peripheral blood pressure, and EXN may thus impart cardiovascular risk reduction by its effect on lowering CPP. These effects appear to be independent of overall glycemic control.

Table 1

		CPP (mmHg)	AP (mmHg)	AI (%)	FMD (%)
EXN	**Pre-Tx 0h**	51.0 (15.3)	11.78 (6.4)	22.5 (9.2)	4.6 (2.8)

Exenatide once weekly improved cardiometabolic risk factors in subjects with type 2 diabetes during one year of treatment
R. Bergenstal[1], T. Kim[2], P. Yan[2], T. Darsow[2], B. Walsh[2], T. Okerson[2], J. Han[2];
[1]International Diabetes Center, Minneapolis, [2]Amylin Pharmaceuticals, Inc., San Diego, United States.

Background and aims: Patients with type 2 diabetes (T2DM) often exhibit a number of cardiometabolic abnormalities including hypertension, obesity, and dyslipidemia, which increase the risk for cardiovascular (CV) disease and nonalcoholic fatty liver disease (NAFLD). In a controlled, open-label trial, 30 weeks of exenatide once weekly (QW) improved glycaemic control, reduced weight, and improved markers of CV risk in subjects with T2DM.
Materials and methods: We examined the cardiometabolic profile in subjects who continued exenatide QW for a total of one year (n=120, baseline HbA_{1c} 8.3±1.0%, BMI 35.2±5.0 kg/m^2, age 56±9 y, mean±SD). Changes in concomitant antihypertensive and lipid lowering medications were allowed only if deemed necessary by the investigator.
Results: One year of exenatide QW improved HbA_{1c} (-2.0±0.1%; LS mean±SE), FPG (-2.60±0.16 mmol/L), and weight (-4.1±0.6 kg), with nearly all subjects (98%) exhibiting improvement in HbA_{1c}. Blood pressure, fasting lipids, and the hepatic injury biomarker ALT were also improved, with greater improvements in subjects with abnormal baseline values. Weight change was mild to moderately correlated (r≤0.3125; p<0.05) with changes in DBP, LDL, cholesterol, and ALT, but not significantly correlated with SBP or triglycerides (TG). Nausea, predominantly mild in intensity, occurred in 29% of subjects.
Conclusion: Improvements in cardiometabolic risk factors were sustained during one year of exenatide QW treatment; patients with abnormal baseline cardiometabolic risk factors exhibited the greatest improvements in those parameters. These data indicate that, in addition to improving glycaemic control and body weight, exenatide QW has the potential to improve the overall cardiometabolic risk profile in patients with T2DM.

Cardiovascular safety of exenatide BID: an integrated-analysis from long-term controlled clinical trials in subjects with type 2 diabetes
L. Shen, J. Han, I. Yushmanova, S. Bruce, K. Wilhelm, L. Porter;
Amylin Pharmaceuticals, Inc., San Diego, United States.

Background and aims: Exenatide BID (Ex) is a first-in-class GLP-1 receptor agonist, with more than 750,000 patient-years of marketed exposure accumulated worldwide, that is an antidiabetic medication associated with weight loss, improvements in lipid profile, reduction in blood pressure, and a low risk of hypoglycaemia in the absence of a sulphonylurea. To evaluate cardiovascular (CV) safety, a meta-analysis of CV events was performed.
Materials and methods: An integrated database of 12 completed, randomised controlled clinical trials ranging from 12 to 52 weeks was used to compare the relative risk (RR) of CV events with Ex (5 and 10 μg) versus a pooled comparator group (PC) treated with either placebo or insulin. CV events included: stroke, myocardial ischaemia, myocardial infarction, cardiac mortality, arrhythmia, revascularisation procedures, and congestive heart failure. Events were identified by preferred terms according to the Medical Dictionary for Regulatory Activities (MedDRA 11.0). In this integrated analysis, 2,279 Ex subjects and 1,629 PC subjects were treated for a total of 1,063 and 780 patient-years of exposure, respectively.
Results: Demographics were comparable (mean age 56 y, 53-55% M, BMI 31-32 kg/m^2, HbA_{1c} 8.3-8.4%). The unadjusted incidence of experiencing at least one CV events was 2.0% for Ex and 2.6% for PC; the relative risk between Ex and PC was 0.69 (95% CI: 0.46-1.04) (calculated using Cochran-Mantel-Haenszel estimate using study as a stratification factor). The Exposure Adjusted Incidence Rate (expressed as per 1000 patient years) was 43.7 for Ex and 54.4 for PC with a relative risk 0.80 (95% CI: 0.53-1.22) (calculated using a log-normal approximation method).
Conclusion: This analysis is consistent with long-term clinical trial data demonstrating favourable effects of Ex on CV risk factors and suggests a potential benefit of Ex treatment, warranting further evaluation in an appropriately powered prospective outcomes study.

760

Effects of exenatide vs insulin glargine on cardiovascular risk factors in subjects with type 2 diabetes
E.S. Horton[1], A. Cohen[1], H. Gibson[2], B. Lamparello[1], S. Herzlinger[1], L. McFarland[1];
[1]Joslin Diabetes Center, [2]Harvard School of Public Health, Boston, United States.

Background and aims: Multiple factors contribute to the increased risk for cardiovascular (CV) disease in people with type 2 diabetes (DM2), including postprandial hyperglycemia and hypertriglyceridemia. Exenatide (EXN), a GLP-1 agonist, is an effective glucose lowering therapy, primarily resulting in the reduction of postprandial glycemia. Data in healthy adults suggest GLP-1 may also improve postprandial lipemia, and studies in DM2 show lower postprandial triglycerides (TG) after 1 year of treatment with EXN. We assessed the effects of EXN compared to insulin glargine (IG) on postprandial lipemia and other CV risk factors in subjects with DM2 after 3 months of treatment.

Materials and methods: 56 subjects with DM2 (HbA_{1c} 8.15 ± 1.14%) were randomized to 3 months of treatment with either EXN or IG to obtain similar reductions in HbA_{1c}. Markers of CV risk were assessed, including changes in blood pressure (BP), weight, BMI, and waist circumference. A liquid mixed meal test (MMT) using Boost was done at baseline and after 3 months of therapy. Glucose, insulin, C-peptide, lipids, and free fatty acids were measured prior to and during the 4 hours following the mixed meal.
Results: 28 subjects were randomized to treatment with EXN and 28 to treatment with IG. The EXN and IG groups had similar reductions in HbA_{1c} [-1.37 ± 1.16 vs. -0.85 ± 0.71%, respectively (p=.NS)]. The EXN group had significantly greater reductions in weight [-3.4 ± 2.7 vs. 0.4 ± 1.6 kg (p<.0001)], BMI [-1.16 ± 0.92 vs. 0.14 ± 0.55 kg/m^2 (p<.0001)], and waist circumference [-2.95 ± 3.5 vs. -0.56 ± 3.4 cm (p=.02)] compared to the IG group. There was also a significantly greater reduction in diastolic BP [-4.85 ± 7.3 vs. 0.15 ±9.7 mmHg (p=.038)], and a trend towards a greater reduction in systolic BP [-8.1 ± 12 vs. -2.5 ± 13 mmHg (p=NS)] in the EXN group compared to the IG group. Similar decreases in fasting glucose occurred. (-2.63 ± 2.86 vs -2.2 ± 2.04 mmol/L, p=NS) in the EXN and IG groups, respectively. There were no significant changes in fasting LDL, HDL, total cholesterol or TG in either group. As expected, during the MMT, the decrease in the incremental area under the curve (iAUC) for glucose was significantly greater in the EXN group than in the IG group (iAUC -554 ± 436 vs. -44 ± 355 mmol/L/4h, p=0.000). Importantly, there was also a significantly greater decrease in TG (iAUC -61.2 ± 80.6 vs -6.4 ± 49.8 mmol/L/4h, p=.005) (Fig 1).
Conclusion: In subjects with DM2, treatment with EXN for 3 months, compared to IG, resulted in greater reductions in multiple cardiovascular risk factors, including postprandial changes in plasma glucose and serum triglycerides, and reductions in body weight, BMI, waist circumference, and diastolic BP. These effects appear to be independent of overall glycemic control.

A meta-analysis of six clinical trials demonstrates that the once-daily human GLP-1 analogue liraglutide reduces systolic blood pressure

V. Fonseca[1], A. Falahati[2], M. Zychma[3], S. Madsbad[4], J. Plutzky[5];
[1]Tulane University Medical Center, Tulane University Health Sciences Center, New Orleans, United States, [2]Novo Nordisk, Bagsvaerd, Denmark, [3]Novo Nordisk, Warsaw, Poland, [4]University Hospital, Hvidovre, Denmark, [5]Brigham and Women's Hospital, Boston, United States.

Background and aims: Type 2 diabetes (T2D) patients frequently have hypertension, which contributes to the elevated cardiovascular risk observed in this population. The six large phase 3 Liraglutide Effect and Action in Diabetes (LEAD) studies have shown that, in T2D patients, the once-daily human GLP-1 analogue liraglutide reduces HbA_{1c} by 1.0-1.5% with concomitant mean weight loss of approximately 3 kg and, importantly, that it reduces systolic blood pressure (SBP) by 2.7-6.6 mmHg (min, max baseline SBP, mmHg: 128/76-134/81). We now have investigated the effect of liraglutide on SBP by quartile of baseline SBP.
Materials and methods: A meta-analysis across the LEAD studies was performed. Patients treated with liraglutide 1.8 mg (n=1362), liraglutide 1.2 mg (n=896) or placebo (PBO n=520) were stratified by quartile of baseline SBP. An ANCOVA model adjusted for trial, baseline SBP and baseline SBP quartile was employed to analyse mean SBP changes from baseline. Baseline SBP quartile limits were 80 mmHg≤SBP≤120 mmHg in Q1; 120 mmHg <SBP≤130 mmHg in Q2; 130 mmHg <SBP≤140 mmHg in Q3 and 140 mmHg <SBP≤190 mmHg in Q4. The investigators did not receive specific instructions on lowering blood pressure with medications during the trials, in which HbA_{1c} reduction was the primary endpoint.
Results: Overall, mean SBP decreased significantly from baseline with liraglutide 1.8 mg and liraglutide 1.2 mg by 2.6 mmHg (p=0.0008) and 2.5 mmHg (p=0.0030), respectively, and was sustained for 26 weeks. No significant change was seen with PBO (-0.2 mmHg, p=0.7828). Repeated measure analysis with a model adjusted for baseline SBP quartile was used to investigate the longitudinal effect on SBP from baseline to week 26. Full impact on SBP was achieved at first visit after 2 weeks (Figure) before any major weight loss had occurred. The effect associated with baseline SBP quartile was significant (p<0.0001). The greatest reductions were observed in the quartile with highest baseline SBP. Thus, changes from baseline of -11.4 mmHg in Q4, -4.7 mmHg in Q3, -0.4 mmHg in Q2 and +4.8 mmHg in Q1 were observed with liraglutide 1.8 mg. Similarly, changes of -11.4 mmHg in Q4, -6.2 mmHg in Q3, +0.4 mmHg in Q2 and +5.4 mmHg in Q1 were observed with liraglutide 1.2 mg.
Conclusion: Overall, liraglutide treatment reduces and sustains SBP over 26 weeks, especially in patients with elevated SBP at baseline. The impact on SBP is achieved within 2 weeks and cannot be explained by weight loss alone. Thus, liraglutide treatment may improve the cardiovascular risk profile of T2D patients, with patients with elevated SBP possibly experiencing a greater benefit.

LS-Means ± 95% CIs for SBP over 26 weeks with liraglutide 1.8 mg, liraglutide 1.2 mg and placebo.

Meta-analysis demonstrates that liraglutide, a once-daily human GLP-1 analogue, significantly reduces lipids and other markers of cardiovascular risk in type 2 diabetes

J. Plutzky[1], A. Garber[2], A.D. Toft[3], N.R. Poulter[4];
[1]Cardiovascular Division, Brigham and Women's Hospital, Boston, United States, [2]Baylor College of Medicine, Houston, United States, [3]Novo Nordisk, Bagsvaerd, Denmark, [4]Imperial College, London, United Kingdom.

Background and aims: Type 2 diabetes (T2D) is characterised by abnormal lipid profiles and raised levels of biomarkers that predict cardiovascular risk, including brain natriuretic peptide (BNP), high sensitivity C reactive protein (hsCRP), and apolipoprotein B (Apo B). In clinical trials, the once-daily human GLP-1 analogue liraglutide was shown to improve HbA_{1C} by 1.0-1.5%, produce sustained weight reductions of 2-3 kg, and reduce SBP by 2-6 mmHg when given for up to 52 weeks. We aimed to assess the impact of liraglutide on lipids and other cardiovascular (CV) risk markers using meta-analysis of a clinical trial database.
Materials and methods: We conducted a meta-analysis (ANCOVA, ITT, LOCF) of six randomised controlled phase 3 trials that compared liraglutide 1.8 mg OD with other T2D therapies (glimepiride, rosiglitazone, insulin glargine, exenatide) and placebo (n=3967).

Results: After 26 weeks of liraglutide, total cholesterol, low-density lipoprotein-cholesterol (LDL-C), free fatty acids (FFA) and triglycerides (TG) all decreased significantly compared with baseline (p<0.01 for all) (Table). With other therapies, these lipids did not all decrease significantly vs baseline (Table). BNP decreased vs baseline by 11.9% with liraglutide (p<0.01), but increased by 30.9% with rosiglitazone (p<0.0001); changes with other therapies were not significant (NS). hsCRP decreased by 23.1% (liraglutide, p<0.0001), 42.6% (rosiglitazone, p<0.0001), 12.3% (glimepiride, p<0.05), 15.6% (exenatide, p<0.05), but was NS with glargine or placebo. ApoB levels did not change significantly with any treatments. High-density lipoprotein decreased significantly from baseline with all interventions except rosiglitazone.
Conclusion: In addition to significantly improving levels of total cholesterol, LDL-C, FFA, and TG in patients with T2D, treatment with liraglutide for 26 weeks also significantly reduced BNP and hsCRP, two markers of CV risk. Liraglutide may reduce CV risk by additional mechanisms in addition to its known effects on glycaemia, weight and systolic blood pressure.

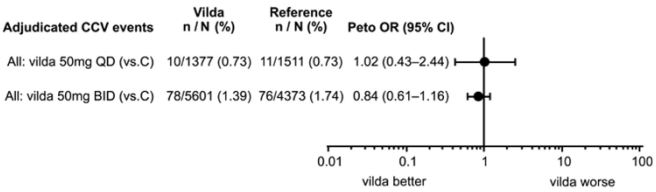
Assessing the cardiovascular safety of vildagliptin: a meta-analysis of adjudicated cardiovascular and cerebrovascular events from a large phase 3 population

A. Schweizer[1], S. Dejager[2], Q. Shao[3], M. Ligueros-Saylan[3], W. Kothny[3]; [1]Novartis Pharma AG, Basel, Switzerland, [2]Novartis Pharma S.A.S., Rueil-Malmaison, France, [3]Novartis Pharmaceuticals Corporation, East Hanover, United States.

Background and aims: While the direct cardiovascular benefits of improving glycemic control are still not clearly established in type 2 diabetes (T2DM), there has recently been an intense discussion of the cardiovascular safety of some anti-diabetic agents. It is therefore critical to provide a thorough evaluation of the cardiovascular and cerebrovascular (CCV) safety of new anti-diabetic agents, even before the results of long-term outcome studies become available.This work aimed to assess the CCV safety of vildagliptin, a potent and selective DPP-4 inhibitor, in a large population representative of T2DM patients, applying methodology put forward by a new FDA guidance.
Materials and methods: Twenty phase 3 double-blind clinical trials (monotherapy and combination therapy; ranging in duration from 24 to more than 104 weeks) were included. A meta-analysis using Peto fixed effects odds ratio was performed to compare vildagliptin treatment groups (doses of 50 mg qd and 50 mg bid; n=6978) to the all comparators group (placebo and active-controlled treatment groups; n=4773) using a composite endpoint of adjudicated CCV events. These events were adjudicated as "confirmed" by the blinded assessment of an independent CCV adjudication committee; categories included were acute coronary syndrome, sudden cardiac death, stroke and transient ischemic attack with imaging evidence of infarction. This meta-analysis combined within-study treatment comparisons and therefore indirectly adjusted for study level factors that could affect the occurrence of adverse events (e.g. different durations of exposure or different study populations).
Results: The phase 3 population was well representative of a T2DM population, with mean age ~56 years, slight male predominance (~55/45%), mean BMI ~31.4 kg/m^2 (> 50% were obese), disease duration of ~4.2 years and mean baseline HbA1c of ~8.1%. About 18% of patients had medical history in the 'Cardiac Disorders' System Organ Class category, ~43% had dyslipidemia and ~ 58% hypertension. The incidences and odds ratios for confirmed adjudicated CCV events are shown below. Vildagliptin was not associated with any increased risk relative to all comparators, the odds ratios being 1.02 for vildagliptin 50 mg qd and 0.84 for vildagliptin 50 mg bid; the 95% CIs included 1 (0.43 - 2.44 and 0.61 - 1.16, respectively).



Reference = Comparators; (vs.C) = vs. Comparators.
Comparators = all non-vilda treatment groups.
Peto fixed odds ratios estimates only includes studies with at least one event.

Conclusion: This large meta-analysis demonstrated that vildagliptin is not associated with an increased risk for adjudicated CCV events relative to all comparators, confirming the favorable cardiovascular safety profile of the drug.

Hepatic safety profile of vildagliptin, a new DPP-4 inhibitor for the treatment of type 2 diabetes

W. Kothny[1], A. Schweizer[2], S. Dickinson[2], M. Ligueros-Saylan[1];
[1]Novartis Pharmaceuticals Corporation, East Hanover, United States,
[2]Novartis Pharma AG, Basel, Switzerland.

Background: Vildagliptin is a potent and selective DPP-4 inhibitor that improves islet function by increasing α- and β-cell responsiveness to glucose. Vildagliptin does not have the preclinical characteristics of a hepatotoxic agent. The product information describes rare cases of potential drug-induced hepatitis and recommends hepatic enzyme monitoring. The results of the most recent hepatic analysis are presented based on an a data integration done in November 2008.
Objective: To characterize the hepatic safety profile of vildagliptin in diabetic patients.
Methods: Safety data from 36 phase 2 and 3 clinical trials (monotherapy and combination therapy, ranging in duration from 12 to more than 104 weeks) were pooled including 3 open-label studies. A meta-analysis using Peto fixed effects odds ratio was performed to compare vildagliptin treatment groups to the all comparators group (placebo and active-controlled treatment groups pooled) with respect to the risk of hepatic adverse events and persistent hepatic enzyme elevations defined as 2 consecutive elevations or an elevation at the last visit.
Results: More than 11000 patients have been treated with vildagliptin. The overall incidences of hepatic events for vildagliptin were generally similar to the comparator incidences with corresponding Peto ORs slightly above or below 1. A similar pattern was observed for serious hepatic events, with overall very small event numbers (Figure).The risk of having an ALT/AST ≥3 x ULN was slightly increased for vildagliptin relative to all comparators with no dose response relationship (Figure). In contrast, for ALT/AST ≥3 x ULN accompanied by bilirubin >ULN the odds ratios were less than 1.0 for each vildagliptin dose regimen (Figure). Hepatic enzyme elevations ALT/AST ≥10 x ULN; or 3 x ULN accompanied by bilirubin ≥2ULN were rare with a incidence similar to comparators. 2 cases of ALT/AST ≥3 x ULN with bilirubin ≥2ULN were attributed to vildagliptin by an independent and blinded expert panel. Both cases were asymptomatic, did not require hospitalization, and resolved on cessation of treatment without clinical sequelae.
Conclusion: Although a slightly higher risk of milder hepatic enzyme elevations was observed with vildagliptin, this does not translate into an increased risk of more severe hepatic enzyme elevations or an increased risk of actual hepatic adverse events. In a clinical setting, however, hepatic enzymes should be monitored consistent with the label and clinical practice.
Figure: Incidence and odds ratio for selected hepatic adverse events (excluding open label safety population) and treatment-emergent persistent on-treatment hepatic enzyme elevations by treatment (including open label safety population).

Selected hepatic events	Vilda n / N (%)	Reference n / N (%)	Peto OR (95% CI)

Alogliptin use in the elderly: a pooled analysis from Phase 2-3 studies

R. Pratley[1], T. McCall[2], P. Fleck[3], C. Wilson[3], Q. Mekki[3];
[1]University of Vermont School of Medicine, Colchester, [2]Takeda Pharmaceuticals North America, Inc., Deerfield, [3]Takeda Global Research & Development Center, Inc., Lake Forest, United States.

Background and aims: Here we report the results of a pooled analysis of elderly type 2 diabetes patients treated with the DPP-4 inhibitor, alogliptin (ALO).
Material and methods: Six phase 2-3 double-blind, placebo (PBO)-controlled, randomized studies evaluated the efficacy and safety of ALO 12.5 or 25 mg qd for up to 26 weeks. Among the subset of elderly subjects (≥65 yrs), 350 received ALO; among the subset of younger subjects (<65 yrs), 1482 received ALO. Comparisons were made on the PBO-corrected data between ALO dose groups and cohorts using an ANCOVA analysis with missing data imputed using the LOCF method (P<.05=significant).
Results: Among ALO-treated younger subjects, 74.3% completed the study vs 83.4% of elderly subjects. Mean age in the younger and elderly cohorts was 52 and 70 yrs, respectively. Mean baseline and LS mean change from baseline (CFB) values for A1c, fasting plasma glucose, and weight showed minor variations between age cohorts. However, there were no statistically significant age-group differences in the PBO-corrected LS mean CFB for any measured parameter between age cohorts. ALO was generally well tolerated in elderly subjects. Overall, the rate of any serious AE and AEs leading to discontinuation were somewhat higher in the elderly subjects.
Conclusion: Elderly patients realized the same beneficial effects of ALO on glycemic endpoints as younger patients. Alogliptin is an effective and well tolerated treatment option for elderly patients with type 2 diabetes.

Efficacy and safety of saxagliptin 5 mg once-daily therapy in elderly patients with type 2 diabetes mellitus

P. Maheux[1], J. Doucet[2], E. Allen[3], S. Ravichandran[3], S. Harris[4], R. Chen[3], C. Brullé[5];
[1]AstraZeneca ISMO Europe, Brussels, Belgium, [2]CHU Rouen, Rouen, France, [3]Bristol-Myers Squibb, Princeton, United States, [4]AstraZeneca, Wilmington, United States, [5]Bristol-Myers Squibb EMEA, Paris, France.

Background: The prevalence of type 2 diabetes mellitus (T2DM) increases with age and most patients require a combination of antidiabetic drugs to achieve glycaemic control (HbA_{1c} <7%). The antihyperglycaemic agent saxagliptin (SAXA) is a potent, selective dipeptidyl peptidase-4 (DPP-4) inhibitor, specifically designed for extended inhibition of the DPP-4 enzyme.
Aims: This subgroup analysis examined the efficacy and safety of SAXA 5 mg treatment in younger (<65 years) and older (≥65 years) patients with T2DM.
Methods: SAXA 5 mg treatment was investigated in 882 patients (18-77 years of age) with inadequately controlled T2DM (HbA_{1c} ≥7.0%) in five double-blind, placebo-controlled, Phase III studies. Following a placebo run-in period, patients were randomised to SAXA 5 mg once daily (o.d.; n=882) or placebo (n=799). The data presented focus on patients who received SAXA 5 mg monotherapy or placebo o.d. (CV181-011; CV181-038), or SAXA 5 mg or placebo o.d. plus each patient's stable dose of metformin (MET; CV181-014), glibenclamide (GLIB; CV181-040), or thiazolidinedione (CV181-013) for 24 weeks. In study CV181-040, blinded up-titration of GLIB was allowed in the GLIB-only arm. The primary endpoint of all studies was HbA_{1c} change from baseline at Week 24.
Results: Treatment groups were well balanced for baseline characteristics within each study. At Week 24, for each age subgroup, larger reductions in pooled adjusted-mean HbA_{1c} change from baseline were observed with SAXA 5 mg, compared with placebo (Table). Adverse events (AEs) rates were similar with SAXA 5 mg compared with placebo in both older and younger patients.
Conclusion: The combined analysis of saxagliptin monotherapy and add-on therapy trials demonstrated similar efficacy (HbA_{1c} reductions) and tolerability in younger (<65 years) and older (≥65 years) patients with inadequately controlled T2DM.

Albiglutide, a long-acting GLP-1-receptor agonist, for the treatment of type 2 diabetes: an analysis of gastrointestinal adverse events over time

M.W. Stewart[1], J.E.B. Reusch[2], M.A. Bush[3], F. Yang[1], J. Rosenstock[4];
[1]GlaxoSmithKline, King Of Prussia, [2]Denver VAMC, Denver, [3]GlaxoSmithKline, Research Triangle Park, [4]Dallas Diabetes and Endocrine Center at Medical City, Dallas, United States.

Background and aims: Gastrointestinal (GI) adverse events can limit adherence to GLP-1-receptor agonist therapies. The goal of this analysis was to systematically assess the time course of nausea or vomiting following treatment with albiglutide (ALB), a GLP-1-receptor agonist suitable for once-weekly or less-frequent dosing.
Materials and methods: A 16-week randomized, multicenter, double-blind, parallel-group study was conducted. A total of 356 subjects (mean age 54 years, BMI 32.1 kg/m^2) with type 2 diabetes (mean duration 5 years, HbA_{1c} 8.0%) received placebo, ALB [weekly (4, 15 or 30 mg), every other week (biweekly; 15, 30 or 50 mg) or monthly (50 or 100 mg)], or exenatide twice daily (open-label reference arm administered per label) over 16 weeks. Rates of nausea or vomiting were captured on a weekly basis.
Results: The incidence of nausea and/or vomiting was 11.8% with placebo and 45.7% with exenatide (used as a clinical reference to put ALB-related nausea/vomiting in perspective). The incidence of nausea and/or vomiting reported for the maximum dose in each ALB schedule was: 29% for 30 mg weekly; 54.3% for 50 mg biweekly; and 55.9% for 100 mg monthly. Of note, the percentage of subjects receiving ALB having nausea or vomiting for more than 7 days ranged from 0-15.6%, compared with 31.4% with exenatide. All nausea or vomiting events for 30 mg weekly ALB were mild, and > 90% of events with 50 mg biweekly or 100 mg monthly dosing were mild or moderate. In the exenatide group, 63.6% of events were mild and 36.4% were moderate. The incidence of nausea or vomiting was lower with more frequent, smaller ALB doses than with less frequent, larger ALB doses. Nausea and/or vomiting correlated with ALB exposure and clearly decreased over time. There was a low incidence of nausea or vomiting in the 30 mg weekly dose of ALB, with no nausea or vomiting reported after week 8. The 50 mg biweekly dose was generally associated with a low incidence of nausea and/or vomiting that decreased gradually over time. For the 100 mg monthly dose, rates of nausea and/or vomiting increased following each injection but markedly dissipated during the interim period between injections. Rates of nausea and/or vomiting for exenatide increased after 4 weeks, when uptitration from 5 μg to 10 μg occurred. Of the 2 symptoms, the incidence of nausea predominated; vomiting followed a similar time course, but with lower incidence. However, more vomiting (with or without nausea) than nausea alone was observed for the 100 mg monthly dose and was associated with the occurrence of peak plasma ALB concentrations.
Conclusion: Weekly 30 mg ALB administration shows a favorable GI tolerability profile as compared with other ALB regimens and exenatide, and in a manner associated with the level of exposure.

Safety and tolerability of exenatide BID in patients with type 2 diabetes: integrated analysis of 3854 patients from 11 comparator controlled clinical trials

M. Wintle[1], S. Bruce[1], L. MacConell[1], C. Brown[1], J. Han[1], D. Nicewarner[1], T. Okerson[1], D. Braun[2], G. Bloomgren[1];
[1]Amylin Pharmaceuticals, Inc., San Diego, [2]Eli Lilly & Company, Indianapolis, United States.

Background and aims: Exenatide BID (Ex) is a first-in-class GLP-1 receptor agonist approved for the treatment of type 2 diabetes (T2DM). The objective of this integrated analysis was to further examine the safety profile of Ex (5 and 10 μg) compared to a population of pooled comparators (PC) treated with placebo or insulin in T2DM patients.
Materials and methods: Data from 11 completed, randomised, controlled clinical trials including 3854 patients followed for 12 to 52 weeks were pooled and analyzed. Incidence rates (IR), exposure-adjusted incidence rates (EAIR) per 100 patient-years (PY), and 95% confidence intervals (CI) around differences (Diff) between cohorts were calculated for adverse event (AE), system organ class by preferred term, and serious AEs.
Results: Baseline demographics were comparable between cohorts (Ex: N=2251; PC: N=1603; 53-55% M; age 56 y; BMI 31-32 kg/m^2; HbA_{1c} 8.3-8.4%; mean days exposure time Ex: 172; PC: 176). The overall IRs of serious AEs were 3.6% vs 3.5% and non-serious AEs were 79% vs 64% for Ex-treated and PC groups, respectively. Transient, mild-to-moderate nausea (Ex: 39%; PC: 9%) was the most frequent AE. Other AEs (≥5%) included vomiting (Ex: 13%; PC: 3%), diarrhea (Ex: 10%; PC: 4%), nasopharygitis (Ex: 8%; PC: 8%), headache (Ex: 8%; PC: 7%), upper respiratory infection (Ex: 7%; PC: 6%), and dizziness (Ex: 6%; PC: 3%). Discontinuations due to AEs were 8% and 2% for the Ex-treated and PC groups, respectively. The IR of mild-moderate hypoglycaemia without concomitant sulphonylurea (SU, Ex: 9%; PC: 8%) or with SU (Ex: 37%; PC: 31%) was comparable between groups. Severe hypoglycaemia was rare [No SU: Ex: 0.2%; PC: 0.5% vs SU: Ex: 0.5%; PC: 0.5%]. Finally, composite EAIRs (rates per 100 PY) were not statistically different between treatment groups for pancreatitis (Ex: 0.28; PC: 0.26; Diff: 0.025 [-0.46, 0.51]), biliary disease (Ex: 0.66; PC: 0.65; Diff: 0.017 [-0.74, 0.77]), and renal impairment (Ex: 1.7; PC: 1.8; Diff: -0.11 [-1.3, 1.13]).
Conclusion: Overall, based on this integrated analysis of 3854 patients representing 1058 PY of Ex exposure, exenatide BID was well tolerated in patients with T2DM.

769

Vildagliptin therapy is not associated with an increased risk of pancreatitis

M. Ligueros-Saylan[1], A. Schweizer[2], S. Dickinson[2], W. Kothny[1];
[1]Novartis Pharmaceuticals Corporation, East Hanover, United States, [2]Novartis Pharma AG, Basel, Switzerland.

Background and aims: Vildagliptin is a potent and selective DPP-4 inhibitor that has been shown to enhance the physiological effects of incretin hormones thereby increasing islet alpha-and beta-cell responsiveness to glucose. Patients with type 2 diabetes may be at increased risk of pancreatitis compared to patients without diabetes and whether the use of pharmacological agents may exacerbate this risk remains unclear. This work aimed at assessing whether treatment with the DPP-4 inhibitor vildagliptin is associated with an increased risk of pancreatitis in patients with type 2 diabetes in a large clinical database.
Materials and methods: Safety data from 24 phase 2 and 3 double-blind controlled clinical trials (monotherapy and combination therapy; ranging in duration from 12 to more than 104 weeks) were pooled. A meta-analysis using the Peto fixed effects odds ratio was performed to compare vildagliptin treatment groups (doses of 50 mg qd and 50 mg bid; n= 7087) to the all comparators group (placebo and active-controlled treatment groups pooled, n= 4880) with respect to the risk of pancreatitis related AEs. Selected preferred terms for pancreatitis-related AEs were used for this analysis.
Results: The incidences in controlled clinical trials and odds ratios for pancreatitis-related events are shown in Figure 1.The odds ratio for pancreatitis-related AEs was < 1 for vildagliptin 50 mg qd and for vildagliptin 50 mg bid (OR = 0.90 and 0.78, respectively), indicating no increased risk relative to all comparators.
Conclusion: There was no evidence of an increased risk of pancreatitis-related AEs following treatment with the DPP-4 inhibitor vildagliptin at the marketed doses of 50 mg qd and 50 mg bid relative to the all comparators group.

770

Surveillance of lipase and amylase levels in type 2 diabetes patients assessed during a randomized clinical study: the EGO study experience

E.J. Bastyr[1,2], A. Vinik[3], C. Owyang[4], C. Cheng[1], J. Shu[5], N.C. Hall[1];
[1]Lilly Research Laboratories, Indianapolis, [2]Indiana University School of Medicine, Indianapolis, [3]Eastern Virginia Medical School, Norfolk, [4]Univeristy of Michigan Medical School, Ann Arbor, [5]i3 statprobe, Ann Arbor, United States.

Background and aims: Serum lipase and amylase elevations may be diagnostic for pancreatitis yet their incidence and prevalence in patients with type 2 diabetes mellitus (T2DM) is not well characterized. Aims of this analysis included 1) cross-sectional analysis of lipase and amylase levels in a cohort of 440 patients with T2DM but without signs or symptoms of pancreatitis or other gastrointestinal (GI) disease and 2) longitudinal surveillance in those patients who participated in the EGO study (clinicaltrials.gov ID: NCT00630825) of the long-acting, glucagon-like peptide-1 (GLP-1) analog LY2189265 (LY).
Materials and methods: EGO was a double-blind, randomized phase 2 clinical trial comparing LY versus placebo in overweight/obese patients with suboptimal control of T2DM despite therapy with 2 oral anti-hyperglycemic agents. Study participants underwent detailed history and physical examination including specific scoring for GI symptoms and were randomized to once-weekly subcutaneous injections for 16 weeks of placebo; LY 1.0 mg; LY 0.5 mg, 4 weeks then 1.0 mg; or LY 1.0 mg, 4 weeks then 2.0 mg. Simple linear regression was used to test associations between rank order of increase in lipase at endpoint and 21 factors including LY treatment, demographic characteristics, laboratory parameters and concomitant medications. Factors with p<.10 were analyzed by multiple linear regression using backward selection with type I error of .10; two-way interactions were examined for significance with type I error of .10.
Results: Of 440 patients screened [48% female, 57±11 years; baseline HbA1C 8.3±1.6% (mean ±SD)], 13% had elevated lipase (≥60 IU/dL), 5% had elevated amylase (≥112 IU/dL), 16% had either enzyme elevated and 3% had both enzymes elevated; comparable frequencies of elevations were observed for randomized study participants [n=262; 49% female; mean age 57±12 years;

mean HbA1C 8.2±0.9%). At study endpoint increases in amylase and lipase, maximum values and changes in categorical lipase or amylase levels, shown in the table below, were not significantly different between treatment groups (all p>.05). Tobacco non-use at baseline; statin use at baseline; and lower endpoint HbA1C were associated in univariate analysis with increase in lipase during study and HbA1C (p=.090) and tobacco non-use (p=.017) were retained in the final multivariate model. Replacing HbA1C with LY in the final model did not result in statistical significance for LY (p=.41).

Amylase and Lipase Measurements

Assessment	Treatment	Baseline Mean (SD), IU/dL	Endpoint Change Mean (SD), IU/dL	Endpoint Maximum Value, IU/dL	Became abnormal during study N (%)	Normalized during study N (%)
Lipase	Placebo	40 (18)	13 (64)	513	8/59 (13.6)	1/3 (33.3)
	0.5/1.0mg LY	40 (14)	20 (87)	709	13/58 (22.4)	1/3 (33.3)
	1.0/1.0mg LY	45 (33)	20 (53)	439	9/49 (18.4)	5/11 (45.5)
	1.0/2.0mg LY	47 (32)	14 (63)	455	11/49 (22.4)	5/12 (41.7)
Amylase	Placebo	57 (21)	6 (18)	177	4/58 (6.9)	0/4
	0.5/1.0mg LY	58 (27)	10 (34)	261	4 /54 (7.4)	1/3 (33.3)
	1.0/1.0mg LY	57 (33)	10 (30)	215	5/53 (9.4)	0/2
	1.0/2.0mg LY	61 (26)	9 (21)	153	6/51 (11.8)	1/5 (20.0)

Conclusion: Elevations in lipase and amylase occur at greater frequency in this population than may be expected and were observed irrespective of treatment. Prospective evaluations are warranted to explore the potential clinical significance of these findings.

771

Exenatide significantly ameliorates increases in pancreatic enzyme secretion in a rat model of acute pancreatitis

D. Parkes, L. Adams, M. Lu, C. Villescaz, T. Whisenant, D. Hargrove, B. Gedulin, P. Smith;
Amylin Pharmaceuticals, Inc., San Diego, United States.

Background and aims: Exenatide (Ex) is a GLP-1 receptor agonist that produces similar glucoregulatory actions to the endogenous incretin GLP-1, via enhancement of glucose-dependent insulin secretion, regulation of gastric emptying, decreased postprandial glucagon secretion and decreased food intake. CCK-8 is a peptide hormone secreted from the duodenum that physiologically stimulates release of digestive enzymes. Caerulein (CRN) is a decapeptide agonist of CCK receptors, which potently stimulates gastric, biliary and pancreatic secretion and is known as an agent that induces acute pancreatitis in experimental animal models. The present study examined the effect of exenatide on basal, CCK-stimulated and CRN-hyperstimulated pancreatic enzyme secretion and pancreatic morphology in rats.
Materials and methods: Fasted, male, anesthetised Sprague Dawley (SD) rats were injected subcutaneously with saline or Ex (0.3, 1 or 3μg/kg) 15 minutes before saline (100μl), CCK-8 (10μg/kg) or CRN (10μg/kg) IP administration. Plasma amylase and lipase concentrations were measured for up to 6 hours after IP injections (t= -15, 0, 5, 15, 30, 45, 60, 90, 120, 180, 240, 300 and 360 min). At completion of the experiment, pancreata were weighed and prepared for histological evaluation.
Results: Exenatide had no significant effect on fasting basal (unstimulated) plasma amylase and lipase activity over the 6-hour time period. Following CCK-8 injection, 3μg/kg Ex showed a tendency to reduce plasma amylase and lipase secretion compared to saline controls, but the reduction was not statistically significant (amylase AUC_{180} 107929 ± 8401U/L (Ex) vs 136369 ± 14029U/L (sal), P=0.12; lipase AUC_{180} 6982 ± 1851U/L (Ex) vs 14957 ± 4546U/L (sal), p=0.15). Following CRN injection, 3μg/kg Ex significantly reduced CRN-induced increases in plasma amylase (AUC_{180} 212730 ± 16675U/L (Ex) vs 331654 ± 36241U/L (sal), P<0.05 ANOVA: Dunnett's test) and lipase (AUC_{180} 39428 ± 5149U/L (Ex) vs 79710 ± 13566U/L (sal), P<0.05 ANOVA: Dunnett's test). CRN induced very mild changes in pancreatic acinar cell vacuolisation and necrosis and exenatide did not significantly change these responses.
Conclusion: Acute treatment with exenatide at doses up to 30-fold those given therapeutically to lower glucose did not change basal pancreatic amylase or lipase secretion in non-diabetic SD rats. Furthermore, exenatide significantly suppressed the increases in pancreatic enzyme activity observed in this rat model of acute, caerulein-induced pancreatitis.

772

Efficacy and safety of early combination of vildagliptin and metformin in comparison to placebo in patients with type 2 diabetes

J.J. Meier[1], M. Vollmer[1], C. Pennartz[1], C. Abletshauser[2], W.E. Schmidt[1];
[1]Department of Medicine I, St. Josef-Hospital, Ruhr-University of Bochum,
[2]Medical Department, Novartis Pharma Germany, Nürnberg, Germany.

Background and aims: To reach treatment goals in type 2 diabetes early combination of antidiabetic drugs without the risk of hypoglycemia is requested. As promising new approach, inhibiting of dipeptidyl peptidase-4 (DPP-4) enhances endogenous glucagon-like peptide-1 activity, improves β-cell insulin secretion, and suppresses hyperglucagonemia and excessive hepatic glucose output. The current study investigated the use of early combination of the highly selective DPP-4 inhibitor vildagliptin in patients inadequately controlled with metformin.
Materials and methods: In this double-blind, randomized, placebo-controlled 24 weeks study with 12 weeks open-label extension 405 patients (HbA1c 6.8-8.0%) have been randomized (ratio 2:1 vildagliptin:placebo). Patients with 18-85 years of age were pre-treated with the maximal tolerated dose of metformin for at least 3 months. During the double-blind and open-label period the dose of vildagliptin was 100 mg o.a.d.
Results: The primary endpoint, change in HbA1c-levels after 24 weeks versus placebo, could be documented in 395 patients. Mean HbA1c-levels were reduced from 7.3% to 6.9% under vildagliptin. In contrast, HbA1c-levels slightly increased from 7.2% to 7.4% in the placebo group. The difference of 0.5% between groups was statistically significant (p<0.0001). FPG-values declined under vildagliptin from 123 mg/dl to 114 mg/dl and from 124 mg/dl to 122 mg/dl under placebo. During the following 12 weeks open-label extension under vildagliptin HbA1c-levels and FPG-levels kept stable. 31 % of patients treated with vildagliptin did reach HbA1c-levels below 6.5% versus 18% under placebo. Rate of SAEs was 5.2% in the vildagliptin group versus 9.4% under placebo. There were no significant changes in liver enzymes in either group. Mild hypoglycemia was reported in 0.4% of patients under vildagliptin and 0.8% of patients under placebo. No severe hypoglycemia occurred during the study.
Conclusion: Early combination of vildagliptin with metformin is a well tolerated and efficacious treatment option of patients with type 2 diabetes.

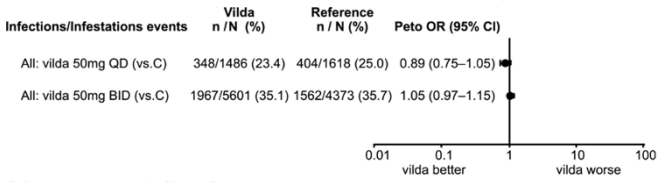
Lack of vildagliptin effects on the immune system

J. Foley[1], P. Hoffmann[1], M. Ligueros-Saylan[1], A. Schweizer[2], W. Kothny[1];
[1]Novartis Pharmaceuticals Corporation, East Hanover, United States,
[2]Novartis Pharma AG, Basel, Switzerland.

Background and aims: Vildagliptin is a potent and selective DPP-4 inhibitor that improves overall glycemic control in patients with type 2 diabetes by reducing both fasting and postprandial glucose levels via GLP-1's effect to increase the sensitivity to glucose of the α- and β-cells of the pancreas. Since DPP-4 is also known as CD26, an effect on the immune system was recognized as a potential side effect of DPP-4 inhibition from the beginning of the development of vildagliptin, particular efforts were made in both the animal toxicology studies and human studies to identify any potential effects of vildagliptin on the immune system.
Materials and methods: The assessment of the immune system's capability to respond to foreign proteins with the generation of specific antibodies was carried out according to the European guideline for repeated dose toxicity testing of medicinal products in rats at doses of 0,50,225, and 900 mg/kg/day. The exposure resulting from a dose of 900 mg/kg/day is 135 times the exposure resulting from the maximum 100 mg daily dose in man. In human studies, the most sensitive and relevant immune system parameter is the infection rate. A meta-analysis using Peto fixed effects odds ratio was performed to compare vildagliptin (at doses of 50 mg qd and 50 mg bid) to the all comparators group (placebo and all active comparators pooled) using adverse events in the System Organ Class of Infections and Infestations from double-blind clinical trials.
Results: In rats, vildagliptin at daily oral doses up to 900 mg/kg was well tolerated and did not affect the capability of the immune system to respond

to foreign proteins with the generation of specific antibodies. Furthermore, in all other toxicity studies in mice, dogs and monkeys no effects related to the immune system were identified. In human studies where patients on vildagliptin doses of 50 mg qd or 50 mg bid were studied there were also no immune system signals. As can be seen from the figure below vildagliptin was not associated with an increased risk of infections and infestations relative to all comparators, the odds ratios being 0.89 (95% CI 0.75-1.05) and 1.05 (95% CI 0.97 - 1.15) for vildagliptin 50 mg qd and 50 mg bid, respectively.
Conclusion: Based on animal and human data there is no evidence to suggest that vildagliptin treatment is associated with any adverse effects related to the immune system.



Reference=comparators (vs.C) = vs. Comparators.
Comparators= all non-vilda treatment groups. Arrows reperesent estimates outside of axis range.
Peto fixed odds ratios estimates only includes studies with at least one event.

Comparative pharmacology of the Dipeptidyl Peptidase-4 (DPP-4) metabolites of GLP-1 and the GLP-1 analogue, liraglutide
K. Tomaselli, J. Herich, K. Xu, D. Yuskin, L. Collins, C. Crogan-Grundy, Y. Wang, F. Brunel, J. Alfaro Lopez, A. Sharma, M. Hanley, S. Ghosh;
Amylin Pharmaceuticals, Inc., San Diego, United States.

Background and aims: The human incretin, glucagon-like peptide-1 (GLP-1), is a glucoregulatory peptide secreted by intestinal L-cells. Mimetics of GLP-1 fall into two structural classes, classified by their peptide backbones. The "exendin class" comprises analogs of exendin-4, a peptide derived from the saliva of *Heloderma suspectum*, and includes exenatide, which is approved for the treatment of type 2 diabetes mellitus (T2DM). The "GLP-1 class" comprises analogs of human GLP-1 peptide, and includes liraglutide, a drug under clinical and regulatory evaluation as a potential T2DM therapy. While exenatide and liraglutide are both GLP-1 receptor (GLP-1R) agonists, they are pharmacologically distinct. For example, exenatide and liraglutide differ in their susceptibility to proteolytic cleavage and inactivation by DPP-4, which removes the N-terminal two amino acids from GLP-1 and liraglutide, but not from exenatide.
Materials and methods: The *in vitro* pharmacological activity of the DPP-4 metabolite of liraglutide, (γ-L-glutamyl)(N-α-hexadecanoyl)-Lys^{26}Arg^{34}-GLP-1 (9-37), was compared to the DPP-4 metabolite of GLP-1, GLP-1 (9-36 amide), in the GLP-1R-expressing rat thyroid C-cell line, 6-23 (ATCC), and in CHO cells stably transfected with the human GLP-1R and β-arrestin (DiscoverX, Freemont, CA), by measuring cAMP production and β-arrestin recruitment, respectively.
Results: In both cell assays, (γ-L-glutamyl)(N-α-hexadecanoyl)-Lys^{26}Arg^{34}-GLP-1 (9-37) and GLP-1 (9-36 amide) were qualitatively and quantitatively similar. Neither metabolite demonstrated appreciable GLP-1R agonist activity. However, both GLP-1 (9-36 amide) and (γ-L-glutamyl)(N-α-hexadecanoyl)-Lys^{26}Arg^{34}-GLP-1 (9-37) demonstrated functional GLP-1R antagonism with apparent K_b values of 1.49-2.10 and 0.42-0.95 μM, respectively.
Conclusion: Proteolysis of liraglutide by DPP-4 yields a biologically active metabolite, (γ-L-glutamyl)(N-α-hexadecanoyl)-Lys^{26}Arg^{34}-GLP-1 (9-37), which, like GLP-1 (9-36 amide), is a functional antagonist of GLP-1 *in vitro*. Further studies on the effects of the liraglutide metabolite, (γ-L-glutamyl)(N-α-hexadecanoyl)-Lys^{26}Arg^{34}-GLP-1 (9-37), *in vivo* are warranted.

775

Liraglutide, the once-daily human GLP-1 analogue, has a protracted profile based on both delayed absoprtion and a long plasma half-life
L. Bjerre Knudsen, P.F. Nielsen, D.B. Steensgaard, P. Bloch, J. Lau, H. Agersoe;
Novo Nordisk, Maaloev, Denmark.

Background and aims: Liraglutide is a once-daily human GLP-1 analogue that has been developed for the treatment of type 2 diabetes and obesity. Liraglutide has a unique structure with a simple fatty acid and a spacer attached covalently to the peptide backbone (C16-γGlu-Lys26,Arg34GLP-1(7-37)) that provides both delayed absorption and long plasma half-life. The mechanism for the protraction is based on app. 99% binding to albumin, providing the long plasma half-life, and heptamer formation in the formulation, providing a delayed absorption. Also, DPP(Di-Peptidyl Peptidase)-IV stability is obtained. We designed a series of analogues of liraglutide that provides insight into the mechanism of protraction by investigating the importance of the length of the fatty acid.
Materials and methods: The pharmacokinetic profiles were measured in pigs. DPP-IV stability was measured by mass spectroscopy. Binding to albumin was measured indirectly, by adding increasing amounts of albumin to a GLP-1 receptor binding assay. Multimer formation was assessed by circular dicroism spectroscopy.
Results: Pharmacokinetic experiments in pigs illustrate how the length of the fatty used is an important parameter for obtaining protraction, both when looking at delayed absorption and plasma half-life. Decreasing the length of the fatty acid decreased half-life after s.c administration (16, 5.1 and 0.8h) and Tmax (7, 1.3 and 0.9h), as well as half-life after i.v. administration (10, 1.7

and 0.3 h) for liraglutide (C16), C11- and C10-analogs, respectively. Stability towards degradation by the DPP-IV enzyme correlated with the length of the fatty acid. The half-life for DPP-IV degradation in vitro was 2.4 min. for GLP-1, and 937, 383, 156 and 108 min. for liraglutide, C14-, C12-, C10-analogs, respectively. Binding to albumin decreased with the length of the fatty acid, measured as the shift in receptor activation by addition of 4% albumin (45, 45, 41, 14 for liraglutide, C14, C12, C10). The un-acylated analogue did not bind to albumin. The apparent K_d for multimer formation in the formulations increased by decreasing fatty acid length. $K_{d,app}$ was <0.1 µmol/l for liraglutide, and 2, 10 and 50 µmol/l for C14, C12 and C10, respectively.
Conclusion: The protraction mechanism for liraglutide includes albumin binding, heptamer formation and DPP-IV stability, resulting in delayed absorption and long plasma half-life, allowing once-daily dosing in humans.

776

Effect of the GLP-1 receptor agonist AVE0010 on the absorption of concomitant oral drugs: acetaminophen and ethinylestradiol/levonorgestrel
Y.-H. Liu, P. Ruus;
R&D Clinical & Exploratory Pharmacology (CEP), Sanofi-Aventis Deutschland GmbH, Frankfurt, Germany.

Background and aims: Glucagon-like peptide-1 (GLP-1) receptor agonists slow gastric emptying, which may alter the rate or extent of absorption of oral drugs. The present study looked at the potential influence of AVE0010 - a new GLP-1 receptor agonist under development for the treatment of type 2 diabetes mellitus - on the absorption of acetaminophen or an oral contraceptive in healthy volunteers.
Materials and methods: The effect of 10 µg AVE0010 on the absorption of 1 g acetaminophen (AC; used as a probe drug for gastric emptying) or an oral contraceptive (OC; 0.03 mg ethinylestradiol [EE]/0.15 mg levonorgestrel [LN]) was assessed in two single-centre, single-blind, placebo (PBO)-controlled, randomised, 5-treatment, 5-period, crossover studies in healthy subjects. In Study 1 (n=15; male and female), AVE0010 or PBO were administered subcutaneously 30 min before breakfast and a single oral AC dose was given -1, +1, or +4 h relative to AVE0010 and -1 or +1 h relative to PBO, with 2-day washout periods between each of the 5 schedules. In Study 2 (n=25 post-menopausal women), AVE0010 or PBO were administered 30 min before dinner/breakfast and a single oral OC dose given in accordance with the following 5 schedules: 1) PBO 8 pm Day 1, OC 7 am Day 2, PBO 8 am Day 2; 2) AVE0010 8 pm Day 1, OC 7 am Day 2, PBO 8 am Day 2; 3) AVE0010 8 pm Day 1, OC 7am Day 2, AVE0010 8 am Day 2; 4) PBO 8 pm Day 1, AVE0010 8 am Day 2, OC 9 am Day 2; 5) PBO 8 pm Day 1, AVE0010 8 am Day 2, OC 12 noon Day 2; with a 7-day washout period between each schedule. All subjects underwent 24-h (Study 1) or 72-h (Study 2) blood sampling to determine drug concentrations. Pharmacokinetic (PK) parameters estimated included area under the plasma concentration-time curve (AUC), maximum plasma concentration (C_{max}) and time to C_{max} (t_{max}), and terminal half-life ($t_{½}$). Between-schedule ratios for AUC and C_{max} were expressed as means with 90% confidence limits (CI). Lack of PK interaction was demonstrated if the lower CI for AUC and C_{max} was greater than the 0.80 non-inferiority specification value.
Results: In Study 1, the absorption of AC was unchanged when given 1 h before AVE0010. When given 1 or 4 h after AVE0010, the C_{max} of AC decreased to 71% [57%, 87%] and 69% [56%, 85%], respectively, of the PBO values, whereas the AUC parameters were unchanged. Median t_{max} increased from <1 to 4.5 h when AC was given 1 h after AVE0010. Food slowed AC absorption, with a reduction in PBO post-meal C_{max} to 52% [42%, 64%] of pre-meal values and an increase in median t_{max} (0.25 to 2 h). In Study 2, EE and LN absorption rates were unchanged when OC was given 11 h after or 1 h before AVE0010. When given 1 or 4 h after AVE0010, t_{lag} (time to concentration exceeding lower limit of quantitation) and t_{max} were increased and C_{max} was reduced to 48% [43%, 53%] (1 h) or 61% [56%, 68%] (4 h) of control values for EE, and 54% [48%, 62%] or 80% [70%, 92%] of control values for LN. AUC parameters and $t_{½}$ were unchanged. AVE0010 was well tolerated in both studies.
Conclusion: These results are consistent with a slowing of gastric emptying by AVE0010. The absorption of AC was completely unaltered if it was administered 1 h before AVE0010, and the absorption of OC was unaltered if it was administered 11 h after or 1h before AVE0010. However, the rate of absorption of AC or OC was altered when given 1 or 4 h after AVE0010. Total drug exposure was unchanged.

Liraglutide pharmacokinetic profile following s.c. dosing is unaltered by co-administration with sitagliptin in Göttingen minipigs
F.S. Nielsen, L. Ynddal, C. Rosenquist, J. Drustrup, L. Bjerre Knudsen;
Novo Nordisk A/S, Maaloev, Denmark.

Background and aims: Liraglutide is a once-daily human Glucagon-Like Peptide-1 (GLP-1) analog that has completed phase 3 clinical testing. Liraglutide is a fatty-acid derived analog of human GLP-1 that binds to albumin as its main mechanism of protraction. Liraglutide is also stabilized against the DPP-IV enzyme. However, liraglutide is subject to a minor degradation *in vivo*, and thus it is interesting if co-administration with a DPP-IV inhibitor lead to increases in liraglutide concentrations. Sitagliptin is a DPP-IV inhibitor that increases endogenous levels of GLP-1, which is the main mechanism for its blood glucose lowering ability. Since both compounds lead to increases in GLP-1-like concentrations (either liraglutide or native GLP-1), we investigated if they could be combined by investigating the pharmacokinetics of liraglutide following co-administration of liraglutide and sitagliptin.
Materials and methods: The study was carried out in minipigs because only pigs have a similar absorption of injectable peptide analogs as compared to humans. Sitagliptin is dosed once daily PO (100 mg) in patients, resulting in a steady state trough plasma concentration of 41 ng/mL. Liraglutide is dosed once-daily SC (1.2 or 1.8 mg). The study was conducted in two parallel groups (+/- sitagliptin) of mini-pigs (n=4). Both groups were dosed SC with liraglutide in a dose of 2 nmol/kg, equivalent to app. 0.6 mg pr 75 kg. The sitagliptin group was dosed three times daily in order to obtain a target steady state trough plasma concentration of sitagliptin above 40 ng/mL.
Results: The key pharmacokinetic parameters (mean ±SD) of liraglutide are given in Table 1. Sitagliptin had no significant effect on the pharmacokinetics of liraglutide as evaluated by T_{max}, C_{max}, AUC/Dose and half-life. The mean plasma concentration of sitagliptin was verified to be above 40 ng/mL.
Conclusion: In conclusion, the DPPIV inhibitor sitagliptin did not alter the pharmacokinetics of liraglutide following SC administration in mini-pigs.

Table 1

Treatment	T_{max} [hr]	C_{max} [pM]	AUC/Dose [hr·pM/pmol/kg]	T½ [hr]
- Sitagliptin	8.5 ±2.5	18000 ±3700	278 ±32	22 ±2.6
+ Sitagliptin	8.0 ±2.8	19600 ±2300	322 ±53	20 ±1.4
p-value (t-test)	0.80	0.52	0.21	0.20

Inhaled GLP-1 and exenatide: different effects on pancreatic and gastric activity following a single dose in type 2 diabetes mellitus
R. Baughman[1], D. Costello[1], M. Marino[1], J. Cassidy[1], A. Boss[1], C. Damico[1], P. Haworth[1], P. Richardson[1], J. van de Wetering[2], A. van Vliet[2];
[1]MannKind Corporation, Valencia, United States, [2]PRA International, Zuidlaren, Netherlands.

Background and aims: MKC253 is GLP-1 adsorbed onto Technosphere microparticles for oral inhalation. A single MKC253 dose in healthy, normal volunteers produced high circulating concentrations of GLP-1 (10 min) with a dose-dependent insulin release, a reduction in fasting plasma glucose, and no nausea or vomiting. This double-blind, double-dummy, placebo- and active-control crossover trial compared the effects of MKC253 (1.5 mg) and s.c. injection of exenatide (EXE; 10 µg) on postprandial glucose (PPG) excursions, postprandial insulin, gastric emptying, and GLP-1 pharmacokinetics.
Materials and methods: Included were 20 nonsmoking subjects with type 2 diabetes mellitus (HbA_{1c} 6.2%-8.5%) on a stable oral antidiabetic regimen. Subjects received five treatments 2 days apart. All received MKC253 or inhaled placebo (InhP) while fasting. EXE or s.c. placebo (SCP) was given 15 min premeal, and MKC253 or InhP was given premeal (Pre) or 30 min postmeal (Post). Subjects received in randomized order: SCP + MKC253 Pre + InhP Post; SCP + MKC253 Pre + MKC253 Post; EXE + InhP Pre + InhP Post; or SCP + InhP Pre + InhP Post. Gastric emptying was measured by absorption of ^{13}C-octanoate from a 575 kcal standardized meal.
Results: MKC253 produced a rapid spike in insulin. Mean maximum insulin concentration occurred <10 min after dosing and fell sharply thereafter. Mean peak insulin was 60 µU/ml. Mean pharmacokinetics of insulin release closely tracked mean GLP-1 kinetics. The insulin response following EXE was slower

and less pronounced. In fasting subjects with baseline glucose <9 mmol/l, MKC253 produced a mean maximal decrease in glucose of 0.75 mmol/l about 30 min after inhalation. Subjects with baseline glucose >9 mmol/l had a 1.2 mmol/l decrease in glucose ≈45 min after inhalation. MKC253 reduced PPG excursions. Compared with InhP, MKC253 Pre decreased PPG by ≥1 mM/l for >1 h and MKC253 Pre + Post decreased PPG for >3 h. Reductions were longer than that predicted by a GLP-1 half-life of <2 min. MKC253 had little or no effect on gastric emptying. In contrast, EXE also reduced PPG but acted by delaying gastric emptying. More than 90% of ^{13}C-octanoate ingested was unabsorbed 4 h after the meal compared with <60% with MKC253. After EXE injection, the insulin response to meal challenge was much smaller than with MKC253. Only 1 of 20 subjects reported nausea with MKC253 vs. rates >66% from literature with injected GLP-1.
Conclusion: Both MKC253 and EXE reduce PPG excursions, but appear to do so by different mechanisms.

779

Response to inhaled GLP-1 is dependent on baseline glucose
D. Costello[1], R. Baughman[1], M. Marino[1], J. Cassdiy[1], A. Boss[1], C. Damico[1], P. Haworth[1], P. Richardson[1], A. van Vliet[2];
[1]MannKind Corporation, Valencia, United States, [2]PRA International, Zuidlaren, Netherlands.

Background and aims: MKC253 is GLP-1 adsorbed to Technosphere microparticles for oral inhalation. This report presents data from two studies: MKC253001 evaluated the effect of MKC253 under fasting conditions in healthy subjects, and MKC253002 evaluated MKC253 in subjects with type 2 diabetes.
Materials and methods: All subjects received 1.5 mg GLP-1 via inhalation. In MKC253001, six healthy subjects received GLP-1. In MKC253002, 15 subjects with type 2 diabetes received GLP-1, and five subjects with type 2 diabetes received Technosphere placebo.
Results: Of the 15 subjects in MKC253002 who received GLP-1, 11 had baseline glucose >9 mmol/l and four had baseline glucose <9 mmol/l. All subjects were nonsmokers with normal lung function. In healthy subjects, MKC253 produced a transient decrease in glucose of 0.8 mmol/l. Minimum levels occurred approximately 15 min after inhalation of MKC253. Following the decrease, glucose returned to baseline levels by 1 h. The duration of response was much longer than the half-life of GLP-1 (≤2 min). Response to GLP-1 in subjects with type 2 diabetes depended on baseline glucose. Subjects with baseline glucose <9 mmol/l had a mean maximum decrease of 0.75 mmol/l. The time to reach the minimum was about 0.5 h. Although glucose values recovered, they did not return to baseline levels after 4 h. Subjects with baseline glucose >9 mmol/l had a 1.2 mmol/l decrease in glucose. The duration of response was longer--the minimum occurred 45 min after inhalation, with no return from the minimum levels. Placebo subjects had no change in glucose over the first 2 h after inhalation.
Conclusion: It has been shown previously that inhalation of MKC253 produces a sharp spike in plasma insulin. This rapid pulse of insulin can produce a long-lasting decline in plasma glucose in fasting subjects with type 2 diabetes.

A phase 1b study of ITCA 650: continuous subcutaneous delivery of exenatide via DUROS® device lowers fasting and postprandial plasma glucose
K. Luskey[1], J. McNally[1], J. Dahms[1], D. Logan[2], G. Weiner[3], D. Denham[4], T. Alessi[1];
[1]Intarcia Therapeutics, Hayward, [2]Medpace, Cincinnati, [3]Cetero, Miami Gardens, FL, [4]Cetero, San Antonio, United States.

Background and aims: Exenatide is a proven effective treatment for type 2 diabetes that improves glucose control and induces weight loss. However, use of exenatide has been limited due to the twice-daily self-injection schedule and frequent nausea which may be associated with peak concentrations of drug. The DUROS® technology is a subcutaneous continuous delivery system which has been utilized in the Viadur® device, an FDA-approved therapy for prostate cancer. It is an osmotic delivery device consisting of a small sterile titanium cylinder (4mm x 45 mm) that is placed subcutaneously for extended periods of time. ITCA 650 is a DUROS device engineered to deliver exenatide at a continuous and consistent rate for treatment durations of 3 to 12 months and over a broad range of dose levels. Preclinical studies have shown that ITCA 650 delivers exenatide at a consistent rate for >6 months with preserved stability of the drug product.
Materials and methods: A phase 1b study to evaluate the safety and tolerability of ITCA 650 treatment is being conducted in subjects with inadequately controlled type 2 diabetes for 28 days. In this study, subjects were randomized to receive either 10 mcg/day or 20 mcg/day of exenatide.
Results: Changes in fasting plasma glucose (FPG) from 24 hours to 2 weeks are indicated in the table below. In addition to changes in FPG, a decrease in the 2-hour postprandial glucose was also observed at two weeks. ITCA 650 was well tolerated primarily with observations of anticipated mild bruising, itching and local pain at the insertion site, as well as transient mild nausea and vomiting in a small number of the subjects. Based on the favorable tolerability observed at the studied doses, higher doses of ITCA 650 are currently under clinical evaluation.
Conclusion: ITCA 650 represents a novel method to deliver exenatide for extended periods of time with 100% compliance for the long-term treatment of type 2 diabetes.

Changes in Fasting Plasma Glucose (FPG)

Dose Arm	Baseline FPG	FPG at 24 hours	FPG at 1 week	FPG at 2 weeks
10 mcg/day (n=12)	161±34 mg/dL	146±30 mg/dL	143±33 mg/dL	139± 36 mg/dL
20 mcg/day (n=11)	170 ±23 mg/dL	145±33 mg/dL	139±28 mg/dL	127±15 mg/dL

781

Safety, tolerability, pharmacokinetics, and insulinotropic activity of single subcutaneous doses of LY2189265, a long-acting glucagon-like peptide 1 analogue in healthy subjects
P. Barrington[1], J. Chien[2], F. Tibaldi[3], H. Showalter[2], K. Schneck[2], B. Ellis[2];
[1]EU Exploratory Program Phase Medicine, Eli Lilly and Company, Windlesham, United Kingdom, [2]Eli Lilly and Company, Indianapolis, United States, [3]GSK Biologicals, Rixensart, Belgium.

Background and aims: LY2189265 is a novel, long-acting glucagon-like peptide 1 (GLP-1) analog being developed for treatment of type 2 diabetes (T2DM). LY2189265 consists of a dipeptidyl peptidase-IV (DPP-IV)-protected GLP-1 analog covalently linked to an Fc fragment of human IgG4, thereby increasing its duration of pharmacological activity. Safety, tolerability, pharmacokinetics (PK), glucose-dependent insulin secretion, and immunogenicity of LY2189265 were evaluated in healthy subjects in this first-time-in-human Phase 1 trial.
Materials and methods: The study was a 3-period, crossover, double-blind, placebo-controlled investigation of single subcutaneous doses of LY2189265 (0.1 mg to 12 mg). Twenty subjects randomly received 2 escalating doses of LY2189265 and placebo given ≥3 weeks apart; 16 received all 3 doses and 4 received 1 dose. The PK profile was assessed over 14 days. Insulinotropic activity was measured following a graded glucose infusion (GGI) and an oral glucose tolerance test (OGTT).
Results: LY2189265 was well tolerated up to 6 mg. The most frequent adverse event was dyspepsia. Headache, injection site irritation, nausea, and vomiting increased with increased dose. Compared with placebo, statistically significant ($p<.01$) dose-dependent increases were observed in supine heart rate at ≥0.3 mg and in supine diastolic blood pressure at ≥1 mg. No case of hypoglycemia occurred. No subject developed antibodies to LY2189265.

The half-life of LY2189265 was ~90 hours in healthy subjects. The maximum concentration (C_{max}) occurred between 24 and 48 hours. With each doubling of dose, the increase in area under the concentration-time curve from 0 to infinity and C_{max} were less than double (1.84-fold and 1.88-fold respectively). There were glucose-dependent increases in insulin secretion following GGI and suppression of serum glucose following OGTT at all doses of LY2189265 compared with placebo.
Conclusion: LY2189265 exhibited expected GLP-1 pharmacology and safety profiles. PK and sustained pharmacodynamic effects support further evaluation of LY2189265 for once-weekly dosing in patients with T2DM.

Pharmacokinetics, pharmacodynamics, safety and tolerability of single dose exenatide in very elderly patients (≥75 years) with type 2 diabetes
H. Linnebjerg[1], P.A. Kothare[2], M. Seger[2], M. Mitchell[2];
[1]Lilly Research Laboratories, Eli Lilly and Company, Surrey, United Kingdom, [2]Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, United States.

Background and aims: This study assessed the effect of exenatide on pharmacokinetic (PK) and pharmacodynamic (PD) parameters, safety and tolerability in very elderly patients with Type 2 Diabetes (T2D).
Materials and methods: This randomised, placebo-controlled, 3-treatment, crossover study compared control (45-65 years [y], n=15) and very elderly (≥75y, n=15) groups. Patients received single subcutaneous doses of placebo, exenatide 5µg or exenatide 10µg, 15min before a standardised breakfast for 3 consecutive days. Serial blood samples were collected for plasma exenatide and serum glucose concentrations. These PK data were further integrated with 6 other clinical pharmacology studies: 139 control (≤65y) and 28 elderly (>65y) subjects to evaluate exenatide clearance in a larger dataset.
Results: Mean ages (±SD) for control and very elderly groups were 57±5.5y and 78±3.3y, respectively; and renal insufficiency was present in 5 control and 15 very elderly patients. Dose-normalised exenatide maximum concentration and $AUC_{0-\infty}$ was not significantly different between groups. Glucose lowering was dose-dependent and comparable between groups. No hypoglycaemia or serious adverse events were reported, and exenatide was generally well tolerated in both groups. The integrated analysis showed that exenatide clearance was significantly related to renal clearance (test of slope=0, p<0.001), with no additional effect from age (Figure 1).
Conclusion: No clinically relevant differences in PK, PD, safety or tolerability were observed in very elderly patients in this study. These data suggest that exenatide clearance is highly correlated to renal clearance, with no additional effect of age on exenatide clearance besides declining renal function. These results warrant no further dosage changes of exenatide in very elderly patients with T2D.

Postprandial glucose levels and long-term glucose control are improved with taspoglutide, a human once-weekly GLP-1 analogue, in an animal model of type 2 diabetes
E. Sebokova[1], S. Sewing[1], U. Sprecher[1], L. Tobalina[2], A. Benardeau[1], C. Migliorini[1];
[1]F. Hoffmann-La Roche AG, Basel, Switzerland, [2]Ipsen Pharma, San Feliu, France.

Background and aims: Several epidemiological studies confirmed that elevated PPG is a significant predictor of cardiovascular mortality and morbidity in type 2 diabetes (T2D). In this study post-challenge response following an oral glucose tolerance test (oGTT) was used to evaluate the effect of the human once-weekly GLP-1 analogue, taspoglutide (R1583), after acute and chronic treatment on PPG and long-term glucose control in ZDF rats.
Materials and methods: Acute effects of taspoglutide treatment were measured during an oGTT after single sc administration of taspoglutide (0.1, 1 and 10 µg/kg) in 9-wk-old ZDF rats. Long-term glucose homeostasis was assessed 3 wks after single administration of taspoglutide (1 mg/animal, sc, formulated to mimic human exposure) or vehicle to 5-wk-old ZDF rats (n=6/group) during an oGTT. In addition, PPG levels (4 hrs after food removal) were measured on days 7, 14, and 21 and 1,5-anhydroglucitol (1,5-AG) levels (using GlycoMark®) and HbA1c were assessed at the end of the study.
Results: Acute efficacy measured during an oGTT after single sc administration of taspoglutide (0.1, 1 and 10 µg/kg) in 9-wk-old ZDF rats showed significant improvement in glucose tolerance over 2 hrs (AUC_{Glu}: -15; -49 and -71%) and an increase in insulin secretion (AUC_{Ins}: +128; +236 and +184%) in a dose-dependent manner compared to vehicle. Chronic treatment with taspoglutide significantly reduced glucose excursion during the week 3 oGTT at 30, 60, and 120 min and $AUC_{Glu,0\text{-}120\ min}$ (-50%) without affecting insulin levels as compared with vehicle. PPG levels were significantly decreased in rats treated with taspoglutide in comparison to vehicle at Days 14 and 21. An improvement in long-term glucose control with a significant increase in 1,5-AG levels at Day 21 was also shown after single administration of taspoglutide (7.0±1.0 µg/mL) vs. vehicle: (2.3±0.85: µg/mL; p<0.005). Taspoglutide treatment also improved insulin sensitivity assessed by HOMA (taspoglutide: 20.0±2.6 vs. vehicle: 29.4±5.2) and ISI Matsuda (taspoglutide: 360±38 vs. vehicle: 230±27; p< 0.02).
Conclusion: Taspoglutide showed a significant reduction in PPG levels and long-term glucose control in a model of T2D progression, thus improving a significant risk factor for microvascular and macrovascular complications.

784

Chronic administration of the glucagon-like peptide-1 analogue, liraglutide, delays diabetes onset and improves lipids in a novel model of type 2 diabetes, the UCD-T2DM rat
P.J. Havel[1], B.P. Cummings[1], J.L. Graham[1], K.L. Stanhope[1], S.C. Griffen[2], C. Nilsson[3], L.B. Knudsen[3], K. Raun[3];
[1]Veterinary Medicine: Molecular Biosciences, University of California, Davis, United States, [2]Bristol Myers Squibb, Princeton, United States, [3]Novo Nordisk A/S, Måløv, Denmark.

Background and aims: Due to the increasing prevalence of type 2 diabetes (T2DM), there is a need to identify strategies for diabetes prevention. We have investigated the efficacy of liraglutide, a human glucagon-like peptide-1 (GLP-1) analog, to prevent or delay T2DM in UCD-T2DM rats, a model of polygenic obese T2DM that is more similar in etiology to T2DM in humans than other existing rodent models.
Materials and methods: At 2 months of age, rats were divided into three groups: control (CTRL), liraglutide (LIRA) and energy restricted (RSTR) (*n*=32). Rats received LIRA (0.2 mg/kg) or vehicle injections BID for up to 10 months. RSTR rats were food restricted to equalize body weights to LIRA rats. Non-fasting blood glucose was measured weekly to determine diabetes onset (<200 mg/dl) and fasting blood samples were taken monthly from all animals. At 6 months of age 16 animals from each group were euthanized for tissue analysis.
Results: Energy intake and body weight at 4 months of age were lower in LIRA and RSTR rats compared with CTRL rats: (CTRL: 103±3 kcal/d, 618±6 g; RSTR: 80±1 kcal/d, 544±5 g; LIRA: 89±2 kcal/d, 549±6, *P*<0.0001, *n*=32).

Greater energy intake in LIRA compared with RSTR rats, despite identical weight gain suggests that LIRA increases energy expenditure. Compared with CTRL, RSTR and LIRA delayed diabetes onset by ~2 and ~3 months, respectively (P<0.01). Mean ages of diabetes onset were: CTRL 4.9±0.5, RSTR 6.9±0.5, and LIRA 7.8±0.5 months. By 6.5 months of age, only 3/32 LIRA treated animals had become diabetic, whereas 12/32 RSTR and 26/32 CTRL animals were diabetic. Thus, LIRA significantly delayed diabetes onset compared with both the CTRL and RSTR groups (P<0.05). At 6 months of age, fasting plasma glucose and HbA1c concentrations were higher in CTRL (180±27 mg/dl; 9.1 ± 0.6%) compared with both LIRA (119±8 mg/dl; 5.5 ± 0.4%) and RSTR (121±5; 4.9 ± 0.2%) animals (all P< 0.001). Plasma triglycerides (TG) were reduced in LIRA treated (93 ± 5 mg/dl) compared with either CTRL (137 ± 10 mg/dl) or RSTR (175 ± 16 mg/dl) animals (P<0.05). Fasting plasma insulin at 4 months of age was lower in LIRA (1.4 ± 0.1 ng/ml) treated compared with either CTRL (2.9 ± 0.2 ng/ml) or RSTR (2.6 ± 0.2 ng/ml) animals (P<0.001). After excluding animals that had become diabetic and started losing weight before euthanasia, mesenteric and total white adipose tissue weights were lower in LIRA (8.0 ± 0.6g, 74 ± 4g, n=14) and RSTR (8.2 ± 0.4g, 81 ± 5g, n=14) compared with CTRL (11.1 ± 0.5g, 98 ± 4g, n=6) animals (P<0.05), but when expressed as percent body fat only LIRA was significantly lower compared to CTRL (CTRL: 15.1 ± 0.6%, RSTR: 14.1 ± 0.7%, LIRA: 12.8 ± 0.5%, P<0.05). Liver TG content was significantly lower in LIRA (13.2 ± 1.1 mg/g liver) and RSTR (13.0 ± 1.7 mg/g liver) compared to CTRL (23.0 ± 1.4 mg/g liver) animals (P<0.01).

Conclusion: Liraglutide delays the development of diabetes in UCD-T2DM rats and the delay in onset likely involves effects on food intake, weight gain, insulin sensitivity and energy and lipid metabolism. We are currently investigating other potential mechanisms including effects on islet morphology and function.

Effects of long-term dipeptidyl peptidase-IV inhibiton on body composition and glucose tolerance under high-fat diet in mice

X. Liu[1], N. Harada[1], S. Yamane[1], A. Hamasaki[1], E. Mukai[1], K. Toyoda[1], C. Yamada[1], Y. Yamada[2], Y. Seino[3], N. Inagaki[1];
[1]Department of Diabetes and Clinical Nutrition, Graduate School of Medicine, Kyoto University, [2]Department of Endocrinology and Diabetes and Geriatric Medicine, Akita University School of Medicine, [3]Kansai Electric Power Hospital, Osaka, Japan.

Background and aims: Incretins are a group of peptide hormones released from the gastrointestinal tract in response to meal ingestion and potentiate glucose-stimulated insulin secretion. Glucagon-like peptide-1 (GLP-1) and gastric inhibitory polypeptide (GIP) are major incretins. In addition to their action on the enteroinsular axis, GLP-1 decreases body weight through suppression of appetite, while GIP directly facilitates energy accumulation in adipose tissue. DPP-IV inhibitor increases plasma active GLP-1 and GIP. However, the magnitude of the effects of enhanced GLP-1 and GIP signaling by long-term DPP-IV inhibition on body weight and insulin secretion has not been determined. In this study, we compared the effects of long-term DPP-IV inhibition on body composition and insulin secretion of high fat diet (HFD)-fed wild-type (WT) and GLP-1R knockout (GLP-1R$^{-/-}$) mice.

Materials and methods: WT and GLP-1R$^{-/-}$ mice (7-week-old) were fed high fat chow with or without DPP-IV inhibitor by drinking water. Body weight and food intake were measured during 8 weeks of the study. After 8 weeks, Oral glucose tolerance test (OGTT) and CT-based analysis of body composition were performed. And batch incubation study for insulin secretion and mRNA expression of incretin (GLP-1 and GIP) receptors were measured using isolated islets from WT and GLP-1R$^{-/-}$ mice treated with or without DPP-IV inhibitor.

Results: DPP-IV inhibitor had no effect on food and water intake and body weight, but increased body fat mass in DPP-IV inhibitor-treated GLP-1R$^{-/-}$ mice compared to that of untreated GLP-1R$^{-/-}$ mice. DPP-IV inhibitor-treated WT and GLP-1R$^{-/-}$ mice both showed increased insulin secretion and improved glucose tolerance in OGTT. In isolated islets of DPP-IV inhibitor-treated WT and GLP-1R$^{-/-}$ mice, insulin secretion in response to 11.1mM glucose was increased and insulin secretion in response to GLP-1 or GIP was preserved compared to those in DPP-IV inhibitor-untreated WT and GLP-1R$^{-/-}$ mice. The mRNA expression levels of GLP-1 and GIP receptors in the islets of DPP-IV inhibitor-treated and untreated WT mice were similar, as were the mRNA expression levels of GIP receptor in the islets of DPP-IV inhibitor-treated and untreated GLP-1R$^{-/-}$ mice.

Conclusion: Long-term DPP-IV inhibition does not alter body composition, possibly due to the counteracting effects of enhanced GLP-1 and GIP, but does improve glucose tolerance by the synergistic insulinotropic effects of enhanced GLP-1 and GIP, as well as by improved glucose responsiveness in pancreatic islets.

786

Novel fatty acid derivatised forms of glucose-dependent insulinotropic polypeptide with improved glucose-lowering and insulin-releasing properties

V.A. Gault, B.D. Kerr, N. Irwin, F.P.M. O'Harte, P.R. Flatt;
School of Biomedical Sciences, University of Ulster, Coleraine, United Kingdom.

Background and aims: Glucose-dependent insulinotropic polypeptide (GIP) is a physiological insulin-releasing hormone. However, metabolic instability, rapid renal clearance and relative ineffectiveness of native GIP limit its use as a potential therapeutic for type 2 diabetes. The present study reports effects of novel fatty acid (myristic, palmitic or stearic acid) derivatised forms of GIP on metabolic stability, *in vitro* biological characterisation and *in vivo* glucose-lowering and insulin-release.

Materials and methods: Stability of GIP peptides (5 μg) was assessed by incubation (0, 2, 4, 8 and 24 h; 37°C) with DPP-IV (5 mU; n=3) and peptide degradation quantified by rp-HPLC. Cyclic AMP production (n=3) and insulin-releasing activity of GIP peptides were assessed in acute (20 min) studies using BRIN-BD11 cells. Acute and persistent (24 h) effects of GIP peptides (25 nmol/kg bw; ip) on plasma glucose and insulin concentrations were examined in 20-22 week old *ob/ob* mice (n=6). For sub-chronic studies, o*b/ob* mice were divided into four groups (two most potent peptides plus controls, n=6;) and received once-daily injections (17:00 h) of either saline vehicle (0.9%, w/v, NaCl), *N*-AcGIP, GIP(Lys^{37}MYR) or *N*-AcGIP(Lys^{37}MYR) (25 nmol/kg bw) over a 24-day period. Food intake, body weight, glucose and insulin levels were monitored at intervals of 2 to 4 days. Glucose tolerance (18 mmol/kg glucose) and insulin sensitivity (50 U insulin/kg) tests were performed at the end of the study. Furthermore, blood was taken for measurement of triglycerides and pancreatic tissue excised for determination of insulin content.

Results: Although GIP was rapidly degraded by DPP-IV (half-life 2.2 h), GIP analogues remained fully intact during the incubation (half-lives >24 h). All GIP analogues followed a similar pattern of concentration-dependent (10^{-12} to 10^{-6} M) stimulation of cyclic AMP production compared to native GIP (EC_{50} value 0.70 nM) but exhibited improved EC_{50} values (0.07 to 0.27 nM). Similarly, GIP analogues dose-dependently stimulated insulin secretion in BRIN-BD11 cells but with enhanced potency compared to both control (5.6 mM glucose; 2.8 to 4.0-fold; P<0.001) and GIP (1.5 to 2.1-fold; P<0.01 to P<0.001). Administration of GIP analogues to *ob/ob* mice significantly lowered plasma glucose (1.2 to 1.4-fold; P<0.05 to P<0.001), with GIP(Lys^{37}MYR), *N*-AcGIP(Lys^{37}MYR) and GIP(Lys^{37}PAL) additionally enhancing plasma insulin responses (1.2 to 1.8-fold; P<0.05 to P<0.001) compared to GIP-treated animals. Furthermore, GIP(Lys^{37}MYR) and *N*-AcGIP(Lys^{37}MYR) elicited significantly protracted glucose-lowering effect (1.2 to 1.3-fold; P<0.01 to P<0.001) when administered 24 h prior to a glucose load. Daily administration of GIP(Lys^{37}MYR) and *N*-AcGIP(Lys^{37}MYR) to *ob/ob* mice for 24 days decreased glucose (1.4 to 1.7-fold; P<0.05 to P<0.001) and significantly improved plasma insulin (1.4 to 2.2-fold; P<0.01 to P<0.001), glucose tolerance (1.3 to 1.5-fold; P<0.05 to P<0.001) and beta-cell glucose responsiveness (1.5 to 4.4-fold; P<0.01 to P<0.001). Insulin sensitivity, pancreatic insulin content and triglyceride levels were not changed

Conclusion: These data demonstrate that fatty acid derivatisation of GIP, particularly with myristic acid provides a class of stable, longer-acting forms of GIP with good biological effectiveness for further evaluation in diabetes therapy.

Insulinotropic and glucose lowering effects of small molecule GLP-1-receptor agonist 6,7-dichloro-2-methylsulfonyl-3-N-*tert*-butylaminoquinoxaline

S. Patterson[1], N. Irwin[1], B.D. Green[2], P.R. Flatt[1];
[1]School of Biomedical Sciences, University of Ulster, Coleraine, [2]Institute of Agri-Food and Land Use, Queens University, Belfast, United Kingdom.

Background and aims: Enzyme resistant GLP-1 mimetics such as exenatide and liraglutide are employed for the treatment of type 2 diabetes, but must be administered by injection. To improve therapeutic utility of the GLP-1 receptor target and avoid parenteral administration, development of small molecule receptor ligands suitable for oral administration would be an advantage. Therefore, the present study assessed the *in vitro* insulinotropic and *in vivo* glucose-lowering actions of the recently described low molecular weight selective GLP-1 receptor (GLP-1-R) agonist 6,7-dichloro-2-methylsulfonyl-3-N-*tert*-butylaminoquinoxaline (DMB). Biological activity of DMB has been compared with native GLP-1, exenatide and liraglutide.
Materials and Methods: Concentration-dependent acute (20 min) insulin-releasing activity of DMB, native GLP-1, exenatide and liraglutide (n=8) was assessed using clonal pancreatic BRIN-BD11 cells. In addition, acute effects of DMB and related GLP-1 peptides on plasma glucose concentrations were examined in normal mice (14-18 week-old) derived from the colony originally maintained at Aston University. Mice (n=8) received an intraperitoneal injection of glucose alone (18 mmol/kg body weight) or in combination with DMB (2500 nmol/kg body weight) or related GLP-1 peptides (each at 25 nmol/kg body weight). In a second series of experiments, glucose (18 mmol/kg) and DMB (2500 nmol/kg) were administered (i.p.) in the presence and absence of liraglutide, exenatide or exendin-4(9-39) (each at 25 nmol/kg).
Results: As expected, native GLP-1, liraglutide and exenatide induced respective 1.3-1.9 -fold (10^{-11} to 10^{-6} M, P<0.01 - P<0.001), 1.4-2.2 -fold (10^{-11} to 10^{-6} M, P<0.001) and 1.4-2.8 -fold (10^{-12} to 10^{-6} M, P<0.001) increases in insulin secretion from BRIN-BD11 cells. DMB also stimulated insulin secretion in a concentration-dependent manner, but with decreased potency compared to native GLP-1 and either GLP-1-R mimetic (2.3-5.0 -fold increases at concentrations of 10^{-4} M to 10^{-3} M, P<0.001). Administration of DMB in combination with glucose to normal mice significantly lowered individual plasma glucose levels (t=15 min, P<0.05) and decreased overall glucose excursion (1.4-fold; P<0.05) compared to controls (0-60 min AUC values; 365.3 ± 30.2 mmol/l.min *vs*. 501.6 ± 31.2 mmol/l.min for control). Similarly, exenatide and liraglutide significantly (P<0.001) reduced the overall glycaemic excursion when compared to controls and were significantly (P<0.001 and P<0.05; respectively) more potent than DMB. Interestingly, administration of DMB in combination with the GLP-1-R antagonist, exendin-4(9-39), did not significantly effect glucose-lowering actions (0-60 min AUC values; 365.3 ± 30.2 mmol/l.min *vs*. 361.0 ± 11.9 mmol/l.min for DMB + exendin-4(9-39)), confirming allosteric GLP-1-R binding. However, combined administration of DMB with liraglutide or exenatide did not improve therapeutic effect.
Conclusion: DMB stimulates insulin secretion and lowers blood glucose concentrations but is considerably less potent than native GLP-1 or stable peptide GLP-1-R mimetics. Low molecular weight GLP-1-R agonists may have future therapeutic value for type 2 diabetes but potency together with the issues of specificity and safety are major obstacles before the concept can be considered in humans.

788

Presence and characteristics of GLP-1 receptors in osteoblastic cells

B. Nuche-Berenguer[1], P. Moreno[1], N. González[1], A. Acitores[1], S. Portal[2], P. Esbrit[2], I. Valverde[1], M.L. Villanueva-Peñacarrillo[1];
[1]Metabolism, Nutrition and Hormones, Fundación Jiménez Díaz, [2]Laboratory of Bone and Mineral Metabolism, Fundación Jiménez Díaz, Madrid, Spain.

Background and aims: Very recently, it has been reported that GLP-1, an incretin with antidiabetic properties, apart from having direct stimulatory actions upon glucose and lipid metabolism in extrapancreatic tissues, exerts an anabolic effect on the altered bone metabolism of type 2 diabetic and insulin resistant rat models. Exendin-4 (Ex-4) and exendin-9 (Ex-9), structurally homologous with GLP-1, have proven to be agonist and antagonist, respectively, of the pancreatic GLP-1 receptor and of several of its actions in rat liver, muscle and fat. Here, we have searched for the possible presence of GLP-1 receptors, and their characteristics, in osteoblasts.
Materials and methods: MC3T3-E1 osteoblastic cells, grown ($2x10^5$ cells/well) in α-MEM supplemented with 1% penicillin/streptomycin, 2 mM glutamine and 10% FBS, were incubated, at 37ºC or 25ºC -in the same media except for the absence of FBS and presence of Trasylol (500 KIU /ml), 10 mM $MgSO_4$ and 50 mM HEPES-, with 20 fmol mono-^{125}I-GLP-1 (70 MBq/mol) as tracer, for different time periods (0-120 min), in the absence and presence of GLP-1, Ex-4 or Ex-9 (10^{-9}-10^{-6} M), and 10^{-6} GLP-2 or insulin. Degradation of the tracer -by TCA precipitation-, dissociation of ^{125}I-GLP-1-binding -by dilution-, molecular size (Mr) -by cross-linking and SDS-PAGE- and cyclic-AMP content -in the absence and presence of IBMX-, were also studied.
Results: The tracer-GLP-1 binding was time- and temperature-dependent, at 25ºC being detectable at 15 minutes incubation period (2.20±0.11% total tracer, n=4 separate experiments), reaching the maximum value after 30 to 45 minutes (overall mean: 2.65±0.07%, n=10) and decreasing thereafter (120 min: 1.81±0.20%, n=3). At 37ºC, but not at 25ºC, degradation of the ^{125}I-GLP-1 in the presence of cells occurred (TCA precipitated at 20 min: 77±1% total; 30 min: 69±1%, both n=3). The tracer specific binding (Sp B) at 25ºC during 30 min (0.33±0.04% total, n=11) was dissociable, resulting in a reduction to 37.5±2.5% Sp B, (n=5) at minute 30; Sp B was displaced by increasing concentrations of GLP-1, with a 50% inhibition dose (ID_{50}) of $3x10^{-9}$ M; GLP-2 equally displaced GLP-1-tracer Sp B; neither Ex-4 nor Ex-9 or insulin competed with the ^{125}I-GLP-1 binding. The Scatchard analysis of the unlabeled GLP-1 data revealed the presence of high affinity binding sites, with a dissociation constant (Kd) of $1.46x10^{-12}$ M, an affinity constant (Ka) of $6.87x10^{10}$ L/mol, and a binding capacity of 4 fmol/10^6 cells; low affinity binding sites were also present. Cross-linking and SDS-PAGE showed a GLP-1-bound to cell protein estimated in 68,000 Mr. GLP-1 did not apparently modify cAMP content.
Conclusion: These data indicate that the reported insulin-independent anabolic effect of GLP-1 in normal and in states associated with impaired bone metabolism could be exerted through a GLP-1 specific receptor, which is likely different from the pancreatic GLP-1 receptor.

Different modulation of dipeptidyl-peptidase IV activity between microvascular and macrovascular human endothelial cells

I. Dicembrini[1], L. Pala[1], A. Pezzatini[1], S. Ciani[1], S. Gelmini[1], B.G. Vannelli[2], B. Cresci[1], E. Mannucci[3], C.M. Rotella[1];
[1]Department of Pathophysiology, Unit of Endocrinology, University of Florence, [2]Department of Anatomy, University of Florence, [3]Geriatric Section, Department of critical area, Univesity of Florence, Italy.

Background: Glucagon-like peptide-1 (GLP-1) is a gastrointestinal hormone, mainly secreted after meals, which enhances glucose-induced insulin secretion and induces satiety. GLP-1 is rapidly inactivated by dipeptidyl peptidase IV (DPP-IV), an enzyme produced by endothelial cells in different districts and that circulates in plasma. Patients with type 2 diabetes show a reduction of active GLP-1 that could be due to impairment of secretion or its degradation or both. Some authors suggest that metformin has no direct inhibitory effect on DPPIV activity and that metformin and the other biguanides enhance GLP-1 secretion; others suggest a possible role of metformin in the inhibition of the DPPIV activity.
Materials & methods: In order to better elucidate the role of insulin sensitizers on the modulation of GLP-1 circulating levels, DPP-IV activity and mRNA expression were measured in cultured human aortic endothelial cells (HAEC) and human microvascular dermal endothelial cells (HMVEC) exposed to high glucose, Metformin and Rosiglitazone.Human aortic endothelial cells and adult dermal microvascular endothelial cells (HMVEC) were cultured in different glucose concentrations (11, or 22 mmol/L) for a week before experiments. Cells were also cultured in glucose 11 mM and mannitol 11 mM, in order to verify the effects of hyperosmolarity. DPP-IV activity was measure at 4, 12, 24, 48, 72 and 168 hours of incubation with or without Rosiglitazone (20 μM) as used by Benvenuti et al or Metformin (500 μMol/L) as used by Lindsay et al. All experiments are performed in triplicate. Results: Present data show that hyperglycaemia is capable of increasing in a significant manner, the DPP-IV activity only in microvascular endothelial cells. Rosiglitazon is able to modulate in a negative and significant manner the expression of DPPIV but not its activity in macrovascular endothelial cells while at 24 h of exposure it is able to increase significantly DPPIV activity but not its expression in microvascular endothelial cells. Metformin at 48 h only in microvascular endothelial cells is able to reduce in a significant manner (p= 0,01) the activity of DPPIV but not its expression .
Conclusion: The modulation of DPPIV is site specific.

Novel GLP-1 analogues cross the blood brain barrier and enhance synaptic plasticity in the brain: a link between diabetes and Alzheimer's disease

C. Hölscher, K. Fung, R. McCurtin, V.A. Gault, P.L. McClean;
School of Biomedical Sciences, Ulster University, Coleraine, United Kingdom.

Background and aims: Recently, the incretin glucagon-like peptide 1 (GLP-1) has been shown to have neuroprotective properties. We therefore tested whether novel GLP-1 analogues that are resistant to protease degradation and are developed as a treatment for type 2 diabetes (eg. Liraglutide) can cross the blood brain barrier (BBB) and have effects on neuronal communication and synaptic plasticity (LTP) in the brain.
Materials and methods: Male mice were injected ip. with a range of concentrations of GLP-1, Val(8)GLP-1, or Liraglutide. The brain tissue was analysed using protein separation and purification steps and a RIA analysis kit. In the electrophysiology study, male rats were anaesthetised and electrodes lowered into the hippocampus area CA1 to record field excitatory field potentials (fEPSPs). Synaptic plasticity (LTP) was induced using a high frequency protocol (100 stimuli at 200Hz), stimulating the Schaffer collateral projections to CA1 neurons. Liraglutide, asp(7)GLP-1, Val(8)GLP-1, N-glyc-GLP-1, and Pro(9)GLP-1 were injected icv. for this test. Data were analysed using 2-way ANOVAs or t-tests.
Results: Val(8)GLP-1 and Liraglutide both crossed the BBB. Injection of 25nM or 250 nM Liraglutide ip. of either peptide resulted in a significant increase in the brain 30 min or 3 h post-injection. 25nM at 30 min: $p<0.05$; at 3h: $p<0.005$, 250nM at 30 min: $p<0.01$, at 3h: ns. Val(8)GLP-1 25nM ip. at 30 min: $p<0.05$, at 3h: ns., 250nM at 30 min: $p<0.01$, at 3H: p,0.05. In the LTP studies, all novel GLP-1 agonists tested enhanced LTP. The novel GLP-1 analogue Liraglutide injected icv. (15nmol in 5µl) enhanced LTP. A two-way repeated measures ANOVA showed a difference between the drug group and saline control ($p<0.005$) and over time ($p<0.001$). All groups n=6. Native GLP-1 injected icv. (15nmol in 5µl) also increased LTP, a 2-way ANOVA showed a difference between groups ($p<0.001$) and over time ($p<0.001$). N=8 per group. The GLP-1 analogue Val(8)GLP-1 (15nmol icv.) also increased LTP. A 2-way ANOVA showed a difference between groups ($p=0.003$) and over time ($p=0.006$) N=6 per group. The other GLP-1 analogues, Asp(7)GLP-1, N-glyc-GLP-1, and Pro(9)GLP-1 injected icv. (each 15nmol in 5µl) also increased LTP, a 2-way ANOVA showed a difference between groups ($p<0.001$ each peptide) and over time ($p<0.001$). N=6 per group. The inactive metabolite GLP1(9-36) had no effect on LTP.
Conclusion: These results demonstrate that the GLP-1 agonists Val(8)GLP-1 and Liraglutide readily cross the BBB and have pronounced facilitatory effects on LTP. Other novel GLP-1 analogues also had facilitating effects on synaptic plasticity. Since GLP-1 analogues have been shown to be neuroprotective, and impairment of neuronal transmission is one of the symptoms in mouse models of Alzheimer's disease, these novel protease-resistant incretin analogues developed to treat type 2 diabetes also show promise as a treatment of neurodegenerative diseases.

Effects of endogenous glucagon-like peptide-1 on gastric emptying in healthy subjects - relationship to glycaemia

A.M. Deane[1], N.Q. Nguyen[2], J.E. Stevens[3], R.J.L. Fraser[3], R.H. Holloway[2], K.L. Jones[3], L.K. Besanko[2], C. Burgstad[2], M. Summers[2], A. Zaknic[2], M.J. Chapman[1], M. Horowitz[3];
[1]Discipline of Anaesthesia and Intensive Care, University of Adelaide, [2]Department of Gastroenterology, Royal Adelaide Hospital, [3]Discipline of Medicine, University of Adelaide, Australia.

Background and aims: Exogenous glucagon-like peptide-1 (GLP-1), when given in pharmacological doses, attenuates postprandial glycaemic excursions, in part, by slowing gastric emptying (GE). Studies using the specific GLP-1 antagonist, exendin (9-39) amide (ex), have established that endogenous GLP-1 inhibits fasting and nutrient-stimulated antropyloroduodenal motility in humans. However, a previous study using ex(9-39) reported no effect on GE, but the latter was measured using an imprecise technique (xylose absorption). The aims of this study were to determine the effects of endogenous GLP-1 on GE and intragastric distribution of a high carbohydrate meal, as measured with scintigraphy, and to relate any changes in GE to those on postprandial glycaemia.
Materials and methods: Ten healthy subjects (8M:2F, age 48 ± 7 yr) received ex(9-39) (300pmol/kg/min), or placebo, from t=-30-180 min in a randomised, double-blind, fashion. At t=0 a mashed potato meal containing 20g glucose and 45g margarine (2600KJ), labelled with 20MBq ^{99m}Tc-sulphur colloid, was ingested, and GE measured for 180 min. To quantify GE, regions-of-interest were drawn around the total stomach, which was further divided into proximal and distal regions. The time taken for 50% of the meal to empty from the stomach (T50) was calculated. Blood was sampled for measurement of glucose.
Results: Results are shown (mean ± SEM). Ex(9-39) accelerated GE (T50 ex: 68±8 min vs placebo: 83±7 min; $P<0.01$) (figure 1A Retention of meal during infusion of ex(9-39) and placebo; *$P<0.01$), however, there was no difference in intragastric meal distribution. While there was no difference in blood glucose at baseline (at t=0min ex: 6.5±0.4 mmol/l vs placebo: 6.1±0.3 mmol/l; P=NS), ex(9-39) increased postprandial glycaemic excursions ($AUC_{0\text{-}180}$ ex: 1540±106 mmol/l/min vs placebo: 1388±90 mmol/l/min; $P<0.02$) (figure 1B glycaemic response to meal during intravenous ex(9-39) and placebo; #$P<0.02$). There was a relationship between the magnitude of the rise in blood glucose from baseline and T50, so that the rise in glycaemia (at t=60 min) was greater when GE was relatively more rapid ($r=-0.46$; $P=0.04$).
Conclusion: GLP-1 plays a physiological role to slow GE in health, which impacts on postprandial glycaemia.

Glucose-dependent insulinotropic polypeptide (GIP) does not potentiate the antidiabetic effects of glucagon-like peptide-1 (GLP-1) in hyperglycaemic patients with type 2 diabates mellitus

N. Mentis[1], M.A. Nauck[1], L. Köthe[1], J.J. Holst[2], C. Deacon[2], M. Theodorakis[3], I. Vardarli[1];
[1]Diabeteszentrum Bad Lauterberg, Germany, [2]Department of Biomedical Sciences, Panum Institute, Copenhagen, Denmark, [3]Department of Clinical Therapeutics, University of Athens Medical School, Greece.

Background and aims: Glucose-dependent insulinotropic polypeptide (GIP) and glucagon-like peptide 1 (GLP-1) are incretin hormones from the gut mucosa. GLP-1 exerts insulinotropic action in type 2-diabetic patients, whereas GIP effects are no longer prominent in such patients. It was the purpose of the present study to examine whether exogenous GIP can alter the insulinotropic or glucagonostatic activity of exogenous GLP-1 in hyperglycaemic type 2-diabetic (T2DM) patients.
Materials and methods: Twelve patients with T2DM (9 males/3 females; age 61 ± 10 years; BMI 30.0 ± 3.7 kg/m^2; HbA_{1c} 7.3 ± 1.5 %; mean ± SD) were studied in a single-blinded manner within a 4-way cross-over design. In randomized order and after discontinuing antidiabetes therapy (insulin and/or OADs), intravenous infusions of GLP-1 [7-36 amide] (1.2 pmol·kg^{-1}·min^{-1}), GIP (4 pmol·kg^{-1}·min^{-1}), GLP-1 plus GIP, and placebo were commenced after an overnight fast and continued for 360 min. There were 1 day wash-out periods between experiments. Capillary blood glucose was measured and venous blood was drawn for total and active GIP, total and active GLP-1, insulin, C-peptide, glucagon (specific immunoassays) and free fatty acids (FFA). Statistics: repeated-measures ANOVA.
Results: With exogenous GLP-1 alone, glucose was reduced from approximately 185 mg/dl to 91 ± 4 mg/dl. Insulin secretion was stimulated (insulin, $p < 0.0001$ and C-peptide, $p < 0.0001$) and glucagon was suppressed ($p = 0.009$). With GIP alone, glucose was somewhat lowered, but not normalized; insulin and C-peptide were stimulated to a much lesser degree than with GLP-1 ($p < 0.001$). Adding GIP to GLP-1 did not further enhance the insulinotropic activity of GLP-1 (insulin, $p = 0.90$; C-peptide, $p = 0.85$). Rather, the suppression of glucagon elicited by GLP-1 was antagonized by the addition of GIP ($p = 0.008$). FFA were suppressed by GLP-1 ($p < 0.0001$) and hardly affected by GIP ($p = 0.07$).
Conclusion: The addition of GIP is not able to further amplify the insulinotropic and glucose-lowering effects of GLP-1 in T2DM. Rather, the suppression of glucagon by GLP-1 is antagonized by GIP. Upon acute exposure, GIP does not exert a prominent antidiabetic effect, whether administered alone or in combination with GLP-1.

No enhancement of meal-induced GLP-1 secretion and reduced intact GLP-1 levels in Japanese patients with type 2 diabetes as well as healthy controls

D. Yabe[1], A. Kuroe[1], S. Lee[2], C.F. Deacon[3], K. Watanabe[1], T. Hyo[1], M. Hishizawa[1], T. Kurose[1], J.J. Holst[3], T. Hirano[2], N. Inagaki[4], Y. Seino[1];
[1]Division of Diabetes and Clinical Nutrition, Kansai Electric Power Hospital, Osaka, Japan, [2]Department of Diabetes, Metabolism and Endocrinology, Showa University School of Medicine, Tokyo, Japan, [3]Department of Biomedical Sciences, University of Copenhagen, Denmark, [4]Department of Diabetes and Clinical Nutrition, Kyoto University Graduate School of Medicine, Japan.

Background and aims: High levels of intact GLP-1 and GIP among Asians are rarely seen. Here, we investigate intact and total (intact plus degraded) GLP-1 and GIP during OGTT and MTT in Japanese with or without type 2 diabetes.
Materials and methods: Japanese healthy controls (controls; n=17, female 18%; age 51±12; HbA1c 5.2±1.4%; BMI 22.4±5.4) and age-matched and untreated patients with type 2 diabetes (T2DM; n=18, female 22%; age 55±13; HbA1c 7.0±0.2%; BMI 23.9±5.6; duration 3.0±0.9 years) were subjected to OGTT and MTT. Blood samples were corrected sequentially, and levels of intact and total GLP-1 and GIP were measured in addition to those of glucose, IRI and IRG.
Results: Fasting levels of total GLP-1 were 16.4±4.9 and 16.0±4.8pM, and those of intact GLP-1 were 0.8±0.2 and 0.2±0.0pM in controls and T2DM, respectively. During OGTT, total GLP-1 reached peak 30 min after glucose administration, while intact GLP-1 levels remained low and showed no significant peak. AUCs for total and intact GLP-1 were similar in the two groups. During MTT using standard Japanese meal (480kcal, carbohydrate: protein: fat=2.8:1:1), total and intact GLP-1 showed no obvious peak. AUCs for total and intact GLP-1 were also similar. Fasting levels of total GIP were 22.2±6.7 and 29.0±8.9pM, while those of intact GIP were 16.4±4.9 and 16.0±4.8pM in controls and T2DM, respectively. During OGTT, total GIP reached the peak 30 min after glucose administration, and intact GIP reached the peak as early as 10 min after glucose administration. Although total GIP levels measured higher in controls, there was no statistical significance between the two groups. AUCs for total and intact GIP in the two groups were similar. During MTT, total and intact GIP reached peak 30 min after meal ingestion in both controls and T2DM. AUCs for total and intact GIP were similar.
Conclusion: These results indicate that intact GLP-1 but not GIP levels are considerably reduced in Japanese compared to those of Caucasians reported previously, and that meal-induced enhancement of GLP-1 secretion is negligible in Japanese. These differences may underlie reduced insulin secretory capacity in Japanese.

Taspoglutide, a human once-weekly GLP-1 analogue, reduces post-challenge secretion of peptide YY and glucose-dependent insulinotropic peptide in an animal model of type 2 diabetes

S. Sewing[1], A. Benardeau[1], C. Migliorini[1], L. Tobalina[2], E. Sebokova[1];
[1]F. Hoffmann-La Roche AG, Basel, Switzerland, [2]Ipsen Pharma, San Feliu, France.

Background and aims: Taspoglutide is a novel, human once-weekly glucagon-like peptide (hGLP)-1 analogue under clinical development for the treatment of type 2 diabetes (T2D). We evaluated the chronic effect of taspoglutide on postprandial response of glucose, insulin, lipids, and intestinal polypeptides PYY and GIP following an oral glucose tolerance test (oGTT) in the ZDF rat, an animal model of T2D progression.
Materials and methods: Single application of taspoglutide (1 mg sc, formulated to mimic human exposure) or vehicle was administrated to 6-wk-old ZDF rats (n=6/group), and body weight and food intake were monitored daily for 3 wks. Glucose, insulin, total PYY, total GIP, and triglycerides were assessed at 0, 10, 30, 60, and 120 min after an oGTT (2g/kg) in 16-h fasted rats, performed 3 wks after taspoglutide administration.
Results: A significant reduction in body weight was seen during the first week after administration and was maintained until the end of the study when body weight was significantly lower by about 7% in rats treated with taspoglutide

compared with vehicle (276±2.6 vs. 298±3.7 g, p<0.005). Food intake decreased slightly during the first 5 days after taspoglutide administration, but then normalized to control values. Taspoglutide significantly reduced glucose excursion during the oGTT at 30, 60, and 120 min and $AUC_{Glu,0\text{-}120\ min}$ (-50%) without affecting insulin levels compared with vehicle. A significant decrease in GIP levels was observed 30 min after a glucose challenge, and the $AUC_{0\text{-}120\ min}$ was reduced by >30%. More importantly, a 70% decrease in the AUC for PYY was demonstrated over the 2 hours of the oGTT compared with vehicle, which might reflect a suppression of endogenous GLP-1 secretion. There were no significant differences in fasting PYY or GIP levels.
Conclusion: This study demonstrates the pharmacological effect of a GLP-1 analogue on the post-challenge response of PYY and GIP. The suppression of these intestinal peptides is important for the regulation of glucose and insulin secretion in response to a meal. These data bring new insights into the understanding of the mechanism of how taspoglutide affects incretin physiology in T2D.

795

Changes in adipokines in type 2 diabetic patients treated with exenatide versus glimipiride on metformin background - results of a prospective, randomized controlled study over 9 months

B. Gallwitz[1], F. Dotta[2], C. Kazda[3], P. Kraus[3], C. Nicolay[3], L. Rose[4], G. Schernthaner[5];
[1]Medizinische Klinik IV, Universitätsklinikum Tübingen, Germany, [2]University of Siena, Italy, [3]Lilly Deutschland GmbH, Bad Homburg, Germany, [4]Zentrum für Diabetes und Gefäßerkrankungen, Münster, Germany, [5]Department of Medicine I, Rudolfstiftung Hospital, Vienna, Austria.

Background and aims: In addition to the already known laboratory values with a predictive power for cardiovascular disease such as hsCRP and fibrinogen, new fat tissue hormones have been discovered in the recent years. The data presented here originate from the EURopean EXenAtide Study (EUREXA), a long-term prospective, open-label study comparing the effects of Exenatide (EXE) versus Glimipiride (GLIM) on maintainance of glycemic control. One objective of this addendum to the EUREXA study is to explore how EXE versus GLIM differentially affects the adipokine levels adiponectin, fibrinogen, leptin, PAI-1 and TNFα after 9 months of treatment in a subgroup of patients.
Materials and methods: Out of the 1039 patients randomized in the EUREXA study 35 entered the addendum after giving informed consent and 33 overweight (mean body-mass-index (BMI) 32.8±3.98kg/m²) T2D patients (15 female, 18 male) were eligible for analysis. Patients were randomized, stratified on the basis of their BMI, to receive either EXE (n=15) or GLIM (n=18) as an add-on treatment. At baseline (BL) and at endpoint (EP) after 9 months of treatment blood-samples were collected and analyzed centrally. Data were analyzed by means of descriptive statistics and predefined, exploratory treatment groups comparisons were done by either analysis of covariance or the Mann-Whitney test (last observation carried forward approach).
Results: At BL patients had a mean (SD) age of 58.1 (9.0) years and a mean diabetes duration of 5.2 (5.16) years. Mean BL weight was 96.7 kg (13.55) in the EXE-group and 98.0 kg (10.76) in the GLIM-group. While patients in the EXE-group had a LS mean [SEM] weight loss of 5.26 kg [1.03], patients gained 2.14 kg [0.94] on GLIM (p<0.001) with corresponding changes in BMI of -1.75 kg/m² [0.35] for EXE and +0.62 kg/m² [0.32] for GLIM (p<0.001). LS mean BL to EP change [SEM] in HbA1c was -0.80% [0.27] in the EXE- and -0.71% [0.24] in the GLIM-group (p=0.796) with mean (SD) BL-values of 7.5% (0.55) and 7.6% (0.72) for the EXE- and the GLIM-group, respectively. While Adiponectin showed a median [IQR] decrease of 0.6µg/ml [-2.2 to +1.6] in the EXE-group, it increased by 0.3µg/ml [-1.6 to +1.0] in the GLIM-group after 9 months of treatment (p=0.975). Leptin showed a median [IQR] decrease of 2.4µg/l [-6.0 to +0.1] to a median EP concentration of 13.2µg/l [7.5 to 26.2] under EXE, but an increase of 6.8µg/l [+1.9 to +15.3] to a median EP concentration of 27.2µg/l [14.1 to 56.1] under GLIM (p=0.004).
In the EXE-group LS mean [SEM] PAI-1 concentrations decreased by 2.84 U/ml [1.10] to a mean (SD) EP concentration of 4.8 U/ml (2.56). In the GLIM-group the corresponding LS mean change in PAI-1 was +0.53 U/ml [1.06] to a mean EP concentration of 7.9 U/ml (4.50)(p=0.039).
LS mean TNFα statistically significantly increased by 1.64 ng/l ([0.63]; p=0,016) to a mean of 9.2 ng/l (2.21) at EP and by 2.02 ng/l ([0.60]; p=0.003) to 9.9 ng/l (1.98) at EP for EXE and GLIM, respectively. Fibrinogen remained unchanged in both groups after 9 months of treatment.
Conclusion: After 9 months of treatment obese patients with T2D experienced beneficial changes in the adiponectin profile when treated with EXE versus GLIM.

Sitagliptin effects on triglyceride and free fatty acid metabolism

R.H. Nelson, J.M. Miles, A. Vella;
Endocrinology, Mayo Clinic, Rochester, United States.

Background and aims: The effect of dipeptidyl peptidase-4 (DPP-4) inhibitors on lipid metabolism in type 2 diabetes is controversial, with conflicting reports in the literature. No studies of the effect of sitagliptin compared to placebo on postprandial lipemia have been published. Individuals with impaired fasting glucose (IFG) are at increased risk of cardiovascular disease. As part of a study examining the effect of the DPP-4 inhibitor sitagliptin (SITA) on IFG, we determined the effect of SITA on triglyceride (TG) and free fatty acid (FFA) metabolism using a placebo-controlled, parallel-group design.
Materials and methods: A mixed meal study was conducted in subjects with IFG (n=22) at baseline and again 8 weeks after randomization to SITA 100 mg/d or placebo (PL). In a subset of participants (n=17), tracer quantities of [1-^{13}C] oleate and a [oleyl-^{3}H] triolein-labeled lipid emulsion were infused to allow determination of oleate rate of appearance (Ra) as well as the Ra of ^{3}H oleate. Lipoprotein lipase-mediated fractional spillover of fatty acids from dietary fat was calculated from ^{3}H oleate Ra during peak chylomicronemia after ingestion of breakfast (45% carbohydrate, 40% fat, 15% protein). Blood samples were taken at baseline and at intervals for 6 hours after the meal for measurement of plasma TG concentration, ^{13}C oleate enrichment, ^{3}H oleate specific activity, ^{3}H TG and plasma FFA concentration.
Results: In both SITA and PL, there was no change from baseline to week 8 in fasting (453±39 vs. 411±40 and 435±31 vs. 414±37 µmol/L, respectively), 2-hour postprandial (39±5 vs. 44±5 and 40±6 vs. 45±9 µmol/L) or postprandial area under the curve (21±6 vs. 25±10 and 15±2 vs. 16±2 mmol•L^{-1}•6h^{-1}) plasma FFA concentrations (P=NS in all cases). Fractional spillover of ^{3}H oleate from lipolysis of [9,10-^{3}H] triolein was 29±5% in SITA (n=7) and 25±3% in PL (n=10) at week 8 (P=NS). Oleate Ra was calculated assuming steady-state conditions during the frequent sampling interval and also assuming nonsteady-state conditions for the entire postprandial period. With both approaches there was no difference in oleate Ra, comparing both SITA to PL (1.38±0.24 vs 1.03±0.03 µmol/kg/min respectively; P = 0.24) and 8 weeks of SITA to baseline (1.38±0.24 vs 1.36±0.28 µmol/kg/min respectively; P = 0.96). However, average peak (270 to 330 minutes) postprandial TG concentrations decreased from 204±17 to 178±20 mg/dL (P<0.01 comparing groups using a matched pair t-test) in the SITA arm; there was no change in the PL arm (174±16 vs 175±15 mg/dL, P = NS). SITA lowered postprandial TG to a greater extent than PL at week 8 compared to baseline (Δ = -26±7 vs +1±5 mg/dL, P<0.01).
Conclusion: SITA reduced postprandial TG concentrations by ~13% but did not alter adipose tissue lipolysis in subjects with IFG. SITA reduced postprandial lipemia despite no effect on FFA metabolism. The mechanism responsible for this effect is unknown, but could involve an effect of SITA on intrahepatic very low density lipoprotein TG synthesis or secretion, and/or on peripheral metabolism of TG by lipoprotein lipase. Further investigations to define the mechanisms and significance of this finding are required.

No effect of glucose-dependent insulintropic polypeptide, GIP, on triglyceride clearance in humans

M. Asmar[1], S. Madsbad[2], K. Juul Hare[1], J. Juul Holst[1];
[1]Department of Biomedical Sciences, University of Copenhagen, [2]Department of Endocrinology, Hvidovre, Denmark.

Background and aims: GIP is an incretin hormone that has been implicated in fat metabolism but the actions of GIP in humans are unclear. We examined whether exogenous GIP infused intravenously alone or in combination with a concomitant stimulation of endogenous insulin affects the plasma clearance of triglycerides (TG) in man.
Materials and methods: Ten healthy subjects were examined in a randomized, cross-over study on 4 different days: 1 day with Intralipid (IL) infusion; 1 day with IL and glucose infusion, all days with and without GIP-infusion (1.5 pmol/kg/min) for 300 min. IL was given as a bolus of 0.15 g/kg followed by continuous infusion of 0.225 g/kg/h for one hour. Glucose was infused to mimic the meal-induced glucose excursions and to investigate the combined action of insulin and GIP in lipid metabolism.
Results: Basal GIP concentrations averaged 10.83 ± 0.5 pM and increased significantly during GIP infusions to 285.1 ± 8.4 (p<0.0001). On IL + GIP day, plasma insulin concentrations increased significantly during the first 60 min

(2133 ± 188 vs. 1538 ± 156 pM x min, p=0.001) compared to IL + saline day but no difference was seen at time 60-300 min. Likewise, a significant increase in insulin was seen during the first 60 min on IL + Glucose + GIP day compared to IL + Glucose + saline day (13203 ± 1742 vs. 6263 ± 607 pM x min, p=0.001). Maximal TG concentrations were reached after one hour of infusion of IL and resulted in a concomitant plasma FFA and glycerol increase. No difference was seen in the plasma TG or glycerol clearances on all 4 experimental days (p=NS). However, the plasma FFA concentration was significantly reduced at time 60 - 300 on IL + GIP day compared to IL + saline day (p=0.007). No difference was seen in plasma FFA concentration between IL + Glucose + GIP and IL + Glucose + saline days but on both days the FFA concentration was significantly reduced at time 60-300 min when compared to IL + GIP/saline days (p<0.05).
Conclusion: In conclusion, these data suggest that GIP does not affect TG clearance in man. However, both insulin and GIP lower post-IL FFA concentration, GIP probably via stimulation of insulin secretion, increasing FFA reesterification.

Changes in prandial glucagon levels after 2 years treatment with vildagliptin or glimepiride
B. Ahrén[1], J. Foley[2], E. Ferrannini[3], D. Matthews[4], B. Zinman[5], S. Dejager[6], V. Fonseca[7];
[1]Department of Clinical Sciences, Division of Medicine, Lund University, Lund, Sweden, [2]Novartis Pharmaceuticals Corporation, East Hanover, United States, [3]Department of Internal Medicine and CNR Institute of Clinical Physiology, University of Pisa, Italy, [4]Oxford Centre for Diabetes, Endocrinology and Metabolism, Churchill Hospital and NIHR, Oxford Biomedical Research Centre, United Kingdom, [5]Samuel Lunenfeld Research Institute, Mount Sinai Hospital, University of Toronto, Canada, [6]Clinical Research, Novartis Pharma SAS, Reuil-Malmaison, France, [7]Department of Endocrinology, Tulane University Health Sciences Center, New Orleans, United States.

Background and aims: Previous studies indicate that the glucagon levels during meals are reduced following treatment with vildagliptin (VILDA). In order to test the hypothesis that VILDA therapy has favorable long term effects relative to glimepiride (GLIM) on prandial glucagon levels, glucagon levels were measured over 2 hours during a standard meal challenge test following either VILDA or GLIM 2-yrs treatment in combination with metformin.
Materials and methods: These measurements were made in a subset of patients at endpoint in the intent to treat population, from a study that was designed to demonstrate the 2 year efficacy and safety of add-on therapy with 50 mg bid VILDA compared to up to 6 mg qd GLIM in patients with type 2 diabetes inadequately controlled with prior metformin monotherapy (HbA1c > 6.5% and ≤ 8.5%). Insulin secretion rate was determined by deconvolution of C-peptide levels.
Results: At baseline HbA1c was ~7.3%. Prandial glucagon $AUC_{0\text{-}2h}$ at baseline was 55.6±2.3 pmol·hr/L with no difference between the groups. After up to 2 years treatment, the prandial glucagon $AUC_{0\text{-}2h}$ decreased from baseline to study endpoint by 3.4±1.6 pmol·hr/L in the VILDA group (n=137), whereas an increase by 3.8±1.7 pmol·hr/L was seen with the GLIM group (n=121); the between group difference was 7.2±2.1 pmol·hr/L (P<0.001 by ANCOVA). After the treatment, prandial glucose excursions were reduced by 0.89±0.25 mM in the VILDA group and by 0.96±0.25 mM in the GLIM group (P=0.77) and the insulin secretion rates relative to glucose were greater in the GLIM group than the VILDA group (34±0.18 pmol·hr/L for VILDA vs. 91±0.19 pmol·hr/L for GLIM, P< 0.02).
Conclusion: This study thus confirms in a large cohort that the DPP-4 inhibitor VILDA reduces prandial glucagon levels and suggests that the sulfonylurea GLIM increase them. Since glucose excursion was the same in both groups, we conclude that VILDA improves glycemia with less insulin than GLIM by more effectively reducing prandial glucagon levels.

Metabolic and insulin resistance-related indices during pioglitazone and vildagliptin association versus glimepiride and vildagliptin association in type 2 diabetic patients
R. Fogari, A. Cicero, P. Ragonesi, S. Salvadeo, I. Ferrari, F. Querci, I. Franzetti, G. Gadaleta, L. Ciccarelli, M. Piccinni, A. D'Angelo, G. Derosa; Internal Medicine and Therapeutics, University of Pavia, Italy.

Background and aims: The aim of our study was to verify the effects of pioglitazone (P) and vildagliptin (S) association vs glimepiride (G) and vildagliptin (V) association on metabolic and insulin resistance related-indices in type 2 diabetic patients.
Materials and methods: Ninety-one type 2 diabetic patients with uncontrolled type 2 diabetes mellitus (HbA1c > 7.5 %) were randomised to P 30 mg o.d. and V 50 mg b.i.d. or to G 2 mg t.i.d. and V 50 mg b.i.d. All type 2 diabetic patients were resulted not well controlled with diet and physical activity and P at dosage of 30 mg/day and G at dosage of 6 mg/day. The treatment period had a 9 months duration. We evaluated BMI, HbA1c, FPG, PPG, FPI, Homa index and collected plasma samples of adiponectin (ADN), resistin (R), tumor necrosis factor-alpha (TNF-α), and high-sensitivity C reactive protein (Hs-CRP) at baseline, and after 9 months. Eighty-four patients completed the study (42 in PV and 42 in GV group).
Results: Eighty-six patients completed the study (44 in PV and 42 in GV group). BMI does not change in both groups. HbA1c was decreased by 1.3±0.08 % (p< 0.01), and by 1.3±0.08 % (p< 0.01); FPG was reduced by 20±4 mg/dl (p< 0.01), and by 23±5 mg/dl (p< 0.01); PPG was decreased by 36±8 mg/dl (p< 0.01), and by 44±9 mg/dl (p< 0.01), in PV and GV group, respectively. FPI was decreased by 2.3±0.1 μU/ml (p< 0.05, p< 0.05 vs GV), and by 0.4±0.03 μU/ml (p< 0.05), and Homa index by 1.7±0.6 (p< 0.01 vs baseline, p< 0.05 vs GV), and by 1.1±0.4 (p< 0.05) in PV and GV group, respectively. ADN was increased by 0.9±0.01 μg/ml (p< 0.05 vs baseline, p< 0.05 vs GV), and by 0.2±0.002 μg/ml (ns vs baseline), in PV and GV group, respectively. Resistin was reduced by 1.1±0.1 ng/ml (p< 0.05 vs baseline, p< 0.05 vs GV), and by 0.1±0.001 ng/ml (ns vs baseline), TNF-α by 0.9±0.2 ng/ml (p< 0.05 vs baseline, p< 0.05 vs GV), and by 0.1±0.001 ng/ml (ns vs baseline), and Hs-CRP by 0.8±0.007 mg/l (p< 0.05), and by 0.7±0.005 mg/l (p< 0.05), in PV and GV group, respectively. There was a significant correlation between Homa index decrease and ADN increase (r= -0.49, p< 0.01), R decrease (r= 0.52, p< 0.01), and TNF-α decrease (r= 0.54, p< 0.01).
Conclusion: Both combinations ameliorated diabetes control, but only PV improved insulin resistance related-parameters. The ADN increase, R and TNF-α decrease seem to be related to Homa index improvement.

Effect of alogliptin combined with pioglitazone on beta cell function and insulin resistance in metformin-treated patients with type 2 diabetes
C. Burant[1], P. Fleck[2], C. Wilson[2], Q. Mekki[2], R. Pratley[3], R. DeFronzo[4];
[1]University of Michigan School of Medicine, Ann Arbor, [2]Takeda Global Research & Development Center, Inc., Lake Forest, [3]University of Vermont School of Medicine, Burlington, [4]University of Texas Health Sciences Center, San Antonio, United States.

Background and aims: This phase 3, multicenter, randomized, double-blind, placebo-controlled, 12-treatment arm study assessed the efficacy and safety of alogliptin (ALO) alone (12.5 or 25mg qd) or combined with pioglitazone (PIO) (15, 30, or 45mg qd) in patients with type 2 diabetes on metformin with inadequate glycemic control.
Materials and methods: Primary analyses compared PIO alone (all doses pooled; n=387) with ALO 12.5mg plus any dose of PIO (A12.5+PIO; n=390) or ALO 25mg plus any dose of PIO (A25+PIO; n=390) over 26 weeks.
Results: ALO in combination with PIO significantly improved measures of β-cell function (proinsulin:insulin ratio [PI:INS] and HOMA-B) compared to PIO alone. Least-squares mean changes from baseline in PI:INS and HOMA-B were significantly different (*P*<.001) for A12.5+PIO (-0.087 and 18.2) and A25+PIO (-0.076 and 22.2) vs PIO alone (-0.027 and 5.1) at Week 26. HOMA-IR, a measure of insulin resistance, decreased in all treatment groups; however, there was no significant difference between either A12.5+PIO (-2.2) or A25+PIO (-1.7) and PIO alone (-1.6) at Week 26. Combination treatment

with ALO and PIO was well tolerated; the number of patients experiencing ≥1 adverse event was similar across all treatment groups. Hypoglycemia was rare, occurring in 2.1% of patients in the PIO group, 1.0% in the A12.5+PIO group, and 1.5% in the A25+PIO group.
Conclusion: In conclusion, ALO/PIO combination therapy significantly improved β-cell function compared to PIO alone as evident by a decrease in PI: INS ratio and increase in HOMA-B. Comparable improvements in insulin sensitivity were seen with all treatment groups. These results suggest ALO and PIO improve glycemic control in type 2 diabetes mellitus by complementary mechanisms of action, enhancing β-cell function and improving insulin resistance, respectively.

Liraglutide but not vildagliptin restores normoglycaemia in *Psammomys obesus*

R. Heller[1], L. Vedtofte[1], T.B. Bodvarsdottir[2], C.F. Gotfredsen[2], A.E. Karlsen[2], L.B. Knudsen[2];
[1]Developmental Biology, Hagedorn Research Institute, Gentofte, [2]Diabetes Biology, Novo Nordisk, Måløv, Denmark.

Background and aims: *Psammomys obesus*, or the sand rat, is a model of human type 2 diabetes because the development of diabetes resembles what is seen in humans, i.e. initial hyperinsulinemia concomitant with obesity and later hypoinsulinemia and hyperglycemia. We studied the effects of the GLP-1 analog liraglutide and the DPPIV inhibitor vildagliptin in sand rats.
Materials and methods: One group of animals was maintained on low energy diet and seven groups were fed high energy diet (HED) that induced diabetes over a four week period. The diabetic animals were treated for 0, 6 or 14 days with vehicle, 0.2 mg/kg liraglutide twice daily subcutaneously or 30 mg/kg vildagliptin twice daily orally. This dose was demonstrated to decrease DPP4 activity to below 50% 18 hrs after the last dosing. Beta-cell mass (BCM) and proliferation- and apoptosis frequencies were determined using stereological point counting on sections stained for insulin, Nkx6.1, ki67 and tunel activity.
Results: Liraglutide significantly reduced blood glucose (6 day vehicle:13.9 ± 1.8 mM vs. liraglutide:3.1 ± 0.2; 14 day vehicle:16.5 ± 1.2 vs. liraglutide:9.4 ± 2.1). Blood glucose was normalized in all 13 animals treated with liraglutide for 6 days and in 11 of 17 animals after 14 days treatment compared to none in any of the two control groups (n=12 and 14, respectively). HED increased BCM and treatment with liraglutide did not change this (LE:28.3 ± 4.5 mg/kg vs. 0 day:107.5 ± 28.7). There were no significant changes in proliferation frequency after treatment with liraglutide, but there was a tendency for decreased apoptosis frequency in the normalized, liraglutide-treated animals (6 days vehicle:0.013 ± 0.004% vs. liraglutide:0.006 ± 0.003; 14 days vehicle:0.022 ± 0.008 vs. liraglutide:0.009 ± 0.003). Pancreatic insulin content at 6 and 14 days was significantly higher in the normalized animals (P<0.05). Vildagliptin was not able to reduce blood glucose (6 days vildagliptin:16.4 ± 1.8 mM; 14 days vildagliptin: 19.3 ± 1.1), did not alter the HED induced increase in BCM, nor did it increase pancreatic insulin content.
Conclusion: These results suggest that liraglutide improved diabetes in sand rats partly by improving the function of the remaining islets. Vildagliptin did not improve the glycemic state in sand rats.

Dipeptidyl peptidase 4 expression and activity in rodent models of type 1 and 2 diabetes

D. Ikeda, S. Sakaue, I. Tsujino, Y. Ohtsuka, M. Nishimura;
First Department of Medicine, Hokkaido University School of Medicine, Sapporo, Japan.

Background and aims: Glucagon-like peptide 1 (GLP-1) is a gastrointestinal hormone, mainly secreted after meals, which enhances glucose-induced insulin secretion and induces satiety. The increase in plasma GLP-1 levels after mixed meal ingestion is deteriorated in patients with type 2 diabetes, in part, leading to impaired insulin secretion. Secreted GLP-1 is rapidly inactivated in vivo, with the cleavage of an N-terminal dipeptide. Because this reaction is catalyzed by dipeptidyl peptidase 4 (DPP4), plasma DPP4 activity is thought to be one of regulators of circulating active GLP-1. DPP4 activity is much higher in kidneys than in other tissues. Among cells, thymocytes in chief have high DPP4 activity, followed by endothelial cells. DPP4 mRNA expression and enzyme activity have been shown to be up-regulated by high glucose level in human renal glomerular endothelial cells in vitro. In vivo, small studies in patients with type 1 and type 2 diabetes have also suggested that chronic hyperglycemia induces an increase in plasma DPP4 activity. To confirm contribution of diabetes to DPP4 production, we studied DPP4 expression and activity in rodent models of type 1 and type 2 diabetes.
Materials and methods: We used streptozocin (STZ)-induced diabetic mice (C57/BL6) and 10-week-old db/db mice. Vehicle-administered mice and db/+ mice were used as controls, respectively. STZ diabetic mice were induced at 8 weeks old by intraperitoneal administrations of STZ (180 mg/kg weight). After 2 weeks of the inductions, the mice were investigated. DPP4 activity was determined using synthetic substrate, and DPP4 mRNA levels in kidney were measured with real-time RT-PCR.
Results: STZ mice were less in body weight (STZ 17.5±2.1 g, control 20.3±0.9 g, n=8 each, p<0.05) and had higher plasma glucose levels than control mice (STZ 537±173 mg/dl, control 146±12 mg/dl, p<0.05). Seven of eight STZ mice had plasma insulin levels below the measurable limit (0.1 ng/ml). Plasma DPP4 activity in STZ mice was increased about 1.7 times of that in control mice, but not statistically significant (p=0.07). There was no difference in DPP4 mRNA levels in kidneys between STZ mice and controls. Body weights of db/db mice were increased (db/db 38.0±1.3 g, db/+ 26.1±0.8 g, n=6 each, p<0.05). Both plasma glucose levels (db/db 556±51 mg/dl, db/+ 186±39 mg/dl, p<0.05) and insulin levels (db/db 11.7±4.3 ng/ml, db/+ 1.6±0.8 ng/ml, p<0.05) of db/db mice were increased. Plasma DPP4 activity in db/db mice was significantly increased (2.2 times) compared with that in db/+ mice. DPP4 mRNA expression in kidney was also up-regulated in db/db mice.
Conclusion: Our results suggested that hyperglycemia increases plasma DPP4 activity but not DPP4 mRNA in kidneys. Plasma insulin level and body weight seemed to be unrelated with plasma DPP4 activity. Because the increase in plasma DPP4 activity can contribute to the reduction in circulating GLP-1 and to the further hyperglycemia in type 2 diabetic patients with poor metabolic control, increased DPP4 activity due to hyperglycemia may account for the mechanism of glucotoxicity. In contrast, DPP4 mRNA levels in kidneys may not be regulated by plasma glucose levels.

803

The efficacy of exendin(9-39)amide as a GLP-1 receptor antagonist in human

M. Morper, M. Nicolaus, J. Wörle, B. Göke, J. Schirra;
Department of Internal Medicine II, Campus Großhadern, University of Munich, Germany.

Background and aims: GLP-1 is a gut born hormone postprandially released from L-cells of the lower intestine. It stimulates insulin release glucose-dependently by action on specific receptors on the pancreatic B-cell. In addition, GLP-1 may play a role as regulator of gastric motility, secretion and of satiety. In humans, the specific GLP-1 receptor antagonist exendin(9-39) (Ex-9) was shown to reduce the GLP-1 stimulated insulin secretion by approximately 85%. However, human research in vivo on the GLP-1 physiology requires a more complete inhibition of GLP-1 action. Therefore, we aimed to fully characterize the dose-response characteristic of Ex-9.
Materials and methods: 6 healthy subjects underwent 6 experiments in random order. In each experiment, blood glucose was adjusted to 8 mmol/l for 180 min (glucose clamp). On five days, GLP-1 was IV infused from 0-90 min at 0.3 pmol/kg/min to establish physiological postprandial plasma levels, and from 90-180 min at 0.9 pmol/kg/min to induce supraphysiological plasma levels. Saline or Ex-9 at 300, 600, 900 or 1200 pmol/kg/min were IV infused as a background infusion. A sixth day with an infusion of saline only served as control. Blood glucose concentration, glucose infusion rate (GIR) and plasma levels of insulin were evaluated during the last 45 min of each of the two periods.
Results: Ex-9 was well tolerated without any side-effects. During all experiments blood glucose concentration was held constant at 143.3±0.2 mg/dl. During both doses of GLP-1, the insulin inhibition with increasing doses of Ex-9 followed an exponential pattern similar to a receptor binding curve (R^2=0.938 and 0.891, low and high dose of GLP-1). The dose range of Ex-9 was sufficient to cover the whole receptor-mediated insulinotropic capacity of GLP-1 with an ID50 of 98 and 60 pmol/kg/min for the low and high dose of GLP-1, respectively.
Conclusion: Ex-9 is well tolerated and inhibits dose-dependently the insulinotropic action of a low and high dose of synthetic GLP-1 in human. With Ex-9, it is possible to eliminate the effects of GLP-1. Ex-9 at a dose of 900

pmol/kg/min is necessary to inhibit the GLP-1 action by at least 95%. This may allow the analysis of the effects of endogenous GLP in vivo more quantitatively.

Table: Glucose infusion rate (GIR) and plasma insulin concentrations

	Saline+ Saline	GLP-1+ Saline	GLP-1+ Ex-300	GLP-1+ Ex-600	GLP-1+ Ex-900	GLP-1+ Ex-1200
GLP-1 at LOW DOSE						
GIR (mg/kg/min)	4.0±0.5	13.2±1.2*	5.0±0.4*	3.9±0.3	4.3±0.3	4.3±0.7
Insulin mU/l/10 min	21±3.4	125±23*	33±6.0*	29±5.5	27±3.9	22±2.3
% insulin stimulation	-	100%	11±3.8%	4.8±6.3%	2.9±5.6%	-0.2±4%

Higher serum dipeptidyl peptidase-4 activity and insulin resistance index in non-alcoholic fatty liver disease than in type 2 diabetes without liver disease

G. Firneisz[1], T. Varga[1], G. Lengyel[1], J. Feher[1], L. Selmeci[2], Z. Tulassay[1], A. Somogyi[1];
[1]Semmelweis University 2nd Department of Medicine, [2]Heart and Vessel Surgery Clinic, Budapest, Hungary.

Background and aims: Dipeptidyl peptidase-4 inhibitors were introduced in the treatment of type 2 diabetes mellitus and increased serum DPP-4 activity (sDPP-4) was reported in chronic liver diseases. We studied the sDPP-4 and the insulin resistance index (HOMA2-IR) in patients with type 2 diabetes mellitus (T2DM) and non-alcoholic fatty liver disease (NAFLD) and in healthy controls (CNTRL).
Materials and methods: sDPP-4 activity was measured by kinetic assay in 39 NAFLD (F/M:19/20, age: 47.42 yrs (95%CI: 43.83-51) and 86 T2DM (F/M:50/36, age: 62.8yrs (95%CI: 60.46-62.14) pateints and 23 (F/M:12/11, age:35.33yrs (95%CI: 28.76-41.91) healthy individuals. In order to generate non-overlapping groups we excluded those patients from the T2DM group who were clinically with liver disease (abnormal liver tests within 1 year or abnormal liver ultrasound morphology). All patients with NAFLD from the hepatology outpatient unit -except the 9 previously known diabetic individuals- underwent 75g CH OGTT. Insulin resistance index (HOMA2-IR) was calculated by the computational method. Kolmogorov-Smirnov-test, T-test, One-way ANOVA and Pearson correlation were used.
Results: Patients in the 2DM (BMI: 29.27 kg/m2; abdominal circumference M/F: 107.6/109.9 cm), and the NAFLD groups (BMI: 30.36 kg/m2; abdominal circumference M/F: 103.7/110.6 cm) were with similar degree of obesity. 75g CH OGTT in 39 NAFLD pts: 24 normal glucose tolerance (NGT), 4 impaired glucose tolerance (IGT) or impaired fasting glucose (IFG) and 11 type 2 diabetes. HOMA2-IR step by step increase: CNTRL: 1.98; T2DM (liver disease excluded): 2.58; NAFLD-NGT: 3.2 ($p<0.05$ vs CNTRL); NAFLD-IFG/IGT/T2DM: 3.82 ($p<0.01$ vs CNTRL, $p<0.05$ vs T2DM) (Figure1). sDPP-4 activity was higher in the 39 NAFLD pts (mean:32.49U/L, 95%CI:29.57-35.4) than in controls (26.08U/L,95%CI: 24.29-27.87 $p<0.01$) or in the T2DM group (24.16U/L,95%CI: 22.54-25.77 $p<0.001$). Correlations were detected among sDPP-4 and ALT ($r=0.4637$,$p=0.0038$) and gGT ($r=0.4991$,$p=0.0017$) activities and HOMA2-IR ($r= 0.5295$,$p=0.0026$) in NAFLD and among the HOMA2-IR and ALT ($r=0.4340$,$p=0.0147$) and gGT ($r=0.4128$,$p=0.0210$) within the NAFLD group.
Conclusion: In contrast to NAFLD, the serum DPP-4 enzyme activity was not increased in patients with T2DM without liver disease, where the inhibitor therapy is approved. sDPP-4 activity correlated with liver tests in NAFLD supporting that the excess is of hepatic origin. Based on the association of liver tests and HOMA2-IR and on the higher HOMA2-IR values in NAFLD than in the similarly obese T2DM pateints without liver disease we concluded that liver disease should contribute to the development of insulin resistance.

Correlation between the serum DPP-4 enzymatic activity and the CD26 expression on CD3+ lymphocytes in T1DM

Prolonged GLP-1 and Ex-4 treatment on fat Glut-4 expression in insulin-resistant state

I. Gutierrez-Rojas, P. Moreno, B. Nuche-Berenguer, I. Ramos-Álvarez, A. Acitores, I. Valverde, M.L. Villanueva-Peñacarrillo;
Fundacion Jimenez Diaz, Madrid, Spain.

Background and aims: It is known that GLP-1 has direct stimulatory effects, through specific receptors, upon the respective main metabolism of liver, muscle and fat. Exendin-4 (Ex-4) although being a peptide of non-mammalian nature, shares with GLP-1 a 52% structural homology and its glucoregulatory actions in normal and diabetic states; in fat tissue, both GLP-1 and Ex-4 stimulate glucose transport and also lipogenesis and lipolysis in a kinase-dependent manner. Here we studied the effect of prolonged treatment with GLP-1 and Ex-4 upon Glut-4 expression in fat tissue of insulin-resistant (IR) rats, compared to normal (N).
Materials and methods: IR model was induced in male Wistar rats by chronic feeding -8 weeks- with standard chow combined with D-fructose (20% in the drinking water). IR (n=5-8/group) and N (n=5-13/group) rats were 3-days treated with saline (control), GLP-1 (0.86 nmol/kg/h) or Ex-4 (0.1 nmol/kg/h); blood samples were taken before and by the end of the treatment for plasma glucose and insulin (RIA) measurements; Glut-4 expression -protein, by Western blot, and mRNA, by RT-PCR- was studied in the epididimal fat pads.
Results: Glut-4 mRNA in IR-control was lower ($p<0.001$) than normal (0.38±0.04 times N-control) while the glucotransporter protein value was not altered. In N, and as previously observed, GLP-1 treatment reduced both, Glut-4 mRNA (0.20±0.07 times N-control, $p<0.001$) and protein (42±5% N-control, $p<0.001$); in IR, GLP-1, while failing to modify the Glut-4 mRNA, induced though an increase ($p<0.02$) in the protein level (126±5% IR-control). In N, Ex-4 treatment reduced the Glut-4 mRNA (0.69±0.13 times N-control, $p<0.05$) without modifying the protein value; yet, in IR, Ex-4 induced an increase in the Glut-4 mRNA level (2.1±0.5 times IR-control, $p<0.05$) which was not accompanied by changes in the glucotransporter protein value (93±6% IR-control).
Conclusion: GLP-1 and Ex-4 have beneficial effects in the altered fat Glut-4 expression in insulin-resistant rats, GLP-1 by acting at the translational and Ex-4 at the transcriptional level. These effects could account for the previously observed improvement in fat glucose transport in this insulin-resistant state.

Beta cell stimulation by saxagliptin in patients with type 2 diabetes

J.F. List[1], R. Henry[2], S. Smith[3], S. Schwartz[4], R.Y. Duan[1], R. Chen[1];
[1]Bristol-Myers Squibb Company, Princeton, [2]Va San Diego Healthcare System, San Diego, [3]Louisiana State University, Baton Rouge, [4]Diabetes And Glandular Disease Research Assoc., PA, San Antonio, United States.

Background and aims: Saxagliptin (SAXA) is a potent, selective DPP-4 inhibitor, specifically designed for extended inhibition of the DPP-4 enzyme. DPP-4 inactivates incretins that stimulate glucose-dependent insulin secretion and inhibit glucagon secretion. A proposed MOA of SAXA involves protecting incretins from DPP-4 degradation, thus improving beta-cell response. This randomized, parallel-group, double-blind, placebo (PBO)-controlled study (CV181-041) assessed SAXA's effect on beta-cell function by intravenous hyperglycemic clamp (IV HC) in patients with type 2 diabetes (T2D).
Materials and methods: Patients were assessed at baseline (BL) and wk 12 in the fasting state (0-180min, IV HC) and after stimulating incretin secretion by orally ingesting 75g glucose (180-480min, IV-oral HC). HC infusions were adjusted to maintain plasma glucose at 280mg/dL. Insulin secretion was calculated by C-peptide deconvolution. Primary endpoint was %Δ from BL in total insulin secretion (%Δ insulin) during IV-oral HC (180-480min). Secondary endpoint was %Δ insulin during IV HC (120-180min). Patients were drug-naïve with T2D aged 43-69yrs with BL A1C range 5.9%-8.1%. Twenty patients received SAXA 5mg od; 16 received PBO.
Results: After 12 wks, SAXA significantly increased %Δ insulin from BL during IV-oral HC (adj% difference of 18.5% vs PBO, p=.035). In the fasting state during IV HC SAXA significantly increased %Δ insulin from BL (adj% difference of 27.9% vs PBO, p=.020). At wk 12 insulin secretion increased from BL with SAXA but not with PBO (Fig). Glucagon AUC during IV-oral HC also improved from BL with SAXA (adj% difference of -21.8% vs PBO, p=.031). SAXA was generally safe and well-tolerated.
Conclusion: SAXA improved pancreatic beta-cell function in the postprandial and fasting states and decreased postprandial glucagon concentration.

Gender-specific response of uncoupling protein 3 gene in the newborn mice to moderate supplementation of maternal diet by n-3 long-chain polyunsaturated fatty acids

Z.M. Jilkova[1], D. Medrikova[1], P. Janovska[1], M. Rossmeisl[1], E. Tvrzicka[2], J. Kopecky[1];
[1]Dept. of Adipose Tissue Biology, Institute of Physiology, [2]4th Department of Internal Medicine, Charles University, Prague, Czech Republic.

Background and aims: Perinatal development is affected by long-chain omega-3 polyunsaturated fatty acids (n-3 LC-PUFA) transported into foetus from maternal circulation and ingested by newborns with milk during lactation. Aim of this work was to characterize the effects of a moderate n-3 LC-PUFA supplementation of mothers' diet on (i) the content of eicosanoic (EPA) and docosahexaenoic (DHA) acid in milk and liver of the offspring, (ii) body weight gain of the newborns, and (iii) expression of genes of energy metabolism in the muscle of the newborns, also with regard to possible gender-specific differences.
Materials and methods: Adult C57BL/6N female mice were randomly assigned to standard (ST) diet containing 6 % (wt/wt) fat, or ST diet with 5% of dietary fat replaced by EPA/DHA concentrate EPAX1050 TG (EPAX AS, Aalesund, Norway; ST-FO diet). Mice and their pups remained on experimental diets during pregnancy and lactation. After weaning at 31 d, pups of both dietary groups were randomly assigned either ST or high-fat (HF; 35% fat wt/wt) diet. Mice of all four subgroups (ST-HF, ST-FO-HF, ST-ST and ST-FO-ST; n=8) were maintained on the ST or HF diet for 2 weeks. Milk consumption and fatty acid composition, as well as liver fatty acid composition were evaluated at 10 d after birth, while muscle gene expression was characterized at 2 weeks after initiation of ST or HF feeding.
Results: Milk consumption was not affected by n-3 LC-PUFA intake. Milk EPA concentration was marginally elevated (0.19±0.02 vs. 0.26±0.01 Mol%; $p<0.05$), while milk DHA concentration was elevated 10-fold (0.09±0.01 vs. 0.88±0.05 Mol%; $p<0.05$), due to dietary supplementation by n-3 LC-PUFA. Also liver concentrations of both EPA and DHA were increased due to supplementation, but the increase was similar for both fatty acids (2.6- and 1.4-fold for EPA and DHA, respectively). These results are in agreement with a high metabolism of n-3 LC-PUFA in the liver. HF diet induced higher body weight gain compared with ST diet, but n-3 LC-PUFA intake during gestation and lactation had no effect. Among several genes studied, uncoupling protein 3 gene (*Ucp3*) showed by far the most significant induction due to HF diet, namely in gastrocnemius muscle of male mice. A similar pattern of changes in *Ucp3* expression was observed in soleus but not in gastrocnemius muscle of female mice, where the interaction with n-3 LC-PUFA was only observed.
Conclusion: Our results indicate muscle type- and gender-specific differences in the effects of n-3 LC-PUFA on expression of genes of energy metabolism in murine muscle during early postnatal development, namely in response to elevated DHA intake during lactation. Possible lasting metabolic consequences of these effects will be studied.

Supplementation with conjugated linoleic acid causes isomer-dependent anti inflammatory effects in human monocytes

J. Herrmann[1], U. Helwig[2], R. Haesler[3], D. Rubin[2], D. Bell[4], P. Winkler[5], C. Laue[5], M. Pfeuffer[1], S. Schreiber[2], J. Schrezenmeir[6];
[1]PBE, MRI, Kiel, [2]First Department of Medicine, UKSH, Kiel, [3]Institute for Clinical Molecular Biology, UKSH, Kiel, [4]Nutrition & Health - Global R & D, Cognis Germany GmbH & Co. KG, Monheim, [5]Center of Clinical Research, Tecura GmbH Medizin & Biotechnik, Kiel, [6]PBE, MRI, Kiel/Karlsruhe, Germany.

Background and aims: Diabetes mellitus is associated with inflammatory endothelial activation and production of proinflammatory cytokines. Various beneficial of conjugated linoleic acids (CLAs) effects including decreasing atherosclerosis, diabetes and inflammation were described in vivo and in vitro. In humans evidence is currently conflicting. Aim of the presented study was to investigate effects of CLA supplementation on gene expression in monocytes and to elucidate the mechanisms involved.
Study design and methods: In a randomized, double blind, cross-over study, 34 healthy males (45-65y), consumed 4.25g preparation per day of either ref-

erence oil (linoleic acid) or cis-9, trans-11 CLA isomer or trans-10,cis-12 CLA isomer or a 1:1 mix of both isomers for 4 weeks. Intervention periods were separated by 4 weeks wash out. After each intervention monocytes were separated, genome wide expression analysis using microarrays was performed, and several regulated genes of interest were verified by a real-time PCR.
Results: 42 genes were verified by real-time PCR out of those 17 genes could be confirmed as regulated significantly after at least one intervention. The strongest change compared to reference oil was found after consuming trans-10, cis-12 CLA proinflammatory genes like IL-8 (-3.1 fold change (fc)), IL-1b (-2.6 fc) and COX2 (-1.48 fc) were significantly lower expressed. After 1:1 mix intervention the effect was similar (IL-1β 1.6 fc; IL-8 -1.3 fc; COX2 -1.3 fc). Both preparations regulated a number of additional genes. Whereas after cis9, tans11 CLA administration only a few genes were affected and changes were weaker (IL-8 -1.6 fc; IL-1b -1.6 fc; all other not significantly regulated).
Conclusion: These data suggest that CLA achieves isomer-specific anti-inflammatory effects and that the potency of a 1:1 CLA mixture of both isomers does not equal the added up effect of its single isomers. The strongest antiinflammatory effects in monocytes were found after tans-10, cis-12 CLA supplementation.

Effects of choline/methionine-deficient diet upon hepatic carbohydrate metabolism and bioenergetics in perifused liver cells or isolated mitochondria from fatty livers
D. Detaille[1], C. Sánchez-Martín[1], M.N. Sanz[1], F. Gómez-Peralta[2], J. Recio-Córdova[2], X. Leverve[3], J.M. González-Buitrago[4], M.Y. El-Mir[1];
[1]Physiology and Pharmacology, S-12, University of Salamanca, Spain, [2]Endocrinology Unit, Hospital University of Salamanca, Spain, [3]INSERM U884, University of Grenoble 1, Grenoble, France, [4]Research Unit, Hospital University of Salamanca, Spain.

Background and aims: Nonalcoholic steatohepatitis (NASH) is an important form of liver disease that may progress to cirrhosis and liver failure. Feeding rodent a lipogenic methionine-choline deficient diet (MCDD) is a frequently employed non-physiological nutritional model that leads to hepatic injuries similar to those seen in human steatosis. Nevertheless, the mechanisms underlying this major pathogenesis remain still unknown at the energy metabolism level. Using, for the first time, the liver cell perifusion system from fatty livers, the purpose of this study was to explore the alterations in both glucose utilization and mitochondrial bioenergetics induced in MCDD Wistar rats.
Materials and methods: Rats (200-250 g) were separated in two different groups and received either a standard diet or the high fat-MCDD provided in small pellets during 4 weeks. Hepatocytes, isolated from the livers of starved animals by the collagenase method, were perifused at 37°C with Krebs-bicarbonate-calcium medium saturated with O_2/CO_2, then titrated with increasing amounts of dihydroxyacetone (DHA) as gluconeogenic substrate to get seven consecutive steady states. For each of them, the net rates of glucose ($J_{Glucose}$) or lactate-plus-pyruvate (J_{L+P}) production were assessed in the cellular perifusate. We further studied the mitochondrial consequences of fat accumulation in this model by determining oxidative phosphorylation and production of reactive oxygen species (ROS) in isolated mitochondria.
Results: In DHA-perifused liver cells, MCDD significantly reduced (-52%, $p<0.001$) global metabolism of this carbohydrate source (J_{2G+L+P}), as compared with control diet. This response was largely explained by a strong inhibition of both gluconeogenesis ($J_{Glucose}$) and glycolysis (J_{L+P}). Furthermore, a decrease in L/P ratio, which reflects a more oxidized cytosolic NADH/NAD^+, was also evidenced in MCDD rats. On the other hand, liver mitochondria from these treated rats exhibited a higher oxygen consumption rate (+ 25%) in presence of succinate as energetic substrate, but these MCDD organelles had the same respiratory index than the control mitochondria. Interestingly enough, a low ROS formation was found in MCDD animals.
Conclusion: Our data show that MCD diet causes a net inhibition of the DHA global metabolism, but it also triggers a response mechanism on the bioenergetic level, likely designed to overcome, at least partially, the induced steatosis. We could suggest this dietary model as a tool for some pharmacological approach of the fatty liver diseases management.

Restoration of impaired intestinal permeability and changes in the gut cytokine profile are mechanisms in type 1 diabetes prevention by a hydrolysed casein diet
J.T.J. Visser[1], A. Fasano[2], A. Hoogendijk[1], S. Brugman[3], H. Harmsen[4], G. Welling[4], M. Walther Boer[1], N. Bos[1], F. Stellaard[5], K. Lammers[2], J. Rozing[1];
[1]Cell Biology, Section Immunology, University Medical Center Groningen, Netherlands, [2]Mucosal Biology Research Center, Baltimore, United States, [3]Gastroenterology and nutrition, Erasmus Medical Center Rotterdam, Netherlands, [4]Medical Microbiology, University Medical Center Groningen, Netherlands, [5]Laboratory of Liver, Digestive and Metabolic Diseases, University Medical Center Groningen, Netherlands.

Background and aims: Diabetogenic triggers from the food and gut micro flora can induce the autoimmune cascade leading to type 1 diabetes (T1D). However, in order to induce the autoimmune process, these diabetogenic antigens have to pass the intestinal barrier. T1D patients and animal models for T1D show an impaired intestinal barrier function. In this study we investigated whether prevention of T1D by the hydrolysed casein (HC) diet is related to restoration of this impaired intestinal barier function.
Materials and methods: To this end, Diabetes Prone (DP)-BB rats were given the HC-diet from weaning on and followed for the development of T1D. At fixed time points feces, gut tissue and blood was collected. Composition of the bacterial flora was established in the feces by qPCR. From the gut tissue RNA was isolated and expression of tight-junction (TJ) related proteins such as Myo9B, claudins and occludin and the cytokine profile was analysed. Serum zonulin levels (protein that regulates TJ function) were measured by ELISA. The transepithelial electrical resistance (TEER; indicator of intestinal permeability) was measured on ileum samples in vitro by snap well assay. In addition, BB-DP rats were subjected to a Lactulose Mannitol (LA/MA) test to measure intestinal permeability in vivo.
Results: BB-DP rats showed increased serum zonulin levels and a reduced TEER as compared to diabetes resistant (DR) rats. Serum zonulin levels were decreased in DP BB rats receiving the HC-diet. In addition the TEER was increased in BB-DP rats on the HC-diet. Moreover, the rats on the HC-diet showed a decreased Lactulose Mannitol ratio (which indicates a low intestinal permeability) as compared to the BB-DP rats on the standard diet. The HC-diet caused a reduction of the Myo9B expression, an increase of claudin-1 and a reduced claudin-2 expression in the ileum. Moreover, the HC diet caused an increase in IL-10 and TGF-beta expression. The percentage of rats responding with a decrease of their intestinal permeability (increase in TEER and reduction of LA/MA ratio) after feeding the HC-diet correlated with the rate of protection against T1D development. Intriguingly, the change in TEER of the ileum was negatively correlated with the bacteroides levels in the gut. This further strengthens our previous observations that high bacteroides levels are negatively correlated with T1D development (Brugman et al., Diabetologia 2006).
Conclusion: Prevention of T1D by feeding BB-DP rats an HC-diet, correlated with the restoration of the intestinal barrier function. Modification of the gut micro flora, direct effects on the tight junctions, changed cytokine profile and reduced zonulin production might be important mechanisms for this effect. Interfering with intestinal permeability via modification of the gut microflora and tight junctions might lead to novel therapies in the prevention of T1D.

Ethanol consumption patterns determine the effect of ethanol on insulin sensitivity in high-fat diet-fed rats: role of adiponectin and AMPK α
L. Feng, L. Gao, J. Zhao;
Shandong Provincial Hospital affiliated to Shandong University, Jinan, China.

Background and aims: Protective and detrimental effects of ethanol on insulin sensitivity have been widely reported. This may be due to the different ethanol dosage and the variations in consumption patterns. Here we investigated the effect of two moderate ethanol consumption patterns on insulin sensitivity in high-fat (HF) diet-fed rat and explore the possible mechanisms mediated by adiponectin and AMP-activate protein kinase (AMPK).
Materials and methods: Total 48 male wistar rats were randomly divided into four groups and received either normal diet (group C) or high-fat diet

(group HF, HF+E1, and HF+E2). Rats in group HF+E1 received edible ethanol twice daily by gastric tube, while animals in group HF+E2 drank ethanol solution instead of tap water and the total daily ethanol dosage in both groups was the same (5 g/kg/d, a moderate ethanol dosage). After treated for 22 weeks, fasting blood samples and epididymal and perirenal fat pads were obtained. Gene transcription and protein expression were tested by RT-PCR and western blotting, respectively.

Results: As shown in table 1, ethanol administration lessened the weight gain effect of HF diet. Coincident with body weights (BWs), the epididymal and perirenal fat masses in group HF+E1 and HF+E2 were smaller than that in group HF. Elevated fasting glucose level and fasting insulin concentration in group HF were reduced by ethanol addition. Accordingly, evaluated by HOMA-IR, insulin resistance was found in HF diet-fed rats, but was then ameliorated after ethanol administration. Twice daily ethanol administration pattern was observed better than continuously drinking pattern in improving adverse effect of HF diet.

Table 1: Characterization of the Rats in 4 groups

	C	HF	HF+E1	HF+E2
BWs (g) Initial	220.3±13.1	219.5±15	224.6±19.5	221±13.9
BWs (g) Final	477.7±34.5	540.7±58.4**	495.3±43$^{\#}$	515.8±45.2
Epididymal fat mass (% of BW)	0.9±0.3	1.3±0.3*	1.0±0.5	1.2±0.3
Perirenal fat mass (% of BW)	1.3±0.5	2.3±0.5**	1.6±0.7$^{\#\#}$	2.2±0.8
Fasting glucose level (mmol/L)	4.1±1.7	5.2±1.0	4.8±1.4	5.2±1.3
Fasting insulin concentration (mIU/L)	20.6±5.2	26.4±5.6*	21.2±3.4$^{\#}$	25.1±4.3
HOMA-IR	3.7±1.2	6.5±2.3**	4.6±1.9$^{\#}$	5.9±2.1
Serum ethanol concentration (mg/dl)	0	0	10.8±4.4	4.0±1.1
Serum adiponectin concentration (μg/ml)	25.8±3.2	16.5±3.7*	22.7±6.5$^{\#\#}$	17.7±5.2
Adiponectin contents in epididymal adipose tissue (μg)	88.8±20.3	47.3±18.9**	82.6±19$^{\#\#}$	55.8±17.1

*P<0.05, **P<0.01 vs. group C, $^{\#}$P<0.05, $^{\#\#}$P<0.01 vs group HF.

Ethanol consumption increased adiponectin concentration in both serum and epididymal adipose tissue in the setting of HF diet, such an effect was more obvious in group HF+E1 than in group HF+E2. As we know, adiponectin is an activator for AMPK. In concert with the changes of adiponectin, HF diet alone reduced the ratio of activated-AMPK α to Total-AMPKα to 39.08% of that in group C ($P< 0.01$ *vs.* C) and twice ethanol consumption and continuously ethanol drinking recovered the ratio to 88.9% ($P< 0.01$ *vs.* HF) and 45.8% ($P> 0.05$ *vs.* HF) of that in group C. In parallel with the changes of AMPK activation, both GLUT4 mRNA and protein expression were significantly impaired in group HF ($P< 0.01$ *vs.* C), and were then recovered to nearly normal levels in group HF+E1 ($P< 0.01$ *vs.* HF), but only recovered to 60.1- and 68% of normal levels in group HF+E2 ($P> 0.05$ *vs.* HF).

Conclusion: Moderate ethanol consumption might ameliorate the adverse effect of HF diet on insulin sensitivity in rats, twice administration pattern was much better than continuously drinking pattern. The mechanism for the protective effect of ethanol might be mediated by increased serum and adipose tissue adiponectin levels, subsequently improved activation of AMPK α, then GLUT4 expression in adipose tissue.

Acute effect of oral administration of dietary products enriched in antioxidants on post-prandial endothelial function in apparently healthy adults

I. Zavaroni[1], L. Franzini[1], S. Haddoub[1], D. Del Rio[2], C. Melegari[3], L. Cavani[2], F. Brighenti[2], D. Ardigò[1];
[1]Internal Medicine and Biomedical Sciences, University of Parma, [2]Public Health, University of Parma, [3]R&D Department, Barilla G&R Fratelli, Parma, Italy.

Background and aims: Oxidative stress has been advocated as a major cause for cardiovascular disease and low plasma antioxidant's concentrations have been associated with endothelial dysfunction (ED), the first step to atherosclerosis. Since food ingestion induces a temporary burst in oxidative stress and acutely impairs endothelial function (EF), it is conceivable that the long-term development of atherosclerosis might be at least partially attributed to repeated exposures to post-meal ED. Although experimental data show that the co-administration of antioxidants to an oral glucose tolerance test improves post-prandial ED, it is still unclear whether the supplementation of regular food with antioxidants is associated with an improved post-prandial EF profile.

Materials and methods: To address this issue, we conducted a placebo-controlled cross-over intervention study on 31 apparently healthy adults (13F/18M, mean age = 65 ± 4 years) who underwent to the single administration of a breakfast snack supplemented with antioxidants or a placebo snack, in a randomized order, with a week of wash out between the two tests. The antioxidant-enriched snack was composed by two products -a beverage (green tea or berries juice) and a cereal bar- supplemented with vitamin E (12 mg per serving of beverage and 15 mg per serving of bar), vitamin C (90 mg per beverage and 80 mg per bar) and cathechins (35 mg per serving of both). Placebo snacks were prepared to be identical to the active ones in terms of appearance and organoleptic properties. All subjects came in the morning, after overnight fasting, and underwent to a Flow Mediated Dilatation (FMD) test fasting, 2, and 3 hours after snack ingestion. Blood was drawn with the same time-course to evaluate changes in plasma antioxidant concentrations.

Results: We observed a significant and sustained decline in EF in the placebo meal 2 and 3 hours after snack ingestion (maximal post-ischemic vasodilation during FMD test decreased from 6.4±3.5% at baseline to 4.9±2.6% and 4.9±2.8% respectively; p<0.05 for both), whereas the assumption of the antioxidant-enriched snack was associated with a significant improvement (p<0.05) of FMD values ranging from 5.4±3.3% at baseline to 6.6±3.4% after 2 and 6.5±3.5% after 3 hours. In addition, we observed the appearance of measurable concentrations of epigallocathechin gallate at 2 and 3 hours (29.8±22.1 and 27.8±24.8 nMol/L, respectively) after the assumption of the antioxidant-enriched meal and a significant increase in vitamin C plasma levels at 2 and 3 hours (p<0.01 for both). No significant variation was identified in vitamin E plasma concentrations.

Conclusion: In a population of apparently healthy subjects, the supplementation of a mixed meal with antioxidants is able to reverse the temporary decline in endothelial function usually observed in the post-prandial phase, inducing an acute increase in endothelial-dependent vasodilation. These data suggest that functional foods supplemented with antioxidants (like snacks and beverages) could have a favourable effect on post-prandial EF, raising the speculation that their introduction in a regular diet might produce positive long term effect on atherosclerosis development.

Impact of the oral glucose spray, liquid sugars or dextrose tablets on the evolution of plasma glucose concentration in healthy persons

R. Chlup[1,2], J. Zapletalova[3], K. Peterson[1], R. Perera[1], K. Langova[3], A. Tancred[1], J. Smital[1], H. Pribylova[1], I. Poljakova[1];
[1]Dept. of Physiology, Faculty of Medicine, Palacký University, [2]IInd Dept. Of Medicine, Teaching Hospital, [3]Dept. of Biophysics, Faculty of Medicine, Palacký University, Olomouc, Czech Republic.

Background: In order to combat hypoglycaemia in persons with diabetes, oral glucose spray was believed to offer a sophisticated solution of this complication. However, clear references to the effects of oral glucose spray on plasma glucose concentration (PG) are missing.

Aims: The purpose of this prospective controlled trial was to assess the efficacy of three commercially available glucose products on the evolution of PG: (1) the oral glucose spray, (2) liquid sugar jelly, (3) dextrose tablet.

Methods: Sixteen healthy volunteers aged 21.8 ± 0.78 y (mean ± SE), BMI 23.5 ± 0.84 kg/m^2, tested their PG over the course of three sets of 4 sessions (S) each: S_0-control fasting, S_1 with oral administration of 10 glucose spray-doses (5 doses on the mucosa of each cheek, as indicated by the manufacturer, without swallowing), i.e., 0.84 g of glucose at time 0; S_2 with consumption of 1 sachet (13 ml) of the liquid sugar (ca. 5.2 g glucose, 5.2 g fructose, 5.2 g sucrose); S_3 with chewing and consumption of 1 dextrose tablet (6 g). Each S was performed between 6 and 9 h a. m., after fasting for the previous 6 hours. PG was tested in finger-prick capillary blood using personal glucometer Linus, Wellion, Agamatrix, Inc., Salem, NH, at start, at 5, 10, 15, 20 and 30 min. During all tests, the subjects remained seated, and did not engage in any physical activity. Statistical software SPSS v. 15, SPSS, Inc, Chicago, IL, was used. Means of 3 sessions in each of 16 subjects were analyzed.
Results: Wilcoxon-signed-rank-test revealed no differences between the change of the mean PG at start vs. 5-minute intervals neither in control- nor in intervention sessions. For the 30-minute time period after ingestion, analysis of regression coefficients demonstrated increase of PG after consumption of a sachet of liquid sugar (0.068 mmol/l/min, p = 0.001) which prevails over a single dextrose tablet (0.052 mmol/l/min, p = 0.002) but does not appear after oral glucose spray (0.005 mmol/l/min, p = 0.215), as compared to control session (see boxgraphs in Figure for details).
Conclusion: Liquid sugar jelly and dextrose tablets are effective means to increase PG within 10 minutes after ingestion. Oral glucose spray resulted in no increase of PG in the course of 30 minutes after its use. So, oral glucose spray cannot be recommended to combat hypoglycaemia.

Differential effects of protein quality on postprandial lipaemia in response to a fat-rich meal in type 2 diabetes: comparision of whey, casein, gluten and cod protein

L.S. Mortensen[1], M.L. Hartvigsen[1], L.J. Brader[1], A. Astrup[2], J. Schrezenmeir[3], J.J. Holst[4], C. Thomsen[1], K. Hermansen[1];
[1]Department of Endocrinology and Metabolism C, Aarhus University Hospital, Denmark, [2]Department of Human Nutrition, Faculty of Life Science, University of Copenhagen, Denmark, [3]Federal Research Institute for Nutrition and Food, Institute for Physiology and Biochemistry of Nutrition, Kiel, Germany, [4]Department of Biomedical Sciences, The Panum Institute, University of Copenhagen, Denmark.

Background and aims: Enhanced and prolonged postprandial triglyceride responses involve increased cardiovascular risk in type 2 diabetes (T2DM). Dietary fat and carbohydrates profoundly influence postprandial hypertriglyceridemia whereas little information exists about the effect of proteins. The aim of this study was to compare the effects of the proteins casein, whey, cod, and gluten on postprandial lipid and incretin responses to a high-fat meal in T2DM.
Materials and methods: Cross-over study of twelve type 2 diabetics. Blood samples were collected over 8 h after ingestion of a test meal containing 100g butter and 45g carbohydrate in combination with 45g of either casein (Cas-meal); whey (Whe-meal); cod (Cod-meal); or gluten (Glu-meal). We measured plasma levels of triglyceride, retinyl palmitate (RP), free fatty acids (FFA), insulin, glucose, glucagon, glucagon-like peptide1 (GLP-1), and glucose-dependent insulinotropic peptide (GIP). For statistical analysis were used One way repeated measurement ANOVA. $p<0.05$ are considered as statistical significant.
Results: The incremental area under the curve for triglyceride was significantly lower after the Whe-meal than after the other meals (p=0.008). The RP response was lower after Whe-meal than after Cas- and Cod-meal in the chylomicron-rich fraction (p=0.019) and higher after Whe-meal than after Cod- and Glu-meal in the chylomicron-poor fraction (p=0.003). FFA was most pronouncedly suppressed after whey ($p<0.001$). The glucose response was lower after the Whe-meal than after the other meals (p=0.015), whereas no significant differences were found in insulin, glucagon, GLP-1, and GIP responses.
Conclusion: The data suggest that as a supplement to a fat-rich meal in T2DM subjects, whey protein seems to outperform other proteins in terms of postprandial lipemia improvement possibly owing to formation of fewer chylomicrons or increased clearance of chylomicrons.

The effet of vitamin D status on insulin action and secretion in subjects with the metabolic syndrome

H.L. Gulseth[1,2], I.M.F. Gjelstad[2], J.A. Lovegrove[3], C. Defoort[4], E.E. Blaak[5], A. Dembinska-Kiec[6], J. Lopez-Miranda[7], B. Karlström[8], H.M. Roche[9], C.A. Drevon[2], K.I. Birkeland[1];
[1]Department of Endocrinology, Oslo University Hospital Aker, Norway, [2]Department of Nutrition, University of Oslo, Norway, [3]Hugh Sinclair Unit of Human Nutrition, Department of Food Biosciences, University of Reading, United Kingdom, [4]INSERM, 476 Human Nutrition and Lipids, University Méditerranée Aix-Marseille 2, France, [5]Department of Human Biology, NUTRIM, School for Nutrition and Toxicology and Metabolism, University of Maastricht, Netherlands, [6]Department of Clinical Biochemsitry, Jagiellonian Medical College, Krakow, Poland, [7]Lipid and Atherosclerosis Unit, Department of Medicine, Reina Sofia University Hospital, Cordoba, Spain, [8]Department of Public Health and Caring Sciences/Clinical Nutrition and Metabolism, Uppsala University, Sweden, [9]Nutrigenomics Research Group, UCD Conway Institute & School of Public Health, Population Science, University College Dublin, Ireland.

Background and aims: Accumulated evidence suggests that low levels of vitamin D is associated with impaired glucose metabolism and an increased risk of developing type 2 diabetes. However, very few studies have examined the role of vitamin D status for β-cell function with appropriate methods. We have evaluated the relationship between serum 25-hydroxyvitamin D_3 (25-OHvitD_3) and insulin action and secretion in subjects with the metabolic syndrome (MetS).
Materials and methods: 25-OHvitD_3 was measured with HPLC-MS in baseline samples from 446 subjects with MetS recruited for the LIPGENE dietary intervention study. Subjects (45% males) were from eight European centres, mean age was 54.6 ± 8.9 years and mean BMI 32.4 ± 4.2 kg/m^2. Insulin sensitivity (Si), acute insulin response to glucose (AIR_g) and disposition index (DI) were assessed by frequent sampling insulin modified intravenous glucose tolerance test (FSIVGTT) and MINMOD Millenium software. The HOMA-calculator version 2.2 was used to calculate HOMA IR and HOMA β. Non-parametric Kruskall-Wallis test was used to compare groups and correlations were calculated using Spearman's rank method. Data are presented as median (inter quartile range).
Results: The median 25-OHvitD_3 concentration was 51.3 (32.7) nmol/L, and only 91 (20.4%) had a serum level of 25-OHvitD_3 considered to be sufficient (≥75 nmol/L). 25-OHvitD_3 levels were significantly negatively associated with BMI (r=-0.23, p<0.001) and parameters of insulin secretion (HOMA β) and insulin resistance (HOMA IR) estimated from fasting levels of insulin and glucose (r=-0.15, p=0.001 and r=-0.14, p=0.003, respectively). The IVGTT derived parameters S_i and DI did not correlate with 25-OHvitD_3 status (r=0.06, p=0.21 and r=-0.059, p=0.24).

Median (IQR) levels of BMI and parameters of insulin action and secretion across tertiles of vit D

25-OH-vit D_3 (nmol/L)	**< 41.9**	**42-63.1**	**> 63.1**	**Kruskal-Wallis p**
n	149	149	148	
BMI (kg/m²)	33.1 (5.2)	32.4 (4.9)	31.1 (6.4)	< 0.001
Si	2.4 (2.0)	2.5 (1.7)	2.7 (1.9)	0.23
AIR	319 (377)	276 (258)	255 (360)	0.33
DI	762 (861)	697 (996)	725 (883)	0.40
HOMA β (%)	89.5 (48)	83.7 (38)	78.7 (43)	0.02
HOMA IR	1.5 (1.1)	1.4 (0.9)	1.3 (1.0)	0.02

Conclusion: Although associations between serum levels of 25-OHvitD_3 and insulin secretion and action were found when assessed by HOMA-methods, we were not able to confirm these relationships when we used FSIVGTT in a large sample of subjects with MetS.

Effects of the dietary omega-3 polyunsaturated fatty acids on atherosclerosis progression and cardio-metabolic parameters in metabolic syndrome patients

A.D. Dragomir[1,2], G. Radulian[1,2], E. Rusu[1,2], S. Dragan[3], D.M. Cheta[2];
[1]Healthy Food Foundation, Bucharest, [2]"Carol Davila" University of Medicine, Bucharest, [3]"Victor Babes" University of Medicine, Timisoara, Romania.

Background and aims: To test the functional effects of a diet containing omega-3 PUFA supplements vs. baseline diet recommended to patients with metabolic syndrome.
Materials and methods: A total of 156 patients with metabolic syndrome (MS) according to IDF criteria, aged 61±5.4 years, without clinical evidence of atherosclerosis were allocated to 2 groups, matched by sex and age: group A (76 patients) - diet according to ESC/EASD recommendations and individual needs; group B (80 patients) - the same diet + capsules of fish oil (1,0 g eicosapentanoic acid, 1,0 g docosahexanoic acid and 0,1 g α-tocopherol acetate). Body fat mass (BFM) and body fat percent (%BF) were measured by bioimpedance analysis (BIA) using InBody 3.0 Analyzer. Fasting plasma glucose, HbA1c, total cholesterol, LDL cholesterol, HDL cholesterol, triglycerides, plasma insulin, adiponectin and leptin were measured according to standard procedures. Insulin resistance was measured using HOMA-IR index. Oxidative stress was assessed using FormOx systems monitor on a blood drop. The progression of atherosclerosis was determined by measuring intima-media thickness (IMT) at commune carotid artery (ACC). The duration of the study was 6 months.
Results: Baseline characteristics were similar between groups. After 6 months, omega-3 supplements determined a significant improvement of metabolic parameters, decrease of oxidative stress (Table 1) and a statistically significant increase in adiponectin levels (from 9.46 ± 2.76 to 10.86 ± 2.68). Mean BMI, mean %BF, mean BFM and mean waist-to-hip ratio (WHR) were significantly lower in group B vs. group A (BMI- 31.12 kg/m^2 vs 29.1; %BF - 30.48 vs 27.48; BFM - 29.42 kg vs 26.78; WHR - 1.07 vs 1.02). BMI was statistically correlated with BFM (p<0.0001) and %BF (p<0.0001). Intima-media thickness was significantly decreased in group B (IMT in left ACC - 0.610 ± 0.06 vs. 0.621 ± 0.071 mm p=0.002; IMT in right ACC - 0.593 ± 0.074 vs. 0.612 ± 0.068) and was correlated with %BF (p<0.001), WHR (p=0.016), leptin values (p<0.001), adiponectin values (p<0.05) and leptin/adiponectin ratio (p<0.001).
Conclusion: Omega-3 PUFA enriched diets bring metabolic parameters closer to target values, thus lowering cardiovascular risk of MS patients. Also, IMT values and oxidative stress are decreased, underlying the role of omega-3 in the delay of atherosclerosis progression and endothelial cells damage.

Table 1

Parameters	**Group A - diet**	**Group B - diet + omega-3**	**P value**
Total cholesterol (mg/dl)	213 ± 20.5	198 ± 18.0	P<0.002
HDL-cholesterol (mg/dl)	46 ± 14	55 ± 12	P<0.05
Triglycerides (mg/dl)	143 ± 71	132 ± 58	P=0.002
HOMA-IR	4.62 ± 3.2	4.57 ± 2.4	P=0.016
Fasting Plasma Glucose (mg/dl)	121 ± 18	110 ± 14	P<0.0001
FormOx (Fort units)	319 ± 94	268 ± 76	P<0.0001

Does a low-fat vegetarian diet improve insulin resistance and beta cell function in individuals with type 2 diabetes?

H. Kahleova, T. Neskudla, T. Pelikanova;
Diabetes Center, Institute of Clinical and Experimental Medicine, Prague, Czech Republic.

Background and aims: Diabetes prevalence is relatively low among individuals consuming plant-based and vegetarian diets, and clinical trials using such diets have shown greater effect on weight loss, greater reduction of LDL cholesterol, HbA1c and diabetes medication than conventional diabetic diet.

The aim of our study was to evaluate the effect of low-fat vegetarian diet compared to conventional diabetic diet with similar caloric restriction on insulin resistance, β-cell function, body weight and resting energy expenditure in individuals with type 2 diabetes after a 3-month-diet-intervention.
Materials and methods: Open, parallel randomized study. 70 individuals with type 2 diabetes were randomly assigned to either experimental group (EG) following a low-fat vegetarian diet or the control group (CG) following conventional diabetic diet with similar caloric restriction (-500 kcal/day). We measured all common anthropometric and laboratory parameters; glucose tolerance and insulin secretion was evaluated after standard meal stimulation; we assessed insulin resistance by a 3-hour hyperinsulinemic isoglycemic clamp; resting energy expenditure was measured by indirect calorimetry. All the procedures were done at start (0) and after 12 weeks.
Results: Average weight loss was greater in the EG than in the CG (6.41±4.23 vs. 3.47±4.07 kg; p<0.01). Diabetes medication was reduced according to the study protocol in 15 subjects from the EG (42.86%) vs. in 2 subjects from the CG (6.45%). We noticed an increase in post-load plasma C-peptide concentrations in the EG (p<0.05), whereas changes in stimulated C-peptide in the CG were not significant. We observed a trend to a greater reduction of plasma HbA1c, cholesterol, free fatty acids and both fasting and post-load glucose in the EG, but the differences were not statistically significant. Insulin resistance decreased (p<0.01) similarly in both groups. Respiration coefficient decreased (p<0.01) and fasting fat oxidation increased (p<0.01) similarly in both groups.
Conclusion: Our results indicate that low-fat vegetarian diet leads more effectively to reduction of diabetes medication and improvement of β-cell function than the conventional diabetic diet and it could be a more convenient alternative in treatment of type 2 diabetes.

Association between regularity and frequency of meals and metabolic parameters in type 2 diabetic patients
S. Kim[1], S. Hong[1], M. Nam[1], Y. Kim[1], J. Woo[2], Y. Kim[2], S. Baik[3], Y. Park[4], G.-W. Lee[5];
[1]Internal Medicine, Inha University College of Medicine, Incheon, [2]Internal Medicine, Kyung Hee University School of Medicine, Seoul, [3]Internal Medicine, Korea University College of Medicine, Seoul, [4]Internal Medicine, Hanyang University College of Medicine, Kuri, [5]Internal Medicine, Ajou University School of Medicine, Suwon, Republic of Korea.

Background and aims: Medical Nutritional therapy is a key component for preventing diabetes, managing existing diabetes, and preventing the development of diabetic complications. The aim of this study was to assess the association between dietary habits and metabolic parameters in Korean type 2 diabetic patients who live in a different culture and have different dietary habits and patterns from those of western countries.
Materials and methods: 1,251 diabetic patients from the Korean National Diabetes Program (KNDP) cohort who completed a dietary habit questionnaire and clinical evaluation from March, 2006 to November, 2007 were included in this study. Dietary intake was assessed using a 24 hour dietary recall method and anthropometric data and biochemical data were collected.
Results: The mean age of the patients were 54.0±10.1 years, duration of diabetes 5.0±5.9 years, body mass index 25.1±3.1 kg/m^2, HbA1c 7.2±1.2%. 56.3% of the patients were male and 6.5% of the patients were on insulin therapy. 87% of the patients had meals 3times per day and 13% of the patients had meals 1 or 2 times per day. Patients who had meals 3 times per day were older (54.6±9.8 vs 50.5±10.9kg, p<0.001), had a lower BMI (25.0±3.0 vs 26.0±3.4 kg/m^2, p<0.001) and higher intake of fibers (26.4±10.0 vs 23.6±9.7 g/day, p=0.001) and higher intake of calories (1764.8±454.4 vs 1647.7±588.8 kcal/day, p=0.015) compared with those who had meals 1 or 2 times per day. Three times per day frequency of meals was associated with lower BMI after adjustment for age and sex (p<0.001). Assessing the regularity of time of meals, 63% of the patients kept a meal schedule that was regular most of the time (≥5days per week) and 37% of the patients had a more irregular meal schedule (regular time of meals < 5 times per week). Patients who's meal schedule was regular most of the time were older (55.2±9.9 vs 51.98±10.0 years, p<0.001), had a lower BMI (24.8±2.9 vs 25.6±3.3 kg/m^2, p<0.001), a lower waist circumference (87.2±7.8 vs 88.3±8.4 cm, p=0.02), and a lower fasting glucose level (134.5±36.8 vs 139.4±41.4 mg/dl) compared with those who's meal time was more irregular (regular time of meal <5times per week). Regularity of meal time schedule was associated with lower BMI (p<0.001) but not lower fasting glucose (p=0.06) after adjustment for age and sex.
Conclusion: Meal frequency of 3 times per day and more regular meal schedules was associated with decreased BMI but not glycemic control. Dietary habits seem to be an important factor for maintaining lower body weight in type 2 diabetic patients.

Satiating effects of milk but not sugar- or artificial-sweetened soft drinks and water
M.M. Nielsen[1], A. Belza[2], B.E. Larsen[1], S.B. Pedersen[1], A. Astrup[2], B. Richelsen[1];
[1]Department of Internal Medicine/Endocrinology C, Aarhus Hospital, [2]Faculty of life sciences, Copenhagen, Denmark.

Background and aims: Energy intakes from drinks may not be compensated for by proper satiety sensation. Consequently weight gain, obesity and type 2 diabetes may occur as a result of the excessive energy consumed. We aim to provide evidence linking drinks to insufficient satiety and excessive energy intake as well as elucidating the mechanisms underlying this association, as far as they can be explained by variations in concentrations of the appetite-regulating hormones Ghrelin, PYY, GIP and PP.
Materials and methods: The present study is a cross-over, intervention clinical trial including 24 overweight (BMI: 31.4 +/- 2.9kg/m^2) subjects (12men and 12woman). Baseline blood-samples were collected after an overnight fast and a 500ml drink (sugar-sweetened beverage (250 kcal/1 MJ), aspartam-sweetened beverage, semi-skimmed milk (240 kcal/0.9 MJ) or water) was served. Blood-samples and satiety score using a visual analogue scales (VAS) were collected and filled in every 30 minutes. After four hours an ad libitum meal was served and the energy intake calculated.
Results: Compared to water milk causes 94% higher satiety VAS score (dAUC = 64.8mm (95% CI: 15.0;114.6), P= 0.008) and 122% higher fullness VAS score (dAUC = 62.2mm (95% CI:10.9;113.5), P= 0.04) whereas the effects of a sugar-sweetened drink were no different than water. Ghrelin concentration is significant lower after consumption of milk than after consumption of water (0.76fmol/ml (95% CI:0.61;0.95), P=0.008), and there is a tendency (not significant) towards ghrelin concentration being less decreased by the soft drinks preloads compared to milk (artificial-sweetened: P=0.2, sugar-sweetened: P=0.9). However between the four preload drinks there were no significant differences in energy intake. Although the ad libitum energy intake was 4654±383 kJ after milk and 4924 ±481 kJ after the sugar-sweetened beverage.
Conclusion: So far our study supports the notion that milk is more satiating than equicaloric sugar-sweetened soft drink, aspartam-sweetened soft drink and water. The association between milk and increased satiety is reflected in subjective appetite sensation. However no differences in energy intakes between the four preloads support the notion that energy in drinks may cause higher total energy intake.

Changes of plasma free amino acids in type 2 diabetes
T. Chen[1], X. Zhang[2], Y. Long[2], X. Ran[1], Y. Ren[1], H. Tian[1,2];
[1]Endocrinology and Metabolism, [2]Laboratory of Endocrinology and Metabolism, West China Hospital, Sichuan University, Chengdu, China.

Background and aims: Dietary components are strongly associated with type 2 diabetes. High fat diet and high carbohydrate diet have been intensively investigated, and been found to contribute to the high prevalence of type 2 diabetes. Another major diet component, proteins, has drawn more and more attention recently. Some studies indicated that high protein diet (HPD), especially high meat protein intake, may also contribute the increased risk of type 2 diabetes, while many other studies didn't discover any positive association. On the other hand, old and new evidence indicated that plasma free amino acids (AA) are associated with both plasma insulin level and insulin sensitivity. To understand what happened to plasma free AAs in type 2 diabetic patients may give some interesting clues to the discrepancy among high protein diet or AAs studies. Given the fact that the data about the profile of plasma free AAs in type 2 diabetic and normal individuals was very limited, the primary aim of this study was to investigate the alterations of plasma free AAs in type 2 diabetic patients so as to provide some valuable information for further clinical high protein diet and AAs researches.

Materials and methods: Our study was a cross-sectional case-control study. Both T2DM patients and non-diabetic controls were from a part of an ongoing cross-section survey in China, designed to investigate the prevalence of type 2 diabetes and metabolic syndrome among Chinese populations. These participants were of Yi population, an old minor nationality in China. A total of 132 type 2 diabetic patient and 137 age, sex, cigarette and alcohol use matched controls were included in this study. All of them had no history of severe disease such as pulmonary, heart, liver and kidney diseases, and they were included before AAs measurement. Dichotomous data were described as percent (%). Continual data with normal distribution or near normal distribution was described as mean ±S.D., others were described as median and quartiles and logarithm transformed before statistical analysis. Categorical variables were compared by chi square tests. Continuous variables were evaluated by Student's t tests. Correlations between analyzed by Pearson test. All reported P values were two tailed, and those $\alpha<0.05$ were considered statistically significant

Results: 1. Levels of total plasma free amino acids (TAA), essential amino acids(EAA) and branched chain amino acids (BCAA) in type 2 diabetic patients were higher than those in controls (P=0.000 for all). Non-essential amino acids (NEAA)' level was also high in type 2 diabetic patients but with marginal significant difference (P=0.044). Statistic results of individual AAs showed that plasma alanine, valine, leucine, isoleucine, phenylalanine, tyrosine, methionine, glutamate and lysine were higher in type 2 diabetes than in control (P<0.01 for all) , while plasma glycine, glutamine were lower in type 2 diabetes than in control (P=0.003 and P=0.034 respectively) 2. TAA, especially EAA and BCAA, and individual AAs, alanine, valine, leucine, isoleucine and glutamate were positively associated with BMI, waist, GGT, ALT, while, glutamine was negatively related to GGT, and glycine negatively related to ferritin.

Conclusion: There were significant differences in plasma amino acids between type 2 diabetic patients and controls. Some AAs, especially BCAA and glutamate were correlated with identified type 2 diabetes risk factors. Whether abnormal metabolism of AAs contributed to increased risk of type 2 diabetes is very necessary to be further investigated by prospective studies.

Diet induced 2-year weight loss initiates a cluster of inter-correlated changes in lipids, inflammation and insulin resistance, more profound among diabetics than in non-diabetics; results from the DIRECT study

R. Golan[1], A. Rudich[1], Y. Henkin[2], D. Schwarzfuchs[3], I. Harman-Baham[2], A. Tirosh[4], O. Tangi[1], J. Thiery[5], G. Fiedler[5], M. Blüher[6], M. Stumvoll[6], I. Shai[1];
[1]Ben Gurion University, Beer Sheva, Israel, [2]Soroka University Medical Center, Beer Sheva, Israel, [3]Nuclear Research Center, Dimona, Israel, [4]Sheba Medical Center, Department of Internal Medicine, Tel-Hashomer, Israel, [5]Institute of Laboratory Medicine, University Hospital, Leipzig, Germany, [6]University of Leipzig, Germany.

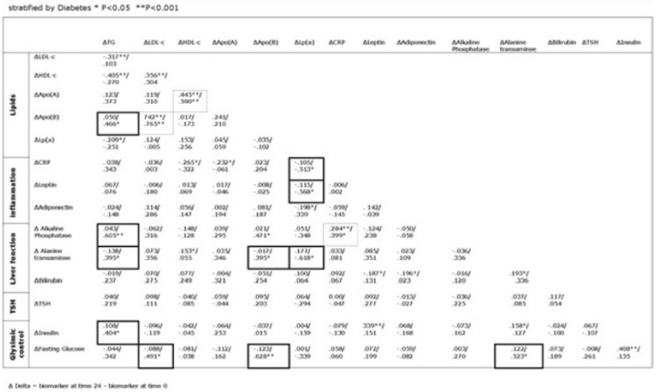
Background: Data regarding inter-correlations of *changes* of biomarkers induced by long term dietary interventions and the differential effect among patients with type 2 diabetes (T2D) and non diabetics is sparse.

Methods: 322 Participants of the Dietary Intervention Randomized Controlled Trial (DIRECT) were randomly assigned to one of three dietary strategies over 2 years. We compared the intra- correlations of *changes* in lipids, markers of inflammation, liver function tests, glycemic control and TSH during the 2 year weight loss trial among non-diabetic controls (n=277) and patients with T2D (n=45).

Results: Mean weight change was -3.49 kg among patients with T2D and -4.10kg among non-diabetics (p=0.50). In absolute values, the improvement in HDL-c was higher among diabetics that among non-diabetics (+9.41 vs. + 6.57mg/dL, p<0.05). Correlations adjusted for Age, sex and 2-year change in BMI revealed than beyond the common inter-correlations found between biomarkers in both groups [such as significant correlations between the 2 year decrease in triglycerides and the 2 year increase in both LDL-c, HDL-c and Lp(a) levels (p<0.05 for all)], we found specific correlations among the T2D patients only: A 2-year decrease in fasting glucose was significantly associated with a decrease in LDL-c, Apo(B), and alanine transaminase (p<0.05 for all). Among T2D patients only, a decrease in triglyceride levels was significantly associated with a decrease in fasting insulin, Apo(B), alanine transaminase, and alkaline phosphatase (p<0.05 for all). Surprisingly, a decrease in Lp(a) levels was significantly correlated with an increase of hs-CRP, leptin and alanine transaminase (p<0.05 for all). However, a 2-year decrease in waist circumference was positively associated with a decrease in TSH levels (p<0.05).

Conclusion: A cluster of biomarkers change during 2-years of a weight-loss dietary intervention, which are more inter-correlated among patients with T2D diabetes as compared to non-diabetic obese controls, underscoring the ability to particularly improve insulin resistance, inflammation and lipids by dietary intervention in this population.

Table 1: Changes after 2 years of dietary intervention: Intra -correlations (r) between *changes* (delta) in biomarkers; adjusted for age, sex and ΔBMI, stratified by Diabetes * P<0.05 **P<0.001



Δ Delta = biomarker at time 24 – biomarker at time 0

Food composition database harmonization for between-country comparisons of dietary data in the TEDDY Study

U. Uusitalo[1], C. Kronberg-Kippilä[2], C.A. Aronsson[3], M.-L. Ovaskainen[2], I. Mattisson[4], S. Schakel[5], W. Sichert-Hellert[6], S. Schoen[6], M. Stevens[5], H. Reinivuo[2], J.M. Norris[7], S.M. Virtanen[2,8], for the TEDDY Study Group;
[1]University of South Florida College of Medicine, Tampa, United States, [2]National Institute for Health and Welfare, Helsinki, Finland, [3]Lund University, Malmo, Sweden, [4]National Food Administration, Uppsala, Sweden, [5]University of Minnesota, Minneapolis, United States, [6]Research Institute of Child Nutrition, Dortmund, Germany, [7]University of Colorado, Denver, United States, [8]University of Tampere, Finland.

Background and aims: Between-country comparison of diet sets special requirements and challenges on national food composition databases (FCDBs) used for analyses. The aim of this study was to evaluate the comparability of FCDBs used in Finland, Germany, Sweden, and the U.S. - countries participating in The Environmental Determinants of Diabetes in the Young Study (TEDDY).

Materials and methods: TEDDY is a prospective multi-center, multi-national study, in which approximately 8000 children with increased genetic susceptibility to type 1 diabetes will be followed across six study centers in Europe and the U.S. The participants are monitored for islet autoantibodies and diabetes until the age of 15 years. The study aims at examining the associations between islet autoimmunity and various environmental exposures, e.g. diet. The first dietary assessment is carried out by 24-hr recall at the age of 3 months and after that by 3-day food record every 3 months until the child is 12 months old and then every six months. In order to produce comparable results the national FCDBs have to contain mutually comparable food composition data. Systematic comparison (definition, unit of measurement, method of analysis) of energy, protein, fats, carbohydrates, cholesterol, fiber, 12 vitamins and 8 minerals was carried out among the FCDBs.

Results: The original version of the nutrient calculation program used with German FCDB (LEBTAB) did not take yield and retention factors into account in data processing. They will be added to the LEBTAB food composition database as part of the harmonization efforts. Nitrogen values were added to the Swedish and U.S. databases. Total fat, cholesterol, vitamin A (retinol equivalents and beta-carotene), thiamin, riboflavin, niacin, pyridoxine, vitamin B12, calcium, phosphorus, iron, potassium, magnesium, and zinc are comparable between the databases. Carbohydrates, sugars, fatty acids, vitamin D, vitamin K, vitamin C, pantothenic acid, manganese, copper, and fiber are comparable or can be converted comparable only across three databases. Vitamin E is comparable after Finland and Germany have subtracted tocotrienols from their values. After recalculation of protein from nitrogen (Sweden and USA), and recalculation of energy these values will be comparable across the countries. Starch and folate are not comparable.

Conclusion: According to this comprehensive review, most of the nutrients are comparable or can be converted to be comparable among the four FCDBs.

Effects of protein on gastric emptying and the glycaemic, insulin and gastrointestinal hormone responses to a carbohydrate meal in type 2 diabetes

J. Ma[1,2], J.E. Stevens[1,2], K. Cukier[3], A.F. Maddox[1,2], J.M. Wishart[1,2], J. Bowen[4,2], K.L. Jones[1,2], M. Horowitz[1,2], P.M. Clifton[4,2], C.K. Rayner[1,2]; [1]Discipline of Medicine, Royal Adelaide Hospital, The University of Adelaide, [2]Centre of Clinical Research Excellence in Nutritional Physiology, Interventions and Outcomes, The University of Adelaide, [3]Endocrine & Metabolic Unit, Royal Adelaide Hospital, [4]Human Nutrition, Commonwealth Scientific and Industrial Research Organisation, Adelaide, Australia.

Background and aims: Strategies that slow gastric emptying and stimulate incretin hormones can potentially attenuate postprandial glycaemic excursions. We evaluated whether a whey protein "preload" could slow emptying of a subsequent meal, stimulate glucagon-like peptide-1 (GLP-1), glucose-dependent insulinotropic polypeptide (GIP) and insulin release, and thereby reduce blood glucose.
Materials and methods: 8 diet-controlled type 2 diabetic patients were studied on three days each in random order. On each day, subjects ingested beef flavoured soup 30 min before a mashed potato meal; either 55 g whey protein was added to the soup ("whey preload"), or to the potato ("whey in meal"), or no whey was given ("no whey"). Data were given as mean ± SEM.
Results: Gastric emptying was slowest after "whey preload" (half emptying time: 87.3 ± 5.4 min), and slower after "whey in meal" (53.0 ± 8.3 min) than "no whey" (39.0 ± 6.2 min; P < 0.0005). The incremental area under the blood glucose curve was substantially less after "whey preload" (363.7 ± 64.5 mmol.min/l, P < 0.005) and "whey in meal" (406.3 ± 85.9 mmol.min/l, P < 0.005) than "no whey" (734.9 ± 98.9 mmol.min/l), and the peak glucose level was lower after "whey preload" (11.3 ± 0.5 mmol/l) and "whey in meal" (11.7 ± 0.6 mmol/l) than "no whey" (14.3 ± 0.5 mmol/l; P = 0.0001). Cholecystokinin, GIP and insulin concentrations were higher on both whey days than after "no whey", whereas GLP-1 was greatest after "whey preload" (P < 0.05 for each).
Conclusion: Whey protein consumed before a carbohydrate meal in type 2 diabetes stimulates insulin and incretin hormone secretion, and slows gastric emptying, leading to a marked attenuation of the postprandial glycaemic response. This observation has substantial implications for dietary management of type 2 diabetes.

Impact of a brief lifestyle advice intervention on physical activity

H.C. Price[1], S.J. Griffin[2], R.R. Holman[1]; [1]Diabetes Trials Unit, University of Oxford, [2]MRC Epidemiology Unit, Cambridge, United Kingdom.

Background and aims: To determine if a brief lifestyle advice intervention could increase physical activity in adults at increased risk of cardiovascular disease (CVD).
A lack of regular physical activity may contribute to the early onset and progression of CVD. Moderate and high levels of physical activity are associated with a 2-21% reduction in CVD and all-cause mortality.
Materials and methods: Participants were randomised in a 2x2 factorial design to receive or not receive a personalised 10-year CVD risk estimate and, simultaneously randomised to receive or not receive a brief lifestyle advice intervention. We report here the brief lifestyle advice intervention arm. The primary outcome was the change in physical activity measured by an accelerometer, with 80% power at the 5% level of significance to detect a difference of 30,000 total accelerometer counts per day between groups (approximately equivalent to 10 minutes of brisk walking). A total of 215 individuals without known CVD but at increased CVD risk (defined as a Framingham-derived 10-year CVD risk >20%) were recruited from 4 general practices in Oxfordshire, UK. Of 194 eligible participants, 98 were randomised to receive a brief lifestyle intervention informed by self-regulation theory and aimed at motivating behaviours designed to reduce CVD risk. The other 98 received no intervention. The brief lifestyle intervention involved the setting of goals and steering behaviour towards them. It took the form of a 15 minute computerised presentation focusing on increasing physical activity and fruit and vegetable consumption and smoking cessation (if necessary). The physical activity goal was 30 minutes of brisk walking per day. Accelerometer, anthropometric and biochemical information was collected before and one month after randomisation.
Results: Participants had median (IQR) age 62.3 (54.9, 66.1) years, with 67% men, 19% having known diabetes and 19% current smokers. At baseline, mean (SD) accelerometer counts per day (x1000) were 297 (110), blood pressure 140/81 (18/11) mmHg, LDL cholesterol 3.1 (0.9) mmol/L, HDL cholesterol 1.23 mmol/L (0.29) in men and 1.53 mmol/L (0.37) in women and plasma vitamin C 61.8 (21.2) μmol/L. Triglycerides were median (IQR) 1.4 mmol/L (1.0, 1.9), body mass index 28 kg/m^2 (26, 31), serum cotinine in smokers 50 (49, 62) ng/ml and estimated 10-year CVD risk 48% (34, 60) in men and 31% (22, 43) in women. Baseline accelerometer counts were higher than expected equating to 77% achieving 30 minutes or more of moderate intensity activity per day. In the 185 (95%) participants attending follow-up, no significant within or between group differences were seen in accelerometer counts, body mass index, blood pressure, LDL or HDL cholesterol, plasma vitamin C or estimated 10-year CVD risk. In the group randomised to receive the brief lifestyle advice intervention, compared to control, there was a reduction in waist circumference in men (2.6%, p=0.006) but not in women, 10.2% reduction in triglycerides (p=0.02) and 7.9% reduction in serum cotinine in smokers (p=0.028).
Conclusion: A brief lifestyle advice intervention in adults at increased CVD risk did not alter physical activity but achieved small improvements in some CVD risk factor levels. The lack of physical activity response may reflect the large number of participants already at target at entry. Our findings suggest that a theory-based brief lifestyle advice intervention alone is insufficient to increase physical activity.

Implementation and effectiveness of the first community lifestyle intervention program to prevent type 2 diabetes in Greece. The DEPLAN Study

K. Makrilakis, S. Liatis, S. Grammatikou, D. Perrea, N. Katsilambros; First Department of Propaedeutic Medicine, Athens University Medical School, Greece.

Background and aims: To report the experience and the initial results of implementing the first community-based lifestyle intervention program to prevent Type 2 diabetes mellitus (T2DM) in a sample of the general population in Athens, Greece

Materials and methods: The FINDRISC questionnaire was distributed to a total of 3,240 people in the city and the suburbs of Athens in order to detect high-risk individuals for the development of T2DM. A total of 191 persons entered the intervention program (bi-monthly sessions with a dietician) and 125 of them returned for a repeat oral glucose tolerance test (oGTT) one year later.
Results: Participants lost on average 1.0±4.7 kg (1.1% of initial body weight, p=0.022). Higher adherence to the intervention sessions resulted in greater weight loss. Persons with impaired fasting glucose (IFG) and/or impaired glucose tolerance (IGT) at baseline lost more weight than the normal glucose tolerance (NGT) ones (1.5±4.8 vs. -0.02±4.5 kg). The percentage of people with any type of glucose abnormality (IFG/IGT) decreased with the intervention (68% at baseline vs. 53.6% one year later, p=0.009). A total of 5.6% developed DM (2.5% of NGT, 7.1% of IFG/IGT participants). Multivariate logistic regression analysis revealed that the probability of deterioration of the glycemic status was associated only with the amount of weight lost (inversely) during the intervention (β=-0.11, OR=0.89, p=0.045).
Conclusion: The implementation of a lifestyle intervention program to prevent T2DM in the community is practical and feasible.

One risk questionnaire to identify persons at risk for cardiovascular disease and type 2 diabetes - the Hoorn Study
M. Alssema[1], G. Nijpels[1], C.D.A. Stehouwer[2], J.M. Dekker[1];
[1]EMGO Institute for Health and Care Research, VU University Medical Center, Amsterdam, [2]Department of Internal Medicine, Academic Medical Center Maastricht, Netherlands.

Background and aims: The common aim of risk prediction of cardiovascular disease (CVD) and type 2 diabetes (T2DM) is identification of high-risk groups that would benefit from early treatment. Since the strategy for prevention of these so-called cardio-metabolic diseases largely overlaps, we investigated whether it was possible to develop one tool that predicts risk for both CVD and T2DM.
Methods: The study population consisted of 1258 participants, aged 50-75 years, from the Hoorn Study who were free of prevalent CVD or known T2DM at baseline (1989). All participants had an oral glucose tolerance test at the follow-up examination in 1996, and complete follow-up information on CVD morbidity and mortality until 1996. The outcome to be predicted was a composite end-point of CVD morbidity and mortality (ICD-codes 390-459), sudden death (ICD-code 798) or T2DM, as measured by an oral glucose tolerance test. Logistic regression analysis with backward selection of predictors (demographics, medical history, dietary and lifestyle habits) was used to develop the model. Discriminative value of the models was assessed by the area under the receiver operating characteristic curve. Model validation was done in a subsample of the study population with follow-up duration until 2000.
Results: During a follow-up period of 6.4 (0.5) years, 375 (29.8%) out of 1258 persons developed the composite end-point. For the risk questionnaire, age, sex, waist circumference, use of anti-hypertensive medication, history of gestational diabetes, parent or sibling with T2DM, shortness of breath during walking, current smoking and parent or sibling with myocardial infarction or stroke were selected as predictors. Discriminative value of the risk questionnaire was 0.74 for the composite end-point. The separate outcome measures were equally well predicted (discriminative value was 0.70, 0.76 and 0.74 for CVD morbidity, CVD mortality and T2DM, respectively). Nearly similar discriminative values were found in the validation dataset, so internal validation was good. In the development dataset, a cut-off value at the optimum sensitivity and specificity captured 71% of the incident cases (sensitivity). Furthermore, 68% of the persons who did not develop the outcome were indeed in the low-risk category (specificity). According to the questionnaire, 44% of this elderly population had a high risk. Persons in this high-risk group had a risk of 47% to develop CVD and/or T2DM within 6 years (positive predictive value).
Conclusion: Risk of cardiovascular disease and type 2 diabetes can be predicted by one single risk questionnaire to identify individuals at high risk, which is useful for public health purposes.

Leicestershire self assessment score for impaired glucose regulation for use in a multi ethnic setting
L.J. Gray[1], M.J. Davies[2], N. Taub[1], S. Hiles[3], K. Khunti[1];
[1]Dept of Health Sciences, [2]Dept of Cardiovascular Sciences, [3]Dept Diabetes Research, University of Leicester, United Kingdom.

Background and aims: One in five of those screened in the ADDITION-Leicester population based screening study had some form of Impaired Glucose Regulation (T2DM or impaired fasting glucose (IFG) or impaired glucose tolerance (IGT)) (IGR). Modelling studies have shown that early detection of IGR and appropriate intervention can decrease morbidity and early mortality from cardiovascular disease. Self assessment scores identify those at high risk and are particularly useful in populations where response rates to screening programmes are low. To date no self assessment scores have been developed and validated for multi ethnic populations.
Materials and methods: We used data on 6,390 subjects aged 40-75 from the ADDITION-Leicester screening study from a multi ethnic UK setting (76% White European, 22% South Asian, 3% other). All participants were given a 75g Oral Glucose Tolerance Test. We developed logistic regression models for predicting IGR (IFG/IGT/T2DM) using data from self reported questionnaires. Using the best fitting model we developed the Leicester Self Assessment Score. Initial analysis was carried out using complete cases only, then missing data indicators were used as a check for robustness of the modelling. We externally validated the tool using data from 3,298 subjects aged 40-75 screened as part of a second screening study.
Results: The final model includes age, ethnicity (White European versus other - predominantly South Asian), sex, 1st degree family history, antihypertensive therapy or history of hypertension, waist circumference and body mass index. The score ranges from 0 to 47. Validating this model using the STAR data gives an area under the ROC curve of 71% (95% CI 68% to 74%). Using a cut point of 16 to predict those at high risk of IGR had a sensitivity of 82%, specificity of 47% and correctly classified 53% of cases.
Conclusion: The Leicester Self Assessment Score can be used to reliably identify those at high risk of IGR in multi ethnic populations. The score is simple (7 questions) and non invasive.

Automated detection of high risk for impaired glucose regulation and type 2 diabetes mellitus, using primary care electronic data, in a multi-ethnic UK community setting
N.A. Taub[1], K. Khunti[1], K.R. Abrams[1], L.G. Gray[1], S.L. Hiles[2], M.J. Davies[2];
[1]Health Sciences, [2]Cardiovascular Sciences, University of Leicester, United Kingdom.

Background and aims: Screening for cardiovascular risk factors is now acknowledged to be a high priority, and much research continues to be carried out on the most effective and efficient risk scores. To complement this work, it would be valuable to have an accepted and reliable risk score for type 2 diabetes (T2DM) and impaired glucose regulation (IGR) which use only data routinely recorded on computerised primary care databases. Tools using routine data would be invaluable to determine people at high risk for further investigation. The aim of this study was to construct a primary care computer risk score for use in a multi-ethnic population with substantial (30%) south Asian ethnic minority.
Materials and methods: A random sample of people aged 35-70 years from 24 general practices in Leicestershire was invited for a 75g Oral Glucose Tolerance Test (OGTT), as part of ongoing screening studies in Leicester, UK. Demographic and anthropometric characteristics were recorded using standard operating procedures. The variables we considered for inclusion were - age, gender, BMI, ethnicity (as the proportion of south Asians in the individual's general practice), family history (of Type 1 or Type 2 diabetes mellitus, with separate terms for any first degree relatives, and for only relatives of second or degree or more distant), smoking status (never, ex-smoker or current smoker), history of high blood pressure (as indicated by prescription of anti-hypertensive medication), and whether the BMI had been recorded in the practice data base (as a possible proxy for level of deprivation). We could not assume that ethnicity or any socioeconomic indicator would be available for individuals. Logistic regression modelling was used to identify sets of variables independently predictive of T2DM/IGR; interaction terms were used

to assess the values of complex combinations of predictors, and fractional polynomial terms were used to examine potential nonlinear relationships.
Results: 6,203 individuals participated. 5,086 individuals (82%) had all relevant data recorded and were included in the analysis, of these 149 (2.9%) were diagnosed at OGTT with screen-detected T2DM, and an additional 633 (12.4%) were diagnosed with IGR; the age range was 35-70 years; mean age was 55.3 (SD 8.7), 47.2% were male and 25.7% were of south Asian ethnicity. The strategy of logistic modelling resulted in a risk score incorporating age, gender, average ethnicity in the practice, body mass index, family history of T2DM (any degree), and previous hypertension. Internal validation with a cut-point identifying the top 10% individuals by risk gave 44% sensitivity and 80% specificity for T2DM/IGR; similar validation on an external data set gave sensitivity around 51% and specificity around 76%.
Conclusion: We have developed a practical low cost risk score for identification of prevalent T2DM and IGR in primary care. This tool can be used for screening people at high risk for appropriate interventions.

Risk and predictors of deterioration of glucose metabolism in subjects with and without CV complications - a prospective observational study
O. Johansen[1,2], A.-P. Ofstad[1], M. Sørensen[1], K.G. Blaasaas[3], L. Gullestad[3,4], K.I. Birkeland[5,3];
[1]Medical department, Asker and Baerum Hospital, Rud, [2]Boehringer-Ingelheim, Asker, [3]University of Oslo, [4]Oslo University Hospital, Rikshospitalet, [5]Oslo University Hospital, Aker, Norway.

Background and aims: Abnormal glucose metabolism is more prevalent among subjects with, than without cardiovascular (CV) complications. However, it is not known whether rate of glycaemic deterioration is different or more associated to certain parameters of inflammation or the insulin-like growth factor (IGF) system. In a 4-yr prospective observational study, we examined risk for, and rate of, glycaemic deterioration in subjects without diabetes mellitus (DM) with and without CV complications and explored its association of traditional risk factors and markers of inflammation (high sensitivity C reactive protein (CRP), soluble tumor necrosis factor receptor type I (sTNF-RI), transforming growth factor (TGF)-β1, Interleukin (IL)-10) and parameters in the IGF system (IGF-1, IGF binding protein (BP)-1 and IGFBP-3).
Materials and methods: We studied 72 subjects (31 female, 66 years, BMI 24.6±3.6 kg/m^2) with a previous CV complication (42% coronary artery-, 28% cerebrovascular- and 30% peripheral arterial disease) and 61 (38 female, 60 years, BMI 25.1±4.5 kg/m^2) without. At both time points a 75 g oral glucose tolerance test, classified according to the WHO criteria (DM, impaired glucose tolerance (IGT) or impaired fasting glycaemia (IFG)) was conducted. Inflammatory and IGF-system parameters were analysed in fasting serum samples.
Results: Respectively, 14 (23%) subjects without and 29 (40%) with a CV complication deteriorated in glycaemic status (i.e. normal to IFG/IGT/DM or IFG/IGT to DM) yielding DM incidence rates from normal or IFG/IGT respectively of 1.06 and 1.77 versus 1.67 and 5.65 cases pr 100 patient year. Odds ratio (OR) for glycaemic deterioration was 2.24 (95% CI 1.03 - 4.88). The magnitude of the OR (2.05 - 2.38) did not change when adjusted for baseline factors (age, weight, homeostasis-insulin resistance [HOMA-IR], insulin, TGF-β1, CRP, sTNF-R1, IL-10, IGF-1, IGF-BP1, IGF-BP-3) or longitudinal parameters (degree of physical activity or daily sleep hours). Only parameters of the IGF system were significantly associated with glycaemic deterioration (table 1), which was further underscored with elevated OR and 95% CI for progression of highest vs lowest quartile adjusted for CV-complications for low levels of IGFBP-1 and elevated HOMA-IR and insulin. This was also the case for weight (3.95 (1.32, 11.80)), but not age (1.12 (0.35, 3.60)).
Conclusion: Subjects with CV complications have a 2-fold higher risk for deterioration of glucose metabolism and should receive regular assessment of glycaemic status. Our findings also support that low levels of IGFBP-1 may play a role in the deterioration of glycaemic status. These findings may have implications for future strategies aiming at identifying individuals at high risk for DM for prevention.

Serial measurement of fasting and postload glucose and HbA_{1c} in subjects who did and did not develop diabetes during a 10-year period in the Hoorn Study
J.M. Dekker[1], C.D.A. Stehouwer[2], G. Nijpels[3];
[1]EMGO Institute for Health and Care Research, VU University Medical Center, Amsterdam, [2]Internal Medicine, Maastricht University Medical Centre, [3]VU University Medical Center, Amsterdam, Netherlands.
Background and aims: Three markers of hyperglycemia are currently used for diagnosis and management of diabetes: fasting glucose, postload glucose -2 hours after a 75 g oral glucose tolerance test, and HbA1c. It is not known whether any of these three markers changes earlier, or more rapidly, during the development of diabetes. Therefore we compared fasting and postload glucose levels and HbA1c in people who did and did not develop diabetes during a 10-year period.

Deterioriation of glucose metabolism according to basline inflammatory and IGF system parameters.

Data given as mean (95% CI) or OR (95% CI)
*: $p < 0.05$ (ANOVA), §: 1st vs 4th quartile.
Abbreviations: NGT - normal glucose tolerance.

Materials and methods: The Hoorn Study is a population-based cohort study of diabetes, which started with 2484 men and women, aged 50-75 at baseline in 1989. Follow-up examinations were performed in 1996-98, and in 2000, in all subjects with fasting glucose ≥ 6.1 mmol/l or postload glucose ≥ 7.8 mmol/l in 1996-98 and a sample of those with normal glucose metabolism. In 2000, 564 subjects without diabetes at baseline participated. Diabetes was defined by fasting glucose ≥ 7.0, postload glucose ≥ 7.8 mmol/l, or HbA1c ≥7 % or use or glucose lowering medication.
Results: A total of 92 subjects had developed diabetes within 10 year. The mean fasting and postload glucose and HbA1c levels at the 3 examinations according to diabetes status in 2000 are shown in the table. All three markers were significantly increased at all time-points in those who developed diabetes, with slightly lower levels of significance for HbA1c differences. Of those who had diabetes in 2000, 56% already had developed diabetes as defined by abnormal glucose levels at the first follow-up measurement in 1996-1998, and only 8 % still had normal glucose fasting and postload glucose levels. In contrast only 3 % had an HbA1c ≥ 7 %, 6 % HbA1c ≥ 6.5 % and 49 % of those with diabetes in 2000 had HbA1c < 6% at the first follow-up. At the baseline examination in 1989, 63 % of those who developed diabetes in the next 10 year already had impaired fasting glucose or impaired glucose tolerances, but only 20 % had HbA1c ≥ 6%.
Conclusion: Fasting and postload glucose levels increase more rapidly than HbA1c during the process of developing diabetes. This may have consequences for decisions on the preferred method in diagnostic testing for diabetes.

Mean (SD) of hyperglycemia markers in people with and without diabetes after 10 year

period:	1989		1996-1998		2000	
	no DM 2000	DM 2000	no DM 2000	DM 2000	no DM 2000	DM 2000
Fasting glucose (mmol/l)	5.31 (0.49)	5.87 (0.52)	5.83 (0.66)	6.92 (1.00)	5.68 (0.52)	7.34 (1.62)

Prediction of rapid and slow progression from IFG or IGT to diabetes in a high-risk screening programme. The ADDITION study, DK.
S.S. Rasmussen[1,2], T. Lauritzen[3], A. Sandbaeck[3], K. Borch-Johnsen[2];
[1]Bispebjerg Hospital, Copenhagen, [2]Steno Diabetes Center, Gentofte, [3]Department of General Practice, Institute of Public Health, Aarhus, Denmark.

Background and aims: Only few baseline risk factors predicted progression to diabetes in a group identified with impaired fasting glycaemia (IFG) and impaired glucose tolerance (IGT) in a high-risk screening programme. The aim was to see whether different predictors were associated with "rapid" and "slow" progression to diabetes in this population.
Materials and methods: Patients aged 40-69 years in general practices received a diabetes risk score questionnaire. Random blood glucose (RBG) and HbA1c were measured followed by fasting blood glucose (FBG) and 2-hour blood glucose (2hBG) after an oral glucose tolerance test (OGTT). At baseline 1821 individuals were identified with IFG or IGT (WHO 2006 definition). In 1510 individuals follow-up data are available with an OGTT performed after about 1 and 3 years. Conversion to diabetes within 0 to 1.5 years was defined as "rapid" progression; conversion within 1.6 to 3.5 years as "slow" progression. Progression rates were calculated per 100 person-years using a regression model for interval censored follow-up data. Baseline predictors for progression to diabetes for "rapid" and "slow" progression were identified by backward elimination including: age, sex, BMI, known hypertension, family history of diabetes, physical inactivity, RBG, HbA1c, FBG, 2hBG, waist, systolic BP, total cholesterol, triacylglycerol, myocardial infarction and smoking status.
Results: There were 442 diabetes cases. For the IFG and IGT groups the progression rates in the first 1.5 years were 16.0 (95% CI: 13.1-19.0) and 23.8 (20.7-26.9), and in the following 1.6 - 3.5 years the progression rates were 6.1 (4.0-8.2) and 7.2 (5.2-9.3). Baseline predictors for "rapid" progression were in the IFG group: BMI (per kg/m^2, rate ratio [RR] 1.05 [1.01-1.10]), physical inactivity (yes vs no, RR 1.99 [1.02-3.89]), FBG (per 0.5 mmol/l, RR 4.33 [2.90-6.45]) and triacylglycerol (per twofold increase, RR 2.32 [1.42-3.77]), and in the IGT group: HbA1c (per 0.5%, RR 1.35 [95% CI 1.10-1.65]), FBG (per 0.5 mmol/l, RR 1.69 [1.40-2.05]), and 2hBG (per 0.5 mmol/l, RR 1.30 [1.20-1.42]). Baseline predictors for "slow" progression were in the IFG group: HbA1c (per 0.5 %, RR 1.58 [1.09-2.29]), FBG (per 0.5 mmol/l, RR 2.01 [1.25-3.22]), systolic BP (per mmHg, RR 1.02 [1.00-1.03]) and total cholesterol (per mmol/l, RR 1.42 [1.05-1.93]), and in the IGT group: sex (female vs male, RR 0.61 [0.40-0.93]), physical inactivity (yes vs no, RR 1.93 [1.00-3.73]), FBG (per 0.5 mmol/l, RR 1.56 [1.26-1.96]) and 2hBG (per 0.5 mmol/l, RR 1.22 [1.10-1.35]).
Conclusion: The cumulative risk of diabetes in this study was high. The decline in progression rates after the first year indicates that some individuals progress more rapidly than others. It has been suggested that prediction of "rapid" versus "slow" progression to diabetes would make sense with regard to risk assessment. In the present analyses, baseline predictors differed between "rapid" versus "slow" progression, yet high levels of blood glucose were significant predictors in all situations and to some extend physical inactivity. Prediction of progression to diabetes in high-risk individuals with IFG or IGT may seem meaningless with regard to risk assessment and intervention.

Body mass index, physical inactivity and type 2 diabetes - are these associations explained by genetic selection? Results from the Swedish twin register
S. Carlsson[1], T. Andersson[1], P. Lichtenstein[2], A. Ahlbom[1];
[1]Institute of Environmental Medicine, [2]Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, Sweden.

Background and aims: Overweight and lack of physical activity are the most well-known environmental risk factors for type 2 diabetes. However, twin studies indicate that both high BMI and physical inactivity have a strong genetic component. If the same genes that are associated with type 2 diabetes also promote high BMI and inactivity, part of these associations could be due to genetic factors rather than a causal relationship. The aim of this study was to investigate to what extent genetic factors explain the association between BMI, physical inactivity and type 2 diabetes using twin data.
Materials and methods: Data are based on twins born 1926-1958 of the Swedish Twin Register who answered a postal questionnaire in 1973. Self-reported information on diabetes was collected by telephone interviews between 1998 and 2000. We used regression models to investigate the risk of type 2 diabetes associated with BMI and physical inactivity among all twins, without taking genetic factors into account and with control for genetic factors in co-twin control analyses of diabetes-discordant dizygotic (DZ) (N=480) and monozygotic (MZ) (n=253) twin pairs.
Results: Among 25,531 twins, 844 cases of type 2 diabetes were identified at follow-up (3.4%). In the cohort analysis, in which twins are analyzed as independent individuals, the odds ratio (OR) of type 2 diabetes was 1.27 (95% CI=1.24-1.29) for 1 unit increase in BMI and 1.24 (95% CI=1.07-1.44) for physical inactivity (low vs. moderate or high activity). When we compared twins with diabetes to their healthy co-twins, the OR of diabetes in DZ twins was 1.20 (95%CI=1.12-1.27) per BMI unit and 1.19 (95% CI=0.86-1.65) for physical inactivity. Corresponding analyses in MZ twins indicated that BMI was associated with an increased risk of diabetes (OR=1.26, 95% CI=1.12-1.42) but no association could be demonstrated between physical inactivity and type 2 diabetes (OR=0.83, 95% CI=0.51-1.36).
Conclusion: The results indicate that the association between BMI and type 2 diabetes is not due to genetic factors and thus supports a causal link between BMI and type 2 diabetes. However, the weak association between physical inactivity and type 2 diabetes seen in MZ twins is compatible with a contribution of genetic factors to this association.

Predicting the effects of lifestyle or pharmacological intervention on progression of type 2 diabetes: evaluation of a novel mathematical model against results of the DPP

A. De Gaetano[1,2], T. Hardy[3], E. Abu-Raddad[3], P. Palumbo[1], J. Bue-Valleskey[3], N. Porksen[3];
[1]CNR-IASI BioMatLab, UCSC, Roma, Italy, [2]Axiosis Sprl, Bousval, Belgium, [3]Lilly Research Laboratories, Indianapolis, United States.

Background and aims: Mathematical models have recently been used to evaluate the risk of development of, and the progression of, type 2 diabetes over an individual's lifetime. Models attempt to coherently integrate commonly accepted physiological mechanisms in order to predict the long-range behavior of disease processes, where long-term clinical observations may be lacking. A fundamental question, preliminary to the practical use of such models, concerns their validation against known medium-term disease progression data.
Materials and methods: We have developed a mathematical model for the long-term development of diabetes (the 'DiabProg' model). The DiabProg model mathematically represents phenomena such as progressive worsening of insulin resistance, the effects of glucose toxicity, and changes in beta-cell net replication/apoptosis rates. Parameter values for the model have been derived from a careful assessment of the literature. It is anticipated that the model can be used to test hypotheses about the natural history of the disease and about the effects of therapies. A valid disease and therapeutic model can also be used to inform clinical trial design. For example, decisions about study population, sample size, and treatment duration can be based on model simulations and predicted interactions between drug mechanisms and disease progression.
Results: In the present work, the DiabProg model has been used to simulate the course of glucose homeostasis and diabetes incidence in the Diabetes Prevention Program (DPP). A population of virtual subjects was 'selected' to resemble the DPP study population based on key entry criteria for that study. We then examined changes in glucodynamics over several years in subjects randomized to the same therapies used in the DPP (placebo, lifestyle modification, metformin, or troglitazone). The model is shown to replicate very well the results of the placebo and lifestyle arms of the DPP clinical trial, in particular reproducing closely the observed cumulative incidence of diabetes at years 1 through 4 of study, as well as the observed overall diabetes incidence while in study (simulated incidence of 11.3 cases/100 person years on Placebo and 5.1 cases/100 person years with Life Style intervention vs. observed incidences of 11.0 and 4.8, respectively) The ability of DiabProg to predict changes in insulinemia, glycemia, and diabetes incidence in the troglitazone and metformin arms of the DPP will also be presented.
Conclusion: The results obtained so far indicate that the DiabProg model, a mathematical representation of the most relevant and generally accepted mechanisms in the pathogenesis of T2DM, is capable of predicting medically important diabetes progression endpoints with good fidelity, and has a good potential to be used for in silico clinical trial evaluation and design.

Early identification of type 2 diabetes in primary care medical offices in Austria. A multicentre randomized study

F.C. Prischl[1], E. Rebhandl[2], S. Zehetmayer[3];
[1]Dept. Nephrology, Klinikum Wels-Grieskirchen, Wels, [2]Diabetes Study Group, Austrian Society of Family Medicine, Haslach, [3]Section for Medical Statistics, Medical University of Vienna, Austria.

Background and aims: As in many western countries also in Austria type 2 diabetes (DM2) is the most frequent disease to cause end stage renal disease. Prevalence of DM2 increases, thereby representing a serious problem that has to be recognized by all physicians. The early identification of patients with DM2 and initiation of adequate treatment may be crucial to public health budgets. Diabetic complications account for a high burden to both patients and reimbursement systems that pay for its management. Current guidelines recommend diagnostic tools not really feasible within the setting of a general practitioners office. A simple diagnostic parameter is desirable, independent of fasting state and performable quickly.
Materials and methods: We, therefore, have studied HbA1c as a diagnostic tool to identify patients with DM2 in 9 offices of family medicine. The gold standard for comparison was an oral glucose tolerance test (OGTT) with 75g of glucose. During 8 months 3724 patients were screened. History and/or medical records revealed known DM2 in 19.73 % and impaired glucose tolerance (IGT) in 15.81 %. Due to therapy with corticosteroids 3.2 %, and because of active infectious disease 7.16 % of patients had to be excluded. The inclusion criterion of age ≥ 40 years was fulfilled in 2805 of the screened persons. Finally, 573 agreed to participate in the study and filled in a questionnaire. Among these 231 were selected randomly to have extensive blood tests and urine analyses.
Results: Using OGTT 10 patients with de novo DM2 were identified (blood glucose at 2 hours ≥200 mg/dl. In these patients the mean HbA1c was 5.77 ± 0.64 % and differed statistically significant from study participants with normal OGTT who had a mean HbA1c of 5.07 ± 0.37 % (p=0.0001). Patients with IGT (blood glucose at 2 hours >140 and <200 mg/dl; n = 26) had a mean HbA1c of 5.49 ± 0.54 %. ROC analyses using HbA1c of 5.2% as a threshold revealed sensitivity and specificity of 0.72 each. A specificity of 100 %, i.e. having no DM2 or IGT, is given at a HbA1c value of ≤4.6 %, and a sensitivity of 100 %, i.e. manifest DM2, is given at a HbA1c value of ≥6.6 %. Univariate analyses of No-DM2 versus IGT + DM2 showed that a significant impact on diagnosis was seen of higher age (p=0.0001), higher body mass index (p=0.0133), higher systolic blood pressure (p=0.0015), higher total cholesterol (p=0.0462) and presence of proteinuria (p=0.0017). Using stepwise multivariate logistic regression analysis age (p=0.0007), body mass index (p=0.0118) and proteinuria (p=0.0365) were included in the model to significantly influence the diagnosis of No-DM2 versus IGT + DM2.
Conclusion: We conclude that measurement of HbA1c is a reliable diagnostic parameter to diagnose DM2 irrespective of the fasting state and thus day time with only one blood sample to be drawn. Our analyses show that the pretest probability to identify patients with IGT or DM2 increases with increasing age, body mass index, higher systolic blood pressure and presence of proteinuria.

Predictors of cardiometabolic control in intensified, multi-factorial treated, screen detected type 2 diabetics; results of ADDITION the Netherlands study

R. van der Lugt, M. van den Donk, K.J. Gorter, B. Sparen, G.E.H. Rutten;
Julius Center, UMC Utrecht, Netherlands.

Background and aims: To assess determinants of optimal cardiovascular control after four years of intensified multi-factorial treatment in patients with screen-detected type 2 diabetes.
Materials and methods: This study is embedded in the Dutch part of the ADDITION Study (Anglo-Danish-Dutch Study of Intensified Treatment in People with Screen-detected Diabetes in Primary Care), that studies the effects of intensified multi-factorial treatment compared with usual care on cardiovascular morbidity and mortality in screen-detected type 2 diabetes patients. Data of patients from the intensified arm of the ADDITION the Netherlands were retrieved at baseline and after four years of follow-up. The patients were treated to the following targets: 1) HbA1c% < 6.5 % mmol/L 2) cholesterol level < 3.5 mmol/L and 3) blood pressure < 120/80 mm Hg. Non-optimal cardiovascular control after four years of follow-up was defined as reaching zero or one goals. Optimal cardiovascular control was defined as reaching two or three goals. Univariate and multivariate logistic regression analyses were performed in order to assess which factors were related to cardiovascular control and to what extent.
Results: A total of 206 patients from the intensified arm were analysed. 14.1% (n=29) reached none of the targets, 48.1% (n=99) reached one target, 29.6% (n=61) reached two targets and 8.3% (n=17) reached three targets. Therefore 62.1% (n=128) had non-optimal cardiometabolic control and 37.9% (n=78) achieved optimal cardiometabolic control. On univariate analysis the following characteristics were associated with the achievement of optimal cardiometabolic control (P<0.2): alcohol use at baseline, systolic blood pressure at baseline and a decrease in BMI between baseline and four years of follow-up. On subsequent multivariate analysis only a decrease in BMI between baseline and four years of follow-up was an independent predictor for optimal cardiometabolic control (p=0.042).
Conclusion: Weight loss is an independent predictor for achieving optimal cardiometabolic control in patients with screen detected type 2 diabetes.

FINDRISC (Finnish Diabetes Risk Score): a useful tool as a predictor of both diabetes risk and cardiovascular risk in an Italian population

C. Bianchi, L. Pucci, A. Agostini, D. Lucchesi, E. Storti, E. Russo, A.G. Daniele, G. Penno, S. Del Prato, R. Miccoli;
Endocrinology and Metabolism, University of Pisa, Italy.

Background and aims: Risk scores based on phenotypic characteristics have been developed in several populations to identify individuals at risk of developing or having undiagnosed diabetes (T2D). FINDRISC is currently the best available tool for use in daily practice in Caucasian populations. FINDRISC seems also a reasonable predictor of coronary heart disease, stroke, and total mortality.
Materials and methods: FINDRISC, 75-g oral glucose load, and major cardiovascular risk factors together with the HeartScore (10-year cardiovascular mortality estimation) were assessed in 1051 Caucasian nondiabetic subjects (435 men, 41%; 616 women, 59%) attending opportunistic diabetes screening at the Regional Centre for Diabetes and Metabolic Disease in Tuscany, Italy. The study, part of a larger European project (DEPLAN) was aimed to assess: 1. distribution of main risk factors for T2D; 2. prevalence of high risk subjects; 3. the predictive power of FINDRISC for prediabetes and undiagnosed T2D; 4. relationship between FINDRISC, cardiovascular risk factors and HeartScore.
Results: Men (M) and women (W) differed by age (51±11 vs 49±12 years, p<0.0001) and smoking habits (no-/ex/current-smokers: M 36/42/22%; W 57/21/22%, p<0.0001). There was no difference for family history of diabetes (M 64%, W 70%), personal history of high glucose values (M 34%, W 28%), fruit and vegetable consumption (M 83%, W 86%), antihypertensive drug use (M 28%, WD 26%). Physical inactivity was more frequent among women (74% vs 66%). Distributions of BMI (30 kg/m2: M 23/48/29%, W 27/30/43%, p<0.0001) and waist circumference (102/88 cm: M 24/34/42%, W 8/16/76%, p<0.0001) were less favorable in W, while distribution for age strata (<45, 45-54, 55-64, ≥65 years: M 26/27/35/12%, W 37/25/27/11%, p=0.003) less favorable in M. The distribution of classes of risk for diabetes (FINDRISC: low, score <10; modest, 10-14; moderate, 15-19; high, ≥20) was superimposable in M (27/37/27/9%) and W (20/42/27/11%, X2=6.36, p=0.17). Prevalence of subjects with isolated impaired fasting glucose (IFG: M 15.2%, W 11.3%), impaired glucose tolerance (IGT±IFG: M 31.3%, W 29.0%) and undiagnosed T2D (M 17.2%, W 6.5%) was higher in men (X2=40.74, p<0.0001). The performance of FINDRISC in detecting undiagnosed T2D or T2D+IFG+IGT has been evaluated employing score ≥15 as the discriminant threshold. In the whole cohort, sensitivity, specificity and positive predictive value resulted 57%, 64%, 16% for diabetes and 52%, 77%, 72%, for diabetes+IFG+IGT; in M, 54%, 66% e 24% for T2D and 48%, 79% e 79% for T2D+IFG+IGT; in W 63%, 63%, 11% for diabetes and 56%, 76% e 67% for T2D+IFG+IGT. The increase in FINDRISC score was associated with progressive increase in systolic and diastolic BP (p<0.0001), non-HDL cholesterol (p<0.001), triglycerides (p=0.01), reduction of HDL (p<0.0001). The 10-year mortality risk for cardiovascular events (HeartScore) in subjects with IFG (1.7%), IGT (1.7%) and undiagnosed diabetes (2.4%) was higher than in subjects with normal glucose tolerance (0.7%; p<0.0001), and increasing FINDRISC score (<10: HeartScore 0.9%; 10-14: 1.0%; 15-19: 1.9%; ≥20: 2.1% (p<0.0001).
Conclusion: The FINDRISC seems to be useful to estimate future risk of diabetes and to detect undiagnosed diabetes and prediabetes in the Italian population. Furthermore, the FINDRISC can also identify individuals at high risk for cardiovascular disease and mortality.

Elevated serum levels of transforming growth factor-beta1 (TGFbeta1) precede the development of type 2 diabetes: MONICA/KORA Augsburg case-cohort study, 1984-2002

C. Herder[1], A. Zierer[2], W. Koenig[3], M. Roden[1,4], C. Meisinger[2], B. Thorand[2];
[1]Institute for Clinical Diabetology, German Diabetes Center, Düsseldorf, [2]Helmholtz Zentrum München, Neuherberg, [3]University of Ulm Medical Center, [4]Department of Medicine/Metabolic Diseases, Heinrich Heine University Düsseldorf, Germany.

Background and aims: Subclinical inflammation represents an important mechanism in the development of insulin resistance and beta-cell dysfunction, but it is unknown whether elevation of circulating anti-inflammatory immune mediators predicts a lower risk for type 2 diabetes. Therefore, the aim of this study was to assess the association between transforming growth factor-β1 (TGF-β1), a mainly immunosuppressive regulator of the immune system, with incident type 2 diabetes.
Materials and methods: We measured serum levels of TGF-β1 by ELISA in 460 individuals with and in 1474 individuals without incident type 2 diabetes during a follow-up period (± SD) of 10.9±4.7 years in a prospective case-cohort study within the population-based MONICA/KORA Augsburg cohort.
Results: In Cox proportional hazards models, elevated TGF-β1 concentrations were associated with higher risk for type 2 diabetes in the age, sex and survey-adjusted model (HR (95% CI) for increasing TGF-β1 tertiles: 1.0; 1.08 (0.83; 1.42); 1.41 (1.08-1.83); p for trend = 0.012). Adjustment for BMI, metabolic factors (systolic blood pressure, ratio of total cholesterol to HDL cholesterol, parental history of diabetes) and lifestyle factors (smoking status, alcohol consumption, physical activity) had virtually no impact on the effect size. Additional analyses included tests for interaction with age, sex and obesity. These analyses indicated that the association between high TGF-β1 levels and increased risk of type 2 diabetes may be stronger in younger participants (<55 years; p for interaction = 0.033) and in obese participants (p for interaction = 0.013), whereas no sex differences were found.
Conclusion: Elevated serum concentrations of TGF-β1 indicate an increased risk for type 2 diabetes that is independent of multiple potential confounders. This association may be caused by upregulation of TGF-β1 in response to as yet unidentified metabolic or immunological disturbances before the clinical manifestation of type 2 diabetes.

Diabetes, pre-diabetes and associated risks on Minnesota code-indicated major ECG abnormality among Chinese: a cross-sectional diabetic study in Fujian province, southeast China

G. Chen, L. Lin;
Fujian Provincial Hospital, Fujian Medical University, Fuzhou, China.

Background and aims: This study 1) investigated the incidence of diabetes mellitus (DM), impaired glucose regulation (IGR) and related metabolic disorders(overweight, obesity and hypertension) in a population 20-74 years in Fujian China and 2) explored the relationship between glucose metabolism and Minnesota code-indicated major abnormal electrocardiogram (MA-ECG).
Materials and methods: Of 3,960 people selected from urban and rural areas from July 2007 to May 2008 by multi-stage stratified sampling, 3,298 completed and 3,208 of 20-74 years old eventually analyzed (including physical measurements, blood biochemical analysis, oral glucose tolerance test and 12-lead resting ECG).
Results: According to WHO diagnostic criteria, prevalence of DM and IGR were 9.51% (male, 10.08%; female, 9.14%) and 14.40% (male, 14.48%; female, 14.35%), respectively. Fully 53.44% were newly diagnosed DM patients. Based on the 2000 China census, the age-standardized prevalence of DM was 7.19% (male, 7.74%; female, 6.61%), and 11.96 % for IGR (male, 12.35%; female, 11.56%). Age-standardized prevalence of DM and IGR in urban areas (7.74% and 12.97%, respectively) was slightly higher than in rural areas (6.67%, 10.86%) but not statistically significant. Prevalence of overweight, obesity and hypertension were 25.50%, 3.52% and 28.52%, respectively (age-sex standardized rates: 23.69%, 3.02 % and 22.45 %). After adjusting for other risk factors, DM and IGT remained independent risk factors for MA-ECG. Non-diabetic subjects with increased 30 min post glucose level showed higher risk of MA-ECG after adjusting for other factors, especially for those NGT with 30min PG≥7.8mmol/l[OR:1.371(1.055-1.780)].
Conclusion: Prevalence of DM, IGR following with other metabolic disorders has increased dramatically in the last decade in China, especially in rural areas, with many undiagnosed cases of DM. Even slightly raised glucose levels indicate early cardiovascular events.

Trajectories of HbA_{1c} prior to the diagnosis of diabetes. The Inter99 study

S. Engberg[1], A.C. Jensen[1], B. Carstensen[1], A.G. Tabák[2], C. Glümer[3], T. Jørgensen[3,4], K. Borch-Johnsen[1,5], D.R. Witte[1];
[1]Department of Epidemiology, Steno Diabetes Center, Gentofte, Denmark, [2]Department of Epidemiology and Public Health, UCL, London, United Kingdom, [3]Research Centre for Prevention and Health, Glostrup, Denmark, [4]Faculty of Health Sciences, University of Copenhagen, Denmark, [5]Faculty of Health Sciences, University of Aarhus, Denmark.

Background and aims: In view of the increasing emphasis on HbA_{1c} as a diagnostic tool for diabetes, it is important to understand the natural history of HbA_{1c} changes prior to disease onset. Our aim was to compare the trajectory of HbA_{1c} in the years prior to the diagnosis of diabetes to the trajectory for a control group free of diabetes during the study, based on repeated HbA_{1c} measurements.
Materials and methods: We studied 4,635 individuals from the population-based Inter99 study without diabetes at baseline who had at least one follow-up examination. The participants had a median of 2 HbA_{1c} measurements each (range: 2-4) giving a total of 12,833 measurement points. The study population was divided into incident diabetes cases (86% diagnosed through a 75g oral glucose tolerance test) and controls who did not develop diabetes during the observation period. We used a mixed effect model with an added spline term for incident cases.
Results: During a median observation period of 5.3 years (range: 1.0-6.3 years), 231 individuals developed diabetes. HbA_{1c} levels were 5.8% five years prior to the diagnosis/the last examination in both cases and controls. In cases, HbA_{1c} levels increased on average by 0.05% per year in the first half of the observation time. The rate of increase accelerated to an average of 0.08% per year in the second half of the observation time, reaching 6.2% at the time of diagnosis. In controls, the estimated HbA_{1c} level remained unchanged at 5.8% during the observation period.
Conclusion: We found that the level of average glycaemia, as measured by HbA_{1c}, starts to increase at least five years prior to the diagnosis of diabetes, and the rate of increase accelerates prior to diagnosis. In contrast, HbA_{1c} levels in those who did not develop diabetes remain unchanged. Our findings indicate that HbA_{1c} can be used to track pathophysiological changes that precede the diagnosis of diabetes.

Population-based screening for type 2 diabetes in Denmark, the Netherlands and the United Kingdom: uptake and prevalence in the ADDITION study

M. Van den Donk[1], A. Sandbaek[2], K. Borch-Johnsen[2], T. Lauritzen[2], R.K. Simmons[3], N.J. Wareham[3], S.J. Griffin[3], M.J. Davies[4], K. Khunti[5], G.E.H. Rutten[1];
[1]Julius Center for Health Sciences and General Practice, University Medical Center Utrecht, Netherlands, [2]General Practice, University of Aarhus, Denmark, [3]MRC Epidemiology Unit, Cambridge, United Kingdom, [4]Cardiovascular Sciences, University of Leicester, United Kingdom, [5]Health Sciences, University of Leicester, United Kingdom.

Background and aims: The Anglo-Danish-Dutch Study of Intensive Treatment in People with Screen-detected Diabetes in Primary Care (ADDITION) evaluates whether screening for undiagnosed type 2 diabetes is feasible and whether subsequent intensified treatment is beneficial. The present study describes the different screening strategies applied in ADDITION.
Materials and methods: Diabetes was defined according to WHO 1999 criteria. We describe the different strategies used to identify those at high risk of undiagnosed diabetes, the overall attendance rates (screening uptake), and the number of screen-detected type 2 diabetes patients identified in each country.
Results: In Denmark, the Danish Diabetes Risk Score was a) mailed to eligible patients aged 40-70 years, or b) completed by patients visiting their general practitioner (step 1). Those at high risk were invited to attend a screening procedure including a random blood glucose (RBG) test and HbA_{1c} test (step 2), a fasting blood glucose (FBG) test (step 3) and an oral glucose tolerance test (OGTT; step 4). In the Netherlands, the Hoorn Diabetes Risk Score was mailed to eligible patients aged 50-70 years (step 1). Eligible individuals were invited to attend a four-step procedure consisting of RGB (step 2), FBG (step 3) and OGTT (step 4), or a three-step procedure consisting of FBG (step 2) followed by OGTT (step 3). In Cambridge, routine electronic data were searched to identify individuals aged 40-70 years at high risk of undiagnosed type 2 diabetes using the Cambridge Diabetes Risk Score (step 1). Those at high risk were invited to attend a screening for which steps 2-4 were identical to those used in Denmark. In Leicester, a sample from eligible people aged 40-70 years (step 1) were invited to attend an OGGT (step 2). Numbers of target populations, invited individuals, individuals diagnosed with type 2 diabetes, and screen-detected diabetes prevalence are shown in the table. Data on the use of OGTTs in the different steps and screening strategies will be presented at the EASD conference.
Conclusion: The results suggest that population-based screening for type 2 diabetes is challenging but feasible. Although the response rates may be confounded by centre-specific covariates such as ethnicity, culture, social class, invited age groups, and different strategies, the different yields of screen-detected diabetes only range from 0.42% to 1.09%.

A school-based physical activity program increases fitness and decreases adiposity and cardiovascular risk factors in primary school children: a cluster-randomized trial

J.J. Puder[1], L. Zahner[2], C. Schindler[2], U. Meyer[2], H. Hebestreit[3], H. Brunner-La Rocca[2], W. van Mechelen[4], S. Kriemler[2];
[1]University of Lausanne, Switzerland, [2]University of Basel, Switzerland, [3]University of Würzburg, Germany, [4]VU University, Amsterdam, Netherlands.

Introduction: Childhood obesity and physical inactivity are increasing dramatically worldwide with detrimental effects on the prevalence of diabetes as well as on cardiovascular and psychological health. Schools provide an ideal setting for preventive interventions. We therefore conducted a randomised controlled trial to determine whether a school-based physical activity (PA) program during a full school-year improves physical fitness and cardiovascular risk factors in young schoolchildren.
Methods: Twenty-eight classes were randomly allocated in a single blinded manner to the intervention (16 classes, n=297) and control (12 classes,

n=205) groups. The intervention consisted of a multi-component PA intervention program including daily physical education. Primary outcomes included body fat (skinfold thickness), aerobic fitness (shuttle run test), PA (accelerometry), and quality of life (questionnaires). Secondary outcomes included a cardiovascular risk factor score including all components of the metabolic syndrome.
Results: Compared with controls, children in the intervention group showed statistically significant decreases in body mass index z-scores (adjusted difference -0.09; 95%-percent confidence interval [CI], -0.18 to -0.003), sum of four skinfolds (adjusted difference -2·10mm; 95%-CI -3·48 to -0·90), and significant improvements in aerobic fitness z-score (adjusted difference 0·22; 95%-CI, 0·01 to 0·42) and moderate-vigorous PA at school (adjusted difference 14; 95%-CI, 5 to 23). There was also a significant improvement of the cardiovascular risk score (adjusted difference -0.18; 95%-CI, -0.30 to -0.05, intervention: n=227 and control: n=103). Quality of life did not change.
Conclusion: Our findings show that a stringent school-based PA intervention is effective in improving physical fitness and in reducing cardiovascular risk factors in children.

Low serum levels of insulin-like growth factor binding protein-2 predict type 2 diabetes
A. Hilding[1], K. Brismar[1], J. Frystyk[2], A. Flyvbjerg[2], C.-G. Östenson[1];
[1]Dept. of Molecular Medicine and Surgery, The Endocrine and Diabetes Unit, Karolinska Institutet, Stockholm, Sweden, [2]Medical Department M (Diabetes and Endocrinology) and the Medical Research Laboratories, Aarhus University Hospital, Denmark.

Background and aims: Obesity is a major risk factor for type 2 diabetes (T2D). Insulin-like growth factor binding protein-2 (IGFBP-2) and adiponectin are both secreted by adipose tissue. Studies have shown that adiponectin as well as another binding protein, IGFBP-1, are inversely associated with incident T2D. The aim of the present study was to evaluate circulating levels IGFBP-2 in the prediction of T2D, and in comparison to adiponectin and IGFBP-1.
Materials and methods: Individuals with normal OGTT at baseline who developed abnormal glucose regulation at follow-up 8-10 years later (199 women and 278 men) were selected from a prospective cohort study comprising middle-aged Swedish men and women. T2D was detected in 60 women and 107 men. Age-matched controls were selected among those having normal glucose regulation at both examinations, 210 women and 290 men. Logistic regression analysis was performed, estimating odds ratio (OR) and 95% confidence interval (CI). Associations between biomarkers and T2D were evaluated and areas under receiver-operating-characteristic (AUC-ROC) curves were assessed.
Results: Levels of IGFBP-2, as well as levels of adiponectin and IGFBP-1, were at baseline significantly lower in individuals developing T2D as compared to controls. In women, the lowest quartile of IGFBP-2 conferred an OR for T2D of 18.5 (95%CI: 6.4-53.7), while the ORs for the lowest quartile of adiponectin and IGFBP-1 were 18.1 (6.7-48.9) and 16.7 (5.8-48.2), respectively. In men corresponding OR was 8.1 (4.0-16.5) for IGFBP-2, 3.6 (1.9-7.0) for adiponectin and 18.2 (8.1-40.9) for IGFBP-1. The associations remained significant also after controlling for BMI. ROC-AUC was 0.78, 0.80 and 0.79 for IGFBP-2, adiponectin and IGFBP-1 respectively, as compared to 0.80 for BMI in women. In men, corresponding ROC-AUCs were 0.71, 0.64, 0.78 and 0.70, respectively. In multivariate analysis, including IGFBP-2, adiponectin and IGFBP-1, they were all significantly and independently associated to T2D in women, whereas in men only IGFBP-1 remained significantly associated.
Conclusion: Low baseline levels of IGFBP-2 are, similar to adiponectin and IGFBP-1, associated with increased risk of incident T2D, suggesting IGFBP-2 as a marker for the development of T2D.

Plasma procalcitonin is related to obesity and obesity-related development of type 2 diabetes mellitus
A. Abbasi[1], E. Corpeleijn[1], D. Postmus[1], R.T. Gansevoort[1], P.E. de Jong[2], R.O.B. Gans[2], J. Struck[3], H.L. Hillege[2], R.P. Stolk[1], S.J.L. Bakker[2], G. Navis[2];
[1]Epidemiology, University Medical Centre Groningen, Netherlands, [2]Internal Medicine, University Medical Centre Groningen, Netherlands, [3]Research, BRAHMS AG, Hennigsdorf, Germany.

Background and aims: A cumulating body of evidences suggests that inflammation plays a role in the development of type 2 diabetes mellitus (DM2). Recent studies suggest that adipose tissue produces procalcitonin (PCT), a pro-inflammatory hormokine previously thought to be confined to sepsis and bacterial infections, under non-infectious conditions. We aimed to investigate whether plasma PCT concentration is associated with obesity and whether it predicts development of DM2 in apparently healthy non-diabetic population.
Materials and methods: Data were from the Prevention of Renal and Vascular End Stage Disease (PREVEND) study, an ongoing, community-based cohort of 8592 subjects in the Netherlands, that started in 1997. Plasma PCT was assessed in baseline samples using an ultra-sensitive immunoluminometric assay (BRAHMS PCT sensitive LIA). Subjects with DM at baseline and subjects with plasma PCT concentrations indicative of potential presence

of infectious conditions (>0.10 ng/mL) were excluded. Development of DM2 was defined according to ADA criteria after a median (interquartile range) follow-up of 4.2 (4.0- 4.5) years in 5084 eligible subjects.
Results: A total of 159 participants (3.1%) developed DM2. Subjects who developed DM2 vs. subjects who did not develop DM2 had higher baseline BMI (29.6±4.6 vs. 25.8±4.0 kg/m^2, p <0.0001) and were older (55.7±10.5 vs. 47.8±11.8 years, p <0.0001). Baseline plasma PCT was positively associated with age (r=0.25, p < 0.0001) and BMI (r=0.24, p < 0.0001). It was also higher in men than in women (0.018 [0.015-0.022] vs. 0.014 [0.012-0.017] ng/mL, p < 0.0001). In a univariate model, the odds ratio (OR) for development of DM2 was 1.68 (95%CI 1.38-2.04, p < 0.0001) per doubling of PCT. After adjustment for age and sex the OR was 1.47 (1.17-1.85, p = 0.001). Adjustment for BMI markedly attenuated the OR to 1.19 (0.93-1.53, p = 0.18).
Conclusion: In the non-infectious range (<0.10 ng/mL), PCT is related to age, BMI and sex, and predicts type 2 DM independent of age and sex. However, the predictive value of PCT disappears after adjustment for the association of PCT with BMI. Based on this finding, we hypothesize that excessive exposure to PCT is involved in the pathogenesis of obesity-related diabetogenesis.

A quantitative change in core tissue microbiome is associated with type 2 diabetes
J. Amar[1], C. Chabo[2], J. Ferrieres[1], R. Burcelin[2];
[1]INSERM U 558, [2]Institut de Médecine moléculaire, INSERM U 858, Toulouse, France.

Background and aims: Although the role of gut microbiome on weight intake has been established, the role of gut and tissue microbiome on the onset of type 2 diabetes is poorly understood. We explored in the present study the changes in intestine, blood and tissue microbiome related with the onset of diabetes.
Materials and methods: First, we assessed using DGGE analysis profile the changes in intestine, blood and mesenteric adipose tissue (MAT) microbiome in diabetic mice fed a high fat diet. Then, we explored the role of leptin and of CD14 receptor: a key receptor of innate immunity on bacterial translocation. Finally we assessed in humans the relevance of these experimental data in a cross sectional population based sample.
Results: Distinct intestinal bacterial 16s rDNA sequences determined using DGGE analysis profiles were observed in diabetic mice fed a high-fat diet when compared with mice fed a normal chow. Conversely to the large diversity observed in the intestine, in blood only a few bacterial 16s rDNA bands were found. Importantly, the blood and MAT bacterial DNA concentrations were higher in diabetic animals than in controls. Arguing in favor of an intestinal origin of the increased bacterial DNA concentration in diabetic state we showed in four week HFD fed diabetic mice that after a single oral administration of fluorescent E Coli more fluorescent bacteria were present in the intestinal mucosa and MAT. Then, we explored the role of leptin and of the lipopolysaccharide receptor CD14 pathway on bacterial translocation and its consequences on the onset of diabetes. Blood and MAT bacterial DNA concentration were significantly higher in the leptin deficient mice. This was reversed when the mutant mice were also CD14 deficient (ob/ob CD14 KO). Importantly, the glucose tolerance test was improved in CD14 KO mice and in ob/ob CD14 KO mice as compared with ob/ob mice. Then, we assessed the clinical relevance of these data. We found in a population based-sample (n=311) that bacterial 16S rDNA blood concentrations are positively and independently associated with diabetes and high fasting glucose.
Conclusion: We find that a quantitative change in tissue microbiome is associated with type 2 diabetes. This change is driven by leptin and CD14 pathways.

Short sleep duration is a potential risk factor for newly-diagnosed type 2 diabetes in Taiwanese
Y.-C. Yang[1,2], J.-S. Wu[1,2], F.-H. Lu[1,2], C.-J. Chang[1,2];
[1]Department of Family Medicine, College of Medicine, National Cheng Kung University, [2]Department of Family Medicine, National Cheng Kung University Hospital, Tainan, Taiwan.

Background and aims: Short sleep duration is independently associated with an increased risk of obesity, coronary heart disease, symptomatic diabetes and mortality risk. However, there are few studies investigate the relationship between sleep duration and newly-diagnostic diabetes/prediabetes, esp. no study from Asia. The aim of this study is to examine the potential effect of short sleep duration on the risk of newly diagnosed Type 2 Diabetes in Taiwanese.
Materials and methods: All subjects received a health examination in our hospital from 2006-2007 in Tainan, Taiwan were invited. After excluding subjects who had a history of diabetes or taking hypnotic drug, a total of 3686 subjects (62.7% men) were recruited for analysis. A 75-g OGTT was applied and diabetes/prediabetes (impaired fasting glucose and impaired glucose tolerance) were defined according to the American Diabetes Association diagnostic criteria. The number of hours of sleep was assessed through self-administered questionnaire. Subjects were classified into three groups: short sleeper (≤ 5 hours), normal sleeper (6-7 hours) and long sleeper (≥ 8 hours)
Results: Comparing to subjects with normal glucose tolerance, subjects with newly diagnosed diabetes and prediabetes were older, and had a higher percentage of obesity, family history of diabetes, cigarette smoking habit, alcohol drinking habit, but lower education levels, lower percentage of coffee drinking and regular exercise habit and shorter sleep hours. In multi-nominal regression analysis using normal sleeper as a reference, after adjusting for age, sex, education level, family history of diabetes, BMI, cigarette smoking, alcohol drinking, tea drinking, coffee drinking, regular exercise habit, the odds ratios for newly-diagnostic diabetes and prediabetes were 1.47(1.03-2.08) and 1.16(0.94-1.43) for short sleeper, respectively.
Conclusion: Short sleeper, but not long sleeper, had a higher risk of developing newly diagnosed diabetes in Taiwanese population.

The association of serum triglyceride changes over 4 years of period with type 2 diabetes risk in Korean adults
E.-S. Choi[1], E.-J. Rhee[1], S.-H. Yoo[1], W.-J. Kim[1], J.-H. Kim[2], S.-E. Park[1], C.-Y. Park[1], W.-Y. Lee[1], K.-W. Oh[1], S.-W. Park[1], S.-W. Kim[1];
[1]Endocrinology, Kangbuk Samsung Hospital, [2]Endocrinology, Hong Ik hospital, Seoul, Republic of Korea.

Background: Hypertriglyceridemia is one of the common features of Type 2 diabetes mellitus, and is caused from dyslipidemia due to insulin resistance, one of the main mechanism of the disease. We investigated the association of

the changes in triglyceride (TG) concentrations in 4 years of foll-up and type 2 diabetes in apparently healthy Korean adults.
Methods: Serum TG levels at baseline (time 1) and 4 years later (time 2) were measured in 23,147 subjects (mean age 42.5 years, males 66%) with TG<500mg/dL. Subjects with diabetes mellitus at baseline, were excluded. We separated the subjects into 3 groups according to TG concentrations at baseline and 4 years later; low, intermediate,high.
Results: After 4 year, 315 cases of diabetes occurred in 23,147 subjects. Baseline age,BMI,LDL-C, exercise and smoking status correlated positively with future development of diabetes. HDL-C levels negatively correlated with the development of diabetes. Subjects who were in the lowest tertile of TG concentration at time 1 and progressed to the hightest tertile over 4 years (low-high), exhibited a hazard ratio (HR) of 5.50 (95% CI 2.14-14.12) for diabetes risk compaired with those remaining in the lowest tertile at both time points (reference group:low-low). Whereas subjects which belong to high-high group had a HR for diabetes of 7.23 (95% CI 3.80-13.72), those whose TG level decreased to the lowest tertile(high-low & intermediate-low) did't exhibit significant risk statistically.Alterations in TG levels during 4 years of follow-up were associated with BMI,HDL-C, LDL-C and hypertension status. In multivariate model with age, BMI,HDL-C and LDL-C and hypertension in the model, TG changes and hypertension were the sigificant determenants for future diabetes risk.
Conclusion: The increased or persistently high serum TG concentrations in 4 years of period were the independent predictors for type 2 diabetes in Korean adult.

847

Association of compensatory beta cell dysfunction and obesity and plasma nonesterified fatty acid concentration in young Korean men with normal glucose tolerance

S. Chon[1], Y.-J. Lee[1], M. Choi[1], Y. Hwang[1], S. Oh[1], K. Ahn[1], H. Chung[1], J.-T. Woo[1], S.-W. Kim[1], J.W. Kim[1], Y. Kim[1], Y.-K. Choi[2];
[1]Kyung Hee University Hospital, [2]College of medicine, Pochon-cha University, Seoul, Republic of Korea.

Background and aims: Obesity is known to increase the risk of the development of type 2 diabetes mellitus(T2DM), and the prolonged elevation of nonesterified fatty acid(NEFA) is also known to be an important factor attributed to progressive β-cell dysfunction in T2DM. But association of obesity and NEFA with β-cell function in young healthy people with normal glucose tolerance(NGT) is not well elucidated as yet. This study thus compared compensatory β cell function according to obesity in Korean young men with NGT.
Materials and methods: Standard 75g OGTT was performed in 362 healthy young men. Obesity was classified based upon the Asia-Pacific obesity criteria(Normal weight:18.5≤BMI<23, Overweight:23≤BMI<25, Obese: BMI≥25). The Whole Body Insulin sensitivity Index(WBISI) and $HOMA_{IR}$, Insulinogenic Index(IGI), and Disposition Index(DI = IGIxWBISI) and NEFA were measured.
Results: NGT was 260(mean age 25.6±3.3 years). Compensatory β-cell function (DI) was higher among overweight group than in the normal group (8.86 in overweight vs 7.04 in normal, P=0.055). But in the obese group, Disposition Index was significantly lower than the overweight group (6.46 in obese vs 8.86 in overweight, P=0.045). Regression analysis between BMI and Disposition Index showed a nonlinear relationship in spite of normal glucose tolerance. NEFA concentration was higher in the obese group compared with overweight and normal group, and NEFA had a negative linear regression relationship with Disposition Index (p=0.015). Also, after multiple regression analysis, NEFA showed a negative linear relationship with Disposition Index (p=0.017). In stratified analysis for NEFA concentration, the subject with NEFA more than 400 uEq/L showed significantly lower Disposition Index than subject with NEFA less than 200 uEq/L (p=0.009). And also, normal weight subject and obese subjects with NEFA more than 400 uEq/L had a low Disposition Index (5.84 in normal weight and 5.79 in obese, respectively).
Conclusion: This study suggests that obesity is associated with the decrease of compensatory ß-cell function in Korean young men with normal glucose tolerance. In particular, regardless of general obesity, metabolic obesity, which is status with elevated NEFA, may account for compensatory ß-cell dysfunction in the early stage of the natural history of type 2 diabetes.

Effect of metabolic syndrome and altered glucose tolerance on diastolic cardiac function and intima-media thickness

C. Alagona, F. Palermo, L. Spadaro, S. Piro, S. Calanna, F. Purrello, A.M. Rabuazzo;
Dept Internal Medicine, University of Catania, Italy.

Background and aims: Metabolic syndrome (MS) and type 2 diabetes are both associated with high risk for cardiovascular diseases (CVD). However the respective role of MS and altered glucose tolerance on vascular damage is under debate. We investigated whether MS affects early markers of vascular injuries induced by altered glucose tolerance.
Materials and methods: 132 subjects, divided in two groups by the presence of MS according to ATP-III criteria, underwent to an OGTT. Intima-media thickness (IMT) was assessed by carotid ultrasound. Augmentation and Augmentation Index (Aug and Aug I), surrogate markers of arterial stiffness, and subendocardial viability ratio (SEVR), index of diastolic cardiac function, were assessed by applanation tonometry.
Results: Gender, age, BMI, waist circumference, total and LDL cholesterol were not significantly different among subjects with (n=64) or without MS (n=68). Subjects with MS had significantly higher levels of triglycerides, fasting glucose and blood pressure and lower levels of HDL-cholesterol. Maximal IMT was significantly higher in MS than in non MS group [1.35 mm (CI 1.21-1.51) vs 1.05 mm (CI 0.96-1.16), p=0.001]. Aug and Aug I were higher, but not significantly, in MS subjects (13.4±17.5 vs 8.4±5.5 mmHg, p=ns and 25±14.4 vs 24±13.3 %, p=ns, respectively). SEVR was significantly reduced in MS compared to non MS (149±26.9 vs 159.9±31.7 mmHg, p=0.03). After OGTT, the subjects were divided in normotolerants (NT) and with altered glucose tolerance (AGT, blood glucose at 120' > 140 mg/dl). IMT was similar in AGT subjects with MS [1.37 mm (CI 1.21-1.55)] and without MS [1.38 mm (CI 1.11-1.70)], p=ns. In contrast, IMT was significantly higher in NT subjects with MS [1.32 mm (CI 1.05-1.65)] as compared with NT without MS [(0.91 mm (0.8-0.98), p<0.001]. SEVR was significantly reduced in AGT patients with MS (148±28 mmHg) compared to AGT without MS (163±30 mmHg, p=0.05) and in NT with MS (148±23 mmHg) compared to NT without MS (159±32 mmHg, p<0.05). Logistic regression analysis showed that both altered glucose tolerance and MS were independently associated with high risk of increased IMT (OR=2.326, p=0.03 and OR=2.771, p=0.03, respectively).
Conclusion: Diastolic cardiac function is impaired in MS independently by the presence of altered glucose tolerance. In contrast, IMT was increased both in altered glucose tolerance and MS.

849

Skeletal muscle microvascular exchange capacity is associated with hyperglycaemia in non-diabetic subjects with central obesity

C.D.T. Byrne[1], M. Turzyniecka[1], S.H. Wild[2], A.J. Krentz[1], A.J. Chipperfield[3], J. Gamble[4], G.F. Clough[1];
[1]University of Southampton, [2]Public Health Sciences, University of Edinburgh, [3]School of Engineering, University of Southampton, [4]University of Birmingham, United Kingdom.

Background and aims: Poor glycaemic control is associated with increased risk of microvascular disease but the relationship between glycated haemoglobin levels (HbA1c) and microvascular function in skeletal muscle has not been described. We tested the association between HbA1c and a measure of microvascular exchange capacity (Kf) in skeletal muscle controlling for fatness, insulin sensitivity, physical activity and fitness in people at risk of developing type 2 diabetes.
Materials and methods: Microvascular function was measured in 28 women and 19 men (mean (SD) age 51 (9) years) with central obesity who did not have diabetes. We estimated insulin sensitivity (M/I), visceral and total fatness, fitness (VO2 max), physical activity energy expenditure (Metabolic Equivalents of TaskS (METS)), and skeletal muscle microvascular exchange capacity (Kf).
Results: In regression modelling, age, sex and fasting plasma glucose accounted for 30.5% of the variance in HbA1c (r^2=0.31, p=0.001). Adding Kf to this model explained an additional 26.5% of the variance in HbA1c (r^2=0.57, p=0.0001 and Kf was strongly and independently associated with HbA1c (standardised B coefficient -0.45 (95%CI -0.19, -0.06), p=0.001). The independent association between Kf with HbA1c was unchanged by adding M/I or visceral fat to the model and neither were independently associated with HbA1c.

Conclusion: We found a strong negative independent association between a measure of skeletal muscle microvascular exchange capacity (Kf) and HbA1c that explained almost as much of the variance in HbA1c as fasting plasma glucose. The association between Kf and HbA1c was independent of insulin sensitivity, fatness, fitness and physical activity.

Do serum potassium levels influence the metabolic effects of combined RAS blockade with hydrochlorothiazide in obese hypertensive individuals?

P.C. Deedwania[1], E. Ofili[2], J.R. Sowers[3], I. Jialal[4], B.M. Egan[5], L. Raij[6], D. Purkayastha[7], R. Samuel[7], D.H. Zappe[7];
[1]University of California at San Francisco, [2]Morehouse School of Medicine, Atlanta, [3]Univeristy of Missouri-Columbia, [4]UC Davis Medical Center, Sacramento, [5]Medical University of South Carolina, Charleston, [6]University of Miami Miller School of Medicine, Miami, [7]Novartis Pharmaceuticals Corporation, East Hanover, United States.

Background and aims: Traditionally, a reduction in serum potassium (K^+) has been implicated as the prime mechanism by which diuretic therapy increases the risk for the development of diabetes mellitus. This 16-week randomized, multi-center, study compared valsartan and hydrochlorothiazide (V/HCTZ) to amlodipine/HCTZ (A/HCTZ) on glucose metabolism in obese hypertensives. We evaluated the metabolic response in patients (pts) who had a low (≤3.9mmol/L) or normal K^+ (>3.9mmol/L) level at the end of the study in the two groups.
Materials and methods: 412 obese (BMI=35±7 kg/m^2; BW=98±23 kg), hypertensives (seated BP=159±8/94±8 mmHg) (aged 56±9 years, 66% females) entered double-blind treatment with V/HCTZ 160/12.5 mg or HCTZ 12.5 mg after a 4-week washout period. Pts were force-titrated to V/HCTZ 320/25 mg or A/HCTZ 10/25 mg, respectively. At week 16, changes were measured from baseline in fasting and 2-hour postprandial glucose and insulin after an oral glucose tolerance test.
Results: At Week 16, fasting glucose increased with A/HCTZ in both low and normal K^+ groups, with significantly greater increases vs. V/HCTZ ($p<0.05$) in the low K^+ group (Table). Significantly greater increase in postprandial glucose at 2 hours was also observed with A/HCTZ vs. V/HCTZ ($p< 0.05$) in both K^+ stratified groups.
Conclusion: The metabolic response to HCTZ was not different in patients with low K^+ compared to those pts with normal K^+. In the V/HCTZ group the addition of valsartan reduced the postprandial glucose level in the low and normal K^+ groups through a greater and earlier postprandial insulin response. Thus the mitigating effect of valsartan on HCTZ induced hyperglycemia is not influenced by serum potassium levels.

Parameter	Low K^+ (≤ 3.9mmol/L) EOS#		Normal K^+ (> 3.9mmol/L) EOS#	
	A/HCTZ	V/HCTZ	A/HCTZ	V/HCTZ
N (%)	123 (63)	92 (49)	71 (37)	96 (51)
K^+ at baseline (mmol/L)	4.22	4.12	4.44	4.36
K^+ - EOS (mmol/L)	3.55*	3.67	4.31	4.3
Fasting glucose at baseline (mmol/L)	5.51	5.45	5.49	5.45
Fasting glucose - EOS (mmol/L)	5.73*	5.39	5.68	5.52
Postprandial glucose (Δ baseline) at 2h (mmol/L)	1.1*	0.1	1.0*	0.1
Fasting insulin at baseline (pmol/L)	138.9	121.5	141.7	149.3
Fasting insulin - EOS (pmol/L)	163.2	153.5	165.3	168.8

eZscan, a new non-invasive technology, has the same sensitivity to detect abnormalities in insulin resistance subjects as the 45' OGTT glucose values

A. Ramachandran[1], A. Moses[2], C. Snehalatha[1], J. Deslypere[3];
[1]India Diabetes Foundation, Chennai, India, [2]Moses Diabetes Centre, Chennai, India, [3]SGS, Singapore.

Background and aims: The eZscan is a new patented technology which uses low level DC voltage inducing reverse iontophoresis, together with chronoamperometry to evaluate the functions of tissues in specific locations of the body. The whole test takes only 3 minutes, does not require patient preparation and does not cause inconveniences for the subjects. The aim was to determine the ability of eZscan to detect abnormalities in carbohydrate metabolism as compared to a 45 minute OGTT.
Materials and methods: A cross-sectional study was done in Chennai, India with subjects who were not known to have any abnormalities in carbohydrate metabolism. A frequent sampling OGTT with measurements of glucose and insulin levels at 10 time points was done. Testing with the eZscan was done. A reading of >40% was considered positive on the eZscan Insulin Resistance scale. The criterion was used for the cut-off values of the 45 min OGTT (8.60 mmol/l).
Results: A total of 29 subjects were assessed. Age was 41±11 yrs, BMI 28±6, M/F ratio 1, $OGTT_{45mins}$ (mmol/l) 8.65 ±2.33, and $OGTT_{2hours}$ (mmol/l) 7.21±2.22. Of the 6 subjects who were found to have abnormal $OGTT_{45mins}$ results (Fig 1 A), 4 had IGT and 2 had DM. Five of these cases tested positive with the eZscan (83% sensitivity), while one case (23 yrs old Type I DM) was not detected by the eZscan. There was a good correlation between the results of the eZscan as compared to the $OGTT_{45mins}$ (r=0.55, p=0.02) (Fig 1 A). Graphical plots of the time profile of glucose (Fig 1 B) and insulin (Fig 1 C) levels show that the eZscan measurements (NER=normal eZscan Reading and AER=abnormal eZscan Reading) correlate better with presence of insulin resistance rather than insulin deficiency (comparison of IGT45-AER and NGT-NER/AER curves).
Conclusion: The eZscan is a promising tool which is able to detect the presence of early carbohydrate metabolism dysfunctions in insulin resistance subjects.

Pioglitazone and Rosiglitazone have significantly different effects on lipid metabolism in mouse cultured liver explants

P. Degrace[1], L. Djaouti[1], T. Jourdan[1], L. Demizieux[1], M. Chevrot[1], J. Gresti[1], B. Vergès[1,2];
[1]INSERM CRI 866, [2]Service Endocrinologie-Diabétologie CHU, Dijon, France.

Background and aims: Pioglitazone (PioGTZ) and rosiglitazone (RosiGTZ) are widely used as oral antidiabetic agents for treatment of type 2 diabetes. While these medications exert similar effects on blood glucose, clinical studies indicate that PioGTZ has a more pronounced beneficial effect on lipid parameters than RosiGTZ. This prompted us to set up a study designed to test whether PioGTZ, compared to RosiGTZ, could exert direct effects on lipid liver metabolism in relation with plasma triglycerides and HDL-Cholesterol.
Materials and methods: Thin liver slices were incubated 21h either with RosiGTZ (1 µM) or PioGTZ (7.5 µM) or vehicle. Intracellular lipid content, lipid uptake and secretion and the expression of several genes involved in lipid metabolism were studied.
Results: Both glitazones slightly reduced HMG-CoA reductase mRNA levels at the same degree but only PioGTZ reduced intracellular cholesterol content, suggesting an alteration of cholesterol uptake rather than an inhibition of cholesterol biosynthesis. This concept was supported by the reduction of SR-BI expression, hepatic lipase activity and HDL-cholesterol uptake in PioGTZ-treated liver explants. Conversely, hepatic lipase mRNA levels were increased 3.5-fold. RosiGTZ induced acetyl-CoA carboxylase and fatty acid synthase gene expression and increased apoB secretion suggesting a stimulation of lipogenesis. FAT/CD36 and acyl-CoA oxidase mRNA levels were modified neither by PioGTZ nor by RosiGTZ suggesting that PPARγ and PPARα activations were not required for direct action of glitazones on liver explants. Besides, PioGTZ appeared to be a more potent activator of AMPK than RosiGTZ.
Conclusion: PioGTZ and RosiGTZ exert specific direct effects on liver independently of PPARγ or PPARα activation. RosiGTZ promotes lipogenesis and increases lipid content in hepatic cells, but PioGTZ does not. These differences could explain the significant improvement in plasma lipids observed in diabetic patients treated with PioGTZ, but not with RosiGTZ.

853

BNP elevation following 12-week pioglitazone treatment in patients with type 2 diabetes

S. Shirabe[1], K. Sasamoto[2], A. Araki[3], Y. Tamura[4], S. Yamada[5], Y. Mizuno[6], M. Takahasi[6], M. Miyao[6], T. Yanagawa[7], M. Nogawa[1], T. Yamanouchi[8];
[1]Shinkawabashi Hospital, Kanagawa, [2]Suzuki Clinic, Tokyo, [3]Tokyo Metropolitan Geriatric Medical Center, [4]Tokyo Metropolitan Geriatric Medical Center,Gerontology, [5]Kitazato Institute Hospital, Tokyo, [6]Kanto Central Hospital of the Mutual Aid Association of Public School Teachers, Tokyo, [7]Nerima General Hospital, Tokyo, [8]Teikyo University School of Medicine, Tokyo, Japan.

Background and aims: Some studies show that thiazolidinediones (TZD) and Alpha-glucosidaseinhibitors (AGI) decrease incidence of coronary artery disease among diabetic patients. The aim of this study was to see the differences in cardiac function between TZD and AGI treatment among mild type 2 diabetic patients.
Materials and methods: After obtaining informed consent, eighty-nine Japanese type 2 diabetic patients were enrolled and randomized into
the two treatment groups, TZD and AGI group.Pioglitazone was administrated in TZD group (n=50) and miglitol in AGI group (n=39) for 12 weeks. We evaluated fasting plasma glucose (FPG),1,5-anhydroglucitol (1,5AG), HbA_1C and brain natriuretic peptide (BNP),which was considered as a surrogate marker of congestive heart failure,at baseline (before administration), 4 weeks, 8 weeks and 12 week s after treating TZD or AGI.
Results: A significant improvement of 1,5AG was shown in the AGI treatment group (+5.20±3.70 µg/ml) compared with TZD group (+2.10±0.87µg/ml). HbA_1C reduced significantly at 12 weeks (-0.39±0.28%) in AGI group,whereas -0.59±0.65% in TZD group. The reduction of FPG was -10.0±21.5 mg/dl in AGI group and -25.6±36.8 mg/dl in TZD group, respectively. We observed a tendency of BNP reduction in AGI group and significantly increase in TZD group at 12 weeks (-2.76±15.0 pg/ml vs +9.15±17.5 pg/ml, two-way layout ANOVA, $p<0.05$). When we performed subanalysis in patients with BNP more than 18.5 pg/ml at baseline, 37% of patients in AGI group remained within normal range of BNP (<18.5 pg/ml) at 12 weeks,while none of TZD group showed normal BNP (Fisher analysis, $p<0.05$). In patients with BNP less than 18.5 pg/ml at baseline, 5% of AGI group showed abnormal BNP (>18.5) at 12 weeks, whereas 30% of TZD group abnormal (Fisher analysis, $p<0.05$).
Conclusion: The possibility of unfavorable BNP change should be taken into account when administrating TZD on mild type 2 diabetic patients.

854

Effect of pioglitazone and metformin fixed-dose combination on glycaemic control in untreated patients

Z. Zhao[1], R. Spanheimer[2], A. Perez[1];
[1]Takeda Global Research & Development Center, Inc., Lake Forest, [2]Takeda Pharmaceuticals North America, Inc., Deerfield, United States.

Background and aims: The fixed-dose combination (FDC) of pioglitazone (PIO) and metformin (MET) uses complementary mechanisms to improve glycemic control in type 2 diabetes mellitus (T2DM). PIO reduces insulin resistance via activation of peroxisome proliferator-activated receptor γ. Metformin improves glycemic control primarily by suppressing hepatic glucose production. This study evaluated the effects of initial therapy with FDC PIO/MET compared with the effects of each drug alone on efficacy and safety in a randomized, double-blind, parallel-group controlled trial in T2DM patients.
Materials and methods: These patients were on no treatment with antidiabetes medications for 12 weeks and had a hemoglobin A1c (A1c) ≥7.5 but ≤10. The primary endpoint was change from Baseline in A1c of PIO/MET FDC (N=201) compared with PIO (N=189) or MET (N=210) monotherapy after 24 weeks of treatment. Fasting plasma glucose (FPG) was evaluated as a secondary endpoint.
Results: A significant decrease in A1c from Baseline was observed in all 3 study groups at Week 24 ($P<0.0001$ compared with Baseline of respective group). A1c reduction was -1.83% for FDC from Baseline 8.89 vs -0.96% and -0.99% for PIO monotherapy from Baseline 8.69, and MET from Baseline 8.65, respectively, demonstrating the nearly additive effects of the FDC relative to PIO and MET alone ($P<0.0001$ compared with FDC). Results for FPG were consistent in direction and degree in each group with A1c changes. FPG reduction was -39.9 mg/dL from Baseline (177.5 mg/dL) for FDC vs -22.2 and -24.8 mg/dL for PIO (Baseline 170.8 mg/dL) and MET (Baseline 170.5 mg/dL) monotherapy, respectively ($P<0.0001$ compared with Baseline of respective group). Significant differences were also observed between FDC and each monotherapy ($P<0.002$). Endpoint responder (A1c ≤7%) rates were higher in PIO/MET FDC (63.8%) than for PIO (46.3%) and MET (38.9%) monotherapy. There were no significant differences in hypoglycemic event rate (1.0%, 0.5%, and 1.4% for FDC, PIO, MET, respectively), and total treatment-emergent adverse events were similar among all 3 study groups, with 50.7% for PIO/MET FDC and 52.1% and 53.1% for PIO and MET monotherapy, respectively.
Conclusion: PIO/MET FDC showed significantly improved glycemic control compared with monotherapy in T2DM patients as first-line therapy without an increase in hypoglycemia.

PIOace-Study: pioglitazone, but not ramipril improves thrombocyte function and reduces low grade inflammation in non-diabetic patients with increased cardiovascular risk

A. Pfützner[1], M. Hanefeld[2], L. Afzal-Dekordi[1], J. Müller[3], I. Kleine[4], W. Fuchs[4], T. Forst[1];
[1]R&D, IKFE Institute for Clinical Research and Development, Mainz, [2]Clinical Research, GWT, Dresden, [3]Acromion, Frechen, [4]Takeda Pharma, Aachen, Germany.

Background and aims: Non-diabetic patients with isolated vascular insulin resistance suffer from reduced nitric oxide production in the endothelial cells. This may lead to hypertension, impaired endothelial function and a higher tendency for thrombocyte aggregation. The aim of this analysis was to investigate the effects of pioglitazone (PIO), ramipril (RAM) or their combination (PIRA) on low grade inflammation and thrombocyte function in hypertensive patients with increased cardiovascular risk.

Materials and methods: This placebo-controlled, double-blind, multicentre, randomized, parallel study was performed with 149 non-diabetic patients (72 male, 77 female, age: 60±9 yrs., BMI: 30.4±4.7 kg/m², duration of hypertension: 9±8 yrs.). Patients were treated with 15/30 mg PIO (dose titration), 2.5/5 mg RAM or a combination thereof for 12 weeks. Efficacy parameters for this analysis were hsCRP, Plasminogen-activator-inhibitor I (PAI-I), thromboxane B2 (TXB2, degradation product of TXA2), and endothelin-1. In addition, transforming growth factor 1ß (TGF1ß, reduces inflammation and activation of macrophages) and 6-keto-prostaglandin-F1α (6K-PGF, degradation product of the vaso-dilatator prostacyclin) were determined in a subpopulation of 35 patients at a single site.
Results: A pronounced and general improvement of biomarkers indicating reductions of chronic systemic inflammation and thrombocyte activation was observed by (co)treatment with PIO only. There was a reduction in hsCRP. Baseline and endpoint values are provided in the table. RAM alone had a positive impact on the 6k-PGF values.

Baseline and endpoint values of the obseration parameters (mean±SD)

parameter	week	PIO (n=52)	RAM (n=44)	PIRA (n=53)
hsCRP [mg/l]	0	3.54±2.54	2.90±2.26	2.98±2.15
	12	2.65±2.02*	3.47±2.62	2.50±1.98*
TXB2 [ng/ml]	0	2.92±3.14	2.08±2.07	2.81±3.13
	12	2.32±2.50	2.53±2.93	2.45±2.86
PAI-I [ng/ml]	0	57.9±20.1	62.3±19.3	54.2±19.0
	12	48.0±21.6*	62.7±20.8	47.2±19.4*
TGF1ß [ng/ml]	0	15.8±5.7	12.6±3.4	12.0±3.2
	12	18.0±10.0*	12.7±4.3	12.0±2.9
6k-PGF [ng/ml]	0	2.2±1.6	1.8±1.7	1.3±1.2
	12	1.2±0.9*	3.2±3.7*	1.1±1.0

*:p<0.05 vs.baseline

Conclusion: Activation of PPARγ by pioglitazone had an anti-inflammatory and platelet aggregation inhibiting effect in a three month treatment with PIO in non-diabetic hypertensive patients as shown by a mean decrease of hs-CRP, PAI-I and the anti-inflammatory cytokine TGF1ß, and a slight non-significant decrease in TXB2 and endothelin-1. ACE inhibition by ramipril showed an increase in prostacyclin concentrations. These findings may help to understand the results from outcome trials regarding cardiovascular risk reduction performed with both drugs.

Thiazolidinediones, but not sitagliptin, exacerbate ovariectomy-induced bone loss in rats

T. Cusick[1], J. Mu[2], B. Pennypacker[1], Z. Li[2], K. Lu[2], H. Glantschnig[1], C. Johnson[2], X. Shen[2], D.B. Kimmel[1], N.A. Thornberry[2], B.B. Zhang[2];
[1]Merck Research Laboratories, West Point, [2]Metabolic Disorders, Merck Research Laboratories, Rahway, United States.

Recent reports have established that thiazolidinediones (TZDs) increase risk of bone loss and fracture in non-osteoporotic fracture sites in patients with type 2 diabetes. Sitagliptin (Sita) represents a new class oral antihyperglycemic agents and is a potent, selective and once daily inhibitor of dipeptidyl peptidase-4 (DPP-4). We compared the effects of rosiglitazone (Rosi), pioglitazone (Pio), and Sita on ovariectomy (OVX)-induced bone loss in virgin female non-diabetic Sprague-Dawley rats (group size = ~11). Rats (18 weeks old) were OVXd and immediately treated once daily by oral gavage for three months with vehicle (Veh), Sita (100 and 300 mg/kg; both dose groups achieved ≥ 80% inhibition of plasma DPP-4), Rosi (5 and 30 mg/kg), Pio (5 and 30 mg/kg), or alendronate (ALN) (0.015 mg/kg; 2x/wk, sc). A sham-operated (Sham) group was included. No significant treatment-related differences in body weight or glucose occurred. Veh rats had significantly lower bone mineral density (BMD, mg/cm²) in trabecular regions of the femur than Sham. This BMD loss was prevented by ALN. Sita-treated rats did not differ from Veh in either trabecular or cortical regions. However, Rosi and Pio exacerbated OVX-induced bone loss, and were below both Veh and Sita, particularly in cortical regions (central femur, CFBMD). The mean±SD CFBMD values were as follows: Sham: 229±14; Veh: 220±11, Rosi [5 & 30]: 213±9 and 206±9*; Pio [5 & 30]: 212±8 and 208±7*; Sita [100 & 300]: 214±8 and 222±10; ALN: 225±7; *p<0.05, vs. Veh. The negative effect of the TZDs on BMD was more marked at the central femur, a yellow marrow site, than the distal femur, a red marrow site. In contrast, Sita had no effect on any BMD endpoint. Rats treated with TZDs also gained more fat body mass during the experiment than did Veh or Sita-treated rats. These animal data reveal TZD-associated regional bone mass changes (principally in yellow marrow sites) that appear to parallel the human fracture profile (concentrated in yellow marrow sites, as in cortical foot bones) observed with TZDs in clinical studies and demonstrate potentially important differences between the bone effects of Sita and TZDs.

857

Differential action of pioglitazone and metformin on hepatic fat, substrate metabolism and perfusion in type 2 diabetic patients

L.J. Rijzewijk[1], R.W. van der Meer[2], M. Lubberink[3], H.J. Lamb[2], J.A. Romijn[4], A. de Roos[2], J.W. Twisk[5], R.J. Heine[1,6], A.A. Lammertsma[3], J.W.A. Smit[4], M. Diamant[1];
[1]Diabetescenter, VU University Medical Center, Amsterdam, Netherlands, [2]Radiology, Leiden University Medical Center, Netherlands, [3]Nuclear Medicine and PET research, VU University Medical Center, Amsterdam, Netherlands, [4]Endocrinology, Leiden University Medical Center, Netherlands, [5]Clinical Epidemiology and Biostatistics, VU University Medical Center, Amsterdam, Netherlands, [6]Eli Lilly & Company, Indianapolis, United States.

Background and aims: Hepatic steatosis is frequently found in type 2 diabetes (T2DM) and is causally linked to features of the metabolic syndrome, cardiovascular and chronic liver disease. Hepatic steatosis and insulin resistance are closely related phenomena and affect hepatic glucose production, triglyceride output and insulin clearance, but have also been implicated in the impairment of splanchnic glucose and fatty-acid metabolism and hepatic hemodynamics. Consequently, insulin sensitizing and anti-steatotic therapies may be beneficial in correcting hepatic physiology.
Materials and methods: Effects of 24 weeks of treatment with pioglitazone (30mg/day) versus metformin (2000mg/day) and matching placebo in 78 T2DM males (mean age±SE 56.5±0.6 years, BMI 28.7±0.4 kg/m2, HbA1c 7.1±.0.1%) without hepatic or cardiovascular disease on hepatic fat content were determined using proton MR-spectroscopy and positron emission tomography (PET). The following PET measurements were performed: hepatic perfusion, fatty acid and glucose uptake using [15O]H2O, [11C]palmitate under fasting conditions and [18F]-2-fluoro-2-deoxy-glucose under euglycaemic hyperinsulinaemic conditions, respectively.
Results: Seventy-one patients completed the trial and no adverse events were registered. Both pioglitazone and metformin similarly improved glycemic control (P=0.146) and whole-body insulin sensitivity (P=0.501). Pioglitazone versus metformin reduced hepatic fat content (6.9 (2.6-17.4) % to 4.1 (1.9-12.1) % versus 7.7 (3.7-23.9) to 10.7 (5.1-22.0), between-group P<0.001). Pioglitazone, but not metformin, increased insulin-mediated hepatic glucose uptake (P=0.025) and fasting liver perfusion (P=0.044) from baseline. Neither treatment affected fasting hepatic fatty-acid uptake.
Conclusion: In spite of similar effects of pioglitazone and metformin on glycemia and whole body insulin sensitivity, only pioglitazone reduced hepatic fat content in T2DM patients. This was associated with improvements in both insulin mediated hepatic glucose uptake and fasting perfusion.

Erythrocyte metformin concentrations and alteration of renal function

C. Briet[1], M. Saraval-Gross[1], L. Harry[2], J.-D. Lalau[1];
[1]Endocrinology, Diabetology and metabolism, University Hospital of Amiens, [2]Pharmacology, University Hospital of Amiens, Amiens-Salouel, France.

Background and aims: As metformin is eliminated solely by the kidney, renal impairment is a logic contraindication. It is usually recommended not to use metformin when glomerular filtration rate (GFR) is under 60 ml/min/1.73m2. However, since metformin clearance is 4 to 5 times that of creatinine, the degree of renal dysfunction associated with significant metformin accumulation is not known. From transverse data reflecting clinical practice, we therefore studied blood metformin concentrations according to renal function. We chose erythrocyte metformin concentration which is known to be a better marker of chronic accumulation than that in plasma.

Research design and methods: We studied all metformin concentrations measured in 2008. GFR was estimated with abbreviated MDRD equation (Modification of the Diet in Renal Disease). Patients were divided into five groups depending on the GFR corresponding to the stages of chronic kidney disease: GFR 0-15 (stage 5), 15-30 (stage 4), 30-60 (stage 3), 60-90 (stage 2), and >90 (stage 1).
Results: 126 subjects were studied: sex ratio H/F 83/43, mean age of 65±9, mean GFR 47.8±24.1 ml/min/1.73m2, 74.4% having a creatinine clearance < 60 ml/min/1.73m2. The following figure describes the erythrocyte metformin concentrations in the different groups (means ± SD).
Conclusion: Metformin concentrations were somewhat elevated in mild renal failure (stage 2) as compared to stage 1, while remaining within the normal range, but not further in stages 2, 3 and 4. Given that metformin dosage was reduced by half from stage 1 to stage 4, the question arises as to whether metformin administration could be safely continued in mild or moderate renal failure provided the dose is adequately adjusted to renal function.

Effect of pioglitazone on proliferation of mature adipocytes
T. Ishizuka, K. Kajita, T. Hanamoto, T. Ikeda, I. Mori, K. Fujioka, H. Okada, T. Fujikake, Y. Uno, H. Morita;
Department of General Internal Medicine, Gifu University Graduate School of Medicine, Japan.

Background and aims: Adipocyte has been believed be generated from multipotent mesenchymal stem cell via its precursor cell, preadipocyte, whereas mature adipocyte has been considered to be unable to proliferate. On the other hand, thiazolidinedione, anti-diabetic agent, increases subcutaneous fat and decrease visceral fat. However, precise mechanisms have not been fully understood. In this study, we investigate the mechanism that pioglitazone, a thiazolidinedione, increases the number of adipocytes.
Materials and methods: Male Wistar rats were treated with or without 0.005% pioglitazone containing food for 28 day. 5-Bromo-2'-Deoxyuridine (BrdU: 200 mg/kg) was intraperitoneally administered before sacrifice, and then each subcutaneous, epididymal and periintestinal fat was collected. Immunohistochemical staining of BrdU was carried out. Moreover, isolated adipocytes and stromal vascular fraction (SVF) were obtained with collagenase digestion and then DNA was extracted. Equal amount of each DNA was absorbed in nitrocellulose sheet to quantify the BrdU uptake using anti-BrdU antibody. On the other hand, fully differentiated 3T3-L1 adipocytes were incubated with 10μM pioglitazone (Pio), populations in the G0/G1, S and G2/M phases were analyzed with flow cytometry. Morphological analysis and gene expression in these cells were also examined.
Results: Immunohistochemical study using anti-BrdU antibody revealed that BrdU positive cells were identified both in SVF and mature adipocuyes. BrdU uptake into adipocyte DNA was markedly prominent in periintestinal fat compared with subcutaneous fat. Pioglitazone treatment increased BrdU uptake in subcutaneous fats, whereas it decreased in epididymal and periintestinal fats. Cell cycle analysis using flow cytometry revealed that incubation with Pio increased G2/M phase. In contrast, treatment with aphidicolin (Aphi), a DNA polymerase inhibitor, increased the population of G0/G1. 3T3-L1 adipocytes treated with Aphi contained large shape and abundant fat droplets. It also decreased PPARγ and adiponectin mRNA levels and increased MCP-1 and IL-6 mRNA levels.
Conclusion: These results suggest that pioglitazone decreases visceral fat accumulation and increases subcutaneous fat via differentiation of cell cycle, and that finally, mature adipocyte has the ability to proliferate.

Validation of treatments for metformin monotherapy failure in type 2 diabetic patients. A meta-analysis of randomized clinical trials
C. Lamanna, E. Mannucci, N. Marchionni, M. Monami;
Critical Care Medicine and Surgery, Unit of Gerontology - University of Florence, Italy.

Background and aims: The choice of drugs to add to metformin in type 2 diabetic patients failing to monotherapy should be formulated on the basis of randomized clinical trials (RCTs) performed in this specific population. This meta-analysis compares different agents as add-on treatments for metformin monotherapy failure.
Materials and methods: Placebo-controlled and active comparator RCTs with a duration ≥24 weeks were retrieved from Medline (any date up to November 1st,2008) and included in this meta-analysis. Data for analysis were extracted independently by two observers and potential contrasts were resolved by a senior investigator.
Results: Twelve placebo-controlled and 16 active comparator studies were included. In placebo-controlled studies, thiazolidinediones, alpha-glucosidase inhibitors, DPP-4 inhibitors, and GLP-1 agonists produced a significant reduction of HbA1c at 24 weeks (OR, 95%CI: -0.3[-0.5;-0.2], -0.7[-0.9;-0.5], -0.8[-1.0;-0.6], and -0.7[-0.9;-0.5]%, respectively). In comparisons with thiazolidinediones (N= 6), insulin secretagogues produced a similar reduction of HbA1c (-0.1[-0.2;0.1]%, p=0.33) and increase of BMI (OR: -0.32[-1.18;0.53]Kg/m^2; p=0.46), with a higher hypoglycaemic risk.
Conclusion: Available data are not sufficient to establish the superiority of any class of hypoglycaemic drugs in the treatment of metformin monotherapy failure. Further evidence should be collected in order to formulate a well-validated algorithm.

861

Long-term effects of metformin on endothelial function and inflammation in type 2 diabetes treated with insulin: a randomized, placebo-controlled trial
A. Kooy[1,2], J. de Jager[1,3], M.G. Wulffelé[1], C.G. Schalkwijk[4], P. Lehert[5], D. Bets[6], A.J.M. Donker[7], C.D.A. Stehouwer[4];
[1]Bethesda Diabetes Research Center, Hoogeveen, Netherlands, [2]Department of Internal Medicine, Bethesda General Hospital, Hoogeveen, Netherlands, [3]Department of Ophthalmology, Academic Medical Center, Amsterdam, Netherlands, [4]Department of Internal Medicine, Maastricht University Medical Center, Netherlands, [5]Department of Statistics, Faculty of Economics, Mons, Belgium, [6]Clinical Research and Development, E. Merck, Amsterdam, Netherlands, [7]Department of Internal Medicine, Free University Medical Center, Amsterdam, Netherlands.

Background and aims: Three out of 4 patients with type 2 diabetes will die from cardiovascular disease. Treatment with metformin reduces rates of cardiovascular morbidity and mortality in type 2 diabetes, possibly through improvements of endothelial function and/or reduction of low-grade inflammation. Therefore, we studied the effects of metformin on markers of endothelial function and low-grade inflammation in patients with type 2 diabetes.
Materials and methods: 390 insulin-treated patients with type 2 were randomly allocated to either placebo or metformin. 277 subjects (= 72%) completed the trial. During a follow-up of 4.3 years, plasma samples were taken to measure markers of endothelial function (urinary albumin excretion, plasma levels of vWf, sVCAM-1, sE-selectin, t-PA and PAI-1) and markers of low-grade inflammation (plasma levels of CRP and sICAM-1). For each subject, each variable was expressed as standard deviation of difference from the population mean. Mean standard deviation scores (= z-scores) were calculated as:
• endothelial dysfunction z-score = {urinary albumin excretion + vWf + sVCAM-1 + sE-selectin + t-PA + PAI-1}/6
• inflammation z-score = {CRP + sICAM-1}/2.
Results: Metformin treatment versus placebo was associated with a decrease in vWf of 11% (-16 to -6; p<0.001); a decrease in sVCAM-1 of 5% (-8 to -3; p<0.001); a decrease in t-PA of 15% (-20 to -9; p<0.001); a decrease in PAI-1 of 21% (-31 to -9; p=0.001); and a decrease in the endothelial dysfunction z-score of 7% (-10 to -4; p<0.001). Changes in urinary albumin excretion and sE-selectin were not significant. Metformin treatment versus placebo was associated with a decrease in CRP of 17% (-31 to -1; p=0.036); a decrease in

sICAM-1 of -5% (-8 to -2; p=0.004); and a decrease in the inflammation z-score of -5% (-10 to +1; p=0.074).
Conclusion: This is the first long-term randomized controlled trial showing that metformin treatment is associated with decreases in the plasma concentrations of vWf, sVCAM-1, t-PA, PAI-1, CRP and sICAM-1, reflecting an improvement of endothelial regulation of haemostasis (vWf), of leukocyte adhesion (sVCAM-1), and of fibrinolysis (t-PA and PAI-1), as well as a reduction of low-grade inflammation.

The effects of thiazolidinediones on mitochondrial function are related to their lipophilicity
Z. Szöcs[1], B. Brunmair[1], D. Dey[2], C. Bolten[3], K. Stadlbauer[1], C. Fürnsinn[1];
[1]Department of Medicine III, Division of Endocrinology & Metabolism, Medical University of Vienna, Austria, [2]Drug Discovery and New Pharmaceutical Development, Bexel Pharmaceuticals, Union City, United States, [3]Exploratory Immunology, Pfizer Research, St. Louis, United States.

Background and aims: We have previously shown that thiazolidinediones (TZDs) inhibit cell respiration by a direct effect on isolated skeletal muscle. This mechanism is independent of peroxisome proliferator-activated receptor-γ (PPAR-γ) and accounts for many actions of TZDs seen *in vitro.* Modulation of cell respiration could also contribute to insulin sensitization and/or adverse effects of TZDs *in vivo.* In the present study, we compared the efficacies of various TZDs as inhibitors of cell respiration and noted an association with their respective lipophilic/hydrophilic properties.
Materials and methods: Isolated strips of soleus muscle from Sprague-Dawley rats were exposed to 10 µmol/l of different TZDs for 24 h. To quantify effects on cell respiration, rates of CO_2 production from palmitate and anaerobic glycolysis (lacate release) were measured during the last hour. ATP and PCr content were determined at the end of the experiment.
Results: 10 µmol/l of almost every tested TZD impaired cell respiration as indicated by reduced CO_2 production and increased lactate release (see table). Only BLX-1002, the most hydrophilic compound, failed to affect respiration at 10 µmol/l, but it also exerted inhibitory action at higher concentrations (% decrease in CO_2 production: 30 µmol/l BLX-1002, -17±12%, ns; 100 µmol/l BLX-1002, -24±8%, p<0.02%; increase in lactate release: 30 µmol/l BLX-1002, +24±11%, p<0.05; 100 µmol/l BLX-1002, +62±14%, p<0.001). Decreased respiration was accompanied by proportionate reductions in the ATP/PCr ratios (% decrease: pioglitazone, -27±6%, p<0.001; rosiglitazone, -16±6%, p<0.05; BLX-1002, -2±6%, ns). The results also revealed that compounds with higher clogP values, indicative of low hydrophilicity and high lipophilicity, were more efficient inhibitors of cell respiration (see table). This conclusion is corroborated by significant correlations between clogP values and relative changes in CO_2 production (r=-0.79; p<0.04) and lactate release (r=0.83; p<0.025).
Conclusion: Direct PPAR-γ-independent impairment of cell respiration is a group effect of TZDs which is more pronounced for more lipophilic compounds. This hints at a possible location of the responsible molecular target in a lipophilic compartment like, e.g., the mitochondrial membrane. TZD-induced impairment of cell respiration can reduce the cellular energy state. Since regular or chronic cellular energy loss seems to be a trigger for insulin sensitization, this mechanism could contribute to the antidiabetic effects of TZDs and explain why some TZDs are effective insulin sensitizers despite carrying relatively weak PPAR-γ-agonistic activities.

Relationship between salt-sensitivity and thiazolidinedione-induced oedema
A. Nakamura[1], T. Osonoi[2], Y. Terauchi[1];
[1]Department of Endocrinology and Metabolism, Graduate School of Medicine, Yokohama City University, [2]Naka Kinen Clinic, Japan.

Background and aims: Although there is growing recognition that fluid retention and edema are common adverse effects with thiazolidinediones (TZDs), the underlying mechanisms remain unclear. To unravel the relationship between salt-sensitivity and TZD-induced edema, we analyzed sodium excretion before and after administration of TZDs.
Materials and methods: After obtaining the approval of the institutional review board and written informed consent from the patients, we analyzed sodium excretion before and after 8 weeks of administration of pioglitazone to female subjects with type 2 diabetes who did not have heart failure, severe liver or renal dysfunction, or a severe infection. Before administration they were asked to measure daily salt excretion by using a salt monitoring system to measure sodium in overnight urine and to measure their blood pressure daily for 21 days, and when a significant correlation was found between salt excretion and blood pressure (correlation coefficient >0.4, p<0.05), the patient was classified as salt-sensitive.
Results: The data of the 26 patients who satisfactorily completed the follow-up examinations were included in the analysis. Six patients (23.1%) were classified into a salt-sensitive group and 20 patients (76.9%) into a non-salt-sensitive group. There were no differences between the characteristics of the two groups in age, body mass index, HbA1c, blood pressure, or salt excretion before administration of pioglitazone. After 8 weeks of pioglitazone administration, 5 patients (19.2% of the total) had developed edema**,** and, surprisingly, all 5 subjects were salt-insensitive. We therefore divided the subjects into three groups based on the presence of salt-sensitivity and edema, a group that was not salt-sensitive and had edema (group A), a group that was salt-sensitive and did not have edema (group B), and a group that was not salt-sensitive and did not have edema (group C). Salt excretion after administration of pioglitazone was significantly lower than before pioglitazone administration in groups A and B, but not group C (A: -1.16 ± 0.96 gram; p<0.05, B: -0.99 ± 0.72 gram; p<0.05, C: 0.03 ± 0.96 gram), and the hematocrit was significantly lower after administration in group B, but not in group A or C (A: 0.02 ± 0.68 %, B: -1.47 ± 0.55 %; p<0.05, C: -0.21 ± 0.38 %). There were no differences in body weight gain among the three groups.
Conclusion: In subjects who developed edema (group A), TZD caused fluid retention because of sodium reabsorption, and increased fluid in the intravascular space would be mobilized into the extravascular space because of a vascular mechanism, and edema was observed as a result. By contrast, in the subjects classified as salt-sensitive (group B), TZD caused fluid retention, but the increased fluid was retained in the intravascular space, explaining why they did not develop edema. In subjects who were salt-insensitive and did not who develop edema (group C), TZD did not cause fluid retention, therefore hematocrit did not decrease. Thus, TZD-induced edema would be caused not only by fluid retention but also by vascular hyperpermeability. In addition, TZD-induced edema was unrelated to body weight gain. Because administration of a TZD caused fluid retention in the subjects who developed TZD-induced edema as well as in the salt-sensitive subjects, assessment of sodium excretion and salt-sensitivity may be useful in preventing the adverse effects of TZDs.

Prospective study on the mechanism of weight gain by pioglitazone in Japanese patients with type 2 diabetes (Manda Study 1). Pioglitazone induced the distribution shift in abdominal adipocytes from visceral fat to subcutaneous fat
S. Taneda, K. Misawa, H. Nakayama, K. Tsuchida, H. Bando, N. Manda, Y. Akimoto, T. Nawa, S. Hagiwara;
Diabetes Center, Manda Memorial Hospital, Sapporo, Japan.

Background and aims: We investigated the mechanism of pioglitazone-induced weight gain by comparing a change in the abdominal distribution between visceral fat and subcutaneous fat.
Materials and methods: Sixty patients with type 2 diabetes without insulin treatment, in addition to the current medication, were taken 15 or 30 mg of pioglitazone throughout the period of this study and their abdominal visceral and subcutaneous fat tissues were compared by computed tomography before

and after 24 weeks of intervention. Several clinical parameters such as glycemic control, congestive and metabolic state were also compared.
Results: Seven patients were withdrawn because of extensive edema (3), muscle pain (1), general fatigue (1), poor compliance (2). The remaining 53 patients were subjected to analysis. HbA1c was improved in 42 patients, indicating that most patients were responder to pioglitazone in terms of glycemic control. Body weight was increased in 40 patients. Whereas a decrease in visceral adipose tissue occurred insignificantly, subcutaneous adipose tissue and V/S ratio were significantly increased. Human atrial natriuretic peptide (ANP) was increased more significantly than brain natriuretic peptide (BNP). The increase in these peptides occurred even in patients without edema, suggesting some mechanism other than pioglitazone-related congestive factor. An increase in adiponectine and the concurrent decrease in high sensitive reactive protein (hCRP) were also seen after pioglitazone treatment. These anti-atherosclerotic beneficial effects were seen even in the patients with weight gain or non-responders with regard to glycemic control.
Conclusion: This study clearly demonstrated the pioglitazone-induced distribution shift in abdominal adipocytes from visceral adipose tissue to subcutaneous adipose tissue. This mechanism may explain pioglitazone-induced beneficial effects both on glucose metabolism in type 2 diabetes and atherosclerotic processes.

The effect of rosiglitazone on fasting plasma retinol binding protein-4(RBP-4) in patients with type 2 diabetes
L. Renzhe[1,2], L. Li[1,2], G. Yang[3], K. Li[3], Y. Liu[3];
[1]The Key Laboratory of Laboratory Medical Diagnostics in the Ministry of Education, [2]Department of Clinical Biochemistry, [3]Department of Endocrinology, the Second Affiliated Hospital, Chongqing Medical University, China.

Background and aims: Retinol binding protein 4 (RBP4) has recently reported as an adipocyte-secreted molecule that is highly expressed in the adipose tissue of the adipocyte-specific glucose transporter 4 (GLUT4) knockout mice. Transgenic expression or injection of recombinant RBP4 induces insulin resistance, whereas experimentally decreased RBP4 levels ameliorates insulin resistance. In mice lacking GLUT4, rosiglitazone is found to decrease circulating RBP4 levels and to reduce insulin resistance. But the role of RBP4 in human is controversial. In this study, we have investigated whether or not plasma RBP4 levels were different in patients with newly diagnosed type 2 diabetes mellitus and type 2 diabetes mellitus patients with poor glycemic control, and also observed the effects of rosiglitazone treatment on RBP-4 levels in poor glycemic control patients with type 2 diabetes.
Materials and methods: 34 type 2 diabetic patients with poor glycemic control on top of ongoing metformin therapy (11 men, 23 women, age 57±1.5 years, T2DM group) and 30 sex-, age-and BMI-matched patients with newly diagnosed T2DM (12 men, 18 women, age 59±1.2 years, nT2DM group) participated the study. T2DM group patients were treated with rosiglitazone (4mg/d) for 12 weeks. The body composition and metabolic parameters were assesses. Blood samples were drawn after an overnight fast and plasma insulin, FFA, HbA1c, TG, TC, LDL-C, HDL-C were measured. Plasma RBP-4 levels were measured with a radioimmunoassay. The homeostasis model assessment of insulin resistance (HOMAIR) and the homeostasis model assessment of β-cell insulin secretion (HOMAIS) were calculated. The relationship between plasma RBP-4 levels and metabolic parameters was also analyzed.
Results: The plasma RBP-4 levels were found to be markedly increased in type 2 diabetes mellitus patients with poor glycemic control compared with newly diagnosed T2DM patients (P<0.01). The addition of rosiglitazone markedly decreased free fatty acids, HbA1c, fasting plasma glucose, 2h postprandial blood glucose, HOMAIR (all P <0.01) and fasting insulin (P<0.05), but there were no statistical differences in plasma RBP-4 levels between pre- and post-treatment with rosiglitazone (P>0.05). Plasma RBP-4 levels were correlated with sex (r=0.292, P=0.019), triglyceride (r=0.287, P=0.021) and 2h plasma insulin after glucose overload (2hPIns) (r=0.329, P=0.008). Multiple regression analysis showed that only 2hPIns was independent related factor with plasma RBP-4 levels.
Conclusion: The present work indicates that short-term treatment with rosiglitazone can not reduce the fasting plasma RBP-4 levels in patients with type 2 diabetes. Plasma RBP-4 is unlikely to be a useful biomarker of insulin resistance and type 2 diabetes.

Effect of pioglitazone and metformin fixed-dose combination on hs-CRP and adiponectin in patients with type 2 diabetes
A. Perez[1], Z. Zhao[1], R. Spanheimer[2];
[1]Clinical Sciences, Takeda Global Research & Development Center, Inc., Lake Forest, [2]Medical and Scientific Affairs, Takeda Pharmaceuticals North America, Inc, Deerfield, United States.

Background and aims: Patients with type 2 diabetes mellitus (T2DM) have evidence of low-grade systemic inflammation, with increased levels of pro-inflammatory markers such as high sensitive C-reactive protein (hs-CRP) and decreased levels of anti-inflammatory molecule adiponectin, which may contribute to their risk for cardiovascular disease. Pioglitazone (PIO) is proven to improve blood sugar control through increased insulin sensitivity.
Materials and methods: This 24-week, double-blind clinical trial compared efficacy and safety of fixed-dose combination (FDC) of pioglitazone/metformin (PIO/MET) (N=201) with PIO (N=189) or MET (N=210) monotherapy in T2DM patients who had stable HbA1c for 3 months and were on no antidiabetes medications. The primary endpoint was change from Baseline in hemoglobin A1c (A1c). Changes in adiponectin and hs-CRP were evaluated as secondary endpoints.
Results: Median Baseline hs-CRP ranged from 2.89 to 3.55 mg/L across groups and decreased by Week 8 through Week 24 in all treatment groups (Figure top). Statistically significant decreases were observed in both PIO/MET FDC and PIO relative to MET at Weeks 8, 16, and 20. A significant increase in adiponectin was observed in both PIO/MET FDC and PIO relative to MET at Weeks 16, 20, and 24 (Figure bottom), with the increase due to PIO alone. Change in levels of adiponectin at the final week in PIO/MET FDC and PIO were 7.8 and 9.2 mcg/mL, in contrast with MET treatment (-0.3 mcg/mL). Analysis of treatment-emergent adverse events showed similar results among all 3 study groups, with 50.7% for PIO/MET FDC and 52.1% and 53.1% for PIO and MET monotherapy, respectively.
Conclusion: PIO/MET FDC improved levels of both hs-CRP and adiponectin, with the major contribution due to PIO.

Aleglitazar, a balanced dual PPAR α/γ activator, exerts potent insulin-sensitizing and glucose-lowering effects in a nonhuman primate model of metabolic syndrome and type 2 diabetes mellitus

B.C. Hansen[1], X.T. Tigno[2], A. Benardeau[3], M. Meyer[3], E. Sebokova[3], J. Mizrahi[3];
[1]Department of Internal Medicine, Pediatrics, and Physiology, University of South Florida, Tampa, United States, [2]Department of Molecular Pharmacology and Physiology, University of South Florida, Tampa, United States, [3]F. Hoffmann-La Roche AG, Basel, Switzerland.

Background and aims: An ideal peroxisome proliferator activated receptor (PPAR) agonist should provide a therapeutic dose that can achieve good glycemic control and an improved lipid profile while being well tolerated. Aleglitazar is a balanced agonist for PPARα and PPARγ, designed to optimize glycemic and lipid benefits, and minimize PPAR-related adverse effects, weight gain and peripheral edema. Competitive binding assays indicate that aleglitazar is a potent high affinity ligand for both PPARα and PPARγ, which may distinguish it from previously investigated dual PPAR agonists. Under natural and optimal "healthy" diet conditions nonhuman primates frequently develop the metabolic syndrome, and progress to prediabetes and overt type 2 diabetes mellitus (T2DM) with features identical to those of human obesity-associated middle-age onset T2DM. The aim of this study was to evaluate the effect of aleglitazar on insulin sensitivity and glucose homeostasis in obese, prediabetic rhesus monkeys.
Materials and methods: Following pharmacokinetic assessments with a single dose of 0.1 mg/kg aleglitazar and a 4-day washout, 6 insulin-resistant obese monkeys entered a 28-day baseline phase during which they received vehicle (piece of fruit). The monkeys were then treated with aleglitazar (0.03 mg/kg/day) given orally for 42 days. Glucose, HbA1c, insulin, adiponectin (a surrogate marker of insulin sensitivity), triglycerides in circulation, and serum chemistry were measured prior to and at the end of the study.
Results: During euglycemic hyperinsulinemic clamp after insulin-stimulating conditions, glucose infusion rate increased by 60% from a mean of 7.8 mg/fat free mass/min at basal/vehicle conditions to 12.5 mg/fat free mass/min following administration of aleglitazar 0.03 mg/kg/day (p=0.001). This significant improvement in insulin sensitivity was in accordance with an increase in plasma adiponectin levels (from 12.8 to 33.2 μg/mL; p=0.003) and reductions in fasting plasma glucose and fasting insulin. Fasting plasma glucose was reduced by 17% in the whole group from 86.3 to 71.8 mg/dL (p=0.119), and by 30% in a hyperglycemic subgroup (n=3; from 102 to 71.5 mg/dL). Normoglycemia in rhesus monkeys is 65-75 mg/dL following an overnight fast. Fasting insulin was reduced by 61% from 146 to 56.4 μU/mL (p=0.036). HbA1c was also reduced by 13% from 6.7% to 5.8% (p=0.078). In addition, fasting triglyceride levels in circulation decreased by 88% from 392.7 to 48.1 mg/dL (p=0.099). Interestingly, body weight was significantly reduced from 20.5 to 19.5 kg (mean weight loss 4.8%; p=0.040). Biochemistry and hematology profiles showed no concerns about safety, and there were no signs of peripheral edema.
Conclusion: In prediabetic, minimally hyperglycemic monkeys, the balanced dual PPARα/γ agonist aleglitazar mitigated the metabolic imbalance, in particular substantive and significant improvement in insulin sensitivity and reductions in fasting plasma glucose and HbA1c. Given the close accordance between this model and the diabetic state in humans, these data indicate that aleglitazar may have an important role in the reduction of glycemic and cardiovascular risk factors in humans.

WISP2, a novel wnt-related adipokine, is a PPARgamma antagonist and promotes inflammation

S. Hedjazifar, A. Hammarstedt, L. Jenndahl, S. Gogg, U. Smith;
Department of Molecular and Clinical Medicine, The Lundberg laboratory for diabetes research, Göteborg, Sweden.

Background and aims: Our recent gene expression analysis showed that the expression of the wnt-related molecule, WISP-2, is upregulated in the adipose tissue in obesity characterized by enlarged fat cells. Furthermore, WISP-2 expression correlated with different markers of inflammation and markers of macrophage infiltration. WISP-2 is a secreted protein and, hence, may exert autocrine, paracrine and possibly endocrine actions. Therefore, the purpose of this study was to characterize the possible role of this protein in pathogenesis of adipose tissue inflammation.
Materials and methods: Several cell types including 3T3 L1 preadipocytes, THP-1 cells (a human monocyte cell line), HUVECs (a human umbilical vein endothelial cell line), primary human macrophages and primary human preadipocytes were served as model systems for our investigation. To study the function of WISP-2, we used recombinant WISP-2 protein, and DNA constructs for overexpression or knockdown of the WISP-2 gene. The gene expression was analyzed with real-time RT-PCR (TaqMan). The secretion of cytokines were measured by multiplex electrochemiluminescence using the Meso Scale Discovery technology. Western blot analysis, immunoprecipitations and confocal image analysis are the other methods used in this study.
Results: Interestingly, our *in vitro* studies have shown that WISP-2 is secreted from preadipocytes and has pro-mitogenic, pro-inflammatory and anti-adipogenic properties in these cells consistent with its PPARgamma-inhibitory effect. Remarkably, we have found that conditional shRNA-mediated knockdown of WISP-2 gene in 3T3 L1 preadipocytes induces spontaneous adipocyte differentiation and the induction of several adipogenic markers like aP2, adiponectin and GLUT-4. The pro-inflammatory effect of WISP-2 in preadipocytes also raised the question whether this protein affects macrophage recruitment to the adipose tissue. WISP-2 increased THP-1 cell proliferation as well as their binding to HUVECs. WISP-2 also induced proliferation and secretion of inflammatory cytokines in fully differentiated human primary macrophages. Furthermore, exposure to WISP-2 antagonized the action of rosiglitazone, a PPARγ ligand, and primed human macrophages into the M1 phenotype with marked pro-inflammatory properties.
Conclusion: The wnt-related protein WISP-2 is a novel adipokine which is overexpressed in obesity and has profound effects on preadipocyte differentiation and inflammation. WISP-2 may play an important role for the adipose tissue dysfunction seen in obesity characterized by insulin resistance and inflammation.

DSP-7238, a novel dipeptidyl peptidase (DPP) IV inhibitor, has a superior selectivity and longer duration of action compared with other DPP IV inhibitors

Y. Furuta, M. Horiguchi, E. Sugaru, Y. Masui, M. Sakai, T. Kawamura, M. Ono, J. Deguchi, J. Shimakura, H. Tashibu, H. Nakahira, T. Nakagawa, M. Taiji;
Drug Research Division, Dainippon Sumitomo Pharma Co., Ltd., Osaka, Japan.

Background and aims: DSP-7238 is a novel non-cyanopyrrolidine dipeptidyl peptidase (DPP) IV inhibitor currently under clinical development for the treatment of type 2 diabetes. The aims of studies were to investigate DSP-7238 on the enzyme inhibition profiles *in vitro* and to evaluate efficacy on glucose tolerance in Zucker fatty (ZF) rats, pharmacokinetic (PK) and pharmacodynamic (PD) properties in comparison with other DPP IV inhibitors. Moreover, excretion of DSP-7238 was investigated in rats and monkeys.
Materials and methods: The inhibitory potency and property was evaluated using plasma and recombinant enzyme including DPP IV, DPP II, DPP8, DPP9 and fibroblast activation protein (FAP) α with fluorogenic substrates. Substrate selectivity of each DPP IV inhibitor was evaluated by mass spectrometer with the changes in molecular weight of peptide substrates by the release of the N-terminal dipeptides. To examine the PK/PD profile, plasma concentration of compound and plasma DPP IV activity was measured for up to 24 hr after single oral administration of each DPP IV inhibitor. Radio activity was measured in urine and feces after oral administration of [^{14}C] DSP-7238 in rats and monkeys to asses the excretion profile.
Results: DSP-7238 and Sitagliptin (Sita) both competitively inhibited recombinant human DPP IV (rhDPP IV) *in vitro* with Ki of 0.60 and 2.1 nM, respectively. Neither vildagliptin (Vilda, Ki, 2.9 nM) nor saxagliptin (Saxa, 0.59 nM) exhibited competitive inhibition of rhDPP IV. DSP-7238 did not inhibit DPP IV-related enzymes including DPP8, DPP9, DPP II and FAPα (IC50, >50 μM for all enzymes), whereas Vilda and Saxa showed inhibitory potential on DPP8 and DPP9 (respective IC_{50} for DPP8 and DPP9, 1.2 and 0.062 μM for Vilda, 0.16 and 0.053 μM for Saxa). Inhibition of GLP-1 degradation by DSP-7238 was apparently more potent than that of IP-10 or SDF-1α degradation. In contrast, Vilda and Saxa showed comparable inhibition for all substrates tested. Following OGTT in ZF rats, DSP-7238 decreased AUC of blood glucose concentration in dose dependent manner with ED_{50} of 0.089 mg/kg, as well as Sita (0.326 mg/kg) and Vilda (0.172 mg/kg). Inhibition of plasma DPP IV activity was demonstrated with a lower dose of a DSP-7238 single administration at 1 mg/kg, compared with Sita and Vilda (10 and 30 mg/kg, respectively) to produce 80% inhibition over 8 hr. In cynomolgus monkeys, a single oral administration of DSP-7238 exhibited more prolonged plasma DPP IV inhibition and sustained PK profile compared with Sita. Following an oral administration of [^{14}C] DSP-7238, the cumulative urinary excretion of unchanged DSP-7238 up to 48 hr postdose was approximately 5% in rats and monkeys. As a primary elimination pathway is not associated with renal excretions, it is possible that a dose adjustment for the renal insufficiency is not required for DSP-7238, as cautioned for Sita.
Conclusion: These data suggest that DSP-7238 is a selective and long-lasting DPP IV inhibitor without potential concerns on adverse reactions caused by inhibitions of DPP8/9 or chemokine degradation. DSP-7238 can be used as once-daily doses for type 2 diabetes including patients with renal insufficiency.

Silibinin fully reverses insulin resistance in high fructose fed-rats through a possible inhibition of glucose-6-phosphatase and pyruvate kinase metabolic pathways

C. Sanchez-Martin[1], M.N. Sanz[1], D. Detaille[1], F. Gomez-Peralta[2], J.M. Recio-Cordova[2], G. R-Villanueva[1], J.M. Gonzalez-Buitrago[3], M.Y. El-Mir[1];
[1]Department of Physiology and Pharmacology, University of Salamanca, [2]Endocrinology Unit, University Hospital of Salamanca, [3]Research Unit, University Hospital of Salamanca, Spain.

Background and aims: Fructose-enriched diet causes insulin resistance (IR) and disturbances in glucose metabolism in Wistar rats. The natural antioxidant silibinin (SB) has recently displayed important properties to be used in the treatment of type 2 diabetes. Previous studies *in vitro* of our group have shown that SB inhibits hepatic gluconeogenesis and glycolysis in perifused rat hepatocytes by an inhibition of both glucose-6-phosphatase and pyruvate kinase enzymes. The aim of this study was to explore the capacity *in vivo* of silibinin to reverse the alterations of glucose metabolism related to IR induced in high fructose-fed rats, as well as the underlying mechanisms.
Materials and methods: Male Wistar rats were divided into two batches. One batch received a standard diet, and the other received a fructose-enriched diet. After 4 weeks, each batch of rats was subdivided into two groups. One group received SB (50 mg/kg/day, i.p. injection) for additional two weeks, while the other received SB vehicle. Hepatocytes were isolated from starved rats according to the method of Berry and Friend. They were perifused at 37°C with Krebs-bicarbonate-calcium saturated with O_2/CO_2, then titrated with increasing substrate concentrations of dihydroxyacetone (DHA). We measured glucose, pyruvate and lactate concentrations in the cellular perifusate. Dihydroxyacetone phosphate (DHAP), glucose-6-phosphate (G6P), fructose-6-phosphate (F6P), 3-phosphoglycerate (3PG) and phosphoenolpyruvate (PEP) concentrations were measured fluorimetrically in the cellular fraction.
Results: In perifused hepatocytes, fructose diet increased both gluconeogenesis ($J_{Glucose}$) and glycolysis (J_{L+P}) as compared with control, by 25% and 22% respectively (DHA 2.4 mM, $p<0.001$). Administration of SB fully reversed these metabolic alterations in fructose fed rats to normal values (DHA 2.4 mM, $p<0.001$). Also, fructose-enriched diet changed the relationship between $J_{Glucose}$ and DHAP, G6P or F6P as compared with control. Dietary treatment

increased DHAP, F6P and G6P concentrations at each steady state, giving a double relationship between $J_{Glucose}$ and DHAP, G6P and F6P. SB reversed this effect and normalized the relationship between $J_{Glucose}$ and DHAP, G6P or F6P. On the other hand, fructose-treated rats showed an increase of PEP concentration, leading to a double relationship between J_{L+P} and DHAP or PEP compared with control rats. SB also prevented this alteration.
Conclusion: SB reverses metabolic alterations proper to insulin resistance in rats by a possible inhibition of glucose-6-phosphatase and pyruvate kinase enzymes. We suggest that SB could be beneficial as complementary therapy for the treatment of type 2 diabetes.

871

Impact of INT131, a selective PPARγ modulator (SPPARM), on glycaemic control in patients with type 2 diabetes in a 24 week phase 2b Study (INT131-007)

A.M. DePaoli[1], R.R. Henry[2], F.L. Dunn[3], P.C. Pakele[1], C.S. Mantzoros[4], L.S. Higgins[1];
[1]InteKrin Therapeutics, Los Altos, [2]University of California San Diego, San Diego, [3]University of Texas Sounthwestern, Dallas, [4]Harvard University, Boston, United States.

Background and aims: Insulin resistance is a key etiologic factor in Type 2 Diabetes Mellitus (T2DM). INT131 is a novel, potent, non-TZD selective PPARγ modulator (SPARRM) designed to improve insulin sensitivity and glucose metabolism while minimizing the typical side effects of the full PPARγ agonists: excessive weight gain, fluid retention, and CHF. In rodent models of T2DM, INT131 demonstrated similar insulin sensitizing and glucose lowering activity as full agonist TZDs with little or no side effects. Further, INT131 demonstrated no significant weight gain, edema, cardiac hypertrophy, or adipocyte replacement of bone marrow in 6 month safety studies in rodent and monkey. A 4 week phase 2a study of INT131 in patients with T2DM on no medications for their diabetes has previously demonstrated potent insulin sensitizing activity and glucose lowering with 1 and 10 mg INT131 QD. The magnitude of glucose lowering of 1 mg INT131 in that study was consistent with modeled glucose lowering of 45 mg QD pioglitazone, but without significant TZD side effects. Based on these data, a 24 week head-to-head dose-finding clinical study of INT131 compared to 45 mg pioglitazone and placebo was carried out.
Materials and methods: INT131-007 is a 24 week double blind, placebo and active controlled phase 2b study with either INT131 (0.5. 1, 2, or 3 mg QD), pioglitazone 45 mg QD, or placebo in patients with inadequately controlled T2DM (HbA1c 7.5-10.0) on a stable dose of sulfonylurea with or without metformin. Enrollment across the US and Mexico of 372 patients was completed on March 10, 2009. Patients underwent 2 screening visits separated by 1 week, followed by a 1 week lead-in period with home glucose monitoring. A glucose rescue policy focusing on FPG and HbA1c was monitored throughout the 24 week study.
Results: Key baseline characteristics (± SD) for the INT131-007 study patients include: age 55.9 ± 9.5 yrs, duration of diabetes 8.4 ± 6.1 yrs, 47% women, BMI 32.0 ± 5.5, FPG 9.59 ± 2.30 mmol/l (172.6 ± 41.4 mg/dl), and HbA1c 8.32 ± 0.72%. The objective of the study is to assess change from baseline in glycemic control (FPG and HbA1c) after 24 weeks of INT131 (0.5. 1, 2, and 3 mg QD), or full dose (45mg QD) pioglitazone or placebo.
Conclusion: Available data support the potential of INT131 to function as a SPPARM to provide potent insulin sensitization and glucose reduction in patients with poorly controlled T2DM separate from the undue effects of full-agonist TZDs such as weight gain and fluid retention. The design of the trial, baseline demographics, adverse events, and key efficacy assessments will be presented.

872

ARRY-403, a glucokinase activator with potent glucose-dependent anti-hyperglycaemic activity in animal models of type 2 diabetes mellitus

R.J. Hinklin, T.D. Aicher, S.A. Boyd, K.R. Condroski, W.E. DeWolf, J.B. Fell, J. Fischer, P.A. Lee, M. McVean, N.A. Neitzel, A. Singh, F.X. Sullivan, W. Voegtli, E.M. Wallace, L.M. Williams;
Array BioPharma, Boulder, United States.

Background and aims: Glucokinase (GK) is the rate-limiting, glucose-sensing enzyme in several key tissues involved in glucose homeostasis. GK stimulates insulin release in pancreas in a glucose-dependent manner, regulates glucose utilization and production in hepatocytes. We sought to utilize structure-based drug design to identify a potent, efficacious and safe GKA, and to further characterize that molecule.
Materials and methods: ARRY-403 was tested in a variety of *in vitro* assays (EC_{50}, $S_{0.5}$, predicted metabolism, permeability, physiochemical determinations, broad selectivity panels for kinases, receptors, ion channels) and orally in normal and diabetic animal models (C57Bl/6J, *ob/ob*, ZDF and NONcNZO10/LtJ) as monotherapy and in combination with standard of care therapies. Nonfasted glucose, and $AUC_{glucose}$ in OGTT studies, were monitored.
Results: Through iterative optimization, we identified ARRY-403 for advanced preclinical evaluation. ARRY-403 potently activates human GK *in vitro* (EC_{50} = 79 nM at 5 mM glucose), with an $S_{0.5}$ = 0.93 mM glucose (ARRY-403 at 5 μM) and V_{max} = 134% compared to the no activator control. It possesses good *in vitro* properties (aqueous solubility, cell permeability, low potential for drug-drug interactions, low predicted hepatic clearance), and selectivity against broad panels of receptors and enzymes. PK analyses (1 mg/kg IV and 10 mg/kg PO) showed low IV clearance and high oral exposure in a number of species. ARRY-403 elicited glucose-dependent glucose-lowering activity in an acute OGTT study in C57Bl/6J mice (dosed 3, 10, and 30 mg/kg, with AUC reductions of 15, 32, and 37% respectively, vs. 10% for sitagliptin dosed 30 mg/kg PO), with no safety issues. In a 28-day study in *ob/ob* mice, dose-dependent glucose lowering in an OGTT was demonstrated (reductions of 30, 49, and 62% compared to vehicle at 3, 10 and 30 mg/kg, respectively, on day 28). ARRY-403 treatment resulted in fasted and nonfasted blood glucose levels comparable to those of normal mice. A 14 day study in NONcNZO10/LtJ mice dosed at 10 mg/kg resulted in a 56% AUC decrease from control and was as efficacious as metformin (100 mg/kg) or sitagliptin (30 mg/kg). Combination therapy of ARRY-403 with metformin, sitagliptin or pioglitazone in diabetic high fat-fed ZDF female rats resulted in greater efficacy than the comparator compounds alone (fasting, non-fasting, and postprandial blood glucose endpoints).
Conclusion: Based on these data, ARRY-403 shows significant promise as a therapeutic agent for Type 2 diabetes, and has advanced into Phase 1 clinical testing.

873

BI 10773, a novel and selective SGLT2 inhibitor, lowers blood glucose and improves glycaemic control in diabetic rodent models

P. Eickelmann[1], R. Grempler[1], L. Thomas[1], M. Eckhardt[2], F. Himmelsbach[2], A. Sauer[3], M. Mark[1];
[1]Cardio-Metabolic Diseases Research, [2]Chemical Research, [3]Drug Metabolism and Pharmacokinetics, Boehringer Ingelheim Pharma GmbH & Co KG, Biberach, Germany.

Background and aims: BI 10773 is a novel potent and selective inhibitor of sodium-dependent glucose cotransporter 2 (SGLT2). SGLT2 inhibitors are a new and promising class of oral antidiabetic agents, which increase urinary glucose excretion. BI 10773 is currently under clinical development for the treatment of type 2 diabetes. Here, we show the *in vitro* potency and selectivity of BI 10773 together with the *in vivo* efficacy in comparison to remogliflozin etabonate, another SGLT2 inhibitor from a different structural class being in clinical development by GSK.
Materials and methods: described under results.
Results: BI 10773 has high *in vitro* potency for inhibiting human SGLT2 (IC_{50} 3.1±0.7 nM). The selectivity of BI 10773 for SGLT2 over SGLT1, SGLT4 and SGLT5 is >2500-fold, >3500-fold and >250-fold, respectively, whereas remogliflozin is less potent (IC_{50} 12±4 nM) and less selective (SGLT1 (>650-fold), SGLT4 (>125-fold) and SGLT5 (>40-fold)). Both compounds induced urinary glucose excretion (UGE) and reduced blood glucose in *db/db* mice and ZDF rats. While a single oral dose of 1 mg/kg of each compound led to a similar increase of UGE within the first three hours post application in both animal models, the UGE achieved with BI 10773 over 24 hours was significantly higher than that achieved with remogliflozin etabonate (*db/db* mice 24 h UGE: BI 10773: 17.7 mmol glucose/ kg body weight vs. remogliflozin etabonate: 9.2 mmol glucose/ kg body weight), due to a longer duration of action of BI 10773. Furthermore, blood glucose was lowered in *db/db* mice and ZDF rats after single oral dosing of BI 10773 for more than 7 h. In ZDF rats, blood glucose 7 h post dose was still significantly lowered by 36% with 3 mg/kg BI 10773, while remogliflozin etabonate at the same dose was ineffective 7 h after administration. In an OGTT in *db/db* mice, performed with 1 mg/kg of both compounds, remogliflozin etabonate did not reduce glucose excursion. In contrast, BI 10773 reduced glucose AUC by 35%. Multiple once daily oral dosing of ZDF rats with BI 10773 achieved a reduction of blood

glucose under fed and fasting conditions. After 5 weeks of treatment, HbA1c was also decreased vs. vehicle treated animals by 1.5% and 2.2% with 1 mg/kg and 3 mg/kg BI 10773, respectively. Thus, the glucose lowering achieved with the SGLT2 inhibitor BI 10773 after single dosing is reflected in an improved glycemic control after multiple dosing.
Conclusion: In conclusion, our data show that our SGLT2 inhibitor BI 10773 has a favourable potency and selectivity profile. In comparison to remogliflozin etabonate, BI 10773 has a longer duration of action in rodents *in vivo*, which most likely reflects a superior pharmacokinetic profile. Our preclinical data show that BI 10773 is a promising drug candidate for the treatment of type 2 diabetes.

874

The fructose-1,6-bisphosphatase inhibitor CS-917 generates an N-acetylated metabolite that alters cellular lactate homeostasis
P.D. van Poelje, S.C. Potter, J. Hou, J.W. Stebbins, S.J. Hecker, M.D. Erion;
Metabasis Therapeutics Inc., San Diego, United States.

Background and aims: CS-917 is the 1st member of a new class of antidiabetic agents that reduces the overproduction of glucose by gluconeogenesis, an abnormality which is commonly observed in patients with T2DM. Following its absorption, CS-917 undergoes conversion to MB05032, a potent inhibitor of fructose-1,6-bisphosphatase (FBPase; IC_{50} 16 nM). In humans, MB05032 is extensively metabolized by N-acetylase-1 to MB05099, a long-lived metabolite ($t_{1/2}$ ~30 h) that is not an inhibitor of FBPase. MB05099 achieves high, variable plasma levels (~3-20 uM) that exceed those of MB05032 at steady state. To better understand the clinical profile of patients treated with CS-917, the metabolic effects of MB05032 and MB05099 were studied in cells. Metformin, a mild mitochondrial respiratory chain inhibitor that is known to affect cellular lactate homeostasis, was included in the assays.
Materials and methods: Cultures of human hepatocytes, rat hepatocytes, and HepG2 cells were exposed to MB05032 or MB05099 (3-100 μM), a prodrug of MB05099 (10-100 μM), and/or metformin (30-3000 μM) for up to 24 h. LAC, pyruvate (PYR), and LAC dehydrogenase (LDH) were measured by enzyme-coupled spectrophotometric assays. Redox potential and ATP content of cells were analyzed by a dye (MTT) reduction assay and a luciferase-based assay, respectively. Respiration was measured with a Clark-type O_2 electrode. Drug uptake was assessed by HPLC.
Results: Exposure of rat hepatocytes to MB05099 or metformin, but not MB05032, increased the intracellular LAC/PYR ratio in a concentration-dependent manner by up to 2-fold, indicating a reduction in oxidative capacity. Further, overnight exposure of human hepatocytes to MB05099 resulted in a concentration-dependent increase in the LAC/PYR ratio (up to 3-fold) as well as an increase in extracellular LAC levels (from 0.5 up to 1.0 mM). Treatment with MB05032 also increased lactate release by human hepatocytes, but had no effect on the LAC/PYR ratio. MB05099, which is an anion at physiological pH, did not penetrate HepG2 cells and was pharmacologically inactive in this cultured cell line. However, 6- to 24-h exposure to the prodrug of MB05099 (30 μM) yielded high intracellular levels of MB05099 and resulted in reduced ATP content (55%), lowered redox potential (74%), and increased LAC levels in the growth medium (by ~100 μM). At 100 μM, the prodrug increased LDH release and reduced LAC release by HepG2 cells, which likely reflects loss of function. Consistent with the effects on cellular redox state, MB05099 reduced glucose-driven respiration by rat hepatocytes and succinate-driven respiration by rat liver mitochondria with ~12% and ~15% inhibition, respectively, at 30 μM.
Conclusion: The current studies suggest CS-917 treatment may not only reduce lactate clearance by inhibition of gluconeogenesis (via generation of the active metabolite, MB05032), but also by reducing mitochondrial oxidation (via generation of the N-acetylated metabolite, MB05099). The mitochondrial effects may predispose patients to disturbances of acid-base balance as has been observed with other drugs that affect mitochondrial function. The current findings at clinically relevant concentrations of MB05099 may have safety implications for 2nd generation FBPase inhibitor MB07803, which generates an N-acetylated metabolite with similar properties to MB05099 but at >100-fold reduced levels in humans relative to CS-917.

875

Pronounced and rapid glucose lowering with the fructose-1,6-bisphosphatase (FBPase) inhibitor MB07803 in poorly controlled type 2 diabetes mellitus (T2DM) subjects
B. Gumbiner, S. Watling, M. Milad, T. Stern, A. Longcore, T. Le, A. Fereshetian, H. Foyt, M. Erion;
Metabasis Therapeutics, Inc., La Jolla, United States.

Background and aims: MB07803, an oral prodrug of a potent, selective FBPase inhibitor, was studied in T2DM subjects to determine safety, tolerability, pharmacokinetics, and glucose lowering response.
Methods: A randomized, double-blind, placebo (PBO)-controlled, ascending dose (50, 200, 400 mg Q12h), 14-day domiciled study was conducted in 42 noninsulin-requiring T2DM subjects (mean baseline FPG=221 mg/dL, HbA1c=8.8%; T2DM duration=7.l years) after a 2-week wash off of antidiabetic therapy. Change from baseline in glycemic endpoints was analyzed.
Results: Plasma MB07803 active metabolite exposure, assessed by AUC(0-tau)ss, increased proportionally from 50 to 200 mg Q12h dose, but not from 200 to 400 mg Q12h dose. Dose-related glucose lowering was observed.

Change from Baseline - Glucose Parameter

MB07803 Treatment Group (Q12h)	PBO-Adjusted LSM	PBO-Adjusted 95% CI	P-value vs. Placebo
FPG AUC 0-6 hrs (mg•hr/dL) Day 13/14			
50 mg	-143	-351.7, 65.7	0.1726
200 mg	-349.4	-557.1, -141.8	0.0017
400 mg	-439.4	-656, -222.8	0.0002
FPG (mg/dL) Day 15			
50 mg	-16.4	-63, 30.1	0.4791
200 mg	-58.2	-104, -12.4	0.0142
400 mg	-55.1	-104.6, -5.6	0.0302
24h Glucose AUC (mg•hr/dL) Day 13/14			
50 mg	-763.5	-1503.5, -23.5	0.0435
200 mg	-1185.7	-1926.8, -444.6	0.0026
400 mg	-1507.9	-2278.5, -737.3	0.0004
24h Weighted Mean Glucose (mg/dL) Day 13/14			
50 mg	-30.4	-61.3, 0.5	0.0537
200 mg	-49.8	-80.7, -19	0.0024
400 mg	-62.2	-94.3, -30.1	0.0004

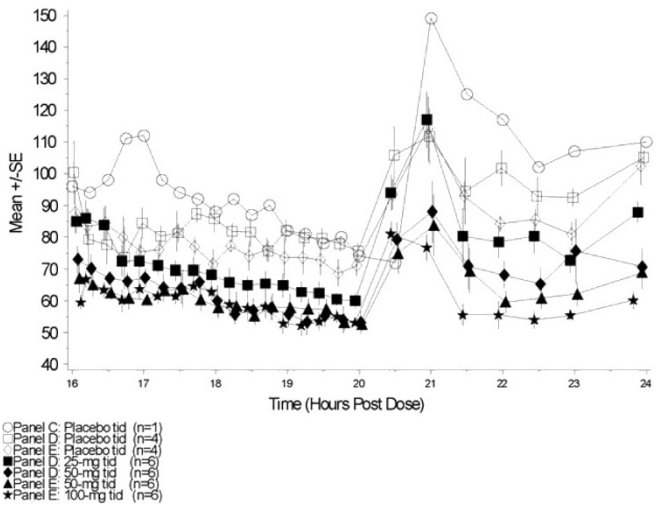
In the 400 mg group, 5 of 10 subjects manifested vomiting. Of these 5 subjects, 4 were down-dosed to 200 mg Q12h and completed the trial. In the 200 mg group, 4 subjects experienced at least 1 episode of mild nausea but all completed the study. In the 50 mg group, no patient experienced nausea or vomiting and the group's overall adverse event profile was similar to PBO. Neither lactic acidosis nor consecutive lactate > 4.5 mM occurred. Nonconsecutive, asymptomatic lactate > 4.5 mM occurred in 1 subject in association with glucose <60 mg/dL and symptoms of hypoglycemia during the last 2h of an 18h fast. 4 other subjects had asymptomatic glucose <60 mg/dL while fasting at least 12h.
Conclusion: MB07803 was safe at all doses and well-tolerated to a dose of 200 mg Q12h. All doses demonstrated statistically and clinically significant effects on 24h glycemic measures. The 200 and 400 mg doses also showed statistically and clinically significant reductions on FPG AUC 0-6 hrs and FPG. These results suggest that FBPase inhibitors are capable of pronounced and rapid reduction of fasting and postprandial glycemia in patients with well-established and poorly-controlled T2DM.

876

The glucokinase (GK) activator mk-0599 lowers plasma glucose concentrations in healthy non-diabetic subjects

E.M. Migoya[1], J. Miller[1], T. Laetham[1], L. Maganti[2], K. Gottesdeiner[1], J.A. Wagner[1];
[1]Department of Clinical Pharmacology, [2]Department of Clinical Biostatistics, Merck, Rahway, United States.

Background and aims: Glucokinase (GK) activators are expected to be associated with a dual mechanism for lowering blood glucose concentrations - enhancement of glucose uptake, metabolism and glycogen synthesis in the liver and potentiation of glucose-dependent insulin secretion from pancreatic β-cells. MK-0599 is an orally active, potent and specific allosteric activator of GK. A double-blind, randomized, placebo-controlled, sequential panel study was conducted to assess the safety, tolerability, pharmacokinetics and glucose-lowering effects of MK-0599 in healthy non-diabetic adult male subjects.
Materials and methods: Separate study panels consisting of 8 subjects each were randomized to receive MK-0599 or matching placebo in a 3:1 ratio, respectively, in up to 5 treatment periods. Study drug was administered after an overnight fast and blood samples for determination of plasma glucose concentrations (glucometer measurements) were taken as frequently as every 5 to 15 minutes for up to 24 hours postdose. Single 0.4- to 160-mg doses and 13- to 100-mg doses given 3 times daily (TID) were administered to study participants.
Results: The pharmacokinetics of MK-0599 were less than dose-proportional after administration of single doses up to 160 mg, whereas the AUC was increased by approximately 3-fold with TID administration compared with a similar dosage given as a single administration. After administration of 50 mg TID or more, clinically significant (compared with placebo) glucose-lowering effects were observed after administration of the last dose (16 to 24 hours after administration of Dose #1; figure).
Conclusion: Hence, GK activators lower plasma glucose concentrations in healthy non-diabetic (normoglycemic) subjects and are considered to be a potentially novel treatment for patients with type 2 diabetes.



877

Colesevelam improves insulin resistance in diet-induced obesity (F-DIO) rat models by increasing release of GLP-1

G. Xu[1], Q. Shang[1], M. Saumoy[1], J.J. Holst[2], G. Salen[3];
[1]Medicine, University of Medicine & Dentistry of New Jersey, East Orange, United States, [2]Department of Biomedical Sciences, University of Copenhagen, Denmark, [3]Medicine, University of Medicine & Dentistry of New Jersey, Newark, United States.

Background and aims: Bile acid sequestrants have been shown to improve glycemic control in humans. This study investigated how colesevelam improves glucose levels.
Materials and methods: Studies were carried out in an insulin-resistant rat model: the high energy chow-fed F-DIO rat. There were four treatment groups: F-DIO rats fed regular chow (control); high energy chow-fed F-DIO alone (HE); high energy chow containing 2% colesevelam (WC); and high energy chow containing 0.02% SC-435 (SC). Colesevelam HCl is a bile acid sequestrant and SC-435 is an ASBT inhibitor which also reduces intestinal bile acid absorption. After 4 and 8 wks of treatment, oral glucose tolerance test (OGTT) was performed and GLP-1 levels were assessed.
Results: In both the HE and SC groups, plasma glucose and insulin levels remained significantly higher ($p<0.001$) than the baseline throughout the OGTT. In contrast, insulin in the WC group reached peak level in 15-30 min, and then returned to baseline within 30-60 min. This pattern was similar to that in the control group. In the WC group, plasma glucose returned to baseline during OGTT and was lower ($p<0.001$) than that in the HE (-23%) or SC (-18%) at the 120 min timepoint. After 4 wks treatment, fasting total GLP-1 values in the WC group were 60% and 65% higher than in the HE and SC groups, respectively. After 8 wks of treatment, the fasting GLP-1 levels were 100% higher ($p<0.05$) with the WC compared to the HE group. During OGTT, the plasma GLP-1 levels in WC treated rats was 100% ($p<0.05$), 61% ($p<0.05$), and 97% higher ($p<0.001$) than the HE group at 15, 30 and 60 min, respectively. Concentrations of the potent FXR ligands (chenodeoxycholic, deoxycholic and cholic acids) in the portal blood did not decrease in the HE group but were significantly reduced in both WC (71%, $p<0.001$) and SC (77%, $p<0.001$) groups.
Conclusion: The results from this study suggest that colesevelam reduces plasma glucose levels by improving both insulin-resistance and first phase insulin release in an insulin-resistant rat model. This effect is not due to reduced bile acid flux returned to the liver but may be related to increased fasting and post-prandial GLP-1 secretion. Further studies are warranted to explore how colesevelam results in increased GLP-1 release.

Postprandial glucagon levels associates with glycaemic control in Danish children and adolescents with new onset type 1 diabetes

M.-L.C.M. Andersen[1], J. Svensson[1], S. Pörksen[1], J.V. Jørgensen[2], J. Thomsen[3], T. Hertel[4], P. Hougaard[5], L. Hansen[1], H.B. Mortensen[1]; [1]Pediatrics, Glostrup University Hospital, [2]Skejby Hospital, Århus, [3]Pediatrics, Kolding Hospital, [4]Odense Hospital, [5]University of Southern Denmark, Odense, Denmark.

Background and aims: Glucagon release is often perturbed in patients with type 1 and type 2 diabetes leading to a state of hyperglucagonaemia. The role of hyperglucagonemia on metabolic control is not fully understood. The aim of this study is to investigate the role of glucagon on the glycaemic control as assessed by stimulated blood glucose, HbA1c and insulindose adjusted HbA1c (IDDA1c) during the first 12 months after diagnosis.
Materials and methods: 130 children and adolescents aged < 17 years from 4 centres in Denmark with newly diagnosed type 1 diabetes were followed for 12 months. A 90-minutes Boost-test (mixed meal) was carried out in each patient at 1, 3, 6, and 12 months after diagnosis to characterise the residual beta cell function (stimulated C-peptide, and rise in post-prandial blood glucose) and stimulated glucagon. Postprandial glucagon, HbA1c and insulin dose adjusted HbA1c were analysed using linear regression in a compound symmetric model over 1, 3, 6 and 12 months. Postprandial blood glucose, gender, age and stimulated C-peptide were included as explanatory factors. The measure for IDAA1c was developed by a multiple regression analysis, where a negative association between stimulated C-peptide (dependent variable) and HbA1c (-0.21, regression coefficient, p<0.001) and insulin dose (U/kg bodyweight) (-0.94, regression coefficient, p<0.001) (independent variables) and was calculated as: IDAA1c = actual HbA1c (%) + [4 x insulin dose (U/Kg/24h)]
Results: The postprandial levels of glucagon were highly associated with the rise in postprandial glucose (p=0,0001). We also observed a significant positive association between stimulated glucagon levels and both HbA1c (est.: 0.18, p=0.02) and IDAA1c (est.: 0.24 and p=0.03). In a separate model we found no significant relationship of glucagon and postprandial blood glucose at 1 month when residual beta cell function is present. However, by 3, 6 and 12 months after diagnosis the rise in postprandial glucose was associated with increased glucagon levels (est.: 2.55, 2.78, 3.08 with corresponding p-values: <0.0001, 0.0191, 0.0016). In the same model postprandial glucagon levels associated significantly with HbA1c at 3 and 6 months (p=0.05 and <0.0001) after diagnosis and with IDDA1c only at 6 months (0.0052).
Conclusion: The rise in blood glucose associates with postprandial glucagon. Our data also suggest that postprandial glucagon associates with worsening of the glycaemic control. Therapies aimed at blocking the effects of glucagon might improve glycaemic control.

879

Diabetic ketoacidosis at diagnosis in Austrian children - a population based analysis 1989-2008

E. Schober[1], T. Waldhoer[2], B. Rami[1], Austrian Diabetes Incidence Study Group;
[1]Department of Paediatrics, [2]Department of Epidemiology, Center of Public Health, Medical University Vienna, Austria.

Background and aims: Diabetic ketoacidosis (DKA) is a life-threatening complication of type 1 diabetes present in 15- 67 % of children at the time of diagnosis. Studies on the prevalence vary widely but most of them are hospital based. The aim of our study was to analyze the prevalence of onset ketoacidosis during a period of 20 years (1989-2008) population based in the whole of Austria.
Materials and methods: In a prospective population based incidence study all newly diagnosed patients with diabetes ≤15 years of age were registered by the Austrian Diabetes Incidence Study Group. The completeness of the case-ascertainment was >93 % with a uniform completeness of ascertainment over time. The registered data set comprises blood glucose, pH, ketonuria and clinical symptoms of DKA at manifestation. DKA was defined as pH < 7.3 and severe DKA as pH < 7.1. Time trends were estimated by linear regression models
Results: During the study period 3331 children < 15 years of age (1797 boys and 1534 girls) were registered with type 1 diabetes in the incidence data base. 1238 (37.2%) presented with DKA, 855 (25.7%) had a mild DKA (pH 7.1) and 383 (11.5%) a severe form (pH<7.1), one patient died at onset. The frequency of DKA was negatively associated with age at onset. In children <2 years the frequency of DKA was 60 % (p < 0.0001). In this age group a trend to more DKA episodes in girls was observed (70% vs. 54%, p <0.05). Mean blood glucose at diagnosis was significantly higher in children presenting with DKA (563.8 ±226.4 mg/dl vs. 443.4 ± 183.3 mg/dl, p < 0.0001). Despite a significant increase in diabetes incidence in Austria during the observation period from 8.4/100 000 to 18.5/100 000 (p < 0.0001) no significant change in the prevalence of DKA at manifestation could be observed within the same time period.
Conclusion: The overall frequency of DKA in children with newly diagnosed type 1 diabetes in Austria is still high and did not change in the last 20 years despite a clear increase in the manifestation rate. Especially young children < 2 years of age have a high risk of DKA at onset. Efforts to reduce the occurrence of onset DKA must be focused upon earlier diagnosis and intervention in newly diagnosed patients.

Ketoacidosis at diabetes onset is still frequent in children and adolescents: a multicentre analysis of 14,664 patients from 106 institutions

S.E. Hofer[1], A. Neu[2], B. Karges[3], R. Oeverink[4], J. Rosenbauer[5], R.W. Holl[6], the DPV Science Initiative and the German BMBF Competency network for Diabetes Mellitus;
[1]Department of Pediatrics, Medical University of Innsbruck, Austria, [2]Department of Pediatrics, University of Tübingen, Germany, [3]Department of Endocrinology and Pediatrics, University of Aachen, Germany, [4]Medical practice for children and adolescents, Oldenburg, Germany, [5]Deutsches Diabeteszentrum, University of Duesseldorf, Germany, [6]Department of Epidemiology, University of Ulm, Germany.

Background and aims: We aimed at analyzing the frequency, clinical characteristics, risk factors and trends associated with the occurrence of ketoacidosis at the onset of type 1 diabetes mellitus, on the basis of long-term follow-up data.
Materials and methods: A total of 106 paediatric diabetes centres in Germany and Austria participated in this study. Data was collected between 1995 and 2007 by means of a diabetes software programme for prospective documentation (DPV). The data of 14,664 patients with type 1 diabetes were suitable for evaluation. Ketoacidosis (DKA) was defined and classified according to the ISPAD consensus guidelines: mild DKA, 7.2 ≤ pH < 7.3; moderate DKA, 7.1 ≤ pH < 7.2; severe DKA: pH < 7.1).
Results: DKA (pH values < 7.3) was observed in 21.1% of patients. The frequency of DKA, including the severe form, remained unchanged throughout the 13 years' observation period. The frequency of DKA was particularly striking among children < 5 years of age (26.5%) and in patients with a migration background (27.3%). DKA occurred more frequently among girls (21.8%) than in boys (19.4%).
Conclusion: Ketoacidosis occurring at diabetes onset continues to be a difficult problem. Our data show no significant change in the frequency and magnitude of DKA over the last 13 years.

YKL-40 is elevated in type 1 diabetic children which show components of metabolic syndrome compared to those without, as well as to healthy control subjects

T. Hoertenhuber[1], F. Hoellerl[1], C. Hoebaus[1], A. Steffan[1], M. Grujicic[1], B. Rami[2], E. Schober[2], G. Schernthaner[3], R. Koppensteiner[1], G.H. Schernthaner[1];
[1]Angiology, Medical University of Vienna, [2]Pediatric and Adolescent Medicine, Medical University of Vienna, [3]Medicine I, Rudolfstiftung Hospital, Vienna, Austria.

Background and aims: Despite therapeutical advances in glycemic control in type 1 diabetes mellitus (T1DM) in children and adolescents, the risk for cardiovascular morbidity and mortality before the age of 40, is still increased up to 30-fold compared to non-diabetic controls. The mechanisms behind are still not clear. Recent studies showed, that the protein YKL-40, which is in-

volved in endothelial dysfunction and vascular inflammation, is co-responsible for plaque rupture in cardiovascular disease (CVD). Thus we investigated YKL-40 in T1DM children and adolescents.
Materials and methods: In the current study YKL-40 was measured in 153 children and adolescents with T1DM. As control group (CO) 24 healthy gender-matched subjects from 7 to 19 years were defined. The presence of risk factors for CVD, metabolic syndrome and vascular inflammation was studied. YKL-40 levels were measured using a commercially available ELISA (Quidel Corporation, San Diego, CA). Inter-assay coefficient of variation (CV) was 12.4%, and intra-assay CV was 6.9%. Statistical analyses were done with students' unpaired t-test, ANOVA, correlation analysis and multivariate regression modeling as appropriate.
Results: T1DM children and adolescents showed significantly elevated YKL-40 levels: T1DM: 44.08± 46.04 ng/ml vs. CO: 34.04±11.83 ng/ml; p=0.025. Analysing the T1DM patients responsible for the difference, we discovered a sub-group of patients with high YKL-40 levels. We defined a cut-off limit of mean of the total study population plus one standard deviation; approximately 80 ng/ml. Thus we obtained 138 patients below this limit and 15 above. The T1DM sub-group with YKL-40 > 80 ng/ml showed significant differences (T1DM, YKL-40 80 ng/ml) for systolic blood pressure (BP): 114±15 vs. 122±13 mmHg; p=0.034; for body mass index (BMI): 21.4±4.0 vs. 24.0±3.9 kg/m2; p=0.021; for triglycerides (TG): 108±80 vs. 213±172 mg/dl; p<0.001; for VLDL: 19±11 vs. 28±10 mg/dl; p=0.009; fasting glucose: 155±84 vs. 155±85 mg/dl; p=0.971; for gamma-glutamyl-transferase (GGT): 16±5 vs. 24±12 U/l; p=0.027; C-reactive protein (CRP): 0.3±0.4 vs. 0.5±0.5 mg/dl; p=0.046.
In a next step, univariat regression analysis in the T1DM patients was performed. Univariat significant predictors for YKL-40 (age, diastolic BP, BMI, TG, GGT, CRP) were further analyzed by multivariate regression. GGT (beta=0.379, p<0.001) and TG (beta=0.318, p<0.001) were revealed to be significantly associated with YKL-40. The single most independent predictor was GGT (beta=0.538, p<0.001).
Conclusion: This is the first study which investigated YKL-40 in non-diabetic as well as in T1DM children and adolescents. YKL-40 was significantly higher in T1DM and especially high in those with concomitant cardiovascular risk factors like hypertension, hyperlipidemia, elevated weight, and systemic inflammation, all parameters being involved in an insulin resistance/metabolic syndrome. Recently it was postulated, that the increased CVD risk in T1DM might be associated with an underlying "metabolic" like syndrome. Our finding of elevated YKL-40, which is involved in plaque rupture, might explain how this "metabolic" like syndrome evolves to cardiovascular events.

882

Predictors of recurrent diabetic ketoacidosis in children and adolescents with type 1 diabetes. Experience from a large multicenter data base
M.J. Fritsch[1], J. Rosenbauer[2], E. Schober[1], A. Neu[3], K. Placzek[4], R. Holl[5], German competence network diabetes mellitus and the DPV initiative;
[1]Department of pediatrics and adolescent medicine, Medical University of Vienna, Austria, [2]Institute of Biometrics and Epidemiology, German Diabetes Center at Heinrich Heine University Düsseldorf, Germany, [3]University Children´s Hospital of Tübingen, University of Tübingen, Germany, [4]Clinic for child and adolescent medicine, Medical University of Halle-Wittenberg, Germany, [5]Institute of Epidemiology, University of Ulm, Germany.

Background and aims: Diabetic ketoacidosis (DKA) remains the leading cause of hospitalisation and death in children and adolescents with established type 1 diabetes despite DKA preventing strategies in diabetes education. Thus the aim of this study was to determine the risk factors for recurrent DKA in a large cohort of children and adolescents with previously diagnosed type 1 diabetes.
Materials and methods: This study is an observational investigation using the DPV (Diabetes-Patienten-Verlaufsbeobachtung) -Wiss data base containing clinical data on 28 770 type 1 diabetic patients < 20 years of age at follow up from Germany and Austria. DKA was defined as pH< 7.3 and/or hospital-admission due to DKA. Data are presented as mean ± SEM of the latest year of therapy if not otherwise stated. DKA at manifestation was not included in the analysis. DKA rate is given as incidence of DKA per 100 patient years. Statistical analyses were performed using Wilcoxon rank sum test and multiple Poisson regression analyses.
Results: Mean age of the study cohort was 13.96 ± 3.97 years (mean ±SD) (47.9% females). 94.12% had no episode of DKA, 4.85% of patients presented with 1 episode and 1.03% of patients with recurrent DKA (≥ 2 episodes). When comparing patients without, with one or recurrent DKA, age at manifestation (p<0.01), HbA1c (p<0.001) and insulin dose (p<0.001) were significantly higher in patients with recurrent DKA. According to multiple Poisson regression incidence of DKA was found to be significantly higher in female patients (females: 7.3 ±0.46 males: 5.81±0.23; p=0.03) and in patients with positive migration background (migration background: 7.81±0.56 vs. no migration background: 6.33±0.27; p=0.02). Children of the age group 10-15 years were at significantly higher risk (<5y.: 3.23 ±0.66, 5-10y.: 3.34 ±0.30, 10-15y.: 8.04 ±0.34; 15-20y.: 6.68 ±0.44; p<0.01) as well as children with longer duration of diabetes (≤ 2 y: 5.69 ±0.49, 2-5 y.: 6.68 ±0.30, 5-10 y.: 6.19 ±0.27; > 10 y.: 7.60±1.20; p<0.05). No significant association was found with the type of treatment (CT: 5.44±0.42; ICT: 7.01±0.35, CSII 5.71±0.33) or centre size (<100 patients: 6.49 ±0.26 vs.> 100 patients: 7.09±0.72).
Conclusion: In a large cohort of European paediatric patients with type 1 diabetes the rate of DKA was found to be significantly higher in females, in children with a positive migration background in early teenage years. Further risk factors were age at onset and duration of diabetes.

883

Rapid GlucoseSpray: an innovative tool to control hypoglycaemia and improve HbA_{1c} in children with type 1 diabetes
E. Pronina[1], C. Guglielmi[2], H. Petraikina[3], M. Antsiferov[3], O. Duchareva[3], P. Pozzilli[2];
[1]Endocrinology Department, Morozovskaya Children City Clinical Hospital, Moscow, Russian Federation, [2]University Campus Bio Medico, Roma, Italy, [3]Morozovskaya Children City Clinical Hospital, Moscow, Russian Federation.

Background and aims: Hypoglycaemia continues to be a composite situation to tackle especially in children up to 5 years of age because of difficulties in administering the correct dose of glucose as well as child compliance. Aim of the this study was to evaluate the effect of administering small amounts of glucose through the Glucose RapidSpray (GRS) during first signs of hypoglycaemia in children affected by type 1 diabetes (T1D) to estimate whether such treatment was able to improve the metabolic control over a period of 9 months follow up. This device consists of a 19 ml bottle containing 10 g glucose solution with the addition of artificial flavours and excipients to facilitate buccal absorption delivering by spray puffing glucose in quantities as small as 0.5 grams.
Materials and methods: We designed an open randomized trial in 27 T1D children up to 5 years of age. They were randomly allocated into two groups: group A) GRS (10 to 20 puffs of GRS, 0.5 g to 1 g glucose) depending on hypoglycaemic symptoms; group B) traditional treatment of hypoglycaemia episodes (sugar, fruit juice, candies, etc). The following factors were evaluated at entry into the trial, at 3 and 6 months follow-up, and at the end of the study (9 months): HbA1c, number and characteristics of hypoglycaemic episodes, compliance to treatment and quality of life of children and their parents.
Results: HbA1c at at entry was 9.4% ± 1.2 in group A and 9.1% ± 0.6 in group B (p NS). After 3 months both groups showed a significant improvement in HbA1c with no differences between groups (group A: 8.7% ± 1, group B: 8.6% ±0.7) which further improved at 6 months (group A: 8.4% ± 0.9, group B: 8.4% ±0.6) and at the end of the study (group A: 7.8% ± 0.5, group B: 8.2% ± 0.3). There was a statistically significant difference in the improvement of the HbA1c in the GRS treated group vs. control group over the period of observation (1.63% vs. 0.86% difference, respectively, p=0.02, paired T test). Moreover, children in group A showed a tendency for less severe hypoglycaemic episodes during the day compared to group B during the whole observational period.
Conclusion: A more acceptable and practical tool to control and manage hypoglycaemia especially in toddlers and young children represents a very relevant therapeutic issue. GRS is able not only to reduce the risk of hypoglycaemia but to improve the overall metabolic control, as shown by a reduction of HbA1c.

884

Phenotypes of prediabetes and non alcoholic fatty liver disease in obese children and adolescents

M. Manco[1], A. Gastaldelli[2], G. Bedogni[3], C. Tiribelli[3], F. Agosti[4], G. Grugni[4], A. Sartorio[4];
[1]Direzione Scientifica, Ospedale Pediatrico Bambino Gesù, IRCCS, Roma, [2]Istituto di Fisiologia Clinica, Fondazione Toscana Monasterio e CNR, Pisa, [3]Centro Studi Fegato, AREA Scientifica e Tecnologica, Basovizza, Trieste, [4]Istituto Auxologico Italiano, IRCCS, Verbania e Milano, Italy.

Background and aims: Obesity is becoming epidemic especially in the youth. It associates not only with disturbed carbohydrate metabolism but also with non alcoholic fatty liver disease.
Aim of this study was to assess the association between fatty liver, diagnosed by ultrasound, and disordered metabolic status.
Materials and methods: We have studied 541 children (age 8-18 years) with various degrees of obesity (BMI 24.4-62 kg/m2). In all subjects we evaluated metabolic profile, glucose tolerance by OGTT (using a dose of 1.75 g glucose/kg body weight to a maximum of 75 g), presence of fatty liver (FL) by ultrasonography, insulin resistance by HOMA and Matsuda index, beta cell function by the ratio of AUC of insulin to glucose measured every 30min during OGTT.
Results: Children with FL had higher levels of fasting glucose, insulin, triglycerides, ALT, AST, GGT, mean OGTT glucose. Moreover, FL subjects had impaired glucose tolerance (IFG/IGT/DM was present in 5/55/3 and 0/24/2 of children with and without FL, p<0.001), increased insulin resistance (HOMA and Matsuda-index) and slight decreased, although not significant, beta cell function. In a multivariate model, fatty liver was the strongest predictor of 2h and mean OGTT glucose and of reduced insulin sensitivity (Matsuda-index), after correcting for gender, BMI, age and liver enzymes. No significant association was found with altered beta cell function.
Conclusion: Screening for presence of fatty liver by ultrasound can identify young subjects with altered glucose metabolism and be a target for improving metabolic dysfunction.

885

Effect of overweight/obesity on cardiometabolic risk profile in children with type 1 diabetes

M. van Vliet[1,2], J.C. van der Heyden[3], M. Diamant[4], I.A. von Rosenstiel[1], R.K. Schindhelm[5], H.J. Aanstoot[3], H.J. Veeze[3];
[1]Pediatrics, Slotervaart Hospital, Amsterdam, [2]VU University Medical Centre, Amsterdam, [3]Pediatrics, Diabeter, Rotterdam, [4]Diabetes Center, VU University Medical Centre, Amsterdam, [5]Clinical Chemistry, Isala Clinics, Zwolle, Netherlands.

Background and aims: Although cardiometabolic risk factors are abundantly present in overweight children, only few studies have assessed the prevalence of these factors in paediatric cohorts with type 1 diabetes (T1DM). The aim of this study was to determine and compare the prevalence of traditional cardiometabolic risk factors and to assess the effect of overweight/obesity on these risk factors in a cohort of normal and overweight/obese children with T1DM.
Materials and methods: This cross-sectional study included 283 consecutive patients (aged 3-18 years) attending a dedicated out-patient clinic for T1DM care. After stratification for weight status, the prevalence of cardiometabolic risk factors, the metabolic syndrome (according to a modified paediatric definition), and high alanine aminotransferease (ALT; a marker of liver steatosis), were assessed.
Results: Out of 283 children (median age 12.8 years, interquartile range [IQR] 9.9-16.0, median diabetes duration 5.3 years, IQR 2.9-8.6), 67.5% was aged ≥11 years, and 38.5% were overweight/obese (Z-BMI ≥1.1). Median HbA1C levels were 8.2%, IQR 7.4-9.8, and HbA1C ≥7.5% was present in 73.9%. Microalbuminuria was found in 17.7%, high triglycerides in 17.3%, high LDL-cholesterol in 28.6%, low HDL-cholesterol in 21.2%, and high blood pressure in 13.1% of the children. The vast majority had a positive family history for either type 2 diabetes or cardiovascular disease (63.3%), while smoking was only reported by 3.9%. In total, 95.1% of children had one or more of the nine forementioned cardiometabolic risk factors, 31.4% of children showed exactly two risk factors, and the percentage of children with more than three risk factors was still 20.8%. A higher prevalence of the metabolic syndrome (7.3% vs. 1.7%), ALT >30 IU/L (15.6% vs. 4.5%) and high blood pressure (22.9% vs. 5.7%) were found in overweight/obese as compared to normal-weight children (all $P<0.05$).
Conclusion: Cardiometabolic risk factors were frequently present a paediatric cohort of children with T1DM, however, only hypertension, the metabolic syndrome and ALT >30 IU/L were more abundant in overweight/obese compared to normal weight children.

886

Calcitriol administration in the youth reduces bone turnover and may prevent bone loss in type 1 diabetes

N. Napoli[1], D. Pitocco[2], E. Di Stasio[2], C. Bizzarri[3], D. Maggi[1], R. Strollo[1], I. Barchetta[1], C. Suraci[4], P. Pozzilli[1], IMDIAB group;
[1]Università Campus Bio-Medico, [2]Università Cattolica del Sacro Cuore, [3]Ospedale Pediatrico Bambino Gesù, [4]Ospedale Sandro Pertini, Rome, Italy.

Background and aims: In patients affected with type 1 diabetes (T1D), some factors such as a lack of anabolic effects of insulin and amylin on bone mass cause both a bone loss in adults and a lower peak of skeletal mass in younger subjects. According to several studies, vitamin D may reduce bone turnover and prevent bone loss in non diabetic patients. However, considering also the effect of vitamin D in reducing insulin requirement in type 1 diabetes patients, this compound might be considered as a novel therapeutic adjuvant in this disease. The objective of this study was to determine the effect of 1 year treatment with calcitriol on bone turnover in subjects with T1D by analyzing Osteocalcin (a bone formation marker) and β-CrossLaps (a bone resorption marker).
Materials and methods: In a double blind study designed to evaluate the effect of calcitriol to preserve beta cell function in recent onset T1D, we have investigated the effect of this treatment on bone turnover markers. A group of 25 subjects with recent-onset T1D and baseline C-peptide > 0.25 nM, were randomized to calcitriol at 0.25 μg daily dose or placebo (1:1) and followed-up for 1 year. Osteocalcin and β-CrossLaps, were evaluated by ECLIA method (modular E170, Roche Diagnostics, Mannheim, Germany) at diagnosis and at 1 year follow-up.
Results: At 1 year follow-up osteocalcin and β-CrossLaps dropped by 38.6% and 47.3%, respectively in the calcitriol treated group but their levels were not significantly different compared to diagnosis due to high variability. No significant differences were also found at 1 year comparing calcitriol vs. the placebo group for both osteocalcin (25.1±3.6 (sem) ng/mL vs 46.1±14.2 (sem) ng/mL, respectively; P=0.157) and β-CrossLaps (0.29±0.6 (sem) ng/mL vs 0.48±0.1 (sem) ng/mL, respectively; P=0.151). However, by stratifying patients according to age, we found that at 1 year follow-up as compared to diagnosis, calcitriol treated patients <18 years of age (mean age 16 years ± 1.46) showed statistically significant 61% drop of osteocalcin (68.8±17.6 (sem) ng/mL vs 26.8±11.5 (sem) ng/mL, respectively, p=0.04) and a 67% reduction in β-CrossLaps (0.92±0.77 (sem) ng/mL vs 0.31±0.08 (sem) ng/mL, respectively, p=0.09). In this age range, patients on calcitriol therapy vs. placebo showed at 1 year follow-up a trend for lower osteocalcin (74.2±23.7 (sem) ng/mL vs 26.8±4.8 (sem) ng/mL, respectively, p=0.08) and significantly lower β-CrossLaps (0.76±0.15 (sem) ng/mL vs 0.31±0.1 (sem) ng/mL respectively, p=0.03). Differences were not statistically significant in patients older than 18 years of age.
Conclusion: Our preliminary data suggest that in young subjects with T1D calcitriol therapy for 1 year at dose of 0.25 μg daily decreases bone remodelling and may contribute to preserve bone mass in T1D related osteopenia.

PS 74 Insulin analogues

887

Changes of glycaemic control, anthropometric parameters and fasting lipid profiles in patients with type 2 diabetes mellitus starting insulin therapy with premixed insulin analogues BID

V. Pīrāgs[1], M. Dąbrowski[2], M. Sait Gönen[3], A. Ertekin[4], S.P. Cleall[5], B. Mozejko-Pastewka[6], J. Kiljanski[6];
[1]Pauls Stradins' Clin Univ Hosp, Riga, Latvia, [2]Diabetic Outpatient Clinic, Rzeszow, Poland, [3]Selcuk Univ, Konya, Turkey, [4]Lilly Res, Istanbul, Turkey, [5]EuMIS Statistics, Lilly Res, Erl Wood, United Kingdom, [6]Lilly Area Med Ctr, Vienna, Austria.

Background and aims: Weight gain associated with initiation of insulin treatment in type 2 diabetes mellitus (T2DM) and its metabolic consequences remain an important concern in clinical practice. It is not well understood how initiation of conventional insulin regimen with insulin analogues affect distribution of adipose tissue and body weight changes. We report here anthropometric and lipid endpoints from a study of premixed insulin analogues (PIA; 75% insulin lispro protamine suspension, 25% insulin lispro or 70% insulin aspart protamine suspension, 30% insulin aspart).
Materials and methods: Body weight (BW), BMI and distribution of adipose tissue (waist circumference [WC], hip circumference [HC], WHR) and fasting lipid profiles were recorded along with HbA_{1c} in T2DM pts starting PIA BID after failure of oral antihyperglycemic medication (OAM) in a 1-year, prospective, observational study conducted in Europe, Middle East and Asia. Data were summarized using means (SD), 95% CIs, percentages. *P*-values for changes from baseline were calculated using *t*-tests.
Results: Out of 1139 enrolled, 991 (87%) pts completed the study (595 [52.2%] males, age 57.9 (10.1) years, diabetes duration of 9.3 (5.9) years, body weight 81.5 (15.9) kg, BMI 29.2 (4.7) kg/m^2, baseline HbA_{1c} 9.9 (1.8) %). Initial daily dose of PIA 35.9 IU (13.7) increased to 41.4 IU (19.4). 951(83.5%) patients received insulin in combination with one or more OAMs (656 [69%] pts with 1, 267 [28.1%] with 2, 27 [2.8%] with 3, and 1 [0.1%] patient with 4 OAMs). 546 patients (48.6% of enrolled pts) received at least one hypolipaemic medication (504 [92.3%] pts 1, 41 [7.5%] 2, 3 [0.2%] pts 3) during the observation period. In patients who completed 12 months of follow-up, following mean changes were observed: HbA_{1c} decreased by 2.5% (CI 2.4-2.7); BW and BMI increased by 1.5kg and 0.6kg/m^2 (Table); WC and HC increased by 0.7cm (CI 0.5-1.0; p<0.001) and by 0.5cm (CI 0.3-0.8; p<0.001). There was no observed change in WHR. Total and LDL cholesterol and triglycerides decreased (p<0.001) whereas HDL cholesterol increased from baseline (< 0.001) (Table).
Conclusion: Following introduction of premixed insulin analogues in a group of patients with type 2 DM observed for 12 months glycemic control and fasting lipid profiles improved. No changes in mean WHR were observed despite increases in mean body weight, BMI, waist and hip circumferences.

Change of HbA1c, weight and fasting blood lipids (N=1139; n=patients with observed measures)

Characteristic	Baseline mean (SD), n	After 12 months mean (SD), n	Change from Baseline mean (95% CI), n	*P*-value
HbA_{1c} (%)	9.9 (1.8), 1098	7.3 (1.1), 951	- 2.5 (2.4-2.7), 938	< 0.001
Weight (kg)	81.5 (15.9), 1139	83.6 (14.9), 978	+ 1.5 (1.3-1.8), 978	< 0.001

Improved glycaemic control in over 11,000 elderly patients from the IMPROVE™ Study of biphasic insulin aspart 30/70 (BIAsp 30) in eight countries

V. Borzi[1], S. Shah[2], V.K. Knudsen[3];
[1]Department of Internal Medicine, Vittorio Emanuele Hospital, Catania, Italy, [2]S.L. Raheja Hospital, Mumbai, India, [3]Epidemiology, Novo Nordisk, Bagsvaerd, Denmark.

Background and aims: IMPROVE™ is an international, open-label, non-randomised, non-interventional, 26-week observational study of biphasic insulin aspart 30/70 (BIAsp 30) in patients with type 2 diabetes in routine clinical practice. The analysis presented here examines whether elderly patients, given their generally poorer disease status and longer diabetes duration, can benefit from BIAsp 30 therapy.
Materials and methods: Enrolled patients aged ≥65 years (N=11,988) were initiated on, or switched to, BIAsp 30 during routine care. Safety and effectiveness data were obtained at baseline and 26 weeks. Where available, analysis was also performed according to pre-study treatment (no pharmaceutical therapy, oral antidiabetic drugs [OADs] only, and insulin±OADs).
Results: Patients had a mean (standard deviation, SD) age of 71.3 (5.2) years, weight of 69.8 (14.5) kg, body mass index (BMI) of 26.3 (4.9) kg/m^2, diabetes duration of 10.4 (7.4) years and HbA_{1c} of 9.18% (1.88%). Mean HbA_{1c} decreased by 2.1% by study end (p<0.0001; Table 1). Significant reductions in HbA_{1c} were also observed when analysed according to pre-study therapy: no therapy -3.2%, OADs only -2.1%, insulin±OADs -1.7% (all p<0.0001). Mean fasting blood glucose (FBG) and postprandial plasma glucose (PPBG) after all main meals also improved significantly. The rate of major and minor hypoglycaemic events decreased significantly during the study (both p<0.0001). There was a small increase in body weight. BIAsp 30 dose increased by 0.06 IU/kg from baseline to final visit. The HbA_{1c} target of <7% with no hypoglycaemia was achieved by 33.1% of patients (n=3972, mean HbA_{1c} [SD] 6.3% [0.5%]).
Conclusion: The IMPROVE™ study demonstrates that BIAsp 30 exerts beneficial effects in terms of blood glucose control in patients aged ≥65 years with long diabetes duration. These positive effects appear independent of prior diabetes therapy, and are accompanied by significant reductions in rates of hypoglycaemia. BIAsp 30 therapy may be of particular advantage to older patients, as starting and intensifying therapy is simplified when only one type of insulin is used.

Table 1

Variable N=11,988	.	Mean (SD)	n

Lower treatment costs with insulin glargine compart to insulin detemir as part of a basal-bolus regime in type 2 diabetes: results from the LIVE-COM study in Germany

R.A. Bierwirth;
Diabetes Centre, Ambulance, Essen, Germany.

Background and aims: The basal insulin analogues glargine (GLA) and detemir (DET) are well-established in the treatment of diabetes. In addition to clinical aspects the economic impact of basal insulin analogues on health care expenditures is of importance. The aim of this study was to compare resource utilization and costs incurred by a basal-bolus insulin regimen in type 2 diabetes (T2D) patients when using either GLA or DET as basal insulin from the perspective of the Statutory Health Insurance (SHI) in Germany under real-life conditions.
Materials and methods: LIVE-COM was a non-interventional, cross-sectional, retrospective study performed between April and September 2008 in randomly selected primary care practices in Germany. T2D patients with SHI status were eligible for documentation if aged ≥18 years and either using GLA or DET as part of a basal-bolus regimen for ≥6 months prior to documentation. The primary objective was to compare the mean direct diabetes-specific treatment costs (DTC) between the GLA and DET groups over 6 months. DTC comprised antidiabetic medication (insulins, oral antidiabetics), needles, blood glucose self-monitoring (test strips, lancets), and hypokits to treat severe hypoglycaemia. Mean costs were adjusted for relevant influencing factors by analysis of covariance (ANCOVA). Differences in means were regarded significant with a 2-sided p<0.05.
Results: LIVE-COM enrolled a total of 1731 T2D patients from 138 primary care practices (GLA, 1150; DET, 581). Patient characteristics for the GLA (53.3% male) and DET (48.7% male) groups were (mean±SD): age (66.0±10.7 vs. 64.7±10.1 years, p=0.01), BMI (31.3±5.8 vs. 32.7±6.2 kg/m^2, p<0.01), HbA1c (7.5±1.2 vs. 7.7±1.2 %, p<0.01), and fasting blood glucose (140±46 vs 148±48 mg/dl, p<0.01). Diabetes duration (>10 years: 60.0% vs. 59.0%, n.s.,onset of first insulin therapy (>5 years: 61.6% vs. 64.4%, n.s, and number of diabetic complications and risk factors (mean±SD: 3.0±1.7 vs. 2.9±1.6, n.s.) were similarly distributed in both groups. Adjusted mean DTC per patient and 6 months were lower in the GLA compared to the DET group (€932 vs. €1060, p<0.01). The adjusted average DTC savings were €128 (95% CI: €90; €167; p<0.01) per patient. Adjusted mean single costs in the GLA and DET groups were: basal insulin €223 vs. €246 (p<0.01), bolus insulin €241 vs. €289 (p<0.01), needles €67 vs. €80 (p<0.01), test strips €347 vs. €393 (p<0.01), lancets €14 vs. €16 (n.s.), oral antidiabetics €37 vs. €36 (n.s.), and hypokits €2 vs. €1 (n.s.). Mean daily total insulin dose of 27.7/40.3 U (basal/bolus) was found to be significantly lower in the GLA compared to 32.1/47.1 U in the DET group (p<0.01). GLA patients had fewer basal insulin injections per day (1.1 vs. 1.3, p<0.01) and required also less test strips per day for blood glucose self-monitoring (3.2 vs. 3.6, p<0.01) compared to DET patients. Reported hypoglycaemic events, hospitalization rates and frequency of physician contacts did not differ between the GLA and DET groups.
Conclusion: Under real-life conditions, a glargine vs. detemir based basal-bolus regimen was associated with considerable lower costs of diabetes care from the SHI perspective in a 6-month head-to-head comparison in T2D patients.

Insulin glulisine has a faster onset of action than insulin aspart

U. Hövelmann[1], S. Arnolds[1], K. Rave[1], A. Fischer[1], C. Sert-Langeron[2], T. Heise[1];
[1]Profil Institut für Stoffwechselforschung, Neuss, Germany, [2]sanofi-aventis, Paris, France.

Background and aims: Insulin glulisine (GLU) might have a faster onset of action than do other short-acting analogs owing to its zinc-free formulation. We compared the pharmacokinetics and pharmacodynamics (PK/PD) of GLU with those of insulin aspart (ASP) in a euglycaemic clamp study performed in healthy volunteers.
Materials and methods: Twelve healthy subjects (six male; mean±SD age, 42±12 years; BMI, 24.6±2.2 kg/m^2; normal HbA1c and fasting plasma glucose) participated in this randomised, double-blind, crossover, euglycaemic glucose-clamp trial. After an overnight fast, subjects were connected to a Biostator and, after establishing baseline for a period of 90 minutes, received 0.2 U/kg of either GLU or ASP sc in the abdomen. Glucose infusion rates (GIRs) were automatically adjusted every minute by the Biostator to maintain blood glucose levels at 5% below the individual fasting value for 10 hours post-dosing.
Results: Shortly after injection, insulin concentrations and early metabolic activity were significantly greater with GLU than with ASP, as indicated by a higher AUC[INS 0-30min]/AUC[INS total] ratio (p=0.0001) and a nearly twofold higher area under the GIR curve (AUC[GIR 0-30 min]; p=0.0421) (Table). Shorter times to 10 and 20% of INS[max] (p=0.0005 each) and a 50% shorter time to 10% of GIR[max] (p=0.0146) showed a significantly faster insulin absorption and onset of action for GLU than for ASP, whereas INS t[max] and total metabolic activity (AUC[GIR total]) were comparable.
Conclusion: Similar to previous comparisons with insulin lispro, GLU also shows an earlier onset of action than does ASP, probably because of its zinc-free formulation.

Use of rapid-acting insulin aspart reduces costs and cardiovascular complications in type 2 diabetes when compared with human insulin

R.F. Pollock[1], W.J. Valentine[1], T.L. Thomsen[2], H. Nishimura[3];
[1]Ossian Health Economics and Communications GmbH, Basel, Switzerland, [2]Novo Nordisk A/S, Virum, Denmark, [3]Osaka Saiseikai Nakatsu Hospital, Japan.

Background and aims: The NICE study was a five-year, open-label, randomized controlled trial which compared cardiovascular outcomes in Japanese type 2 diabetes patients intensively treated with human insulin (HI) or insulin aspart (IAsp), a rapid-acting insulin analog. The within-trial cost-effectiveness of IAsp versus HI was evaluated from the perspective of a third-party healthcare payer.
Materials and methods: A cost-effectiveness model was developed in Microsoft Excel® based on mortality data, cardiovascular events and resource use information from 5 years of observation in the NICE study. Cardiovascular events/interventions captured in the model included: myocardial infarction, angina pectoris, percutaneous coronary intervention, coronary artery bypass grafting, transient ischemic attack and cerebral infarction. Mortality and cardiovascular event probabilities were derived from the annual rates observed during the trial period. Health-related quality of life (HRQOL) was estimated in the model by applying HRQOL scores in the year of the event and, in the case of myocardial and cerebral infarction, in subsequent years as a health state utility. Event costs were expressed in 2008 Japanese Yen (JPY) and were calculated from hospital receipt data supplied by the Japanese Medical Data Center. Insulin costs were obtained from the trial. Other pharmacy costs (e.g. oral antidiabetic agents and concomitant medications) were assumed to be the same in both treatment arms and were not captured in the analysis. Life expectancy, quality-adjusted life expectancy, cardiovascular event rates and costs were evaluated over a 5-year time horizon (in line with the NICE study). All future costs and clinical benefits were discounted at 3% annually. Sensitivity analyses were performed.
Results: Over five years of treatment, IAsp was dominant (life- and cost-saving) versus HI. Compared with HI, IAsp was associated with a small improvement in discounted life expectancy of 0.005 years (4.688 versus 4.683 years) and an improvement in quality-adjusted life expectancy of 0.034 quality-adjusted life years (QALYs) (3.787 versus 3.753 QALYs). IAsp also incurred lower costs (JPY 470,753 versus 579,974, difference -109,221) when compared with HI. The reduction in cost resulted from the decreased inci-

dence of cardiovascular events with IAsp (0.013 events per patient year versus 0.030 on HI). Breakdown of costs indicated that drug costs were higher with IAsp (JPY 337,066 versus 267,781), however these costs were more than offset by the reduced costs associated with cardiovascular complications over five years of treatment.
Conclusion: In a Japanese type 2 diabetes population, prescribing rapid-acting insulin aspart significantly reduced cardiovascular complications, resulting in increased quality of life and decreased costs when compared with human insulin.

Insulin detemir and insulin glargine have similar effects on hepatic glucose metabolism

M.C. Moore[1], M.S. Smith[1], M. Turney[1], T.D. Farmer[1], P. Williams[2];
[1]Molecular Physiology & Biophysics, [2]Surgery, Vanderbilt University, Nashville, United States.

Background and aims: Insulin detemir (Det) is an insulin analog that binds reversibly to albumin. These studies were designed to compare direct effects of Det and insulin glargine (Glg), another basal insulin analog, on hepatic glucose production. The studies also compared the indirect effects of the two analogs, elicited via delivery of insulin into the peripheral circulation and the brain.
Materials and methods: Studies were carried out in chronically catheterized overnight fasted conscious dogs using arteriovenous difference and tracer techniques. Pilot studies were done to establish Det and Glg infusion rates that would suppress net hepatic glucose output (NHGO) ≈50% during hepatic portal vein insulin infusion (Low Insulin; 0.1 and 0.3 mU·kg^{-1}·min^{-1}, respectively). For the primary (non-pilot) studies, a primed continuous infusion of [3-^{3}H]glucose began at 0 min, basal sampling occurred from 90-120 min, and a euglycemic pancreatic clamp was carried out from 120-540 min. During the clamp, somatostatin was infused i.v. and glucagon was replaced intraportally at a basal rate. Dogs received Det or Glg into the hepatic portal vein (Po), a peripheral vein (IV), or the head (H; bilateral carotid and vertebral arteries) (6 groups, *n*=5-6/group). Low Insulin was infused from 120-420 min and High Insulin (4× Low Insulin) was infused from 420-540 min. Biopsies from the liver and hypothalamus were taken at the end of study.
Results: Arterial plasma glucose was 114±1, 110±1, and 108±1 mg/dl (Basal, Low Insulin, and High Insulin, respectively), and arterial plasma glucagon was 38±2, 38±2, and 34±1 ng/l. Neither parameter differed among groups. Basal NHGO (1.5±0.2 mg·kg^{-1}·min^{-1}); glucose R_a (2.2±0.3 mg·kg^{-1}·min^{-1}); and arterial plasma NEFA (916±45 μM) did not differ among groups. Data from the last h of Low and High Insulin are shown in the Table.
In Det Po, IV, and H, respectively (*n*=3/group), liver p-Akt (μg/mg protein) was 100±17, 115±10, and 139±46; in hypothalamus, it was 26±0.8, 36±14, and 28±10. In Glg Po, IV, and H, respectively (*n*=3/group), liver p-Akt was 71±19, 113±21, and 132±48; hypothalamus p-Akt was 21±2, 26±9, and 28±5 (no significant differences between groups or among routes).
Conclusion: Det and Glg have similar effects on the regulation of hepatic glucose metabolism in vivo. Portal and IV Det delivery reduces circulating NEFA to a greater extent than Glg, suggesting a greater indirect effect on hepatic glucose production.

Baseline HbA_{1c} predicts the likelihood of reaching the 7.0% HbA_{1c} target with structured titration of add-on insulin glargine: patient-level analysis of 12 studies in type 2 diabetes mellitus

R. Zhou[1], A.A. Vlajnic[2], D. Orloff[1], J. Rosenstock[3], M. Riddle[4];
[1]Medpace, Inc, Cincinnati, [2]sanofi-aventis, Bridgewater, [3]Dallas Diabetes and Endocrine Center, Dallas, [4]Oregon Health & Science University, Portland, United States.

Background and aims: Addition of insulin glargine with systematic dosage titration can improve glycemic control to 7.0% HbA_{1c} or better in many patients with type 2 diabetes mellitus (T2DM) not well-controlled with oral agents. Baseline HbA_{1c} may be a useful predictor of reaching this target.
Materials and methods: We report here an analysis of patient-level data pooled from 12 randomized controlled studies with similar design, including structured basal insulin titration seeking fasting plasma glucose ≤100 mg/dL (≤5.5 mmol/L), to determine the likelihood of reaching 7.0% HbA_{1c} and the frequency of hypoglycemia when starting from various baseline HbA_{1c} levels.
Results: Data are from 2312 T2DM patients (mean [±SD] age 58.4±10.1 y; BMI, 31.0±5.45 kg/m^2; baseline HbA_{1c} 8.78±1.06%) after 24 weeks of treatment. Among 12 studies , at study end (mean 24weeks), HbA_{1c} was 7.07% (range 6.73%-7.45%) and 55.0% of patients (range 41%-78%) reached ≤7.0%. Mean HbA_{1c} reduction from baseline was 1.71% and the value at 24 weeks correlated strongly with baseline HbA_{1c}; continuous data for both variables was used (Pearson correlation coefficient=0.39, P<0.0001). Higher baseline HbA_{1c} correlated with greater reduction from baseline (Pearson correlation coefficient=-0.62, P<0.001). The table shows HbA_{1c} reductions from baseline, percentages of patients achieving HbA_{1c} ≤7.0%, and rates of symptomatic or severe hypoglycemia for ranges of baseline HbA_{1c}. Among patients with baseline HbA_{1c} <8.0%, 75.4% achieved the target HbA_{1c} ≤7.0%.
Conclusion: Despite greater reductions from baseline HbA_{1c}, those patients in higher baseline HbA_{1c} ranges were less likely to reach ≤7.0%. The risk of hypoglycemia was not significantly related to baseline HbA_{1c}, using this structured titration of basal insulin glargine.

Glycaemic outcomes 1 year after initiation of insulin glargine or detemir in type 2 diabetes in the US

L. Blonde[1], L. Vaur[2], P. Levin[3], D.M. Kendall[4];
[1]Ochsner Medical Center, New Orleans, United States, [2]sanofi-aventis, Paris, France, [3]MODEL Clinical Research, Baltimore, United States, [4]International Diabetes Center, Minneapolis, United States.

Background and aims: To date, there are limited data on glycemic control comparing initiation of insulin glargine (GLAR) or detemir (DET) in the clinical setting.
Materials and methods: A database of 47 US managed care plans was analyzed to determine the real-world experience with the 2 therapies in patients enrolled between March 2005 and 2008 who were treated with oral antidiabetic agents before initiating GLAR (*n*=11,861) or DET (*n*=2285).

Results: Patient characteristics from the 6 month (baseline) prior to initiation of GLAR vs DET included mean age of 54 years in both groups. Fewer patients initiating GLAR (12%) vs DET (25%) were seen by endocrinologists. Baseline A1C was similar in both groups (9.4% [GLAR] vs 9.6% [DET], p=0.49). The percentage of patients with any medical claim for hypoglycemia during the 6-month baseline period was 4.8% in GLAR vs 3.9% in DET (p=0.073). 23% of GLAR vs 10% of DET patients had been hospitalized (p<0.001) during the baseline period with an average of 8.2 vs 5.4 hospital days, respectively. 23% in GLAR vs 16% in DET used emergency services (p<0.001). Hospital insulin initiation occurred in 9.4% of GLAR vs 3.7% of DET patients (p<0.001). Unadjusted 1 year A1C change from baseline was -1.3% with GLAR (n=1303) vs -1.0% with DET (n=289) (p=0.037). The unadjusted percentage of patients who achieved A1C < 7% was 26.7% in GLAR group vs 22.6% in DET group (p<0.069) one year after initiation. Adjustment for age, sex, baseline A1C, hypoglycemia, diabetes medication, access to an endocrinologist, hospitalization, Charlson comorbidity index score, concomitant medication, and total daily insulin dose resulted in an adjusted mean A1C at 1 year of 7.8% for GLAR vs 8.2% for DET (Δ=0.4%, p=0.04) and 8.1% vs 8.6% (Δ=0.5%, p=0.01) among patients who had initiated insulin in an ambulatory clinic (excluding patients who initiated insulin in a hospital). Excluding patients with hospitalizations during the baseline period, adjusted mean A1C at 1 year was 8.0% for GLAR vs 8.6% for DET (Δ=0.6%, p=0.005). Average daily insulin dose was modestly higher in DET vs GLAR (36 vs 31 U, p<0.001). The 2 groups did not differ in the rate of claims for hypoglycemia (7.3% for GLAR vs 6.6% for DET, p=0.275).
Conclusion: Patients initiating GLAR vs DET as basal insulin in real-world clinical settings demonstrated greater A1C improvement with no increase in medically coded hypoglycemia.

Effects of insulin glargine vs thiazolidinediones on glycaemic and lipid variables in type 2 diabetes mellitus: the impact of obesity
P. Dandona[1], N. Rosenberg[2], P. Hollander[3], J. Rosenstock[4], L. Meneghini[5]; [1]SUNY at Buffalo, [2]sanofi-aventis US, Bridgewater, [3]Baylor University Medical Center, Dallas, [4]Dallas Diabetes and Endocrine Center, [5]University of Miami Miller School of Medicine, Miami, United States.

Background and aims: Obesity is a common risk factor for diabetes and may affect the therapeutic response to antidiabetic medications. We compared the effect of baseline BMI on glycemic and lipid variables in patients with uncontrolled type 2 diabetes mellitus (T2DM) (glycated hemoglobin A1C [A1C] >7.0%).
Materials and methods: This post hoc analysis of pooled data from 2 similarly designed randomized controlled studies compared insulin glargine (GLAR) vs thiazolidinediones (TZDs) added to oral therapy: rosiglitazone (ROSI) added to metformin (MET) + sulfonylurea (SU) combination therapy or pioglitazone (PIO) added to SU or MET monotherapy. This analysis was stratified by obesity class: BMI<30 kg/m^2 (n=183); BMI ≥30-34 kg/m^2 (n=170); BMI ≥35-39 kg/m^2 (n=103); and BMI ≥40 kg/m^2 (n=95).

GLAR vs TZD: [a]P<0.0005; [b]P<0.01; [c]P<0.05; [d]P<0.005; [e]P=0.504; [f]P=0.0528. From ANCOVA with terms for study and baseline value.
Analysis population for glycemic control: GLAR (N=264) and TZD (N=288).
Analysis population for lipid variables: GLAR (N=258) and TZD (N=278).

Results: Overall, reductions in A1C, fasting plasma glucose (FPG), low-density lipoprotein cholesterol (LDL-C), and total cholesterol (TC) were greater in the GLAR arm (N=264) than in the TZD arm (N=288) (P<0.0005). In patients with BMI <30 and BMI ≥30-34, GLAR significantly reduced A1C and FPG compared with TZDs (P<0.05); this difference was attenuated with increasing BMI. GLAR was associated with more favorable changes in triglycerides (TG), LDL-C, and TC in all BMI groups, and in non-esterified fatty acids (NEFA) at all BMIs except ≥40. Differences were statistically significant for the following: TC in all BMI groups except ≥40 (P<0.005); LDL-C when BMI was ≥30-34 and ≥35-39 (P<0.05); and NEFA when BMI was <30 (P<0.05). High-density lipoprotein cholesterol (HDL-C) increased significantly (P<0.005) with TZDs in all BMI groups. There was no consistent pattern in TG, NEFA, and TC changes by BMI. Effects on lipid variables varied with the TZD used in each study, with more favorable changes associated with PIO vs ROSI. Hypoglycemia was more frequent with GLAR. Weight gain was greater with TZDs (P=0.0024) and there was a progressive increase in weight gain across BMI groups with TZDs, but not with GLAR.
Conclusion: Despite more frequent episodes of hypoglycemia, GLAR more effectively improved glycemic control than did TZDs, particularly at lower BMI, and was associated with less weight gain and more favorable changes in TG, LDL-C, TC, and NEFA in less obese patients.

Treatment patterns and persistence among elderly patients with type 2 diabetes: data from a US managed care claims database

S. Gravenstein[1], S.F. Thompson[2], R.G. Stefanacci[3];
[1]Alpert Medical School of Brown University and Quality Partners of Rhode Island, Providence, [2]sanofi-aventis, Bridgewater, [3]University of the Sciences in Philadelphia, Philadelphia, United States.

Background and aims: The ADA/EASD consensus statement for the management of type 2 diabetes mellitus calls for lifestyle intervention plus metformin, followed by the addition of basal insulin or sulfonylurea. In the elderly population, diabetes remains suboptimally managed owing to greater frailty, impaired cognition, and comorbidities, with <50% of patients following current guidelines. While a general treatment consensus needs to be better defined for this population segment, achieving glycemic control for most elderly patients should be prudent and individualized as functional disabilities and/or comorbidities often increase the complexity of diabetes management.
Materials and methods: This longitudinal retrospective cohort study assessed treatment patterns among patients (≥65 years; n=182,458) with at least 1 diabetes medication prescription claim from 2004 to 2007 using a national managed care claims database of 46 health plans, and tracked medication changes from their initial treatment record in the data: 1 oral antidiabetic drug (OAD) 39.75%, 2 OADs (28.06%), ≥3 OADs (9.80%), OAD + insulin (11.46%), and insulin only (10.93%) therapies.
Results: From 2004 to 2007 the number of patients staying on therapy decreased as the number of OADs increased. Treatment persistence remained highest in patients using insulin who were more likely to stay on therapy: patients staying on 1 OAD were 87.58% in 2004 vs 86.39% in 2007; 2 OADs, 82.23% vs 78.25%; ≥3 OADs, 79.36% vs 69.55%; OAD + insulin, 83.95% vs 80.74%; and insulin only, 93.79% vs 93.94%. Compared with a younger cohort (18-64 y), a smaller proportion of elderly patients used metformin (43.90% vs 63.20%), but not sulfonylurea (41.96% vs 21.31%). Transition of therapy occurred in a greater proportion of patients from metformin or sulfonylurea monotherapy, as well as 2 OADs, to multiple combinations including the use of insulin glargine over the same period (Table). Average prescription cost was also less for patients on insulin and insulin + OAD therapies compared with ≥3 OADs or other combination therapies with exenatide.
Conclusion: Although metformin is the preferred initial oral agent, it may not be appropriate for older patients with comorbid conditions, such as renal or cardiac disease. As more elderly patients with diabetes are switching to multi-agent regimens, greater adherence to recommended treatment algorithms should be emphasized and individualized to improve outcome in diabetes-related quality measures, such as those covered under the Physician Quality Reporting Initiative, and avoid unnecessary costs.

Medical costs in a US managed care cohort with oral antidiabetics maintenance therapy in type 2 diabetes patients who achieved HbA_{1c} <7.0

B.J. Pandya[1], M. Bron[1], A.P. Yu[2], K. Chen[2], E. Wu[2], A. Kaltenboeck[2], M. Mattson[2], S. Sun[1];
[1]Takeda Pharmaceuticals North America, Inc., Deerfield, [2]Analysis Group, Inc., Boston, United States.

Background and aims: One-year medical costs were evaluated for patients with type 2 diabetes mellitus (T2DM) treated with sulfonylurea (SU), pioglitazone (PIO), or metformin (MET) as maintenance therapy after achieving a target HbA1c < 7.0%.
Materials and methods: T2DM patients treated with SU, PIO, or MET monotherapy were identified in the Ingenix Impact database (01/01/00-03/31/07), a large managed care claims database including medical, pharmacy and enrollment records. Inclusion criteria were: 1) continuous insurance enrollment 6 months before and 12 months after the date of glycemic goal achievement of HbA1c < 7.0% (the index date); 2) a baseline HbA1c value > or = 7.0%; 3) exclusive use of the study medication during the 6-month baseline period; 4) at least one drug refill after the index date; and 5) age 18 years or greater at the index date. Medical, pharmacy, and total costs were compared over the 1-year post-goal achievement period using a non-parametric Wilcoxon test. Subgroup analysis was performed among patients with 24 months of post-index continuous insurance enrollment. A generalized linear model with log-link function and gamma distribution was used to compare costs when adjusting for baseline characteristics such as demographics, prior comorbidities, medications, and resource utilization.
Results: Final cohorts included 1,869 SU, 427 PIO, and 1,163 MET patients. Over the first year of follow-up, descriptive results showed numerically higher medical costs for SU patients (8,362 US dollars) than PIO patients (6,881 US dollars) and MET patients (8,198 US dollars), $P<0.05$. Specific components of the medical costs that were lower for the PIO cohort compared to the SU cohort included diabetes-related costs, emergency-room costs, office visits, and inpatient costs, although these were not all statistically significant. Using multivariate regression, PIO patients had risk-adjusted medical costs of 7,849 US dollars, which was 1,298 US dollars ($P=0.0211$) less than medical costs for SU patients (9,147 US dollars). MET patients had risk-adjusted medical costs of 8,174 US dollars, which was 973 US ($P=0.0155$) lower than medical costs for SU patients. Risk-adjusted total healthcare costs (including prescription and medical costs) were 12,083 US dollars for SU, 12,146 US dollars for PIO, and 11,543 US dollars for MET. Neither of these comparisons were statistically significant. Among the subgroup of patients with 24 months of post-index continuous insurance enrollment, PIO showed risk-adjusted medical costs of 16,251 US dollars while SU showed medical costs of 20,435 US dollars, a 2-year cost savings for PIO of 4,184 US dollars ($P=0.0110$). MET also showed lower 2-year medical costs (18,170 US dollars) compared to SU.
Conclusion: Patients receiving PIO as maintenance therapy incurred significantly lower risk-adjusted 1- and 2-year medical costs compared with patients receiving SU as maintenance therapy after glycemic goal achievement in the US managed care setting.

The high prevalence of malnutrition and unnecessary drug therapy in very old diabetic patients

U.M. Vischer, S. Ardigo, L. Perrenoud, C. Genet, Y. Registe-Rameau, F.R. Herrmann;
Dept of Rehabilitation and Geriatrics, Geneva University Hospitals, Thônex/Geneva, Switzerland.

Background and aims: Type 2 diabetes usually occurs in the context of obesity and associated insulin resistance. Current treatment recommendations are based on lifestyle modifications and incremental drug therapy to achieve optimal glycemic control. However, this approach may lead to inappropriate priorities upon aging, when diabetes may be compounded by malnutrition.

Materials and methods: We undertook a systematic evaluation of glycemic and nutritional parameters in a cohort of very old diabetic patients admitted to our geriatric service. We also implemented nutritional support therapy and a scheme of drug therapy adjustment. Oral hypoglycemic agents (OHA) withdrawal was attempted in case of good glycemic control (HbA1c <7.5% or fasting blood sugar (FBS) <7.5 mmol/l) or when contra-indications to OHA were present.
Results: 80 diabetic patients (mean age 82.8+7.4 years, 22% men, 78% women) have been included in this ongoing survey. Mean BMI was 29.6+6.6 kg/m2, and mean HbA1c was 6.8+1.2%. 75% patients had an HbA1c 85% of which on metformin), 33% on insulin and 5% on combined insulin/OHA therapy. Malnutrition, as evidenced by a MNA (Mini nutritional Assessment) score <23.5, indicating "Malnutrition" or "risk of malnutrition", was observed in 71% patients. Severe hypoalbuminemia (<30 g/l), usually without proteinuria, was observed in 49% patients. We also observed a high prevalence of vitamin B12 (< 200 pmol/l) and 25-hydroxy vitamin D (<30 nmol/l) deficiency (34 and 32% respectively). Among patients treated by OHA, complete drug withdrawal was attempted in 72% patients (mean HbA1c 6.2+1.0%, mean FBS 6.9+1.8 mmol/l), much more often than new drugs were added (p=0.002 by McNemar's test). In spite of in-hospital nutritional therapy, FBS remained <7.5mmol/l (mean value 6.6+1.0 mmol/l) at hospital discharge without new drug therapy in 78% patients.
Conclusion: The prevalence of malnutrition is high in very old diabetic geriatric patients. Malnutrition should be screened for in these patients, and when present should prompt a revision in diet and drug therapy. In particular, the possibility of reducing unnecessary drug therapy should be considered. Malnutrition and consequently reduced insulin resistance (occurring even in overweight/obese patients) is most likely a key factor for successful OHA withdrawal.

Effect of glitazones on cancer mortality in type 2 diabetes
S.L. Bowker[1], Y. Yasui[1], P. Veugelers[1], S.H. Simpson[2], J.A. Johnson[1];
[1]School of Public Health, [2]Department of Pharmacy, University of Alberta, Edmonton, Canada.

Background and aims: Numerous studies have observed an association between type 2 diabetes (T2DM) and cancer, with recent reports suggesting a modulating role of antidiabetic therapy. There is little epidemiologic information, however, exploring the effect of the glitazones and cancer mortality in T2DM. We hypothesized a decreased risk of cancer mortality associated with glitazones use, compared to sulfonylurea monotherapy use.
Materials and methods: This was a population-based retrospective cohort study using administrative data from Saskatchewan Health. We identified new users of metformin or sulfonylureas from January 1, 2000 to December 31, 2005, with follow-up until death, departure from the province, or December 31, 2006. We compared cancer mortality between glitazone users (plus metformin), metformin and sulfonylurea combination users, metformin monotherapy users, and sulfonylurea monotherapy users (reference group).A time-varying Cox analysis was used to estimate the hazard ratio (HR) of cancer mortality, accounting for oral antidiabetic therapy, insulin therapy, age, sex, and chronic disease score (CDS). Exposure to oral antidiabetic therapies was defined by use of each agent (i.e., yes/no) within 1-year time windows. We examined the dose-response gradient for insulin exposure. Firstly, we created a count of insulin dispensations for each 1-year time window. Cumulative insulin exposure/year was then calculated by summing insulin counts at the end of each year and dividing by the person years of insulin use since insulin index. We stratified the cumulative insulin exposure level into high, low, and no exposure to insulin.
Results: We identified 20,448 new users of metformin or sulfonylureas during the index period, with an average (SD) follow-up of 3.5 (1.8) years. The mean age for the cohort was 61.3 (14.3) years and 53.8% were men. Unadjusted cancer mortality was 9.8% (154/1,577) for sulfonylurea monotherapy users and 1.3% (43/3,365) for glitazone (plus metformin) users (p < 0.0001). After adjusting for age, sex, CDS, and insulin use, glitazone (plus metformin) users had a significantly lower risk of cancer mortality compared with the sulfonylurea monotherapy cohort (HR: 0.42, 95% CI: 0.24 - 0.72; p=0.002). The adjusted HRs (95% CI) for insulin use were 1.33 (0.83 - 2.13) and 7.08 (5.27 - 9.51) for <12 and ≥12 cumulative insulin dispensations/year, respectively, compared to those using no insulin.
Conclusion: These finding add further support that antidiabetic therapies may play a role in the relationship between type 2 diabetes and cancer outcomes. Our results suggest that patients with type 2 diabetes exposed to glitazones had a significantly decreased risk of cancer mortality compared to patients exposed to sulfonylurea monotherapy. It is uncertain whether this decreased risk is related to a protective effect of glitazones or a toxic effect of sulfonylureas.

Severe hypoglycaemia: are patients correctly selected for sulphonylurea therapy?
J.M. Ng, M. Ramlall, D. Mellor, B.J. Allan;
Diabetes Centre, Hull, United Kingdom.

Background: Hypoglycaemia is a well recognised side effect of some treatment modalities for diabetes mellitus, particularly in patients with tight glycaemic control. Recent NICE guidelines recommend hypoglycaemia advice for those with Type 2 Diabetes Mellitus (T2DM) before starting insulin or sulphonyurea therapy (SU).
Aims: To further define the different forms of therapy associated with hypoglycaemia and patient groups at greater risk.
Materials and methods: We performed a retrospective analysis of patients who developed severe hypoglycaemia in our Trust over a 4 month period. We included episodes of severe hypoglycaemia referred to the Diabetes service from Dec 2008 to March 2009. We defined severe hypoglycaemia as any hypoglycaemic event that required emergency services intervention. Data was also obtained from regional ambulance service. Trust approval was obtained prior to the commencement of the analysis
Results: A total of 76 patients suffered severe hypoglycaemia over the study period. The median age was 63 years (IQR 43 to 78 years) and 40 patients were male and 36 female. The median HbA1c was 8.1%. (31 T1DM, 33 T2DM, 11 not recorded, 1 non diabetic). Of the 76 patients, 61 (80%) patients were taking insulin (56 on insulin only and 5 in combination with Metformin), 10 (13%) patients were taking SU (5 with Metformin and 2 with thiazolidinediones(TZD)) and 1 patient on both insulin and SU. Therapy in 3 patients was not recorded and 1 patient developed hypoglycaemia due to severe liver failure. The results of the analysis is summaried in Table 1 and Table 2. When the SU treated and non SU treated group was compared, patients on SU were significantly older and had significantly lower HbA1c. Five patients in the SU group had HbA1c levels < 6.0%.
Conclusion: Our analysis shows that almost 15% of patients who suffered from severe hypoglycaemia were on SU therapy. Patients from this group were more elderly and had lower levels of HbA1c's. This study is inherently limited by its retrospective component and relatively small numbers. However, we feel that whilst the use of SUs are effective in the treatment of T2DM, caution is advised when considering this therapy in the more elderly population in particular those with tight glycaemic control. Access to self capillary glucose monitoring and crucially the ability to recognise and treat this condition must be considered when commencing treatment with SU in each individual patient. Whilst national HbA1c targets are useful for clinicians to ascertain glycaemic targets, this should not apply in all cases.

Table 1 * Mann Whitney U

	Type 2 Patients On Insulin (T2I)	Type I Patients	Type 2 Patients on Sulphonylurea (T2S)	p value p1: T2I vs T2S p2 = T1 vs T2S

Older patients with newly diagnosed type 2 diabetes are less likely to be treated with oral antihyperglycaemic agents compared to younger patients
S. Rajagopalan[1], E. Marrett[2], L. Radican[2], Q. Zhang[2];
[1]MedData Analytics Inc, Williamsville, [2]Global Outcomes Research and Reimbursement, Merck & Co., Inc, Whitehouse Station, United States.

Background and aims: This study compared older (≥ 65 yrs) and younger patients with newly diagnosed type 2 diabetes (T2DM), and evaluated factors associated with oral antihyperglycemic agent (OAHA) initiation.

Materials and methods: This is a retrospective cohort study using the General Electric (GE) Centricity electronic medical record database in the US. Patients aged ≥30 yrs with newly-diagnosed T2DM (Jan 2003 to Dec 2005) were included. Newly-diagnosed was defined as no diabetes diagnosis or treatment within 2 years prior to the new T2DM diagnosis. Their medical records 1 year prior to (baseline) and 2 years after (follow-up) diagnosis were extracted. OAHA initiation was estimated based on the first OAHA prescription during follow-up. Multivariable Cox proportional hazards regression model was fitted. Untreated patients were censored at the end of 2 years follow-up.
Results: Among 10,760 newly-diagnosed T2DM patients, 55% were female, 43% Caucasian. The mean age at T2DM diagnosis was 61.3(±12.5), with 4,617 (43%) ≥65 yrs. At baseline, older patients relative to younger patients had lower HbA_{1c} (6.7% vs. 7.2%, with only 38% vs. 32% attaining HbA_{1c} <7% goal), fasting blood glucose (117.9 vs. 132.8 mg/dL) and BMI (30.6 vs. 35.2), higher rates of acute myocardial infraction (MI) (2.1% vs. 0.9%), heart failure (5.1% vs. 1.8%), stroke (3.1% vs. 0.8%), and renal disease (17.5% vs. 6.2%), and more co-medications (all p-values <0.05). Within the 2 years after T2DM diagnosis, 56% older and 40.5% younger patients (P<0.001) had not received OAHA. Older patients were 16% less likely to be treated than younger patients (adjusted hazard ratio 0.84, p<0.001). Additionally, patients with MI or renal disease at baseline were less likely to be treated (p<0.05). Higher BMI or HbA_{1c} at baseline, and heart failure, initiating antihypertensive or lipid lowering drugs after T2DM diagnosis were factors associated with increased likelihood of OAHA treatment (p<0.05).
Conclusion: This study found that older patients with newly diagnosed T2DM had milder hyperglycemia but more comorbid conditions, and experienced more delayed OAHA therapy than younger patients.

The effect of nateglinide combined with metformin on the repairment of abnormal glucose tolerance in new-onset type 2 diabetic patients and its mechanisms
B.-C. Chang, M.-Y. Zheng, L.-M. Chen;
Diabetic Nephrology, Tianjin Medical University Metabolic Diseases Hospital, China.

Background and aims: To analyze the effects of nateglinide combined with metformin on the repairment of abnormal glucose tolerance as well as insulin resistance and islet β cells' early phrase insulin secretion in patients with new-onset type 2 diabetes mellitus.
Materials and methods: 60 new-onset type 2 diabetic patients were divided into nateglinide combined with metformin group(nateglinide group, 32 patients)and acarbose combined with metformin group(acarbose group, 28 patients)randomly. Oral glucose tolerance test and insulin releasing test were performed before and after 4 months' treatment. We compared oral glucose tolerance before and after treatment and observed the changes in insulin resistance, islet β cells' insulin secretion and glucose disposition index. The insulin resistance was evaluated by the ratio of area under insulin curve/area under glucose curve (AUC_I / AUC_G) and HOMA-IR. HOMA-β,MBCI ,early phrase insulin secretion (represented by ΔI30/ΔG30) and the second-phase insulin secretion (represented by AUC_I)were calculated to estimate islet β cells secretary function.
Results: After 4-month treatment, 1 case restored normal glucose tolerance and 7 cases changed from diabetes to impaired glucose tolerance in the nateglinide group, the AUC_G decreased from 30.21±7.47 to 27.45±5.91(P<0.05); 5 cases changed from diabetes to impaired glucose tolerance in the acarbose group, the AUC_G decreased from 7.45±6.15to24.86±4.96(P<0.05). Before treatment, no statistical difference existed in blood glucose level during OGTT between the two groups. After 4-month treatment, the peak blood glucose value was observed at 60-minute point during OGTT in the nateglinide group and at 120-minute point in acarbose group. Compared with pretreatment, HOMA-IR was obviously improved in the two groups, it changed from 8.29±1.64 to 7.09±1.27(P<0.01)in the nateglinide group and 8.41±1.82 to 6.89±1.31(P<0.05)in the acarbose group; The longer the course of disease, the lower MBCI appeared in the two groups(P>0.05). After treatment, the HOMA-βdecreased slightly in the two groups(P>0.05); and the $\Delta I_{30}/\Delta G_{30}$ was recovered from 5.03±0.85 to 6.72±0.79(P<0.05)in the nateglinide group, compared with the acarbose group, the $\Delta I_{30}/\Delta G_{30}$ was also extremely improved after treatment(P<0.05). The AUC_I in the two groups was decreased after treatment(P<0.05). After 4-month treatment, the peak serum insulin level was observed at 60-minute point during OGTT in the nateglinide group and at 120-minute point in acarbose group, and there is statistical difference at 60min,120min and 180min points during OGTT between this two groups. The DI increased from 0.711±0.161 to 0.964±0.206(P<0.01)in the nateglinide group.
Conclusion: The treatment of nateglinide combined with metformin ameliorated impaired glucose tolerance in patients with new-onset type 2 diabetes mellitus via improving the insulin resistance and promoting the recovery of islet β cell's first phrase insulin secretion.

903

The efficacy of lowering HbA_{1c} with a gliclazide modified release-based intensive glucose lowering regimen in the ADVANCE trial
J. Chalmers[1], M. Marre[2], B. de Galan[1,3], S. Zoungas[1,4], P. Hamet[5], B. Neal[1], N. Poulter[6], A. Patel[1];
[1]The George Institute for International Health, Sydney, Australia, [2]Hopital Bichat-Claude Bernard, Universite Paris, France, [3]Rabdoud University Nijmegen Medical Centre, Netherlands, [4]Monash University, Melbourne, Australia, [5]Centre Hospitalier de l'Universite de Montreal, Canada, [6]Imperial College, London, United Kingdom.

Background: Intensive glucose control with a gliclazide modified release (MR)-based regimen in people with type 2 diabetes in the ADVANCE trial (Action in Diabetes and Vascular disease: Preterax and Diamicron Modified Release Controlled Evaluation), reduced the risk of combined microvascular and macrovascular events, predominantly through reductions in the development of new or worsening nephropathy. In the present analyses we assess the efficacy of this strategy in reducing glycated haemoglobin (HbA1c) to the target level of 6.5%.
Methods: All 11,140 patients randomised to receive either intensive (n=5,571) or standard glucose control (n=5,569) were included in analyses of treatment efficacy as either the absolute HbA1c reduction, the HbA1c level achieved or the percentage of patients reaching various HbA1c targets (<=7.0%, <=6.5% and <6.0%) at the end of follow-up (median 5 years). Simple linear and multiple regression models were also used to assess treatment efficacy in those assigned to intensive glucose control according to subgroups defined by age, duration of diabetes, body mass index (BMI), HbA1c level and glucose lowering treatment (diet alone, monotherapy or combination therapy with 2 or more oral hypoglycaemic drugs) at study entry.
Results: At the last study visit, HbA1c was reduced to a mean of 6.5% with 81, 65 and 21% achieving HbA1c levels of <=7.0%, <=6.5% and <6.0% respectively in those assigned to intensive glucose control, amongst whom, 70% were receiving the maximum daily dose of gliclazide MR of 120mg. In those assigned to standard control, HbA1c was reduced to7.3% with only 50, 29 and 8% achieving comparable HbA1c levels. With intensive glucose treatment, substantial reductions in HbA1c were observed across all subgroups defined by baseline age, duration of diabetes, BMI, HbA1c or glucose lowering treatment at study entry (all p<0.0001). By the end of the study HbA1c was reduced to 6.1% in those receiving gliclazide MR alone, 6.4% in those on other oral regimens including gliclazide MR and 6.8% in those also requiring insulin. In a model including all these baseline variables, HbA1c and BMI emerged as the only independent predictors of reduction in HbA1c (p<0.001). While severe hypoglycaemia was more frequent in the intensive control group, it was uncommon overall (0.7 vs. 0.4 episodes per 100 patient years in the intensive versus standard care groups). Furthermore the reductions in HbA1c were achieved without weight gain.
Conclusion: Intensive glucose control with a gliclazide MR-based regimen was effective in lowering HbA1c, irrespective of age, duration of diabetes, BMI or HbA1c at study entry, and irrespective of initial glucose lowering treatment. The decrease in HbA1c was more marked in those with higher HbA1c levels and lower BMI at baseline. This regimen was well tolerated with acceptable rates of severe hypoglycaemia and without weight gain.

Cost-related medication underuse and perceptions about medication in patients with type 2 diabetes
E.J. Edson, R.P. Hayes;
Global Health Outcomes, Eli Lilly and Company, Indianapolis, United States.

Background and aims: Medication adherence may be linked to improved outcomes in people with type 2 diabetes. Previous research has identified

multiple factors influencing cost-related medication underuse (that is, taking less medication than prescribed due to costs) such as patient-provider communication, health literacy, income, and prescription drug coverage. Patients' perceptions about their diabetes medication, such as perceived side effects and convenience, may also be factors in affecting cost-related medication underuse. The objective of this study was to determine the association between perceptions about diabetes medication and cost-related medication underuse in patients with type 2 diabetes.
Materials and methods: A United States-based online survey was administered to participants with type 2 diabetes. Survey measures included the validated Perceptions about Medication for Diabetes-25 (PAMD-25) instrument containing four scales: Perceived Effectiveness, Convenience and Timing, Emotional Side Effects, and Physical Side Effects. Higher scores indicate more positive perceptions about medication for all scales except for the Physical Side Effects scale where higher scores indicate more negative perceptions about medication. Two items exploring the participants' perceptions of the amount paid for diabetes medication as being reasonable/unreasonable and financially draining/not draining were also included. Covariates included socio-demographic information, patient characteristics such as general health status, physician-patient prescribing relationship, polypharmacy, and financial factors such as out of pocket costs for diabetes medication. Analyses were based on binary logistic regression models to test univariate effects of the perceptions about medication and covariates on cost-related medication underuse, the dependent variable. Significant factors were entered in a forward stepwise logistic regression analysis to determine the effect of diabetes medication perceptions on cost-related medication underuse while controlling for covariates. Significance was determined at $p < 0.05$ for all analyses.
Results: The analytic sample included 604 participants (male = 53.0%; Caucasian = 85.6%; mean age [SD] = 58.6 [11.5] years). Overall, 61 subjects (10.1%) reported cost-related medication underuse. All four scales of the PAMD-25 were significant variables in the univariate regression analyses: Perceived Effectiveness (OR = 0.58; 95% CI, 0.41 - 0.83, $p < 0.01$), Convenience and Timing (OR = 0.27; 95% CI, 0.18 - 0.42; $p < 0.001$), Emotional Side Effects (OR = 0.32; 95% CI, 0.22 - 0.45; $p < 0.001$), and Physical Side Effects (OR = 2.07; 95% CI, 1.61 - 2.66; $p < 0.001$). Also significant were the statements that the amount paid for diabetes medication was reasonable as compared to unreasonable (OR = 0.15; 95% CI, 0.09 - 0.26; $p < 0.001$) and that the amount paid was not financially draining (OR = 0.08; 95% CI, 0.05 - 0.14; $p < 0.001$). Controlling for covariates, Emotional Side Effects (OR = 0.45; 95% CI, 0.28 - 0.72; $p < 0.01$) and stating that the amount paid for diabetes medication was not financially draining (OR = 0.19; 95% CI, 0.09 -0.40; $p < 0.001$) retained their significance in the final model (Nagelkerke $R^2 = 0.42$).
Conclusion: Patients' perceptions about diabetes medication, particularly emotional side effects and perceived financial burden, may moderate the effects of other factors such as income and insurance coverage on patients' response to medication cost pressures.

PS 76 Clinical aspects of insulin therapy

905

Predictors of responders to insulin therapy at one year among adult patients with type 2 diabetes: a retrospective study
I. Idris[1], I. Seetho[1], V. Owen[2];
[1]Diabetes and Endocrinology, Sherwood Forest Hospital Foundation Trust, Sutton in Ashfield, [2]Trent RDSU, University of Nottingham, United Kingdom.

Background and aims: Among patients with type 2 diabetes (T2D), the decision to initiate insulin often becomes necessary when lifestyle intervention and oral pharmacotherapy have failed to achieve glycaemic targets. The effectiveness of insulin therapy to lower blood glucose levels however may depend on a variety of factors. This study aims to determine baseline parameters that might predict responders to insulin therapy.
Materials and methods: This was a retrospective UK population based study derived from 358 general practices electronic dataset. We used standardised computerised routines to extract codes data on demographic, medical, biochemical and drug prescription history. T2D was defined as non-insulin requiring within 12 months of diagnosis. We included all patients with T2D, diagnosed at the age of >18 years old and who were initiated on insulin from January 2000 to December 2006. Insulin responders were defined as HbA1c of <7.5% and/or HbA1c reduction by >1% at 12 months post insulin initiation.
Results: Mean (SD) 6032 patients were identified. Baseline age was 63.7(11.7). 61% of patients (3696) responded to insulin therapy. At 1 year post insulin initiation, HbA1c was significantly reduced (9.8 v 8.4%, P<0.001) and BMI increased (30.3 v 31.1, P<0.001). Using a logistic regression model, older age (P<0.001), lower BMI (P=0.046), higher Hba1c (P<0.001) and basal bolus insulin therapy and premixed insulin, compared to basal insulin alone at baseline were independent predictors of responders to insulin. Gender and Townsend quartile were not significant predictors of insulin responders. A BMI of <35.3 was derived as a cut-point for response to insulin (P=0.038)
Conclusion: Overall, insulin therapy confers significant HbA1c reduction and weight increase in patients with T2D. In this cohort, responders to insulin at 1 year was seen in 61% of patients.The responsiveness to insulin therapy appears to depend on a variety of baseline factors which includes age, BMI, HbA1c and insulin regime. Clinicians should to take these factors into account when making a decision to initiate insulin therapy in patients with T2D.

906

Treatment satisfaction was impaired in patients with diabetes type 2 using ICT with human insulin and who were obliged to keep a regular injection to meal interval. A randomised cross-over study
T. Frank[1], N. Müller[2], C. Kloos[2], G. Wolf[2], U.A. Müller[2];
[1]Gemeinschaftspraxis, Merseburg, [2]Department of Internal Medicine III, University Hospital Jena, Germany.

Aims: In the pre-analogue-insulin era diabetic patients were usually instructed to keep an injection meal interval (IMI) of 20-30 minutes to compensate for the delayed onset of the action of regular insulin. All studies examining IMI were performed exclusively in patients with diabetes mellitus type 1. We studied the influence of IMI on HbA1c and hypoglycaemia in patients with diabetes mellitus type 2 (DM2).
Patients/methods: In a randomized cross-over-study (ClinicalTrials.gov NCT00529165) 100 patients with DM2 (age 66.9 years; diabetes duration 12.7 years; HbA1c 7.1%; 93% keeping an IMI before study-onset) on prepandial insulin therapy with human insulin (minimum 1 year) and stable glycaemic control, were randomised in two groups (Group A: IMI 20min then no IMI, group B: no IMI then IMI 20min). All patients were obligated to attend 8 visits during the study, 4 visits in each period. Visit 4 (V4) took place after the first period, before the cross-over was initiated, visit 8 (V8) at study end. Treatment satisfaction was assessed with the DTSQ (C. Bradley, max. score 33) and diabetes dependent quality of life with the ADDQoL (C. Bradley). The study was performed in a general practice. The dropout rate was 4%.
Results: At baseline HbA1c in group A was 6.96 vs. group B 6.85% (p=0.437) Treatment satisfaction (max. score 36) was in group A: 32.5 vs. group B 33.3;

(p=0.165). In period 1 treatment satisfaction increased more in the group without IMI than with IMI (9,4 vs. 4,2 points; p=0.001). After cross-over treatment satisfaction decreased in the group without IMI (period 1 IMI 20min) by 1.9 points and increased substantially in the group without IMI (period 1 IMI 20min) by 9.0 points (p=0.001). Diabetes dependent quality of life did not show differences at any time during the study, regardless of doing an IMI or not, neither did HbA1c nor hypoglycaemia. At the end of the study 86.5% of the patients decided against a meal injection interval,, irrespective of having or not having applied an IMI during the last study period.
Conclusion: Treatment satisfaction in patients with diabetes mellitus type 2 and good glycaemic control on preprandial therapy with human regular insulin is lower with a meal injection (IMI) interval of 20 minutes compared to insulin injection immediately before the meal and did not improve HbA1c. Diabetes dependent quality of life is not influenced by an IMI. Hence, a meal-injection-interval can not be regularly recommended for patients with type 2 diabetes on? preprandial therapy with human regular insulin.

907

Randomized 2-phases-crossover-study to examine the necessity of an injection-to-meal-interval in patients with diabetes mellitus type 2 and flexible insulin therapy with human insulin

N. Müller[1], T. Frank[2], C. Kloos[1], G. Wolf[1], U.A. Müller[1];
[1]Dept. Internal Medicine III, University Hospital Jena, [2]Primary Care Physician, Merseburg, Germany.

Background and aims: In the pre-analogue-insulin era diabetic patients were usually instructed to use an interval of 20-30 minutes between injection and meal to overcome the slow onset of regular insulin preparations. All studies deal with injection-meal-intervals (IMI) in patients with diabetes mellitus type 1. We studied influence of IMI on HbA1c and hypoglycaemia in patients with diabetes mellitus type 2 (DM2).
Materials and methods: In a randomized Cross-over-Study (ClinicalTrials.gov NCT00529165)with two phases of 3 months 100 patients with diabetes type 2 (age 66.9 years; diabetes duration 12.7 years; HbA1c 7.1%; 93% keeping IMI) on prepandial insulin therapy with human insulin (minimum 1 year) have been randomized to group A (Phase 1: IMI 20min, Phase 2: no IMI) or group B (Phase 1: no IMI, Phase 2: IMI 20min). All patients received 8 visits, visit 4 (V4) was after phase 1 and visit 8 (V8) was after phase 2. The study was held in a general practice. The drop out was 4%. The study was powered on the expectation that 100 patients would be evaluated. This had 80% power to detect no difference of HbA1c (α=0.15).
Results: HbA1c was not different at baseline (V1: A: 6.96 vs. B 6.85%; p=0.437) neither at the end of phase 1 (V4: 6.70 vs. 6.76%; p=0.669) nor at the end of phase 2 (V8: 6.73 vs. 6.83%; p=0.434). In group A HbA1c decreased in phase 1 (IMI 20min) 0.32% (p=0.001) and increased in phase 2 (no IMI) 0.13% (p=0.005). In group B HbA1c decreased in phase 1 (no IMI) 0.09% (p=0.097) and did not change in phase 2 (IMI 20min). The incidence of mild hypoglycaemia did not differ between group with IMI or no IMI at any time of the study (V1: 0.69 vs. 1.04; p=0.367; V4: 0.81 vs. 0.67; p=0.578; V8: 0.79 vs. 0.73; p=0.836). In group A the incidence of hypoglycaemia increased in phase 1 (IMI 20min) by 0.12 episodes per month (p=0.604) and decreased in phase 2 (no IMI) by 0.08 (p=0.647) and decreased in group B phase 1 (no IMI) by 0.37 (p=0.276) and increased in phase 2 (IMI 20min) by 0.125 (p=0.612). There was no case of severe hypoglycaemia in the study.
Conclusion: We did not find differences in HbA1c or mild hypoglycaemia if patients obey an injection-to-meal-interval or not. Marginal, clinical not relevant changes in HbA1c and mild hypoglycaemia were observed within the groups. An injection-to-meal-interval is not necessary for patients with type 2 diabetes and preprandial therapy with human regular insulin.

908

Real-life prescription patterns of insulin for patients with type 2 diabetes in The Netherlands

E.M. Heintjes[1], A.W. Plat[1], T. Lyager Thomsen[2], T.E. Christensen[2], F.J.A. Penning-van Beest[1], R.M.C. Herings[1];
[1]PHARMO Institute, Utrecht, Netherlands, [2]Global Marketing, Novo Nordisk A/S, Virum, Denmark.

Background and aims: Studies have suggested that in type 2 diabetes (T2D) insulin analogues may improve the balance between glycaemic control and hypoglycaemia compared with human insulins; for example, basal analogues provide similar glycaemic control with less hypoglycaemia. The aim of this study was to assess the real-life prescription patterns of insulin use in patients with T2D in The Netherlands, in particular with respect to the prescribing of human insulins or analogues.
Materials and methods: The PHARMO database contains community pharmacy drug dispensing records from primary and outpatient secondary care for approximately 2.5 million patients in The Netherlands. We selected patients with T2D starting a new insulin treatment (human or analogue basal/premix/basal-bolus) in the period 2004-6. The patients were categorised into insulin-naïve users (no insulin in previous year) and prior users. We determined the insulin used at start for naïve and prior users. For prior users we also determined the insulin type used before start, to identify treatment changes.
Results: The study included 10,739 patients with T2D of whom 7116 (66.3%) were insulin naïve and 3623 (33.7%) were prior insulin users. Among the 7116 naïve patients 52.0% started on a basal regimen, 32.7% started on premixes and 15.3% started with a basal-bolus regimen (Table 1). Within each regimen type the majority of patients received analogues rather than human insulin (range 54.9-61.0%; overall proportion receiving analogues 58.7%). Among the 3623 prior insulin users 17.1% started on a basal regimen, 33.3% started on premixes and 49.6% started with a basal-bolus regimen. As with the insulin-naïve users the majority of patients received analogues rather than human insulin (range 67.3-87.4% among regimen types; overall proportion receiving analogues 74.1%). Of the 541 patients starting on basal analogues, 60.4% were switched from neutral protamine Hagedorn (NPH) insulin and 10.2% from human premix. Of 812 patients starting on premix analogues, 33.0% were switched from human premix, 26.7% from NPH insulin and 26.1% from basal analogue. Of 1331 patients starting on basal-bolus analogues, 48.0% were switched from human basal-bolus and 13.2% from human premix.
Conclusion: Among patients with T2D starting a new insulin treatment the majority were prescribed an insulin analogue, which indicates that both general practitioners and internists in The Netherlands prefer long-acting insulin analogues or analogue premixes over human insulin.
Table 1. Proportions of patients starting on different insulin regimens and using human or analogue insulins within each regimen.

Table 1

	Insulin naïve N=7116		Prior users N=3623	
New regimen	**n**	**%**	**n**	**%**
Basal[a]	**3702**	**52.0**	**619**	**17.1**
Neutral protamine Hagedorn[b]	1444	39.0	78	12.6
Basal analogue[b]	2258	61.0	541	87.4
Premix[a]	**2324**	**32.7**	**1206**	**33.3**
Human[b]	1002	43.1	394	32.7
Analogue[b]	1322	56.9	812	67.3
Basal-bolus[a]	**1090**	**15.3**	**1798**	**49.6**
Human[b]	492	45.1	467	26.0
Analogue[b]	598	54.9	1331	74.0

Sex differences in insulin dose and postprandial glucose (PPG) as BMI increases in patients with type 2 diabetes (T2D)

L. Jovanovic[1], C.R. Heilmann[2], M.S. Lewis[2], L.B. Lacaya[2], A.L. Peters[3], J.A. Jackson[2];
[1]Sansum Diabetes Research Institute, Santa Barbara, [2]Lilly USA, LLC, Indianapolis, [3]Keck School of Medicine of the University of Southern California, Los Angeles, United States.

Background and aims: To make sex-specific comparisons of efficacy and safety, which are rarely included in the development and reporting of clinical trials (CTs) in T2D.
Materials and methods: This post-hoc analysis examined sex differences in efficacy and safety parameters within groups of patients on lispro mixtures twice daily (BID) (LMBID, n=319) or three times daily (TID) (LMTID, n=344), basal bolus therapy (BBT=glargine [G] with lispro TID, n=184), NPH (n=355),

or G (n=203). An integrated CT database was evaluated for CTs which were at least 12 weeks in duration and included only insulin-using T2D patients (±oral agents). Six such trials were identified and used for this analysis.
Results: At endpoint, with increasing baseline BMI, 2-h PPG (LMBID) and insulin dose (LMBID and NPH) were significantly different in women vs men (figure-LMBID), although change in HbA1c was not significantly different. For NPH-treated patients, weight gain was also greater in women than men (all LS mean±SE) (1.45±0.23 vs 0.21±0.29 kg; p=0.005). With LMTID, women had lower endpoint 2-h PPG after lunch and dinner than men (8.08±0.19 vs 8.66±0.18 mmol/l, p=0.028; and 8.55±0.21 vs 9.14±0.21 mmol/l, p=0.046, respectively), while women on LMBID and G had less hypoglycaemia (LMBID: 0.56±0.10 vs 0.87±0.11 episodes/patient/30 days, p=0.035; G: 1.06±0.19 vs 1.64±0.21 episodes/patient/30 days, p=0.042). BBT had no significant differences between sexes in any variables.
Conclusion: In conclusion, sex differences in response to insulin therapy in T2D appear to exist, and may have implications for the safety, efficacy, and optimal utilisation of insulin therapy. Thus, sex differences should be explored and considered in future CT design and analyses in diabetes.

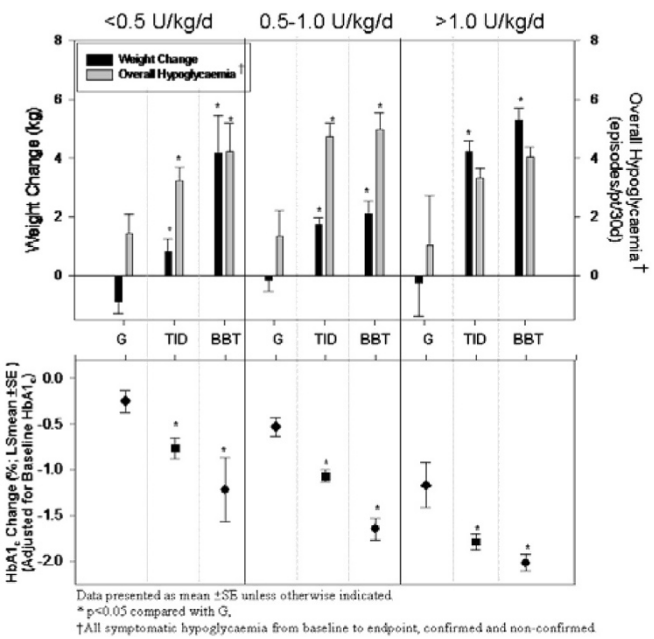
910

Escalating insulin dose with intensified insulin therapy regimens may achieve greater glycaemic efficacy than basal-only therapy, particularly in obese type 2 diabetes patients

J.A. Jackson[1], H. Jiang[1], L.B. Lacaya[1], M.S. Lewis[1], A.L. Peters[2], R.M. Bergenstal[3];
[1]Lilly USA, LLC, Indianapolis, [2]Keck School of Medicine of the University of Southern California, Los Angeles, [3]International Diabetes Center at Park Nicollet, Minneapolis, United States.

Background and aims: To investigate the relationship of endpoint insulin dose to baseline parameters, efficacy, and safety for different insulin regimens in type 2 diabetes (T2D).
Materials and methods: This pooled post-hoc analysis compared the effect of insulin dose and baseline BMI on change in $HbA1_c$, weight, and symptomatic hypoglycaemia between groups of T2D patients (pts) on glargine (G, n=159), lispro mixtures TID (LMTID, n=345), or basal bolus therapy (BBT=G with lispro TID, n=187). Two trials in an integrated CT database - one comparing G vs LMTID (n=317, baseline $HbA1_c$ 6.5-11.0%), and the other LMTID vs BBT (n=374, baseline $HbA1_c$ 7.5-12.0%)-met criteria of being 24 weeks in duration and including insulin-using T2D pts (±oral agents).
Results: For 3 insulin dose categories (≤0.5 U/kg/day [d], 0.5-1.0 U/kg/d, and >1.0 U/kg/d), the effects of G, LMTID, and BBT on change in $HbA1_c$ (adjusted for baseline $HbA1_c$), weight, and hypoglycaemia are shown in Figure 1. For reaching target $HbA1_c$<7.0%, therapies were similar when insulin dose was low (<0.5 U/kg/d), but for 0.5-1.0 U/kg/d, more pts on BBT reached $HbA1_c$<7.0% vs G (65% vs. 36%, p<0.05), and for >1.0 U/kg/d, more pts reached A1C<7.0% in both LMTID and BBT vs G (53% and 63% vs 21%, p<0.05). When pts were grouped by baseline BMI categories, insulin dose was larger with LMTID and BBT vs G (BMI<30 kg/m^2: 0.86±0.05 and 1.58±0.09 vs 0.54±0.07 U/kg/d; BMI ≥30 kg/m^2: 0.97±0.03 and 1.34±0.04 vs 0.63±0.05 U/kg/d; all LMTID and BBT p<0.05 vs G). $HbA1_c$ change mirrored insulin dose in LMTID and BBT vs G (BMI <30 kg/m^2: -1.0±0.1% and -1.7±0.2% vs -0.8±0.1%; BMI ≥30 kg/m^2: -1.4±0.06% and -1.6±0.08% vs -0.6±0.1%; all LMTID and BBT p<0.05 vs G). For BMI <30 kg/m^2, only BBT had more pts reach $HbA1_c$<7.0% vs G (74% vs 46%, p<0.05), while more pts reached $HbA1_c$<7.0% with both LMTID and BBT vs G at BMI ≥30 kg/m^2 (54% and 59% vs 32%, both p<0.05). LMTID and BBT also had significantly more weight gain and hypoglycaemia in both BMI categories (p<0.05). Severe hypoglycaemia did not differ between treatments at any insulin dose or baseline BMI category. A study limitation is that G and LMTID may have been less aggressively titrated in the first study than in the LMTID vs BBT study, which may understate the efficacy of G and LMTID and overstate the efficacy of BBT.
Conclusion: This post-hoc analysis suggests escalating insulin dose with intensified regimens may achieve greater $HbA1_c$ reduction and attainment of targets, especially in obese pts and those requiring ≥0.5 U/kg/d of insulin. Intensified insulin therapy may be associated with more weight gain and hypoglycaemia compared to basal-only therapy.



Data presented as mean ±SE unless otherwise indicated.
* p<0.05 compared with G.
†All symptomatic hypoglycaemia from baseline to endpoint, confirmed and non-confirmed

Basal insulin treatment of type 2 diabetes mellitus is associated with greater increases in satisfaction and HRQoL than treatment alternatives: an empirical review

J.M. Boltri[1], Q. Zhang[2], M.J. Atkinson[3], W.D. Smith[4], D.D. Smith[5];
[1]Department of Family Medicine, Mercer University School of Medicine/ Medical Center of Central Georgia, Macon, [2]sanofi-aventis, Bridgewater, [3]HEOR Specialist PRO-Spectus & UCSD Health Services Research Center, San Diego, [4]M.D. Anderson Cancer Center, The University of Texas, Houston, [5]Department of Biostatistics, City of Hope National Medical Center, Duarte, United States.

Background and aims: We examined current treatments for Type 2 diabetes mellitus (DM) to determine whether differences in patient-reported treatment satisfaction and HRQoL exist between three medication groupings (basal insulins, rapid acting insulin and oral agents).
Materials and methods: Data were obtained from an empirically-based systematic literature review of 280 randomized controlled trials (RCTs) of

treatments for Type 2 DM conducted since 1998. After restricting the articles to adult samples and removing duplicates, we identified 230 articles for consideration. Seventeen of these studies included measures of treatment satisfaction and/or health-related quality of life (HRQoL) in ways that allowed for the quantitative assessment of change-from-baseline treatment effects. Separate fixed-effects meta-analyses compared the standardized effect sizes of changes in patient outcomes within the RCT treatment arms of basal insulin (+/-OAD) vs. rapid acting insulin (+/- OAD) vs. oral agents.

Results: The effect sizes associated with change from baseline of treatment satisfaction outcomes were significantly greater among patients on basal dosing of intermediate and long acting insulin regimens (Std Diff in Means = .44 (95% C.I. .39 - .48) than the rapid acting insulin administered two or more times per day (Std Diff in Means = .15 (95% C.I. .091 - .20) or among patients on only oral medications (Std Diff in Means = .10 (95% C.I. .075 - .13). Within the injectable medication groups, treatment effects assessed across treatment satisfaction measures were larger than those associated with HRQoL measures (see Table).

Conclusion: Treatment satisfaction and HRQoL changes were highest among patients treated with basal insulin. We conjecture that Basal insulin may be associated with improved health status due to greater medication effectiveness; while greater patient satisfaction is due to less frequent dosing and lower self-monitoring requirements than regimens involving shorter acting insulin. Differences in the patient samples (e.g., by disease progression) could be an influential variable. Across all treatment types patients' responses to treatment satisfaction versus HRQoL scales may be differentially effected by response bias, since patients are often not blind to the efficacy of their medication, and by improvements in recently developed treatment satisfaction measures.

Patient Reported Dimension	Basal Insulin Std Diff in Mean (95% C.I.)	Rapid Insulin Std Diff in Mean (95% C.I.)	Oral Medications Std Diff in Mean (95% C.I.)
Treatment Satisfaction	.55 (95% C.I. .49 - .61) (8 studies, 1062 patients)	.29 (95% C.I. .18 - .38) (4 studies, 391 patients)	.05 (95% C.I. .008 - .098) (6 studies, 1871 patients)
Health Related QoL	.23 (95% C.I. .15 - .31) (4 studies, 327 patients)	.078 (95% C.I. .017 - .16) (4 studies, 231 patients)	.14 (95% C.I. .10 - .17) (4 studies, 698 patients)

Comparison of mealtime pramlintide, insulin, or a combination of both, when added to basal insulin treatment in patients with type 2 diabetes

D. Karounos[1], R. Pencek[2], W. Huang[2], S. Miller[2], K. Lutz[2], L. Porter[2]; [1]Lexington VA Medical Center & University of Kentucky College of Medicine, Lexington, [2]Amylin Pharmaceuticals, Inc., San Diego, United States.

Background and aims: Addition of mealtime injections of insulin to basal insulin therapy can increase glycaemic control for many patients with type 2 diabetes (T2DM); however, this approach increases the risks of weight gain and hypoglycaemia. Pramlintide can improve glycaemic control and reduce weight without increasing insulin-induced hypoglycaemia; therefore the addition of prandial pramlintide instead of or in conjunction with prandial insulin may offer additional therapeutic options for T2DM patients using basal insulin. This study examined the safety and efficacy of intensification of basal insulin therapy with prandial pramlintide (PRAM, 120 µg TID), rapid-acting insulin (RAI), or both agents.

Materials and methods: This was a randomised, open-label, multicenter, 36-week study in patients with T2DM (N=112, age 54 ± 11 y, HbA_{1c} 8.2 ± 0.8%, FPG 8.9 ± 2.5 mg/dL, BMI 36 ± 6 kg/m^2, mean ± SD) and it consisted of 2 phases. Phase 1 (24 weeks) compared PRAM with RAI when added to basal insulin. Phase 2 (12 weeks) explored additional prandial therapy for patients failing to achieve HbA_{1c} ≤6.5% at W24 (PRAM patients added RAI at W26, n = 31; RAI patients added PRAM at W26, n = 36). Patients with HbA_{1c} ≤6.5% continued their Phase 1 treatment (PRAM, n = 17; RAI, n = 14).

Results: In Phase 1, PRAM and RAI resulted in similar HbA_{1c} reductions (-0.9 ± 0.2% vs -1.1 ± 0.2%; LS mean ± SE) and FPG (6.7 ± 0.4 vs 6.8 ± 0.3 mmol/L) at Week 24 (W24), however significant weight gain was seen with RAI treatment (RAI: 4.2 ± 0.6 kg, p<0.001; PRAM: -0.3 ± 0.7 kg, p = 0.978 vs baseline). Throughout Phase 2, HbA_{1c} levels were stable for PRAM (6.3 ± 0.1% at W24 vs 6.4 ± 0.1% at W36) and RAI subjects (6.1 ± 0.1% vs 6.4 ± 0.1%). Despite the addition of another prandial agent, HbA_{1c} levels also remained relatively stable for combinations (PRAM+RAI: 7.7 ± 0.2% at W24 vs 7.4 ± 0.2% at W36; RAI+PRAM: 7.3 ± 0.2% at W24 vs 7.4 ± 0.2% at W36). No significant weight change occurred in Phase 2. Addition of PRAM in patients using RAI allowed a reduced RAI dose (38.6 ± 3.8 U/d at W24 vs 19.4 ± 3.2 U/d at W36). The incidence of hypoglycaemia was lower with PRAM compared to RAI (55% vs 82% in Phase 1; 41% vs 71% in Phase 2) with no severe hypoglycaemia. Patients on combination prandial regimens experienced comparable hypoglycaemic rates (PRAM+RAI, 58%; RAI+PRAM, 53%). Nausea was observed in some patients initiating PRAM (21% in Phase 1; 11% in Phase 2).

Conclusion: Compared with RAI, PRAM added to basal insulin therapy resulted in similar improvements in glycaemic control, a lower risk of hypoglycaemia, and no weight gain. Addition of the alternate prandial agent in Phase 2 resulted in maintenance of HbA_{1c} and weight. Addition of PRAM in Phase 2 for subjects on RAI in Phase 1 allowed a decrease in daily RAI dosage.

Day-to-day variation of insulin requirements in type 2 diabetic patients with end-stage renal disease treated by maintenance haemodialysis

S.T. Enoru[1], E. Sobngwi[1,2], G. Ashuntantang[1], M. Dehayem[1], M. Azabji[1], D. Biwole[1], A.E. Onana[1], M.D. Chobufo[1], G.E. Loni[1], J.-C. Mbanya[1]; [1]University of Yaounde 1, Cameroon, [2]Newcastle University, Newcastle upon Tyne, United Kingdom.

Background and aims: We aimed to evaluate day-to-day variations of insulin needs in Type 2 diabetic patients with end-stage renal failure on maintenance haemodialysis (HD), as significant glycaemic excursions are frequent in this population.

Materials and methods: We developed a 24-hour euglycaemic clamp applicable to free living conditions in patients receiving 2200 calories with 55% carbohydrate in a standardized 3-meal and 2-snack regimen per day. Insulin was infused intravenously at variable rates, adjusted every 30 minutes to clamp the glycaemia at 5.55±1.11mmol/l over 24 hours pre-HD, during HD session, and 24 hours post HD. We studied 10 volunteers (6 men and 4 women, age: 55.7±8.7 years, duration of DM: 11.9±4.5 years, BMI: 22.7±4.5kg/m2, dry weight: 61.6±10.7 kg, duration of HD: 2.3±2.3 years).

Results: The mean capillary glycaemia was 5.5±0.3mmol/l pre-HD and 5.3±0.2mmol/l post-HD (p=0.39). This was achieved with the infusion of 23.6±7.7 IU/24h pre-HD vs. 19.9±4.9 IU/24h post-HD, indicating an overall 15.3% decrease (p=0.09). The basal insulin needs per hour were decreased significantly from 0.4±0.1/hour pre-HD to 0.3±0.1/hour post-HD (p=0.01). The total boluses were decreased by 2.2±3.1 IU (-18.6%, p=0.15). The change in blood urea induced by HD did not correlate with the change in daily insulin needs (r=0.1, p=0.79).

Conclusion: In conclusion, the 15% reduction in insulin needs to achieve normoglycaemia after versus before HD observed in these type 2 diabetic patients , being equivalent to almost 4 IU per day is likely to be clinically significant despite marginal statistical significance. Further investigations with intermittent subcutaneous protocol based on the present results are warranted to further guide clinical practice recommendations.

PS 77 Safety of insulin therapy

914

Lower rate of hypoglycaemia but comparable glycaemic control with insulin detemir compared to NPH insulin in patients with type 1 diabetes

K. Hermansen[1], S. Heller[2], M. Andersen[3], D.L. Russell-Jones[4];
[1]Department of Endocrinology and Metabolism, Aarhus University Hospital, Denmark, [2]Endocrinology and Metabolism, School of Medicine and Biomedical Sciences, Sheffield, United Kingdom, [3]Statgroup DK, Copenhagen, Denmark, [4]Department of Diabetes and Endocrinology, The Royal Surrey Country Hospital NHS Trust, Guilford, United Kingdom.

Background and aims: In clinical trials, focus is often on efficacy, and these trials are rarely powered for analysis of difference in hypoglycaemia between treatment arms. Here we wish to present a meta-analysis to explore the relationship between glycaemic control as measured by last recorded HbA_{1c} on treatment and hypoglycaemia (plasma glucose level < 3.1 mmol/L) in subjects with type 1 diabetes treated with either insulin detemir (IDet) or NPH insulin (NPH) once or twice daily as the basal component of a basal-bolus therapy.
Materials and methods: Data were collected from seven randomised clinical trials more than 16 weeks (112 days) in duration reported up to March 2008 and with individual patient data (IPD) available. The trials included 1801 subjects on IDet and 1080 on NPH; treatment was from 16 to 104 weeks. A negative binomial regression model was used to analyses the number of hypoglycaemic episodes (last 90 days of treatment), with trial and treatment as factors, HbA_{1c} as covariate and log-transformed exposure time as offset. No heterogeneity was found (p=0.33 for test of trial and treatment interaction).
Results: As shown in the Forest plot a significantly lower rate of hypoglycaemia was estimated with IDet than with NPH (p<0.0001) which amounted to a lower estimated rate of hypoglycaemia of 19%. A model of HbA_{1c} versus hypoglycaemia indicates that the lower the HbA_{1c}, the larger the difference between treatments for risk of hypoglycaemia.
Conclusion: IDet was associated with a lower rate of hypoglycaemia than NPH at all levels of glycaemic control (HbA_{1c}).

915

Estimating number-needed-to-treat with insulin glargine compared with NPH insulin to avoid a hypoglycaemic episode in people with type 2 diabetes mellitus: a meta-analysis

P.D. Home[1], A. Fritsche[2], S. Schinzel[3], M. Massi-Benedetti[4];
[1]Institute of Cellular Medicine – Diabetes, Newcastle University, Newcastle upon Tyne, United Kingdom, [2]Medizinische Klinik IV, Universität Tübingen, Germany, [3]Sanofi-Aventis Deutschland GmbH, Frankfurt, Germany, [4]Department of Internal Medicine, University of Perugia, Italy.

Background and aims: Studies have shown that for similar blood glucose control, insulin glargine (glargine) is associated with a decreased risk of hypoglycaemia compared with NPH insulin (NPH) in type 2 diabetes mellitus (T2DM). We have evaluated the number of people needed to be treated (number-needed-to-treat [NNT]) with glargine vs NPH to save one person from experiencing hypoglycaemia based on a meta-analysis of trials comparing glargine with NPH.
Materials and methods: The formula $NNT=1/(p_N-p_G)$ was used, where p_N and p_G represent the risk of ≥1 hypoglycaemia episode in an NPH- or glargine-treated person, as derived from meta-regression adjusted for change in HbA_{1c}. Where NNT is large (>100), glargine is favoured over NPH, but the clinical advantage is small; where NNT is smaller (e.g. <20) the treatment difference is clinically important. Study selection criteria were: randomized, parallel-group design; basal glargine vs basal NPH (both with oral agents); comparable dosing regimens; ≥24-week duration. Hypoglycaemia rates (severe [study definition] or symptomatic with self-monitored levels of <2.0 or <3.9 mmol/l) were extracted and adjusted for HbA_{1c} change from baseline. Five comparative studies using evening injections (n=2641) were found and analyzed. A random effects model was used if there was significant heterogeneity (p≤0.100) between studies; otherwise a fixed effects model was used.
Results: Evening glargine vs NPH treatment resulted in a significantly lower risk of nocturnal hypoglycaemia for all categories (symptomatic <3.9 mmol/l, NNT=8, p<0.001 [OR=0.52, p=0.009]; symptomatic <2.0 mmol/l, NNT=107, p=0.008 [OR=0.44, p=0.003]; severe: NNT=112, p=0.047 [OR=0.52, p=0.0498]). Daytime symptomatic hypoglycaemia was to be numerically lower with glargine vs NPH (NNT=184, p=0.085 [OR=0.64, p=0.073] and NNT=35, p=0.136 [OR=0.88, p=0.136] with self-monitored plasma glucose <2.0 and <3.9 mmol/l, respectively), but these differences were not statistically significant.
Conclusion: Overall, these results confirm that glargine has the benefit of a risk reduction of nocturnal hypoglycaemia vs NPH, with one person in every eight treated avoiding a confirmed (self-monitored plasma glucose <3.9 mmol/l) nocturnal event, and additional avoidance of other events at lower frequency.

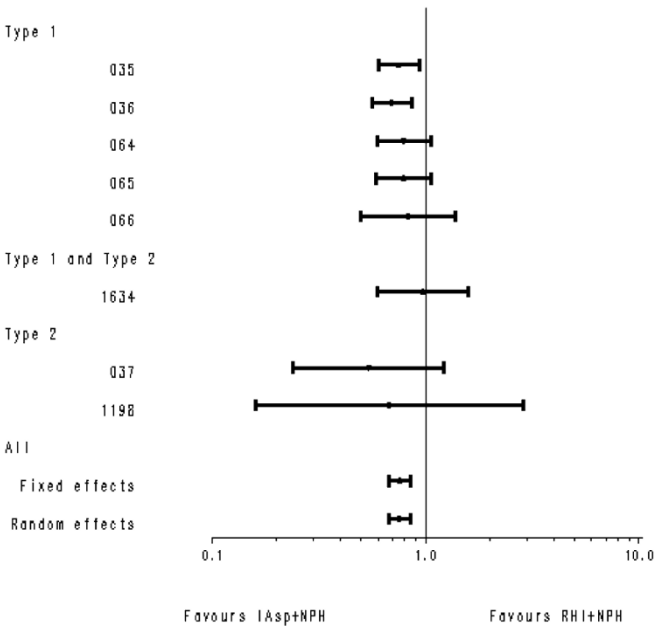
Examining the glycaemic and hypoglycaemic benefits with rapid-acting insulin analogues: a meta-analysis of insulin aspart versus regular human insulin in randomised controlled trials

S. Heller[1], B.W. Bode[2], P. Kozlovski[3], A. Svendsen[4];
[1]Endocrinology and Metabolism, School of Medicine and Biochemical Sciences, Sheffield, United Kingdom, [2]Emory University School of Medicine, Atlanta, United States, [3]NovoNordisk Medical & Science, Bagsvaerd, Denmark, [4]Biostatistics, NovoNordisk A/S, Bagsvaerd, Denmark.

Background and aims: A meta-analysis of the efficacy and safety of insulin aspart (IAsp) vs regular human insulin (RHI) in a basal-bolus regimen with NPH insulin in subjects with type 1 or type 2 diabetes was undertaken with focus on a comparison of rate of hypoglycaemia.
Materials and methods: Data were collected from 10 randomised, controlled clinical trials (≥ 12 weeks) including 3727 subjects (53.9% male), with mean age 41.4 year, mean body mass index 25.5 kg/m² and mean HbA_{1c} 8.2% at baseline. Change in HbA_{1c} was analysed in a linear mixed model using repeated measurements and a spline for time, with a knot at 12 weeks controlling for trial. Hypoglycaemic episodes were modelled using negative binomial regression.
Results: The model found a significant difference in HbA_{1c} in favour of IAsp+NPH after 12 weeks of treatment, with a fixed estimate = -0.10 CI [-0.15; -0.04], a difference that was maintained over the next 12 weeks. A statistical test showed that heterogeneity was not significant (see figure). After 12 weeks the average prandial blood glucose increment was significantly lower

with IAsp+NPH, overall estimate = -0.61, CI [-0.88; -0.34] whereas no group difference was found for change in fasting plasma glucose. The incidence of hypoglycaemic episodes (overall and daytime) was similar in both groups, but the risk of nocturnal episodes was significantly lower with IAsp+NPH; overall estimate = 0.76, CI [0.67; 0.85].
Conclusion: After 12 weeks of treatment and onwards, glycaemic control was modestly but significantly improved with IAsp+NPH compared to RHI+NPH. The risk of overall and daytime hypoglycaemia was similar with the two regimens, but with IAsp+NPH the risk of nocturnal hypoglycaemia was significantly lower by about 25%, a finding not reported in previous systematic reviews or meta-analyses



917

Basal/bolus with prandial inhaled Technosphere insulin plus insulin glargine vs biaspart 70/30 insulin in type 2 diabetes inadequately controlled on insulin with/without oral agents

L. Gnudi[1], D. Lorber[2], J. Rosenstock[3], C. Howard[4], R. Petrucci[4], D. Shearer[4], D. Bilheimer[4], P.-C. Chang[4], P. Richardson[4];
[1]Diabetes and Endocrinology, King's College London, United Kingdom, [2]Diabetes Care and Information Center of New York, Flushing, United States, [3]Dallas Diabetes and Endocrine Center, United States, [4]MannKind Corporation, Valencia, United States.

Background and aims: Technosphere Insulin (TI) is a fast-acting inhaled insulin with a pharmacokinetic profile well suited for earlier control of postprandial plasma glucose (PPG). This randomized, active-control, parallel-group study compared the efficacy and safety of basal/bolus prandial TI plus bedtime glargine insulin (G) vs. premixed biaspart 70/30 insulin BID (BPA 70/30) in type 2 diabetes mellitus inadequately controlled (HbA_{1c} >7.0% and ≤11.0%) despite insulin with or without oral antihyperglycemic therapy.
Materials and methods: Subjects were randomized to a 52-week course of TI+G (n=334) or BPA 70/30 (n=343) with insulin adjustments according to investigator discretion to achieve predefined glycemic goals but without enforcing a structured titration regimen. Primary outcome was change in HbA_{1c}. Secondary objectives were proportion of subjects reaching specific HbA_{1c} levels, PPG, and fasting plasma glucose (FPG).
Results: Mean baseline characteristics were similar for TI+G and BPA 70/30 (age 55.9, 55.9 years; disease duration 13.1, 13.6 years; baseline HbA_{1c} 8.7%, 8.7%; BMI 31.55, 31.07 kg/m^2). HbA_{1c} was reduced by 0.58% and 0.70% in the TI+G and BPA 70/30 groups (intent-to-treat last observation carried forward), respectively, and the proportion of subjects achieving HbA_{1c} <7.0% were comparable between treatments (22% vs. 27%). Mean FPG at week 52 was 7.8 mmol/l for the TI+G group and 8.7 mmol/l for the BPA 70/30 group, and the FPG change from baseline was 2.0 vs. 1.0 mmol/l (p=0.0029). The absolute 1-h PPG (9.5 vs. 11.6 mmol/l; p<0.0001) was significantly lower with TI+G. TI+G produced significantly less weight gain (0.9 vs. 2.5 kg; p=0.0002) and significantly less mild/moderate and severe hypoglycemia (Table). The final insulin doses were TI, 198 U (approximately equivalent to 53 IU of rapid-acting insulin); G, 47 IU; and BPA 70/30, 88 IU. Mean changes from baseline to week 52 in forced expiratory volume, forced expiratory vital capacity, and carbon monoxide diffusing capacity were similar in the two groups.
Conclusion: TI+G vs. BPA 70/30 resulted in comparable HbA_{1c} reductions but lower 1-h PPG with less weight gain and less hypoglycemia.

Hypoglycemia Incidence, Event Rate, and Odds Ratio

Hypoglycemia	Incidence (%)		Event Rate		Odds Ratio	Odds Ratio *p* Value
	TI+G	BPA 70/30	TI+G	BPA 70/30		
Mild/moderate	47.99	68.88	0.40	0.59	0.417	<0.001
Severe	4.33	9.97	0.01	0.02	0.409	<0.007
Total	47.99	68.88	0.41	0.61	0.417	<0.001

Reduced incidence and frequency of hypoglycaemia in an integrated analysis of pooled data from clinical trials of subjects with type 2 diabetes using prandial inhaled Technosphere insulin

D. Lorber[1], C. Howard[2], H. Ren[2], A. Rossiter[2], A. Boss[2];
[1]Diabetes Care and Information Center of New York, Flushing, [2]MannKind Corporation, Valencia, United States.

Background and aims: Technosphere Insulin (TI) is a rapid-acting insulin with a pharmacokinetic profile well suited for earlier control of postprandial plasma glucose (PPG). This integrated analysis includes the pooled data from six phase II/III clinical trials in subjects with type 2 diabetes mellitus inadequately controlled (HbA_{1c} ≥6.6% and ≤12.0%) despite insulin with or without oral antihyperglycemic therapy.
Materials and methods: Subjects were randomized to treatment regimens to achieve predefined glycemic goals: TI (n=1,795) or s.c. insulin (n=942), which included BPA 70/30, or insulin aspart and "usual care," with insulin adjustments according to investigator discretion in five trials and forced titration in one trial. A structured titration regimen was not enforced. When experiencing hypoglycemic-like symptoms, subjects were instructed to confirm the event with a blood glucose reading. Subjects experiencing a severe hypoglycemic episode were required to report the details of third-party assistance (if needed), the presence of neurologic symptoms, and the specifics of treatment.
Results: Mean baseline characteristics were similar for TI and s.c. insulin (age 56.2, 55.6 years; disease time since diagnosis 10.8, 12.4 years; baseline HbA_{1c} 8.82%, 8.84%; BMI 31.07, 31.07 kg/m^2). Subjects treated with TI experienced statistically significantly fewer hypoglycemic episodes in regard to both incidence and frequency compared with subjects treated with s.c. insulins. For incidence, significantly fewer subjects reported hypoglycemia with TI: 31.8% vs. 49.6% for total hypoglycemia; 31.6% vs. 49.4% for mild/moderate hypoglycemia; and 2.8% vs. 7.5% for severe hypoglycemia, with the three comparison p values <0.0001. For frequency, TI also had significantly fewer events, evaluated by event rate (number of events per 100 subject-months): 23.87 vs. 38.78 for total hypoglycemia (p<0.0001); 23.16 vs. 37.32 for mild/moderate hypoglycemia (p<0.0001); and 0.66 vs. 1.37 for severe hypoglycemia (p<0.0184).
Conclusion: TI, often in combination with a basal insulin, consistently reduced the incidence and frequency of both mild/moderate and severe hypoglycemic events under conditions of comparable glycemic control. The reduction in the risk of hypoglycemia in patients with type 2 diabetes under inadequate control may facilitate the introduction of insulin therapy.

Hypoglycemia	Incidence(%)		Odds Ratio	Odds Ratio *p* Value	Event Rate (per 100 subject-months)		Event Rate *p* Value
	TI	s.c. insulin			TI	s.c. insulin	
Mild/moderate	31.6	49.4	0.466	<0.0001	23.16	37.32	<0.0001
Severe	2.8	7.5	0.359	<0.0001	0.66	1.37	0.0184
Total	31.8	49.6	0.466	<0.0001	23.87	38.78	<0.0001

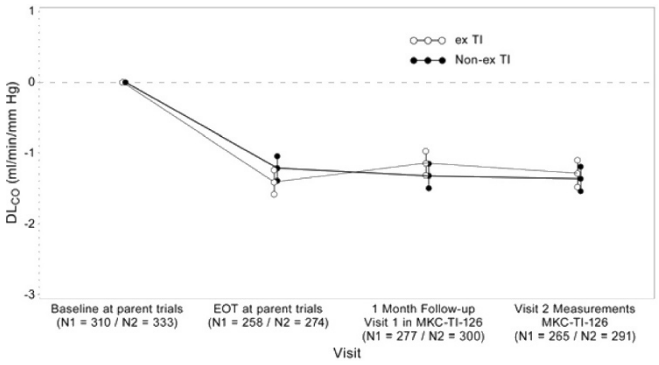
Pulmonary function tests remain similar in patients who received Technosphere insulin and in patients currently receiving standard antidiabetic therapy

R. Petrucci, N. Amin, P. Lovertin, A. Boss, P. Richardson;
MannKind Corporation, Valencia, United States.

Background and aims: Previous controlled clinical studies have demonstrated that regimens of basal insulin plus Technosphere Insulin (TI) were as effective as basal insulin plus rapid-acting s.c. insulin in patients with diabetes. In previously reported studies, we have been unable to detect a consistent change in pulmonary function tests (PFTs). Small but clinically non-significant differences have been observed. This clinical trial was designed to assess the changes in pulmonary function after cessation of TI therapy and resumption of standard antidiabetic treatment in patients with type 1 or type 2 diabetes.
Materials and methods: Adults with diabetes who participated in any of four controlled clinical trials of TI were invited to participate in this follow-up trial to evaluate changes in PFTs after completing the study and being switched to usual antidiabetic therapy without TI. Patients were followed for a total of 3 months after cessation of study therapy. PFTs were assessed at the end of the parent trial and 1 and 3 months after subjects completed the parent trial.
Results: Of 649 patients in this study, 315 subjects (121 with type 1 diabetes, 194 with type 2 diabetes) received TI and 334 subjects (129 with type 1 diabetes, 205 with type 2 diabetes) received the antidiabetic regimen without prandial TI during the parent trials. Small, non-progressive treatment group differences in mean changes from baseline in forced expiratory volume in 1 second (FEV_1) and carbon monoxide diffusing capacity (DL_{CO}) observed during the comparative phase of the controlled trials disappeared when comparing the two groups at 3 months after cessation of TI therapy and resumption of standard antidiabetic therapy (FEV_1: -0.08 l in the TI group, -0.11 l in the non-TI group [p=0.1388]; DL_{CO}: -1.29 ml/min/mm Hg in the TI group, -1.37 ml/min/mm Hg in the non-TI group [p=0.9360]). In addition, there was no statistical difference in FEV_1 between the two groups when examining subjects with type 1 and type 2 diabetes (p=0.6158 and p=0.1795, respectively).
Conclusion: These data suggest that the pattern and magnitude of PFT changes associated with the use of TI in subjects with type 1 and type 2 diabetes are not likely due to any structural alterations in the lungs and are not clinically meaningful.

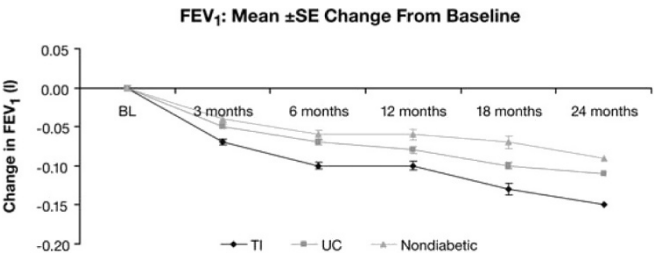


920

Pulmonary functions (over 2 years) in diabetic subjects treated with Technosphere insulin or usual antidiabetic treatment

M. Phillips, N. Amin, A. Boss, P. Richardson;
MannKind Corporation, Valencia, United States.

Background and aims: Technosphere Insulin (TI) is a rapid-acting inhaled insulin with an action profile that mimics early meal-related insulin release. The goal of this multicenter study was to evaluate and compare changes in lung function in diabetic subjects treated with TI or with usual antidiabetic treatment (UC).
Materials and methods: Pulmonary function tests (PFTs), including forced expiratory volume in 1 second (FEV_1), forced vital capacity, total lung capacity, and carbon monoxide diffusing capacity (DL_{CO}), were prospectively followed over a 2-year period in subjects with type 1 and type 2 diabetes mellitus receiving TI (n=730) or UC (n=824), along with a cohort of nondiabetic subjects who did not receive any specific therapy (n=145).
Results: The treatment groups were similar for age (TI group: 50.8±11.6 years; UC group: 50.4±11.6 years; p=0.40), gender distribution (p=0.85), proportion of ethnic group composition (p=0.93), and baseline PFT. Over 2 years, PFTs declined in all groups, including the nondiabetic group (Figure). TI was non-inferior to UC for mean change in FEV_1 from baseline to 24 months using Mixed Model Repeated Measure analysis with a prespecified non-inferiority margin of 50 ml/year. After a slightly larger initial decline at the first post-baseline assessment visit, annual rate of change (slope) in PFTs from month 3 to month 24 was not statistically different between the TI- and UC-treated subjects. Annualized change in FEV_1 between 3 to 24 months was -0.047 l/year for TI-treated subjects and -0.036 l/year for UC-treated subjects (difference between the treatment groups, 0.010 l/year [95% CI -0.003, 0.022]); DL_{CO} was -0.507 ml/min/mm Hg per year for TI-treated subjects and -0.455 ml/min/mm Hg per year for UC-treated subjects (difference between the treatment groups, 0.117 ml/min/mm Hg per year [95% CI -0.058, 0.292]).
Conclusion: Small declines from baseline in PFTs were observed in diabetic subjects treated with TI and UC and also in subjects without diabetes. Observed differences between TI and UC groups in the change from baseline in FEV_1 and DL_{CO} were small, noted at the first post-baseline assessment visit (3 months) and thereafter remained non-progressive over 2 years of continuous therapy.



921

Pulmonary safety of inhaled Technosphere insulin therapy in adults with diabetes using high-resolution computerized tomography of the chest

A. Rossiter, N. Amin, R. Harris, A. Boss, P. Richardson;
MannKind Corporation, Valencia, United States.

Background and aims: Technosphere Insulin (TI) is a rapid-acting inhaled insulin with pharmacokinetics well suited for control of postprandial plasma glucose. Because TI is intended to be administered via the pulmonary route, the TI clinical program was designed to assess possible radiological changes associated with the chronic use of TI therapy.
Materials and methods: Adult subjects with diabetes were evaluated with high-resolution computerized tomography (HRCT) of the chest during the clinical trials. In controlled clinical trials, MKC-TI-005 (N=217; 174 TI group, 43 Technosphere inhalation powder [TIP] group) and PDC-INS-0008 (N=121; 60 TI group, 61 TIP group) subjects were randomized to receive TI or TIP without insulin. Chest HRCTs were obtained at baseline and at the end of the 12-week treatment period. After completion of these two trials, 206 subjects continued in the uncontrolled open-label extension trial (MKC-TI-010) and underwent annual chest HRCTs (or magnetic resonance imaging [MRI] in Germany) for up to 4 years. In addition, subsets of subjects with type 1 or type 2 diabetes participating in trial MKC-TI-030 (n=127; 55 TI group, 72 usual care [UC] group) were also randomized to an annual chest HRCT during the 24-month treatment period. All HRCT images were reviewed centrally following a prespecified adjudication protocol by an independent, blinded, board-certified radiologist. All images for any subject with HRCT findings other than normal underwent secondary joint review by an independent board-certified radiologist (different from the primary reviewer) and an independent board-certified pulmonologist, who were blinded to the treatment group.
Results: A total of 667 subjects had a baseline and at least one post-baseline chest HRCT or MRI examination. Of these, 494 subjects were treated with TI, 101 were exposed to TIP, and 72 were in the UC group with no exposure to TI or TIP. Chest HRCTs for 94% of the TI group, 92% of the TIP group, and 96% of the UC group showed normal findings or the findings were not clinically significant (Table). Radiological findings considered abnormal and clinically significant consisted of atelectasis, septal thickening, peri-bronchial thickening, bronchial dilatation or mild bronchiectasis, one or more new or non-enlarging nodules, and ground glass densities; these findings were seen with comparable frequency in all three treatment groups.

Conclusion: Overall, HRCT and MRI findings suggest that there were no clinically significant radiological changes from baseline in all three groups. Observed radiological findings were not suggestive of a safety signal with the long-term use of TI therapy.

Total Subjects with HRCTs (N=667)

HRCT Results	Technosphere Insulin n (%)	Technosphere Inhalation Powder n (%)	Usual Care n (%)
Normal	140 (28.3)	40 (39.6)	14 (19.4)

Fears of hypoglycaemia and complications in insulin-treated patients with diabetes in Japan: preliminary results of a multi-center study

K. Okazaki[1], M. Nishi[1], Y. Sano[1], T. Murata[2], K. Kotani[1], M. Narimiya[3], K. Yamada[2], N. Sakane[1];
[1]Preventive Medicine, Kyoto Medical Center, [2]Diabetes Center, Kyoto Medical Center, [3]Internal Medicine, Nishisaitama-chuo Hospital, Tokorozawa, Japan.

Background and aims: Insulin-treated patients with diabetes seem to have many kinds of fear in their daily lives. Especially, fears of hypoglycemia and diabetic complications are considered major concerns of them. The aim of this study was to investigate which fear is mostly concerned among the fears of hypoglycemia, severe hypoglycemia, blindness, and dialysis in insulin-treated type 1 and type 2 patients by a multi-center cross-sectional survey in Japan.
Materials and methods: The study design was cross sectional multi-center study using questionnaire. As of February 2008, 15 hospitals or clinics throughout Japan joined this study. The questionnaire was originally developed and consisted of occurrence of hypoglycemia (including severe and nocturnal hypoglycemia); fears of hypoglycemia, severe hypoglycemia, blindness, dialysis; and socio-demographic factors (gender, age, height, weight, duration of diabetes, duration of insulin therapy, details of the therapy, status of complications, HbA1c, and so on). The strength of fear was measured by a 5-point Likert scale with 1 never feel fear, and 5 strongly feel fear. In this study, hypoglycemia was defined as a low blood glucose level less than 50mg/dl by meter or any hypoglycemia-related symptoms and severe hypoglycemia was defined as a low blood glucose level that results in loss of consciousness or requiring the treatment from another person.
Results: By the end of February 2008, 554 patients and their physicians at outpatient department of 15 hospitals or clinics had completed a questionnaire. The response rate was 75%. The total number of subjects was 554 (193 type 1 and 361 type 2, mean age 57 years, male 52%, mean duration of diabetes 16.9 years, mean duration of insulin therapy 7.3 years, and mean HbA1c 7.3%). Fear scores were 3.7 for hypoglycemia, 4.3 for severe hypoglycemia, 4.7 for blindness, and 4.7 for dialysis on a scale of 1 to 5. One way analysis of variance showed no significant difference between the fears of blindness and dialysis. However, there was significant difference between complications and severe hypoglycemia ($p<0.05$). There was also significant difference between severe hypoglycemia and hypoglycemia ($p<0.05$). Additionally, using logistic regression analysis, two factors such as an experience of severe hypoglycemia in the past year and age were significantly associated with an increased likelihood of fear of hypoglycemia (odds ratio = 3.5 and 1.0, respectively). Other factors such as gender, type of diabetes, duration of diabetes, presence of diabetic neuropathy and level of HbA1c were not significantly associated with fear of hypoglycemia.
Conclusion: Insulin treated patients with diabetes in Japan had stronger fears of complications than of hypoglycemia (blindness = dialysis > severe hypoglycemia > hypoglycemia). However, fear of hypoglycemia was definitely not low. Additionally, an experience of severe hypoglycemia in the past year was a major factor for fear of hypoglycemia. Thus, it seems to be critical for patients and health professionals to take various measures to reduce severe hypoglycemia.

PS 78 Continuous glucose monitoring

923

Continuous glucose monitoring versus self-monitoring of blood glucose in non-pregnant patients with type 1 diabetes mellitus: meta-analysis and systematic review

K. Jeitler[1,2], A. Siebenhofer[2,3], A. Berghold[3], E. Matyas[2], N. Pignitter[2], U. Püringer[2], T.R. Pieber[1,4], K. Horvath[2,4];
[1]Institute of Medical Technologies and Health Management, Joanneum Research, Graz, [2]Department of Internal Medicine, EBM Review Center, Medical University of Graz, [3]Institute for Medical Informatics, Statistics and Documentation, Medical University of Graz, [4]Department of Internal Medicine, Division of Endocrinology and Nuclear Medicine, Medical University of Graz, Austria.

Background and aims: Continuous glucose monitoring (CGM) provides information about the direction and magnitude of changes in blood glucose levels and thus theoretically facilitates optimal treatment decisions for patients with type 1 diabetes mellitus (T1DM). However, possible beneficial effects in terms of glycaemic control remain to be evaluated. The aim of this review was to compare the effects of CGM to self-monitoring of blood glucose (SMBG) on glycaemic control and the risk of hypoglycaemic episodes.
Materials and methods: A systematic literature search for controlled clinical trials was conducted in the electronic databases MEDLINE, EMBASE and CENTRAL up to November 2008 and a systematic review and meta-analyses were performed.
Results: From 18 studies fulfilling the inclusion criteria 6 did not provide sufficient data on HbA1c and 2 more had to be excluded because the authors did not report data separate for adults and children. Out of the 10 remaining studies that could be included in the analyses of the HbA1c difference during follow-up, 2 provided data on adult patients, 6 on children only, and 2 on both age groups. The juvenile subgroup (n=110) of one trial included adults as well and therefore was not included in our analyses. All trials were published after the year 2000, and the follow-up periods of those relevant for the meta-analyses ranged from 3 to 6 months. Based on their methodological quality, many studies were judged to be at risk for bias. *Adults with T1DM (n=318)*: CGM use resulted in a statistically significant but clinically debatable difference in the change of HbA1c of -0.38% [-0.69, -0.06] (p=0.02) compared to SMBG. There was evidence of heterogeneity among the studies (I^2=69%). Severe hypoglycaemia was comparable between the groups and occurred in 0 to 10% of CGM patients and in 0 to 9% of patients in the SMBG groups. *Children with T1DM (n=514)*: No significant difference between the intervention groups regarding the change in HbA1c during follow-up could be shown (-0.04% [-0.23, 0.16] (p=0.71)). The percentage of patients experiencing at least one severe hypoglycaemic episode was comparable in both groups: 0 to 7% (CGM) vs. 0 to 10% (SMBG). Since reporting on mild hypoglycaemia and blood glucose fluctuation was scarce and heterogeneous for both adults and children, it was not appropriate to conduct a meta-analysis or reach a conclusive interpretation.
Conclusion: Use of CGM in the therapy of adults with T1DM resulted in a significant but clinically debatable reduction of HbA1c compared to SMBG, seemingly with a comparable rate of severe hypoglycaemia. In children with T1DM, CGM provides similar glycaemic control when compared to SMBG. The rates of severe hypoglycaemic episodes were comparable. More and larger long-term studies are still needed to allow a firm conclusion about whether CGM use in the therapy of T1DM provides an additional beneficial effect compared to SMBG.

Comparison of three different techniques for subcutaneous glucose monitoring in type 1 diabetic patients

J.K. Mader[1], G. Köhler[1], J. Plank[1], M. Suppan[2], D. Ikeoka[1], H. Köhler[2], T.R. Pieber[1,2], M. Ellmerer[1];
[1]Internal Medicine / Endocrinology and Nuclear Medicine, Medical University Graz, [2]Institute of Medical Technologies and Health Management, Joanneum Research GmbH, Graz, Austria.

Background and aims: Continuous subcutaneous glucose monitors might be important tools in the treatment of diabetes, revealing 24-hour glucose

patterns leading to a better adjustment of insulin therapy, and also in the establishment of closed loop systems. The aim of the present study was to investigate and compare the accuracy between two marketed products and a standard microdialysis sampling technique with reference measurements from arterialized venous blood in type 1 diabetic patients.
Materials and methods: Seven type 1 diabetic patients (age: 32.7 ± 8.1 years; BMI: 25.0± 1.8 kg/m²; diabetes duration: 14.6 ± 7.0 years) were investigated over a period of 26 hours in an inpatient setting. For subcutaneous glucose monitoring, the Guardian RT system (subcutaneous glucose sensor; GRT), the GlucoDay S system (microdialysis based extracorporeal glucose sensor; GDS) and a standard microdialysis catheter (MD) for sampling of interstitial fluid were applied. For reference glucose measurements, arterialized venous samples were obtained in frequent intervals and analyzed using a Beckman Analyzer. GRT and GDS systems were calibrated according to manufacturers' instructions. Measurements from interstitial fluid were analyzed using a Cobas Mira analyzer and prospectively calibrated to reference six hours after catheter insertion.
Results: Whereas all MD systems could be applied without restrictions, 2 subjects of GRT and 1 subject of GDS were not included in the analysis due to malfunction of the devices. Mean glucose difference [2SD] between reference blood glucose vs. interstitial glucose readings were as follows: GRT -10.5 [41.8]%; GDS 20.2 [55.9]%; and MD 6.5 [35.2]%, respectively. Median absolute relative difference (MARD) was 15.0[5.6; 23.4]% (median[IQR]) for GRT, 19.7[6.1; 37.6]% for GDS and 8.7[4.1; 18.3]% for MD, respectively.
Conclusion: Individual glucose readings indicated substantial deviations from reference blood glucose. Although the systems appear adequate for retrospective data analysis or as an adjunctive measure to reference glucose measurements, subcutaneous measurement technologies require substantial improvement until therapeutic decisions can be drawn from individual glucose readings.

Accuracy of a novel intravascular fluorescent continuous glucose sensor in an 8 hour outpatient clinical feasibility study
H.C. Zisser[1], L. Jovanovic[1], U. Khan[1], T. Peyser[2], S. Gamsey[2], M. Romey[2], H. Spencer[2], J. Suri[2], D. Markle[2];
[1]Clinical Research, Sansum Diabetes Research Institute, Santa Barbara, United States, [2]Glumetrics, Irvine, United States.

Background and aims: The results of the Nice-Sugar study have raised questions about the appropriate target levels for tight glycemic control (TGC) in ICU patients. The increase in mortality in the intensive control group may have been related to the fourteen-fold increase in episodes of severe hypoglycemia (< 40 mg/dL) compared with the conventional control group. A continuous glucose sensor (CGM), accurate in the hypoglycemic range, has been cited as a new technology that could permit successful implementation of TGC in the critically-ill in the future without increasing the risk of severe hypoglycemia. The purpose of the study was to assess the accuracy of a novel fluorescent intravascular CGM, the GluCath, in human subjects, especially in the hypoglycemia range.
Materials and methods: The sensor is based on quenched-fluorescence using a modified boronic-acid glucose receptor. The sensor chemistry is immobilized in a hydrogel matrix and placed on the distal tip of an optical fiber which can be inserted in a blood vessel. In the presence of glucose, the bond between the quencher and the fluorophore is weakened resulting in an increase of fluorescence. In contrast to electrochemical enzymatic sensors, the GluCath fluorescent sensor exhibits a nonlinear modulation response function giving the highest level of accuracy in the hypoglycemic range. Red blood cells are excluded by a microporous membrane surrounding the sensor and by the hydrogel, resulting in a measurement of plasma glucose. The sensor was evaluated in an 8-hour outpatient feasibility study. The sensor was placed in a peripheral vein at the antecubital fossa in five subjects with type 1 diabetes. Sensor insertion was performed using a 22 Ga needle and a retractable cannula.
Results: One sensor failed during insertion due to mechanical damage. Data from the other four sensors were taken at one-minute intervals and compared with hospital and laboratory blood glucose measurements from venous samples in the contralateral arm every 15 minutes. Data was analyzed retrospectively using a temperature-corrected factory calibration with a one-point in vivo adjustment made within thirty minutes of the sensor insertion. The GluCath results were compared with measurements made on an ABL Radiometer 805, a Yellow Springs Instrument analyzer 2300 StatPlus and the LifeScan SureStep Flexx Pro. Comparison of the GluCath results to the Radiometer values found the GluCath accuracy met the performance standard in ISO-15197: 100% (30/30) of all values </= 75 mg/dL were within ±20% of the reference values. The mean absolute relative difference (MARD) was 8.95%.
Conclusion: This is the first use in human subjects of a fluorescent glucose sensor. The sensor was found to be highly accurate compared with laboratory reference measurements, especially in the hypoglycemic range. Sensors of this type may be useful in the future in permitting safe and effective implementation of TGC protocols in the critically-ill and other hospitalized patients.

Intensification of therapy and better glucose control after the continuous use of real time glucose monitoring combined with insulin pump (PRT system) in type 1 diabetes mellitus
A.C. Pappas[1], O. Kepaptzoglou[2], E. Kyrlaki[1], I. Taraoune[2], M. Sfakianaki[1], P. Garoutsou[2], H. Vasilopoulos[3], N. Kefaloyannis[1], C.S. Zoupas[2];
[1]Diabetic Clinic, Venizelion Hospital, Heraklio, Crete, [2]Diabetes Center, "Hygeia" General Hospital, Athens, [3]Diabetes Center, "Evaggelismos" General Hospital, Athens, Greece.

Background and aims: JDRF- Study demonstrated that the continuous use of REAL- Time Continuous Glucose Monitoring (RT-CGM)can be associated with improved glycemic control in Type1 Diabetes. PRT is an Insulin Infusion Pump combined with a RT-CGM. The aim of our study was to evaluate the effect of PRT on glycemic control, glucose fluctuations and insulin requirements for a long period of time.
Materials and methods: A total of 11 patients, mean age 34.0±20.3 years and diabetes duration 16.7± 9.1 years (X± SD), wore the Sensor-Augmented Pump system continuously for 12 months. Eight of them continued the continuous use for 18 months. All subjects for educational purposes were only on RT-CGM during the 1th month (remained on MDI). The Pump therapy was added the 2th month. HbAlc, average monthly glucose, hypo/hyperglycemic excursions, total daily dose (TDD) and mean units/bolus were evaluated at baseline, 4, 6, 12 and 18 months respectively
Results: HbAlc(%) decreased from 8.14±1.70 at baseline, to 6.88±0.58 and 6.71±0.37 after 4 and 12 months (p=0.019). Glycemic control improved from the beginning and the average Daily and Monthly Glucose Values did not significantly differ after 1, 4, 6, and 12 months. The average Area Under the Curve (AUC) above 180 mg/dl*24h tend to be reduced after the introduction of Pump and remained lower at 12th month. Average AUC below 70mg/dl remained constant throughout the study period. Severe hypoglycemia occurred only once! No significant weight gain was noticed. There was a statistically significant decrease of TDD of Insulin from 53.27±7.90 in baseline to 45.22±14.19 and 43.87±14.30 units at 4 and 12 months. In addition the TDD of Bolus Insulin decreased gradually despite the increased number of boluses given by the patients in order to be proactive to high glucose excursions. (Table1).

Table I: 11+8 patients, 1 year and 18 months continuous use

	11 patients				8 patients				
	Baseline	4 months	12 months	p	Baseline	4 months	12 months	18 months	p
Mean Glucose (mg/dl)	142.2	142.6	140.1		148.8	149.8	143.5	147.3	
Std Deviation (mg/dl)	52.1	51.0	47.4		54.8	52.6	48.6	53.5	
AUC above 180 mg/dl (mg/dl*24h)	9.75	8.86	7.70		11.98	10.79	8.28	10.18	
AUC below 70 mg/dl (mg/dl*24h)	0.47	0.33	0.51		0.45	0.33	0.46	0.40	
HbA1c (%)	8.15	6.88	6.71	0.019	8.65	7.11	6.83	6.86	0.022
TDD (units)	53.27	45.22	43.87	0.022	54.00	43.85	44.14	46.44	ns
No Bolus	3.00	6.17	6.82	<0.001	3.00	6.17	6.70	6.85	<0.001
Mean Units/ Bolus	8.29	4.40	3.25	<0.001	8.52	3.48	2.93	2.69	0.001

These results are significantly certified in the group of 8 patients after 18 months of use. HbA1c and glucose variability remain stable. We observed a further statistically significant increase of the number of bolus/day between 4th and 18th month of use. (6.17±2.03 vs 6.85±1.66, p<0,05) and at the same time a decrease of the mean units/bolus (3.48±0.66 vs 2.69±1.31 p<0,05)
Conclusion: The continuous use of PRT provides a useful tool to normalize glycemic control in T1DM. It decreases HbA1c and AUC of high glucose excursions. To derive full potential benefit from RT-CGM, patients were driven by the system to the intensification of insulin therapy with more frequent bolus but with less units/bolus. As the time pass the patient learns to react correctly to the predictive alarms of high and low excursions and remains motivated to achieve his targets for a long period of time

Evaluation of the effect of different sensor insertion methods on the accuracy of a continuous glucose monitoring system
W.K. Doll, W. Regittnig, S. Korsatko, S. Lindpointner, E.-M. Pichler, E. Krusinova, T.R. Pieber, M. Ellmerer;
Endocrinology and Nuclear Medicine, Medical University Graz, Austria.

Background and aims: Continuous glucose monitoring may offer the important advantages of decreasing the risk of severe hypoglycemia and improves the adjustment of insulin therapy in type 1 diabetes. Recently several useful continuous glucose sensing devices have been brought to market. Most of them measure glucose in subcutaneous adipose tissue (SAT) by applying an enzyme-tipped catheter sensor. Placing the catheter sensor in the SAT is usually performed with the help of the inserter provided by the sensor manufacturer. The sensor insertion is then typically followed by a run-in period during which sensor sensitivity might be attenuated and unstable. It has been shown that the duration of the run-in period may last up to ten hours before the sensor attains steady-state glucose sensing conditions. One explanation for this prolonged run-in period may be an increased tissue trauma caused by the commercial product sensor inserter. The aim of the present study was to compare a commercial product sensor insertion technology with a manual, less invasive sensor insertion method.
Materials and methods: After an overnight fast, four identical glucose sensors were inserted in the SAT of 15 healthy volunteers, whereby two of the sensors were placed using a commercial product sensor inserter (AUTO_1, AUTO_2) and two were inserted manually by lancing the skin with a 0.6 mm needle and placing the sensor into the pierced tissue (MAN_1, MAN_2). The glucose data obtained from each sensor were calibrated against the plasma glucose value obtained 30 minutes after sensor insertion and the glucose sensor data were recorded continuously over a period of 11 hours. To quantify possible sensitivity changes we calculated the time courses of the Normalized Glucose Sensitivity (NGS) for each sensor as the ratio between the observed sensor glucose and plasma glucose values, normalized to the median sensitivity value obtained during the last hour of the experiment (hour 10 to 11).
Results: The glucose concentration measured with the AUTO-sensors fell rapidly during the first 3h after insertion, and then declined more slowly during the remainder of the study. A comparable behavior was observed for the MAN-sensors, however the rate of decline during the first 3h was less pronounced. By the end of the experiment glucose concentrations of the AUTO- and MAN-sensors were 49.3 ± 4.2 mg/dl and 58.9 ± 2.5 mg/dl, respectively. Both concentrations were significantly lower than the corresponding plasma glucose concentration (78.6 ± 1.1 mg/dl, p<0.01). This pattern of decline was also reflected in the shape of the derived NGS time courses, where during the first 3h the NGS for AUTO- and MAN-sensor fell rapidly to a value of 73.5 ± 4.8% and 87.6 ± 3.0% of the initial NGS value, respectively. Thereafter the NGS of both sensors decreased more slowly with comparable rates. By the end of the study, at 11h, the final NGS values for AUTO- and MAN-sensors were 63.1 ± 5.2% and 75.1 ± 3.3% of the initial NGS value (p<0.01).
Conclusion: The results obtained from these experiments indicate that sensor insertion into SAT is associated with sensitivity attenuation and that this attenuation is less pronounced with manually inserted glucose sensors compared to those placed with a commercial product sensor inserter. Thus, the duration of the run-in period after sensor implantation may be shortened when less invasive insertion techniques are applied.

928

Time lag differences of two continuous glucose monitoring systems
S.K. Garg, M. Voelmle, P.A. Gottlieb;
Barbara Davis Center, University of Colorado Denver, Aurora, United States
.

Background and aims: The potential time lag between a subcutaneous sensor measuring electrons resulting from the glucose oxidase reaction using interstitial glucose (IG) and the venous blood glucose (BG) is currently not well understood. The aim of this pilot study is to evaluate the total system time lag of two FDA approved continuous glucose monitoring (CGM) systems, the SEVEN® and the Navigator®, as compared to YSI laboratory measurements; in adults with type 1 diabetes.
Materials and methods: Fourteen subjects with type1 diabetes, 33 ± 6 (mean ± SD) years old, contributed frequently sampled venous (~15 minutes)YSI blood glucose readings during three 8-hour in-clinic sessions conducted on days 5, 10, and 15 of this 15 day study. All subjects wore both CGM systems concurrently during the entire 15 days (both sensors changed every 5 days). YSI and CGM data from the in-clinic control sessions were evaluated for the time lag between IG and BG. The total system time lag of both CGM systems was estimated using various regression method related statistical estimators, including correlation coefficient, transformed R-squared Acceptance Criteria (AC), Root Mean Squared coefficient of Variation (RMS (CV)), Root Mean Squared Error (RMSE), and Mean Absolute Relative Difference (MARD). The time lag was assessed by linearly interpolating and then time shifting the CGM curves to obtain the optimum statistics criteria. A non-parametric Wilcoxon test was used to test the difference between the two CGM systems in the time lag estimate. Time lags were also estimated for steady state, increasing, and decreasing rates of change of glucose. A bootstrapping re-sampling analysis was also used to provide a 95% confidence interval for each time lag estimate.
Results: The overall time lag based on correlation coefficient criteria is estimated as 4.5±5 minutes (median±IQR) for the SEVEN System, and15±7 minutes for the Navigator System. The overall range of the estimator's median estimated total time lag, in minutes, for the two CGM systems versus YSI was different: [2,6] and [14,15] for SEVEN and Navigator, respectively (p < 0.01, for every time lag estimator; Table). The estimated time lags based on different statistical measures are similar within each CGM system

Table: Time lag Estimates (in minutes)

	SEVEN		Navigator		Wilcoxon
Estimator	Median	IQR	Median	IQR	p-value
Pearson	2.0	4	15.0	7	0.0002
Spearman	4.5	5	15.0	8	0.0012
AC	4.5	5	15.0	7	0.0002
Pearson(ln)	4.5	5	15.0	7	0.0002
RMSE	6.0	8	15.0	9	0.0001
RMS(CV)	5.0	5	14.0	7	0.0001
MARD	5.5	11	14.5	9	0.0013

Conclusion: Our study findings suggest that the use of commonly accessible statistics for the application to time lag estimation of CGM systems, such as correlation statistics, offer estimates that are comparable to more sophisticated approaches. The clinical significance of this difference in the time lag (SEVEN's total lag time at least 2 fold less than that of the Navigator) needs to be further evaluated in a larger clinical study.

929

Continuous Glucose Monitoring (CGM) reduces glucose variability and improves glycaemic control in patients using Multiple Daily Injections (MDI) or insulin pumps
D. Rodbard[1], S. Garg[2], L. Jovanovic[3];
[1]Clinical Research and Biostatistics, Biomedical Informatics Consultants LLC, Potomac, [2]Clinical Research, Barbara Davis Center for Diabetes, Aurora, [3]Clinical Research, Sansum Research Institute for Diabetes, Santa Barbara, United States.

Background and aims: We compared the effectiveness of CGM with real time display in patients with type 1 diabetes utilizing MDI vs Continuous Subcutaneous Insulin Infusion (CSII; Insulin Pump).
Materials and methods: CGM using DexCom SEVEN was studied in 64 patients with type 1 diabetes using MDI (26 patients) or CSII (38 patients), The

CGM data was masked during Week 1 and displayed during Weeks 2 and 3. We computed 30 parameters of glucose variability and glycemic control.
Results: Fifteen parameters significantly improved in response to CGM display ($P<0.05$), e.g., the relative percentage of glucose values within the target range (3.9-7.8 mmol/l) increased by 17% and 19% during the display period for CSII and MDI respectively. There were significant reductions in the mean glucose, standard deviation (SD), SD between daily means (SD_{dm}), SD between days - within time periods (SD_b), and Service's Mean Amplitude of Glycemic Excursion (MAGE) and Mean of Daily Differences (MODD). There were improvements in quality of glycemic control (Schlichtkrull's $M_{5.56}$ (reference glucose 5.56 mmol/l or 100 mg/dL), Wojcicki's J Index, a new Index of Glycemic Control (IGC), and Hill's GRADE score (Figure). Changes were linearly related to baseline A1C but these relationships were not significantly different between groups.
Conclusion: Use of CGM SEVEN system with continuous display in subjects with type 1 diabetes resulted in significant improvements in multiple measures of glucose variability and glycemic control. These improvements were indistinguishable in patients using MDI and CSII.

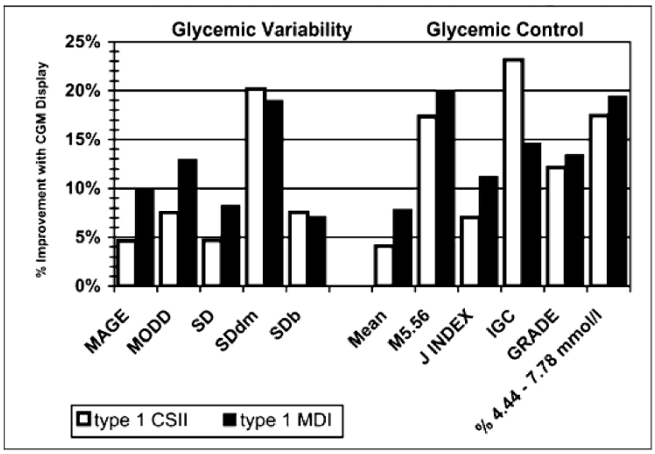

Figure Legend: Ordinate: % improvement with display of CGM during Week 3 relative to control Week 1 (no display). Abscissa: Measures of Glycemic Variability and Glycemic Control for patients with type 1 diabetes using CSII (white bars) or MDI (black bars). When CGM data were displayed in real time, there was significant improvement ($P<0.05$) in 15 parameters, but there were no significant differences between CSII and MDI ($P>0.05$). $M_{5.56}$, IGC, and GRADE are averages of related but distinct noninear transformations of glucose values giving greater influence to glucose values that fall progressively further outside the target range.

New features and performance of a next generation SEVEN day continuous glucose monitoring system with apparent short lag time
T. Bailey[1], H. Zisser[2], A. Chang[3];
[1]AMCR Institute, Escondido, [2]Sansum Diabetes Research Institute, Santa Barbara, [3]John Muir Physician Network, Concord, United States.

Background and aims: Since the introduction of the continuous glucose monitoring system for diabetes management, there have been significant technological advances. The purpose of this study was to establish the new features and evaluate the performance of SEVEN® system (DexCom, Inc.), the next generation version of seven (7) day, real-time continuous glucose monitoring (CGM) system, as well as to evaluate the lag time between the subcutaneous (ISF) glucose and parallel reference blood glucose (BG) in a controlled in-clinic setting. Accuracy was compared relative to Yellow Springs Instrument (YSI) and self-monitoring of blood glucose (SMBG) measurements.
Materials and methods: Fifty-three (53) subjects were enrolled at 3 US centers. 43 (81%) of the subjects had T1DM and 10 (19%) had insulin-requiring T2DM. Subjects inserted and wore 1 or 2 sensors for 7 days. A subgroup of patients (n=18) wore 2 sensors to track precision. Subjects participated in one 8h in-clinic session with blood draws every 15 minutes on study Day 1, 4, or 7 to collect YSI and SMBG reference measurements. For the remainder of the week, CGM was used as an adjunct to SMBG during out of clinic monitoring. Clarke-Error Grid Analysis (EGA) and Continuous Glucose Error Grid Analysis were used to quantify the clinical accuracy of CGM in reference to laboratory standard YSI. Various statistics measurements includes Pearson correlation coefficient (ρ), regression root mean squared Coefficient of Variations (RMSCV), and R-squared of transformed linear regression (R2),were used to estimate the time lags associated with subcutaneous (ISF) glucose sensing and parallel reference blood glucose (BG).
Results: User features, such as sensor life (89% lasted 7 days) and data capture (87% of sensors provided 76-100% of readings) were significantly improved relative to the current generation SEVEN system. The overall median Absolute Relative Difference (ARD) vs. YSI was 13.0%. The pooled %20/20 accuracy results relative to YSI was 76.1%. A and B regions of the Clarke Error Grid of CGM measurements was 73.8% and 22.1%, respectively. Precision ARD was 15.3% ± 6.2% (mean ± SD). The median ARD vs. SMBG was 12.1%. No difference was found between in-clinic and out of clinic monitoring. Glucose rate of change (trend arrow) and data input were made available for the users. The time lag obtained with various measures, between CGM and YSI blood samples were similar and estimated as 7 ± 10 minutes (median ± IQR). Subjects elected to check and view the glucose trend while wearing the SEVEN PLUS receiver 44 ± 21 (mean± STD) times per day. No serious adverse events or infectious complications were reported.
Conclusion: We conclude that use of this new generation of a 7-day continuous glucose monitoring device was accurate, safe, well-tolerated and frequently-used. This study is the first to show all characteristics of the new generation of SEVEN PLUS device. The performance of the system compares favorably to the current SEVEN system in terms of accuracy, precision, sensor life, and rate of data capture. Analysis of data suggests a short lag time, which may help patients better manage their diabetes.

Safety of overnight closed-loop using FreeStyle Navigator® continuous glucose monitoring system (FSN) and model predictive control (MPC) algorithm: in silico assessment
M.E. Wilinska[1], E.S. Budiman[2], J.A. Allen[1], D. Elleri[1], C.L. Acerini[1], G.A. Hayter[2], M.B. Taub[2], D.B. Dunger[1], R. Hovorka[1];
[1]Institute of Metabolic Science, University of Cambridge, United Kingdom, [2]Abbott Diabetes Care, Alameda, United States.

Background and aims: Hypo- and hyperglycaemia during closed-loop (CL) insulin delivery based on subcutaneous glucose sensing may arise due to (i) over- and underdosing of insulin by control algorithm and (ii) difference between plasma glucose (PG) and sensor glucose (SG), which may be transient (kinetics origin and sensor artifacts) or persistent (calibration error). Using extensive *in silico* testing, we assessed hypo- and hyperglycaemia risk during overnight CL and made comparison against incidence observed during open-loop (OL) studies in young people with type 1 diabetes (T1D) treated by CSII.
Materials and methods: Simulation environment comprising 18 virtual subjects with T1D and combining experimentally-derived characteristics of FSN sensing error was used to simulate overnight CL study with MPC algorithm. A 15 hour long experiment started at 17:00 and ended at 08:00 the next day. CL commenced at 21:00 and continued for 11 hours. At 18:00, protocol included meal (50g CHO) accompanied by prandial insulin. MPC algorithm advised on insulin infusion every 15min. Transient SG-PG differences were obtained by combining model of interstitial-plasma glucose kinetics with FSN error artifacts calculated as a difference between two sensor traces provided by simultaneously inserted sensors in 58 subjects with T1D over 194 night-time periods. Persistent SG-PG difference due to FSN calibration error was quantified from 585 sensor insertions yielding 1421 calibration sessions from 248 subjects with diabetes.
Results: Episodes of severe (PG<2.0mmol/l) and significant (PG<2.5mmol/l) hypoglycaemia, and hyperglycaemia (PG>16.7mmol/l) were extracted from 18,000 simulated CL nights. Severe hypoglycaemia was not observed when calibration error defined as (SG - PG)/PG was less than 40%. Hypo- and hyperglycemia frequency during OL was assessed from 21 overnight studies in 17 young subjects with T1D (M 8; age 13.5±3.6 yrs; BMI 21.0±4.0 kg/m²; duration diabetes 6.4±4.1 yrs; A1C 8.5±1.8%; mean±SD) participating in the Artificial Pancreas project at Cambridge. Severe and significant hypoglycaemia occurred once every 105 and 5.6 years during CL compared to once every 21 and 10.5 days during OL, respectively. Hyperglycaemia occurred once every 278 weeks during CL and once every 2.3 days during OL. Recalibrating FSN when difference between SG and PG exceeded 3mmol/l reduced

frequency of severe and significant hypoglycaemia during CL to 353 years and 7.4 years.
Conclusion: Using simulations with experimentally-derived FSN error, the risk of severe and significant hypoglycaemia reduced 2000 and 200 fold during overnight CL with MPC control compared to that observed during OL. Hyperglycaemia was 800 times less likely. Overnight CL with FSN and MPC control is expected to reduce substantially the risk of hypo- and hyperglycemia.

Improved system for non-invasive glucose monitoring at home
S. Zilberman[1], A. Kononenko[1], A. Weinstein[1], E. Gabis[1], A. Karasik[2,3];
[1]OrSense LTD, Nes Ziona, [2]Endocrinology Dept., Sheba Medical Center, Ramat Gan, [3]Faculty of Medicine, Tel-Aviv University, Israel.

Background and aims: OrSense has developed the NBM device, a general platform for non-invasive detection of blood analytes. The device is based on red/near infrared Occlusion Spectroscopy technology, which has been previously shown to measure blood glucose (BG) accurately. The NBM uses a multi-wavelength sensor shaped as a ring, located at the finger's base. It utilizes an enhanced optical signal resulting from a temporary over systolic occlusion produced by a finger based pneumatic cuff. OrSense's NBM device has recently entered the clinic as a device for hemoglobin and oxygenation determination. In the present study we evaluate the performance of a new sensor, which includes improved mechanical and optical design, as well as a new calibration scheme. The device was operated in a *profiler* mode, which reports the daily BG profile at the end of each daily session.
Materials and methods: The trial was carried out in a home-like setting. The NBM's probe was placed on each patients' thumb, where it performed non-invasive continuous measurements for up to 10 hours, with readings every 10 minutes. Four calibration points were used in each session in proximity to breakfast and lunch times (one calibration point just before each meal and another, one hour after each meal starts). Accuracy was assessed by comparing NBM data with paired self-monitoring blood glucose meter readings (FreeStyle, Abbot Inc.), taken at 30 minutes intervals. A total of 150 sessions were carried out on 9 patients (7F, 2M; 26-70 y/o; 4 Type 1, 5 Type 2; 6 subjects participating in 20-26 sessions each, and the 3 other in 2-4 sessions). 20 sessions were excluded from our analysis due to calibration failures as identified by our algorithm.
Results: Reference BG values were in the range 47 to 378 mg/dL. In all cases there was good patient compliance and no adverse effects were identified. The median relative absolute deviation (RAD) is 11.2%. Clarke error grid analysis based on 1926 paired data points shows that 98.3% of the results are in the A+B zone, with 68.8% in the clinically useful A zone, 29.5% in the clinically benign B zone and none in the potentially dangerous E zone. Deming regression slope is 1.0 (assuming variances ratio λ=1).
Conclusion: This study substantiates the potential use of OrSense's NBM device as a non-invasive sensor for continuous BG monitoring. The device was comfortable for subjects, safe and well tolerated. Further studies are underway, to examine use of this truly non-invasive continuous glucose-sensing device in other settings.

933

Wavesense algorithms account for haematocrit variations while determining blood glucose
A. Rao, S. Iyengar, M. Wiley, E. Mallery;
AgaMatrix, Inc., Salem, United States.

Background and aims: Studies have shown that controlling blood glucose can reduce the onset and progression of the long-term microvascular and neuropathic complications associated with the chronic course of diabetes mellitus. Blood glucose monitoring is a very useful metric to evaluate glycemic control at a point in time. Effective interpretation of readings is dependent on obtaining frequent and accurate glucose readings. While frequency of testing depends on patient motivation, measurement accuracy is influenced by a variety of known factors. It is understood that system errors attributable to sample characteristics such as: hematocrit (Hct), testing environment (ambient temperature, humidity) or manufacturing errors (lot-to-lot variability in reagent strips) can all affect blood glucose readings.
Hematocrit affects results of blood glucose testing because red blood cells in the sample can alter the ratio of blood glucose to plasma glucose, as well as the flow of plasma and delivery of oxygen into the test strip. Blood glucose meters typically tend to underestimate blood glucose levels at higher Hct, and overestimate the levels when the Hct is lower-than-normal. The positive and negative bias are relevant because Hct variations are quite common in the diabetic population. Renal dysfunction can cause anemia, while smoking or living at high altitudes can lead to an increase in red blood cells. Wavesense technology includes a suite of algorithms that corrects for several different sources of errors and variations, including hematocrit.

Materials and methods: A total of 416 adult patients previously diagnosed with either of Type 1 or Type 2 DM were tested using Wavesense Technology no code meters embedded with novel algorithms for improving accuracy. The studies were conducted at 4 different locations with known differences in climatic conditions. Results from fingerstick samples were correlated with the YSI 2300 Stat Plus.
Results: The results demonstrate that the bias does not change over a wide range of Hct (31 - 53.8) since the linear regression has a slope close to zero (Figure 1).
Conclusion: Wavesense algorithms account for the variations in Hct and thus strive to provide better readings that may be helpful in achieving tighter glycemic control in the management of DM.

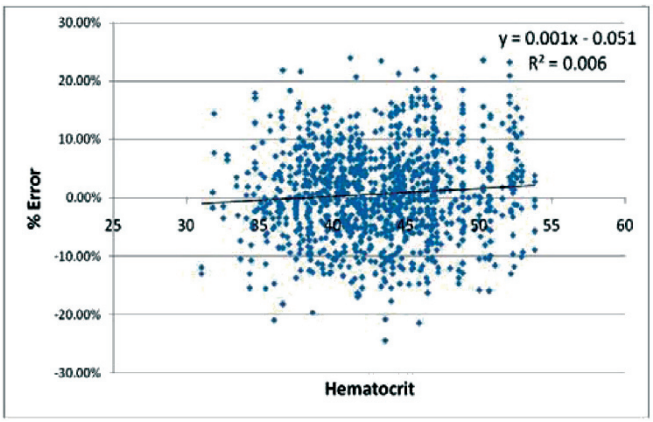

Figure 1: A slope &0.0014) near zero indicates that the bias does not change with Hct (n=471)

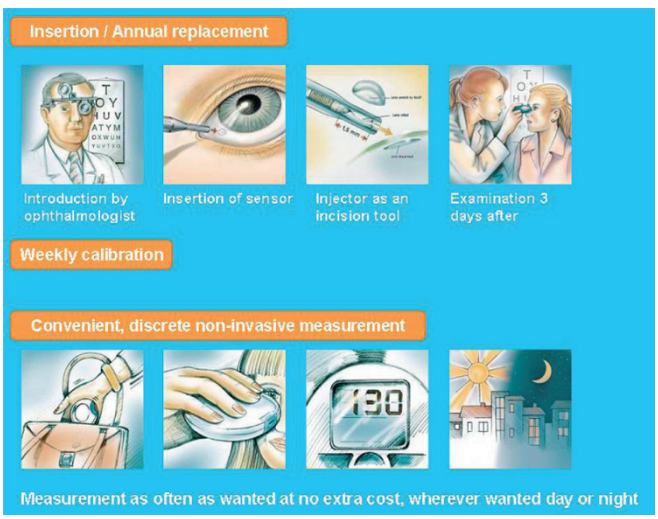
934

New optical method for blood glucose self-monitoring
P. Herbrechtsmeier[1], A.J. Mueller[1], C. Hasslacher[2], G.U. Auffarth[3];
[1]EyeSense GmbH, Großostheim, [2]St. Josefskrankenhaus, Heidelberg, [3]Univ. Augenklinik, Heidelberg, Germany.

Background and aims: Blood sugar self- monitoring is a basic component of diabetes therapy. Since years new technologies capable of doing this without taking a droplet of blood via finger pricking are in high demand. So far all approaches failed mainly due to insufficient accuracy.
Materials and methods: The goal of the new concept is to overcome the hurdles of the alternative measuring technologies by using a glucose specific sensor placed at a body site, which basically lacks severe foreign body reactions. This is the eye used as a window to the body and benefiting from an immune privilege. More specifically, a small hydrogel chip with a chemical sensor in it is inserted below the conjunctiva in a painless minimally invasive procedure. The read out of the glucose concentration is done optically with the help of a small, handheld photometer.



Results: A clinical study was run with 11 insulin-dependent diabetics in 44 measurement series over 18 days. 1944 combined data points were registered. An excellent correlation with corresponding conventionally measured blood glucose concentration was found (r=0,93 p< 0,001). The Clarke Error Grid Analysis resulted in more than 99,5% of data points falling into combined zones A and B. 7 data points fall in zone D, however, they droped out of zone A by only 2 - 3 mg/dL. The mean average relative error was 10,3%. A lag time of 5 - 15 min was observed versus capillary blood measurements depending on the dynamics of blood glucose changes. Patients experienced the insertion as painless and simple. The implant was well tolerated over the whole wearing time.
Conclusion: The first clinical results impressively show the potential of the new technology to replace finger sticking for blood glucose measuring. It allows non-invasive measurement after the insert is placed below the conjunctiva in a convenient way, reversibly as often as wanted without extra costs.

935

A truly non-invasive SMBG device for home use
A. Gal[1], I. Harman-Boehm[2], A. Raykhman[3], V. Kashin[3], J. Zahn[4], V. Dobrushkin[5], Y. Mayzel[1], E. Naidis[1];
[1]Integrity Applications, Ltd., Ashkelon, Israel, [2]Internal Medicine and the Diabetes Unit, Soroka University Medical Center, Beer-Sheva, Israel, [3]InESA Inc., East Greenwich, United States, [4]Department of Biomedical Engineering, Rutgers, the State University of New Jersey, Piscataway, United States, [5]Division of Applied Mathematics, Brown University, Providence, United States.

Background and aims: For over a decade, the medical and industrial communities struggle to provide an answer for people with diabetes and replace painful finger- prick glucose monitoring with a non-invasive methodology. Generally, Non-Invasive (NI) devices measure physiological phenomena which are reflected in tissue parameters changes that are correlated with blood glucose. These devices (in development stages) produce either trend analysis or continuous glucose values. However, the actual glucose value derived from such correlation is different than the real glucose value, since factors, other than glucose, influence tissue parameters as well and cause inaccuracies in the reading. Previous publications suggest a unique way to minimize the impact of such disturbances through an approach of combining technologies. Three independent NI methods are used: Ultrasound, Electromagnetic and Thermal. The weighted average reading reflects blood glucose value with smaller impact of interferences, leading to more accurate, *real-time (prospective) spot* glucose readings.
Materials and methods: Clinical trials were performed at the Diabetes Unit, Soroka University Medical Center, Beer-Sheva, Israel. 30 subjects were evaluated (427 measurement pairs): 5 T1DM (2F, 3M), 25 T2DM (11F, 14M), aged 52 ± 29 years, BMI of 30.9 ± 9.1Kg/m^2. The measurements were performed externally on the earlobe, which has a large blood supply and is also a convenient site that doesn't interfere with daily activities. The calibration was individually performed against invasive basal and post-prandial blood glucose references using HemoCue® Glucose 201+ Analyzer from capillary fingertip blood. The calibration procedure is easy, takes about 1.5 hours and more importantly, valid for one month. The majority of the values during the trials were measured on a different day than the calibration process.
Results: Clarke Error Grid analysis of the weighed result shows 98% of the points in the clinically accepted zones A+B, of which 61% in zone A. $MARD_{mean}$ is 21.3% and $MARD_{median}$ is 15.9 %. Further work is currently done to improve the accuracy level even further.
Conclusion: We have shown that the present model of *GlucoTrack*™ gives promising results. The upgraded version is in its final stages and new set of clinical trials is scheduled for April 2009. A key benefit of the device is its long intervals between re-calibrations and the ability to perform frequent spot measurements without the need to continuously wear the device. This small, i-pod size, user friendly and easy to operate device is intended for home use and provides answers for the diabetic population. The device can mainly (however not only) be beneficial for non-insulin dependent type 2 DM, because it does not need to be worn continuously and does not require expendables. *GlucoTrack* will improve monitoring adherence and allow diabetics a frequent and painless way to monitor and track their BG, leading to tighter glucose control.

936

Laboratory investigation for the assessment of haematocrit interference on handheld blood glucose meters for patients' self blood glucose testing

T. Forst, P.B. Musholt, M. Schneider, M. Dannappel, A. Pfützner;
R&D, IKFE Institute for Clinical Research and Development, Mainz, Germany.

Background and aims: Recent reports have indicated that the majority of hospital-based point-of-care blood glucose meters show pronounced interference with hematocrit (HCT) variations. The purpose of this laboratory investigation was to explore to what extend hand-held glucose meters for patient self-monitoring (SBGM) may also be affected by this phenomenon.
Materials and methods: Seven SBGMs (AccuCheck Aviva, Ascencia Contour+, Ascencia Breeze 2, Precision Xceed, FreeStyle Freedom, OneTouch Ultra 2, and FineTouch) were tested with laboratory samples with different hematocrit values (20, 30, 40, 50, and 60 %) and at three different glucose concentrations (50, 170, 370 mg/dl). Each individual sample was tested 6 times with each meter. In addition, two point-of-care devices and one reference method were tested (HemoCue, StatStrip, Cobas). For the interference analysis, the value determined with 40 % hematocrit was used as the reference value. Mean deviations were calculated for all meters over all three blood glucose ranges. No analysis of precision or accuracy was undertaken, as the study was performed with artificially modified laboratory samples and not with capillary whole blood, the natural specimen for these devices.
Results: The mean percent deviation results for all glucose ranges are provided in the Table. Different degrees of interference were observed for many of the SBGMs at either low or high hematocrit values (or both). Only the FineTouch device showed a stable measurement performance together with one point of care device (StatStrip) and the reference method (Cobas).
Conclusion: Small hematocrit variations (especially increases) showed pronounced effects with some meters. Although this study was not performed in capillary blood samples, an appropriate education and clear labelling appears to be strongly recommended for these meters. Only one point-of-care meter (StatStrip, Nova Biomedical) and one handheld SBGM (FineTouch, Terumo) were not substantially influenced by hematocrit interference. As variation in hematocrit can occur in daily life (e.g. in patients with dehydration or during hemodialysis), this can be considered to be an advantage of these meters in practical routine use.

Deviations from the reference measurement (at 40 % hematocrit) by device

Hematocrit	20 %	30 %	40 %	50 %	60 %
AccuCheck Aviva	2.7 %	2.2 %	0.0 %	-12.4 %	-24.1 %
Ascentia Contour	6.4 %	2.2 %	0.0 %	-9.1 %	-9.4 %
Ascencia Breeze2	38.9 %	20.3 %	0.0 %	-17.3 %	-34.7 %
FreeStyle Freedom	20.5 %	2.3 %	0.0 %	-7.1 %	-8.5
Precision Xceed	12.8 %	8.7 %	0.0 %	-15.3 %	-31.2 %
OneTouch Ultra 2	10.3 %	6.6 %	0.0 %	-22.3 %	-35.2 %
FineTouch	-1.7 %	-8.1 %	0.0 %	3.5 %	2.7 %
StatStrip (POC)	0.4 %	1.7 %	0.0 %	-3.1 %	-5.0 %
HemoCue (POC)	4.8 %	7.6 %	0.0 %	-10.7 %	-19.1 %
COBAS	-3.6 %	0.0 %	0.0 %	-1.8 %	2.4 %

Waste of test strips compared among four blood glucose monitoring systems

R. Ng[1], S. Schwartz[2], E. Taylor[3];
[1]Abbott Diabetes Care, Alameda, [2]Diabetes and Glandular Disease Clinic, San Antonio, [3]MassResearch, Waltham, United States.

Background and aims: Applying insufficient blood or getting an error message can result in wasting of a test strip. Some waste of strips is inevitable to confirm questionable results and avoid errors. However, test strips represent most of the cost in blood glucose monitoring. The Abbott FreeStyle Lite Blood Glucose Monitoring System does not require coding, uses a very small blood sample (0.3 µL), is designed to start the test only after an adequate sample has been applied, and allows the user to apply more blood for up to 1 minute. A study was conducted to assess whether a device with these features is associated with less wasted strips than other systems when used by diabetic patients at home.
Materials and methods: 180 diabetic subjects who routinely performed blood glucose monitoring were enrolled at three clinics to use two systems which they had no prior experience with. The two systems consist of FreeStyle Lite system and one of the following: LifeScan OneTouch Ultra2 (sample size required: 1 µL), Roche Accu-Chek Aviva (0.6 µL) and Bayer Contour (0.6 µL). The Ultra2 and Contour are not designed for blood reapplication; more blood may be applied to the Aviva within 5 seconds of the first application. Each system was used by the subject at home 3 times a day for 2 weeks. The test results, number of strips used and error messages were recorded in the subject diary; 165 subjects completed the study.
Results: More than 6,000 tests were performed in this study. Approximately 1,000 tests (range: 916-1,182) were completed with each system in the paired testing. ANOVA analysis was used to compare the average % strips wasted of the 4 systems in the study. The results showed that significantly more strips were wasted with the OneTouch Ultra2, Accu-Chek Aviva and Contour than with the FreeStyle Lite system. All statistical tests were two-sided with alpha=0.05.

Study Site	Strips wasted among systems, % (strips wasted / total strips tested)				Chi-square p-value
	FreeStyle Lite	OneTouch Ultra2	Accu-Chek Aviva	Contour	
A	3.1% (33/1145)	5.9% (70/1182)			0.0009
B	3.3% (30/916)		5.4% (50/926)		0.025
C	2.7% (32/1175)			6.5% (81/1162)	<0.0001
	Strips wasted among subjects				
A	2.8%	5.5%			0.0057
B	3.0%		4.9%		0.12
C	2.5%			6.1%	0.0007

Paired t-test was used to compare the average % strips wasted among subjects. The results indicated that subjects on average experienced less wasted strips with the FreeStyle Lite system than with OneTouch Ultra2 and Contour, but not significantly different from Accu-Chek Aviva. One subject had a higher % strips wasted with FreeStyle Lite system than the rest of the subjects. If this subject was excluded, the results show that the average % strips wasted of subjects for FreeStyle Lite system was significantly less than that for Accu-Chek Aviva ($p = 0.02$ instead of $p=0.12$).
Conclusion: Overall, strip waste was 2.5-3.3% with the FreeStyle Lite system versus 4.9-6.5% with the other three systems. For the patients, reducing waste of strips by approximately half, as seen with the FreeStyle Lite system, should be encouraging. For the payers of diabetic supplies, a 2 to 3% decrease in expenditures could be viewed favorably.

938

A review of adverse events associated with false glucose readings measured by glucose dehydrogenase pyrroloquinolinequinone (GDH-PQQ)-based glucose monitoring systems in the presence of interfering sugars

J. Frias[1], C. Lim[2], J. Ellison[3], C. Montandon[4];
[1]Clinical Affairs, LifeScan, Inc., West Chester, [2]Medical Affairs, LifeScan, Inc., Milpitas, [3]Clinical Affairs, LifeScan, Inc., Milpitas, CA, United States, [4]Regulatory Affairs, LifeScan, Inc., West Chester, United States.

Background and aims: GDH-PQQ, a commonly used glucose test strip enzyme, is not glucose-specific. As such, it measures other sugars (maltose, galactose, xylose) in addition to glucose if they are present at detectable concentrations. This may result in falsely elevated "glucose" readings in patients treated with agents containing or metabolized to interfering sugars. Such agents include icodextrin-containing peritoneal dialysis (PD) solutions, some intravenous immune globulins (IVIG), abatacept (ORENCIA®) and ADEPT® Solution. Over the past 10 years there have been several case reports in the literature and from global regulatory agencies describing events of severe hypoglycemia and death due to overtreatment with insulin guided by GDH-PQQ-measured false glucose readings. We report a quantitative review of the medical literature and the US Food and Drug Administration Manufacturer and User Facility Device Experience (MAUDE) database of adverse events related to this issue.

Materials and methods: MAUDE, Ovid, and PubMed databases (1998-2009) were searched for published reports of adverse events due to discrepancies between glucose monitoring systems and reference values. Search terms included blood glucose, maltose, galactose, xylose, icodextrin, peritoneal dialysis, maltodextrin, abatacept and IVIG. The bibliographies from key articles were searched manually. Reports were independently assessed by multiple reviewers and summarized. Cases found in both the MAUDE and literature databases (n=3) were counted once.
Results: The search revealed 76 reports related to falsely elevated glucose readings due to the non-specificity of GDH-PQQ test strips (57 in MAUDE database, 19 in literature). Approximately half the reports (47%) were from outside the US. Of the 76 reports, 11 (14%) resulted in death, 45 (59%) in severe hypoglycemia, 11 (14%) in non-severe hypoglycemia, and 9 (12%) were unclassified. Four cases of severe hypoglycemia resulted in permanent impairment. Agents or disorders associated with events were icodextrin-containing PD solution (60 events, 79%), IVIG (10 events, 13%), a "maltose-containing substance" (3 events, 4%), galactosemia (2 events, 3%) and maltodextrin (1 event, 1%). Results from the MAUDE database revealed that 34 (60%) events occurred in an inpatient setting, 14 (25%) in an outpatient setting, and 9 (15%) were not classified. For the year 2008, the MAUDE database contained 2 fatal cases and 4 cases of severe hypoglycemia associated with this issue.
Conclusion: A significant number of adverse events, including death, related to glucose non-specificity of GDH-PQQ test strips have been reported globally over the past 10 years despite mitigations by manufacturers and global health authorities. This important drug-device interaction should be recognized by healthcare providers and patients, and actions must be taken to further enhance patient safety.

939

System accuracy evaluation of 27 blood glucose monitoring systems according to DIN EN ISO 15197
A. Baumstark, N. Jendrike, E. Zschornack, C. Haug, G. Freckmann;
Institute for Diabetes-Technology GmbH, Ulm, Germany.

Background and aims: Self monitoring of blood glucose (SMBG) is used for metabolic control and for a therapy adjustment by the patient himself. As insulin therapy is controlled by the measured values, high-quality blood glucose monitoring systems are required. This study intended to verify if the accuracy requested by DIN EN ISO 15197 is achieved in 27 SMBG devices currently available in Europe.
Materials and methods: In this study 27 CE-labelled SMBG devices of 18 manufacturers, were evaluated for system accuracy according to EN ISO 15197 versus a reference method: glucose oxidase (YSI 2300 STAT PLUS) or hexokinase (Gluco-quant / Hitachi 917) depending on the method used by the manufacturer. Two measurements performed from 100 samples with a defined distribution of glucose concentrations were included in the evaluation. According to EN ISO 15197 the minimum acceptable accuracy limits for blood glucose self-testing systems are as follows: 95 % of the results shall fall within ± 15 mg/dl of the results of the reference measurement at glucose concentrations 75 mg/dL.
Results: The tested samples had glucose concentrations between 20 and 500 mg/dL. Data of 3 of the 27 systems were evaluated versus the hexokinase reference, 24 systems were evaluated versus glucose oxidase. Sixteen of 27 tested systems complied with the system accuracy requirements of EN ISO 15197 with >95 % of the results showing the minimum acceptable accuracy. Eleven systems did not meet the system accuracy requirements. The percentage of results complying with the ISO criteria ranged from 73.5 to 100 % for the different systems and reached 94.6 ± 6.6 % [mean ± SD] on average.
Conclusion: In a system accuracy evaluation according to EN ISO 15197 only 16 of 27 SMBG systems met the minimum acceptable accuracy limits. SMBG systems providing inaccurate results bear the risk of false therapeutic decisions by the patient with the risk of severe health injury. In conclusion the EN ISO 15197 describes a reliable and highly standardized method to assess the quality of SMBG systems and thus, as the results demonstrate, could be useful to have systems analyzed by independent organisations.

Evaluating the feature of glycaemia excursion detected by continuous glucose monitoring system during temporary continuous subcutaneous insulin infusion
M. Li;
Shanghai No6 People's Hospital, China.

Background and aims: The aim of this study was to find out glycemia excursion feature via continuous glucose monitoring system(CGMS) in diabetes patients on early stage of continuous subcutaneous insulin infusion(CSII) treatment.Discuss the relationship between bedtime glucose level and nocturnal hypoglycaemia. Summarized the distribution feature of insulin dosage.
Materials and methods: 257 diabetes patients (156 males and 101 females , age from 12~88 years) with 0.1~31 years diabetic history were recruited. Their HbA1c level was(10.97±2.11)%. Glycated albumin level was (31.88±7.51)%. All patients changed to CSII therapy while a 72 hours period CGMS was performed. Participants were divided into hypoglycemia group and no hypoglycemia group according to the hypoglycemia events read from CGMS data.
Results: 1. From CGMS profiles we find 243 hypoglycemia events occurred in 118 participants at early stage of CSII treatment. The HbA1c, fasting C-peptide values,HDL-C and BUN were statistical difference between the two groups($P< 0.05$). Mean blood glucose(MBG) were significantly lower and standard deviation of blood glucose(SDBG) were significantly higher in hypoglycemia group($P< 0.05$). Multiple regression results indicated that MBG and fasting C-peptide were negatively correlated with hypoglycemia but SDBG and duration of diabetes were positively correlated with hypoglycemia. When bedtime blood glucose was below 5.9mmol/L, the youden index was max which was analysed by ROC. The sensitive was 54.8%, specificity was 77.8%. Positive predictive value was 44.3%, negative predictive value was 84.2%. So the cut-point of bedtime blood glucose to predict nocturnal hypoglycaemia might be 5.9mmol/L.2. The average total daily dosage(TDD) was (0.78±0.23)u·kg^{-1}·d^{-1}, basal rate was (0.34±0.09)u·kg^{-1}·d^{-1}, bolus dose was (0.45±0.16)u·kg^{-1}·d^{-1} during CSII. The insulin sensitive factor(ISF) was 1.77±0.49, insulin-carbohydrate ratio(ICR) was 9.55±2.67. TDD and bolus were correlated with BMI, urine glucose and 120minute C-peptide. Basal rate was correlated with BMI, urine glucose, HbA1c and 30minute C-peptide. The TDD and basal rate were higher in which the diabetic duration was over 5 years. The nocturnal basal rate was lower in whose age was over 60 years old.
Conclusion: 1.Hypoglycemia detected by CGMS were occurred in about 1/3 type 2 diabetes patients at the early stage of CSII therapy. 2. Beside of MBG and β-cell function, glycemic excursions were related closely to hypoglycemia. 3.There was a higher risk of nocturnal hypoglycaemia if the bedtime blood glucose concentration was below 5.9mmol/L. 4.At the beginning of CSII a low nocturnal basal rate would be appropriate to avoid hypoglycemia in elder patients. 5. The TDD would be large if the body weight was increased or the glycemia control was poor.

941

Continuous subcutaneous insulin infusion improved glycaemic control and health-related quality of life (HRQoL) in type 2 diabetes mellitus
X. Chen[1], J.P. Frías[2], S.V. Edelman[3], M.F. Peyrot[4], R.R. Rubin[5];
[1]Clinical Affairs, LifeScan, Inc., Milpitas, [2]Clinical Affairs, LifeScan, Inc., West Chester, [3]Department of Medicine, University of California, San Diego, [4]Loyola College Center for Social Research, Baltimore, [5]Dept of Medicine and Pediatrics, Johns Hopkins University School of Medicine, Baltimore, United States.

Background and aims: Limited information exists about the use of continuous subcutaneous insulin infusion (CSII) in type 2 diabetes mellitus (T2DM). This 16-wk, open-label, uncontrolled, pilot study evaluated insulin dosing requirements and patterns aimed at achieving normal or near-normal glycemic control with CSII in patients with T2DM. HRQoL and treatment preference were also assessed.
Materials and methods: Fifty-six insulin pump-naïve patients (28 male, 28 female) were enrolled (age 57±10y, DM duration 13±6y, A1C 8.4±1.3%, FPG 9.3±2.9mmol/l, weight 99±19kg, BMI 34±5kg/m², mean±SD)). Baseline DM therapy was either Cohort A: ≥2 oral agents (OA) (n=18), Cohort B: basal insulin ± OA (n=17; mean daily insulin dose 32±20U) or Cohort C: multiple

daily injections ± OA (n=21; mean daily insulin dose 99±65U). All antihyperglycemic agents except metformin were discontinued and CSII (Animas® 2020 insulin pump with insulin glulisine) was initiated with one daily basal rate and bolus doses at meals. Insulin dose was titrated to safely achieve the best possible glycemic control, and additional basal rates were added at the investigator's discretion. The Insulin Delivery System Rating Questionnaire (IDSRQ) was used at Baseline and Wk 16 to assess HRQoL and patient perception of insulin delivery system in Cohorts B and C. In Cohort A, a modified version of the IDSRQ, the Diabetes Medication System Rating Questionnaire (DMSRQ), was used. The score for each of the 7 questionnaire subscales ranged from 0 to 100.

Results: Glycemic control improved after 16 wks of CSII: A1C 7.2±0.9% (-1.2±1.2%, p<0.001) and FPG 7.2±1.9mmol/l (-2.1±3.4mmol/l, p<0.001). In patients with baseline A1C >8.5% (n=23, mean baseline A1C 9.6±0.9%), A1C was reduced by 2.1±1.1% (p<0.0001). At Wk 16, the mean daily basal, bolus, and total insulin doses were 51±30U, 45±32U, and 95±59U, respectively, and ~90% of patients were treated with ≤2 basal rates/day. Body weight increased by 1.9±3.3kg (p<0.001). Mild hypoglycemia was experienced by 59% of patients, with no severe hypoglycemia. Change from baseline at Wk 16 for the DMSRQ/IDSRQ are presented below.

Conclusion: CSII significantly improved glycemic control in this heterogeneous group of T2DM patients. In patients using insulin by injection at baseline, the majority of HRQoL measures improved significantly after 16 wks of CSII. Each Cohort perceived increased clinical efficacy with CSII and preferred CSII to baseline therapy despite weight gain. Future trials are needed to further define the role of CSII in managing T2DM.

Change from baseline at Wk 16 for the DMSRQ/IDSRQ

DMSRQ/IDSRQ Subscale	Cohort A (n=18)	Cohort B (n=17)	Cohort C (n=21)	All Cohorts (n=56)

Fasting plasma glucose rather than HbA_{1c} more linked to lipid profiles and IL-10 in subjects with type 2 diabetes treated via long-term continuous insulin infusion therapy

S.B. Choi[1], Y.H. Noh[2], J.H. Lee[2], J.H. Lee[2], J.H. Park[2];
[1]Internal Medicine, Konkuk University Hospital, Chungju, [2]Biochemistry, Konkuk University, Seoul, Republic of Korea.

Background and aims: Continuous subcutaneous insulin infusion (CSII) treatment has been reported to be effective in amelioration of hyperglycaemia and dyslipidaemia in type 2 diabetes. However, the significance of maintaining normal fasting plasma glucose (FPG) rather than HbA_{1c} level obtained via CSII has not been investigated in the aspect of clinical and laboratory beneficial outcomes.

Materials and methods: We discontinued oral antidiabetic drugs (OADs) and lipid lowering agents and applied CSII therapy to subjects with type 2 diabetes who had failed to control hyperglycaemia with OADs and/or insulin injections (number, 20 with 25% of male; age, 61.2 ± 7.8 years; duration, 13.3 ± 7.7 years; HbA1c 8.8 ± 2.5%). Three months after CSII treatment we divided the subjects into two groups, i.e., normal FPG (N-FPG, < 7 mmol/l) and high FPG (H-FPG, ≥ 7 mmol/l) groups and compared the changes in BMI, blood pressure and laboratory findings, including serum lipids and cytokines between two groups.

Results: Baseline characteristics were not significantly different between N-FPG and H-FPG groups (Before CSII in Table 1). The means of HbA_{1c} and free fatty acids decreased in both groups 3 months after CSII therapy ($p < 0.01$ for both). Although the means and medians of HbA_{1c} after CSII treatment were the same in two groups, means of FPG, HDL-cholesterol, and IL-10 were significantly different between two groups (After CSII in Table 1). Moreover, means of BMI and HDL-cholesterol significantly increased ($p < 0.01$ and $p < 0.05$, respectively) and the diastolic blood pressure level decreased ($p < 0.05$) in N-FPG group after CSII treatment as compared with those at baseline, but these findings were not observed in H-FPG group. Instead, the mean triglyceride level increased in H-FPG group after CSII treatment when compared with the level at baseline ($p < 0.05$). The means of IL-6 and sICAM-1 after CSII treatment appeared lower in N-FPG than in H-FPG group but did not reach to the statistical significance. FPG showed correlation with triglycerides ($r = 0.546$, $p = 0.013$) and HbA_{1c} correlation with IL-10 ($r = 0.71$, $p = 0.03$).

Conclusion: Excursion of FPG level seemed to be linked to lipid profiles or cytokine levels, indicating frequent examination of FPG may be recommended together with a periodic determination of HbA_{1c} for optimal diabetic care, although HbA_{1c} has been known as a useful parameter in the assessment of glycaemic control.

Continuous subcutaneous insulin infusion in patients with type 2 diabetes safely improved glycaemic control using a simple insulin dosing regimen

S.V. Edelman[1], B.W. Bode[2], T.S. Bailey[3], M.S. Kipnes[4], X. Chen[5], J.P. Frías[6];
[1]Department of Medicine, University of California San Diego, La Jolla, [2]Atlanta Diabetes Association, Atlanta, [3]North County Endocrine, Escondido, [4]Cetero Research, San Antonio, [5]LifeScan, Inc., Milpitas, [6]Clinical Affairs, LifeScan, Inc., West Chester, United States.

Background and aims: Limited information exists about the use of continuous subcutaneous insulin infusion therapy (CSII) in patients with type 2 diabetes (T2DM). This 16-week, open-label, uncontrolled, multicenter pilot study was designed to evaluate insulin doses and dosing patterns aimed at achieving normal or near-normal glycemic control with CSII in patients with T2DM.

Materials and methods: Fifty-six insulin pump-naïve patients (28 male, 28 female) were enrolled (age 57±10y, DM duration 13±6y, A1C 8.4±1.3%, FPG 9.3±2.9mmol/l, body weight 99±19kg, BMI 34±5kg/m², mean±SD). Baseline diabetes therapy was either ≥2 oral agents (OA) (n=18), basal insulin ± OA (n=17; mean daily insulin dose 32±20U) or multiple daily injections ± OA (n=21; mean daily insulin dose 99±65U). All antihyperglycemic agents except metformin were discontinued and CSII (Animas® 2020 insulin pump with insulin glulisine) was initiated with one daily basal rate and bolus doses at each meal. Insulin dose was titrated to safely achieve the best possible glycemic control, and additional basal rates were added at the investigator's discretion. CGM (DexCom SEVEN®) was conducted for a week at baseline and repeated during the final week of the study.

Results: Glycemic control improved significantly after 16 wks of CSII: A1C 7.2±0.9% (-1.2±1.2%, p<0.001) and FPG 7.2±1.9mmol/l (-2.1±3.4mmol/l,

p<0.001). At Wk 16, 45% and 28% of patients had A1C values <7.0% and <6.5%, respectively. In patients with baseline A1C >8.5% (n=23, mean baseline A1C 9.6±0.9%), A1C was reduced by 2.1±1.1% (p<0.0001). Mean pre-prandial and postprandial glucose values from self-monitored 7-point glucose profiles declined significantly from baseline at Wk 16 (pre-prandial -1.2±2.6mmol/l, p=0.002; postprandial -2.1±3.1mmol/l, p<0.001). CGM revealed significantly more values within the 3.9-10.0mmol/l range during the last week of the study compared with baseline (Baseline=59%; end-of-study=71%, p<0.001). At Wk 16, the mean daily basal, bolus, and total insulin doses were 51±30U, 45±32U, and 95±59U (0.94U/kg), respectively, and ~90% of patients were treated with ≤2 basal rates per day (1 basal rate 70%; 2 basal rates 18%; >2 basal rates 12%). Body weight increased by 1.9±3.3kg (p<0.001). Total cholesterol (TC) and triglycerides (TG) improved significantly during the course of the study (TC: Baseline=4.7±1.1mmol/l, Wk 16=4.5±1.2mmol/l, p<0.05; TG: Baseline=2.4±1.7mmol/l, Wk 16=1.8±1.1mmol/l, p<0.001). There was no change in LDL or HDL cholesterol. Mild hypoglycemia was experienced by 59% of patients during the 16-wk study period with no episodes of severe hypoglycemia.
Conclusion: Glycemic control was significantly improved with CSII using a minimal number of basal rates in a heterogeneous group of T2DM patients. Future well-controlled, randomized trials are needed to further assess the benefits of CSII in T2DM.

944

Intensified insulin therapy vs CSII: the influence on family cohesion and adaptability of type 1 diabetics
E. Liouri[1], A. Koutsovasilis[1], K. Kounenou[1], A. Kamaratos[1], M.-P. Koukouli[1], A. Nikolaou[1], S. Iraklianou[1], D. Damianaki[2], A. Melidonis[1];
[1]Diabetes Center, [2]Pediatrics, Tzanio General Hospital of Piraeus, Greece.

Background and aims: Type 1 diabetes mellitus appears at a young age and is treated with intensified regimes of insulin therapy or continuous subcutaneous insulin infusion (CSII), following the patient and changing not only his/her life, but also that of the family. With this study, we attempt to establish possible differences between families of type 1 diabetes patients following intensified regimes of insulin therapy and those using continuous subcutaneous insulin infusion as to the adaptability, the cohesion and the type of family as defined by Olson.
Materials and methods: 72 patients following intensified insulin therapy (Group A), and 46 patients using CSII (Group B) of comparable age and gender filled out an approved questionnaire (FACES-III) of 40 questions determining the level of family adaptability (rigid, structured, flexible, very flexible) and cohesion (disengaged, separated, connected, very connected), as well as its type according to international literature where 4 types of family are specified (extremely imbalanced, moderately imbalanced, moderately balanced, balanced). HbA1c and somatometric characteristics were recorded in both groups. Statistical analysis was carried out using SPSS 15.0. A p-value<0.05 was considered significant.
Results: There was no statistically significant difference between groups A and B as to HbA1c (7.62 vs 7.47, p=0.394), age (34.97 vs 36.06, p=0.403) and diabetes duration in years (13.83 vs 13.65, p=0.900), while there was a difference as to BMI (28.02 vs 25.35, p=0.001). Concerning adaptability, a statistically significant difference was found between the two groups (p=0.041), with patients using CSII scoring better on the fourth level (very flexible) of adaptability (73.5% vs 50%). There is also a significant difference in cohesion, with patients using CSII having a higher percentage (55.9% vs 20.8%) on the level of very-connected families (p=0,004). Patients using CSII outnumber patients in intensified insulin therapy in the fourth atype of family (64.7% vs 33.3%, p=0,009), with the former showing higher rates in the third family type (50.0% vs 26.5%, p=0.012). The level of adaptability, as well as the level of cohesion and the type of family, affects the regulation of diabetes mellitus. A higher level of adaptability is correlated with lower insulin values for the group in intensified regime as well as the group using CSII, with similar results concerning cohesion for the first (p=0.014) as well as the second (p=0.002) group of patients. The same applies for the effect of family type (intensified insulin therapy group: p=0.044; insulin pump group: p=0.030).
Conclusion: Families of patients with type 1 diabetes following a continuous subcutaneous insulin infusion show higher adaptability and cohesion compared τo families of patients using an intensified insulin regime. The findings are similar concerning the type of family. Family type, adaptability and cohesion play a crucial role in the regulation of diabetes mellitus irrespective of the kind of treatment followed by the patient.

945

Retrospective case-controlled long-term study on continuous subcutaneous insulin infusion vs multiple daily injections for functional insulin treatment in type 1 diabetes
K. Howorka, J. Pumprla, M. Puck, N. Howorka, E. Perneczky, I. Mihaljevic;
Centre of Biomedical Engineering & Physics, Medical University of Vienna, Austria.

Background and aims: In intensified insulin treatment, pump therapy is sometimes preferred to multiple insulin injections. Our aim was to compare treatment outcomes in FIT (functional insulin treatment, discriminating between correctional, prandial and basal insulin use) educated patients with type 1 diabetes who later on have chosen on their own an insulin pump (CSII) vs. those who have chosen multiple daily injections (MDI).
Materials and methods: Retrospective case-controlled study where for each CSII patient two MDI controls have been selected, matched for diabetes duration, FIT duration, associated diseases at time point of FIT training and if possible, gender. Patients have been selected from participants of an annual structured outpatient FIT UPDATE module (educational weekend developed for FIT patients). Thirty type 1 diabetic FIT patients with CSII (females n=23, 77%), and 60 with MDI (6.3±1.4 daily injections, females n=40, 67%) comparable in age (CSII: 45.2±12.2 vs. MDI: 44.6±13.0 yrs), diabetes (24.2±13.3 vs. 23.4±10.2 yrs) and FIT (13.0±6.4 vs. 14.0±5.9 yrs) duration, and associated diseases were included in the study, their glycemic control was traced and extracted from electronic and paper patient files. The impact of diabetes treatment was measured with ADDQoL (Bradley), DTSQ extended for FIT State version and DES (Anderson) and with a specifically developed ranking scale for advantages and disadvantages of pumps and/or injections.
Results: There was no significant difference in HbA_{1c} values between the two groups at any point of observation. HbA_{1c} values remained good in both patient groups on the level comparable to that one of the intensified treatment of DCCT group for the mean observation period of CSII treatment of 5.0±2.8 years, however already slightly higher as after the initial main educational intervention of FIT training. Mean HbA_{1c} level during the period of the controlled study was 7.4±0.7 (CSII) vs 7.2±1.0% (MDI), p=0.36. Initial pre-pump HbA_{1c} level was slightly (p=0.09) higher in the CSII group (7.5±0.8 vs.7.3±1.0%), but it improved with CSII initiation reaching its nadir of 7.2±0.5 after 7-12 months following the initiation of the pump treatment. Thereafter, HbA1c values tended to increase and after 19-24 months of CSII reached the values comparable to those in the pre-pump period. No significant differences for frequency of severe hypoglycaemia were found. Behavioural differences between groups were given for reported number of daily blood glucose self-measurements (CSII: 5.6±0.9 vs MDI: 5.1±0.8, p=0.01). The differences in treatment satisfaction were significant only for item 13 of the DTSQ extended for FIT, dealing with satisfaction with basal insulin where pump patients displayed somewhat higher satisfaction. Additional questions for basal insulin dealing with stability of blood glucose values between meals and with fasting values did not reach statistical significance nor the other subscores did. The results of ADDQoL, and DES did not show any significant differences among the two groups.
Conclusion: No significant differences were found between outcomes of CSII and MDI in FIT educated patients beyond an initial HbA_{1c} improvement of 6-12 months. Functional insulin use with in average more than 6 daily injections results in FIT-educated patients in similar outcomes independently of the mode of insulin delivery.

946

Integrated real-time continuous glucose monitoring/insulin pump system (PRT) usefulness in 122 children with type 1 diabetes. A 3-year follow-up study
A.E. Scaramuzza[1], R. Bonfanti[2], P. Buono[3], D. Iafusco[4], F. Lombardo[5], I. Rabbone[6], R. Schiaffini[7], N. Sulli[8], S. Toni[9], A. De Palma[1], G. Zuccotti[1], Italian Society of Paediatric Endocrinology and Diabetology;
[1]Paediatrics, University of Milano - Luigi Sacco Hospital, [2]Paediatrics, University Vita e Salute - San Raffaele Institute, Milano, [3]Paediatrics, University Federico II, Naples, [4]Paediatrics, Second University of Naples, [5]Paediatrics, University of Messina, [6]Paediatrics, University of Torino, [7]Paediatrics, Bambin Gesù Hospital, Rome, [8]Paediatrics, Umberto I Hospital, Rome, [9]Paediatrics, University of Firenze, Italy.

Background and aims: Real-time continuous glucose monitoring and the insulin pump have been combined into the sensor-augmented pump system

(PRT) (Medtronic MiniMed, Sesto San Giovanni, Italy). The objective of the study was to evaluate the clinical effectiveness and safety of PRT in a large series of children with type 1 diabetes using insulin pump therapy.
Materials and methods: This is a multicenter observational study. A questionnaire was sent to all paediatric diabetologic centres in Italy (n=65); data was analyzed only regarding patients aged 18 or less and using PRT for 6 months or more.
Results: A total of 48 centres (73.85%) answered the questionnaire. The total number of patients with type 1 diabetes followed by the centres is 12.549, of whom 1437 (11.4%) have been using insulin pump therapy for more than 6 months. Of all patients using an insulin pump, 129 have been using PRT for at least 6 months, with a mean follow-up of 1.4±0.7 yrs (range 0.5-3 yrs). Their age was 13.5±3.8 yrs, with disease duration of: 6.3±3.4 yrs). After 0.5-3 yrs of using PRT, HbA1c showed a significant improvement (8±1.5 vs 7.4±0.8%, p = 0.002). Insulin requirement showed a significant decrease (0.88±0.25 vs 0.79±0.23 U/kg/day, p =0.003). BMI did not change during the observational period. Mean usage of PRT per month was 8.1 day/month and any significant correlation between sensor use and HbA1c has been observed (r2=0.0005, p=0.239). No DKA was observed during the follow-up, while episodes of severe hypoglycemia significantly decreased (p=0.04).
Conclusion: The increased availability of continuous glucose sensors is likely to have a significant impact on pediatric diabetes therapy and education in the near future. Selection of patients capable and motivated to use sensor-augmented pump with proper age-appropriate education could be the key factors for the long-term success of these new technological advances in diabetes therapy as we have seen in our large group of children using PRT.

PS 81 Improving insulin

947

A new approach for oral delivery of insulin
C. Damge[1], C. Reis[2], F. Veiga[2], A. Ribeiro[2], R. Neufeld[3];
[1]Institute of Physiology, University of Strasbourg, France, [2]Laboratory of Pharmaceutical Technology, University of Coimbra, Portugal, [3]Queen's University, Kingston, Canada.

Background and aims: Oral administration of insulin is the most physiological and comfortable way. However, insulin a 51 amino acid peptide, is less absorbed by the gastrointestinal tract and is degraded by proteolytic enzymes. Thus, in order to circumvent these difficulties, we have encapsulated insulin in nanoparticles (NPs) composed of alginate, coated with chitosan-PEG (polyethylene glycol 4000)-albumin.
Materials and methods: The biological, metabolic and toxicological effects of insulin NPs were investigated after oral delivery in diabetic rats induced by streptozotocin.
Results: (1) NPs, less than 600 nm in size, were able to encapsulate more than 85% of insulin. They protect insulin againt pepsin. In vitro, at pH 1.2 (gastric pH), they released 25% of their insulin content and 70% at pH 6.8 (intestinal pH). (2) When administered orally in fasted diabetic rats, insulin NPs (25, 50, 100 I.U./kg) reduced dose-dependently glycemia from 2h, with a maximal effect at 10h (-53%, p<0.001) and maintained this effect up to 48 h. Insulin NPs also improved the glycemic profile after an oral glucose overload (2 g/kg) and increased (9 times) plasma insulin level. (3) The pharmacological bioavailability calculated against a s.c. administration of free insulin was about 21% for a dose of 50 I.U./kg insulin. (4) After a daily administration of 50 I.U./kg insulin NPs during 4 days, the water and food intakes, urine volume and proteinuria were significantly reduced. (5) After a 15 days daily administration at the dose of 50 I.U./kg, there was none hematological nor tissular toxicity. (6) Finally, encapsulated insulin labelled with FITC was absorbed through the intestinal epithelium and the Peyer's patches.
Conclusion: NPs composed of an alginate core coated with chitosan-PEG-albumin induced a prolonged anti-diabetic effect after oral administration. This effect may be explained by the protection of insulin against proteolytic enzymes in the GIT and the facilitation of its absorption due to chitosan which transiently opens the tight junctions.

948

***In vivo* validation of a double encapsulation of insulin for an oral administration**
N. Reix[1], E. Seyfritz[1], N. Ebel[2], C. Vodoue[1], A. Parat[2], L. Danicher[2], Y. Frere[2], M. Pinget[1], S. Sigrist[1];
[1]Centre Européen d'Étude du Diabète, [2]Institut Charles Sadron, Strasbourg, France.

Background and aims: The purpose of this study was to develop a new formulation of oral insulin in order to improve the treatment for diabetic patients. Normally, peptide hormones like insulin are given by parenteral injections routes because they are destroyed by the acid and proteolytic enzymes in stomach and intestine. Our project focuse on insulin double encapsulation for oral administration.
Materials and methods: The first system of encapsulation of insulin is based on Poly(Lactide-co-Glycolide) Acid (PLGA) nanoparticles. This should allow the uptake and the transport across mucosal intestinal barrier. These nanoparticles are put in a gastroresistant capsule made of methacrylic acid and ethyl acrylate (1/1). The gastroresistant property of the capsule was observed by x-ray tomography after gavage of baryum chloride capsule to rats. Concerning the nanoparticles, microscopic visualizations were done by TEM and CSEM, the encapsulation rate of insulin was evaluated by the Bradford's test and the insulin conformation can be analysed by Circular Dichroisme. *In vivo*, the biofunctionnality of the nanoparticles was evaluated after subcutaneous injections. The absorption of insulin was first performed by the visualization of insulin-FITC loaded nanoparticles injected in the duodenum. In a second way, we measured the kinetic of the glycemia and the biofunctionnality of NP in streptozotocin-induced diabetic rats after intra-duodenal injections of insulin nanoparticles and intraperitoneal injections of insulin. The bioavaibility was evaluated after quantification of the insulinemia after intra-peritoneal injections of insulin and after intraduodenal injections of the same quantity of encapsulated insulin.

Results: The gastroresistance of the capsule was confirmed as 5h after gavage the capsule was still intact in the stomach of the rats. After synthesis, the size of nanoparticles is 160 ±10nm and the rate of encapsulation is around 95%. Circular dichroïsm indicated that insulin conformation was preserved during particles synthesis. Sub-cutaneous injections of insulin nanoparticles induce the same decrease of glycemia than subcutaneous injections of insulin showing the biofunctionnality of the system. *In vivo*, fluorescence microscopy carried out on portions of the small intestine revealed the presence of concentrated fluorescence into the mucosa 30min after the administration of insulin-FITC loaded nanoparticles. So nanoparticles can efficiently protect insulin in the intestine and can be absorbed. Intraduodenal injections of insulin nanoparticles induce a significant decrease of glycemia from 5,2 ±0,5g/L to 0,9 ±0,2g/L 9h after injection (t test; p≤0,001). In comparison with intra-peritoneal injections, results showed that nanoparticles' biodisponibility is at less 20%.
Conclusion: PLGA insulin-loaded nanoparticles are efficient and the biological effect of insulin is preserved. These polymeric particles allow the absorption of insulin through intestinal mucosa into the bloodstream. Thus this new delivery insulin formulation seems to be an interesting approach.

949

Combination of intestinal goblet HT29 and Raji-B cells with absorptive Caco-2 cells to predict intestinal absorption of insulin encapsulated into nanoparticles

B. Sarmento[1,2], A. Neto[1], C. Gehm[1], J. Teixeira[1], V. Seabra[2], D. Ferreira[1];
[1]Department of Pharmaceutical Technology, Faculty of Pharmacy, University of Porto, [2]Department of Pharmaceutical Sciences,, Health Sciences Research Center (CICS), Instituto Superior de Ciências da Saúde-Norte, Gandra, Portugal.

Background and aims: Oral delivery of therapeutic proteins like insulin is desired due to its convenience. Pharmacokinetics and biodistribution of insulin after oral administration can be improved with the incorporation into nanoparticles. Solid lipid nanoparticles (SLN) are an alternative in the production of pharmaceutical systems. The use of chitosan to coat SLN constitutes an important advance to enhance the permeability of drugs towards the intestinal epithelium. The Caco-2 line is a well-established in vitro cell model for predicting the absorption of orally administered drugs in humans. The prediction of intestinal drug absorption by an appropriate in vitro cell model based on Caco-2 cells incorporating different intestinal cells like HT29 mucus-producing goblet cells or Raji B M-cell phenotype cells, in order to mimic as close as possible the intestinal epithelium, would avoid costly and time-consuming animal experiments. In this work the aim was to investigate the permeability of insulin loaded into SLN and chitosan-coated SLN across different Caco-2/HT29 and Caco-2/Raji co-culture cells monolayer, attempting future correlation with in vivo physiologic absorption.
Materials and methods: Insulin was entrapped into SLN by W/O/W multiple emulsion and further coated by chitosan to take advantage of its mucoadhesive properties. For permeability experiments, Caco-2, HT-29 and Raji B were seeded single and in the co-culture system using different proportions onto Transwell® permeable supports 3,0 µm, polycarbonate membrane. Transepithelial electrical resistance (TEER) of the cell monolayers was measured using an EVOM epithelial voltohmmeter to check monolayer integrity and were cultured for 21-28 days before the initiation of an experiment. Transwell® insulin absorption experiments were run at 37ºC from apical to basolateral chamber. Insulin was measured by HPLC.
Results: Permeability assays realized in Transwells® showed insulin permeability increase with increase of HT29 cell content for all formulations (insulin in solution, insulin loaded SLN and insulin loaded chitosan-coated SLN). Permeability results for Caco-2/HT29 90:10 co-culture was more consistence with the human intestine cell distribution. The effect of number of Raji cells on insulin absorption also demonstrates the implication of M-like cells on drug absorption. Although latter onset, probably due to delay of release from nanoparticle matrix, chitosan coating of SLN demonstrated absorption enhancing effect. This may occur due to mucoadhesion and opening of the tight conjunction between the epithelium cells that can improve the insulin permeability into the co-culture monolayer. TEER values were measured during the experiment to evaluate the integrity of the cell monolayer. During all experiments, TEER values decreased, but the integrity of the cells was maintained.
Conclusion: Results demonstrate that Caco-2/HT29 and Caco-2/Raji co-culture cell model are reliable systems to correlate in vitro insulin absorption with in vivo animal model. Absorption of insulin entrapped into chitosan-coated SLN seems to be a promising alternative for the development of a formulation for oral insulin administration.

Management of impaired glucose tolerance using buccal spray insulin

A. Palermo, N. Napoli, F. Costanza, G. Beretta, S. Manfrini, P. Pozzilli;
University Campus Bio-Medico, Rome, Italy.

Background and aims: Postprandial hyperglycaemia occurs as the consequence of a reduced first phase insulin response after a meal and has been associated with an increased risk of cardiovascular events and mortality. Subjects with postprandial hyperglycaemia often present with dyslipidaemia, hypertension, abdominal obesity, microalbuminuria, endothelial dysfunction and markers of inflammation. Correction of the first phase insulin response using fast insulin is an attractive option. The objective of this phase II study was to investigate the safety and efficacy of treatment with buccal spray insulin (Oral-lyn™)on post-prandial plasma glucose and insulin levels in subjects with impaired glucose tolerance (IGT).
Materials and methods: A total of 20 Caucasian subjects, mean age 48.7 ±14.3 SD years, a body mass index of 32± 6 Kg/m2, 13 females and 7 males, with confirmed IGT were included in the study. Subjects were randomized to take 4, 6 or 12 Oral-lyn™ puffs, split in two equal doses each, one before and the second 30 minutes after a standard 75 gr oral glucose tolerance test (OGTT). Glucose excursions and insulin levels were measured at baseline and 30, 60, 90, 120, 180 min afterwards.
Results: There were no significant differences in plasma glucose levels during OGTT with 4 or 6 puffs compared to OGTTs performed without insulin administration. Treatment with 12 Oral-lyn™ puffs (equal to 12 IU) was followed by a significant 29.6% decrease in mean plasma glucose at two-hours (from 175.3± 14.0 to 124.0±39.1 mg/dl), and a 26.8% decrease at three-hours (from 124.7±50.5 to 91.3±26.0 mg/dl), altogether p=0.01. Considering all time points of the OGTT up to 180 min, there was a mean reduction of 15.8% in plasma glucose levels. There was a trend for increased insulin (µU/L) levels at all measurements. Finally, no adverse events were observed during the study period and no hypoglycaemic episodes were complained at any timepoints.
Conclusion: This proof of concept study demonstrates that treatment with buccal spray insulin is a simple and valuable therapy for reducing postprandial hyperglycaemia in obese subjects with IGT. Importantly, this treatment was safe and none of the study subjects experienced hypoglycaemia. The use of insulin through an alternative route such as the buccal mucosa can represent a novel approach for treatment of postprandial hyperglycaemia.

951

Comparison of glycaemic variations in Japanese patients with type 1 diabetes receiving long-acting soluble insulin as assessed by continuous glucose monitoring (CGM)

D. Tsujino, R. Nishimura, K. Taki, A. Morimoto, N. Tajima;
The Jikei University School of Medicine, Tokyo, Japan.

Background and aims: Japanese patients with type 1 diabetes receiving the long-acting soluble insulin preparations insulin glargine and insulin detemir were compared for glycemic variation by using continuous glucose monitoring (CGM).
Materials and methods: A total of 16 patients with type 1 diabetes (males/females, 5/11) were enrolled in the study. Their median age was 55.0 years (range, 35.0-60.8), median BMI 22.5 kg/m^2 (range, 19.5-23.6), median HbA1c 7.2% (range, 6.7-8.8), and median urinary CPR 1.1 µg/day (range, 0.7-5.5). Of these, 2 patients received one insulin injection, and 14 received two insulin injections. The subjects were crossed over from insulin glargine or insulin detemir or vice versa with no change in the number of insulin preparations injected or in the timing for such injections, and were monitored by CGM while on either preparation for glycemic variation in a non-blinded fashion during the 4-day hospitalization, with the timing for another hospital stay scheduled more than 1 month after change of insulin preparations. CGM data obtained on day 3 of their hospitalization were used for analysis. Mean glucose levels, their standard deviations (SD), M values, duration of hypoglycemia (< 70 mg/dL), duration of hyperglycemia (> 200 mg/dL), range of postprandial glucose increase and time to peak glucose values (time to peak glucose values after each meal and a mean time to peak glucose values after 3

meals) were compared between those given insulin glargine and those given insulin detemir by using Mann-Whitney's U test. All statistical analyses were performed by using SPSS 16.0. The present study was approved by the Ethics Committee of the Jikei University School of Medicine.
Results: There was no significant difference between those receiving insulin glargine and those receiving insulin detemir with their mean glucose level being 158.5 mg/dL (133.5-200.5) and 154.0 mg/dL (129-178.5), their SD being 53.5 mg/dL (41.5-80.3) and 50.5 mg/dL (41.5-64.5), and their M values being 36.0 (26.8-76.0) and 34.5 (20.8-66.0). Those receiving insulin glargine or insulin detemir were not significantly different, either, with regard to the duration of hypoglycemia (< 70 mg/dL) or duration of hyperglycemia (> 200 mg/dL). In addition, there was no significant difference between those receiving insulin glargine and those receiving insulin detemir with regard to the range of postprandial increase in glucose levels after morning meals, evening meals as well as the mean range of increase after 3 meals, and the time to peak glucose levels, while those on insulin detemir tended to show a narrower range of postprandial glucose increase (P = 0.10) and a shorter time to peak glucose levels (P = 0.067). After completion of the study, asked to choose between the two insulin preparations, more patients tended to opt for insulin detemir over insulin glargine, with 12 out of 16 (75%) choosing insulin detemir (P = 0.077).
Conclusion: A comparison of glycemic variations in type 1 diabetic patients receiving insulin glargine or insulin detemir by CGM demonstrated that both insulin preparations were almost equally efficacious. It was also shown that insulin detemir could potentially offer better glycemic control after midday meals than insulin glargine and that more patients tended to choose insulin detemir over insulin glargine after completion of the study.

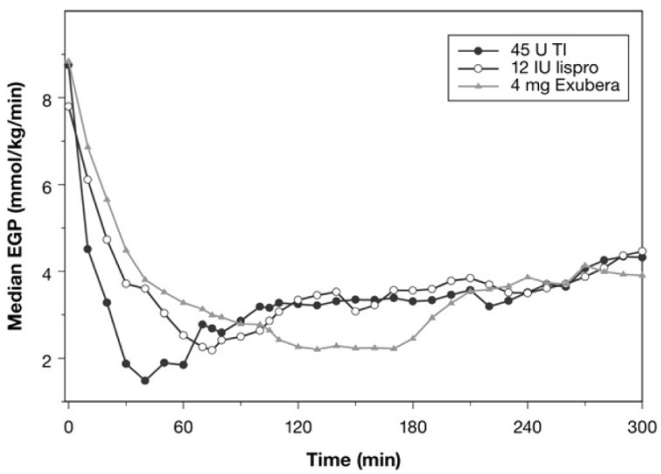
Technosphere insulin suppresses endogenous glucose production earlier than a rapid-acting analogue (lispro) and an inhaled insulin (Exubera®)
E. Potocka[1], R. Hovorka[2], R. Baughman[1], M. Umpleby[3], M. Diaz[1], R. Chen[1], J. Cassidy[1], A. Boss[1], P. Richardson[1];
[1]MannKind Corporation, Valencia, United States, [2]University of Cambridge Metabolic Research Laboratories, United Kingdom, [3]University of Surrey, Guildford, United Kingdom.

Background and aims: Available insulins are unable to replicate normal hepatic glucose suppression, presumably due to slow absorption. Technosphere Insulin (TI) is a rapid-acting insulin generating peak insulin levels within 12 to 14 minutes of dosing. We conducted a study to determine whether the unique pharmacokinetic profile of TI resulted in a more rapid suppression of endogenous glucose production (EGP).
Materials and methods: We compared 45 U TI administered by inhalation with 12 IU s.c. insulin lispro and 4 mg inhaled Exubera (EXB) in an open-label, single-dose, three-way crossover study incorporating a meal challenge (nutritional energy drink [12 fl oz] enriched with U13-C-glucose) in 18 insulin-treated subjects with type 2 diabetes and normal pulmonary function. A continuous glucose infusion enriched with 6,6-$^2H_2$ glucose was used to assess EGP. Prior to the meal, subjects' blood glucose was adjusted to 90 mg/dl using an individual continuous low-dose i.v. insulin infusion, which was fixed 90 minutes before dosing. If necessary, glucose was infused to maintain blood glucose at ≥90 mg/dl.



Results: EGP suppression occurred markedly earlier with TI, followed by insulin lispro and EXB (40, 75, and 130 minutes post-dose of the median EGP-time profiles, respectively). Significant differences between insulin lispro and EXB were observed up to 40 minutes compared with TI (p<0.002) and up to 2 hours for the EXB-TI comparison (p<0.05). Median total areas over the EGP curve were comparable across groups (1,938, 1,842, and 2,294 µmol/min). Median postprandial blood glucose AUCs were 53,343, 50,608, and 54,598 mg/dl•min for TI, insulin lispro, and EXB, respectively.
Conclusion: EGP was suppressed earlier following TI administration compared with s.c. insulin lispro and inhaled EXB, which suggests that treatment with TI may result in a more physiologic EGP suppression.

953

Accelerated insulin pharmacokinetics and improved glycaemic control in patients with type 1 diabetes mellitus by coadministration of prandial insulin with recombinant human hyaluronidase
M. Hompesch[1], D. Muchmore[2], L. Morrow[1], D. Mongiovi[2], D. Vaughn[2];
[1]Profil Institute for Clinical Research, Inc., Chula Vista, [2]Halozyme, Inc., San Diego, United States.

Background and aims: Recombinant human hyaluronidase (rHuPH20) is a locally and transiently acting enzyme that catalyzes depolymerization of hyaluronan, thus reducing the barrier to local bulk fluid flow and increasing the permeation of coinjected drugs. This prospective Phase 2 study compares the pharmacokinetics (PK) and postprandial glucose (PPG) response to SC insulin lispro (lispro) and regular human insulin (regular) ± coinjected recombinant human hyaluronidase (rHuPH20) following a liquid meal in T1DM.
Materials and methods: Patients fasted (10 h) and refrained from SC insulin for 12 h before dosing. Starting 2 h before a liquid meal (60 g CHO) challenge, patients were titrated to 100 mg/dL glucose target with IV glucose and/or insulin followed by a 30 min intervention-free equilibration. The same dose of insulin lispro (mean 5.7 ± 3.0 U, optimized for each patient) ± rHuPH20 (0.2 µg/U insulin) was injected SC immediately before the meal, and plasma insulin and glucose concentrations were monitored for 8 h. This program was then repeated for regular (mean 6.2 ± 3.5 U) ± rHuPH20.
Results: Of a planned 20 patient 4-way crossover study, final PK data are available for the first 12 and final glucose data for all 21 completers (14 male, 7 female, age = 41.3 ± 10.6 SD yr, BMI = 24.4 ± 2.9 SD kg/m^2). PK for both lispro + PH20 and regular + Ph20 showed accelerated but overall comparable exposure as compared to each without PH20. Early $t_{50\%\ max}$ decreased from 19.9 to 12.6 min (p=.0002) for lispro and 40.1 to 14.8 (p=.033) for regular; t_{max} decreased from 43.8 to 27.9 min (p=.002) for lispro and 96.7 to 52.1 (p=.086) for regular; late $t_{50\%\ max}$ decreased from 98.6 to 68.6 min (p=.0001) for lispro and 195.0 to 111.2 (p=.007) for regular. Corresponding glycemic response curves are shown in the figure. AUC>140 mg/dL (0-4 h) was reduced from 3217 to 1298 min*mg/dL (p=.044) for lispro and 6606 to 1854 (p=.006) for insulin; peak glucose (0-4 h) fell from 179 to 152 (p=.006) for lispro and 211 to 168 (p=.004) for insulin. All injections were well tolerated and there were no serious, significant or moderate adverse events. The most common adverse event (mild) was low blood glucose concentration, which was similar between treatment groups.
Conclusion: Coinjection of rHuPH20 accelerated insulin PK and led to improved PPG control for both lispro and regular insulin.

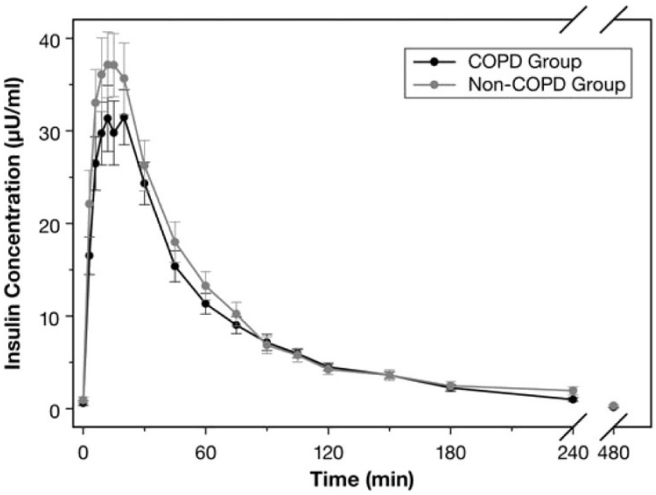
Pharmacokinetics of Technosphere insulin unchanged in patients with chronic obstructive pulmonary disease

P. Richardson[1], E. Potocka[1], R. Baughman[1], S. Schwartz[2], M. Gray[1], M. Diaz[1];
[1]MannKind Corporation, Valencia, [2]Diabetes & Glandular Disease Research Associates, PA, San Antonio, United States.

Background and aims: Inhaled insulin has historically been shown to decrease the rate and extent of insulin exposure by approximately 20% to 50% in subjects with chronic obstructive pulmonary disease (COPD).
Materials and methods: The pharmacokinetics (PK) of Technosphere Insulin (TI), a rapid-acting insulin for pulmonary delivery, was evaluated in an open-label, single-dose, euglycemic glucose clamp study in 37 non-diabetic, non-smoking healthy subjects (N=19; baseline mean ± SD age 51±14 years; BMI 29±3 kg/m^2; forced expiratory volume in 1 second [FEV_1] 3.5±1) and subjects with COPD (N=17; aged 60±9 years; BMI 29±5 kg/m^2; FEV_1 2.6±0.8).
Results: Thirty-four subjects were age-, gender-, and BMI-matched. One COPD subject was excluded. Each subject received a single dose of 30 U of TI via inhalation. Serial blood samples were drawn for insulin and C-peptide concentration determination until 480 min post-dose. Insulin concentrations were C-peptide corrected to account for endogenous insulin, and C-peptide corrected values were used for PK parameter estimation. There was no statistically significant difference in absorption in the two groups. Mean peak insulin was 34.7 and 39.5 μU/ml (p=0.285) with a median time to maximum insulin concentration of 15 and 12 min (p=0.241) in the COPD and non-COPD groups, respectively. Mean insulin exposure from time 0 to 240 min post-dose ($AUC_{0\text{-}240}$) was 2037 and 2270 μU/ml•min (p=0.469) for the COPD and non-COPD groups, respectively. Dosing was well tolerated.
Conclusion: These results indicate that the characteristic absorption pattern of TI is not significantly altered in the COPD population.



955

Lung deposition and absorption of insulin from Technosphere insulin

M. Gotfried[1], J. Cassidy[2], M. Marino[2], N. Amin[2], R. Baughman[2], M. Gray[2], A. Boss[2], P. Richardson[2];
[1]University of Arizona/Pulmonary Associates, Phoenix, [2]MannKind Corporation, Valencia, United States.

Background and aims: A clinical trial in 12 healthy subjects determined the pulmonary concentrations of insulin and fumaryl diketopiperazine (FDKP) using bronchoalveolar lavage (BAL) before and after administration of a rapid-acting insulin, Technosphere Insulin (TI) Inhalation Powder.
Materials and methods: Each subject received a 60 U dose and had two bronchoscopies at 0.5 and 6 h, or 4 and 8 h, or 0.5 h before dosing and 12 h after dosing. At each bronchoscopy, two independent BAL samples were collected. Serum samples for serum insulin, FDKP, and serum C-peptide were collected at baseline and up to 475 min post-dose. Urea concentrations in BAL samples and blood urea nitrogen were measured and used for correcting BAL concentrations (see figure below).
Results: We previously reported a phase I trial using ^{99m}Tc-labeled TI inhalation particles. These particles were evenly distributed with approximately 28% to 48% (mean 39.4%) of the ^{99m}Tc TI delivered to the deep lung. In this study, subjects were dosed with 60 U of TI. Concentrations of insulin and FDKP in BAL fluid were corrected for urea BAL to serum concentration ratios. The amount of insulin and FDKP remaining in the lung epithelial lining fluid was highest (21.5 mIU/ml) in the first post-dose BAL samples (0.5 h). By 4 h, levels were 31% of maximum; at 12 h, insulin and FDKP values in BAL were 0.3% and 0.4% of maximum, respectively. Accumulation of insulin and FDKP in the lungs after chronic dosing is unlikely.
Conclusion: Preliminary pharmacokinetic modeling of insulin (see solid line figure below) suggests a two-compartment lung absorption model, one with fast absorption reflected in the plasma profile of insulin. The other compartment reflects reduced absorption, which is presumably due to proteolysis and mucociliary clearance of insulin.

PS 82 Technical aspects of insulin delivery

956

Comparison of glycaemic stability with long acting insulin analogue vs CSII in type 1 diabetic patients during the fasting period of functional insulin therapy

C. Halter, M. Floriot, P. Bohme, O. Ziegler, B. Guerci;
Diabetology, Endocrinology, Metabolic Disease, Toul, France.

Background and aims: The aim of our study was to compare the pharmacodynamics properties of the two modes of basal insulin administration during a 36-h fast in 24 type 1 diabetic patients training for functional insulin therapy.
Materials and methods: Only basal insulin was delivered during the 36-h fast and glycemic stability was evaluated by continuous glucose monitoring (Glucoday®). The basal insulin dose was determined for each patient using the Howorka formula. In case of hyper or hypoglycaemia, insulin correction (1 or 2 UI of lispro or aspart) or carbohydrate collation (10 or 20 g) were respectively provided in order to recover normoglycaemia (80 - 120 mg/dL). Fifteen patients (8 Men 7 Women, age = 39.6 ± 12.5 years, weight = 76.4 ± 13 Kg, HbA1c = 7.67 ± 1%, diabetes duration = 20.5 ± 9.8 years) were treated with one long acting analog insulin injection (Glargine group). Nine diabetic patients (5 Men 4 Women, age = 43.3 ± 12.3 years, weight = 70 ± 13 Kg, HbA1c = 7.93 ± 0.9%, diabetes duration = 21.77 ± 7.7 years) were treated with continuous subcutaneous insulin infusion (CSII) of fast acting analog (Lispro or Aspart) at a constant basal infusion rate (CSII group). The analysis of the interstitial glucose curves (Glucoday®) recorded during the fast has allowed to determine the following asymptomatic glycaemic variability indexes: standard deviation of mean interstitial glucose concentration, MAGE (Mean Amplitude Glycaemic Excursions) and MODD (Mean Of Daily blood glucose Differences).
Results: During the fasting period, the basal insulin dose was similar in the two groups (0.28 ± 0.08 UI/Kg/day in the Glargine group vs 0.29 ± 0.07 UI/Kg/day in the CSII group, p=NS). However, the number of insulin corrections necessary to maintain normoglycaemia was much higher in the CSII group (n = 3.2 ± 1.2 vs 2.1 ± 1.8, p = 0.05), but the number of « carbohydrate intake » necessary to maintain normoglycaemia was similar in the two groups (n = 2.7 ± 1.8 vs 2.7 ± 1.5 , p = NS). Mean interstitial glucose level and standard deviation of the mean interstitial glucose level (CSII = 99 ± 9 mg/dl vs glargine = 99 ± 15 mg/dl), MAGE index (CSII = 78 ± 38 mg/dL vs glargine = 75 ± 31 mg/dl) and MODD index (CSII = 44 ± 22 mg/dl vs glargine = 37 ± 26 mg/dl) were not significantly different between the two groups.
Conclusion: Fasting glycaemia regulation is as effective with subcutaneous long acting insulin injection as it is with CSII at a constant basal infusion rate.

957

The optimal type of bolus following a 'Mediterranean' meal in children and adolescents with type 1 diabetes using insulin pump therapy

M. Macedoni[1], A.E. Scaramuzza[1], D. Iafusco[2], D. Spiri[1], A. Bosetti[3], E. Giani[1], A. Gazzarri[1], C. Mameli[1], V. Fabiano[1], A. De Palma[1], G. Zuccotti[1];
[1]Paediatrics, University of Milano - Luigi Sacco Hospital, [2]Paediatrics, Second University of Naples, [3]Dietetics, University of Milano - Luigi Sacco Hospital, Italy.

Background and aims: Few is known about the best type of bolus before meals in patients with type 1 diabetes (T1DM) using insulin pump therapy. Last year we observed that the best bolus for a 'pizza' meal (pizza 'margherita') is 30/70 dual wave bolus extended over 6 hours. After this, we start to consider that for a 'Mediterranean' meal (more carbohydrate and less proteins and lipids) a dual wave bolus might be better than a simple bolus. The aim of our study is to compare a simple bolus with different kind of dual wave bolus in order to identify the optimal one in case of a Mediterranean meal.
Materials and methods: We evaluated 26 children and adolescents, aged 5-23 yrs (mean 15.40±4.84 yrs) with T1DM from 1 to 19 yrs (9.67±4.91 yrs), BMI 22.01±4.41 kg/m2, in therapy with subcutaneous insulin infusion (insulin requirement 0.76±0.14U/kg/day). Each patient participated in a study to compare postprandial glucose values following 6 meal bolus regimens for a daily meal (1600-2000 kcal according to children age). Each patient utilized the following 6 aspart regimens on three consecutive days, and glucose values were recorded with SMBG: a) a single-wave bolus (100% of insulin given immediately) injected 15 min before the meal; b) a single-wave bolus (100% of insulin given immediately) injected just before the meal; c) 4-h dual-wave bolus (50% of insulin given immediately and 50% given over a 4-h period) injected 15 min prior the meal; d) 4-h dual-wave bolus (50% of insulin give immediately and 50% given over a 4-h period) injected just before the meal; e) 4-h dual wave bolus (70% given immediately and 30% given over a 4-h period) injected 15 min before the meal; and f) 4-h dual wave bolus (70% given immediately and 30% given over a 4-h period) injected just before the meal. Total CHO was kept constant for each meal; insulin dose was calculated according to glycaemic value and CHO, using ISF and INS:CHO ratio. personalized for each patient.
Results: The results are shown in the table.
Conclusion: 70/30 double wave bolus extended over 4-h period following a Mediterranean meal injected 15 min before provided significantly less postprandial hyperglycemia during the 4-h period. Single-wave bolus could be used only if given 15 min before meal, even if we observed a rise in glycaemic values in the last two hours of the study.

Glycaemic values according the different bolus types in the children studied.

Type of bolus	T' 0	T' 30	T' 60	T' 90	T' 120	T' 180	T' 240	T' 300	T' 360

Intraperitoneal insulin delivery gives higher circulating IGF-I activity than CSII in type 1 diabetes

C.A. Hedman[1], J. Frystyk[2], T. Lindström[1], P. Oskarsson[3], H.J. Arnqvist[4];
[1]Department of Medicine and Health, Linköping, Sweden, [2]Medical Research Laboratories, Aarhus University Hospital, Denmark, [3]Dept. of Endocrinology Karolinska University Hospital Huddinge, Stockholm, Sweden, [4]Department of Clinical and Experimental Medicine, Linköping, Sweden.

Background and aims: In type 1 diabetes the circulating IGF-system is altered with low IGF-I and changes in IGF-binding proteins (IGFBPs). These alterations may be of importance for development of diabetes complications. We hypothesized that the IGF-system is affected by the route of insulin administration and that intraperitoneal (IP) insulin infusion has a more pronounced effect than subcutaneous insulin administration.
Materials and methods: We compared 10 patients with type 1 diabetes and implantable insulin pumps administrating IP insulin to 20 age-and sex matched patients on continuous subcutaneous insulin infusion (CSII) treatment, age 53.1± 9.1 years vs 52.8±9.0 (mean±SD), diabetes duration 24.2±11.3 years vs 30.8±6.0 and HbA1c 8.6±1.4 % vs 7.9±0.8 % (DCCT standard)(ns). Circulating levels of IGF-I bioactivity and IGFBP-1 were measured with validated in-house assays. IGF-I bioactivity was measured with an IGF-I specific kinase receptor activation assay (KIRA).
Results: Fasting levels of bioactive IGF-I was 1.83±0.76 µg/L in patients with IP insulin infusion compared with 1.16±0.24 µg/L in patients with CSII (p=0.02). The corresponding concentrations of IGFBP-1 were 48.5(77.3) and 80.6(42.2) µg/L [median (IQR)](p=0.07). Regression analysis showed a sig-

nificant inverse correlation between bioactive IGF-I and IGFBP-1 (r=-0.59, p=0.001).
Conclusion: The IGF-I bioactivity is higher in patients with intraperitoneal pumps compared to CSII supporting the theory that the route of insulin administration is of importance for the IGF-system. Intraperitoneal insulin administration may therefore be beneficial by normalising the alterations of the IGF system in type 1 diabetes.

959

Time delay to occlusion detection of various insulin pumps
D. Wehbrink, A. Buhr, D. Bosshard, F. Kühni, L.G. Krinelke;
Disetronic Medical Systems AG, Burgdorf, Switzerland.

Background and aims: Patients on pump therapy have only a small subcutaneous depot of insulin and therefore encounter an increased risk of ketoacidosis if basal insulin delivery is interrupted. To limit this risk all insulin pump models are equipped with occlusion alarm mechanisms that, however, differ in sensitivity. A new, additional occlusion detection algorithm was developed and implemented into Accu-Chek Spirit Combo to detect occlusions earlier. The algorithm analyses the change in pressure over time to detect occlusions before the specified absolute force threshold is reached. The aim of this study was to compare the occlusion detection performance of the new pump to other commercially available insulin pumps.
Materials and methods: The response to an infusion set occlusion was tested in two to five insulin pumps of each model according to the standardized procedure specified in IEC 60601-2-24 section 51.101b. Plastic cartridges and infusion sets with 110 cm tubing were used (Accu-Chek TenderLink, Paradigm Silhouette® and Paradigm Quick-set®).
Results: First results demonstrate that the time to occlusion alarm was dependent on the basal rate and significantly differed between pump models and settings (Table 1).
Conclusion: Accu-Chek Spirit Combo and Animas® 2020 (sensitivity set to "high") detected occlusions on average 2 to 5 times earlier at the lower basal rate tested. Time delays for MiniMed Paradigm® 522/722 were much longer compared to the other models or settings used. Measured time delays were compatible with the information of the respective user manuals. The marked different delay times in occlusion detection should be considered when selecting the insulin pump model for a patient since these differences may become relevant during the night and between meals when no boluses are given.

Table 1: Time to occlusion alarm depending on insulin pump and basal rate delivery

	Basal Rate 0.05 IU/h	**Basal Rate 1.0 IU/h**
	Mean ± SD (hh:mm)	
Accu-Chek Spirit Combo (n=5)	11:07 ± 5:04	0:51 ± 0:16

The influence of needle length on glycaemic control and injection-related complaints in obese diabetic subjects
G. Kreugel, B.H.R. Wolffenbuttel, J.C. Keers;
Endocrinology, University Medical Center, Groningen, Netherlands.

Background and aims: A correct injection technique is important for optimal glucose control with insulin injections. Recent studies show that 5mm needles are safe and associated with unchanged HbA1c levels and reduced discomfort for patients compared with 8 or 12mm needles. Obese patients are usually advised to use 8-12mm needles when injecting insulin. This study investigated the effects of using 5mm x 31G needles vs 8mm x 31G needles in obese DM patients.
Materials and methods: In this multicenter, open-label, cross-over study, 130 patients with either type 1 or type 2 DM, injecting insulin with a pen and a BMI ≥ 30kg/m^2 were randomized into 2 groups. Group A used a 5mm needle in the first period and an 8mm needle in the second period; group B used the reverse order - each period was 3 months. The effects on HbA1c, fructosamine, 1.5 Anhydroglucitol (1,5 AG) and patient-reported hypoglycemic events, bleeding, bruising, backflow of insulin and pain were compared.
Results: 126 patients, mean BMI 36.4 (range 30-62), completed the study. Baseline parameters of HbA1c, amount of insulin, and BMI of the 2 groups were similar. There was no significant change in HbA1c while using either needle length, in either group. For all patients, mean HbA1c decreased from 7.6 to 7.5 (p=0.03) when using the 5mm needle, and stayed 7.6 % with the 8mm needle. Group B showed a minor decrease of insulin with the 5mm needle. The 1,5 AG and fructosamine assays are pending. Table 1 shows HbA1c in relation to needle length before enrollment to the end of the first treatment period. Differences were not significant. They support the primary findings of little HbA1c difference due to needle length within the two trial periods.

HbA1c at baseline and after 3 months, needles classified to length 5 and length 8

Needle length before inclusion	First Period	Baseline HbA1c	HbA1c after 3 months
5mm (n=65)	Length 5 (n=31)	7.5 ± 1.1	7.4 ± 1.1
	Length 8 (n=34)	7.3 ± 0.9	7.5 ± 0.8
8mm (n=54)	Length 5 (n=31)	8 ± 1.2	7.7 ± 0.9
	Length 8 (n=23)	7.8 ± 0.9	7.5 ± 0.9

There were no differences in hypoglycemic events, bruising and pain in either group during both periods. Patients reported less bleeding (p=0.04) with the 5mm needle, and less insulin backflow with the 8mm needle (p=0.01). The 5mm needle was preferred by 46% of patients, the 8mm needle by 41%; 13% had no preference. Neither needle length before inclusion or BMI were correlated to preference. No correlation (with both needle lengths) was found between backflow of insulin and BMI, WHR, HbA1c, amount of used insulin units, skinfold or injection site. There was a strong correlation (p<0.01) between bleeding and bruising. Results of hypoglycemic events, bleeding, bruising, backflow of insulin and pain with the first-period questionnaire were strongly correlated (p<0.01) with the outcomes of the second-period questionnaire.
Conclusion: 5mm needles can be safely used in obese DM patients without negative effects on HbA1c and without differences in local injection-related complaints, compared to 8mm needles. Injection complaints in obese patients appear more patient-dependent than needle-length dependent. Patients should receive information about the various needle lengths available and if they experience problems when injecting insulin, a trial of a different needle may be helpful.

The best insulin injection pen device for caregivers: results of simulation injection trials using 5 insulin injection devices
F. Yakushiji[1], H. Fujita[2], J. Hiroi[3], Y. Terayama[3], M. Yasuda[1], S. Nishimura[2], K. Nagasawa[4], M. Shimojo[5], K. Taniguchi[1], K. Fujiki[1], J. Tomiyama[1], H. Kinoshita[1];
[1]Internal medicine, Tokyo Metropolitan Bokutoh Hospital, [2]Transfusion Medicine, Tokyo Metropolitan Bokutoh Hospital, [3]Pharmacy, Tokyo Metropolitan Bokutoh Hospital, [4]Endocrinology and Metabolism, Toranomon Hospital, Tokyo, [5]Internal medicine, Kanagawa Prefectual Shiomidai Hospital, Yokohama, Japan.

Aim: In Japan, trained caregivers, generally family members, are allowed to administer insulin injections to diabetic patients who cannot self-inject insulin. An increased elderly and diabetic population has caused an increase in the number of diabetics who cannot self-inject insulin, requiring a greater number of caregivers who possess this skill. Here, we assessed the problems when insulin was injected by caregivers, and performed subjective evaluations of insulin injection devices.
Methods: We evaluated 5 devices_Opticlik®, SoloStar®, MirioPen® without an antiskid tool (Mirio(-)), MirioPen® with an antiskid tool (Mirio(+)), and

FlexPen®. The 22 respondents performed a sham injection to themselves (self-injection) and others (other-injection). Thereafter, respondents evaluated the feel and ease of the use of the pen devices through questionnaires. (1) Thickness of the insulin pen device, (2) Length, (3) Weight, (4) Stability of the needle on injecting into prosthetic skin , (5) Ease in seeing the dial at injection: the ease with which the dial and its movement can be seen, (6) Ease of pushing at injection: the usability and the presence of sound with successful injection button at the time of insulin injection, (7) Recapping the needle after injection: the ease of recapping the needle and any awkward arm movements required for recapping, (8) Needle disposal after recapping: the series of movements required for the disposal of needle after recapping it for destroying the needle, (9) Comprehensive evaluation were scored by respondents. For (4), (5), (6), (7) , (8) , (9) , a score of 5 meant good, 4(slightly good), 3 (normal), 2 (slightly bad), 1 (bad).

Results: Scores of comprehensive evaluation in self-injection were (Mean± S.D.) : 2.909 ± 1.192 for OptiClik, 3.273 ± 0.985 (SoloStar) , 3.227 ± 0.813 (Mirio(-)), 2.818 ± 0.958 (Mirio(+)), 3.545 ± 0.912 (FlexPen). Scores of comprehensive evaluation in other-injection were 3.364 ± 0.790 (OptiClik) , 2.864 ± 0.774 (SoloStar) , 3.091 ± 0.868 (Mirio(-)), 2.818 ± 0.958 (Mirio(+)), 2.591 ± 0.854 (FlexPen). FlexPen was selected to as the best device for self-injection but as the worst device for other-injection. Opticlik was selected to as the second worst device for self-injection but as the best device for other-injection. Moreover, for other-injection, FlexPen was considered to be too long, less stable, difficult to see the dial, difficult to recap, and comprehensively inferior.

Conclusion: We identified problems that were not apparent during studies evaluating conventional self-injection. We consider that the viewpoint from a caregiver is necessary for developing an insulin device specifically meant for insulin injection by other-injection.

Risk of repeated use of needles for insulin pen needle in patients with diabetes mellitus

I.V. Misnikova, A.V. Dreval, V.A. Gubkina, E.V. Rusanova;
Endocrinology, Moscow Regional Resaerch Clinical Institute, Russian Federation.

Background and aims: Repeated use of needles for insulin pen needles is a serious violation of insulin injection technique. At repeated use, needle is exposed to significant deformation that increases injection morbidity and, probably, risk of lipodystrophy in sites of insulin injections. In literature, there are evidences that repeated use of insulin needles increases risk of infection development. Aim of study was to estimate danger of repeated use of needles BD Micro-Fine *Plus* for insulin pen needles on degree of contamination of needles with bacterial microflora, intensity of pain and presence of local reaction in sites of insulin injection.

Materials and methods: Blind, randomized study. 45 patients with diabetes mellitus of 1 and 2 types, age over 18 years old, on regimen of triple injections of short-acting insulin action and signed informed consent form were included in the study. The patients were randomized in 3 groups - 15 people in each. First group of patients used needle one time, second group - for 4 days (12 injections), and third group - within 7 days (21 injections). Changing of needles was carried out by medical staff. Duration of observation in all groups was 7 days. After use, microbiologic washouts were obtained from needles on aerobic, anaerobic flora and fungi. Intensity of pain after injection was estimated using the Visual-Analogue Scale (VAS) on 1, 4 and 7 day of study. Presence of local reaction in insulin injection site was determined by doctor on 1, 4 and 7 day of the study. Statistical processing of the received results was carried out using programs SPSS version 11.0 for Windows, for detection of differences between the groups, the nonparametric method of assessment - Mann-Whitney criterion (U-criterion) was used. Differences considered statistically significant at p <0,05 (95 % level of significance).

Results: Growth of microbe flora (Staphylococcus.koar - (Hly +) was revealed in 26,6 % of DM patients, who used a needle one time. Maximum quantity of needles contaminated by microbe microflora was registered in 3^{d} group (33,3 %) (Staphylococcus.koar - (Hly +) and Gram+ bacilli. Intensity of pain was significantly higher in 2nd group, than in 1st one (p=0,45) on fourth day of study, and in 3^{d} group pain was considerably more intense than in 1st group (p=0,03) on 7 day of the study. Hyperemia foci in injection sites on 4 and 7 days of the study were revealed only in 2nd and 3^{d} groups (13,3 and 26,6 %, correspondingly).

Conclusion: Already after single use, risk of microbe contamination of an insulin needle increases. Repeated use of needles amplifies risk of needle contamination. Patients using insulin needles several times suffered from pain caused by insulin injections more often.

Microneedle-based intradermal injection of lispro or human regular insulin accelerates insulin uptake and reduces post-prandial glycaemia

L. Heinemann[1], R.J. Pettis[2], L.J. Hirsch[3], L. Nosek[1], C. Kapitza[1], D.E. Sutter[2], N.G. Harvey[2];
[1]Profil Inst. für Stoffwechselforschung, Düsseldorf, Germany, [2]Advanced Diabetes Care, BD Technologies, Research Triangle Park, United States, [3]Diabetes Care, BD Medical, Franklin Lakes, United States.

Background and aims: Previously, intradermal (ID) insulin injection has demonstrated increased insulin uptake and action under glucose clamp conditions. This study investigated the effects of injection route, timing, and insulin type on the pharmacokinetics (PK) and prandial pharmacodynamics (PD) of insulin lispro (IL) and regular human insulin (RHI) under standardized meal conditions.

Materials and methods: After blood glucose stabilization at 120 mg/dL, 29 Type 1 diabetic males (mean age 35 yrs, BMI 25.7 kg/m^2, HbA_{1c} 7.4%) received 0.125U/kg of insulin at 2 or 17 mins before a standardized high-carb liquid meal (82g CHO), in a 5-arm randomized crossover study (Table 1). ID injections were administered using 1.5 mm x 34G microneedles or 8 mm x 31G needles for subcutaneous (SC) delivery.

Results: PK: Both insulin types showed markedly faster uptake and increased C_{max} when given ID compared to SC. Although total bioavailability over 4 hrs was similar between routes, ID delivery increased early phase absorption by 40-50% during the first 90 mins post-dosing. Likewise, the median T_{max} was reduced by one-half or greater for each insulin type. PD: The post-prandial glycemic (PPG) excursion (measured by primary PD endpoint: BG-AUC, 0-1.5h) for ID RHI was significantly reduced vs SC injection when both were given at -17 mins premeal (p<0.0001). Injection timing was also a significant factor, as ID RHI had a lower PPG when injected -17 mins pre-meal vs -2 mins. Overall, the mean BG response curve for ID IL tended to be lower and more level than that observed for SC IL when administered immediately pre-meal. However, the PPG for ID injection was not significantly different (NS) vs SC IL (P=0.1). Interestingly, the 4 hr PPG excursion for ID RHI given at -2 min was also NS from SC IL as measured by BG-AUC, although the BG max was slightly higher and occurred later. SC RHI at -17 mins had the highest BG responses, while ID RHI at -17 mins had one of the better PD outcomes. ID injection was well tolerated.

Conclusion: This study demonstrates that microneedle-based ID administration has a substantial impact on insulin PK, with a faster onset time observed for both insulin types. The reduction of prandial BG seen for ID regular insulin and the BG trends observed for ID insulin lispro may offer promise for improved outcomes with prandial insulin therapy.

Clinical outcomes at 24 months following insulin initiation in Europe: data from the INSTIGATE study

A. Liebl[1], S. Jones[2], M. Benroubi[3], C. Castell[4], A. Goday[5], H.T. Smith[6], C. Nicolay[7], A. Simpson[6];
[1]Center for Diabetes and Metabolism, Bad Heilbrunn, Germany, [2]James Cook University Hospital, Middlesborough, United Kingdom, [3]Polyclinic General Hospital, Athens, Greece, [4]Department de Salut, Barcelona, Spain, [5]Hospital del Mar, Barcelona, Spain, [6]Eli Lilly & Co, Surrey, United Kingdom, [7]Eli Lilly & Co, Bad Homburg, Germany.

Background and aims: INSTIGATE is a prospective observational study in Europe, investigating patients with type 2 diabetes who initiate insulin during usual care. Follow up data to 24 months (m) were collected in Germany (De), Greece (Gr) and Spain (Es). An objective of the study is to describe metabolic control and clinical outcomes following insulin intitiation. This abstract describes diabetes therapy and observed clinical outcomes over the 24m following insulin initiation.
Materials and methods: Data on medication, clinical outcomes, health related quality of life and resource use were collected when patients initiated insulin and at regular intervals for 24m.
Results: Of 726 patients entering the study (De 256; Gr 263; Es 207), 564 (De 155; Gr 237; Es 172) had at least a 12m visit and 498 (De 119; Gr 227; Es 152) were followed to 24m.
In De patients were prescribed more intensive insulin regimens, at baseline 76% of patients (118/155) were on prandial based regimens, mean 3.1 injections per day. In contrast in Gr and Es at baseline either basal only or premix only were more common; 80% (190/237) in Gr and 88% (152/172) in Es, mean daily injections of 1.8 and 1.4, respectively. There were few changes in insulin regimens over the first 24m; in Gr 25 patients (11%) and in Es 12 (8%) changed their insulin regimen, there were more changes in De where 34 patients (29%) changed regimen. At baseline mean total daily dose (IU/Kg) was highest in Gr 0.41 (De 0.28, Es 0.27), by 24m mean dose in De was highest at 0.59 (Gr 0.54, Es 0.34). Mean HbA1c fell in all countries in the 6m following insulin initiation, and remained relatively stable over the subsequent 18m follow up. Only in De did mean HbA1c fall below 7% (Figure 1). Increase in weight was variable; mean weight change (Kg) in the 24m following insulin initiation was +0.23 in Es, +2.96 in Gr and +3.81 in De. Data was also collected on hypoglycaemia. The % of patients reporting at least one episode of hypoglycaemia in the first 6m of insulin therapy were Es 20%, De 23% and Gr 29%; but rates fell over time. Between 18 and 24m 8% in Es, 10% in De and 23% in Gr reported at least one episode. The number of episodes requiring 3rd party assistance or hospitalisation was low, particularly in De where in the 24m following insulin initiation there were no episodes requiring hospitalisation (Es 3, Gr 2) and only 4 episodes requiring 3rd party assistance (Es 42, Gr 65).
Conclusion: There was a consistent lowering of HbA1c in the 6m following initiation thereafter HbA1c remained stable. There was relatively little change in insulin regimens over time. It is evident that across different countries approaches to diabetes management with insulin therapy vary; due to local guidelines and health care systems, which impact patient outcomes.

Prandial-basal insulin regimens to improve mealtime glycaemia in type 2 diabetes: comparison of two approaches in starting and intensifying insulin

L.L. Ilag, X. Mao, for the PRIME T2D Study Group;
Eli Lilly and Company, Indianapolis, United States.

Background and aims: Many type 2 diabetes (T2D) patients initiate insulin with basal insulin, then need prandial insulin coverage to achieve blood glucose (BG) targets. A premix insulin with 50% basal/50% prandial insulin (insulin lispro mix 50, 50% insulin lispro/50% insulin lispro protamine suspension [ILPS]; LM50) may be a practical alternative. This 36-wk international study tested noninferiority between the addition of once-daily basal insulin with up to 3 injections of premeal prandial insulin, (glargine + lispro; G+L) if needed, vs addition of once-daily premix insulin (LM50) with progressive escalation to 2-3 injections if needed, in patients with T2D and inadequate glycemic control on 2 or more oral antihyperglycemic drugs (OAD).
Materials and methods: Adult T2D pts with HbA_{1c} ≥7.5 and ≤12.0% on at least 2 OAD (metformin, thiazolidinedione, or sulfonylurea) were randomized to begin 10 U of dinnertime LM50 or 10 U of morning insulin glargine, each continuing on OAD. Protocol-driven dose titrations and addition of insulin injections (LM50 or lispro) targeted pre-meal BG 4.44-5.56 mmol/L and HbA_{1c} <7% at 12- and 24-wks. Insulin injections were not added after wk 24. The primary outcome was change in HbA_{1c} from baseline to endpoint (36 wks or LOCF). Noninferiority was established if the upper bound of the two-sided 95% CI (confidence interval) for treatment difference was <0.3%. Other measures included 7-pt BG profile, hypoglycemia, insulin dose and weight.
Results: Both groups had similar baseline age (59 vs 60 yrs), duration of diabetes (11 vs 12 yrs), weight, OAD use and HbA_{1c} (results in table).
While endpoint HbA_{1c} and proportion of pts with HbA_{1c} <7% had no statistically significant difference between groups, noninferiority was not met (primary objective CI upper limit 0.3%). Majority of pts (286/469~61%) had >1 injection at study end (median=2 in both). Eleven pts replaced dinnertime LM50 with LM25 (25% insulin lispro/75% ILPS). Endpoint 7-pt BG profiles remarkably improved in both groups from baseline, and profiles were similar at all time points except fasting and evening 2-h pp. Endpoint hypoglycemia rate was significantly higher for G+L at endpoint, but not over the entire study (p=0.22). A statistically significant difference was noted in daily insulin dose at endpoint. There was no significant difference in weight over the study (p=0.80).
Conclusion: Starting once-daily insulin glargine then adding mealtime insulin lispro, compared to starting with once-daily LM50 then advancing to 2-3

Once-daily insulin glargine requires a significantly lower dose than insulin detemir twice daily to achieve good glycaemic control in patients with type 2 diabetes failing oral therapy

S.G.H. Swinnen[1], M.P. Dain[2], R. Aronson[3], D. Roberts[4], M. Davies[5], H.C. Gerstein[6], A.F.H. Pfeiffer[7], J.H. DeVries[1], J.B.L. Hoekstra[1], F. Holleman[1]; [1]Academic Medical Centre, Amsterdam, Netherlands, [2]sanofi-aventis, Paris, France, [3]LMC Endocrinology Centres, Toronto, Canada, [4]Logan Hospital, Meadowbrook, Australia, [5]University of Leicester, United Kingdom, [6]McMaster University, Hamilton, Canada, [7]Charité University Medicine, Berlin, Germany.

Background and aims: Basal insulin is recommended for the initiation of insulin therapy in type 2 diabetes (T2D). However, studies comparing the two basal insulin analogues insulin glargine (GLAR) and insulin detemir (DET) are limited. This 24-wk multinational, open-label, parallel-group, randomized trial compared the efficacy and safety of GLAR once-daily (od) vs DET twice-daily (bid) in patients (pts) with T2D inadequately controlled on oral glucose-lowering drugs (OGLDs). The primary objective was to demonstrate the non-inferiority of GLAR vs DET with respect to the percentage of pts reaching HbA_{1c} < 7% without symptomatic hypoglycaemia confirmed by plasma glucose (PG) ≤ 56 mg/dL (3.1 mmol/L).
Materials and methods: 964 insulin-naïve pts, aged 40-75 yrs, T2D duration ≥ 1 yr, BMI < 40 kg/m^2, with inadequately controlled T2D (HbA_{1c} 7.0-10.5%) on OGLDs (including metformin [MET] ≥ 1 g/day) were randomized to either GLAR (n=478; at dinner or bedtime) or DET (n=486; at breakfast and before dinner), added to stable doses of MET. For both insulins the starting daily dose was 0.2 U/kg, which was then titrated every 2 days by 2 U to obtain fasting PG (FPG) < 100 mg/dL (5.6 mmol/L). For DET, there also was a predinner titration target < 100 mg/dL.
Results: Baseline mean (± SD) age was 58.4 ± 8.3 yrs, T2D duration 9.9 ± 5.8 yrs, FPG 173.8 ± 42.0 mg/dL and HbA_{1c} 8.7 ± 0.9%. GLAR od was non-inferior to DET bid; 27.5 and 25.6% of pts reached HbA_{1c} < 7% without confirmed hypoglycaemia (difference 1.85% [95% CI: -3.78; 7.48]). Change from baseline to endpoint HbA_{1c} was similar with GLAR and DET (-1.46 ± 1.09 and -1.54 ± 1.11%; p=0.149), endpoint HbA_{1c} levels were 7.2 ± 0.9 and 7.1 ± 0.9%, respectively. Endpoint FPG was lower with GLAR vs DET (108 ± 24 vs 119 ± 32 mg/dL) and decreased significantly more with GLAR vs DET (-64 ± 45 vs -58 ± 45 mg/dL; p<0.001). There was a lower rate of daytime symptomatic hypoglycaemia confirmed by PG ≤ 56 mg/dL (3.1 mmol/L) in the GLAR vs DET group (1.06 ± 3.13 vs 1.64 ± 5.42 events/patient yr; p=0.046). Frequencies of asymptomatic, overall symptomatic, nocturnal symptomatic and severe hypoglycaemia were comparable between treatment groups. Compared with the GLAR group, pts treated with DET gained significantly less weight (0.6 vs 1.4 kg, difference 0.77 kg [95% CI: 0.38; 1.16]; p<0.001) and required significantly higher daily insulin doses (76.5 vs 43.5 U, difference 33.1 U [95% CI: 27.8; 38.3]; p<0.001). Significantly more pts in the DET group terminated the study early (10.1 vs 4.6%; p=0.001), the most common reason was adverse events (4.5 vs 1.5%), in particular skin reactions (9 vs 0 pts).
Conclusion: GLAR od was non-inferior to DET bid with respect to the percentage of pts reaching the current glycaemic goal of HbA_{1c}< 7% without symptomatic confirmed hypoglycaemia. GLAR od and DET bid resulted in similar improvements in HbA_{1c}. However, pts treated with DET bid required higher daily insulin doses, had less weight gain and more drop outs vs the GLAR od group.

967

A quantitative assessment of patients' barriers to insulin

R. Casciano[1], E. Malangone[1], A. Ramachandran[2], J. Gagliardino[3]; [1]Analytica, New York, United States, [2]India Diabetes Research Foundation, Chennai, [3]CENEXA (UNLP-CONICET), La Plata, Buenos Aires, Argentina.

Background and aims: The International Diabetes Management Practices Study (IDMPS) is a 5-year study aimed at assessing therapeutic management of diabetic patients in Africa, Asia, Latin America and the Middle East. Within the third wave of the study (2008), a patient questionnaire was administered to assess preferences and perceptions of diabetes treatments, with a focus on identifying patient barriers to insulin treatment.
Materials and methods: The questionnaire was administered using indirect and direct methods. Discrete choice modeling was used to assess how product attributes (formulation [oral / injection], dosing [number of daily doses], blood sugar maintenance, risk of hypoglycemia symptoms, and presence of side effects [dermatological, GI, and cardiac]) influence patients' preferences for diabetes treatment. These attributes were translated into hypothetical scenarios within choice sets for inclusion in the patient questionnaire. A multinomial logit model was used to analyze the discrete choice data and to find the odds ratio for each parameter. This model allowed for analysis of the probability of selecting a chosen alternative given a choice set as well as the derivation of relative attribute importance, an indication of how influential product attributes are in the respondents' choices. Sub analyses were performed to explore the impact of factors such as diabetes understanding, comfort with needles and geographic location.
Results: The IDMPS questionnaire was administered to 14,033 diabetes patients in 18 countries. The majority of respondents were female (54%), with a high proportion suffering from Type 2 diabetes (T2DM) (n=11,883; 85%). More than half (56%) of respondents reported receiving diabetes education. Additionally, 48% of patients self-monitor their blood glucose levels. Across subgroups, formulation was a primary driver of patient preference while risk of hypoglycemia symptoms did not heavily influence treatment decisions. Patient preferences vary significantly by diabetes type, with T2DM patients assigning much higher relative importance to formulation than Type 1 patients (30.86% vs.4.99%, respectively; p<0.0001). Experience with insulin treatment also has a significant impact on the importance placed on formulation. Insulin treated T2DM patients placed less importance on formulation than insulin naïve T2DM patients (3.09% vs. 47.48%, respectively; p <0.0001). Furthermore, patients treated with insulin placed greater importance on side effects compared to insulin naïve patients (31.59% vs. 13.75%, respectively; p=0.0298). Diabetes education also appears to have a significant effect on the priority given to formulation between T2DM patients who received diabetes training and those who did not (33.68% vs. 28.21%, respectively; p<0.0001).
Conclusion: The insulin barriers perceived by patients with diabetes evolve with their experience of the disease. Formulation is the primary driver of preference for insulin naïve patients. However, patients become increasingly concerned with more clinically relevant barriers (eg side effects, blood glucose levels) as they gain experience with insulin. This finding indicates that patients using insulin understand the importance of achieving an optimal balance between safety and efficacy. Education is important when selecting a treatment option, as the optimal regimen will change over the course of disease duration.

Pharmacodynamic and pharmacokinetic effects of subcutaneous insulin glulisine versus insulin aspart prior to a standard meal in obese subjects with type 2 diabetes

G.B. Bolli[1], S. Luzio[2], F. Porcellati[1], C. Sert-Langeron[3], B. Charbonnel[4], Y. Zair[4], D. Owens[2]; [1]Department of Internal Medicine, Endocrinology and Metabolism, University of Perugia, Italy, [2]Diabetes Research Unit, Llandough Hospital, South Glamorgan, United Kingdom, [3]sanofi-aventis, Paris, France, [4]Centre de Recherche en Nutrition Humaine, INSERM U 915, Nantes, France.

Background and aims: This multinational, randomized, double-blind, two-way crossover trial (7-day washout) compared the pharmacodynamic (PD)/pharmacokinetic (PK) profiles of insulin glulisine (GLU) versus insulin aspart (ASP) followed by a standard meal in insulin-naïve, obese subjects with Type 2 diabetes (T2D). The primary endpoint was glucose excursion (AUC_{0-1h}) during the first hour after the beginning of the test meal.
Materials and methods: Overnight-fasted subjects received a 0.2 U/kg dose of GLU or ASP subcutaneously within 2 min before starting the meal. Blood

samples were taken every 15 min, starting 20 min before the meal and ending 6 hr post-meal. After a 1-week washout period, the same procedure was repeated using the alternative insulin preparation.
Results: Of the 37 subjects who were randomized (13/24 females/males; mean ± SD age, 60.3 ± 8.3 yr; BMI, 33.7 ± 3.3 kg/m^2; T2D duration, 7.3 ± 4.9 yr; HbA_{1c}, 7.1 ± 0.8%), 30 were eligible for PD/PK analyses. $AUC_{0\text{-}1\,h}$ and maximal glucose concentration ($glucose_{max}$) were significantly lower with GLU than with ASP (Table). For the total study period, however, plasma glucose concentration was similar between GLU and ASP (Table). Insulin levels throughout the study (geometric [arithmetic] means: 2002 [2007] vs 1289 [1333] pmol.hr/L; p<0.0001), and peak insulin concentration (534 [570] vs 363 [385] pmol/L; p<0.0001) were significantly higher with GLU than with ASP. Among the 37 patients randomized, hypoglycaemia events (<3.9 mmol/L with or without symptoms) were reported in 13 subjects on GLU and 16 subjects on ASP; there were no cases of severe hypoglycaemia.
Conclusion: In this study, GLU was associated with lower glucose levels during the first hour post-meal, owing to a faster subcutaneous absorption rate than for ASP in obese subjects with T2D.

Table

PD parameters	GLU	ASP	p value	Estimate for mean ratios (90% CI)[GLU/ASP]*

Diabetes treatment satisfaction in a 20-week, randomized, controlled trial (TITRATE STUDY)

P. Raskin[1], M. Merilainen[2], P.-L. Chu[2], L. Blonde[3], for the TITRATE Study Group;
[1]Department of Internal Medicine, University of Texas Southwestern Medical Center, Dallas, [2]Novo Nordisk, Inc., Princeton, [3]Ochsner Medical Center, New Orleans, United States.

Background and aims: To assess treatment satisfaction using the Diabetes Treatment Satisfaction Questionnaire (DTSQ) in a treat-to-target trial with insulin detemir in combination with OAD therapy using two FPG titration targets
Materials and methods: The TITRATE® study was a 20-week, randomized, controlled trial in subjects with type 2 diabetes who failed to achieve glycemic targets with 1-3 OADs. After a 2-week screening period, subjects were randomized 1:1 to two FPG titration targets (either 3.9-5.0 mmol/l or 4.4-6.1 mmol/l) for basal insulin initiation and dose titration. Results presented elsewhere showed both targets were safe and effective for lowering HbA1c, with the more aggressive FPG target providing superior glycaemic control. Here we assessed treatment satisfaction using the validated DTSQ. Subjects completed this 8-question assessment at randomization (Week 0) and at end of study (Week 20).
Results: Subjects in both groups trended toward improved satisfaction with their current diabetes treatment at Week 20 compared to Week 0. Within each treatment group, the greatest improvements were observed for item #s 1 (How satisfied with current treatment?), 2 (How often were blood sugars unacceptably high recently?) and 8 (How satisfied to continue present treatment?). Improvements were also noted for item #s 4 (How convenient is current treatment?), 5 (How flexible is current treatment?), 6 (Satisfaction with understanding of diabetes) and 7 (How likely to recommend current treatment?). There were no significant differences in improvements between treatment groups. Subjects reported less satisfaction on Item #3 (How often were blood sugars unacceptably low recently?), where they indicated an increase at Week 20 as compared to Week 0. This was the case to a greater extent for those subjects in the FPG 3.9-5.0 mmol/l treatment group (p=0.025 for FPG 3.9-5.0 mmol/l group vs. FPG 4.4-6.1 mmol/l group), even though the overall rates of hypoglycemia between the two groups were low and not statistically significantly different.
Conclusion: Compared to baseline, overall subject satisfaction was improved at end of study for 7 of the 8 DTSQ questions despite subjects beginning insulin therapy, and being asked to aggressively self-titrate their insulin doses. The exception (incidence of low blood sugar) is not surprising given the extent of improved glycemic achieved. Indeed, from a baseline HbA1c of > 7.9 %, > 50% of patients achieved the ADA-recommended HbA1c target of < 7% with mean HbA1c of 6.9% at the end of the study. These results, in formerly insulin-naïve subjects, highlight the importance of patient empowerment and education to enhance achievement of glycemic goals and patient satisfaction.

Comparing insulin glargine (GLAR) with insulin detemir (DET) - effects on HbA_{1c} on weight change and insulin dose in patients with type 2 diabetes

G. Dailey[1], K. Admane[2], F. Mercier[3], D. Owens[4];
[1]Department of Diabetes and Endocrinology, Scripps Clinic Torrey Pines, La Jolla, United States, [2]sanofi-aventis, Paris, France, [3]Stat Process, Port Mort, France, [4]Diabetes Research Unit, Cardiff University, Penarth, United Kingdom.

Background and aims: Basal insulin therapy offers additional improvements in HbA_{1c} for patients with type 2 diabetes (T2D) who have inadequate glycaemic control on oral therapy. Selective comparisons of clinical trials indicate that DET is associated with less weight gain vs GLAR.
Materials and methods: We did a meta-analysis of GLAR and DET randomized controlled trials. Studies with a duration of ≥4 wks in insulin-naïve patients starting basal GLAR/DET were included, regardless of comparators. We used a weighted average method to combine the study results and a random effect model to take into account effects in the studies that may differ. Outcomes were weight, HbA_{1c} change and the weight/HbA_{1c} ratio, in addition to insulin dose and insulin dose/HbA_{1c} ratio. GLAR was taken qd in 20 studies included in this analysis; DET (four studies) was taken qd or bid. 50% of patients were taking DET bid or required therapy intensification. For studies where SDs were not reported, maximum SDs from other studies were used. Estimates were determined using a PROC NLMIXED (SAS v9.2) bivariate model. Two models were developed: one without covariates and one with baseline covariates (baseline values of HbA_{1c}, BMI and insulin dose).
Results: In the unadjusted model (Table), HbA_{1c} change was similar for GLAR and DET (-1.4 vs -1.4%), as was weight gain (2.3 vs 1.7 kg) and weight/HbA_{1c} (1.7 vs 1.2 kg/%) (p=NS for all variables). However, patients required a significantly higher DET vs GLAR dose in order to achieve the same HbA_{1c} (Table).
Conclusion: This analysis reveals that the weight/HbA_{1c} ratio for GLAR is similar to that of DET. DET-treated patients in this analysis required a higher insulin dose than GLAR-treated patients to achieve the same HbA_{1c}. Caution should be taken when interpreting these results, as direct comparison is limited owing to the small number of DET studies.

Table

	GLAR (n=4295)		DET (n=1086)		p value
	Estimate (SE)	95% CI	Estimate (SE)	95% CI	
HbA_{1c} and weight (unadjusted)

Safety and efficacy of insulin glargine compared with NPH insulin in older adults with type 2 diabetes mellitus

P.G. Lee[1], A.M. Chang[1], C. Blaum[1], A. Vlajnic[2], M.F. Miller[3], J.B. Halter[1]; [1]University of Michigan, Ann Arbor, [2]sanofi-aventis, Bridgewater, [3]Glucose Harmonics, LLC, Langhorne, United States.

Background and aims: Hypoglycemia is a deterrent to the use of insulin in older people with type 2 diabetes mellitus (T2DM). In randomized controlled trials (RCTs), adding insulin glargine to T2DM patients poorly controlled on oral hypoglycemic drugs (OHDs) has been similarly effective as adding NPH insulin at controlling hyperglycemia and has caused less hypoglycemia. We hypothesized that glargine is similarly effective as NPH but safer when treating T2DM in older adults.

Materials and methods: We compared the safety and efficacy of adding glargine or NPH to treatment for older adults already on OHDs. The first patient-level analysis was conducted by combining 4 international, multisite RCTs with similar patient selection criteria (ie, age, body mass index [BMI], baseline HbA_{1c}) and treat-to-target study designs. We compared HbA_{1c} reduction and hypoglycemic events at the end of 24 wk in patients ≤65 y (glargine [n=831] vs NPH [n=859]) vs >65 y (glargine [n=215] vs NPH [n=236]). Hypoglycemia was defined by symptoms confirmed with self-monitored blood glucose <70 mg/dL. Combined data were analyzed using fixed- and random-effects models and controlled for age, treatment, study, and baseline HbA_{1c} and BMI.

Results: The older patients had lower BMI (P<0.01). Both insulins achieved similar reductions in HbA_{1c} levels in the younger patients, but the older patients on glargine had significantly greater HbA_{1c} reductions (Table). Daytime hypoglycemic events and insulin therapies were similar in both age groups, whereas the rate of nocturnal hypoglycemic events was less in glargine-treated patients, including those aged >65 y (P<0.01).

Conclusion: These data suggest that when compared with NPH, adding glargine to OHDs in older adults with poorly controlled T2DM was better at lowering HbA_{1c} and was safer. Glargine may be a preferred therapeutic choice for older adults with T2DM.

Baseline Characteristics: Mean (SD)						
	≤65 y		>65 y		Total

Long-acting insulin analogue therapy initiation and follow-up by healthcare practitioners in patients with type 2 diabetes mellitus uncontrolled with oral antidiabetic drugs: the LIGHT Study

B. Vergès[1], J.-M. Brun[1], C. Tawil[2], B. Alexandre[3], V. Kerlan[4]; [1]Service d'Endocrinologie, Hôpital du Bocage, Centre Hospitalier Universitaire de Dijon, [2]Pereire Boulevard, Paris, [3]Medical Affairs, Novo Nordisk Pharmaceutique, Paris La Défense, [4]Centre Hospitalier Universitaire La Cavale Blanche, Brest, France.

Background and aims: Diabetes mellitus has emerged as an important medical condition worldwide. As the disease progresses and oral antidiabetic drug (OAD) treatment fails, patients generally require insulin. Several clinical studies have been conducted in patients with type 2 diabetes (T2DM) investigating long-acting insulin analogues (IA). However, few large observational studies have been published to describe IA initiation in real-life conditions.

Materials and methods: The LIGHT observational study conducted in France in 2007/2008 involved 491 French general practitioners and 270 diabetologists. It described IA initiation (insulin detemir and glargine) in combination with OADs (T0) and at 3-month follow-up (T3) in patients aged ≥40 years old and with poor glycaemic control on OADs alone. Each investigator included the first two patients who conformed to inclusion criteria.

Results: 2541 patients with T2DM (mean age: 64 years; male: 56%; BMI: 29.8 ± 5.2 kg/m²) were included. At T0, 12.6% were treated by monotherapy (44% metformin [Met], 36% sulphonylurea [SU], 15% glinides, 3% glitazones [TZD] and 2% α-glucosidase inhibitors [αGI]), 59.7% by bitherapy (67% Met + SU, 8% Met + TZD and 11% Met + glinides) and 27.7% by tritherapy (45% Met + SU + TZD, 31 % Met + SU + αGI). OAD use was ongoing for 9.0 ± 5.5 years; 48% of patients were diagnosed with diabetes more than 10 years ago and 17% less than 5 years ago. HbA_{1c} at baseline was different in patients with mono (8.9%), bi (8.8%) or tritherapy (9.0%)***, but was not dependent on the OAD or OAD combination prescribed. For 95% of patients at least one OAD was continued at IA initiation; in 96% the IA was prescribed alone; in 4% along with another insulin. The insulin analogue dose and the glycaemic parameters are described in Table 1. At T3, 92.3% of the 1863 patients included were taking IA alone, 4.4% in combination with another insulin. IA was prescribed once a day in 95.5% of patients. A 0.5 kg weight decrease was obtained in the insulin detemir group (p<0.0001 vs. baseline), which was statistically higher in patients with highest BMI at baseline (p<0.0001, up to 1.5 kg weight loss when BMI ≥35 kg/m²).

Conclusion: This study shows that 3-month treatment with IA in insulin-naïve patients with T2DM on OADs resulted in a significant improvement of glycaemic parameters (HbA_{1c} and fasting plasma glucose). This improvement and the IA doses were of the same magnitude for insulin detemir and insulin glargine, and were both associated with a slight increase in the incidence of hypoglycaemia. In addition, insulin detemir showed a 0.5 kg weight decrease.

Improved symptom distress and wellbeing following initiation of insulin glargine in suboptimally controlled type 2 diabetes patients on oral agents. An observational study

T.R.S. Hajos[1], F. Pouwer[2], R. de Grooth[3], F. Holleman[4], M. Diamant[5], F.J. Snoek[1];
[1]Department of Medical Psychology, VU University Medical Centre, Amsterdam, [2]Center of Research on Psychology in Somatic diseases (CoRPS), Tilburg, [3]Sanofi-Aventis, Gouda, [4]Academic Medical Center, Amsterdam, [5]VU University Medical Centre, Amsterdam, Netherlands.

Background: Insulin initiation is often delayed in type 2 diabetes (T2DM) patients, resulting in suboptimal glycaemic control. Switching to insulin is likely to reduce hyperglycaemia, but little is known about the concomitant impact on Quality of Life. We prospectively studied the effects of starting once-daily insulin Glargine on patient-reported diabetes symptom distress and emotional well-being in a cohort of suboptimally controlled insulin-naïve T2DM patients.
Materials and methods: Data were collected in an observational study with a pre-post design, in 363 Dutch primary care practices at baseline, 3 and 6 month follow-up. Patients were included if they were switched from oral medication to once-daily insulin Glargine or insulin Glargine was added to their previous treatment (n=1063), due to poor metabolic control. Treatment was in accordance with the Dutch College of Family Physicians standard. Diabetes symptom distress was assessed using the Diabetes Symptom Checklist revised (DSC-r) and emotional well-being with the WHO-5 Well-being Index (WHO-5). Patients who provided complete data on the DSC-r and WHO-5 for at least two measurement points, were included in the present analysis (N=652). At baseline mean±SD age was 63±11 years, time since diagnosis 6.9±5.7 years, 48.6% was female and 54.2% had a lower education. Mean±SD weight was 87±18 kg, 25% had ≥1 complication and 25.3% had ≥1 co-morbidity.
Results: HbA1c decreased from 8.4±1.7 at baseline to 7.6±1.0 at 3 and 7.3±1.0 at 6-month follow up ($p<0.001$). Diabetes symptom distress (DSC-r) total score significantly decreased from 0.56±0.55 (median: 0.38, 75th percentile: 0.85) to 0.41±0.46 at 3 month and 0.36±0.45 ($p<0.001$) at 6 months follow-up. Similarly, emotional well-being improved as indicated by an increase in the WHO-5 score from 58.3±25.0 at baseline to 65.5±21.3 and 68.0±21.2 ($p<0.001$) respectively. The WHO-5 and DSC-r score were moderately correlated (Spearman's rho = -0.633, $p<0.001$). Patients with initial satisfactory wellbeing (WHO-5≥50) reported relatively low symptom distress at baseline (DSC-r 0.36±0.40, median 0.24, 75th percentile 0.47), yet their DSC-r score improved significantly during the follow-up period (-0.12±0.32, median -0.06, 75th percentile 0.03, $p<0.001$). While negative affect is known to be associated with higher symptom reporting, patients with WHO-5 scores indicative of depression (<28) showed the greatest improvement on the DSC-r, with a decrease of 0.41±0.55 (median -0.38, 75th percentile -0.01) points over the 6-month period ($p<0.001$). Overall, the greatest symptom distress reductions were observed on the subdomains 'Hyperglycaemia' and 'Fatigue' of the DSC-r, which decreased from 0.79±0.92 to 0.41±0.66 ($p<0.001$) and from 1.12±1.11 to 0.66±0.84 ($p<0.001$) respectively.
Conclusion: Improving glycaemic outcomes by means of once-daily insulin Glargine in suboptimally controlled T2DM patients results in a sustained reduction of diabetes symptom distress and subsequent improvements in emotional well-being, particularly in those previously reporting depressive affect.

Network approach to type 1 diabetes: association patterns between diabetic complications and metabolic, clinical and life style risk factors in a set of 4197 patients

V.-P. Mäkinen[1], C. Forsblom[1], L.M. Thorn[1], J. Wadén[1], K. Kaski[2], M. Ala-Korpela[3], P.-H. Groop[1], The FinnDiane Study Group;
[1]Folkhälsan Research Center, Folkhälsan Institute of Genetics, Helsinki, [2]Department of Biomedical Engineering and Computational Science, Helsinki University of Technology, Espoo, [3]Department of Internal Medicine and Biocenter Oulu, University of Oulu, Finland.

Background and aims: Diabetic complications are influenced by numerous genetic and environmental factors. Accurate knowledge of the complex interdependencies between these factors is critical for pinpointing the best targets for research and treatment. Therefore, the aim of this study was to describe the association patterns between clinical and biochemical features of type 1 diabetes (T1DM) complications.
Materials and methods: Baseline clinical data on 4,197 patients with T1DM were collected at the 92 FinnDiane Study Centers in Finland. The study visit included a clinical examination, registering of complications, and questionnaires on education, smoking, alcohol consumption, working status (disabled vs. employed/unemployed), asthma, rheumatoid arthritis and thyroid disease. Blood and 24h urine samples were also collected. The mean age and T1DM duration were 38 and 22 years, respectively and 52% were male. A total of 875 patients (21%) had nephropathy (AER > 300 mg/24h or end-stage renal disease) at the time of study. Vitality status was obtained prospectively from the national population registry after an average of 6.5 years of follow up (25,714 patient years). The dataset comprised 28 clinical and 25 biochemical variables that were regarded as the nodes of a network; the associations between the variables were quantified by pair-wise correlation coefficients (continuous data only) or by linear regression modeling (continuous and binary data combined). The resulting structures were visualized by a force-directed node-positioning algorithm.
Results: Heavily connected cliques of dependent variables such as HDL-related lipid markers, indicators of kidney failure and indices of body mass were observed. The links between the cliques showed biologically relevant interactions: an inverse relationship between HDL cholesterol and the triglyceride clique ($P < 10\text{-}16$), a connection between triglycerides and body mass via C-reactive protein ($P < 10\text{-}16$) and estimated IDL cholesterol as the connector between lipoprotein metabolism and macroalbuminuria ($P < 10\text{-}16$). The regression-correlation network showed strong associations between blood pressure, working ability and complications.
Conclusion: There was modularity in the dataset and several biologically relevant connections were visible, which supported the use of networks in clinical data analysis. In particular, accelerated vascular aging was seen in blood pressure correlations and IDL emerged as a putative lipoprotein covariate in the pathogenesis of diabetic nephropathy.

TSH receptor autoantibodies in patients with type 1 diabetes mellitus

D. Witkowski[1], E. Piontek[2], E. Moszczyńska[1], R. Janas[3];
[1]Dept. of Metabolic Diseases, Endocrinology and Diabetology, [2]Out-door Diabetological Clinic, [3]Department of Radioimmunology, The Children's Memorial Health Insitute, Warsaw, Poland.

Background and aims: Autoimmune thyroid disease (AITD) is the most prevalent autoimmune disorder associated with type 1 diabetes (T1D). It is known that AITD may be presented as hypothyroidism, subclinical dysfunction of the thyroid gland, euthyroid state with positive antithyroid auto antibodies or rarely hyperthyroidism i.e. Graves' disease. The course of autoimmunological diseases, including AITD, is mostly clinically silent therefore autoimmunological markers of AITD should be seeked to discover patients at risk, predict and monitor AITD. The third thyroid autoantigen - besides TPO and TG - is the TSH receptor. The purpose of the study was to determine TSH receptor autoatibodies (TSHR Ab) levels in the group of type 1 diabetic pediatric patients with or without thyroid dysfunction.

Materials and methods: In the group of 84 children and adolescents with T1D, age 2 - 18 yr (mean age: 11,3 ± 4,47), girls (58,3%), with T1D duration from 1 up to 11 yr. (mean T1D duration: 2,89 ± 2,35) anti TSH receptor autoantibodies (TSHR Ab), thyroid peroxidase antibodies (TPO Ab) and thyroblobulin antibodies (TG Ab) levels were measured in serum. TSHR Ab > 14 U/l, TPO Ab > 50 U/mL, TG Ab > 70 U/mL were considered positive. Radioreceptor assay (RRA) for quantitative determination of TSHR Ab was performed. TPO Ab and TG Ab levels were measured by ELISA. In all children clinical, hormonal examination and thyroid ultrasound, if necessary, were performed to establish thyroid function.
Results: None of 84 children had TSHR Ab. (+) TPO Ab, (+) TG Ab or both (+) TPO Ab and TG Ab determination were present in 24 of 84 patients (28,6%). Girls (77,8%) had more frequently raised antibodies than boys. (+) TPO Ab were present in 13 children (15,5%) - in 2 of them subclinical hypothyroidism was recognised and 1 patient was treated with L-thyroxine due to hypothyroidism. (+) TG Ab were present in 11 children (13,1%) - in 2 of 11 subclinical hypothyroidism was recognised, only 6 patients (7,2%) were positive for both TPO Ab and TG Ab - in 2 of 6 children subclinical hypothyroidism was determined. Subclinical hypothyroidism is recognised in 4 children with (-) TPO Ab and TG Ab levels. The hyperthyroidism was determined in 1 patient with (+) TPO Ab.
Conclusion: 1) TSH R Ab-based screening is not probably useful at the beginning of autoimmune thyroid disease in type 1 diabetic patients 2) further studies should be conducted to study the benefits of TSHR Ab determination particularly among those type 1 diabetic patients who have longer T1D duration.

976

High prevalence of sleep apnoea syndrome in a type 1 diabetic adult population

P.-Y. Benhamou[1], A.-L. Borel[1], J.-P. Baguet[2], I. Debaty[1], P. Levy[3], J.-M. Mallion[2], J.-L. Pépin[3];
[1]Endocrinology, Pole digidune, University Hospital, [2]Cardiology, University Hospital, [3]Rehabilitation and Physiology, University Hospital, Grenoble, France.

Background: Sleep Apnoea Syndrome (SAS) is an established cardiovascular risk factor. Its occurrence is high among obese or type 2 diabetic patients. No studies have addressed the question of SAS prevalence in type 1 diabetes.
Objectives: To prospectively evaluate the prevalence of SAS among a type 1 diabetic adult population, and whether SAS could be associated with any clinical characteristics in these patients.
Patients and methods: 40 type 1 diabetic patients were consecutively included for a screening oximetric procedure seeking sleep breathing disorders. According to the result of oximetry (normal, doubtful or abnormal), an overnight polysomnography was systematically proposed to subjects with doubtful or abnormal oximetry and randomly to 1/10 patients with normal oximetry.
Results: Among the 40 subjects (age 43 ± 13 years, Body Mass Index 24.7 ± 3.0 kg/m2, disease duration 23 ± 14 years, HbA1c 7.8 ± 0.9%), forty percent of patients exhibited SAS proven by polysomnography (apnea+hypopnea index> 15/h). Age of subjects was positively correlated with variability of oxygen saturation (higher variability reflecting repetitive occurrence of apneas) (R=0.61, p<0.001). In patients presenting with SAS, those suffering from macrovascular disease and retinopathy had lower nocturnal mean oxygen saturation. Mean SaO2 90.8 ± 2.9 vs. 94.4 ± 1.3% p=0.05 and 92.1 ± 2.4 vs. 94 ± 2.7% p=0.06 for patient with vs. without macrovascular disease and retinopathy respectively.
Conclusion: We demonstrated an unexpected high prevalence of SAS among type 1 diabetic patients. Sleep apnea was associated with age and the amount of oxygen desaturation with macrovascular angiopathy and retinopathy this suggestion SAS diagnosis as a key issue in type 1 diabetes.

Gastric emptying as prognostic factor for life expectancy in patients with type 1 diabetes

R.W. Lipp[1], W.J. Schnedl[2], G. Bock[1], G. Köhler[1], K. Horvath[1], J.K. Mader[1], T.R. Pieber[1,3], J. Piswanger-Soelkner[1];
[1]Internal Medicine/Endocrinology and Nuclearmedicine, Medical University Graz, [2]Internal Medicine, Medical University Graz, [3]Institute of Medical Technologies and Health Management, Joanneum Research, Graz, Austria.

Background and aims: Diabetic gastropathy is with an incidence of up to 58% an underestimated complication in patients with type 1 diabetes. To our knowledge only one existing study assessed the prognostic factor of gastric emptying disorders in diabetes. The aim of the present study was to investigate the influence of gastric emptying disorder on life expectancy in patients with type 1 diabetes and a long diabetes duration.
Materials and methods: 50 patients with long-standing diabetes type 1 were examined by gastric emptying scintigraphy. Following ingestion of a standardized semisolid test meal labeled with 37 MBq Tc-99m bound to 0.5 grams Dowex 2X8, gastric emptying was continuously recorded in supine position for a duration of 90 minutes with a dual-head gamma camera. After 30 minutes of postprandial walking, recording was resumed for additional 20 minutes. Subjects were followed up with a mean duration of 94±30 months. We assessed and analyzed gastric emptying rates in relation to HbA1c, diabetes duration, diabetic neuropathy and diabetic nephropathy. Kaplan Meier analysis and student's t-test were used if applicable.
Results: At baseline 29 patients (58%) had normal gastric emptying rates, 21 (42%) presented with gastric emptying disorders (accelerated in 4 subjects, delayed gastric emptying in 17 subjects). Between these groups diabetes duration and diabetic peripheral neuropathy was not statistical significant. HbA1c was comparable (8.9 ±1.4% vs. 8.3±0.8%). At time of follow up 12 patients have deceased (50% with normal gastric emptying, 25% with accelerated and 25% with delayed gastric emptying at baseline). 38 patients were still alive, of whom 60% showed a normal gastric emptying and 40% had a gastric emptying disorder (14 patients with delayed and 1 patient with accelerated gastric emptying rates).
Conclusion: Our data imply that patients with type 1 diabetes and accelerated gastric emptying have a decreased survival in comparison with patients with delayed gastric empting, suggesting accelerated gastric empting has a negative prognostic impact on survival.

978

The influence of gastric emptying patterns on blood glucose in type 1 diabetes

J. Piswanger-Soelkner[1], W.J. Schnedl[2], G. Bock[1], G. Köhler[1], K. Horvath[1], J.K. Mader[1], T.R. Pieber[1,3], R.W. Lipp[1];
[1]Internal Medicine/Endocrinology and Nuclearmedicine, Medical University Graz, [2]Internal Medicine, Medical University Graz, [3]Institute of Medical Technologies and Health Management, Joanneum Research, Graz, Austria.

Background and aims: Diabetic gastropathy is a common complication of long-standing diabetes. Few studies describe the influence of gastric emptying disorders on blood glucose levels.
What is the influence of gastric emptying patterns on blood glucose levels in long-standing type I diabetes mellitus? We investigated the correlation between gastric emptying patterns and blood glucose in 26 patients with long-standing type I diabetes.
Materials and methods: We invited 26 patients with long-standing type I diabetes (mean diabetes duration: 32 ± 10 years, mean age: 50 ± 13years) for gastric scintigraphy to evaluate gastric emptying rates. After ingestion of a standardized semisolid test meal (mashed potatoes, 21 g carbohydrates) labelled with Tc-99m, gastric emptying was continuously recorded in supine position during 90 min with a dual-head gamma camera. After 30 min of postprandial walking, recording was resumed for 20 min. Individual gastric emptying rates of the patients with diabetes were compared with the emptying rates of 25 healthy controls. Blood samples for glucose-assessment were performed before ingestion of the testmeal and continuously every 15 minutes during the investigation.
Results: In 13 patients the emptying rates (mean ± SD %) were normal (56±18 % vs. 31±13 % in controls), accelerated in 8 pts (24±11 % vs. 50±10 %) and delayed in 5 pts (74± 7 % vs. 31±13 %). The duration of diabetes was

similar between the groups (31 ± 11 vs. 32 ± 10 vs. 30 ± 7 years). At baseline glucose values were similar between the groups but at time point 90 minutes the blood glucose was significant different. Patients with normal gastric emptying rates showed a slow and smaller increase of glucose; the blood glucose profiles of patients with accelerated gastric emptying had an initial increase with higher values but after 90 minutes a decrease of glucose. Patients with delayed gastric emptying showed a continuous increase and the peak glucose values 150 minutes after ingestion of the testmeal (table with blood glucose values).

Conclusion: The different gastric emptying patterns influence the postprandial blood glucose profiles. The changed emptying rates due to diabetic gastropathy modify meal appearance of glucose. Our results should be taken in account in the management of type 1 diabetes in order to optimise prandial insulin replacement.

Emptying patterns	Glc (mg/dl) 0 min	30 min	60 min	90	120 min	150 min
Normal	205	231	254	266	257	286
Accelerated	225	255	299	315	289	267
Delayed	206	258	275	290	326	363

Reproducibility of the glucose response to moderate intensity exercise in people with type 1 diabetes exercise

G. Aitken[1], J. Charlton[1,2], R. Davison[1], G. Hill[1], L. Kilbride[1], J. McKnight[2];
[1]School of Nursing, Edinburgh Napier University, [2]Western General Hospital, NHS Lothian, Edinburgh, United Kingdom.

Background and aims: For people with type I diabetes achieving optimal blood glucose levels whilst exercising can be challenging; erratic blood glucose levels including hypoglycaemia can be problematic and a deterrent to participation in exercise. Prior to developing intervention strategies to improve blood glucose control during exercise it is vital to assess the typical variation of blood glucose during this period. Therefore the aim of the study was to determine the reproducibility of the blood glucose response to four repeated sessions of forty minutes of moderate intensity exercise in people with type I diabetes, and thus establish the typical variation of blood glucose in this experimental design.

Materials and methods: From a target population of 113 individuals, 14 participated in this quasi experimental study. Pre experiment, a sub maximal incremental walking treadmill test was used to determine 50%VO2max for each participant. All participants were currently using a basal bolus insulin regimen and were experienced in adjusting insulin dose and carbohydrate counting. All participants were habitual exercisers. The participants undertook the experiment over 2 consecutive weeks. On days 1 and 3 of each week the subjects undertook a 40 minute bout of exercise at 50% VO2max. In week 1 participant's self-managed their diabetes. In week 2 they used an exercise self management protocol devised by the research team to adjust insulin dose and carbohydrate intake, targeted to blood glucose levels. In each week from day 1 - 4 the blood glucose levels were recorded using a continuous blood glucose monitor at 5 minute intervals. The participant's heart rate was also monitored. To assess reproducibility all blood glucose data during the 40 minute exercise period were paired and analysed to assess the difference in mean values, standard error of measurement (SEM) and co-efficient of variation (CV%).

Results: Mean demographics of the participants at baseline were: 38 years of age, BMI 25 kg/m² and HbA1c 7.5%. There was a significant (p= 0.0003) difference (95%CI, 0.77 to 2.6 mmol·l^{-1}) between blood glucose levels between days 1 + 2 (7.2±2.4 vs. 8.8±3.8 mmol·l^{-1}), and a significant (p=0.04) difference (95%CI, 0.03 to 1.6 mmol·l^{-1}) between days 3 + 4 (10.7±2.6 vs. 9.8±4.2 mmol·l^{-1}). In terms of reproducibility the SEM between days one and two was 2.4 mmol·l^{-1} (CV= 33.2%), and between days 3 and 4 the SEM was 2.7 mmol·l^{-1} (CV= 33.7%).

Conclusion: This study has demonstrated a relatively large co-efficient of variation and thus poor reproducibility. However the magnitude of the CV% is comparable with other published literature which has examined the decline in blood glucose as a result of a bout of moderate exercise. This finding has implications for intervention studies attempting to alter the blood glucose response during exercise in people with type I diabetes.

A 6-month treatment with diazoxide at bedtime in newly diagnosed subjects with type 1 diabetes does not influence measured parameters of beta cell function, but improves glycaemic control

M. Radtke[1], I. Nermoen[2], M. Kollind[3], S. Skeie[4], J.I. Sørheim[5], J. Svartberg[6], V. Grill[1];
[1]Department of Cancer Research and Molecular Medicine, Faculty of Medicine, Norwegian University of Science and Technology, Trondheim, [2]Section of Endocrinology, Akershus University Hospital, Oslo, [3]Department of Internal Medicine, Levanger Hospital, [4]Dept. of endocrinology, Division of Internal Medicine, Stavanger University Hospital, [5]Haukeland University Hospital, Norwegian University of Science and Technology, Bergen, [6]Research Unit, Tromsø University Hospital, Norway.

Background and aims: Continuous beta cell rest with K-ATP channel openers, such as diazoxide, is shown to have long term beneficial effects on residual insulin secretion in type
1 diabetes. However, disturbing side effects have hampered the possibility for implementation in clinical use. In a double blind study we tested whether lower and intermittent dosing of diazoxide could produce beneficial effects in the absence of side effects.

Materials and methods: Thirty-eight subjects (11 female and 27 male aged 18- 40 years, BMI 24±4 kg/m2), with newly diagnosed type 1 diabetes were randomized to 6 months of treatment with either placebo or diazoxide, 100 mg at bedtime. Glucose, HbA1C and C-peptide (fasting and glucagon-stimulated) were measured at baseline, during intervention and 3 and 6 months after intervention.

Results: Two subjects in the diazoxide, and one in the placebo group were excluded due to perceived side effects (rash, dizziness, sleep disturbance respectively). Other adverse effects were absent. During intervention there was no negative influence by diazoxide on insulin dosage. The insulin dose in the diazoxide treated group was at base-line 33 ± 20 U/24h and the increment during intervention 1 ±11 U. In the placebo group the insulin dose at baseline was 34 ±.30 U, with a decrement during intervention at 2 ± 37 U (difference between groups non-significant). Diazoxide treatment led to improved glycemic control following the intervention period. Thus, there was a significant reduction in HbA1c with a decrement of -2.16 after 3, and -2.19 % 6 months after the end of intervention. In contrast, in the placebo group, there was no clear improvement of glycemic control (HbA1c decrement of -0.40 and -0.71 % respectively). The differences between groups were significant, p = 0.046 at 3 months, p= 0.039 at 6 months after intervention. Fasting and stimulated C-peptide decreased markedly during and after the study in both arms of the study. There was no indication of improved beta cell function after treatment with diazoxide 3 and 6 months after intervention. At these time-points the ratio between fasting C-peptide and fasting glucose was reduced by 24 and 40 % respectively from baseline after treatment with diazoxide, compared to 17 and 31 % after placebo. Following glucagon stimulation, the decrement of C-peptide/glucose ratio was 16 and 33 % in the diazoxide group, and 10 and 27% in the placebo treated group. Differences between the groups were not significant.

Conclusion: Intermittent beta cell rest with diazoxide in newly diagnosed type 1 diabetes is well tolerated but does not improve measured parameters of beta cell function. Improvement of other aspects of the beta cell function could possibly explain the diazoxide-associated improvement of metabolic control.

PS 85 Insulin therapy - type 1 diabetes

981

Effectiveness of a day without carbohydrates

S. Murillo;
CIBERDEM Centro de Investigación Biomédica en Red de Diabetes y Enfermedades Metabólicas Asociadas, Hospital Clínic de Barcelona, Spain.

Background and aims: Nowadays, multiple insulin doses (MID) is one of the most common insulin treatment used in type-1 diabetes. This insulin therapy combines long-acting insulin, as basal insulin, with short-acting insulin, depending on the amount of carbohydrates included in each meal. However, doses of long-acting insulin are established in relation to patient body weight but there aren't others methods to individualize these insulin requirements. To evaluate if a day without carbohydrates (DWC) could be an effective method to evaluate long-acting insulin needs in patients with type-1 diabetes.
Materials and methods: We have included 24 individuals with type-1 DM, older than 18 years, with poor glycaemic control (HbA1c >7.5%) and treated with MID, using glargine as long-acting insulin. During a day, patients maintain long-acting insulin injection but they had to eliminate short-acting insulin and couldn't eat carbohydrates in their diet. Moreover, in this day, patients had to do glycaemic controls before and 2-hours after every meal and, depends of the result obtained, add short-acting insulin or eat glucose supplements if glycaemic values were >130mg/dl or <70mg/dl respectively. To improve the knowledge of glycaemic fluctuations during this day we had monitorized glycaemic values using a Continuous Glucose Monitorized Sensor (CGMS) of Medtronic Minimed during a 4-days period, including the DWC. We considered a long-acting insulin dose as no correct if, during this day, patient had to add short-acting insulin to correct hyperglycaemia or eat carbohydrates to treat hypoglycaemia. In this case, patient should repeat the DWC with a new long-insulin dose, calculated depending on the quantity of insulin added or carbohydrates consumed during the first DWC. We collect data about HbA1c, weight, BMI, and short and long-acting insulin doses, frequency of hypoglycaemia, physical activity and carbohydrates intake in their usual days, before and 4-months after the DWC. Results obtained were compared with a control group of type-1 DM patients that undergo the same protocol without the DWC (N=21).
Results: Four months after the DWC, HbA1c levels of the DWC group had decreased from 8.1±0.9 to 7.5±0.7 ($p<0.05$) compared to the control group (from 8.1±0.6 to 8.0±0.7, p=ns). Moreover, patients had increased usual doses of long-acting insulin from 24.7±8.0 to 27.2±10.5 units/day ($p<0.05$) compared to the control group (from 26.8±5.6 to 26.4±6.5 units/day, p=ns) and had reduced usual doses of short-acting insulin from 20.9±6.9 to 19.3±8.2 units/day (p=ns) compared to the control group (from 23.2±10.3 to 23.1±7.8 units/day, p=ns). The frequency of mild hypoglycaemia before and four-months after the DWC was similar in the DWC group (from 0.9±1.1 to 0.8±0.9 episodes-patient/week, p=ns) and in the control group (from 1.3±1.5 to 1.2±1.1 episodes-patient/week, p=ns). We didn't found episodes of severe hypoglycaemia or presence of ketonuria.
Conclusion: A day without carbohydrates method is an effective tool to evaluate long-acting insulin needs in patients with type-1 diabetes. With this method we have got an improvement in glycated hemoglobin without increase the frequency of hypoglycemic episodes.

Comparative efficacy and safety of technosphere insulin and a rapid-acting analogue both given with glargine in subjects with type 1 diabetes mellitus in a 52-week study

P. Kapsner[1], R. Bergenstal[2], M. Rendell[3], C. Howard[4], A. Boss[4], P.-C. Chang[4], P. Richardson[4];
[1]University of New Mexico HSC, Albuquerque, [2]International Diabetes Center, Minneapolis, [3]Creighton Diabetes Center, Omaha, [4]MannKind Corporation, Valencia, United States.

Background and aims: Technosphere Insulin (TI) is a rapid-acting inhaled insulin with pharmacokinetics well suited for control of postprandial plasma glucose (PPG). This study compared the efficacy and safety of TI and a rapid-acting analog (RAA) both given at meals with insulin glargine, a long-acting analog (LAA).
Materials and methods: Subjects with type 1 diabetes mellitus and HbA_{1c} >7.0% and ≤11.0% were randomized to a 52-week course of basal LAA plus prandial TI (n=301) or prandial RAA (n=288). Prespecified efficacy endpoints included change in HbA_{1c}, 1-h PPG, 2-h PPG, and fasting plasma glucose (FPG) following a standard meal challenge. Adverse events were monitored to compare safety profiles.
Results: At the end of the 52-week treatment period, both groups experienced comparable reductions in HbA_{1c}, and there were no significant differences in LAA doses between treatment groups. FPG levels and 1-h PPG values were significantly lower with TI than with RAA, and 2-h PPG levels were similar between both groups. The TI group had weight loss, whereas the RAA group gained weight, with the difference statistically significant. Finally, the TI group had a statistically significant reduction in the incidence of mild/moderate (odds ratio [OR]: 0.474; confidence interval [CI]: 0.0271, 0.831; p=0.0091) and total hypoglycemia (OR: 0.488; CI: 0.278, 0.856; p=0.0124).
Conclusion: Compared with RAA in subjects with type 1 diabetes mellitus, TI in combination with LAA resulted in comparable HbA_{1c} reductions; more favorable 1-h PPG and FPG; significantly less weight gain; and significantly less risk of hypoglycemia.

Parameter	TI+LAA	RAA+LAA	*p* Value, 95% CI, or OR
ΔHbA_{1c} from baseline (%)	-0.17 ± 1.09	-0.47 ± 0.91	CI 0.11, 0.38
ΔFPG from baseline (mmol/l)	-2.5 ± 5.8	-1.3 ± 5.7	p=0.0052
1-h PPG (mmol/l)	9.2 ± 4.3	11.2 ± 4.6	p=0.0203
ΔWeight from baseline (kg)	-0.5 ± 4.1	+1.4 ± 3.9	p<0.0001
Total hypoglycemia (%)	86.01	92.65	OR 0.488; p=0.0124
Mild/moderate hypoglycemia (%)	85.67	92.65	OR 0.474; p=0.0091
Severe hypoglycemia (%)	32.76	37.50	OR 0.812; p=0.2387
Incidence of hypoglycemia with blood glucose ≤2.7 mmol/l (%)	76.11	83.82	OR 0.615; p=0.0232

983

Reduced incidence and frequency of hypoglycaemia in an integrated analysis of pooled data from clinical trials of subjects with type 1 diabetes using prandial inhaled Technosphere insulin

C. Howard, H. Ren, A. Rossiter, A. Boss;
MannKind Corporation, Valencia, United States.

Background and aims: Technosphere Insulin (TI) is a rapid-acting insulin with a pharmacokinetic profile well suited for earlier control of postprandial plasma glucose (PPG). This integrated analysis includes the pooled data from three phase II/III clinical trials in subjects with type 1 diabetes mellitus inadequately controlled (HbA_{1c} >7.0% and ≤11.0%) with standard insulin regimens.
Materials and methods: Subjects were randomized to one of three treatment regimens to achieve predefined glycemic goals: TI (n=614) plus a basal insulin; s.c. insulin (n=599), which included insulin glargine plus aspart; or "usual care," with insulin adjustments according to investigator discretion. A structured titration regimen was not enforced. When experiencing hypoglycemic-like symptoms, subjects were instructed to confirm the event with a blood glucose reading. Subjects experiencing a severe hypoglycemic episode were required to report the details of third-party assistance (if needed), the presence of neurologic symptoms, and the specifics of treatment.
Results: Mean baseline characteristics were similar for TI and s.c. insulin (age 38.4, 38.5 years; disease time since diagnosis 16.5, 16.6 years; baseline HbA_{1c} 8.59%, 8.56%; BMI 26.12, 26.03 kg/m^2). Subjects treated with TI experienced fewer hypoglycemic events with regard to both incidence and frequency compared with subjects treated with other s.c. insulins. For incidence, fewer subjects reported hypoglycemia with TI: 75.9% vs. 81.0% for total hypoglycemia; 75.6% vs. 80.8% for mild/moderate hypoglycemia; and 24.3% vs. 27.5% for severe hypoglycemia, with the comparison p values substantially in favour of TI for total hypoglycemia and mild/moderate hypoglycemia. For frequency,

TI had a comparable (not statistically different) number of events, evaluated by event rate (number of events per 100 subject-months), with event rates for severe hypoglycemia lower for the TI group. When evaluated for those subjects with blood glucose values ≤2 mmol/l, TI also was comparable (not statistically different) to s.c. insulin treatment with a lower event rate.
Conclusion: TI, in combination with a basal insulin, consistently reduced the incidence of total and mild/moderate hypoglycemic events and had a lower frequency of severe hypoglycemic events under conditions of comparable glycemic control.

Hypoglycemia	Incidence (%)		Odds Ratio	Odds Ratio *p* Value	Event Rate (per 100 subject-months)		Event Rate *p* Value
	TI + basal insulin	Comparator + basal insulin			TI + basal insulin	Comparator + basal insulin	
Mild/moderate	75.6	80.8	0.743	0.0354	133.16	117.74	0.9097
Severe	24.3	27.5	0.826	0.1576	5.16	6.03	0.5901
Total	75.9	81.0	0.749	0.0413	138.60	124.06	0.9242

984

Better metabolic control, less hypoglycaemia and less weight gain with insulin detemir versus NPH insulin in intensive insulin therapy for patients with type 1 diabetes. A meta-analysis

A. Szypowska[1], D. Golicki[2], L. Groele[1], E. Pańkowska[1];
[1]Department of Pediatrics, Medical University of Warsaw, [2]Department of Pharmacoeconomics, Medical University of Warsaw, Poland.

Background and aims: Detemir insulin characterizes more stable acting profile compared to NPH insulin due to binding with albumins and slow dissociation. In comparison with NPH insulin, basal-bolus treatment with insulin detemir might provide better glycemic control with lower risk of hypoglycaemia. The aim of this study was to compare the effect of treatment with detemir insulin vs. NPH insulin on metabolic control, hypoglycaemic episodes and body weight gain in patients with type 1 diabetes mellitus.
Materials and methods: This analysis is based on studies carried out longer than 12 weeks, comparing basal-bolus regimen therapies using detemir insulin vs NPH insulin in patients with type 1 diabetes mellitus. Two reviewers independently screened randomized controlled trials. Systematic overview included data from MEDLAINE, Cochrane Library and EMBASE until December 2008.
Results: This analysis included 7 studies. Meta-analysis of data of 3026 patients showed statistically significant reduction in HbA1c (WMD -0.10%, 95%CI -0.16 to -0.03, p=0.005) and fasting plasma glucose (WMD -1.11 mmol/L, 95%CI -1.60 to -0.52, p<0.001) in the detemir group compared with the NPH group. Meta-analysis of records obtained from 2667 subjects (5 studies) confirmed statistically significant reduction in all day hypoglycaemic episodes (RR 0.98, 95%CI 0.96 to 0.99, p=0.032) and nocturnal hypoglycaemia (RR 0.91, 95%CI 0.86 to 0.95, p<0.001) in patients using detemir insulin. Analysis of data of 3067 patients pointed out to 34% less frequent severe hypoglycemia (RR 0.66, 95%CI 0.54 to 0.81, p<0.001) and results of 5 studies (n=2306) showed smaller body mass gain (WMD -0.76 kg, 95%CI -0.99 to -0.53, p<0.001) in the detemir group.
Conclusion: In comparison with NPH insulin, basal-bolus treatment with insulin detemir resulted in a significantly better glycemic control expressed as reduction in glycated hemoglobin and fasting plasma glucose. The treatment with detemir insulin was superior to NPH insulin in reducing the risk of all day, nocturnal and severe hypoglycaemia, with added benefits of less weight gain.

985

Comparison of insulin detemir and NPH insulin in children and adolescents with type 1 diabetes mellitus aged 2-16 years: a 52-week randomised clinical trial

N. Thalange[1], A. Bereket[2], J. Larsen[3], L. Conradsen Hiort[4], V. Peterkova[5];
[1]Jenny Lind Children's Department, Norfolk & Norwich University Hospital, Norwich, United Kingdom, [2]Division of Paediatric Endocrinology and Diabetes, Marmara University School of Medicine, Istanbul, Turkey, [3]Insulin Medical & Science, Novo Nordisk, Bagsvaerd, Denmark, [4]Biostatistics, Novo Nordisk, Bagsvaerd, Denmark, [5]Endocrinological Research Centre, Institute of Paediatric Endocrinology, Moscow, Russian Federation.

Background and aims: This randomised, multinational, open-labelled, parallel-group trial compared 52 weeks of treatment with insulin detemir (IDet) and NPH insulin (NPH) in subjects aged 2-16 years with type 1 diabetes (T1DM). This trial was the longest and largest insulin trial ever performed in this age group and 82 (23.6%) of the individuals included were less than 6 years.
Materials and methods: The study investigated the efficacy and safety of IDet vs. NPH used in a basal-bolus multiple daily insulin injection regimen. Of the 347 randomised and exposed subjects (baseline characteristics: mean (SD) age: 9.9 (3.99) yrs, males: 51.9%, diabetes duration: 3.69 (2.58) yrs, HbA_{1c}: 8.4 (1.1)%, fasting plasma glucose (FPG): 8.52 (4.48) mmol/L), 177 received IDet and 170 received NPH, both administered once or twice daily in combination with mealtime insulin aspart (IAsp).
Results: After 52 weeks, non-inferiority of IDet vs. NPH was established for HbA_{1c} (IDet 8.75%, NPH 8.64%, mean difference 0.12% points, 95% CI (-0.12; 0.36%)). Change in mean FPG was -0.60 mmol/L with IDet vs. 0.02 mmol/L with NPH, (NS) and the within-subject variation in self-measured FPG was lower with IDet than with NPH (SD: 3.01 vs. 3.68 mmol/L, p <0.001). The estimated mean rate of 24-hour hypoglycaemia and nocturnal hypoglycaemia (between 22:00 and 07:00) was lower with IDet than with NPH, (respectively 55.4 vs. 72.5 events per exposure year, (rate ratio: 0.76, p <0.05) and 8.7 vs. 13.9 events per exposure year (rate ratio: 0.62, p <0.005)). The reduced rate of hypoglycaemia at night was observed even though pre-breakfast plasma glucose targets between 4.0 and 7.0 mmol/L was achieved by a slightly larger proportion of subjects on IDet compared to NPH (40% vs. 32%) at end of trial. Severe hypoglycaemic episodes were rare (3 with IDet and 12 with NPH) and none of these occurred at night with IDet. Apart from this, the adverse event profile was similar between IDet and NPH. SD scores for body weight (standardized by age and sex) decreased with IDet, but remained unchanged with NPH (change: -0.12 vs. 0.04, p <0.001). Thus, in contrast to NPH, IDet was not associated with inappropriate weight gain. At trial end, the mean daily basal insulin dose was comparable between IDet and NPH (0.60 vs. 0.58 U/kg) as was the dose of IAsp (0.48 vs. 0.45 U/kg).
Conclusion: In this unique trial, long-term treatment of children and adolescents aged 2-16 years with insulin detemir resulted in similar glycaemic control as NPH insulin, but with a significantly lower risk of overall and nocturnal hypoglycaemia and a reduction in weight SD scores.

986

A comparison of efficacy and safety of insulin aspart and human insulin in treatment of type 1 diabetes mellitus. The results of a systematic review

I. Skrzekowska-Baran[1], O. Pankiewicz[2], P. Rys[2], M.T. Malecki[3];
[1]Novo Nordisk Poland, Warsaw, Poland, [2]HTA Consulting, [3]Department of Metabolic Diseases, Jagiellonian University, Krakow, Poland.

Background and aims: There is an on-going debate concerning efficacy and safety of the rapid-acting insulin analogues in type 1 diabetes mellitus (T1DM). While a few systematic reviews have been published so far, most of them provide pooled results for two analogues (lyspro and aspart). Very limited data is available on each individual compound. Our aim was to perform a systematic review-based study to compare clinical outcomes of treatment with aspart (IAsp), a rapid-acting insulin analogue, and regular human insulin (RHI).
Materials and methods: The analysis was based on the results of clinical trials, randomized and their non-randomized continuations in T1DM. Relevant articles were identified by a systematic literature search in the electronic medical databases (MEDLINE, EMBASE, The Cochrane Library and others) up to February 2007. Two authors independently reviewed the articles.
Results: We identified 12 trials (3553 patients) that fulfilled the inclusion criteria. Results are presented as the weighted mean difference and 95%CI, if not

otherwise stated. No study provided data for mortality or morbidity. Pooled data for HbA_{1c} demonstrated a lower level in the IAsp than in the RHI group (-0.14; -0.20 to -0.07). The difference was greater in favour of IAsp in insulin pump therapy (-0.31; -0.55 to -0.08). In addition, meta-analysis revealed statistically significant differences in favour of IAsp for PPG after breakfast (-1.46; -1.80 to -1.11), lunch (-1.13; -1.88 to -0.38) and dinner, (-0.86; -1.16 to -0.55); but not for fasting plasma glucose (FPG) (0.12; -0.96 to 1.20). Data on treatment satisfaction and Quality of Life were presented only in two studies. We observed a benefit when comparing IAsp with RHI (0.33; 0.19 to 0.47) with respect to the part of the Diabetes Treatment Satisfaction Questionnaire scale evaluating treatment flexibility. The safety analysis showed significant reduction of nocturnal hypoglycemias in the IAsp group (relative risk 0.67; 95%CI 0.54 to 0.83).
Conclusion: In conclusion, analyses based on a systematic review showed that treatment with IAsp resulted in moderately better metabolic control, safety and treatment satisfaction in T1DM.

987

Comparison between human insulin and insulin analogues treatment with regard to hypoglycaemia (HYPO score) and metabolic lability (Lability Index) in type 1 diabetes mellitus
J. Caballero-Corchuelo, A. Boltaña, R. Insa, J. Soler, E. Montanya, M. Perez-Maraver;
Endocrine Unit, Hospital Universitari Bellvitge, Hospitalet Llobregat, Spain.

Background and aims: Intensive insulin therapy in order to achieve a strict glycemic control reduces the incidence of complications associated with type 1 diabetes mellitus but increases the risk of hypoglycemia. Therapy with insulin analogues has been associated with a lower risk of hypoglycemia, particularly nocturnal events, and reduced glycemic lability in comparison with traditional human insulin. However, methods for quantifying the global risk of hypoglycemia and metabolic lability are heterogeneous and poorly standarized. HYPO score and Lability Index (LI) are clinically validated quantitative measures associated with global risk of hypoglycemia and glycemic lability respectively. The aim was to evaluate, in type 1 diabetes mellitus patients treated with human insulin, whether treatment with insulin analogues was associated with a lower risk of hypoglycemia and glycemic lability (HYPO score and LI more favourable).
Material and methods: Our study was a 6 months prospective, randomized, open-labelled clinical trial. Consecutively attended patients in our unit were included if they had type 1a diabetes mellitus for at least 5 years, 18-60 years old, HbA_{1c} less than 10%, and were receiving treatment with three or more doses of human insulin (n=47). Patients were randomized in a 1:1 ratio to receive human insulin therapy (regular plus NPH; group 1, n= 21) or an insulin analogues regimen (aspart plus glargine; group 2, n=26). HYPO score, LI, and hypoglycemic episodes and their characteristics were assessed at baseline and at the end of follow-up. Age, gender, diabetes duration, BMI, HbA_{1c}, and insulin dose were also compared between groups at baseline and at the end of the study. A 72-hours continuous glucose monitoring was performed at the end of follow up in a subgroup of patients (n=12). Groups were compared with non-parametric tests. HYPO score and LI are expressed as median (25^{th} to 75^{th} interquartile range). Statistical significance was defined as $p<0.05$.
Results: At baseline both groups were comparable in terms of age (34.5 ± 5.6 vs 35.6 ± 7.8 years), diabetes duration (10.2 ± 4.1 vs 10.7 ± 7.3 years), BMI (26.8 ± 4.3 vs 26.4 ± 3.3 kg/m^2), HbA_{1c} (7.5 ± 0.9 vs 7.5 ± 0.7 %), and insulin dose (0.76 ± 0.16 vs 0.73 ± 0.17 IU/kg), groups 1 and 2 respectively. Initial HYPO score (223.5 (84.5-403.0) vs 149.0 (53.0-224.0)) and LI (89.8 (52.3-156.9) vs 77.4 (51.6-131.5) $mM/l^2/h.week^{-1}$) were also comparable. At the end of the study both groups continued to be comparable in terms of BMI, insulin dose, and HbA_{1c} (7.7 ± 0.9 vs 7.2 ± 1.0 %). However, HYPO score was significantly lower in group 2 at six months (260.0 (52.0-676.0) vs 71.5 (36.0-162.5), $p<0.05$) as well as nocturnal hypoglycemic events (1.4 ± 1.5 vs 0.4 ± 0.8 per 4 weeks, $p<0.05$) and episodes below 45 mg/dl (3.0 ± 2.9 vs 1.4 ± 1.3 per 4 weeks, $p<0.05$). LI was comparable at the end of the study in both groups. HYPO score was positively correlated with % time with glycemia below 70 mg/dl in continuous glucose monitoring (r=0,62, p <0,05).
Conclusion: treatment with insulin analogues in type 1 diabetes mellitus patients, in comparison with human insulin, was associated with a lower risk of hypoglycemia, particularly nocturnal and below 45 mg/dl events, despite comparable insulin dose and metabolic control. In contrast, metabolic lability was not different between groups.

Comparison between the "Diabetes Interactive Diary" telemedicine system and standard carbohydrate counting education: an open label, international, multicentre, randomised study
G. Vespasiani[1], M.C. Rossi[2], P. Di Bartolo[3], C. Sardu[3], D. Bruttomesso[4], M. Dal Pos[4], A. Girelli[5], E. Zarra[5], F. Ampudia[6], D. Kerr[7], A. Ceriello[8], C. De La Cuesta[9], F. Pellegrini[2], D. Horwitz[10], A. Nicolucci[11];
[1]Madonna del Soccorso Hospital, S. Benedetto del Tronto, Italy, [2]Clinical Pharmacology and Epidemiology, Consorzio Mario Negri Sud, S. Maria Imbaro (CH), Italy, [3]AUSL, Ravenna, Italy, [4]Clinical and Experimental Medicine, Policlinico Universitario, Padova, Italy, [5]Diabetes Unit, Spedali Civili, Brescia, Italy, [6]Unit of Endocrinology, Hospital Clínico Universitario, Valencia, Spain, [7]Diabetes and Endocrine Centre, Royal Bournemouth Hospital, Bournemouth Dorset, United Kingdom, [8]University of Warwick, Warwick Medical School, United Kingdom, [9]Unit of Endocrinology, Hospital Universitario Virgen Macarena, Sevilla, Spain, [10]Medical & Clinical Affairs LifeScan Inc., Milpitas, United States, [11]Consorzio Mario Negri Sud, S. Maria Imbaro (CH), Italy.

Background and aims: Carbohydrates (CHO) counting is effective in promoting dietary freedom, quality of life, and glycaemic control, but its widespread use is limited by the complex education required. The Interactive Diary for Diabetes (DID) is an electronic diary/bolus calculator/ telemedicine system based on patient-specialist communication by mobile phone short messages. It enables patients to match insulin to CHO intake on a meal by meal basis. Aim of this study was to compare DID with standard CHO counting education in terms of metabolic and weight control, quality of life, and treatment satisfaction.
Materials and methods: Adults with T1DM were randomised to the DID educational program (Group A, N=67) or to CHO counting standard education (Group B, N=63). Patients were seen after 3 and 6 months. A subgroup of 60 patients was asked to fill in the SF-36 Health Survey and the WHO-Diabetes Treatment Satisfaction Questionnaire at each visit. Between-groups mean changes with respect to baseline values were evaluated using the Mann-Whitney U test.
Results: Of 130 patients enrolled (43% males; age 35.7±9.4 yr; T1DM duration 16.5±10.5 yr), 11 dropped out (9 in group A and 2 in group B). Time devoted to education was of 6 (2-15) hours in group A and 12 (2.5-25) hours in group B (p=0.07). After 6 months, HbA1c levels decreased from 8.2±0.8 to 7.8±0.8 in group A and from 8.4±0.7 to 7.9±1.1 in group B (p=0.68); FBG decreased from 183±86 to 163±67 mg/dl in group A, while it increased from 177±59 to 186±79 mg/dl in group B (p=0.13); body weight increased by 0.68±3.6 Kg in group A and 1.45±2.3 kg in group B (p=0.34). Mean daily doses of short-acting insulin were of 20.6±8.2 UI/die in group A and 20.1±7.8 UI/die in group B (p=0.92), while doses of long-acting insulin were lower in group A than in group B (17.4±7.4 UI/die and 21.4±10.0 UI/die, respectively; p=0.12). No severe hypoglycaemic episode occurred. DTSQ-scores increased significantly more in group A (from 26.7±4.4 to 30.3±4.5) than in group B (from 27.5±4.8 to 28.6±5.1) (p=0.04). Role physical, general health, vitality, and role emotional SF-36 scores improved significantly more in group A than in group B.
Conclusion: DID is at least as effective as traditional CHO counting education, allowing dietary freedom to a larger proportion of T1DM patients. DID is associated with lower weight gain, probably due to lower doses of long-acting insulin, it requires less time for education and does not increase the risk of severe hypoglycaemic episodes. DID significantly improved treatment satisfaction and several quality of life dimensions.

Impact of the READ (Ramadan focused Education and Awareness in Diabetes) programme on HbA_{1c}, weight and hypoglycaemia
V. Bravis[1,2], E. Hui[1], B. Gohel[1], S. Salih[1,3], S. Mehar[1,3], D. Devendra[1,2];
[1]Diabetes and Endocrinology, Jeffrey Kelson Diabetes Centre, Central Middlesex Hospital, [2]Department of Investigative sciences, Imperial College, [3]Brent teaching PCT, London, United Kingdom.

Background and aims: 14 million Muslims are living in Europe and 1 million suffer with diabetes. During Ramadan, Muslims fast from dawn to dusk for

one lunar month. Type 2 Diabetes (T2D) patients who fast during Ramadan have a four-fold increase in hypoglycaemic events (HE) and gain weight. In 2007, we conducted a pilot study, which demonstrated that the READ (Ramadan focused Education and Awareness in Diabetes) programme reduced the risk of HE, prevented weight gain and empowered patients to change their lifestyle. In 2008, we extended the study, aiming to: 1)validate our results, 2)compare the impact of READ on HbA1c, weight, HE before and after Ramadan in a large cohort of Muslim patients with T2D, 3)implement treatment interventions to the education arm and compare their effects on HbA1c, weight, HE during Ramadan.

Materials and methods: 126 patients (Group A) took part in the READ programme about meal planning, physical activity, glucose monitoring, hypoglycaemia, medications. Group B did not attend (n=120). We retrospectively analysed mean weight, HbA1c, HE (blood glucose $\leq$3.5 mmol l^{-1} and/or symptoms) before and after Ramadan. Patients with HbA1c $\geq$ 8.5% who attended the programme were further assigned to two groups. In addition to Metformin 2g daily, group C received vildagliptin 50mg bd (n=26) and group D received gliclazide 80mg bd (n=28). HbA1c, weight, HE were compared before and after Ramadan. Patients on Human Mixtard30 bd insulin regime (n=52) were also divided into two groups before Ramadan. In group E, the evening insulin dose was changed to Humalog Mix50 insulin (n=26). Group F continued on Human Mixtard30 (n=26). We retrospectively analysed mean weight, HbA1c, HE before and after Ramadan.

Results: Group A had mean weight change of -1.52kg (p=0.07, 95%CI -3.41 to 0.37) and mean HbA1c change of -0.7% (p<0.001, 95%CI -0.83 to -0.57). Group B had mean weight change of +0.94kg (p<0.001, 95%CI -0.76 to 2.64) and mean HbA1c change of +0.1% (p<0.001, 95%CI 0 to 0.2). There was relative risk reduction in HE of 20% with education. Group C had mean HbA1c reduction of 1.3% (p<0.001) and mean weight gain of 0.34kg (p=0.08). Group D had mean HbA1c reduction of 1.3% (p<0.001) and mean weight gain of 0.8kg (p<0.001). During Ramadan there were 12 times more HE in the Gliclazide group (n=24) compared to the Vildagliptin group (n=2). Group E had mean weight gain of 0.81kg (p<0.001) and a mean HbA1c reduction of 0.49% (p<0.001). Group F had 0.33kg mean weight gain (p=0.08) after Ramadan and mean HbA1c increase of 0.33% (p<0.05). There was relative risk reduction of 27% in HE with Humalog Mix50.

Conclusion: The READ programme created an opportunity to study the outcomes of fasting in the UK among Muslims. It led to better metabolic control, through weight loss and significant decrease in Hba1c, whilst ensuring safer fasting by decreasing the risk of hypoglycaemia. Vildagliptin use is safer than gliclazide during the month of Ramadan. The Humalog Mix50 regime could be considered as a safer and more effective regime for T2D patients who fast during Ramadan. The benefit of patient education appears to be very relevant to T2D patients who fast during Ramadan. We encourage all healthcare providers in Europe to implement this novel education programme, which is the first to study outcomes of fasting in Europe.

990

International diabetes management practices study (IDMPS): outcomes comparison between educated and non educated people with type 2 diabetes

J.J. Gagliardino[1], P. Aschner[2], S.H. Baik[3], J. Chan[4], N. Hancu[5], H. Ilkova[6], A. Ramachandran[7];
[1]CENEXA (UNLP-CONICET LA PLATA), La Plata, Argentina, [2]Endocrinology Unit, Javeriana University School of Medicine, Bogotá, Colombia, [3]Division of Endocrinology, Korea University Guro Hospital, Seoul, Republic of Korea, [4]Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Shatin, Hong Kong, [5]Diabetes Center and Clinic, Iuliu Hatieganu University of Medicine, Cluj-Napoca, Romania, [6]Department of Internal Medicine, Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey, [7]India Diabetes Research Foundation, Dr. A. Ramachandran's Diabetes Hospitals, Chennai, India.

Background and aims: Achievement of diabetes treatment goals greatly depends on the patient´s active and efficient participation in the control and treatment of the disease. Although education is a valuable tool to obtain such participation, many patients worldwide still lack appropriate diabetes education. This study shows significant improvement of treatment indicators in a population of educated persons with type 2 diabetes and values close to treatment goals according to EASD/ADA guidelines.

Materials and methods: The IDMPS is an international, multicenter, observational study performed in 27 countries within Africa, Asia, Eastern Europe, Middle East and Latin America. Data were collected from people with type 1 and 2 diabetes (≥18 years) seen in current medical practice in yearly cycles (2-week cross-sectional recruitment period followed by a 9-month longitudinal period for type 2 patients) for 5 years. IDMPS was performed in compliance with the Helsinki Declaration and Good Clinical Practice Standards. We currently report and compare results from 11384 people with type 2 diabetes (educated *vs.* non educated, 5692 in each group, paired by age, gender and diabetes duration) recruited during the second cross-sectional period (November and December 2006). Data were analyzed using the Wilcoxon and the chi^2 tests for continuous and categorical variables, respectively.

Results: Values of the different parameters measured in both groups were close to treatment goals proposed by EASD/ADA guidelines; however, the educated group had modestly but significantly (p< 0.001) higher figures of people with normal BMI (28.3 *vs.* 24.4%), diastolic BP <80 mm Hg (36.5 *vs.* 32.3%), HbA1c < 7.0% (38.1 *vs.* 35.8%), LDL-c < 100 mg/dL (39.5 *vs.* 33%) and triglyceride < 150 mg/dL (52.7 *vs.* 49%). The percentage of complications was low (<20%) in both groups but the educated group had significantly lower values of people with proteinuria (16.6 *vs.* 18%) and foot ulcer (2.4 *vs.* 3.5%).

Conclusion: These data represent one of the largest reported on education of people with type 2 diabetes and demonstrate that education can significantly improve treatment outcomes, even in persons with values close to treatment goals. Such improvements can help to prevent the development/progression of chronic complications and the consequent increase in treatment costs.

Evaluating self-management support in type 1 diabetes: design and baseline data from the Irish Dose Adjustment for Normal Eating (DAFNE) Study

S.F. Dinneen[1], M. O'Hara[2], J. Newell[3], M. Byrne[4], for the Irish DAFNE Study Group;
[1]Medicine, National University of Ireland, [2]Diabetes Centre, University Hospital Galway, [3]Clinical Research Facility, National University of Ireland, [4]School of Psychology, National University of Ireland, Galway, Ireland.

Background and aims: Structured education programmes for individuals with Type 1 diabetes have become a recognised means of delivering the knowledge and skills necessary for optimal self-management of the condition. The DAFNE programme has been shown to improve biomedical (HbA1c and rates of severe hypoglycaemia) and psychosocial outcomes for up to 12 months following course delivery. The optimal way to support DAFNE graduates and maintain the benefits of the programme has not been established. We aimed to compare 2 different methods of follow-up of DAFNE graduates in a pragmatic clinical trial delivered in busy diabetes clinics across the island of Ireland.

Materials and methods: Six participating centres were cluster randomised to deliver either group follow-up or a return to traditional one-to-one clinic visits at 6, 12 and 18 months post DAFNE training. Generalisability (external validity) was maximised by recruiting study participants from existing DAFNE waiting lists in each centre, by using broad inclusion criteria (e.g., HbA1c values less than 13 percent with no lower limit) and by using existing clinic staff to deliver the training and follow-up. Internal validity and treatment fidelity were maximised by quality assuring the training of all DAFNE educators, by external peer review of the group follow-up sessions and by striving for full attendance at follow-up visits. Assays of HbA1c were undertaken in a central laboratory.

Results: The target sample size of 400 participants was reached in February 2009. Baseline analyses show that the study population comprises 55 percent females. The mean (±SD) age of the group is 38.1 (±11.7) years with duration of diabetes of 16.0 (±10.8) years and body mass index of 26.1 (±4.2). The mean HbA1c at baseline is 8.3 (±1.3) percent with no statistical heterogeneity across centres. A total of 89 out of 381 respondents (23%) reported one or more episodes of severe hypoglycaemia in the previous 12 months. Baseline psychosocial measures showed mean scores for Hospital Anxiety Depression Scale-Anxiety (HADS-A), HADS-Depression (HADS-D) and Problem Areas in Diabetes (PAID) of 5.0 (±3.5), 4.5 (±3.2) and 27.0 (±18.0) respectively. The percent of participants with values considered clinically significantly abnormal (greater than 8 for HADS-A and HADS-D and greater than 40 for PAID) was 17, 12 and 23 percent respectively.

Conclusion: This pragmatic clinical trial evaluating group follow-up after a structured education programme has been designed to have broad generalisability. The results should inform how best to manage the well educated patient with Type 1 diabetes in the real world of clinical practice.

Patient Engagement And Coaching for Health *(PEACH):* baseline characteristics of patients with type 2 diabetes in cluster RCT of intensive treatment in general practice in Australia

D. Young[1], J.S. Furler[1], I.D. Blackberry[1], J.D. Best[2], on behalf of PEACH study investigators;
[1]Department of General Practice, [2]School of Medicine, The University Of Melbourne, Carlton, Australia.

Background and aims: Significant gaps exist between actual clinical practice and evidence based treatment goals and
outcomes in type 2 diabetes (T2D) care in General Practice. Intensive treatment to reduce HbA1c and other risk factor for T2D complications can be hard to implement in the primary care setting. The PEACH study is a General Practice based, cluster RCT of practice nurse-led telephone coaching to improve health outcomes for patients with poorly controlled T2D in Melbourne, Australia. The practice nurse follows the COACHING program, a scripted format to motivate and empower patients in diabetes self management. Patients receive 8 telephone coaching sessions from the practice nurse over an 18-month period. Coaching focuses on having patients more actively engage with their General Practitioner to achieve HbA1c and other risk factor targets by intensifying pharmacologic treatment. This paper describes the demographics and clinical profiles of the participants at baseline, before randomisation into intervention and control groups.
Methods: T2D patients over 18 years with HbA1c>7.5% in the last 12 months without any complex debilitating coexisting medical condition were recruited from general practices. All patients were approached by mail and asked to fill in a brief personal survey irrespective of their willingness to participate. Those agreeing to participate completed baseline data on biochemical and lifestyle factors such as smoking, diet and physical activity with their practice nurses. Additional information such as diabetes self efficacy, depression, quality of life and level of social support were also obtained.
Results: 468 patients (42% female) from 59 general practices completed baseline assessments. Mean age was 62 years and 19% of participants were from non-English speaking background. Participants had a median duration of diabetes of 9 years with a median HbA1c of 7.8%. Over 90% of participants were overweight or obese, with average BMI of 33 kg/m^2 and over 70% had waist circumference above target. Blood pressure and total cholesterol means were 138/79mm/Hg and 4.5mmol/L, respectively. Proportion of people with normal ranges of albumin/creatinine ratio and eGFR were 73% and 82%, respectively. Nearly 40% of the sample reported mild to severe of depression level. Compared to non-participants, participants were more educated, more likely to have private health insurance, from higher socio-economic occupational groupings, had fewer macrovascular complications, and were more likely to be on combined insulin and oral medications. Participants reported slightly lower self efficacy in managing diabetes and slightly higher levels of perceived availability of support and support accessibility compared to community samples.
Conclusion: While participants are more educated and not as disadvantaged socio-economically as non-participants, this poorly controlled study population is at high risk of significant long term complications from diabetes. The high prevalence of depression and obesity are of concern and are likely to pose challenges to practice nurses undertaking coaching. The Practice Nurses will face additional challenges to coach these patients to improve their diabetes control in view of the natural progression of the disease.

Attitudes and beliefs on self-care of diabetic foot among patients

A.L. Costa, A.C. Caetano, A. Valongo, I. Lessa, A. Recto, R. Oliveira, A. Castela, R. Duarte, J.F. Raposo;

Diabetic Foot, Portuguese Diabetes Association (APDP), Lisbon, Portugal.
Background and aims: The risk of Diabetes Foot Syndrome has increased in patients with long diabetes duration. Preventive measures however can reduce lower limb amputations for diabetic foot disease. Tight glycemic control, patient education and preventive foot care behaviors can substantially reduce that risk. The aim of this study was to assess attitudes, beliefs and the level of preventive foot care among patients with diabetes in an outpatient foot clinic in Portugal.
Materials and methods: A retrospective descriptive analysis based on clinical data collected from all diabetic patients that attended for the 1st time our foot clinic, between January and December 2007. A cohort of 1.048 diabetic patients who went to our screening evaluation, were assessed by their preventive foot care attitudes and beliefs. A questionnaire including items such as foot hygiene, proper foot wear, identification and avoidance of risks, behavior in injury, routine foot surveillance and daily self feet inspection was used during the assessment. The level of awareness was categorized as having "No Awareness", "Some Awareness", "Acceptable Awareness" and "Good Awareness". Details of socio-demographic and clinical profiles were also available. Statistical analysis was performed through SPSS - Statistical Package for the Social for Science). Descriptive statistics are present and comparison between variables was performed using χ^2 test.
Results: We studied 1.048 patients, 46% were female and 54% male. Mean age of the group was 61 ± 14 years and duration of diabetes was 12 ± 9 years. 6,5% were type 1 diabetes, 88,1% were type 2 diabetes and 5,4% had other types of diabetes. The last Hb1A1c in patients with ≤ 6,5% was 19,37%. We found that 82,5% of patients had acceptable awareness of foot care behaviors. Comparative analysis between socio-demographic and clinical variables revealed statistic significant differences in gender (female 56,9% vs male 43,1%); $p < 0,05$. duration of disease for less than 9 years (Pearson Chi- Square value 77, df 42, p= 0.001), school degree to secondary school (Pearson Chi- Square value 2,3, df 3, p= 0,001) and type of diabetes for diabetes type 2 (Pearson Chi-Square value 21,8, df 5, p =0.001).
Conclusion: The evaluation in our sample showed an adequate awareness standard of preventive foot care behavior. Effective education is needed to increase awareness and preventive foot care attitudes (behavior) in the illiteracy community and, with longer duration of diabetes, especially in men and in type 1 diabetics.

994

Self-monitoring of blood glucose in patients with type 2 diabetes who are not using insulin: a 1-year randomised controlled trial

N. Kleefstra[1,2], J. Hortensius[1], S.J.J. Logtenberg[1], R.J. Slingerland[3], K.H. Groenier[4], S.T. Houweling[2,5], R.O.B. Gans[6], H.J.G. Bilo[6,1];
[1]Diabetes Centre, Isala Clinics, Zwolle, [2]Medical Research Group, Langerhans, Zwolle, [3]Department of Clinical Chemistry, Isala Clinics, Zwolle, [4]General Practice, University of Groningen, [5]General Practice Sleeuwijk, [6]Department of Internal Medicine, University Medical Center Groningen, Netherlands.

Background and aims: Self-monitoring of blood glucose (SMBG) improves glycemic control in patients using insulin. Whether this is also true for patients with type 2 diabetes mellitus (T2DM) not using insulin is questionable. Our aim was to investigate the effects of SMBG (postprandial values) in patients with T2DM not using insulin who are in persistent moderate glycemic control.
Materials and methods: Patients were eligible when between 18 and 70 years of age, with an HbA1c between 7 and 8.5% at the start of the study (at annual check-up) and at the previous annual check-up, using 1 or 2 different oral blood glucose lowering drugs without regimen change during the preceding 3 months, and without use of SMBG in the preceding 6 months. Forty patients were randomly assigned to receive either SMBG added to usual care or to continue with usual care during 1 year. SMBG was performed using the Accu-check Aviva blood glucose meter. Twice a week (including either Saturday or Sunday),a fasting glucose value and three postprandial glucose values were measured. All patients were instructed about acceptable glucose values (fasting: 4-8 mmol/L, postprandial: 4-10 mmol/L) and no specific (dietary) advice was given. HbA1c was measured every 3 months. Blood glucose lowering therapy was intensified when HbA1c was ≥ 8.5%. The primary efficacy parameter was change in HbA1c. An intention to treat analysis was performed.
Results: Patients were recruited from March 2006 until October 2007. Mean age was 59 years, median diabetes duration was 6.0 years, and mean BMI was 31 kg/m^2. Mean HbA1c at baseline was 7.58% vs. 7.66% in the intervention vs. control group, respectively. After 1 year HbA1c was on average 7.47% in the intervention group and 7.52% in the control group (see figure: Mean HbA1c values for smbg and no smbg groups with 95% CI). Change in HbA1c between groups was -0.05% (95%CI: -0.51, 0.41; p=0.507).
Conclusion: Although this study cannot fully exclude a possible clinical relevant change in HbA1c caused by SMBG in patients on oral therapy, it largely confirms the results of 2 previous trials with SMBG in T2DM (the DIGEM and ESMON trials). Our study adds data on patients with T2DM in persistent

moderate control, performing fasting and postprandial SMBG. We conclude that there is no evidence that SMBG should be considered of value in T2DM patients not using insulin.

995

Successful optimizing of intensified insulin therapy using a new structured treatment and teaching programme for outpatients with diabetes mellitus type 1

U.A. Müller[1], N. Müller[1], C. Kloos[1], R. Fahr[2], A. Fahr[2], K. Opel[3], A. Opel[3], G. Wolf[1];
[1]Internal Medicine III, University Hospital Jena, [2]Practice for Diabetology, Suhl, [3]Practice for Diabetology, Gummersbach, Germany.

Background and aims: The only certified diabetes treatment and teaching programme (DTTP) for patients with diabetes type 1 in Germany was developed and evaluated by the group of Michael Berger. The programme aims for self management of diabetes and insulin dose adjustment. The evaluation of the DTTP is mainly based on studies on inpatients and one trial on outpatients from Austria. Primary objectives of the programme were starting insulin therapy and switching from conventional to intensified therapy. Today 99% of patients with type 1 diabetes in Germany are on intensified insulin therapy The current objective in the care of patients with diabetes type 1 is to optimize intensified insulin therapy. We adapted the original DTTP to improve metabolic control and reduce severe hypoglycaemia in patients with diabetes type 1 who are already on intensive insulin therapy. The evaluation was done in an outpatient setting in German diabetes practices.
Materials and methods: In an ambulant, multicentre, prospective trial, we recruited 85 patients with diabetes type 1 (age 44.1y, duration of diabetes 16.3y, BMI 26.6kg/m²). The DTTP consisted of 12 teaching sessions in a period of 6 weeks. Data were checked at baseline (V1), 3 weeks after DTTP (V2) and 12 months after DTTP (V3). 74 patients completed the DTTP and 62 patients could be examined after 12 months (V3: age 43y, duration of diabetes 13.7y, BMI 26.7kg/m²). Diabetes treatment satisfaction (DTSQs and DTSQc) and diabetes dependent quality of life (ADDQoL) were assessed with a questionnaire (C. Bradley); HbA_{1c} was DCCT adjusted.
Results: HbA_{1c} at baseline was 7.71%. In patients with baseline HbA_{1c} >7% (88%) HbA1c decreased by 0.36% (V1 8.17; V3 7.81%; p=0.004). The percentage of patients with HbA_{1c} ≤7% increased from 21.3% at V1 to 34.9% at V3 and the percentage of patients with HbA_{1c} above 10% decreased from 6.6% at V1 to 1.6% at V3. We did not observe a significant change in insulin dose (47.85 V1; 50.11 IE/d V3; p=0.380) or number of injections (4.89 V1; 4.77/d V3; p=0.349). The incidence of mild and severe hypoglycaemia decreased significantly: mild hypoglycaemia from 3.31 at V1 to 1.39/episodes/pat/wk at V3 (p=0.001) and severe hypoglycaemia (glucose i.v. or glucagon injection) from 0.16 at V1 to 0.03/episodes/pat/year at V3 (p=0.02). Ketoacidosis with hospital admission was rare (1 event/12 month at baseline; no event at V3). Diabetes treatment satisfaction increased by +10 of a maximal ±18 points. The negative influence of diabetes on quality of life decreased from -1.93 to -1.69 points (p=0.031).
Conclusion: In a group of moderately well-controlled patients with type 1 diabetes being already on intensified insulin therapy, metabolic control, treatment satisfaction and quality of life improved following participation in an ambulatory teaching and treatment programme.

Cost-efficacy of group care in the management of type 2 diabetes. Economic evaluation of the ROMEO (Rethink Organization to iMprove Education and Outcomes) data set

M. Trento[1], J. Sicuro[1], L. Semperbene[1], P. Bondonio[2], F. Cavallo[3], M. Porta[1];
[1]Laboratory of Clinical Pedagogy, Internal Medicine, [2]Departments of Economics, [3]Department of Pubblic Health and Microbiology, University of Turin, Italy.

Background and aims: ROMEO was a 4 years multicenter randomized controlled trial of Group versus individual care, which showed that the former helps achieving better metabolic control, quality of life and health behaviours in patients with type 2 diabetes. We have calculated the costs of hypoglycaemic, antihypertensive and lipid-lowering medication associated with the two approaches.
Patients and methods: the costs of drugs to the Italian National Health Service were calculated by summing the prices of all prescriptions to each patient for the duration of the trial. The data from 479 patients, 246 on Group Care and 233 controls from 4 participating centres were calculated
Results: On average, patients on Group Care cost 383.13 Euro/year and Controls 334.02 Euro/year. Over 4 years, patients on Group Care cost 81,5 Euro more than controls. Since at the end of study patients on Group Care had lower BMI (-1.09), HbA1c (-1.49%) and better quality of life (-16.8) p<0.0001 all Group Care cost Euro 74.78, 54.70 and 4.85 per point gained in body mass, metabolic control and quality of life respectively.
Conclusion: Group Care is a cost-effective alternative to traditional care for the management of type 2 diabetes.

PS 87 Depression in diabetes

997

Impact of weight loss on anxiety and depression in obese patients with type 2 diabetes mellitus

I. Kyrou[1,2], G. Osei-Assibey[2], C. Baker[1], D. Kendrick[1], K. Lois[1,2], P. Saravanan[2], S. Kumar[1,2];
[1]WISDEM, University Hospitals Coventry and Warwickshire, [2]Unit for Diabetes and Metabolism, Clinical Sciences Research Institute, Warwick Medical School, Coventry, United Kingdom.

Background and aims: Obesity and type 2 diabetes mellitus (T2DM) are strongly associated with increased rates of depression. Modest weight loss (5-10%) in obese patients with T2DM has multiple metabolic benefits, improving glycaemic control, lipid profile and blood pressure. Effects of weight management on the psychological status of T2DM patients are less well documented. The aim of this study was to investigate the impact of weight loss on anxiety and depression in obese T2DM patients attending an outpatient specialist obesity clinic.
Materials and methods: Patients with T2DM, on oral hypoglycaemic agents, and body mass index (BMI) over 30 kg/m^2, followed in our obesity clinic, were invited to participate in the study. Weight loss interventions included lifestyle modification and pharmacotherapy with orlistat or sibutramine. Emotional disorders relating to anxiety and depression were assessed by the Hospital Anxiety and Depression Scale (HADS), a validated, self-report instrument consisting of 14 items (7 items for anxiety, HADS-A, and 7 items for depression, HADS-D). The two HADS subscales are independent measures. Anxiety cases on HADS-A and depression cases on HADS-D were defined by a score equal or greater than 8 on each subscale. Participants completed the HADS at baseline and at their annual follow-up visit.
Results: Complete data were available for 32 T2DM patients (40.6% male and 59.4% female, age range: 38-59). At baseline mean BMI was 48.26±7.90 kg/m^2 (mean±SD). Based on their baseline HADS scores (HADS-A mean score: 9.59±4.77 and HADS-D mean score: 8.31±4.47) 62.5% of the participants were classified as cases of anxiety and 53.1% as cases of depression. At 12 months mean body weight was significantly reduced by 5.80±5.23 kg ($p<0.01$) (BMI: 46.30±7.20 kg/m^2, $p<0.01$), representing a mean percent weight loss of 4.06±3.79% for the whole cohort. At 12 months 28.1% of the participants were classified as cases of anxiety and 31.3% as cases of depression with significantly decreased scores in both subscales (HADS-A mean score: 6.75±3.95 and HADS-D mean score: 5.75±3.76, $p<0.05$). Significant positive correlations were found between percent weight loss and reductions in both HADS-A and HADS-D scores ($p<0.05$).
Conclusion: These results suggest that weight loss achieved through a weight management programme in the setting of a specialist obesity clinic can improve the anxiety and depression status of obese patients with T2DM. Future studies are planned to examine the impact of weight management on psychological co-morbidities of T2DM in a larger cohort of patients and in the long-term.

998

Changes in eating behavior, depression and quality of life in patients with type 2 diabetes after a 3-months-intervention with low-fat vegetarian diet and conventional diabetic diet

T. Hrachovinová[1,2], H. Kahleová[1], P. Hackerová[2], T. Pelikánová[1];
[1]Diabetes Center, Institute for Clinical and Experimental Medicine,[2]Department of Psychology, Charles University, Prague, Czech Republic.

Background and aims: When compared to conventional diabetic diet, the clinical trials using vegetarian diets have shown greater effect on weight loss, greater reduction of LDL cholesterol, HbA1c and diabetes medication. The aim of our study was to determine eating behaviour, the degree of depression, and quality of life in patients with type 2 diabetes attending an intervention programme with different hypocaloric diets (low-fat vegetarian diet compared to conventional diabetic diet).
Materials and methods: Open, parallel randomized study. 70 individuals with type 2 diabetes were randomly assigned to a low-fat vegetarian diet (experimental group; EG) or conventional diabetic diet (control group; CG) with similar caloric restriction (-500 kcal/day). All patients were examined, using the The Three-Factor Eating Questionnaire (Stunkard and Messick), Beck's Depression Inventory (BDI), a questionnaire on Quality of life (OWL-QoL) and a questionnaire tracing negative symptoms caused by overweight and obesity (WRSM) at baseline (0) and after 12 weeks of diet intervention.
Results: *I. Both groups as a whole.* Patients in both groups lost weight ($p<0.01$). The average BDI score decreased significantly after the intervention ($p<0.05$). Patients in both groups noticed significantly lower feelings of hunger after the intervention ($p<0.01$). The quality of life improved in both groups ($p<0.01$). *II. Differences between groups.* Average weight loss was greater in the EG than in the CG (6.41±4.23 vs. 3.47±4.07 kg; $p<0.01$). There were no differences between groups in the average BDI score (8.3±5.5 vs. 8.6±8) at start, which did not reach the threshold of depressive symptoms. Nevertheless the average BDI score decreased significantly after the intervention ($p<0.05$). The interindividual variations are remarkable in both groups. The differences between both groups after the intervention are not statistically significant. In the disinhibition scale and hunger score, there are no statistically significant differences between the groups at start, but we can see a trend toward greater food disinhibition score in the EG (6.3 EG vs. 5.4 CG) and stronger feelings of hunger in the EG (4.9 EG vs. 3.4 CG) at start, whereas there is a trend toward greater decrease in feelings of hunger in the EG (1.88 EG vs. 0.83 CG) but there are no significant differences between groups in food disinhibition score after the intervention. The quality of life improved in both groups ($p<0.01$): the WRSM score decreased by 9.1 vs. 11.8 with no statistically significant differences between groups and the OWLQoL score decreased with no statistically significant differences between groups ($p<0.05$). There were no differences between groups in the restriction scale at start (8.7±3.8 vs. 8.4±4.8), whereas after the intervention the conscious control of food increased significantly in both groups, more in the CG (by 2.1 in the EG vs. 4.47 in the CG, $p<0.05$).
Conclusion: The results show a remarkable positive effect of the diet intervention on the quality of life, the BDI score and feelings of hunger. Patients from the CG expressed stronger feelings of restriction in food. In the EG patients lost more weight and expressed feelings of restriction in food and feelings of hunger less frequently.

999

Screening performance of a short versus long version of the patient health questionnaire-depression in outpatients with diabetes

M. Pibernik-Okanovic[1], M. Grgurevic[1], D. Ajdukovic[1], B. Novak[1], D. Begic[2], Z. Metelko[1];
[1]Outpatient Clinic, Vuk Vrhovac Institute, [2]Psychiatric Clinic, University Hospital Rebro, Zagreb, Croatia.

Background and aims: Regular screening for depressive symptoms in diabetic outpatients might improve both diabetes and depression outcomes. This study was aimed at comparing performance of a two-item vs a nine-item version of the Patient Health Questionnaire (PHQ-9) defined as a proportion of positively screened patients with confirmed elevated depressive symptoms by means of a clinical interview.
Materials and methods: Two hundred sixty-three consecutively recruited diabetic patients attending their regular medical check-ups (90% with type 2 diabetes, aged 60±11 yrs., with diabetes duration of 10±8 yrs., 44% insulin-treated, with average HbA1C values of 7.4%±1.4 and BMI of 29.7 kg/m2 ±5.2) were screened for depression by using the PHQ-9 scale. Cut-off scores of 3 for the PHQ-2 and 10 for the PHQ-9 were used to discriminate between positive and negative screenings. Percentages of positive screenings on the two instrument's versions, and proportions of patients who were confirmed for elevated depressive symptoms by a clinical interview were compared.
Results: Twenty-two percent of the patients assessed for depressive symptoms were found to be above the cut-offs indicative of depression. The percengates of positive screening did not differ by using the PHQ-2 and PHQ-9 indicators (22% vs 22% p= 0.88). Patients with elevated depressive symptoms did not differ from those scoring below the cut-offs with respect to age (60±12 vs 60±11 yrs. p=0.86), diabetes duration (10±5 vs 10±7 yrs. p=0.94), type of diabetes ($\chi2$ =0.60 p=0.44), insulin therapy ($\chi2$=0.55 p=0.46), HbA1C values (7.5%±1.5 vs 7.3%±1.4) and BMI (30.2 kg/m2±5.4 vs 29.3 kg/m2±4.4 p=0.21). There were more female patients in the subgroup indicative of depression ($\chi2$=11.6 p=0.0007). Thirty percent of patients positively screened by PHQ-2 versus 37% of those positively screened by PHQ-9 were confirmed for elevated depressive symptoms using a clinical interview ($\chi2$ =0.04 p=0.85).
Conclusion: Finding elevated depressive symptoms in diabetic outpatients by using the PHQ-2 and PHQ-9 indicators was shown to be comparable with respect to both positive screenings per se and their proportion as confirmed by

a more comprehensive diagnostic procedure. PHQ-2 could be recommended for routine use in diabetological check-ups in order to detect diabetic patients at a risk of depression.

Investigation of depressive symptoms in diabetic patients with and without micro- and macro-angiopathic complications
G. Nagy, B. Szémán, A. Máthé, T. Varga, A. Somogyi;
II. Department of Internal Medicine, Semmelweis University, Budapest, Hungary.

Background and aims: The prevalence of depression is twice as common in diabetic patients compared to the general population. Chronic complications of diabetes are thought to be a factor in the increased prevalence of depression. In the present study our goal was to assess depressive symptoms in a group of diabetic patients with macroangiopathy (MA), microangiopathy (MI) and in patients without complications.
Materials and methods: 271 diabetic patients were enrolled in our study. Participants were further divided into subgroups taking in account gender differences and diabetic complications. Patients with a positive medical history for myocardial infarction, stroke, or obliterative atherosclerosis of the lower limb were considered to have macroangiopathy. Individuals with a history of diabetic retinopathy, nephropathy or neuropathy were considered to have diabetic microangiopathy. Thus we gained a male and a female group without macroangiopathic diabetic complications (ACM, ACF) and a male and female group with diabetic macroangiopathic complications (MAM, MAF) respectively. Similarly for microangiopathic complications a male and female group with (MIM, MAF) and without the complications (ICM, ICF) has been established. There was no significant difference between the groups in age, BMI, HgA1C and TSH levels. Short version of the Beck's depression scale was used to evaluate depressive symptoms.
Results: Beck depression scores were higher in all female groups compared to males. Beck depression scores were significantly greater in both male groups with diabetic macro (ACM: 4,59±3,88 MAM: 6,44±3,96 $p<0,05$) and microangiopathic complications (ICM: 3,05±2,89 MIM: 5,29±3,77, $p<0,05$) compared to males without complications. This difference could not be detected in females regarding neither the macro (ACF Beck: 7,01±6,46 MAF Beck: 9,22±5,8) nor the microangiopathic complications(ICF Beck: 7,02±4,72 MIF Beck: 7,8±6,00).
Conclusion: Both MA and MI complications increase depressive symptoms of male diabetic patients. Depression scores of females are greater regardless of their diabetic complications.

Web-based cognitive behavioural therapy for diabetes patients with co-morbid depression: first findings
K.M.P. Van Bastelaar[1], F. Pouwer[2], P. Cuijpers[3], F.J. Snoek[1];
[1]VU University Medical Centre, Amsterdam, [2]Tilburg University, [3]VU University, Amsterdam, Netherlands.

Background and aims: Depression is a common co-morbidity in people with diabetes, negatively affecting well-being and glycaemic outcomes. Research on treatment of depression in diabetes is limited. We are the first to have developed a diabetes-specific version of the online cognitive behavioural self-help course "coping with depression", which is currently tested in an ongoing randomised trial (ISRCTN24874457). Socio-demographic and clinical characteristics of the patients who so far participated are being presented.
Materials and methods: The study is being advertised trough various media, including patient magazines and websites. Inclusion criteria are: 18 year or older, diagnosed with diabetes > 3 months ago, suffering from depressive symptoms, and sufficient language and computer skills. Exclusion criteria are: pregnancy, loss of significant other < 6 months ago, bi-polar disorder, using anti-psychotic medication, unstable antidepressant medication, co-morbid psychiatric disorder, history of suicide attempt, and current suicidal ideation. Patients sign up online for enrolment in the study and fill out questionnaires online. Self-reported information is gathered on depression (CES-D), diabetes-specific emotional distress (PAID), perceived health status, diabetes self-care behaviours, and diabetes outcomes (HbA1c, episodes of hypoglycaemia). If CES-D ≥ 16, patients are offered a telephone-administered diagnostic psychiatric interview (CIDI) for diagnosis of depression and/or anxiety disorders and then enrolled in the study.
Preliminary Results: Between the 24th of June and the 18th of March 2009, 293 participants signed up for our study. N=126 patients were excluded or dropped out, 20% due to not having elevated symptoms of depression (CES-D < 16). Mean age was 41 ± 11 years for T1DM and 56 ± 10 for T2DM (range 21 - 82); 61% was female; 91% of Dutch origin; 57% Type 2 diabetes, of which 45% on insulin treatment. Self-reported mean HbA1c was 7.5% ± 1.1 (range 4 - 13%); 25% did not know their HbA1c. Mean duration of diabetes 21 ± 12 years for T1DM and 8 ± 7 for T2DM. Mean CES-D was 29 ± 8 (ranging from 16 - 51), showing highly elevated symptoms of depression. Mean PAID score 40 ± 19, indicating high levels of diabetes-distress. The telephone administered CIDI was administered to 133 participants, where 59% suffered from Major Depressive Disorder (MDD), and 3% from Dysthymic disorder; 33% of the participants with depressive disorder were diagnosed with a co morbid anxiety disorder. Of the total group of participants, 12% was diagnosed with anxiety disorder only. Of all participants 40% reported a history of depression treatment.
Preliminary Conclusion: There has shown to be much interest in our online treatment of depression in diabetes patients, including a small group with no clear depressive symptomatology. This may point at a need for more education on the interplay between diabetes and depression. The majority of participants was diagnosed with depressive disorder (DSM-IV), warranting anti-depressant therapy. In contrast to our expectation, patients reported only moderately elevated HbA1c levels. Objective HbA1c values will be retrieved for comparison to validate this finding. High diabetes-related distress found in this group however does suggest serious coping problems and confirms the need to address diabetes-related emotional issues as part of the depression treatment.

Long term follow up of a cohort of patients with diabetes and their first foot ulcer-effect of depression on mortality
D.K. Kariyawasam[1], L. Leelarathna[1], K. Winkley[2], D. Stahl[3], K. Ismail[2], M.E. Edmonds[1];
[1]Diabetes Foot Clinic, King's College Hospital, [2]Department of Psychological Medicine,Institute of Psychiatry, King's College Hospital, [3]Department of Biostatistics,Institute of Pshychiatry, King's College London, United Kingdom.

Background and aims: Diabetic foot ulcers, infection and lower limb amputation have a severe negative effect on health related quality of life and may cause depression in individuals with diabetes. There have been no population based studies starting with patients presenting with their first foot ulcer and followed up over several years to assess how psychological and biological factors interact with each other to influence adverse outcomes. The aim of this study was to evaluate whether depression is associated with increased mortality in people with their first foot ulcer at 5 years.
Materials and methods: A retrospective follow up of a previously described cohort of patients, who presented with their first diabetic foot ulcer, were recruited from community and hospital foot clinics in south east London, UK. The original sample consisted of 253 patients prospectively followed up for 18 months. Post 18 months the same sample was retrospectively followed up for 5 years. At baseline, the Schedules for Clinical Assessment in Neuropsychiatry 2.1(SCAN 2.1) was used to define those who met DSM (Diagnostic and Statistical Manual of Mental Disorders)-IV criteria for depressive disorder. Logistic regression analysis controlled for potential covariates; age; sex; marital status; socio-economic status; smoking; A_{1C}; and University of Texas classification based- ulcer severity. The main outcome was mortality at 5 years.
Results: The prevalence of DSM-IV depressive disorder was 32.2% (n=82). There were 88 (34.8%) deaths at five years. Thirty seven patients out of the 82 (40.2%) who were dead at 5 years had clinically significant depression at baseline. In the adjusted logistic regression analysis DSM-IV depression was associated with mortality (odds ratio 2.54, 95% CI 1.31-4.93) compared with the group with no depression
Conclusion: More than a third of people with their first foot ulcer suffer from depression, and this is associated with an increased mortality at 5 years.

1003

Depression, coping strategies, metabolic control and compliance with diabetes care in diabetic patients

H. Parildar, O. Cigerli, N. Demirag Guvener;
University of Baskent, Hospital of Istanbul, Turkey.

Background and aims: Diabetic patients must cope with a wide range of challenges specific not only to the disease but also to other conditions in their lives, which may influence self-management of diabetes and metabolic control. In this study, we aimed to investigate the psychological and metabolic states of diabetic patients and the coping strategies they use.
Materials and methods: This descriptive, cross sectional study included 110 type 2 diabetic patients (62 female, 48 male) who were followed up in the Diabetes Outpatient Clinic of Baskent University. Demographic and clinical data were determined from questionnaires. Metabolic control was measured by glycosylated hemoglobin A1c (HbA1c) levels. The patients were asked to fill the Beck Depression Inventory (BDI) and Ways of Coping Questionnaire (WCQ). For statistical comparisons, Chi-square test, Independent sample T test and Pearson's correlations test were used.
Results: The mean age was 57.9&plusmn10.5 (range, 36-85). Mean HbA1c was 7.1&plusmn 1.7 % (range, 5.3-13.1). A good compliance with treatment and diet was reported among 93 patients (90 %) and 60 patients (57.6 %), respectively. Seventy two patients (65.5 %) had received patient education about diabetes care. Thirty four (30.9 %) diabetic patients were found to be depressed. There was a negative correlation between depression scores and compliance with diet (r = -0.2, p=0.01). Beck depression scores were significantly lower in patients receiving patient education about diabetes care (p&lt0.01) and having good compliance with treatment (p=0.03). The coping strategy most frequently used by the patients was problem solving-optimistic approach followed by fatalistic, escape, helplessness approaches in decreasing order of frequency. Patients who had Beck Depression Inventory scores 17 and over (moderate/severe depression) were more frequently using "fatalistic" and "helplessness" approaches as coping strategies. A positive correlation was found between female gender and depression scores (r =0.3, p=0.01), fatalistic approach (r =0.3, p&lt0.01) and helplessness approach (r =0.2, p&lt0.01). There was a positive correlation between depression scores and duration of diabetes (r=0.2, p=0.01). No correlation was found between HbA1c levels and type of diabetes treatment with depression scores and coping strategies. Also there was no correlation between new onset insulin therapy and depression scores.
Conclusion: Although the frequency of depression is consistent with that reported in the literature, it does not seem to effect glycemic control. Our data showed significant associations between depression scores, female gender, emotional-negative coping strategies and poor compliance with diet or treatment in our patients. This suggests that positive- problem solving coping strategies may be important factors for successful diabetes self-care and treatment. Additionally, we suggest supporting the patients by frequent monitoring, educating and problem solving counseling could be the first line interventions in diabetes care.

Health-related quality of life and macrovascular comorbidities among diabetes patients in the United States

Y. Qiu[1], A.Z. Fu[2], L. Radican[1];
[1]Global Outcomes Research & Reimbursement, Merck & Co., Inc., Whitehouse Station, [2]Department of Quantitative Health Sciences, Cleveland Clinic, United States.

Background and aims: Diabetes mellitus has been defined as one of the global epidemics of chronic diseases by the World Health Organization. Patients with diabetes are at an increased risk of developing macrovascular disease. The purpose of this study was to examine the marginal impact of macrovascular comorbidities on health-related quality of life (HRQoL) of patients with diabetes in a United States nationally representative sample.
Materials and methods: Using the pooled Medical Expenditure Panel Survey (MEPS) 2001 and 2003 data, a nationally representative adult sample (age ≥18) was included in the study. The HRQoL outcomes included the SF-12 physical component summary (PCS) score, SF-12 mental component summary (MCS) score, EQ-5D preference-based index score, and visual analog scale (VAS). Ordinary least square regressions were used to identify the relationship between macrovascular disease conditions and PCS (and MCS) after controlling for age, sex, race, ethnicity, education, income, smoking status, health insurance, proxy response, and number of other comorbid categories. Due to the distributions of the EQ-5D preference-based index and VAS score, censored linear deviations estimator (CLAD) regressions were employed. All statistics were adjusted using the proper sampling weight from the MEPS.
Results: The average PCS, MCS, EQ-5D index, and VAS scores for patients with diabetes were 40.5, 48.5, 0.75, and 66.6, respectively for the sample. Compared to diabetes patients without macrovascular comorbidities (N=2,809), those with macrovascular comorbidities (N=654) had statistically significant lower PCS (-3.38, p<0.001), MCS (-1.43, p<0.05), EQ-5D index (-0.024, p<0.05), and VAS scores (-4.93, p<0.001). Patients with diabetes also had significantly lower HRQoL outcomes than those without diabetes (N=43,326) (p<0.001).
Conclusion: In summary, macrovascular comorbidities significantly decrease HRQoL in patients with diabetes.

Coping styles influence diabetes-related outcomes in newly diagnosed type 1 diabetic patients

E. Pietrzykowska, S. Pilacinski, A. Majchrzak, B. Wierusz-Wysocka, D. Zozulinska-Ziolkiewicz;
Department of Internal Medicine and Diabetology, Poznan University of Medical Sciences, Poland.

Background and aims: Diabetes as a chronic condition influences many aspects of patients' life. Treatment of diabetes should not only concentrate on metabolic control, but also on psychological adaptation to the disease and good quality of life. Thus, it seems important to identify subgroups of patients requiring particular counseling and support. The aim of our study was to assess the influence of different ways of coping with stress on diabetes-related outcomes in newly diagnosed type 1 diabetic patients.
Materials and methods: A total of 152 adults with newly diagnosed type 1 diabetes were recruited for the study (98 men, 54 women, aged 16-35, mean age: 24.8 ± 4.8 years). All patients were admitted to hospital, educated and treated with intensive functional insulin therapy. Shortly after diagnosis each participant's coping styles were assessed with the use of Coping Inventory for Stressful Situations (CISS). Finally 108 patients (64 men, 44 women) were followed prospectively for 18.7 ± 7.2 months. At the end of the observation diabetes-related outcomes were evaluated including: HbA1c, acceptance of illness (Acceptance of Illness Scale) and quality of life (Quality of Life Questionnaire). Pearson's correlation coefficients were calculated. Statistical analysis was performed using Statistica 7.0 software.
Results: Task-oriented coping style at diagnosis correlated inversely with HbA1c value (r=-0.223, p=0.029). Emotion-oriented coping style correlated inversely with acceptance of illness (r=-0.334, p<0.0001) and quality of life (r=-0.283, p=0.003), but no association was found with HbA1c. Avoidance-oriented coping style did not correlate with any of the investigated variables.

Conclusion: The way of coping with stress may influence both objective (HbA1c) and subjective (acceptance of illness, quality of life) diabetes-related outcomes in newly diagnosed type 1 diabetic patients. Delineation of individual coping styles might be useful for identifying patients at risk for poor adaptation to disease.

Evaluation of personality with egogram in patients with diabetes
K. Tsuzawa, E. Sorimachi, M. Shimodaira, A. Fujita, M. Kametaka, K. Honda;
Department of Hematology, Endorinology and Metabolism, Tokyo Metropolitan Hiroo General Hospital, Japan.

Background and aims: Previous studies suggest that some psychosocial factors affect on blood glucose (BG) control in patient with diabetes mellitus. However, we have few useful methods which enable us predicting effectiveness of the treatment and the education on diabetic patients from psychological aspects. We examined ego state in diabetic patients with egogram, to clarify the influence of psychological factors such as ego state in BG control in diabetic patients.
Materials and methods: We evaluated ego state in 136 diabetic patients with the questionnaire, the Tokyo University Egogram version 2 (TEG-II). Ego state was assessed by calculating the scores of 5 components of ego, namely critical parent (CP), nurturing parent (NP), adult (A), free child (FC) and adapted child (AC). Of 136 diabetic patients, 71 patients had metabolic syndrome. Twenty-six patients had low compliance and resistance to any medical treatment despite of repeated administrations for education and treatment (RT group). Sixty-seven patients were elderly (more than 64 years of age) patients. We evaluated ego state especially in these patients groups. All results are expressed as means ± SEM. Statistical analysis was performed using Student's t test. P values less than 0.05 were considered significant.
Results: FC scores in RT group (n=26) were significantly ($p<0.05$) higher than those in other patients (n=110) (15.11 ± 0.60 vs. 13.70 ± 0.40) and AC scores in RT group were significantly ($p<0.05$) lower than other patients (5.54 ± 0.94 vs. 7.57 ± 0.43). (FC - AC) scores in RT group were significantly ($p<0.02$) higher than other patients (9.58 ± 1.35 vs. 6.14 ± 0.65). Other 3 scores of egogram did not have any significant differences between these 2 groups. Each egogram score was not significantly different between patients with metabolic syndrome (n=71) and patients without metabolic syndrome (n=65). FC scores and (FC-AC) scores of elderly patients (n=67) were significantly ($p<0.01$) higher (14.92 ± 0.44 vs. 13.06 ± 0.52, 8.93 ± 0.64 vs. 4.72 ± 0.93) and AC scores were significantly ($p<0.05$) lower(6.00 ± 0.46 vs. 8.33 ± 0.61)than younger patients (n=69). Thus, these results were similar to those observed in RT group. However, age was not significantly different between RT group and other patients (62. 46 ± 1.56 vs. 63.52 ± 0.49).
Conclusion: These results suggest that patients resistant to the education and the treatments have characteristic egogram pattern (high FC scores and low AC scores) and this seemed to be independent from aging. Such ego state can be one of factors which act to aggravate BG control in diabetic patients. Current data suggest that TEG-II give us useful information about personality of patients and it is helpful for us to make a program of education and treatment for each diabetic patient. We observed that elderly diabetic patients have similar characteristic egogram pattern. Further studies are expected to determine whether it is specific in diabetic patients or not.

1007

The youngest children with type 1 diabetes mellitus are affected with the same number of serious life events as children with diabetes recognized at later age
B.M. Zdunczyk[1], A. Szypowska[2], E. Pankowska[2];
[1]Clinical Child and Adolescent Psychology Department, Clinical Pediatric Hospital, Warsaw, [2]The Department of Pediatrics, Medical University of Warsaw, Poland.

Background and aims: Stress is one of factors seen as contributing to diabetes development. Psychological stress due to a link to hormonal levels and nervous signals increases insulin resistance and affects immune system. It may contribute to the induction of type 1 diabetes mellitus (T1DM) related autoimmunity. In the last years the highest increase in the development of T1DM has been noted in children at the age 0-4 years old. Clinical observation and recent studies show the high incidence of stressful events before diabetes diagnosis. The aim of this study was to assess incidence rate of serious life events prior to diabetes diagnosis and examine if there is a difference in occurrence of such events between families of children with T1DM recognized at the age < 5 years and > 5 years.
Materials and methods: There were included 347 participants: 123 parents of children (67 girls, 56 boys) with T1DM onset at the age < 5 years with the mean age 3,1 SD 1,4 ys (range 0-5) and 224 parents of children (108 girls, 116 boys) with T1DM onset at the age > 5 years with the mean age 9,9 SD 2,8 ys (range 6-17). Parents completed a questionnaire during a routine visit in the outpatient clinic. The questionnaire, especially constructed for the purpose of this study, included questions about experience of serious life events which can cause chronic stress (as seen in Posttraumatic Stress Disorder).
Results: The number of serious life events totaled to 243 (in 60% of families) In both groups serious life events appeared more often within 2 year period before T1DM recognition: in 47% vs 13% of families (RR 0,3 95%CI 0,3-0,4 $p<0,0001$). There was no difference in the number of families of children with T1DM recognized at the age < 5 years and > 5 years affected with serious life events 49% vs. 45% respectively. In <2 years before T1DM onset in both groups there were mostly 1 or 2 serious life events per family, without difference between groups. In both groups parents divorce was the most common serious life event which occurs in every 6th family. There was no statistical difference between groups in the number of serious life events except grandparents death (RR 0,9 95%CI 0,8-1, $p=0,004$).
Conclusion: 60% of families with children with T1DM have been affected by serious life events. The most serious life events occurred in the families within 2 year period before T1DM recognition. Children with T1DM onset at the age < 5 years were affected with the same number of serious life events as children with diabetes recognized at later age. Coping strategies for stress and attachment patterns should be carefully looked into in families of children with type 1 diabetes.

Cognitive performance and chronic cerebral ischaemia in diabetes mellitus type 2
I. Semenova[1], L. Chugunova[1], A. Vorontsov[1], A. Ilin[1], A. Knyazeva[1], M. Shestakova[1], I. Dedov[1], P. Kamchatnov[2], A. Chugunov[2];
[1]National Research Center for Endocrinology, [2]Neurology, Russian State Medical University, Moscow, Russian Federation.

Background and aims: Underlying mechanisms for decreased cognitive functions in patients with type 2 diabetes (DMT2) are unclear. Cerebral ischaemia is a risk factor for cognitive disorders and dementia. White matter lesions reflect cerebral small vessel disease and may account for cognitive impairments in diabetic patients.The aim of the present study was to compare cognitive functions and brain magnetic resonans imaging (MRI) between type 2 diabetic patients and non diabetic control subjects and assess the relationship between early cognitive impairment and brain MRI characteristics in DMT2.
Materials and methods: Our study included 126 (42 men and 84 women) patients with DMT2 (age 50-75 years) and 20 (3 men and 17 women) control patients without diabetes and hypertension. MRI scan (T1,T2,Flair) was performed to define white matter lesions(WMLs)as a marker of cerebral small vessel disease.Glycated hemoglobin (HbA1c),body mass index,systolic and diastolic blood pressure, biochemistry assay, albuminuria, neuropsychological tests: Frontal Assesment Battery (FAB), Mini Mental State Examination (MMSE),Clock Drawing Test (CDT),"10 words"test were measured.
Results: WMLs were found in 122 DMT2 cases (97%) and in 7 control cases (35%),$p=0,004$. Patients with DMT2 performed worse results in all neuropsychological tests, $p<0,05$. Early cognitive disfunction was found in 55%patients-mild cognitive disorder (MCD). Structural brain white matter abnormalities were interfacing with: arterial hypertension duration ($r=0,278$ $p=0,002$), intencity of carotid artery atherosclerosis ($r=0,323$ $p=0,02$),chronic inflammation ($r=0,211$ $p=0,024$),albuminuria ($r=0,334$ $p<0,001$), fibrinogen($r=0,351$ $p=0,001$), homocystein ($r=0,254$ $p=0,018$) and HbA1c ($r=0,201$ $p=0,001$). Periventricular lesions (PVLs) were inversely related with MMSE ($r=0,279$ $p<0,001$). Deep white matter lesions (DWMLs) were inversely related with MMSE ($r=0,239$,$p<0,001$), test "10 words" ($r=0,21$,$p=0,025$) and with CDT ($r=0,219$,$p=0,032$).
Conclusion: Early cognitive dysfunctions were associated with WMLs on MRI-scan in patients with DMT2 and reflected the cerebral microangiopathy. Presens of MCD may be a clinical condition of chronic cerebral ischaemia.

Patient reported outcomes in adults with type 2 diabetes using mealtime insulin monomer human (rDNA origin) inhalation powder or metformin+secretagogue or both

M. Peyrot[1], R.R. Rubin[2];
[1]Loyola College, [2]Johns Hopkins University, Baltimore, United States.

Background and aims: This study investigated whether Mealtime Insulin Monomer Human (rDNA origin) Inhalation Powder alone or in addition to Metformin+Secretagogue was associated with improved patient reported outcomes (PRO) over Metformin+Secretagogue alone.
Materials and methods: In this 24-week randomized, multicenter study adults with type 2 diabetes used Mealtime Insulin Monomer Human (rDNA origin) Inhalation Powder (MIMHIP; n=177), Metformin+Secretagogue (MS; n=162) or both (I+MS; n=169). At 12 weeks subjects not adequately controlled with MIMHIP or MS were transferred to I+MS. PRO included: the SF-36, assessing health-related quality of life (HRQOL), and the Insulin Treatment Questionnaire (assessing diabetes worries and treatment satisfaction). Intent to treat (ITT) analysis used mixed effect models to estimate differences in mean group changes in PRO from baseline to week 12 (adjusted for baseline scores); t-tests assessed within-group change from baseline to 12 weeks in all groups and from 12 to 24 weeks in patients adding MIMHIP to MS.
Results: At Week 12 SF-36 mental health composite scores (MCS) increased (p=.0010) in MIMHIP but not in MS or I+MS; the difference in change between MIMHIP and MS was not significant in ITT analysis (p=.0612), but was in the per protocol population (p=.0233). MIMHIP improved more than MS in Role-Emotional scores (p=.0044). At Week 12 SF-36 physical health composite scores (PCS) increased in MIMHIP and I+MS and declined in MS; although none of these changes were significant, the difference in change between I+MS and MS was significant (p=.0084). I+MS showed greater improvement than MS for Bodily Pain (p=.0148), Physical Functioning (p=.0020), and Role Physical scores (p=.0172); MIMHIP showed greater improvement than MS for Role-Physical scores (p=.0124). There were no changes in diabetes worries from baseline to week 12, and no differences in change. There was an increase in treatment satisfaction in MIMHIP (p=.0003) and I+MS (p<.0001); these improvements were greater than MS (MIMHIP p=.0116; I+MS p=.0009). There was no change in MCS, PCS or diabetes worries between weeks 12 and 24 among subjects who added MIMHIP to MS (n=79), but treatment satisfaction increased (p=.0007).
Conclusion: HRQOL and treatment satisfaction improved more among those taking Mealtime Insulin Monomer Human (rDNA origin) Inhalation Powder (with or without oral medications) than those taking oral medications only. Those who added Mealtime Insulin Monomer Human (rDNA origin) Inhalation Powder to oral medications during the trial experienced increased treatment satisfaction.

The importance of parent and friends diabetes social support for adolescents with type 1 diabetes of different age and gender

J.A. Malik, H.M. Koot;
Developmental Psychology, Vrije University, Amsterdam, Netherlands.

Background and aims: This study aimed to determine the instrumentality of diabetes social support in adolescents with type 1 diabetes mellitus.
Materials and methods: 437 adolescents (ages 11 to 19 years) with type 1 diabetes participated in the present study. Multiple linear regression analysis was conducted to investigate moderating effects of emotional problems between diabetes related stress and support from parents and friends. Sample was categorized in four subgroups using a 2x2 design to test the effect of age and gender on importance of support from parents and friends.
Results: Results showed that Emotional Problems moderated the relation between Diabetes Stress and Parent Support ($\beta = 0.125$; $p < .05$), whereas they did not moderate the relation between Diabetes Stress and Friends' Support. The results confirmed our hypothesis that the effect of Parent Support changes direction in the presence of emotional problems which may represent autonomy seeking. To investigate the potentially changing effects of Diabetes Social Support across gender and age, we developed a hierarchy of autonomy seeking based on the assumption of change in importance of support received from parents to friends across age. We assumed that younger girls are most prone to evoke parental support followed by younger boys and older girls who evoke less support from parents but more support from friends as compared to younger girls and finally older boys, who are expected to evoke least support from parents but most support from friends as compared to the other three groups. We also assumed that younger adolescents and girls would get more support from parents and older adolescents and boys get more support from friends. As expected, for younger girls Emotional Problems appeared to moderate the relationship between Parent Support and Diabetes Stress ($\beta = 0.24$, $p < .05$, and $\Delta R^2 = .04$), whereas for older boys Emotional Problems appeared to moderate the relationship between Friends Support and Diabetes Stress ($\beta = 0.27$, $p < .05$, and $\Delta R^2 = .06$). Analysis for specific Parent Support factors showed that Emotional Problems moderated the relationship between Diabetes Stress and two aspects of Parents support: Guidance and Supervision ($\beta = 0.24$, $p < .05$, and $\Delta R^2 = .04$), and Encouragement for Self-care and Exercise ($\beta = 0.25$, $p < .05$, and $\Delta R^2 = .04$) only for younger girls. Analysis for specific Friends Support factors showed a moderation by Emotional Problems of the relation between Diabetes Stress and Friends' Support: Guidance and Encouragement ($\beta = 0.32$, $p < .01$, and $\Delta R^2 = .09$), and Nourishment ($\beta = 0.33$, $p < .01$, and $\Delta R^2 = .10$) only for older boys, whereas for remaining three factors (i.e., Help in Critical Situations, Empathy, and Exercise) emotional problems appeared to have no moderating effects.
Conclusion: Our results are helpful in resolving two critical issues; first they explain, how a positive factor of adjustment (i.e., Diabetes Social Support) may have negative consequences, and second, they enlighten the role of Parent and Friends Support at different ages for girls and boys.

1011

Effects of gender, age, duration of diabetes on dietary self-care in adolescents with type 1 diabetes: a self-determination theory perspective

A. Nouwen[1], S. Austin[2], C. Senécal[2], F. Guay[2];
[1]School of Psychology, University of Birmingham, United Kingdom, [2]School of Psychology, Laval University, Quebec, Canada.

Background and aims: Evidence suggests that age, diabetes duration, and gender are important non-modifiable risk factors associated with non-adherence, with older adolescent girls having more difficulties following their dietary plan than adolescent boys. However, little is known about the mechanisms underlying these findings. Based on Self-Determination Theory (SDT), we hypothesized that for adolescent girls perceived support from parents or health care practitioners does not adequately map onto their needs for emotional support. Alternatively, because of social pressures, older girls may feel less competent (self-efficacious) or motivated to follow a well-balanced diet. The aims of the study were (1) to examine whether age, duration of diabetes and gender, and their interactions, were related to dietary self-care in adolescents with type 1 diabetes; and (2) to test a theoretical model in which these non-modifiable factors influence perceptions of support from parents and health care practitioners, and, in turn, predict dietary self-care through motivational resources (i.e., perceived competence and autonomy).
Materials and methods: 289 adolescents with type 1 diabetes (54% male), recruited from the outpatient clinics from two diabetes centres in Quebec City, Canada, completed questionnaires assessing perceptions of self-efficacy (competence), dietary motivation, support fostering autonomy from parents and health care professionals, and dietary self-care. Duration of diabetes and BMI were also assessed.
Results: Structural Equation Modelling analyses revealed that longer diabetes duration and female gender were indicative of poorer dietary care. This effect was mediated by contextual and motivational factors as posited by SDT. Poorer perceived autonomy support from health care practitioners was predominant in girls with greater diabetes duration. Perceptions of autonomy and competence were associated with greater autonomy support and, subsequently, better self-care. The model was well supported by the data, $\chi^2\ (121) = 132.194;\ p=.23;$ NNFI = 1.00; CFI = 1.00; RMSEA = .02 [.00; .03]; χ^2/df ratio = 1.60.
Conclusion: The study shows that young patients who experience greater feelings of autonomy and competence toward dietary self-care, also display better dietary self-care. The study further indicates that, even if supporting actions of health care practitioners do not differ upon patient gender, girls who have diabetes for longer may perceive and evaluate these support actions quite differently. Correspondingly, health care practitioners may want to adapt the way they support adolescent girls with diabetes to attain more autonomy in dealing with their dietary self-care activities.

A holistic programme of cardiac rehabilitation is able to improve anxiety and depression in diabetic men with coronary heart disease

P.R. Blanc[1], L. Mourot[2], A. Boussuges[3], S. Jowhry[1], F. Riviere[1], S. Chopra[1], X. Debussche[4];
[1]Cardiac Rehabilitation, Sainte Clotilde, Reunion, [2]University of Medicine, Besançon, France, [3]Mediterranean University, Marseilles, Reunion, [4]Diabetology, Felix Guyon Hospital, Reunion.

Background and aims: Anxiety and depression are very common for cardiac patients and have effects on the development of coronary heart disease (CHD). Moreover in patients with CHD, anxiety and depression influence the outcomes including an increased incidence of ischemic events and higher mortality. The aim of this prospective study was to evaluate the effects of a holistic ambulatory cardiac rehabilitation (CR) program on anxiety and depression in diabetic' men with CHD.
Materials and methods: 275 diabetic' men with CHD (D) and 430 non diabetic' men with CHD (ND) used as control group, with identical age (57.2 +-9 / 54 +-55.5 +-11 years respectively) were included in the study. All patients performed a 6-week multidisciplinary holistic CR program including exercise training, psychological screening and support as well as education concerning lifestyle. Reasons of admission were: coronary heart disease artery bypass graft surgery (45%), angioplasty percutaneous coronary interventions and stent (41%), angor pectoris or myocardial infarction (14%). Level of anxiety and depression were measured by the psychologist using the Hospital Anxiety and Depression (HAD) scale, before and after the cardiac rehabilitation program.
Results: At baseline, prevalence of anxiety [HAD≥ 11] was similar in D and ND (31% vs 32%). The prevalence of depression [HAD≥ 8] was higher in D compared with ND (31% vs 24%, p<0.05)At the end of the program of CR, the entire population studied achieved significant improvements characterised by a statistically significant fall in anxiety/depression (HAD scale). The prevalence of anxiety [HAD≥ 11] was similar in D and ND (11% both). The prevalence of depression [HAD≥ 8] was higher but statistically insignificant in D compared with ND (10 vs 6%, p<0.08).
Conclusion: Our study confirms that anxiety and depression are frequent in men with CHD. The prevalence of depression is higher in diabetics compared to non diabetics. A holistic CR program including psychological screening and support is able to reduce significantly the level of anxiety and depression in both diabetics and non diabetics' men. Our results emphasize the need to a systematic screening for depression particularly in diabetics and the positive impact of the CR which should be relevant to improve prognosis, even if it is needed to be confirm.

1013

Development of the diabetes treatment satisfaction questionnaire (DTSQ) for teenagers and parents: the DTSQ-Teen and the DTSQ-Parent

C. Bradley, K. Loewenthal, A. Woodcock, C. McMillan;
Psychology, Royal Holloway, University of London, Egham, Surrey, United Kingdom.

Background and aims: To report psychometric development of the DTSQ-Teen and -Parent, designed by Woodcock et al (2007) from the adult DTSQ using qualitative interviews with 14 teenagers with diabetes and 32 parents of children with diabetes. To compare the views of teenagers and their parents.
Materials and methods: The 12-item Diabetes Treatment Satisfaction Questionnaire for Teens (DTSQ-Teen) and the 13-item questionnaire for Parents (DTSQ-Parent) were completed by 38 adolescent offspring (aged 12-17 years) and 91 parents participating in a study by Pacaud et al (who provided baseline data from their study for questionnaire development). Non-parametric tests were used when Kolmogorov-Smirnoff test indicated data not normally distributed. All probabilities are 2-tailed.
Results: All 13 items on the DTSQ-Parent, except *perceived frequency (p. freq) of hyper- and hypoglycaemia*, had loadings from between 0.509 and 0.746 on a forced one-factor solution of a principal components analysis. Cronbach's alpha=0.787. Ten items retained for the new Treatment Satisfaction-Parent subscale (TS-Parent) were: *satisfied, ease, flexibility, day treatment, liked activities, family life, understanding, low discomfort, medical support, continue treatment*; alpha=0.801. With the 12-item DTSQ-Teen (items as in the DTSQ-Parent, except *family life* which teens do not view as affected by diabetes), factor loadings for all items except *p. freq of hypoglycaemia* and *low discomfort* were between 0.497 and 0.870 on a forced one-factor solution. When the *p. freq hyper-* and *hypoglycaemia* and *control* items were removed for comparability with the TS-Parent, alpha improved from 0.769 to 0.832, and to 0.856 when *low discomfort* was removed. A 2-item subscale, reflecting Perceived Diabetes Control (PDC), emerged from unforced factor analyses extracting factors with eigenvalues >1. Loadings were 0.820 and 0.722 (Parent) and 0.809 and 0.864 (Teen) for *p. freq of hyperglycaemia* and the *control* item. Alphas=0.567 (PDC-Parent) and 0.768 (PDC-Teen). Comparison of parent and teen ratings on DTSQ items, the PDC and the TS subscales indicated moderate agreement: Bivariate correlations between parent and teen ratings were significant for 6 of 12 items (p<0.05, r ranging from 0.38 to 0.67), and for each total subscale score (PDC Spearman's r=0.63, p<0.01; TS r=0.36, p<0.05). Differences between parent and teen ratings on the PDC scale were significant: mean % parent=55.3, teen=62.2 (Wilcoxon matched-pairs signed-ranks p<0.025). On individual items, parents over-estimated discomfort compared to their offspring (means on 0-6 low discomfort scale: parent=4.18, teen=4.99 (Wilcoxon p<0.01) and assessed diabetes as less well controlled (means on 0-6 scale: parent=3.93, teen=4.38, Wilcoxon p<0.05).
Conclusion: The DTSQ-Teen and DTSQ-Parent instruments include subscales to measure diabetes treatment satisfaction which have clear structures and excellent internal consistency reliability in addition to content validity previously demonstrated. *P.frequency of hypoglycaemia* is treated as a single item. Analyses confirmed the importance of examining the teens' reports, since these did not always relate closely to the parents' reports, differing significantly from them on PDC scale, and on two individual items. Both the TS and PDC measures are likely to be useful outcome measures in clinical trials of diabetes treatments for children and teenagers.

Personality traits in association with type 2 diabetes or pre-diabetes in Swedish middle-aged men and women

A.-K. Eriksson[1], A. Ekbom[1], P. Gustavsson[2], F. Granath[1], A. Hilding[3], C.-G. Östenson[3];
[1]Dep. of Medicine, Clinical Epidemiology unit, [2]Dep. of Clinical Neuroscience, Division of Psychology, [3]Dep. of Molecular Medicine and Surgery, Endocrine and Diabetes unit, Karolinska Institutet, Stockholm, Sweden.

Background and aims: Personality traits such as hostility have been recognized as risk factors for CHD. Whether hostility/antagonism or other personality traits may influence the risk of type 2 diabetes is not extensively studied. The aim was to examine the association between personality traits and abnormal glucose regulation (type 2 diabetes or pre-diabetes).
Materials and methods: This cross-sectional study comprised 2152 men and 3143 women aged 43-66 years, in Stockholm Diabetes Prevention Program. All participants had been classified with normal glucose tolerance 8-10 years earlier and about 50% had a family history of diabetes (FHD). None had known type 2 diabetes. OGTT identified 316 and 213 women with type 2 diabetes or pre-diabetes (impaired fasting glucose, IFG; impaired glucose tolerance, IGT; and IFG+IGT). Personality traits were measured by questionnaire with five subscales evaluating facets of the Big Five personality factors, i.e. antagonism (low agreeableness), impulsivity (low conscientiousness), hedonic capacity (high extraversion), negative affectivity (high neuroticism) and alexithymia (low openess). Each subscale comprised four items followed by a four-point Likert response format ranging from 1) "does not apply at all" to 4) "applies completely". The sum of each subscale was divided by the number of items included, and divided into three groups labelled "low" (<1 SD), "middle" (±1 SD) and "high" (>1 SD) according to the gender specific mean distributions. The middle group was considered unexposed to the particular personality sub-trait. OR's and 95% CI's were estimated in logistic regression for associations between personality sub-traits and abnormal glucose regulation, adjusted for age, BMI, FHD, smoking, physical activity, socio-economic position and psychological distress.
Results: For men reporting low values on the antagonism scale the risk of having abnormal glucose regulation was reduced with 70% compared to men that scored in the middle group, age-adjusted OR 0.3 (CI 0.2-0.6), which was not altered when controlled for the other potential confounders. For high antagonism in men there was no association. In women, neither high nor low values on the antagonism scale were associated to pre-diabetes or type 2 diabetes. For the hedonic capacity scale, men and women with high scores showed a 50% and 40% decreased risk of having abnormal glucose regulation, age-adjusted OR's 0.5 (0.3-0.9) and 0.6 (0.4-1.0) respectively, which was not

changed when controlled for the other potential confounders. For the group reporting low hedonic capacity there were no associations, although in women an increased risk was observed, age-adjusted OR 1.7 (1.1-2.6) that was no longer significant when controlled for the other potential confounders, OR 1.4 (0.9-2.4). The results for the alexithymia, impulsivity and negative affectivity scales illustrated no significant associations in either men or women.
Conclusion: In this study, a reduced risk of abnormal glucose regulation was observed in men with low antagonism, and in men and women with high hedonic capacity. For impulsivity, negative affectivity and alexithymia there were no significant associations in either men or women.

Stress hyperglycaemia in a coronary intensive care unit
M.E. Ertorer[1], F.E. Haydardedeoglu[1], T. Erol[2], I. Anaforoglu[1], S. Binici[2], N.B. Tutuncu[1], A. Sezgin[2], N.G. Demirag[1];
[1]Division of Endocrinology and Metabolism, Baskent University Faculty of Medicine, [2]Department of Cardiology, Baskent University Faculty of Medicine, Adana, Turkey.

Background and aims: Newly diagnosed hyperglycemia (NDH) and stress hyperglycemia (SH) among hospitalized patients during acute illness is reported as a non-physiological condition. Affected cases seem to have higher mortality rates and worse functional outcomes than the ones with known diabetes or normal glucose. The aim of this study is to determine the rate of NDH and SH among cases admitted to coronary ICU with coronary disease and to inquire the relationship of SH with disease severity and functional outcomes such as longevity of ICU stay.
Materials and methods: Patients with acute coronary syndrome (ACS) and myocardial infarction (AMI) admitted to our emergency room were recruited consecutively. Admission plasma glucose (APG) and fasting plasma glucose (FPG); the first morning after admission, measurements were obtained and each participant was subjected to capillary glucose measurement (CGM) every six hours within the first day. Patients were separated into 4 groups: GROUP 1: Normoglycemic cases: No known diabetes, APG < 200 mg/dl and FPG < 126mg/dl and all of the CGM < 200 mg/dl. GROUP 2: Newly diagnosed hyperglycemic cases: No known diabetes, APG > 200mg/dl and/or FPG > 126mg/dl and/or any of the CGM > 200 mg/dl. Group 2a: Unrecognized diabetes, hbA1c: >6.0% Group 2b: Stress hyperglycemia <6.0%. GROUP 3: Known diabetes. Age, gender, co-morbidities on admission, adverse outcomes in hospital, duration of stay in ICU, deaths, drugs, and glucose levels were all recorded. Throughout the hospital stay of Group 2 and Group 3, CGMs were performed and treated when necessary (target glucose<180mg/dl). Acute Physiology and Chronic Health Evaluation II (APACHE-II); a severity of disease classification system was used for each case. Duration of ICU stay was categorized into two groups; ≤ 3 days and > 3 days. A logistic regression analyses was performed using ICU stay as dependent variable and age, groups, co-morbidity, additional problem in ICU, APACHE-II score and CGM were used as independent risk factors.
Results: A total of 494 patients; 321 (65%) men, 173 (35%) women with 372 (75.3%) ACS and 122 (24.7%) AMI was included. There were 255 (51.6%) cases in Group 1, 82 (16.6%) in Group 2; 37 (7.5%) cases in Group 2a, 45 in Group 2b (9.1%) and 157 (31.8%) patients in Group 3. Group 2 had more cases with MI (n=35, 42.7%) (p=0.0001). On admission Group 3 had more patients with atherosclerotic co-morbidity (n=138, 87.9%) (p=0.001). The mean APACHE-II score were 11.9±2.9 in Group 1, 12.5±2.8 in Group 2a, 14.1±4.2 in Group 2b and 13.1±2.9 in Group 3 (p=0.0001). The mean duration of ICU stay of the groups were 2.27 days (median:2, min:1-max: 9), 2.95 days (median:3, min:1-max:6,), 4.56 days (median:3, min:1-max:25), and 3.03 days (median:3.0, min:1-max:16), respectively (p=0.0001). Group 2b also exhibited longer ICU stay than Group 1 (p=0.000) and Group 3 (p=0.03). Two (4.4%) cases in Group 2b and 8 (5.1%) in Group 3 died in hospital (p=0.608). In multiple logistic regression analysis, SH was shown to be an independent risk factor for the duration of ICU stay (OR:2.8, 95% CI:1.3-6.2).
Conclusion: In the present study, in accordance with literature, 16.6% of the cases had the diagnosis of NDH and 9.1% were found to be SH. The poor clinical pictures and functional outcomes of the SH cases pointed that these patients had to be considered more carefully.

In hospitalized patients with diabetes mellitus screening for hereditary hemochromatosis by using transferrin saturation is cost effective
I. Vardarli[1], T. Politz[1], W. Schröter[2], M.A. Nauck[1];
[1]Diabeteszentrum Bad Lauterberg, Bad Lauterberg im Harz,
[2]Diabetologische Schwerpunktpraxis KVN, Osterode, Germany.

Background and aims: Homozygosity for C282Y mutation in hemochromatosis gene (*HFE*) is the major contributor to hereditary hemochromatosis (HH). In caucasians, the prevalence of this homozygote mutation is 0.1 to 0.5 %. Due to incomplete penetrance, population-based screening in healthy subjects is not appropriate. However, in patients with diabetes the risk for HH is 5-fold higher. Therefore, screening in hospitalized patients with diabetes

may be relevant. To address this topic, in consecutive patients with all types of diabetes admitted to our institution, we determined the iron indices and assessed cost effectiveness of laboratory screening.
Materials and methods: In a prospective manner, for three consecutive months, phenotypic screening in 527 hospitalized diabetic patients was performed by obtaining the iron indices. Genotyping of *HFE* gene (C282Y mutation) was performed in patients with a transferrin saturation > 45 %. We assessed the diagnostic efficiency and the cost effectiveness of two strategies. The estimated total costs were based on costs for laboratory tests (reagents and manpower) for iron (2.23 €), transferrin (2.76 €) and ferritin (11.62 €) in serum and for genotyping of the *HFE* gene (180,70 €). (Strategy A) Preselection by elevated ferritin (> 400 ng/ml), followed by obtaining transferrin saturation (iron in serum [µg/dl] / transferrin [mg/dl] x 70.9), and genotyping if transferrin saturation was elevated (> 45 %); (Strategy B) Determination of transferrin saturation in all patients, followed by genotyping if transferrin saturation was elevated.
Results: With strategy A, we identified 94 patients with elevated ferritin, 9 of them had elevated transferrin saturation, and two of the latter were homozygous for the C282Y mutation. Costs were 15.60 € per patient, and 4,109.55 € per identified case with HH. The positive predictive value for an elevated ferritin was 2.1 %. With strategy B, we identified 27 patients with elevated transferrin saturation, two of them were homozygous for C282Y mutation. The costs were 14.25 € per patient, and 3,754.32 € per identified case with HH. Positive predictive value for an elevated transferrin saturation was 7.4 %.
Conclusion: Due to relevant clinical consequences of non-treatment of HH and the costs for screening as determined by our analysis, we suggest that phenotypic (laboratory) screening is appropriate in patients with diabetes mellitus. Primary screening by using an elevated transferrin saturation is more efficient and cost effective.

1017

Initiation of glucose lowering therapy among hyperglycaemic patients without prior diabetes hospitalized for acute myocardial infarction

M. Kosiborod[1], J.M. Stolker[1], D.K. McGuire[2], S.E. Inzucchi[3], S.S. Rathore[4], T.M. Maddox[5], F.A. Masoudi[6], F. Tang[1], P.G. Jones[1], J.A. Spertus[1];
[1]Cardiology, Mid America Heart Institute, Kansas City, [2]Cardiology, University of Texas Southwestern School of Medicine, Dallas, [3]Endocrinology, Yale University School of Medicine, New Haven, [4]Cardiology, Yale University School of Medicine, New Haven, [5]Cardiology, Denver VAMC/University of Colorado at Denver, [6]Cardiology, Denver Health Medical Center & University of Colorado at Denver, United States.

Background and aims: Hyperglycemia is common in acute myocardial infarction (AMI) and predicts adverse outcomes, particularly in patients (pts) without known diabetes (DM). AMI hospitalization therefore represents an opportunity for DM recognition and initiation of antihyperglycemic therapy (AHT). However, the incidence, predictors, and the relationship between AHT and post-discharge glycemic control are unknown.
Materials and methods: TRIUMPH is a prospective registry of AMI pts from 26 US centers; we analyzed AHT initiation among hyperglycemic pts (initial glucose ≥140 mg/dL) without known DM. AHT was defined as initiation of a new oral antihyperglycemic agent, exenatide, or insulin at discharge. Baseline HbA_{1c} was measured during hospitalization; follow up HbA_{1c} was obtained at 6 months in pts who consented. Independent predictors of AHT initiation were identified using hierarchical Poisson regression. Among pts with baseline and 6-month HbA_{1c}, the association between AHT and post-discharge glucose control was evaluated, adjusting for baseline HbA_{1c} and hospital site.
Results: Between 2005-08, TRIUMPH enrolled 3469 pts of whom 601 (17%) had hyperglycemia and no known DM. HbA_{1c} was assessed in 332 (55%) of these pts; the level was <7% in 271 (82%), 7-9% in 34 (10%), and >9% in 27 (8%) pts. Overall, 56 hyperglycemic pts (9.3%) were initiated on AHT; a greater proportion of these pts had HbA_{1c} assessment (95% vs 51%, p<0.001). Pts with AHT also had higher initial glucose (248 vs 174 mg/dL, p<0.001), fasting glucose (161 vs 114 mg/dL, p<0.001), HbA_{1c} (8.8% vs 6.4%, p<0.001), and higher rate of intensive in-hospital insulin (23% vs 2%, p<0.001). Independent predictors of AHT initiation are listed in the Figure. In 107 pts with complete baseline and 6-month HbA_{1c}, AHT was associated with significant improvement in glucose control at 6 months (crude ΔHbA_{1c} -2.5 ± 2.1% vs 0.0 ± 0.5%, p<0.001; adjusted 6-month HbA_{1c} 0.5% lower in pts with vs without AHT, p=0.04).
Conclusion: Both HbA_{1c} assessment and higher HbA_{1c} levels are key predictors of in-hospital AHT initiation after AMI in hyperglycemic patients without known diabetes. When HbA_{1c} assessment is performed, about one in five hyperglycemic patients without known diabetes have evidence of suboptimal or poor long-term glucose control. Initiation of AHT in these patients, while uncommon, is associated with significant improvement in post-discharge glucose control.

Prediction of glucose concentrations following cardio-thoracic surgery using continuous glucose monitoring

L. Schaupp[1], J. Plank[2], S. Korsatko[2], G. Koehler[2], M. Ellmerer[2], T.R. Pieber[2];
[1]Institute of Medical Technologies and Health Management, Joanneum Research, Graz, [2]Department of Internal Medicine Devision of Endocrinology and Nuclear Medicine, Medical University Graz, Austria.

Background and aims: The maintenance of near normoglycaemia is of fundamental importance for critically ill patients. Continuous glucose concentration measurements could facilitate this by enabling glucose excursions to be detected at a stage early enough to allow adverse events to be avoided through corrective action. The aim of the present investigation was to examine the predictive power of continuous glucose data using simple linear extrapolation of the trend signal in critically ill patients.
Materials and methods: 20 patients (69±7 years, BMI 28.2±4.9 kg/m, APACHE II score 10.1±3.2) with a blood glucose level >120 mg/dl (6.7 mmol/l) upon admission to the ICU were included in the trial. Glucose was continuously monitored using microdialysis coupled with a glucose sensor. In parallel, throughout the study period (up to 48 hours) whole blood samples were collected at hourly intervals via an arterial line. The prediction horizon was determined by extrapolation of the actual linear trend and assessed in two ways: 1) Analytical assessment: the degree of divergence between the predicted glycaemia and corresponding reference values was calculated using the Root mean squared error (RMSE). 2) Clinical assessment: the predictive power of continuous sensor glucose readings with respect to the reference glucose values was clinically evaluated by Insulin Titration Error Grid (ITEG) analysis.
Results: A total of 538 hours of continuous glucose measurement data were analysed. These correlated very well with the conventional blood glucose reference measurements (mean of residuals: 5.4 mg/dl; relative system error: 4.03%; mean absolute relative difference (MARD): 1.27 %). This correlation was mirrored by a high degree of clinical reliability: when analysed using the ITEG, 98.66% of the data were located in the acceptable treatment zone. A first estimate of a reasonable prediction horizon (PH) - 17.6 ± 4 min - was derived as the mean time interval between successive peak maxima and trough minima. A prediction horizon of 37 min was associated with an increase in the root mean squared error of 10 mg/dl. In clinical terms, a strong increase in the number of data points in the unacceptable violation zone was observed when the prediction horizon exceeded approximately 20 min.
Conclusion: Our data provide evidence that simple linear extrapolation of glucose trend information obtained by continuous glucose monitoring can be used to predict the course of glycaemia in critically ill patients for up to 20 to 30 minutes. This "glimpse into the future" can be used to proactively prevent the occurrence of adverse events.

Risk factors for hypoglycaemia in patients with diabetes during continuous intravenous insulin infusion in hospital setting

A. Ignaczak, M. Saryusz-Wolska, E. Szymanska-Garbacz, M. Loba, L. Czupryniak;
Diabetology and Metabolic Diseases Dept, Lodz, Poland.

Background and aims: Continuous intravenous insulin infusion (CIVII) is often used in hospital setting in the treatment of poorly controlled diabetes. Hypoglycemia, especially with rapid onset and of severe intensity, is the most common adverse event of this mode of diabetes treatment. The aim of this prospective study was to identify risk factors of hypoglycemia during CIVII.
Materials and methods: The study group was 200 patients with type 1 and type 2 diabetes treated with CIVII at the university hospital department (mean age 55±16 years, BMI 29.3±6.4 kg/m2, diabetes duration 10±9 years, HbA1c 10.1±2.5%). CIVII consisted of basal insulin infusion and three 90-min insulin boluses per day administered at the meal time. The boluses consisted of three time periods (20+20+50 min),each with different rate of insulin infusion, which was adjusted individually to the meal absorption and postprandial glucose. In normal conditions capillary blood glucose was measured every 90-120 min throughout the day and night. Hypoglycemia was diagnosed if capillary blood glucose was <60 mg/dl or when CIVII was stopped due to the symptoms of hypoglycemia.
Results: Mean duration of CIVII was 3.8±1.5 days. 135 episodes of hypoglycemia were noted in 48 (24%) patients. Duration of diabetes in the patients with hypoglycemia was significantly longer than in the patients in whom hypoglycemia did not develop (12.4±10.8 vs 9.2±8.2 years; p<0.05), the former had also lower body weight (74.2±15.6 vs 83.9±19.8 kg; p<0.01; BMI 27.0±5.9 vs 30.0±6.4 kg/m2; p<0.01) than patients without hypoglycemia. The strongest risk factor for hypoglycemia was having type 1 diabetes (hypoglycemia occurred in 48% patients with type 1 and 20% with type 2 diabetes), particularly of long duration (14.3±12.4 vs 6.8±7.6 years in type 1 diabetes without hypoglycemia; p<0.01). Degree of metabolic control, presence of late diabetes complications, kidney, gastrointestinal tract, neurological or cardiovascular diseases or complications as well as insulin dose per kilogram of body weight did not contribute to the risk of hypoglycemia.
Conclusion: Patients with long-standing type 1 diabetes are at particularly high risk of hypoglycemia occurrence during CIVII, regardless of present complications or significant co-morbidities. CIVII should be used in this group of patients with utmost caution.

1020

Glucose variability predicts mortality in the ICU

J.H. DeVries[1], J. Hermanides[1], T.M. Vriesendorp[1], R.J. Bosman[2], D.F. Zandstra[2], J.B.L. Hoekstra[1];
[1]Academic Medical Centre, [2]Onze Lieve Vrouwe Gasthuis, Amsterdam, Netherlands.

Background and aims: Mounting evidence suggests a role for glucose variability in predicting ICU mortality. We investigated the predictive value of glucose variability for ICU death across several ranges of mean glucose.
Materials and methods: Two measures of variability, Mean Absolute Glucose change per hour (MAG) and standard deviation (SD), were calculated as measures of glucose variability from patients admitted to an 18-bed medical/surgical ICU from 2004 to 2007. Readmissions, patients with a withholding care policy and patients with only one glucose value measured during admittance were excluded. Patients were treated with a computerized insulin algorithm (target glucose range 4-7 mmol/l).
Results: Mean age was 65 ± 13 years, 34% was female and 6.3% of patients died in the ICU. MAG was a stronger predictor for ICU death than SD; crude Odds Ratio (OR) (highest vs. reference quartile) for ICU death 7.7 (95% CI 5.2-11.6) and 5.8 (4.0-8.4), respectively. In multivariate logistic regression, OR's for death in the ICU were calculated for quartiles of mean glucose, with quartiles of glucose variability as covariate, correcting for age, sex, diabetes mellitus and mean sequential organ failure scale (SOFA) during admittance. The highest OR for ICU death was found in patients with the highest MAG in the upper glucose quartile: OR 15.1 (95% CI 4.8-47.2, p<0.001). The OR's for ICU death were equally low in the lowest MAG quartile, independently of the mean glucose.
Conclusion: High glucose variability is a strong predictor of ICU death, even more in combination with increased mean glucose levels. Low glucose variability seems protective, even when mean glucose levels remain elevated despite glucose lowering therapy.

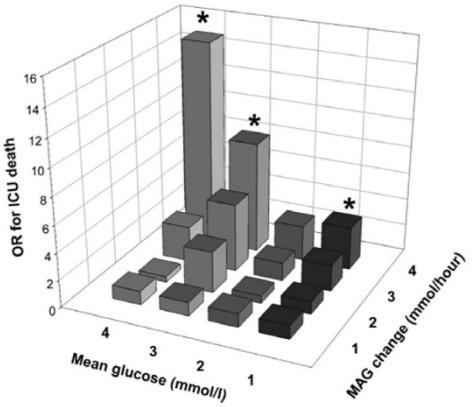

Figure 2: OR for ICU death, adjusted for age, sex, DM and mean SOFA score, *P<0.05 as compared to the lowest MAG quartile.

Quartile	Range mean glucose (mmol/l)	Range MAG (mmol/hour)
1	<6.93	<0.39
2	6.93-7.60	0.39-0.60
3	7.61-8.91	0.61-0.87
4	>8.91	>0.87

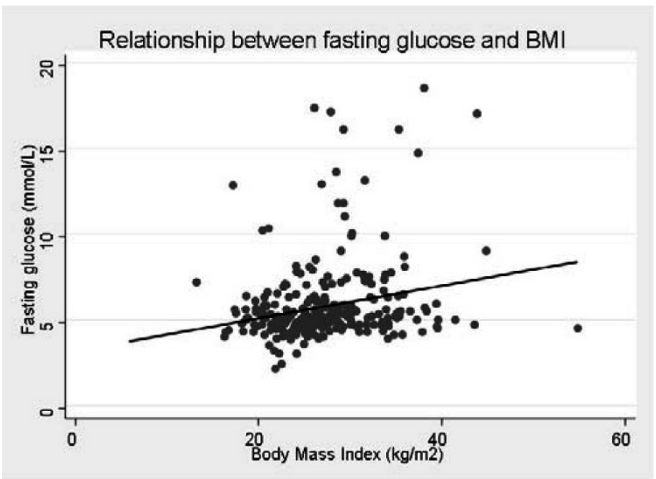
Screening of cardiometabolic risk factors in patients with severe enduring mental illness: results and potential

S.G. Anderson[1], P. Narayanan[2], Z. Qureshi[2], S. Bujawansa[2], H. Knapman[3], A.H. Heald[2];
[1]The University of Manchester, [2]Leighton Hospital, Crewe, [3]Kiltearn Medical Centre, Nantwich, United Kingdom.

Background and aims: People with severe enduring mental illness (SMI) are reported to be twice as likely to die from cardiovascular disease (CVD) than those in the general population with the excess mortality even higher in younger individuals. In a meta-analysis of 18 international studies, 60% of the excess mortality of schizophrenia was attributable to physical illness, with CVD being the major contributor.
Materials and methods: We report the implementation of a primary care programme of screening and intervention for cardiometabolic risk factors in one region of the UK. This involves incentivation of General Practioners by the UK Department of Health through the Quality and Outcomes Framework (QOF). Data search was performed using a database generated through the EMIS software provider.
Results: 453 patients (55.8% male 44.2% female) on the SMI Register in Cheshire, UK were screened for dysglycaemia (screening rate 57.3 %) and dyslipidaemia (screening rate 36.2%). There were no differences in BMI by gender, but a greater proportion of women (25% vs 20%) were obese (BMI ≥ 30 kg/m2). Fasting glucose was in the impaired fasting glycaemia range (6.1-6.9mM) in 6.5% of those screened and at or above the threshold for type



2 diabetes (7.0mM) in 17.3% of the group. Fasting serum cholesterol was high at >5mmol/L in 62.8% of those screened for whom the mean cholesterol was 6.2±0.8 mmol/L). Despite high rates of dysglycaemia and dyslipidaemia, systolic blood pressure was high at >140mmHg in only 13% of those examined. Multivariate linear regression analyses revealed a direct relationship between fasting glucose levels and BMI (Spearman's rho = 0.22, p<0.001) independent of age, sex, systolic blood pressure and fasting cholesterol and triglycerides.
Conclusion: Screening in SMI patients for cardiometabolic risk in a Primary Care setting is feasible. However screening rates need to be improved. The relatively low prevalence of hypertension is likely a consequence of the alpha 1 receptor blocking properties of many neuroleptics. There is scope for cardiometabolic risk reduction with targeted intervention in this group, with potentially significant associated reduction in CVD mortality. Any programme must include active lifestyle measures to encourage weight reduction in addition to pharmacotherapy.

Urinary myoinositol index: a new and better marker for postprandial hyperglycaemia

M. Miyagi[1], K. Kuboki[1], T. Matsumoto[1], N. Masai[1], M. Sue[1], A. Yoshihara[1], K. Iso[1], E. Murakami[2], G. Yoshino[1];
[1]Division of Diabetes, Metabolism and Endocrinology, Department of Internal Medicine (Omori), Toho University School of Medicine, [2]Clinical Laboratory, Toho University Medical Center Omori Hospital, Tokyo, Japan.

Background and aims: A growing body of evidence suggests that reducing postmeal plasma glucose (PG) excursions as well as achieving HbA_{1C} goals is important for the prevention of the cardiovascular disease. Therefore, we examined the relationship between postprandial hyperglycemia and HbA_{1C}, plasma 1,5-anhydroglucitol (1,5-AG) or urinary mioinositol index (UMI) in patients with type 2 diabetes mellitus (T2DM).
Materials and methods: Fifty-eight T2DM patients (18 males and 40 females) were enrolled in this study. The patients with renal or hepatic disease, using insulin or α-glucosidase inhibitors, and with HbA_{1C} above 8.0% were excluded. Test-meal tolerance test was done after informed consent was obtained. Test-meal consists of carbohydrates 51.4% (57.6g), protein 15.3% and lipid 33.3% with total energy of 460kcal. Plasma 1,5-AG was measured by a fully enzymatic method, and UMI by an improved enzymatic cycling method.
Results: Their age, BMI and waist circumference were 67.6 ± 7.9 year-old, 24.9 ± 3.8 kg/m^2, and 90.2 ± 10.4 cm, respectively. Fasting, 1- and 2-hour postmeal PG were 130 ± 23 (7.2 ± 1.3), 178 ± 46 (9.9 ± 2.6) and 149 ± 49 mg/dl (8.3 ± 2.6 mmol/l), respectively. HbA_{1C}, 1,5-AG and 2-hour UMI (three PG markers) were 6.3 ± 0.6 %, 11.9 ± 5.7 μg/ml and 52.0 ± 35.9 mg/gCr, respectively. The correlation coefficient (*r*) between 1-h PG and three PG markers were 0.558, 0.256, 0.496, and that between 2-h PG and the three PG markers were 0.605, 0.306, 0.606, respectively.
Conclusion: Myoinositol is one form of inositol; inositol is a circular D-glucose isomer. Myoinositol concentrations in blood or in urine are reported to be higher in patients with diabetes or chronic renal failure than in healthy individuals. It's concentration in biological samples has been measured by various methods, but it has been difficult to measure accurately. We used the above-mentioned, easy-to-use and highly sensitive method. We calculated a urinary mioinositol/creatinine ratio as UMI at 2-h after meal load. When UMI was measured hourly from fasting until 3 hours at the time of 75g-OGTT for patients with normal glucose tolerance (GT), impaired GT and diabetes, its peak was with 2-h urine in any case though UMI admitted rising according to the level of the GT. The advantages of UMI are to collect samples noninvasively, and to respond rapidly to changes in PG. In this study, 1-h PG was higher than 2-h, but these three PG markers were better related to 2-h PG than to 1-h. Then, the *r* between 2-h PG and UMI was higher than that between 2-h PG and 1,5-AG or HbA_{1C}. Recently, HbA_{1C}, glycoalbumin, 1,5-AG and PG are the mainstream as markers for glycemic control. In these markers, 1,5-AG has been proposed as a marker for postmeal hyperglycemia. However, in this study the *r* between postmeal PG and 1,5-AG was lower than that between postmeal PG and 2-h UMI. Although HbA_{1C} is also a good marker for 1- or 2-h PG, it neither accurately reflects transient elevations of glucose within a few days, nor responds quickly to changes in PG. In conclusion, UMI seems to be a better marker for monitoring postprandial hyperglycemia in comparison with plasma 1,5-AG or HbA_{1C}.

1023

Assessing postprandial hyperglycaemia and glucose variability. The ADAG study

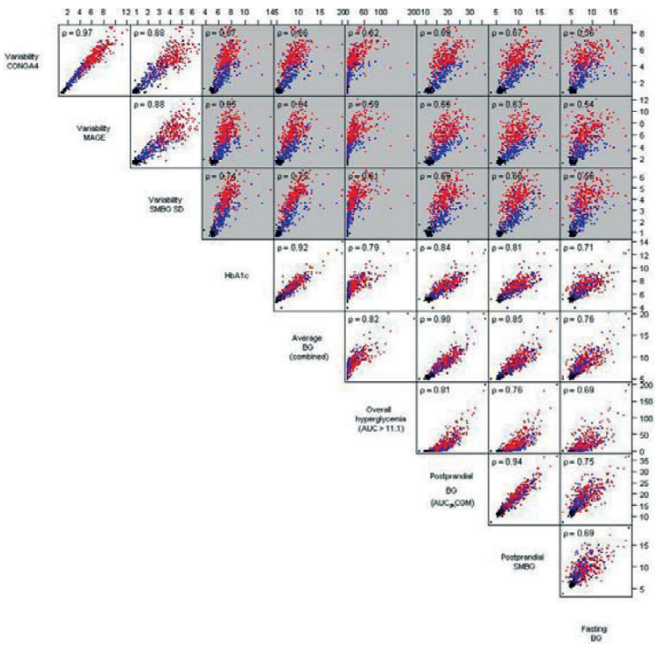
R. Borg[1], J.C. Kuenen[2], B. Carstensen[1], J. Nerup[1], K. Borch-Johnsen[1], H. Zheng[3], R.J. Heine[2], D.M. Nathan[3], D.R. Witte[1];
[1]Steno Diabetes Center, Gentofte, Denmark, [2]VU Medical Center, Amsterdam, Netherlands, [3]Harvard Medical School, Boston, United States.

Background: Glucose variability and postprandial hyperglycaemia have been implicated in risk of cardiovascular disease in patients with diabetes. However, little information exists on the relationship between the different indices of glycaemia.
Materials and methods: 507 participants (268 with type 1 diabetes, 159 with type 2 diabetes, 80 without diabetes) from the ADAG (A1c Derived Average

Glucose) study underwent intensive glucose monitoring during 16 weeks. For each participant, approximately 2,700 glucose values were obtained using continuous glucose monitoring (CGM) and seven-point self-monitored capillary blood glucose (SMBG) on different days. HbA1c was measured. We derived common indices of postprandial glycaemia, over-all hyperglycaemia and glucose variability and studied their association. A combined CGM/SMBG average blood glucose (BG) was calculated. Intraday glucose variability indices were calculated from CGM: the Mean Amplitude of Glycaemic Excursions (MAGE) and the Continuous Overlapping Net Glycaemic Action (CONGA). The standard deviation (SD) was calculated from CGM and SMBG data

Results: CONGA calculated with 1, 2, 4, and 6 hour windows showed strong intercorrelation. The $CONGA_4$ and CGM SD are both strongly related to MAGE with correlation coefficients of 0.97. The SMBG variability index (SD) relates with the CGM indices MAGE, CGM SD, and the $CONGA_4$ with correlation coefficients of 0.88, 0.90, and 0.88, respectively. Selected correlations are shown in the figure. For postprandial indices, the area under the glucose curve (AUC) calculated from CGM 2 hours after a meal is related to the SMBG postprandial measurements with a correlation coefficient of 0.94. FBG only correlates moderately (correlation coefficient between 0.69 - 0.76) with indices of hyperglycaemia, average or postprandial BG levels.

Conclusion: As expected, the different indices of glycaemic variability, average and post-prandial glycaemia correlate within each category and moderately between categories. In particular, the variability indices do not correlate strongly with indices of fasting, postprandial or elevated BG. This suggests that the variability indices convey different information from the other indices of hyperglycaemia, average or postprandial BG levels (shaded area of figure). FBG only has a moderate correlation with other indices of glycaemia, indicating that it is not a clear indicator of general glycaemia. Within the categories, SMBG derived indices are strongly correlated with those derived from CGM, indicating that much information regarding postprandial BG levels and glucose variability is captured by 7-point profile SMBG.



Pairwise scatter diagrams illustrating selected Correlations of Glycaemic indices with Pearson correlation coefficients (ρ) for each pair.

Analytical and clinical evaluation of Lucica GA-L plasma glycated albumin assay in subjects with and without diabetes

S. Shah[1], C. Collison[2], H. Thabit[1], L. Blake[2], K. Wanic[1], V. Crowley[2], J.J. Nolan[1];
[1]Endocrinology, Metabolic Research Unit, [2]Biochemistry Department, Dublin, Ireland.

Background and aims: The measurement of glycated proteins, including HbA1c and plasma glycated albumin (PGA), is a key indicator of glycaemic status in diabetic patients. PGA specifically provides a useful measure of short-medium glycaemic control and may also provide alternative information on the risk of the long-term hyperglycaemic-related complications of diabetes.The objective of this study was to undertake both an analytical and clinical evaluation of a new robust enzymatic assay for PGA in a healthy non-diabetic cohort (controls) and in a cohort with diabetes.

Materials and methods: PGA was measured using a Lucica GA-L Glycated Albumin assay (Asahi Kasei Pharma Corporation) on a Roche Modular-P platform. Control samples were obtained from our Irish Construction Worker cohort and diabetes samples from our Case Control cohort. The baseline characteristics of the two cohorts are outlined in Table 1.Data are expressed as Mean (SEM) or *Median (IQR)

Results: The analytical performance of the assay was very satisfactory with (1) intra-assay precision between 0.9-1.2% and (2) interassay precision between 0.8-1.8%, across a range of concentrations. The reference range for PGA, established using healthy non-diabetic Irish control subjects (n=87), was 8.9% - 14.6%. PGA levels were significantly elevated in diabetic subjects [median (IQR) 17.0% (14.1% - 19.8%)] compared with non-diabetic control subjects [median (IQR) 11.0% (10% - 12%)] (P<0.005). In addition, a significant correlation was found between PGA and fasting plasma glucose in the whole cohort (r=0.58, p<0.05), while PGA was significantly correlated with HbA1c (r=.70, p=<0.005) in diabetics only.

Conclusion: The Lucica GA-L enzymatic assay is a robust and reproducible analytical method for routine measurement of PGA. Furthermore in a cross sectional evaluation it clearly differentiated diabetic and non diabetic subjects, indicating its clinical value as a marker of glycaemic status.

Table 1

	Control (n=184)	Diabetes (n=158)	p value
Age (Years)	40.0 (0.1)	61.3 (1.06)	<0.005
Male/Female	98/86	101/57	---
HbA1c (%)	5.4 (0.05)	7.6 (0.14)	<0.005
*Glycated Albumin (%)	11.0 (10.0-12.0)	17.0 (14.1-19.8)	<0.005

1025

The validity of the CPR index (CPI) in selecting treatment in a patient with type 2 diabetes mellitus

M. Iwata, Y. Kamura, Y. Fukushima, C. Kobashi, A. Takikawa, T. Okazawa, M. Ishiki, I. Usui, K. Yamazaki, M. Urakaze, K. Tobe;
Toyama University, Japan.

Background: Evaluation of residual pancreatic beta-cell function is important in choosing appropriate treatment for diabetic patients, especially deciding whether insulin treatment is required for controlling type2 diabetes. The homeostasis model assessment-β(HOMA-β) and urinary C- peptide collected during 24hours (U-CPR), have been so far widely validated clinical and epidemiological tools for estimating beta-cell function. Recently, we proposed that CPR index (CPI), which is derived from following equation [=fasting serum C-peptide (F-CPR)/ fasting plasma glucose (FPG) x 100], was a useful marker of insulin secretion. In this study, we examined whether CPI is correlated with HOMA-β, F-CPR in a general population. Then, we further examined the validity of the CPI by comparing these indices in deciding which treatment is suitable for patients with type 2 diabetes mellitus.

Group1; Subjects were 658 adult subjects (average age±SD 64.9±10.1 years, range: 31-88 years old: 290 men, 368 women) who had received medical examination in 2008 at Fuchu town, Toyama Prefecture, central Japan. Group2; Subjects were 160 (average age±SD 62.9±12.1 years, range: 28-86 years old:114 men, 56 women) inpatients with type 2 diabetes mellitus admitted to the University of Toyama hospital for controlling glycemic control. In group1: we analyzed relationship between HOMA-βand F-CPR or CPI by simple cor-

relations. In group2: we calculated the CPI in 160 inpatients measuring FPG and F-CPR on the second or third hospital day. They were divided into three groups according to the therapy they received at 3 months after discharge: insulin treatment; n=86 (Insulin group), oral medication; n=50 (O group), and diet therapy; n=24 (D group). We determined CPI cutoff levels between Insulin group and O+D group by histogram and compared the power of CPI, F-CPR, U-CPR and HOMA-β to predict requirement of insulin therapy by receiver operating characteristic (ROC) analysis.
Results: In group1, both F-CPR and CPI were significantly and positively correlated with HOMA-β. However, the correlation coefficient with HOMA-β was significantly greater for CPI (r=0.76) than for F-CPR (r=0.59) (p<0.05). CPI, F-CPR, U-CPR and HOMA-β in Insulin group were significantly lower than those of O+D group: CPI(I: 1.05±0.59 vs O+D: 1.91±0.99, p<0.01),HOMA-β(I: 20.89±21.06 vs O+D: 53.67±35.22, p<0.05),F-CPR(I: 1.84±0.93 vs O+D: 2.37±0.87 , p<0.01),U-CPR(I: 42.24±30.71vs O+D: 57.87±30.72, p<0.01). ROC analysis has shown that the area under the curve (AUC) of CPI was significantly larger than that of F-CPR and U-CPR (p<0.05). The AUC of CPI and HOMA-β were comparable. Histogram of CPI and HOMA-β has shown that insulin treatment is required to control diabetes in patients with the CPI≤1.00 or HOMA-β≤13.69, but not in those with CPI≥1.86 or HOMA-β≥44.55.
Conclusion: CPI and HOMA-β were significantly correlated with each other. ROC analysis revealed that those two indices are useful for a clinical decision of whether insulin was required for controlling Japanese type 2 diabetic patients. When we decide an appropriate therapy in patients with type2 diabetes mellitus, the CPI may be useful because it is an index calculated simply.

1026

Evaluation of exocrine pancreatic function in patients with type 1 and type 2 diabetes

T.T. Várkonyi[1], A. Szabolcs[1], V. Szidor[1], A. Szász[1], É. Börcsök[1], C. Lengyel[1], T. Takács[1], P. Kempler[2], T. Wittmann[1];
[1]1st Department of Medicine, University of Szeged, [2]1st Department of Medicine, Semmelweis University, Budapest, Hungary.

Background and aims: Although the impairment of pancreatic exocrine function in patients (pts) with non-pancreatic diabetes (DM) is documented, its incidence and consequences are not clearly known. The aim of our study was to assess the exocrine pancreatic function in pts with type 1 or 2 DM.
Materials and methods: The stool elastase activity of 146 pts with non-pancreatic DM was measured. Cardiovascular reflex tests (CRT), peripheral sensory function (applying Neurometer; Neurotron Inc. Baltimore, MD), retinopathy, HbA1c, BMI, microalbumin excretion (MAU) were measured and the quality of life (QoL) was assessed by an EORTC QLQ-C30 questionnaire.
Results: 28% of all pts had an affected exocrine pancreatic function. Two groups (n=21 and n=10) were selected from pts based on decreased or normal elastase (mean elastase of pts: 141±11 vs 417±37 μg/g, p<0.00001). The duration, age, BMI, HbA1c, MAU and retinopathy frequency did not differ significantly between the groups: (duration: 16.2±2.7 vs 16.3±3.6 years, p=0.98; age: 58.7±2.6 vs 60.3±4.3 years, p=0.74; BMI: 27.4±1.98 vs 30.5±1.27, kg/m^2 p=0.08; HbA1c: 8.25±0.3 vs 8.98±0.2 % p=0.17; MAU: 20 vs 16 % p=0.98, retinopathy: 50 vs 48 %; p=0.93 decreased vs normal elastase group). A CRT (30/15 ratio) was lower in pts with impaired elastase (0.98±0.01 vs 1.03±0.02, p=0.04), but differences in the overall autonomic neuropathy (AN) scores were not significant (AN score: 4.35±0.75 vs 3.9±0.38, p=0.50). The threshold of perception of both limbs showed a non-significant tendency to increase in pts with low elastase (n. medianus 2000 Hz: 3.07±0.6 vs 2.49±0.55 mA, p=0.64, 250 Hz: 2.26±0.6 vs 0.96±0.2 mA p=0.16, 5 Hz: 1.68±0.63 vs 0.66±0.2 mA p=0.42, n peroneus: 2000 Hz: 5.10±0.76 vs 3.61±0.87 mA p=0.24, 250 Hz: 3.91±0.81 vs 2.1±0.78 mA p=0.26, 5 Hz: 2.82±0.8 vs 1.85±0.75 mA p=0.42). Qol scores were not significantly different between the groups.
Conclusion: Decreased stool pancreatic elastase activity can be found in almost one third of diabetic patients, and it might be related to a neuronal dysfunction without affecting further complications. Prospective trials with a higher number of patients and the investigation of the effect of enzyme substitution are needed to clarify the clinical role of exocrine pancreas function in non-pancreatic diabetes

1027

A new strategy for the sensitive and simultaneous analysis of human insulin and insulin analogues using LC/MS^2 in combination with a tailored sample clean-up procedure

K.E. Pickl[1], C. Magnes[1], T.R. Pieber[2,1], F.M. Sinner[1];
[1]Inst. of Medical Technologies and Healthmanagement, Joanneum Research, Graz, [2]Department of Internal Medicine, Division of Endocrinology and Nuclear Medicine, Medical University Graz, Austria.

Background and aims: In recent years, a number of insulin analogues with altered pharmacokinetic (PK) properties have been designed to improve glucose control in diabetes. Currently, the measurement of insulin in body fluids for the purpose of PK profiling is still performed by immunoassays. These methods however suffer from certain limitations, including cross-reactivity with structurally related peptides, a lack of assays specific for individual insulin analogues and the inability to assay multiple insulins simultaneously. An LC/MS approach able to simultaneously quantify multiple insulins in one sample without the risk of cross reactivity would clearly represent a useful alternative to immunoassays.
Materials and methods: B chains were obtained from human insulin, insulin aspart, insulin glulisine, insulin lispro, insulin glargine and porcine insulin by reduction using TCEP. LC-MS^2 analysis was performed using a LC-Packings Ultimate 3000 HPLC system in the capillary mode. Insulin B chains were eluted with shallow water: acetonitrile gradients with 0.1% formic acid at a temperature of 50°C (column: ACE 4, 150 x 0.3 mm, 3 microm particle size) and detected with a TSQ Quantum Ultra AM mass spectrometer using positive ESI in SRM mode.
Results: The new LC/MS^2 method allowed simultaneous analysis of human insulin and several insulin analogues (insulin lispro, insulin aspart, insulin glulisine, insulin glargine, bovine or porcine insulin) without cross reactivity. A sophisticated sample clean-up procedure involving protein precipitation (PP), solid phase extraction (SPE) and ultrafiltration (UF) enabled the efficient removal of interfering proteins from serum samples and thereby compatibility with LC/MS analysis. The procedure showed excellent sensitivity: 1 fmol (= 1x10^{-15} mol) on column - corresponding to insulin levels of around 4 pM in 250 µl serum - could be detected with signal/noise ratios of >1000 in serum samples.
Conclusion: A sensitive LC/MS^2 method in combination with a tailored sample clean-up procedure enables the sensitive, simultaneous specific detection of human insulin and insulin analogues in serum samples down to physiological basal levels (~ 36 pM) of human insulin in serum.

Diabetes care protocol: effects on patient-important outcomes. A cluster randomised non-inferiority trial in primary care

K.J. Gorter, F.G.W. Cleveringa, M.H. Minkman, M. van den Donk, G.E.H. Rutten;
General Practice, Julius Centre for Health Science and Primary Care, Utrecht, Netherlands.

Background and aims: The Diabetes Care Protocol (DCP) combines task delegation, intensification of diabetes treatment and feedback. It reduces cardiovascular risk in type 2 diabetes (DM2) patients. This study evaluates the effects of DCP on perceived health status, treatment satisfaction and psychosocial self-efficacy.
Materials and methods: A Cluster randomized, non-inferiority trial, by self-administered questionnaires in fifty-five primary care practices across the Netherlands: 29 practices DCP, 26 usual care. DM2 patients treated by their primary care physician were included. Main outcome was the one-year between group difference in Diabetes Health Profile (DHP-18) total score. Secondary outcomes: DHP-18 subscales, general HRQoL (SF-36, Euroqol 5D/ EQ-VAS), treatment satisfaction (DTSQ-status) and psychosocial self-efficacy (DES-SF). Per protocol (PP) and intention-to-treat (ITT) analyses were performed: non-inferiority margin -Δ2%. 1692 patients participated in the usual care group (UCG), 1699 in the DCP group (DCPG). At baseline 2333 questionnaires were returned, 1437 yearly thereafter, 1060 patients (517 UCG; 543 DCPG) completed both DHP questionnaires.
Results: Compared to usual care, in the DCPG the DHP-18 total score decreased 0.88 more in PP (CI: -1.94 - 0,12) and 0.439 more in ITT (CI: -1.01 - 0.08); demonstrating non-inferiority. SF-36 "Health change" increased 3.51 in PP (CI: 1.23 - 5.82) and 1.91 in ITT (CI: 0.62 - 3.23), demonstrating superiority. Other differences in perceived Health status, treatment satisfaction or psychosocial self-efficacy were inconclusive, inconsistent or non-inferior.
Conclusion: Despite intensification of advices and therapy, DCP is non-inferior to usual care regarding perceived diabetes specific healt status and improves the perceived change in general health.

Impaired fasting glucose and impaired glucose tolerance: follow up rates in the community

A.J. Dawson[1], J.M. Ng[2], A.C.C. Teng[3], J.E. Patmore[2], E.S. Kilpatrick[4];
[1]Department of Diabetes and Endocrinology, University of Hull, [2]Department of Diabetes and Endocrinology, Hull and East Yorkshire NHS Trust, Hull, [3]Hull and East Yorkshire PCT, Hull, [4]Department of Clinical Biochemistry, Hull and East Yorkshire NHS Trust, Hull, United Kingdom.

Background and aims: Both impaired fasting glucose (IFG) and impaired glucose tolerance (IGT) convey an increased risk of developing type 2 diabetes (T2DM) in the future. Current guidelines advocate that patients with IFG, IGT or both are to be screened at least annually with either a oral glucose tolerance test (OGTT) or fasting plasma glucose.(FPG). We examined a group of patients with OGTT-diagnosed IFG and IGT to determine the proportion of patients who were subsequently retested based on these recommendations.
Materials and methods: All patients undergoing OGTT from Primary Care in our region between Oct and Dec 2006 were included in the analysis. Patients who were deceased over this period and patients tested for gestational diabetes were excluded from the analysis. Approval was obtained from the Trust Audit Department prior to this undertaking. Data for this study was obtained from the laboratory serving the whole population. The criterion for diagnosis of IFG and IGT were based on the WHO.
Results: There were a total of 683 patients included in the analysis. 199 patients were diagnosed with T2DM and 246 patients had either IGT or IFG. Of the 246 patients with IFG/IGT, (median (IQR) age 67 (54 to 74) years, 127F, 119M), 196 patients had repeat glucose testing in the following 26 months after a mean (SD) of 13(5.5) months. 59% (115/196) were screened using a repeat FPG and 41% (81/196) with an OGTT. Using FPG alone, 52 (45%) patients were noted to have persistent IFG and 11 (9.6%) patients had a glucose level of 7 mmol/L or higher. Repeat OGTT showed 15 (18.5%) patients with persistent IGT, 30 (37%) with IFG and 19 (23.5%) patients with both. 13 (16%) had a glucose level of 7 mmol/L or higher. Crucially, this meant 19% (47/246) of patients (median (IQR) age 60(41 to 69) years, 24F, 23M) did not have a repeat test at all over the 26 months from the initial diagnosis
Conclusion: Patients with IFG and IGT are at greater risk of developing future cardiovascular disease and T2DM It is also known that lifestyle intervention can reduce the risk of progression to T2DM. This data has shown that the follow-up of patients with IFG and IGT in primary care is not systematic, with approximately 1 in 5 patients with IFG and/or IGT not being followed up at all after 26 months of being diagnosed. There are challenges in moving more diabetes care from secondary to primary care environments. This study has shown that one of these challenges is to it develop a consistent means of recalling patients with abnormal OGTTs order to establish (and try to prevent) progression from IFG/IGT to T2DM.

1030

Clinical decision support delivered through EMRs improved glucose and blood pressure control in adults with diabetes

P.J. O'Connor[1], J.M. Sperl-Hillen[1], W.A. Rush[1], P.E. Johnson[2], G.H. Amundson[1], S.A. Asche[1], H.L. Ekstrom[1];
[1]HealthPartners Research Foundation, [2]Carlson School of Management, University of Minnesota, Minneapolis, United States.

Background and aims: Medical groups have invested billions of dollars in outpatient Electronic Medical Records (EMR), but few studies demonstrate a positive impact of EMR-based clinical decision support on clinically important patient outcomes. We conducted this randomized trial to assess the impact of an EMR-based diabetes clinical decision support system on control of glycated hemoglobin (A1c), blood pressure (BP) and LDL-Cholesterol (LDL) in adults with diabetes.
Materials and methods: The study was conducted from October 2006 to May 2007 in Minnesota. Eleven clinics with 41 consenting primary care physicians (PCP) and these physicians' 2556 diabetes patients were randomized either to receive or not to receive an EMR-based advanced pharmacologic and clinical decision support system designed to improve A1c, BP, and LDL in diabetes patients not at recommended clinical goals at the time of an office visit.
Results: Intervention group PCPs used the EMR-based decision support system at over 62.6% of all diabetes patient visits, and intensified drug therapy at 61.9%, 43.6% and 18.8% of visits with uncontrolled A1c, BP, and lipids, respectively. Intervention group diabetes patients had significantly better A1c (p=.014) and SBP (p=.035) but not LDL (P=.63) relative to patients of PCPs randomized to the control arm of the study based on general linear mixed models with a repeated time measurement to control for clustering. Additional analytic models that adjusted for patient age, gender, and comorbidity showed similar results. 94% of PCPs expressed satisfaction with the intervention, and moderate rates of use persisted for over a year after withdrawal of feedback and incentives to encourage use.
Conclusion: An EMR-based advanced pharmacologic and clinical decision support system significantly improved glucose control and BP control in adults with type 2 diabetes who were not at recommended clinical goals.

Management of diabetes in migrants - does ethnical background matter?

K. Schindler[1], H. Brath[2], M. Carballo[3], G. Vlaijc[1], B. Ludvik[1];
[1]Internal Medicine, Medical University Vienna, Austria, [2]Wiener Gebietskrankenkasse, Vienna, Austria, [3]International Center for Migration and Health, Geneva, Switzerland.

Background: Migrants constitute a growing part of the Austrian and European population. There seem to be barriers to the use of health services, access to appropriate treatment and knowledge transfer regarding diabetes due to cultural and religious particularities. We aimed to identify differences between diabetic subjects (TDM2) with different countries of origin regarding knowledge, treatment, as well as self-capacitance to take a responsibility for the diabetes management.
Methods: TDM2 -patients (first generation migrants from Serbo-Croatia (SC, n=52) and Turkey (T, n=54)) living in Austria, aged between between 35 and 60 years were randomly selected. Information was collected by structured interviews in their first language and anthropometry and glycemic parameters were recorded.
Results: Nearly all patients were overweight (T: 96%, SC 85%). Overweight T misclassified themselves regarding the weight category more often than SC

(22% vs.6%, p<0.05). Migrants, independent from the country of origin, were often diagnosed when already presenting with diabetes- related problems (T 79%, SC 77%). Most migrants were treated with oral antidiabetics (OAD)(T 63%, SC 60%) or a combination of OAD and insulin (T 21%, SC 15%). While knowledge regarding the medication was reported to be unproblematic (T 93%, SC 90%), one third of T did not know how to correct hypoglycemia (T 30%, SC 15%, p<0.05) and two thirds were not used to examine their feet for lesions (T 70%, SC 15%, p<0.0001). For both patient groups, physicians are the primary source of information (T 85%, SC 100%), nurses are nearly never experienced as a possible source of support (T 4%, SC 4%). The chance of gathering additional information about diabetes through internet or diabetes associations was completely unused. T report less often recommendation of lifestyle changes (diet: T 41%, SC 81% p<0.001; exercise: T 24%, SC 56% p<0.001). Implementation of dietary changes was difficult for nearly every second patient (T 56%, SC 44%). Regarding physical activity, more T reported difficulties with change (T 44%, SC 27%, p<0.05). Knowledge about causal factors was little in most patients. But there were differences between the groups (table 1). Noticeably, nearly every SC believed in a relationship between diabetes and stress.

Conclusion: We conclude that screening examinations for diabetes are not used by migrants independent of country of origin. All patients exhibit deficits in diabetes knowledge and its transfer into daily practise. Regarding knowledge and self-capacitance the country of origin matters and should be borne in mind when treating migrants with diabetes as well as when planning migrant oriented health promoting initiatives.

Table 1: Knowledge about causal factors for diabetes (% patients agree) #p<0.05 between T and SC

	Genetics	Age	Body weight	Nutrition	Excercise	Stress	God's will
T	33#	7#	37	35#	22	50#	13
SC	46	37	48	56	29	81	8

1032

Insulin dose titration system in diabetic patients using a short messaging service automatically produced by a knowledge matrix

C. Kim[1], J. Kang[1], S. Lee[1], E. Hong[1], S. Ihm[1], D. Kim[1], J. Yu[1], M. Choi[1], H. Yoo[1], K. Huh[2];
[1]Dept. of Endocrinology Hallym University Sacred Heart Hospital, Anyang, [2]Huh's Diabetes Clinic, Seoul, Republic of Korea.

Background and aims: We designed the system in type 2 diabetic patients treated with long acting insulin to produce an automatic adjustment of insulin dose based on real time glucose level data and to provide to the patients the needed insulin dose by using a short message service (SMS) and apply to the clinical practice.

Materials and methods: We developed the system to produce an automatic adjustment of insulin dose based on the mean fasting blood glucose (FBG) level for consecutive 3 days. Moreover we created a web site program (https://uc.healthkorea.net/UDang/dclinic/index.aspx) that was used to formulate messages of insulin dosage through an automated algorithm. By connecting specially designed glucometer to the cellular phone, the measured glucose data is automatically sent to patient's personal data sheet on the web site, then our system automatically composed messages that were then sent to the patient. According to the mean FBG level, patients were asked to increase in glargine dose by 6 U (≥ 180 mg/dL), 4 U (140~179 mg/dL), 2 U (120~139 mg/dL), respectively. If patients showed descended FBG levels for consecutive 3 days, the dose was adjusted based on the last measured day. If one FBG level is higher than 60 mg/dL compared with other levels measured for 2 days, the mean FBG level of other 2 days was used for dose adjustment. 100 type 2 diabetic patients suboptimally controlled on their previous antidiabetic treatment were included. Each participant was assigned to either the intervention or control group, each with 50 patients using adaptive randomization. We applied this system for 12 weeks in the intervention group. In the control group, a conventional titration schedule was used, seeking a target FBG of < 120 mg/dl. If the mean FBG level for consecutive 3 days of ≥ 120 mg/dL, patients were asked to increase in glargine dose by 2 U. In both group, 2 U decreases were allowed if any time glucose level of < 80 mg/dL, insulin dose was decreased by 4 U if glucose level of < 60 mg/dL. Then, we compared A1C and FBG after 12 week trial in both groups. The protocol was approved by the Ethics Committee of the Hallym University. Informed consent was obtained from each participant. Comparison of both groups was based on the independent t-test or Chi-square test, appropriately.

Results: 47 patients in the intervention group (47.8 ± 9.6 yrs, M = 24) and 45 patients in the control group (49.0 ± 10.7 yrs, M = 22) completed the experimental protocol over a 12 week period. A greater ($P = 0.023$) baseline to end point reduction in A1C was observed in the intervention group (9.8 ± 1.3 to 7.4 ± 0.7%) than in the control group (9.8 ± 1.2 to 7.8 ± 0.8%). The FBG after 4 weeks was lower ($P = 0.013$) in the intervention group (121.8 ± 35.9 mg/dL) than in the control group (141.4 ± 38.1 mg/dL), however, the reduction of FBG after 12 wks in the intervention group (200.1 ± 53.7 to 113.1 ± 15.3 mg/dL) was similar with the control group (196.3 ± 48.9 to 117.4 ± 26.5 mg/dL). The incidence of symptomatic, asymptomatic, nocturnal hypoglycemia was similar in both intervention and control groups. There was a small increase in body weight from baseline to end point with both intervention (2.4 ± 3.0 kg) and control group (2.2 ± 2.8 kg).

Conclusion: This study demonstrated that SMS based on our specialized internet supported system is an effective and safe approach to long acting insulin dose adjustment in patient with type 2 diabetes.

We thank "UBCare Company" for its large contribution to the development of our specialized system

1033

A nationwide diabetes campaign: Portuguese pharmacies identify uncontrolled diabetic patients

M.R. Horta, S. Costa, Z. Mendes;
Pharmacy-Based Disease Management Programs, National Association of Pharmacies, Lisbon, Portugal.

Background and aims: The National Association of Pharmacies (ANF) developed a model and tools for a national pharmacy-based intervention campaign targeted to adult patients on diabetes therapy, in collaboration with 2 medical societies in the field of diabetes disease. Tools provided included a Pharmacists' Intervention Protocol on Diabetes©, with capillary blood glucose recommended values, and a spreadsheet to document care provided. The Campaign was launched in November 2007 and was preceded by evening sessions for pharmacists held in the 3 major cities.

Aim: To assess capillary blood glucose (BG), out of reference values, in diabetic patients during the nationwide campaign.

Materials and methods: Between 12 and 17 November 2007, all diabetic patients aged 18 and higher on antidiabetic drugs were included in the Campaign. Pharmacists' intervention were focused on adherence to therapy, self surveillance counselling and capillary BG assessment.

Results: 1 763 pharmacies participated in the Campaign, out of which 723 have sent data to ANF (41.0%). 7 719 adult diabetic patients were assessed, an average of 13 patients per pharmacy. 57.2% were female and average age was 57. A high percentage of patients (91.2%) did not smoke and 36.2% had BMI over 30 kg/m^2. The majority (87.3%) of patients were on oral antidiabetic drugs (ADO), 7.6% were only on insulin and 5.1% were on combined insulin and ADO therapy. Pharmacists performed 11 102 measurements in the 5 days of the Campaign. Average postprandial BG values were 189.5 mg/dL and average fasting BG values were 144.8 mg/dL. Patients with high BMI tend to have higher fasting BG values (p<0.001). The % of patients with postprandial BG > 180 mg/dL or fasting BG > 130 mg/dL were 47%. Compared with the older patients (≥ 65 years old), younger patients have higher probability of having capillary BG within the recommended values (18-44 years old: OR=2.502, IC95%:[1.928-3.247]; 45-64 years old: OR=1.142, IC95%:[1.023-1.275]). Compared with those only on insulin therapy, the patients on ADO had higher probability of being within the recommended BG values (OR=1.297, IC95%:[1.061-1.587]) and the patients on combined ADO and insulin therapy had lower probability of being within the recommended BG values (OR=0.563, IC95%:[0.413-0.768]). A referral to the prescriber was reported for 23.9% of patients, out of which 72.7% had BG above the recommended values.

Conclusion: These results suggest pharmacists may have an important role in identifying diabetic patients with BG values out of the recommended targets, as well as, in reinforcing adherence to therapy and self surveillance counselling.

1034

Organizational characteristics influence quality of diabetes care. The QUASAR (quality assessment score and cardiovascular outcomes in Italian diabetes patients) study

M.C.E. Rossi[1], M. Comaschi[2], C. Coscelli[3], D. Cucinotta[4], P. Di Blasi[5], D. Merante[5], F. Pellegrini[1], U. Valentini[6], G. Vespasiani[7], A. Nicolucci[1];
[1]Clinical Pharmacology and Epidemiology, Consorzio Mario Negri Sud, S. Maria Imbaro [2]Emergency Dept, University Hospital S. Martino, Genoa, [3]Internal Medicine, A.O. Parma, [4]Internal Medicine, Policlinico Universitario, Messina, [5]GlaxoSmithKline S.p.A, Verona, [6]Diabetes Unit, Spedali Civili, Brescia, [7]Diabetes Unit, Madonna del Soccorso Hospital, S. Benedetto del Tronto, Italy.

Background and aims: While process and outcome measures are usually considered for quality of care profiling, the way diabetes care is organized and delivered can undoubtedly play an important role in achieving the desired results. We evaluated how structural and organizational characteristics influence process and intermediate outcome indicators in T2DM, taking patient case-mix into consideration.
Materials and methods: Seventy-eight clinics described their structure and organization and were classified in 3 levels of organizational complexity (high, intermediate, low). Each clinic collected data on 100 random patients, including frequency of HbA1c, blood pressure (BP), lipid profile, and renal function monitoring in the last 12 months and frequency of patients reaching HbA1c<=7%, BP<=130/85 mmHg, LDL-cholesterol<=100 mg/dl, and albumin/ creatinine ratio <=30 mg/g. Multilevel models were applied to identify correlates of the selected indicators.
Results: Overall, 6702 patients were enrolled. Structures with high complexity ensured the highest average number of visits per patient/year. The likelihood of monitoring HbA1c increased by 3 times (OR=3.06; 95%CI 1.14-8.24) for every additional unit in the average number of per-patient visits performed by the centre, while the likelihood of monitoring BP increased by over 4 times (OR=4.35; 95%CI 3.57-5.26). The chance of reaching levels of HbA1c<=7% increased by 62% (OR=1.62; 95%CI 1.01-2.61) for each additional unit in the number of per-patient visits. A lower level of complexity of organization was associated with a lower likelihood of achieving the BP target. Process indicators were not independently associated with outcomes.
Conclusion: Our study suggests that, in addition to process and intermediate outcome indicators, measures able to capture the complexity of structural/organizational aspects should be incorporated in any initiative to evaluate the quality of diabetes care. Diabetes clinics that provide better quality of care are those with higher level of organization and able to ensure an adequate frequency of encounters with patients.

Screening for deprivation using EPICES score: a tool to detect patients at high risk of diabetic complications

M. Ramentol[1,2], C. Auclair[3], L. Gerbaud[3], E. Robu[1], F. Desbiez[1], P. Thieblot[1], I. Tauveron[1];
[1]Diabetes, CHU G. Montpied, [2]UFR medecine, [3]Public Health, CHU Hotel Dieu, Clermont-ferrand, France.

Background and aims: Several studies reported that deprivation was associated with complications in diabetic patients. We hypothesized that screening for deprivation could lead to a more intense action to try and prevent complications. We analyzed the interest of a deprivation score, EPICES (Evaluation of Precarity and Inequalities in Centres d'Examens de Santé), validated in the French general population.
Materials and methods: The study was developed in a single hospital diabetes center from November 2006 to July 2007. Diabetic patients were split in two groups, either deprived (EPICES score > 30.17), or not. Diabetes control, estimated by HbA1c, and prevalence of chronic complications were compared between the two groups, as well as the quality of life, estimated by SF-36 questionnaire.
Results: Of the initial 102 patients, 97 subjects, among which 18 type 1 and 79 type 2 diabetics ,were included in the trial. Interestingly, HbA1c was not correlated to EPICES score. Yet nephropathy was associated with deprivation ($p = 0.049$) and possibly neuropathy ($p = 0.06$; NS). No other complication seemed to be linked to deprivation. Deprived diabetic patients presented with more co morbidities : excess weight ($p = 0.001$), lower HDL-cholesterol ($p = 0.04$). Eventually, quality of life, in all aspects of daily life, was much lower in deprived diabetic patients.
Conclusion: Our results demonstrated that even in an area of moderated deprivation intensity (mixed rural and urban population in Central France), a high EPICES score, an individual index of deprivation, is associated with nephropathy, higher cardiovascular risk factors and lower quality of life in diabetic patients. EPICES score is therefore an easy to calculate useful tool to detect diabetic patients needing specific focus on management of their disease.

Better %HbA_{1c} control among type 2 diabetes patients is associated with higher patient-reported satisfaction with treatment: a meta-analysis of trial results

M.J. Atkinson[1], Q. Zhang[2], D.D. Smith[3], J.M. Boltri[4], W.D. Smith[5];
[1]HEOR Specialist PRO-Spectus & UCSD Health Services Research Center, San Diego, [2]sanofi-aventis US, Bridgewater, [3]City of Hope National Medical Center, Duarte, [4]Mercer University School of Medicine/Medical Center of Central Georgia, Macon, [5]The University of Texas M. D. Anderson Cancer Center, Houston, United States.

Background and aims: We tested the hypothesis that control of HbA1c associated with current treatments for Type 2 diabetes mellitus (DM) increase patients' satisfaction with treatments. Data were obtained from an empirically-based systematic literature review of 280 randomized controlled trials examining medications used to treat Type 2 DM published after 1998. After restricting the articles to adult samples and removing duplicates, we identified 230 articles for consideration. Fourteen of these studies provided quantitative assessment of patient self-reported satisfaction measures associated with treatment-related changes in %HbA1c.
Materials and methods: Fourteen randomized clinical studies where included that involved Type 2 DM patients (n = 2880) that included both patient-reported treatment satisfaction surveys and treatment-related changes in %HbA1c from baseline. %HbA1 changes were standardized using Hedge's g effect size statistics with positive values indicating improvement from baseline. After standardization, we then performed a fixed effects meta-regression on changes in treatment satisfaction; assessed almost exclusively using the Diabetes Treatment Satisifaction Questionnaire (11/14 articles). Both of these meta-analytic methods were applied to: 1) all scales measuring any aspect of treatment satisfaction, and 2) scales which measured overall satisfaction or product preference.
Results: Our fixed effects meta-analysis revealed a statistically significant improvement in treatment satisfaction with a improvements %HbA1c from baseline ($p < 0.0001$). The effect size in the meta-analysis resulted in a positive mean difference with a point estimate and 95% CI of 0.51 (95% CI: 0.47 to 0.55). When we pooled studies in a meta-regression, the slope of the association between %HbA1c change and all treatment satisfaction scales was 0.50 (95% CI: 0.44 to 0.56), $p < 0.0001$. In a meta-regression on overall satisfaction or product preference versus %HbA1c change, the slope of the association was 0.78 (95% CI: 0.70 to 0.87), $p < 0.0001$ (see Table).
Conclusion: Our meta-analyses on randomized controlled trials showed a significant, positive improvement in patients' self-reported treatment satisfaction scores when associated with a positive baseline change in %HbA1c. We can conclude that, for every percentage point improvement in %HbA1c over time, Type 2 DM patient satisfaction improves by 10-20%.

Obesity increases healthcare resource use in patients with type 2 diabetes: a UK database analysis

B.P. Wilson[1], L. Watson[2], J. Alsop[2], S. Kumar[3];
[1]Eli Lilly & Co Ltd, Basingstoke, [2]Louise Watson Consulting Ltd, Buxton, [3]WISDEM, University Hospital, Coventry, United Kingdom.

Background and aims: Little information is available on resource use and diabetic medication prescribing by BMI category in type 2 diabetic (T2DM) patients in general practice in the United Kingdom. This study was designed to investigate these factors from the time of insulin initiation.
Materials and methods: A cohort of patients with diagnostic codes for T2DM was selected from the General Practice Research Database (GPRD) for the period January 1st 2002 - March 31st 2008. No patient had been prescribed insulin in the 6 months prior to the first insulin prescription (index date). Additionally patients had to have ≥ 2 further prescriptions for insulin in the 12 months post index date as well as ≥ 2 BMI and ≥2 HbA1c recordings (one baseline, one post index). Patients also had to have a minimum of 12 months data post the index date. The cohort was stratified into BMI categories at the time of insulin initiation: normal (18.5-24.9 Kg/m^2); overweight (25.0-29.9 Kg/m^2); obese (30.0-34.9 Kg/m^2); clinically obese (35.0-39.9 Kg/m^2); morbidly obese (≥40 Kg/m^2). Prescribed insulin quantities were used to estimate daily insulin requirements at 6, 12, 18 and 24 months. Oral diabetic drug prescribing, GP visits and hospital referrals were calculated and stratified by patients' BMI category in the first year after initiation and in year 2. Rates were calculated with 95% confidence intervals and presented per 100 patient years of observation.
Results: 3783 patients fulfilled the inclusion criteria (normal weight, n=672; overweight, n=1259; obese, n=1070; clinically obese, n=480; morbidly obese, n=302). Mean daily insulin requirement appeared relatively stable between 6-24 months post initiation in normal weight patients (41 [SD 30] rising to 45 [SD 36]units/day) but appeared to increase in all other groups e.g. clinically obese 67 [SD 50] rising to 78 [SD 60] units/day). The rate of oral diabetic therapy prescribed was statistically signficantly higher with increasing BMI, ranging from 699 scripts per 100 patient-years (95% CI 680,720) in normal weight patients to 1066 scripts (95%CI 1038,1095) in clinically obese. GP visit rates for diabetes increased signficantly by BMI from 40.0 per 100 patient-years (95%CI 36.4, 43.8) in normal weight up to 55.7 (95%CI 51.3,60.1) in the clinically obese. Secondary care non-diabetes referrals increased signficantly with BMI from 70.7 per 100 patient-years (95%CI 67.2,74.0) in normal category to 85.2 (95%CI 81.7, 88.1) in clinically obese.
Conclusion: The results from this study indicate that patients who are obese have higher resource use including oral diabetic agents and higher daily insulin requirements as well as higher rates of GP and secondary care non-diabetes referrals.

Cost and resource use following insulin initiation in Europe: 24-month follow up data from the INSTIGATE study

H.T. Smith[1], A. Liebl[2], S. Jones[3], M. Benroubi[4], C. Castell[5], A. Goday[6], C. Nicolay[7], A. Simpson[1];
[1]Eli Lilly & Co, Surrey, United Kingdom, [2]Fachklinik Bad Heilbrunn, Germany, [3]James Cook University Hospital, Middlesbrough, United Kingdom, [4]Polyclinic General Hospital, Athens, Greece, [5]Department de Salut, Barcelona, Spain, [6]Hospital del Mar, Barcelona, Spain, [7]Eli Lilly & Co, Bad Homburg, Germany.

Background and aims: INSTIGATE is a prospective observational study in Europe, investigating patients with type 2 diabetes (T2DM) who initiate insulin during usual care. Follow up data to 24 months (m) were collected in Germany (De), Greece (Gr) and Spain (Es). The primary objective of the study was to assess the direct costs of care for T2DM following insulin initiation.
Materials and methods: Direct costs of diabetes care were calculated by assigning local unit costs (2006) to data collected at each visit on individual resource use (diabetes medication; blood glucose monitoring (BGM); and for the period since the last visit, contact with health care professionals (HCPs) and diabetes related hospitalisations). Reported costs and resource use are for the 6m prior to insulin initiation (baseline) and the 6m between study visits.
Results: Of 726 patients entering the study (De 256; Gr 263; Es 207) in these 3 countries, 564 (De 155; Gr 237; Es 172) had at least a 12m visit and 498 (De 119; Gr 227; Es 152) were followed to 24m. In all three countries median and mean total direct cost of diabetes care increased in the first 6m following insulin initiation then fell and remained reasonably stable over the following 18m (Figure 1). In Gr and Es median costs fell to around the baseline level. In De median costs remained higher than prior to insulin initiation. The main contributors to total costs differed between countries. In De patients were prescribed more intensive insulin regimens (at 6m 79% of patients (119/151) were on prandial based regimens) with mean 3.4 injections per day. In contrast in Gr and Es at 6m; 78% (185/237) and 88% (152/172) respectively were prescribed either basal only or premix only and the mean daily injections were Gr 1.9 and Es 1.4 although OAD usage was higher than in De. There were few changes in insulin regimens over the first 24m. BGM was a major component of total cost. Prior to insulin initiation patients monitored approx. once per day (mean strips/week De 8; Gr 7; Es 7). Following insulin initiation this increased in De to 3 times daily, but changed little in the other countries. In the 6m following initiation mean strips per week were De 21, Gr 8, Es 8; and 18 to 24m following initiation De 21, Gr 8, Es 7. Mean total contact (number of visits & phone calls) with HCPs in the 6m prior to initiation were De 12, Gr 8, Es 10; rising in the 6m following initiation to De 15, Gr 10, Es 12; and falling thereafter, at 18 to 24m following initiation total contacts were De 6, Gr 4, Es 7. There were few hospitalisations in any country
Conclusion: There are considerable additional direct costs associated with starting insulin therapy, particularly during the first 6m, but the cost burden reduces over time. The main contributing factors for cost were BGM and insulin.

Swedish patients with type 2 diabetes show willingness-to-pay for health improvements including weight loss, reduction in hypoglycaemia and glycaemic control

J. Jendle[1], O. Torffvit[2], M. Ridderstråle[3], M. Lammert[4], Å. Ericsson[5], M. Bøgelund[6];
[1]Faculty of Health Sciences, Örebro University Hospital, Sweden, [2]Department of Nephrology, Lund University Hospital, Lund, Sweden, [3]Department of Clinical Sciences, Lund University Hospital, Lund, Sweden, [4]Novo Nordisk Scandinavia, Copenhagen, Denmark, [5]Novo Nordisk Scandinavia, Malmö, Sweden, [6]Incentive Partners, Birkerød, Denmark.

Background and aims: Patient preference for treatments and interventions do not always concur with the physicians' choice or scientific evidence base. This study aimed to investigate the most important aspects of diabetes medication, as measured by the patients' willingness-to-pay (WTP), an indication of patient preference.
Materials and methods: The WTP survey used a discrete choice experiment methodology to evaluate the convenience and clinical effects normally associated with type 2 diabetes treatments. Patients in Sweden were recruited using an existing nationwide e-mail panel administered by GfK Health Care. Patients were included if they were adults (≥18 years) with type 2 diabetes and currently receiving antidiabetic medication(s). Data were collected electronically between September 2008 and November 2008, and results were analysed using a standard statistical model designed for choice games (con-

ditional logit). The WTP was examined for 6 characteristics: weight (gain or loss), HbA_{1c} levels, hypoglycaemic events, nausea, injections (with or irrespective of meals) and blood glucose monitoring.
Results: In total, 461 of 537 (86%) patients with type 2 diabetes completed the internet questionnaire and were eligible for inclusion. The survey sample matched the National Diabetes Register (NDR) in Sweden for all key parameters such as age, duration of diabetes, HbA_{1c} level and BMI, except gender distribution (291 males; 170 females). Patients placed the highest value on the avoidance of weight gain; they needed to receive as much as 795 Swedish kronor (SEK) per month in order to accept a 3kg weight gain. They would also pay as much as 528 SEK per month to lose 3kg. Women were more concerned about gaining weight than men (p=0.0074) and obese patients (BMI>30 kg/m^2) had a higher WTP to lose 6kg compared with non-obese patients (BMI≤30 kg/m^2; p<0.0001). Patients wanting to reduce the number of hypoglycaemic events from two per month to none were willing to pay 419 SEK per month. Patients who had never experienced a hypoglycaemic event had a significantly higher WTP (300 SEK per month) to avoid them completely than patients already experiencing hypoglycaemic events (p=0.0004). Patients valued a 1% reduction in HbA_{1c} level at 414 SEK per month. Patients would require 140 SEK per month in order to accept a 25% risk of medication-related nausea. Participants preferred taking tablets to injections and required a compensation of 376 SEK to accept one injection. Patients already taking tablets did not have a higher WTP to avoid injections than those already having injections. Injections irrespective of meals were preferred to injections with meals (WTP: 140 SEK per month).
Conclusion: Patients were willing to pay a considerable amount of money each month for the health benefits associated with improved diabetes treatment. In particular, patients wanted to avoid gaining weight above other benefits.
Notes: Exchange rates: 100 SEK = 9.15 EUR or 12.41 US$ (26 March 2009)

1040

Patient willingness-to-pay for liraglutide and exenatide in Sweden based on head-to-head clinical trial results

M. Ridderstråle[1], O. Torffvit[2], M. Lammert[3], B. Nilsen[4], M. Bøgelund[5], J. Jendle[6];
[1]Department of Clinical Sciences, Lund University Hospital, Lund, Sweden, [2]Department of Nephrology, Lund University Hospital, Lund, Sweden, [3]Novo Nordisk Scandinavia, Copenhagen, Denmark, [4]Novo Nordisk Scandinavia, Malmö, Sweden, [5]Incentive Partners, Birkerød, Denmark, [6]Faculty of Health Sciences, Örebro University Hospital, Sweden.

Background and aims: Liraglutide is a once-daily human glucagon-like peptide-1 (GLP-1) analogue. As part of the Phase III trial programme the LEAD-6 (Liraglutide Effect and Action in Diabetes 6) trial compared liraglutide 1.8 mg once-daily with exenatide 10 μg twice-daily as add-on to oral antidiabetic drug therapy. Here we assessed patients' willingness-to-pay (WTP) for liraglutide versus exenatide by applying clinical data from LEAD-6 to results generated by a willingness-to-pay (WTP) survey. The WTP survey investigated patients' preferences and WTP for the most important aspects of diabetes medication.
Materials and methods: The LEAD-6 trial was a 26-week, randomised, open-label, parallel group study in patients with type 2 diabetes who were either taking liraglutide 1.8 mg once-daily irrespective of meals (n=233) or exenatide 10 μg twice-daily at the two main meals (n=231). The WTP survey involved 461 participants with type 2 diabetes from Sweden. The electronic WTP survey used a discrete choice experiment methodology to evaluate the convenience and clinical effects of treatments associated with type 2 diabetes. The values from the WTP study were applied to the efficacy and safety data from the two treatment groups in LEAD-6.
Results: The main results from LEAD-6 were differences in change in HbA_{1c} levels (liraglutide -1.12%; exenatide -0.79%, p<0.0001), change in BMI (liraglutide -1.145 kg/m^2; exenatide -1.015 kg/m^2, NS), minor hypoglycaemia rate/month (liraglutide 0.161; exenatide 0.217, p=0.0131), change in SBP (liraglutide -2.51 mmHg; exenatide -2.00 mmHg, NS), and difference in the frequency of nausea (equivalent to a 4.9 % and 12.1% of subjects in liraglutide and exenatide groups respectively with nausea for the 26 weeks trial period) (p not available). Analysing the data with the results from the WTP survey revealed that patients were willing to pay an extra 17 Swedish kronor (SEK) per day in the first year of treatment for liraglutide compared with exenatide. The largest component of this WTP amount was the once-daily dosing of liraglutide; patients were willing to pay an extra 10 SEK per day to reduce drug administration to once per day irrespective of meals (liraglutide) from twice a day in relation to meals (exenatide). They would also pay an extra 5 SEK per day to reduce their HbA_{1c} levels to a greater extent with liraglutide compared with exenatide. Patients were willing to pay 1 SEK per day for the relative reductions in SBP and BMI with liraglutide compared with exenatide, and were willing to pay an extra 0.7 SEK per day in the first year to take liraglutide to reduce their incidence of nausea. Despite a significant difference in minor hypoglycaemic event rates between liraglutide and exenatide, patients were not willing to pay more than 0.2 SEK per day extra to receive liraglutide on this basis.
Conclusion: Patients were willing to pay 17 SEK per day to use liraglutide rather than exenatide. Willingness-to-pay can be calculated for any combination of investigated effects and can be used to make comparisons between treatments from a patient perspective.
Notes: Exchange rates: 100 SEK = 9.15 EUR or 12.41 US$ (26 March 2009)

Cost-effectiveness of motivational enhancement therapy with and without cognitive behaviour therapy for type 1 diabetes

A. Patel[1], E. Maissi[2], I. Rodrigues[3], M. Smith[2], J. Bartlett[4], S. Thomas[5], T. Chalder[2], U. Schmidt[2], J. Treasure[2], K. Ismail[2];
[1]Health Service & Population Research, Institute of Psychiatry, [2]Psychological Medicine & Psychiatry, Institute of Psychiatry, [3]King's College London School of Medicine, [4]Medical Statistics Unit, London School of Hygiene & Tropical Medicine, [5]Guys & St Thomas' Hospitals, London, United Kingdom.

Background and aims: Diabetes' high prevalence, chronic nature and association with complications incur substantial costs for services, patients and wider society, necessitating cost-effective approaches to treatment and long-term management. We examined the cost-effectiveness of two manualised psychological treatments for adults with Type 1 diabetes (T1DM) as part of a multi-centre randomised controlled trial in the absence of such evidence.
Materials and methods: A representative sample of adults with T1DM and persistent suboptimal glycaemic control (HbA1c >8.2%) were recruited from 8 UK hospital diabetes clinics and randomised to motivational enhancement therapy (MET), MET + cognitive behaviour therapy (MET+CBT) or usual diabetes care. We measured costs and health (HbA1c improvement) and quality of life (quality-adjusted life years; QALYs) outcomes over one year. Health care and societal costs (2005/06 prices) were estimated from resource use data collected by interview at 6 and 12 months. Outcomes and costs were linked/compared between groups using incremental cost-effectiveness ratios (ICERs) and cost-effectiveness acceptability curves (CEACs).
Results: 344 participants were randomised to MET (n=117), MET+CBT (n=106) and usual care (n=121); 62%, 69% and 58% of each group respectively had requisite cost and outcome data for the economic evaluation. Only MET+CBT produced a statistically significant HbA1c improvement (+0.45 compared to usual care; 95% CI: 0.10 to 0.78) and neither intervention significantly increased QALYs. Mean costs of the psychological interventions were £195 for MET and £660 for MET+CBT. Both interventions led to significantly higher mean total health care costs compared to usual care alone: +£535 (95% CI: 171 to 857) in MET group and +£790 (95% CI: 5.7 to 1072) in the MET+CBT group. Societal costs were also higher but not statistically significant. ICERs for additional HbA1c point improvements ranged from £514 (MET+CBT vs. MET) to £3,821 (MET vs. usual care) from the health care perspective. At thresholds of £5,000 or higher for an additional HbA1c point improvement, the probability of MET+CBT being cost-effective compared to MET or usual care exceeded 0.7; probabilities for MET versus usual care were lower. Due to minimal QALY differences between groups, cost-effectiveness conclusions based on these were unfavourable for both interventions, although better for MET than MET+CBT: the minimum ICER was £48,636 (MET vs. usual care, health care perspective) and probabilities of cost-effectiveness peaked at 0.39 (MET vs. usual care, societal perspective) for thresholds up to £45,000 per QALY gain.
Conclusion: Additional costs of the two psychological interventions were not offset by savings elsewhere within one year. MET+CBT had high chances of cost-effectiveness based on HbA1c outcomes; conclusions were broadly more favourable in relation to this outcome than QALYs. Treatment provision decisions should thus account for the relative importance of these two outcomes.

Assessment of healthcare resource utilization among type 2 diabetic patients with pre-existing macrovascular comorbidities in Europe: a matched cohort study

P. Mavros[1], Y. Qiu[1], L. Radican[1], D. Yin[1], A.Z. Fu[2];
[1]Global Outcomes Research & Reimbursement, Merck & Co. Inc.,
[2]Quantitative Health Sciences, Cleveland Clinic, Whitehouse Station, United States.

Background and aims: T2DM is a chronic metabolic disorder characterized by hyperglycemia and associated with significant morbidity. This may be particularly so among patients with pre-existing macrovascular conditions (MVC). This study was undertaken to examine differences in healthcare resource utilization between T2DM patients with and without pre-existing MVC in Europe.
Materials and methods: This is a matched cohort study based on the Real-Life Effectiveness and Care Patterns of Diabetes Management (RECAP-DM) study, a multi-center, observational study with retrospective medical chart reviews of T2DM patients in Spain, France, UK, Norway, Finland, Germany, and Poland. Included patients were aged ≥30 year at time of diagnosis of T2DM and added a SU or a TZD to failing metformin monotherapy (index date), and had pre-existing (i.e., with onset date prior to index date) MVC. A control cohort with T2DM but without pre-existing MVC was identified using 1:1 propensity score matching. Logit models were used to identify the relationship between pre-existing MVC and the likelihood of emergency room admission, receiving medical/surgical procedures, and hospitalization during the study period. Negative binomial models were used to predict the number of office visits and length of hospital stay per year attributable to the pre-existing MVC.
Results: Of the 453 patients with pre-existing MVC (cases) and eligible for inclusion, 64% were male, mean (SD) age and time from T2DM diagnosis was 64.5 (9.1) and 6.2 (5.3) years, respectively. HbA_{1c} prior to the index date was 8.0 (1.2). Relative to controls, patients with pre-existing MVC were significantly more likely to report emergency department admissions (Odds Ratio 3.1; 95%CI 1.8-5.2), receiving medical/surgical procedures (OR 2.72; 95%CI 1.7-4.3), and hospitalizations (OR 2.6; 95%CI 1.7-4.0) after controlling for other predictors. Similarly, pre-existing MVC was associated with 2.9 additional office visits per year ($p<0.001$) and 0.41 days of hospital stay per year ($p=0.004$).
Conclusion: This study found that T2DM patients with pre-existing MVC were more likely to use various types of healthcare resources.

Pharmacoeconomic analysis for the future treatment of diabetes mellitus after gestational diabetes

S.Z. Zacharieva[1], K.N. Todorova - Ananieva[2], E.I. Konova[3], V.B. Petkova[4], S.R. Guerguiev[5], Z.D. Dimitrova[5];
[1]Clinical Center of Endocrinology and Gerontology, Medical University, Sofia, [2]High-risk Pregnancy Department, Special Hospital of Obstetrics and Gynaecology, Sofia, [3]Clinical Institute of Reproductive Medicine, Pleven, [4]Department of Social Pharmacy, Medical University, Sofia, [5]Department of Social Pharmacy, Medical University, Plovdiv, Bulgaria.

Background and aims: To outline the risk of developing Diabetes Mellitus (DM) during the first year after giving birth for women with previous Gestational Diabetes Mellitus (GDM), as well as to estimate the social efficiency value of the applied prophylactic method.
Materials and methods: The study has been performed among 50 women, with GDM for one year after delivery. During that period a prophylactic program has been applied for DM prevention. The social efficiency of the applied prophylactic method is presented using the "decision tree" model. All indirect costs for future DM treatment are presented, as well as calculations are given for the disability adjusted life years (DALY).
Results: DM has been observed at 13 (or 26%) out of 50 women with previous GDM in the first year after birth delivery. The total cost per women for the applied preventive programme have been calculated at 12.1€. The total annual expenses for future treatment and control of a women with type 2 DM and good metabolic control is 98.9€, for satisfying metabolic control - 122.1€ and for poor metabolic control - 241.8€. The total annual expenses for future treatment and control of one women with type 1 DM and good metabolic control is 241.8€, for satisfying metabolic control - 303.7€, and for poor metabolic control. The social cost of late diagnosed or complicated type 2 DM is 10,994.80 €. The cost for the complicated type 1 DM treatment is 20,979.38 € at 5% discount. The rate of DALY also varies according to the rate of diabetic complications. The calculated DALY for women with DM at stage of disability are: - 10.1 year for women with DM with no complications, 12.1 years for women with DM and a mild rate of complications, 13.6 years for women with DM and with moderate complications and 15.1 years for women with DM and a severe rate of complications.
Conclusion: Future DM treatment costs depend entirely on the extent of metabolic compensation, probability for later complications and the method of treatment. However, the prophylactic screening the women with previous GDM can considerably save these costs.

Health care expenditures following initiation of insulin glargine or exenatide in type 2 diabetic patients on oral agents in US

W.H. Herman[1], Q. Zhang[2], J. Rosenstock[3];
[1]University of Michigan, Ann Arbor, [2]sanofi-aventis US, Bridgewater, [3]Dallas Diabetes and Endocrine Center, Dallas, United States.

Background and aims: Increasing health care expenditures are a significant challenge when deciding on an effective course of treatment for type 2 diabetes.
Materials and methods: A managed care database of 47 health plans was analyzed between May 2005 and September 2007 to evaluate health care expenditures after initiation of insulin glargine (GLAR; n= 15,695) or exenatide (EX; n= 21,516) in T2DM patients treated with only oral antidiabetic agents (OAD) during the 6 months (baseline) prior to initiation.
Results: Baseline characteristics for GLAR patients vs EX patients, respectively, were mean age, 54 vs 53 years; female, 43% vs 54%; glycated hemoglobin A1C, 9.5% vs 7.9%; hypoglycemia rate on OADS, 4.8% vs 2.7%; use of endocrinologist care, 16% vs 31%; retinopathy, 9.8% vs 7.8%; nephropathy, 5.4% vs 2%; neuropathy, 9% vs 8.3%; myocardial infarction, 3.5% vs 1.1%; and any history of pancreatitis, 1.5% vs 0.3%. Baseline hospitalization rate was 22% vs 5% in GLAR vs EX with 7.5 vs 3.5 hospital days and 22% vs 12% emergency service use, respectively, reflecting possibly a sicker population in the GLAR group. Baseline health plan expenditures for GLAR vs EX, respectively, were as follows: for antidiabetic medications, $626 vs $673; for all medications, $1,805 vs $1,986; for diabetes-related non-pharmacy inpatient and outpatient medical services, $3,206 vs $1,022; and for total medical services, $9,044 vs $2,956. During the year post initiation, 5% in the GLAR group started EX, and 11% in the EX group started insulin. The 1-year adjusted health plan total expenditures for all medical and pharmacy utilization (glucose monitoring supplies not available), were $25,596 vs $26,566 ($\Delta$=$970, $P<0.001$) for GLAR vs EX, respectively (after adjustment for baseline age, sex, total health care expenditures, hospitalization, and Charlson comorbidity). After accounting for concomitant medications, the total expenditures were $24,852 for GLAR vs $27,219 for EX ($\Delta$=$2,368, $P<0.001$). Pair-wise comparisons for GLAR vs EX showed lower 1-year expenditures for antidiabetic drugs (Δ=$419, $P<0.001$), total medications (Δ=$246, $P<0.001$), diabetes-related medical (Δ=$730, $P<0.001$) and total medical (Δ=$207, $P=0.486$).
Conclusion: This retrospective analysis showed lower health care expenditures 1 year following initiation of GLAR compared with initiation of EX. However, differences in patient populations may have affected the results despite adjustment. Our findings require further confirmation with well-designed prospective real-world studies.

Cost-effectiveness analysis of medical intervention in patients with early detection of diabetic nephropathy in a tertiary care hospital in Bangladesh

S.H. Habib[1], S. Saha[1], S. Akter[2], L. Ali[1];
[1]Health Economics Unit, BADAS, [2]Dept of Biochemistry & Cell Biology, BIRDEM, Dhaka, Bangladesh.

Background and aims: The economic burden resulting from diabetic nephropathy (DN) consumes a major portion of resources allocated for healthcare services. Cost-effectiveness of various interventions on DN & its complications has relatively been well explored in developed countries, but these are almost absent in developing countries. The present study was undertaken to assess the cost-effectiveness of medical intervention in patients with DN.

Materials and methods: Two hundred patients with DN, with at least 1 year of follow-up, were purposively selected from Out Patient Department of BIRDEM (tertiary diabetes care hospital), Bangladesh. Of them 100 were late in detection of DN and 100 were detected early. The degree & extent of complications like cardiopathy, peripheral neuropathy, retinopathy & vasculopathy, treatment outcome, clinical effectiveness of interventions and direct, indirect & incremental cost of complications were calculated. Comparison was made between the groups. Cost included drugs, hospitalizations, diagnostics & visits.
Results: A total of 200 patients were considered for an average of 365 days, amounting to 651 person-years of observation in total. The mean±SD serum creatinine of the groups (LDN & EDN respectively) was 4.90±1.17 & 0.89±0.03 mg/dL, fasting serum glucose was 9.36±0.40 mmol/l & 4.78±0.38 mmol/l, total cholesterol was 206.50±42.60 & 104.20±35.50 mg/dl, HbA_{1c} was 9.80±0.50% & 5.70±0.38%, TG was 163.76±99.46 & 155.67±94.84 mg/dl. About 19% patients in LDN & 36% in EDN were free of diabetic complications other than DN. In LDN, 20% had one complication, 29% had two & 32% had more than two complications. On the other hand, in EDN the corresponding values were 48%, 10% & 6% respectively. The most frequent complication was cardiopathy, which affected 33% patients in LDN & 27% in EDN, followed by peripheral neuropathy 21% & 18%, retinopathy 17% & 13%, and vasculopathy 10 % & 6% respectively. The average annual cost of care was US$ 27954 (direct US$ 16983 & indirect US$ 10971), with an average US$ 140 per patient. Among the average annual cost LDN consumed US$ 19837 (US$ 198 per patient) & EDN US$ 8117 (US$ 81 per patient). US$ 13473 (48%) of costs was attributable to drugs for both groups of which US$ 10817 (80%) was for LDN & US$ 2656 (20%) for EDN, US$ 8739 (31%) to hospitalizations of which US$ 5211 (60%) for LDN & 3528 (40%) for EDN. In case of diagnostics & visits the corresponding values were US$ 2136 (60%) & 1419 (40%) and US$ 1673 (76%) & 514 (24%) for LDN & EDN respectively. The annual medical costs increased with the increased number of complications from US$ 1320 to 2296 & to 3989 in LDN with one, two & more than two complications (other than DN) which is increasing at a rapid rate and US$ 917 to 1556 & to 2372 in EDN respectively, increasing at a diminishing marginal rate. The regression equation showed that medical cost is significantly related to complications tested in both univariate (P<0.0001) & multiple linear regression analyses (R^2=0.52; F=82.3, P<0.0001).
Conclusion: Proper management with regular screening substantially reduces the expenditure related to care of patients with diabetic nephropathy & related complications even in a developing country. Strategies aimed at preventing diabetic nephropathy & early detection of the onset of nephropathy complication will reduce medical costs in a substantial way.

Defensive role of mitochondrial fusion against podocyte injury in diabetic nephropathy

E. Koh[1], M. Kim[2], R. K.C.[3], S. Lee[1], E. Kim[1], W. Lee[1], I.-K. Lee[4], H. Jang[5], J.-Y. Park[1], I.-S. Park[3], K.-U. Lee[1];
[1]Internal Medicine, University of Ulsan College of Medicine, Seoul, [2]Asan Institute for Life Sciences, Seoul, [3]Anatomy, College of Medicine, Inha University, Incheon, [4]Internal Medicine, Kyungpook National University School of Medicine, Daegu, [5]Internal Medicine, Seoul National University College of Medicine, Republic of Korea.

Background and aims: Podocytes are highly specialized cells covering the exterior glomerular basement membrane surface of the glomerular capillary, and constitute the final barrier to prevent albumin excretion from the kidney. Podocyte injury is one of the main events that lead to diabetic nephropathy. Podocytes have large amount of mitochondria, but pathogenic role of podocyte mitochondria in diabetic nephropathy is unknown. We unexpectedly found that podocyte mitochondria in animal models of diabetic nephropathy are elongated. We thus investigated the pathogenic role of this mitochondrial pathology (mitochondrial fusion) in diabetic nephropathy.
Materials and methods: Podocyte mitochondrial morphology was examined in the kidneys of two animal models of diabetic nephropathy; Otsuka Long-Evans Tokushima Fatty (OLETF) rats, obese type 2 diabetic animals, and streptozotocin-induced diabetic rats that underwent unilateral nephrectomy. We also examined the effects of combination of various risk factors of diabetic nephropathy i.e., high glucose, high free fatty acid and angiotensin (GFA), on cell apoptosis and mitochondrial morphology in cultured podocytes.
Results: OLETF rats exhibited pronounced albuminuria from 20 weeks of age ($P < 0.001$ vs age-matched control LETO rats). Focal and segmental sclerotic lesions and an increase in desmin expression, a marker of podocyte injury, were noted in the kidney of OLETF rats at 44 weeks of age. Electron microscopy showed extensive effacement with distorted interdigitation of foot processes in podocytes of OLETF rats. In addition, elongation of mitochondria was seen in podocytes of OLETF rats, starting from 12 weeks of age and peaking at 32 weeks of age. This elongation (fusion) of mitochondria was not found in mesangial cells or endothelial cells. At 44 weeks, discontinuation and obliteration of mitochondrial cristae were also noted, and mitochondrial number was markedly lower in OLETF rats than in LETO rats ($P < 0.05$). Consistent with the results in OLETF rats, mitochondrial elongation was also found in the podocytes of type 1 diabetic rats that underwent unilateral nephrectomy. GFA induced significant cellular apoptosis in cultured podocytes ($P < 0.001$ vs untreated cells). Podocytes cultured with GFA displayed morphologic features of fusion and also an increase in the expression of fusion-associated protein, OPA1. OPA1 expression in podocytes was preceded by an increase in the mitochondrial reactive oxygen species (ROS) production as measured by mitoSOX. In addition, downregulation of OPA by siRNA significantly increased cellular apoptosis and mitochondrial ROS production ($P < 0.05$ vs control siRNA-transfected cells), indicating that mitochondrial fusion is an adaptive process to prevent podocyte apoptosis in states of high ROS.
Conclusion: Podocyte mitochondrial fusion is a defensive mechanism that protects the cells from injury in diabetic nephropathy. Podocyte mitochondrial fusion machinery can become a previously unrecognized target to control diabetic nephropathy.

FT011, a novel synthetic anti-fibrotic drug attenuates the progression of experimental diabetic nephropathy

R.E. Gilbert[1], Y. Zhang[2], S. Williams[2], S. Zammit[2], H. Krum[3], D.J. Kelly[2];
[1]University of Toronto, Canada, [2]University of Melbourne, Australia, [3]Monash University, Melbourne, Australia.

Background and aims: Pathological fibrosis is a key feature of diabetic nephropathy (DN) that correlates closely with renal dysfunction and that can be partially attenuated with agents that block the renin-angiotensin system. However, the effects of a more direct approach that specifically targets fibrosis has not been studied in detail, mostly due to a lack of suitable agents. Accordingly, we synthesized a novel anti-fibrotic drug based on a cinnamoyl core structure, FT011 (Fibrotech Therapeutics Pty Ltd, Melbourne, Australia), to

test the hypothesis that preventing pathological fibrosis will attenuate renal injury in advanced experimental model of DN.
The aims of the present study were to determine the effects of FT011 on TGF-beta stimulated matrix synthesis on cultured mesangial cells, and to test the efficacy of FT011 *in vivo* on the structural and functional manifestation of experimental DN.
Materials and methods: Mesangial cells (1097 clone) were studied *in vitro* to determine the effects of FT011 on TGF-β induced collagen synthesis by measuring ^{3}H-proline incorporation. Forty, six-week old female, heterozygous (mRen-2)27 rats, were assigned to receive either 55 mg/kg of STZ or citrate buffer alone (non-diabetic) by tail vein injection following an overnight fast. Control and diabetic groups were then each randomised into 2 groups (n=10), receiving either treatment with FT011 (100mg/kg bid gavage) or without treatment for 16 weeks.
Results: In response to TGF-beta stimulation, mesangial cells demonstrated a dose-dependent inhibition of proline incorporation in response to FT011. Without affecting blood pressure or hyperglycaemia, diabetic Ren-2 rats treated with FT011 had less albuminuria (10.10 ± 1.11 *vs* 1.97 ± 1.46, geometric mean ± tolerance factor mg/day, $P < 0.01$), tubulointerstitial fibrosis (2.28±0.46 *vs* 0.64±0.07, %/area, $P < 0.01$), glomerulosclerosis (1.05±0.05 *vs* 0.63±0.04, glomerulosclerotic index $P < 0.05$), macrophage infiltration (62±16 *vs* 26±5, number/area $P< 0.05$) and glomerular endothelial cell loss (1.04±0.5 *vs* 4.1±0.9, %/glomerular cross section, $P < 0.05$) when compared with untreated diabetic rats. Non-diabetic rats were unaffected by FT011 and no adverse effects of FT011 were observed in either diabetic or non-diabetic groups.
Conclusion: FT011 is a novel anti-fibrotic drug that attenuates the functional and structural manifestations of experimental model diabetic nephropathy, providing a novel therapeutic strategy for the treatment of progressive kidney disease.

Antioxidant tempol reduces albuminuria by decreasing PARP-induced podocyte apoptosis in diabetic hypertensive rats
E.B.M. Peixoto, P.A.O. Ribeiro, J.M. Lopes de Faria, J.B. Lopes de Faria;
Department of Internal Medicine, University of Campinas, Brazil.

Background and aims: It has recently been demonstrated that in diabetic hypertensive rats a superoxide desmutase mimetic (SOD), tempol, reduces albuminuria by restoring the redox imbalance. Increased formation of intracellular reactive oxygen species (ROS) leading to activation of poly(ADP-ribose) polymerase (PARP)-1 and podocyte loss by apoptosis contributes to albuminuria in diabetes mellitus (DM). In the present study we investigate the hypothesis that in diabetic hypertensive rats tempol reduces albuminuria by inhibition of PARP-induced podocyte apoptosis.
Materials and methods: DM was induced in spontaneously hypertensive rats (SHR) by streptozotocin at 4 weeks of age. Blood glucose levels of ≥ 270 mg/L were considered diabetic. The diabetic rats were randomly assigned to receive or not tempol intraperitoneally at a dose of 250 mg/kg. After 20 days, rats were euthanized and kidneys were collected. Glomeruli isolation was performed by differential sieving technique. Apoptosis of renal cells was evaluated by TUNEL staining and expression of WT-1, a marker of podocyte, was estimated by immunohistochemistry. Nephrin expression was assessed by Western blot analysis and immunofluorescence. PARP-1 expression, a nuclear enzyme activated by DNA strand breaks due to oxidative stress, was assessed by Western blot analysis.
Results: Plasma glucose levels were higher in diabetic rats and it was not affected by tempol treatment (169±24 *vs.* 482±52 *vs.* 444±276 mg/dl, respectively, p<0.0001). Systolic blood pressure was unaltered by diabetes or tempol treatment, (control=159±11, untreated diabetic=156±7, tempol diabetic=152±9 mmHg). Albuminuria was significantly higher in diabetic rats (680 (180 - 1815) μg/24h), compared to the control rats (229 (109 - 540), p=0.012) and it was significantly reduced by tempol treatment (366 (109 - 1342), p=0.052). DM increased the number of glomerular apoptotic cells compared to the control group (p=0.0013), and it was markedly reduced by tempol (p=0.0057). DM leads to podocyte loss as accessed by immunohistochemistry for WT-1 (p=0.0143) that was reduced in tempol treated rats (p=0.0369). Similarly, the incubation of isolated glomeruli with high glucose concentration (mimicking DM) or with H_2O_2 (ROS) leads to higher number of apoptotic cells compared with respective controls. Number of apoptotic cells was significantly reduced when isolated glomeruli were incubated with tempol. The expression of nephrin was decreased in the glomeruli of diabetic SHR and restored by tempol treatment. DM increases the expression of PARP-1 in isolated glomeruli from 2490±1801 to 7337±1128 arbitrary units (p=0.0379), and it was markedly reduced (p=0.0262) by tempol treatment to 1977±3242.
Conclusion: In diabetic hypertensive rats treatment with antioxidant tempol reduces albuminuria by prevention of PARP-induced podocyte apoptosis.

Upregulation of chemokines induced by AGEs was inhibited by Chinese herbal medicine YuQuiQing
Z.L. Sun[1], Y. Yuan[1], L. Zhou[1], J.Y. Yu[2], R.F. Bo[3];
[1]Endocrinology, Zhongda Hospital, Southeast University, Nanjing,
[2]Endocrinology, Jiangsu Traditional Medicine Hospital, Nanjing,
[3]Endocrinology, Wuxi People Hospital, Nanjing Medical University, Wuxi, China.

Background and aims: Previous work shown that advanced glycosylation end products (AGEs) increased the expression of chemokines in human renal mesangial cells (HRMCs). The aim of this study was to further investigate the effect of a Chinese traditional drug YuKuiQing on the upregulation of monocyte chemoattractant protein-1 (MCP-1) and fractalkine (FKN) induced by AGEs.
Materials and methods: HRMC cultured in the serum-free medium was incubated with AGE-BSA in the presence or absence of neutralizing anti-MCP-1 and anti-FKN antibody (Ab). HRMC incubated with AGE-BSA was cultured in the medium containing rat serum or special YuKuiQing serum which prepared by using Chinese herbal medicine serum pharmacological approach. The capacity of monocytes transmigration to HRMC was detected with a transwell system. The expression of MCP-1 and FKN mRNA in HRMC were analyzed by RT-PCR, and the content of MCP-1 and FKN in the supernatant of HRMC was measured by ELISA.
Results: 1. The number of monocytes transmigration to HRMC treated with AGE-BSA was significantly higher than control group (17.8±2.04 vs 0.7±0.84, $P<0.01$). But that of anti-MCP-1 Ab (8.6±1.14, $P<0.01$) and anti-FKN Ab (2.2±1.10, $P<0.01$) group was lower than AGE-BSA group. 2. The number of monocytes transmigration to HRMC treated with AGE-BSA in the presence of different concentration of rat serum (0.313%, 0.625%, 1.25%) was increased dose dependently (19.6±0.89, 23.6±1.14, 27.2±0.84, $P<0.05$). But those of YuKuiQing serum groups (17.0±1.00, 14.8±0.84, 12.0±1.22, $P<0.01$) were decreased compare to similar concentration of control serum. 3. The mRNA expression (FKN: 1.03±0.05 vs 0.22±0.05, MCP-1:0.74±0.05 vs 0.26±0.03, $P<0.01$) and the supernatant content (FKN: 289.49±9.77 vs 20.15±8.84 pg·L^{-1}, MCP-1: 33.47±3.14 vs 16.19±0.66 pg·L^{-1}, $P<0.01$) of MCP-1 and FKN in the HRMC treated with AGE-BSA was significantly higher compared to control group. 4. The mRNA expression (FKN: 0.950±0.051 vs 1.106±0.045, 0.885±0.041 vs 1.148±0.044, 0.833±0.040 vs 1.199±0.044,$P<0.01$. MCP-1: 0.724±0.043 vs 0.800±0.060, 0.663±0.031 vs 0.836±0.055, 0.604±0.028 vs 0.856±0.053,$P<0.01$) and the supernatant content (FKN: 280.19±9.31 vs 310.87±10.70, 268.41±9.77 vs 332.57±9.31, 251.98±9.80 vs 343.73±6.33 pg·L^{-1}, $P<0.01$. MCP-1: 27.49±2.16 vs 33.69±3.24, 26.77±2.13 vs 34.03±3.31, 26.06±1.65 vs 34.72±3.01 pg·L^{-1}, $P<0.01$) of MCP-1 and FKN in the HRMC treated with AGE-BSA in the presence of different concentration of YuKuiQing serum was lower than control serum.
Conclusion: 1. AGE-BSA enhance the capacity of MCP-1 and FKN to induce monocytes transmigration to HRMC, which are inhibited by anti-MCP-1 and anti-FKN antibody partially. These findings suggest that MCP-1 and FKN might mediate the role of AGEs in the development of diabetic nephropathy. 2. YuKuiQing markedly reduce the upregulation of MCP-1 and FKN induced by AGE-BSA, and attenuate the capacity of MCP-1 and FKN to induce monocytes transmigration to HRMC, These results indicate that YuKuiQing might play its role of reno-protection via inhibition of MCP-1 and FKN.

Metabolomic profile delineates potential defect in renal transporter function in the proximal tubule of monkeys with diabetic nephropathy

R. Shamekh[1], A.D. Patterson[2], G.S. Eichler[3], K.W. Krausz[2], F. Li[2], S. Aslam[4], J.N. Weinstein[3], B.C. Hansen[1], J.R. Idle[5], F.J. Gonzalez[2];
[1]Internal Medicine, University of South Florida, St Petersburg, United States, [2]National Institutes of Health, Laboratory of Metabolism, Center for Cancer Research, Bethesda, United States, [3]National Cancer Institute, National Institutes of Health, Genomics and Bioinformatics Group, Bethesda, United States, [4]Office of Clinical Research, University of South Florida, Tampa, United States, [5]Charles University, Institute of Pharmacology, Praha, Czech Republic.

Background and aims: Non-invasive biomarkers that predict future disease development will enhance efforts to identify the earliest indications of type 2 diabetes mellitus (T2DM). The urinary metabolomes of well-characterized rhesus macaques that were normal, prediabetic, or overtly spontaneously and naturally diabetic, and had been held under consistent, healthy dietary and environmental conditions, were examined to discover biochemical indicators of T2DM disease pathogenesis and progression.
Materials and methods: The rhesus monkeys selected for this study were under longitudinal study and were fully phenotyped for glucose and lipid metabolism, insulin sensitivity, beta cell function, and renal function prior to collection of clean urine samples. High-resolution ultra-performance liquid chromatography and the accurate mass determination of time-of-flight mass spectrometry were used to analyze spot urine samples from normal (n = 10), pre-T2DM (n = 5), and T2DM (n = 11) male monkeys. Models generated using the random forests machine learning algorithm revealed candidate biomarkers from approximately 8500 ions. Biomarkers were identified based on accurate masses and confirmed by tandem mass spectrometry of authentic compounds.
Results: Random forests models had a misclassification error less than 5%. Urinary compounds significantly increased in T2DMs compared with normals included glycine betaine (9-fold above normal), citric acid (2-fold above), kynurenic acid (1.8-fold above), glucose (67-fold above), and pipecolic acid (2.5-fold above). Compared with the conventional definition of T2DM, the biomarker-based definitions were also useful in defining the three groups.
Conclusion: Elevation of these urinary biomarkers suggest defective renal transporter function in the proximal tubule. This non-invasive urinary metabolomics approach is likely to be valuable in developing a more detailed understanding of complex diseases such as T2DM.

Kidney injury molecule 1 (KIM1) and neutrophil gelatinase-associated lipocalin (NGAL) as markers of tubular kidney injury in type 1 diabetic patients

S.E. Nielsen[1], K.J. Schjoedt[1], A.S. Astrup[1], L. Tarnow[1], M. Lajer[1], P.R. Hansen[2], H.-H. Parving[3], P. Rossing[1];
[1]Dep. 520, Steno Diabetes Center, 2820 Gentofte, [2]Department of Cardiology, 2820 Gentofte, [3]Dep. 520, Department of Medical Endocrinology, Copenhagen, Denmark.

Background and aims: Urinary(u) KIM1 and u-NGAL have been suggested as markers of tubulointerstitial damage in renal disease, mostly acute renal failure. In kidney injury, KIM1 is present on the proximal tubule apical membrane. Inflammation increases NGAL production in tubular cells. Our aim was to evaluate u-KIM1 and u-NGAL in type 1 diabetic patients with different levels of albuminuria and in controls. Subsequently we studied the effect of renoprotective treatment with the ACE inhibitor lisinopril on the level of u-NGAL.
Materials and methods: Cross sectional study of adult Caucasian type 1 diabetic patients from a tertiary referral centre. The patients were divided into three groups: normoalbuminuria (u-albumin <30mg/ 24h), microalbuminuria (u-albumin 30-300mg/24h) and macroalbuminuria (>300 mg/24h) based on three 24h urine collections. We measured u-KIM1 (ELISA, Roche®) and u-NGAL (ELISA, Bioporto®) in morning spot urine adjusted for creatinine concentration. We included 55 patients with normoalbuminuria, 42 with microalbuminuria and 44 with macroalbuminuria. Control group: 53 healthy controls. The groups were matched by gender and duration of diabetes. In addition, in 56 T1D patients with diabetic nephropathy a double blind, placebo controlled randomized crossover trial was performed. After 2 months washout period (baseline), patients were treated with lisinopril 20, 40, and 60 mg once daily, each dose for 2 months. U-NGAL was measured in 24h urine samples after each treatment period.
Results: U-KIM1 [(geometric mean (95%CI), pg/ml]: Normoalb 3.42 (2.62-4.49), microalb 4.06 (3.15-5.23), macroalb 4.17 (3.04-5.71), control 1.50 (1.11-2.03). u-KIM1 was higher in all diabetic groups than in controls (p<0.001). No difference in u-KIM 1 between diabetic groups. No association were found between u-NGAL and age, sex, eGFR, cholesterol, BMI or blood pressure. U-NGAL [Geom.mean (95% CI)]: normoalb 147 (98-221) (ng/mmol creatinine), microalb 225 (159-318), macroalb 257 (173-380), controls 74 (52-104). U-NGAL was higher in macroalb than normoalb and controls (p<0.05). Microalb was not different from macroalb or normoalb. U-NGAL was higher in normoalb vs. controls (p<0.01). U-NGAL was elevated in women and increased with age. No association with cholesterol, BMI or blood pressure. U-NGAL was correlated with u-albumin/creatinine ratio (R^2=0.18, p<0.01) and with eGFR in the macroalb group (R^2=0.15, p<0.01).
U-NGAL did not change significantly during lisinopril treatment: u-NGAL (geometric mean (SD): baseline 8.9(2.5), 20 mg 7.7(2.5), 40 mg 7.9(2.3) 60 mg 7.9(5.4) (N.S)
Conclusion: U-NGAL and u-KIM1 are elevated in type 1 diabetes, with or without albuminuria, indicating tubular damage. U-NGAL, but not u-KIM1, increases significantly with increasing albuminuria suggesting that u-NGAL is a better marker of diabetic nephropathy than u-KIM1.
Short-term treatment with lisinopril does not affect u-NGAL significantly, suggesting that lisinopril does not affect the renal damage reflected by u-NGAL.

Bezafibrate suppresses the expression of TGF-β and type IV collagen mRNA in human mesangial cells loaded with remnant lipoproteins

M. Eto, Y. Hattori, R. Terasawa, M. Saito;
Clinical Medicine, Ohu University, Koriyama, Japan.

Background and aims: Diabetic nephropathy is one of the main causes of death in diabetic patients. Hyperglycemia and hypertension are risk factors for diabetic nephropathy. Recently it has been proposed that hypertriglyceridemia contributes to diabetic nephropathy. In JDCS (Japan Diabetes Complications Study) and UKPDS (UK Prospective Diabetes Study) 74, hypertriglyceridemia was detected as one of the risk factors for diabetic nephropathy. In FIELD (Fenofibrate Intervention Event Lowering in Diabetes) study, fenofibrate therapy reduced plasma level of triglyceride (TG), and prevented and improved diabetic nephropathy in type 2 diabetic patients. Increased remnant lipoproteins underlie hypertriglyceridemia. We first found that increased remnant lipoproteins contribute to diabetic nephropathy. It is proposed that remnant lipoproteins are taken up by mesangial cells, and then cause renal damage. Diabetic nephropathy is characterized by the accumulation of extracellular matrix protein (type IV collagen) in the glomerular mesangium and expansion of the mesangial matrix, resulting in glomerulosclerosis. TGF-β stimulates type IV collagen protein synthesis. Fibrate, which is a ligand for PPARα, reduces plasma levels of TG and remnant lipoproteins and possibly may protect and improve nephropathy thorough PPARα.In the present study we examined the effect of bezafibrate on TGF-β and type IV collagen expression in human mesangial cells (HMCs) loaded with remnant lipoproteins in the medium.
Materials and methods: Remnant lipoproteins were isolated from plasma of a patient with type 2 diabetes and type III hyperlipoproteinemia (apo E2/2 genotype) by ultracentrifugal method. HMCs loaded with remnant lipoproteis were incubated for up to 24 h with bezafibrate at the concentration of 0, $3x10^{-6}$, $3x10^{-5}$ and $3x10^{-4}$ mol/L. To evaluate the expression of PPARα mRNA, TGF-β mRNA and type IV collagen m-RNA in mesangial cells, RT-PCR procedure was performed. All data were analyzed using the expression of the gene encoding GAPDH as a reference.
Results: Remnant lipoproteins significantly (p<0.001) stimulated the expression of TGF-β mRNA (1.38 vs baseline 0.57) and type IV collagen mRNA (0.92 vs baseline 0.72) in HMCs. Bezafibrate significantly (p<0.001) stimulated the expression of PPARα mRNA (1.33 vs baseline 0.20) in HMCs loaded with remnant lipoproteins. Bezafibrate significantly (p<0.001 or p<0.01) suppressed the expression of TGF-β mRNA in HMCs loaded with remnant lipoproteins in a dose-dependent manner (0.82 at $3x10^{-6}$, 0.67 at $3x10^{-5}$ and 0.65 at $3x10^{-4}$ mol/L vs. 1.38 at 0 mol/L). Bezafibrate significantly (p<0.001 or p<0.05) suppressed the expression of type IV collagen mRNA in HMCs loaded with remnant lipoproteins in a dose-dependent manner (0.74 at $3x10^{-6}$, 0.68 at $3x10^{-5}$ and 0.69 at $3x10^{-4}$ mol/L vs. 0.92 at 0 mol/L).

Conclusion: Remnant lipoproteins stimulated the expression of TGF-β and type IV collagen in HMCs. It is concluded that remnant lipoproteins play an important role in the development and progression of diabetic nephropathy through increased TGF-β and type IV collagen. In addition, bezafibrate suppressed the expression of TGF-β and type IV collagen in HMCs loaded with remnant lipoproteins. It is suggested that fibrate is effective to protect and improve diabetic nephropathy in early diabetes as shown in FIELD study.

The orphan nuclear receptor small heterodimer partner attenuates renal fibrosis in obstructive nephropathy

G.-S. Jung[1], Y.-J. Seo[1], M.-K. Kim[1], N.-K. Kim[1], H.-S. Kim[1], K.-G. Park[1], I.-K. Lee[2], E.-H. Koh[3], K.-U. Lee[3], H.-K. Kim[4], H.-C. Jang[5];
[1]Department of Internal Medicine, Keimyung University School of Medicine, Daegu, [2]Department of Internal Medicine, Kyungpook National University School of Medicine, Daegu, [3]Department of Internal Medicine, University of Ulsan College of Medicine, Seoul, [4]Department of Internal Medicine, Andong Medical Center, Andong, [5]Department of Internal Medicine, Seoul National University Bundang Hospital, Bundang, Republic of Korea.

Background and aims: The accumulation of extracellular matrix proteins is the key feature of chronic fibrotic kidney disease including diabetic nephropathy. Accumulating evidence suggests that transforming growth factor-β (TGF-β) and plasminogen activator inhibitor type 1 (PAI-1) act as central components in the development of renal fibrosis by stimulating matrix protein generation and inhibiting matrix protein removal. Previously, we demonstrated that small heterodimer partner (SHP) represses PAI-1 expression in the liver by inhibiting the TGF-β signaling pathway. Therefore, we examined whether SHP prevents renal fibrosis in the unilateral ureteral obstruction (UUO) model and elucidated its mechanism in cultured renal cells.
Materials and methods: The effects of adenovirus mediated overexpression of SHP on PAI-1 expression in Rat mesangial cell (RMC)s and renal tubular epithelial cells (NRK-52E cells) were measured by Northern blot analysis. Transient transfection study with reporter constructs of PAI-1 promoter was performed to measure the effect of SHP on PAI-1 promoter activity. The effects of SHP on Smad 3-DNA binding activity were examined by electrophoretic mobility shift assay. The effects of SHP on renal interstitial fibrosis in vivo were assessed by UUO-induced renal fibrosis model.
Results: UUO markedly increased the expression of PAI-1, type I collagen, and fibronectin but decreased SHP gene expression. Moreover, in kidneys of SHP-/- mice, the expression levels of PAI-1, type I collagen, fibronectin and α-smooth muscle actin (α-SMA) were increased compared with those in kidneys of wild-type mice. In addition, loss of SHP accelerated renal fibrosis after UUO. Adenovirus-mediated overexpression of SHP in cultured RMCs and NRK-52E cells inhibited TGF-β-stimulated PAI-1, type I collagen, and fibronectin expression. SHP inhibited TGF-β- and Smad3-stimulated PAI-1 promoter activities and TGF-β-stimulated Smad3 binding to its response consensus element on the PAI-1 promoter. Moreover, up-regulation of SHP expression in the kidney by adenovirus expressing SHP inhibited the expression of UUO-induced PAI-1, type I collagen, fibronectin, and α-SMA.
Conclusion: This study shows that SHP prevents renal fibrosis in obstructive nephropathy and raises the possibility that SHP can be a target for the prevention of renal fibrosis.

Preliminary study of bone marrow mesenchymal stem cells on diabetic nephropathy

H. Zhou, Y. Gao, H. Tian;
Department of Endocrinology, West China Hospital, Sichuan University, Chengdu of Sichuan Province, China.

Background and aims: Mesenchymal stem cells (MSCs) have been widely studied in protecting against acute renal failure in animals, but studies on the role of MSC in models of chronic kidney disease are largely lacking. Diabetic nephropathy is a very common complication of diabetes mellitus. Current therapies can only delay its progress. In the present study, we aim to discover whether MSC transplantation could treat or attenuate diabetic nephropathy in rats.
Materials and methods: Sprague-Dawley (SD) rats were randomized to five groups: control group (C), diabetic nephropathy control group(DN), ciclosporin A (CsA) group, MSC group, and MSC+CsA group. Bone marrow stem cells were cultured, identified and labeled by 5-bromo-2'-deoxyuridine (BrdU) in vitro. Then they were transplanted to rats with diabetic nephropathy via introcardiac infusion(2×10^6MSCs/200μl). Ciclosporin A was administered daily after transplantation at a concentration of 5mg/kg body weight in CsA group and MSC+CsA group. 1, 2, 4, 8 week after transplantation, rat blood glucose, body weight (BW), kidney weight (KW), urine protein, urine micro albumin, endogenous creatinine clearance rate (Ccr) and profile of kidney hypertrophy (KW/BW) were tested. Renal morphology and labeled cells were examined in the kidney.
Results: 1. The cultured bone marrow stem cells expressed mesenchymal cell phenotype, and could be multidifferentiated to osteogenic and adipogenic cells.
2. Labeled stem cells could be detected in the kidney of nephropathic rats, but they did not propagate after engrafting in kidney.
3. Blood glucose in MSC+CsA group was significantly lower than that in MSC group, CsA group and DN group, but higher than control group at day 3 and 7 after transplantation; blood glucose in MSC group had a transient decrease at week 2, but increased to pretreatment level at week 8 for two groups.
4. At week 4, urine protein in MSC+CsA group was lower compared to MSC group, CsA group and DN group, but higher than control group. The 24h urine micro albumin in MSC+CsA group became significantly lower than other diabetic groups at week 1 and remained low in the first 4 weeks post transplantation; in MSC group urine micro albumin decreased at week 4, but rebounded to the pretreatment level at week 8. At week 1 and 2 urine micro albumin in MSC+CsA group was lower than that in MSC group. At all time points the Ccr in MSC+CsA group and MSC group were higher than control group, though without significant difference, while they were much higher in CsA group and DN group at week 4 compared to control group. KW/BW in MSC+CsA group was significantly lower than that in CsA group and DN group, though still higher than control group at week 2. The morphology of glomerulus was ameliorated after bone marrow stem cell transplantation, while the morphology of renal tubles was improved by CsA.
Conclusion: The cultured bone marrow stem cells express mesenchymal cell phenotype with multilineage potential. Bone marrow stem cells can track to the kidney of diabetic nephropathic rats after cardiac injection. Mesenchymal stem cells can ameliorate diabetic nephropathy temporarily, but long term effects are limited.

PS 94 Nephropathy - clinical 1

Renal hyperfiltration in relation to low renal function and incidence of overt nephropathy among individuals with type 1 diabetes

T. Costacou, T.J. Orchard;
Department of Epidemiology, University of Pittsburgh, United States.

Background and aims: It has been suggested that renal hyperfiltration predicts later deterioration of renal function, though the evidence is conflicting. We thus assessed this hypothesis in a large cohort of individuals with childhood onset type 1 diabetes (diagnosed <17 years of age).
Materials and methods: Participants of the Pittsburgh Epidemiology of Diabetes Complications study cohort with estimated (by the Cockcroft-Gault formula) glomerular filtration rate (eGFR) ≥60 ml/min/1.73 m^2 and free of overt nephropathy (ON, albumin excretion rate<200 μg/min in 2/3 timed urine collections) were selected (n=423). At study entry, mean age was 26 years and diabetes duration 18 years. Hyperfiltration was defined as eGFR ≥130 ml/min/1.73 m^2. The outcomes studied were low renal function (LRF, below 60 ml/min/1.73 m^2) and incidence of ON (albumin excretion rate ≥200 μg/min in 2/3 validated timed urine collections, renal dialysis or transplantation). Descriptive analyses (t-tests for continues variables and chi-square tests for categorical variables) were conducted to assess univariate associations between study participant characteristics at study entry and subsequent LRF and ON incidence. Multivariable Cox proportional hazard models were constructed to assess the value of hyperfiltration in predicting subsequent LRF and ON.
Results: During 18 years of follow-up, 9.3% (39/381) progressed to LRF, whereas 16.5% (70/423) developed ON. No univariate association was observed between presence of hyperfiltration at study entry and either LRF (25.6% vs. 33.6%, p=0.31) or ON incidence (34.3% vs. 33.1%, p=0.85). However, in multivariable Cox proportional hazard models, adjusting for univariately significant variables, including baseline eGFR level and diabetes duration, hyperfiltration emerged as a strong risk factor for LRF (HR=4.58, 95% CI=1.27-16.45). Nevertheless, the increased risk associated with baseline hyperfiltration in relation to incident ON, did not reach statistical significance (HR=1.44, 95% CI=0.85-2.44). When analyses were repeated using the MDRD study formula to estimate GFR, there was no increased risk for LRF associated with hyperfiltration (HR=1.19, 95% CI=0.76-1.87), whereas a borderline increased risk was observed for ON incidence (HR=1.82, 95% CI=0.92-3.62, p-value=0.08), which became significant (p-value=0.02) with further adjustment for weight (as is included in the Cockcroft-Gault formula).
Conclusion: These data suggest that hyperfiltration may increase the risk of low renal function and overt nephropathy, although the strength of such associations appears dependent on the formula used to estimate glomerular filtration rate.

Prognostic value of contrast-induced nephropathy in patients with diabetes mellitus type 2

N. Zaytseva[1], M. Shestakova[1], M. Shamkhalova[1], S. Matskeplishvili[2], A. Deev[3], E. Tugeeva[2], U. Buziashvili[2], I. Dedov[1];
[1]Diabetic Nephropathy Department, Endocrinology Research Center, [2]Clinical Diagnostic Department, Bacoulev Scientific Center of Cardiovascular Surgery, [3]Biomedicine Statistic Department, State Research Center for Preventive Medicine, Moscow, Russian Federation.

Background and aims: To determine the incidence of contrast-induced nephropathy (CIN) after percutaneous coronary intervention (PCI), to reveal independent predictors and determine the prognostic value of CIN among patients with and without diabetes mellitus (DM) type 2.
Materials and methods: We have studied 151 patients with DM and 50 patients without DM who were under coronarography to determine further intervention on the heart vessels. The CIN defined as an increase in serum creatinine (SCr) of at least 25% or 44μmol/l over baseline within 48 hours of PCI.
Results: Baseline SCr, glomerular filtration rate were similar in diabetic and non-diabetic patients. The incidence of CIN was significantly higher among the diabetic, than non-diabetic patients (40.4±4.4% vs. 16.0±5.5% respectively, p<.01). CIN was associated with anaemia -OR=2.19 with 95%CI (0.96,4.99), contrast volume administrated -OR=2.01 per 100ml of medium 95%CI (1.35,2.98), low (<40%) ejection fraction -OR=3.25 with 95%CI (1.15,9.05), diuretics use -OR=2.59 with 95%CI (1.002,1.017), multivessel coronary involvement -OR=2.97 with 95%CI (1.34,6.59), congestive heart failure (CHF, NYHA functional classification III/IV) - OR=4.68 with 95%CI(1.69,12.95). Duration of hospital stay was 17.7±1.3 days in diabetics with CIN, 11.9±0.9 day without CIN (p<0.0001). Importance of CIN was confirmed in Cox time-dependent Proportional-Hazards Model, that had defined survival factors - RR=2.64 with 95%CI (1.17,5.97). CIN was determined as a significant predictor of death, new or hospitalization for CHF, myocardial infarction, stroke, doubling of SCr, coronary artery bypass surgery within 24 months of follow up according to the Kaplan-Meier survival method (p<0.0001).
Conclusion: The patients with CIN had poor prognosis. Control risk factors should be intensified to protect them from future adverse events.

1057

The relevance between endogenous creatinine clearance rate and islet beta cell function in type 2 diabetic patients

L.-M. Chen, M.-Y. Zheng, B.-C. Chang;
Diabetic Nephrology, Tianjin Medical University Metabolic Diseases Hospital, China.

Background and aims: To investigate the relevance between islet β cell insulin secretion, insulin sensitivity and endogenous creatinine clearance rate (Ccr) in type 2 diabetic patients.
Materials and methods: 356 cases of type 2 diabetic patients were divided into 125 cases with normal renal function(90≤Ccr<130 ml/min*1.73^2), 140 cases with mild renal dysfunction(60≤Ccr<90 ml/min*1.73^2) and 91 cases with moderate and severe renal dysfunction (Ccr<60 ml/min*1.73^2). Oral glucose tolerance (OGTT) and insulin releasing test were performed. The insulin resistance (IR) was evaluated by the ratio of area under curve of insulin to area under curve of glucose (AUC_I/AUC_G) and HOMA-IR(HOMA-IR = FG×FI/22.5. The insulin sensitivity was reflected by insulin sensitivity index (ISI) [ISI=-ln(FI×FG)] and Matsuda ISI[Matsuda ISI =10,000/√(FG×FI×G_{mean}×I_{mean})]. The HOMA-β, early insulin secretion index (ΔI30/ΔG30), the second-phase insulin secretion index (AUC_I) and Disposition Index (DI)[DI=ΔI30/ΔG30/ HOMA-IR] were calculated to estimate islet β cell secretary function. The difference of clinical and biochemical parameters were compared among the three groups and the correlation between Ccr and IR was analyzed.
Results: (1) Compared with the normal renal function group, the HOMA-IR of the mild, moderate and severe renal dysfunction groups was significantly higher(P< 0.01), while the ISI and Matsuda ISI were significantly lower(P<0.01); The AUC_I/AUC_G of the moderate and severe renal dysfunction group was higher than that of the other two groups(P<0.05). (2) The AUC_I of the moderate and severe renal dysfunction group was higher than that of the other two groups (P<0.05); the DI of the mild, moderate and severe renal dysfunction groups was significantly higher than that of the normal renal function group (P<0.05). (3) Ccr was negatively correlated with the course of diabetes, systolic blood pressure, diastolic blood pressure, AUC_I, HOMA-IR, AUC_I/AUC_G (P<0.05) and was positively correlated with ISI, Matsuda ISI (P<0.01); Multiple stepwise regression analysis showed that Ccr was negatively correlated with systolic blood pressure,course of diabetes and AUC_I/AUC_G (P<0.05).
Conclusion: Ccr and IR were negatively correlated, so IR may be independent risk factor of renal dysfunction among type 2 diabetes patients.

The early diagnosis of renal disorders in diabetes mellitus patients

G. Zubkova[1], V. Rybalchenko[1], E. Luchitskiy[2], V. Luchytskiy[2], V. Markov[1];
[1]Radiology, , [2]Clinical Andrology, Institute of Endocrinology and Metabolism, Kiev, Ukraine.

Background and aims: Diabetic nephropathy is one of the heaviest complications of diabetes mellitus - occupies a leading place among the main reasons of death rate in such patients. People with type 1 diabetes make more than half of all hemodialis patients. Diabetic nephropathy develops gradually and it clinical signs shows up already on the expressed stage of renal defeat.
Materials and methods: The examination was conducted on the gamma-chamber using renotrophic substance - dietilen-triaminpentaacetate (DTPA), marked

with short-life radionuklide of 99m-Ts(technetium), which hatches from an organism by urinary system and its leading out speed depends on glomerular filtration.Depending on the level of Hba1c, indexes of serum glucose levels and clinical signs of disease we estimated the state of compensation and decompensation of type 1 diabetes. Compensation of diabetes was considered at the indexes of serum glucose level from 6 to 8 mmol/l for a day long, level of HbA1c up to 6.5%, and also practical absence of hypoglycemia and ketoacidosis.
Results: We examined 50 patients with type 1 diabetes in the stage of compensation (29.7 + 3.4 years): in 38 of them (diabetic nephropathy of the II - III stage, mikroalbuminuriya - 30-205 mg/day) under act of angiotensin-trasforming factor inhibitors there was a substantial improvement of lauter and egestiv renal functions, in 8 patients (diabetic nephropathy of the III - IV stage, mikroalbuminuriya - 280-450 mg/day) - we did not look after the substantial changes of scintigraphic indexes, in 4 patients (diabetic nephropathy of the IV stage, stable proteinuriya) - we observed worsening renal functions in spite of reception of preparations.
Conclusion: The received results testify that radioisotope dynamic renal scintigraphy allows to diagnose diabetic nephropathy on the early stages of development, when a process is reversible. Reliable improvement of renal functions under act of angiotensin-trasforming factor inhibitors and at the compensated diabetes mellitus it is observed only for patients with diabetic nephropathy of I - III stages.

The occurrence of impaired renal function and hypoalbuminaemia in the absence of macroalbuminuria in geriatric diabetic patients
S. Ardigo, S. Giannelli, C. Genet, L. Perrenoud, Y. Registe-Rameau, F.R. Herrmann, U.M. Vischer;
Dept of Rehabilitation and Geriatrics, Geneva University Hospitals, Thônex/Geneva, Switzerland.

Background and aims: Albuminuria is considered as an early feature of diabetic nephropathy and a strong cardio-vascular risk marker. Yearly screening for increased urinary albumin excretion rate is currently recommended. However, the capacity of albuminuria to predict impaired renal function in elderly diabetic persons is unclear.
Materials and methods: We monitored renal function (serum creatinine and clearance according to the Cockcroft-Gault formula), urinary albumin excretion, albuminemia and nutritional markers in a survey of very old diabetic patients admitted to a geriatric service.
Results: 80 diabetic patients (mean age 82.8±7.4 years) have been included in this ongoing survey. Moderate to severe renal impairment (creatinine clearance <40 ml/min) and severe hypoalbuminemia (<30 g/l) were observed in 38% and 48% patients respectively. Age was associated with renal failure, hypoalbuminemia and high urinary albumin/creatinine ratio (ACR). The ACR was inversely associated with creatinine clearance (Spearman rho=-0.43 p=0.016) and albuminemia (rho=-0.42, p=0.16). However, macroalbuminuria (ACR>300 mg/g) was rarely observed in renal failure (23%) or hypoalbuminemia (20%). Albuminemia was more strongly related to malnutrition markers than to the ACR.
Conclusion: Impaired renal function and hypoalbuminemia are frequent in diabetic geriatric patients, but are only rarely accounted for by diabetic nephropathy as defined by macroalbuminuria. Hypoalbuminemia indicates associated malnutrition more often than diabetic nephropathy. Low creatinine clearance should be screened for along with albuminuria to detect impaired renal function in these patients.

1061

Increased intact urinary albumin excretion predicts development of microalbuminuria in normoalbuminuric type 2 diabetic patients - six-year follow-up study
T. Narita, M. Hosoba, T. Morii, T. Sato, M. Ishikawa, H. Fujita, Y. Yamada;
Department of Endocrinology, Diabetes and Geriatric Medicine, Akita University Graduate School of Medical Science, Japan.

Background and aims: Conventional immunochemical urinary albumin assay underestimates certain portions of intact (not fragmented) albumin. High performance liquid chromatography (HPLC) method can detect total intact urinary albumin accurately. However a few studies reported advantage of HPLC method compared with immunochemical ones. This study evaluated whether increased intact urinary albumin excretion measured by HPLC (HPLC-U-Alb) method in normoalbuminuric type 2 diabetic patients would predict future development of microalbuminuria (MA) and how are the clinical characteristics of MA progressors with high HPLC-U-Alb level at baseline.
Materials and methods: We analyzed HPLC-U-Alb levels of first voided morning urine samples (geometric means of three serial samples) in 105 normoalbuninuric type 2 diabetic out-patients (mean age of 58.8 years; 51 males and 54 females) defined as normoalbuminuria (turbidmetric immunoassay urinary albumin [TIA-U-Alb] < 30mg/gCr in all three serial spot urine samples measured within one year prior to the registration) and followed during six years. Development of microalbuminuria were defined as two consecutive spot TIA-U-Alb > = 30mg/gCr in our outpatients clinic.
Results: Of 105 patients, 20 progressed to MA. Baseline HPLC-U-Alb in progressors were significantly higher (ANOVA followed by post-hoc Scheffe method) than in non-progressors and 36 control subjects (HPLC-U-Alb: 22.8 +/- 9.8, 15.5 +/- 6.7 and 12.3 +/-5.2 mg/gCr, respectively). Baseline TIA-U-Alb in progressors was also significantly higher than in non-progressors and controls. However, HPLC-U-Alb did not significantly correlated with TIA-U-Alb in progressors (r = 0.015). In contrast, HPLC-U-Alb significantly correlated in non-progressors and controls (r = 0.391 and 0.401, respectively). Urinary N-acetylglucosaminidase (NAG) at baseline significantly correlated with HPLC-U-Alb in diabetic patients but not in controls (Fig). No correlations between NAG and TIA-U-Alb were found in either diabetic patients or controls. At baseline, progressors had higher HbA1C level, higher rates of having retinopathy and higher rate of insulin usage. Cox's proportional hazards model including several clinical characteristics of patients as variables indicated that higher HPLC-U-Alb at baseline was an independent predictor of MA development as well as having retinopathy and high age in our patients.
Conclusion: Increased HPLC-U-Alb in normoalbuminuric diabetic patients predicts future development of MA with relation with urinary NAG elevation, indicating tubular dysfunction of diabetic patients. Immuno-chemical measurement of U-Alb cannot detect this renal dysfunction in normoalbuminuric diabetic patients.

Serum bilirubin level is associated with susceptibility to diabetic microvascular complications
H. Endo, H. Furuta, K. Terao, Y. Furukawa, S. Matsuno, T. Takagi, M. Nishi, H. Sasaki, K. Nanjo;
The First Department of Medicine, Wakayama Medical University, Japan.

Background and aims: Bilirubin is an antioxidant and antiinflammatory substrate and the inverse association of serum bilirubin levels with the risk of coronary artery disease has been reported. We hypothesized that higher levels of bilirubin would reduce susceptibility to diabetic microvasculer complications.

Materials and methods: We compared serum total birilubin levels and the prevalence of nephropathy and retinopathy in 532 type 2 diabetic patients. Nephropathy positive was defined by the presence of microalbuminuria, overt proteinuria, or an elevated serum creatinine level.
Results: Bilirubin levels were higher in patients without than in those with complications (0.74±0.30 vs. 0.65±0.28 mg/dl, p<0.001, for nephropathy, 0.74±0.29 vs. 0.66±0.29 mg/dl, p=0.002, for retinopathy, mean±SD) Multiple logistic regression analysis, adjusted for other risk factors (sex, duration of diabetes, body mass index, hemoglobin A1c, hypertension, dyslipemia, smoking), showed a inverse association between the serum bilirubin levels and the prevalence of nephropathy (odds ration [OR] 0.35, 95% confidence interval [CI], 0.17-0.72, p=0.005) or the prevalence of retinopathy (OR 0.51, 95% CI, 0.25-1.02, p=0.057). We also found a positive correlation between bilirubin levels and estimated glomerular filtration rate (r=0.149, p<0.001) in multiple regression analysis.
Conclusion: Higher serum total bilirubin level is associated with reduced susceptibility to diabetic microvascular complications.

1063

Visceral adiposity and progression of diabetic nephropathy in patients with type 2 diabetes
D.-H. Cho, J.-O. Chung, D.-J. Chung, M.-Y. Chung;
Department of Endocrinology and Metabolism, Chonnam National University Medical School, Gwang-Ju, Republic of Korea.

Background and aims: Visceral adiposity is strongly associated with insulin resistance. Many studies demonstrated that obesity and insulin resistance were known as one of progression factors for chronic kidney disease (CKD). Furthermore, there is a strong correlation between body mass index (BMI) and the relative risk of progression of CKD. Although waist circumference (WC) is a fairly good correlate of the amount of total abdominal fat, it cannot distinguish visceral adiposity from the amount of subcutaneous abdominal fat. Ultrasound (US) measurements have been recently shown to correlate better with visceral adiposity than anthropometric measurements. The aim of our study was to elucidate whether visceral fat thickness (VFT) measured by ultrasonography is associated with progression of diabetic nephropathy in type 2 diabetic patients.
Materials and methods: We recruited a total of 249 type 2 diabetic patients (116 men and 133 women) with CKD (≥ stage 2) by diabetic nephropathy and followed for 2.6±1.4 years. Renal function was evaluated by serum creatinine levels, estimated glomerular filtration rate (eGFR) (calculated by the Cockcroft-Gault equation) and urinary albumin/creatinine ratio (ACR). Anthropometric, clinical, and laboratory data were measured. US procedures were performed by the same examiner using a 3.5-MHz probe. US-determined VFT was defined as the distance between the internal face of the rectus abdominis muscle and the anterior wall of the aorta.
Results: Overall, the mean age was 56.3±10.9 years, duration of diabetes 11.5±7.0 years, HbA_{1C} 7.7±2.9%, ACR 859.4±562.7 mg/gCr, serum creatinine 2.0±1.2 mg/dL, and systemic blood pressure (BP) 149.5±25.3/91.6±15.2 mmHg. Mean calculated GFR was 36.1 ±29.6 mL/min/1.73m^2. Of the study population, 75 patients (30.1%) were smokers or exsmokers, 223 patients (89.6%) were having hypertension, and 237 patients (95.2%) were taking angiotensin converting enzyme inhibitor or angiotensin receptor blocker. BMI (r = 0.463; p< 0.001), WC (r = 0.511; p< 0.001), age (r = 0.356; p< 0.05), duration of diabetes (r = 0.216; p< 0.05), and HOMA-IR (r = 0.264; p< 0.05) were significantly correlated with US-determined VFT. But serum creatinine, eGFR, ACR, lipid profiles, HbA_{1C}, and systolic and diastolic BP were not correlated with VFT. Mean yearly change of eGFR was 5.8±4.1 mL/min/year. Yearly change of eGFR was positively correlated with baseline US-determined VFT (r = 0.271; p< 0.05). Changes of ACR or serum creatinine were not significantly correlated with VFT.
Conclusion: Our data suggests that chronic kidney disease is associated with an increased prevalence of visceral obesity and visceral adiposity measured by ultrasonography may be predictor of progression of diabetic nephropathy in patients with type 2 diabetes.

1064

Association between diabetic nephropathy and atherosclerosis
M. Higa, K. Yamashita, S. Usui, T. Ichijyo, H. Ouchi, N. Hiroi;

Internal Medicine, Saiseikai Yokohamashi Tobu Hospital, Yokohama, Japan.
Background and aims: The link between nephropathy, particularly microalbuminuria, and cardiovascular disease, is becoming increasingly apparent. Diabetic nephropathy and cardiovascular disease share many risk factors. We postulated that insulin resistance may have a role in the contributor to microalbuminuria and cardiovascular disease. The aim of this study was to assess the associations between diabetic nephropathy and structural changes in arteries, such as carotid intima-media thickness (IMT) in type 2 diabetic patients, and determine the pathogenesis.
Materials and methods: The subjects of this study were 56 type 2 diabetic patients (age 57.5±10.7 years, 34 males and 22 females). They were divided into 3 groups according to level of urinary albumin excretion (UAE); a group of 29 patients with normoalbuminuria (N-group), a group of 13 patients with microalbuminuria (M-group), and a group of 14 patients with macroalbuminuria (MA-group). The IMT of the common carotid artery was measured by ultrasonography. The following parameters were compared among the 3 groups; blood pressure, plasma glucose, insulin and lipid levels, and serum adiponectin levels. We assessed insulin resistance using fasting IRI levels and the products of insulin and free fatty acid (FFA) levels (IRI × FFA). Carnitine is required in mammalian tissue to transfer long-chain acyl CoAs across the inner mitochondrial membrane for β-oxidation. Plasma acylcarnitine level (ACAT) is a marker of mitochondrial β-oxidation. ACAT levels were measured in 18 out of 56 patients.
Results: No significant differences in age, duration of diabetes, BMI, smoking, or kind of antihypertensive agent used were found between the 3 groups. Systolic blood pressure in the M-group and MA-group were significantly higher (p<0.01) than in the N-group. There were no significant differences in HbA1c, lipid, serum creatinine or adiponectin levels among the 3 groups. IMT level in the M-group was 1.13±0.32 mm which was significantly higher than those in the N-group and MA-group (0.89±0.26 mm, 0.92±0.18 mm, respectively). Serum IRI level in M-group was 16.1±19.6μU/ml which was significantly higher (p<0.05) than those in the N-group and MA-group. A significant positive correlation was found between log UAE and serum IRI (r=0.46, p<0.05), and it was found, furthermore, that serum IRI level showed a significant positive correlation with IMT. Log UAE showed positive correlations with IRI×FFA (r=0.57, p<0.05) and ACAT levels (r=0.57, p<0.05), respectively.
Conclusion: Microalbuminuria was associated with structural changes in arteries, such as IMT in this study. Insulin resistance might contribute to the development of both macroangiopathy and diabetic nephropathy. Furthermore, ACAT as a marker of mitochondrial β-oxidation may contribute to the development of macroangiopathy in diabetic nephropathy.

PS 95 Nephropathy and treatment effects

Do analogue insulins have nephroprotective effects?

C. Hasslacher[1,2], J. Moecks[3];
[1]Innere Medizin, St. Josefskrankenhaus, [2]Diabetesinstitut Heidelberg,
[3]Bioscience Club Heidelberg, Heidelberg, Germany.

Background and aims: In diabetic patients with nephropathy an improved metabolic activity as well as a decrease of the postprandial hyperperfusion have been shown in case of the analogue insulin (AI) Lispro compared to human insulins (HI). Both factors could positively influence the nephropathy course through improved metabolic control and favourable renal hemodynamics. We investigated the influence of the treatment with AI or HI on renal functional parameters.
Materials and methods: The medical files of all outpatient type 1 diabetics between June 1, 2004 and December 31, 2006 have been reviewed and stratified according to the type of insulin therapy (AI, HI, mixed therapy). Exclusion criteria were pregnancy, dialysis, erythropoietin therapy, severe systemic disease, mixed insulin therapy (AI plus HI), insulin therapy shorter than 24 months. 68 diabetic patients received human insulin and 117 received analogue insulin (glargin 65%, lispro 59%, aspart 34%, detemir 22%, glusiline 4%). Besides demographic and clinical findings the following parameters were methods using standard methods: e GFR (CCL), albumin excretion (AE), Hb, HbA1c, hsCRP.
Results: Concerning the demographic parameters (age, gender, diabetes duration, BMI, prevalence of hypertension, antihypertensive therapy) patients with or without renal insufficiency (CCL >or< 90 ml/min) receiving AI and HI did not differ from each other. However, patients with AI and CCL < 90 ml/min showed significantly better renal function parameters than patients with HI: CCL 69 ml/min vs. < 55.6 ml/min; AE 50.5 vs. 143 mg/l. The Hb levels were also significantly higher with AI: 14.0 vs. 13.2 g/dl. In case of CCL < 60 ml/min the differences were most distinctive. The metabolic control was not different (Hba1c 7.7% vs. 7.9%). In a regression analysis of the treatment effect considering numerous confounders (age, gender, diabetes duration, BMI, hypertension, ACE-AT1-therapy) the positive effect of an AI-therapy did remain. In consideration of the better renal function of the patients treated with AI this positive effect was also measurable in a detailed analysis of the therapeutical effect on the Hb level.
Conclusion: Type 1 diabetics with renal insufficiency had better renal values and a higher Hb level under AI therapy than patients under HI therapy. The cause for this finding described for the first time is unclear; a higher effect on the Hb synthesis is to be discussed so that the negative effects of an anaemia on the nephropathy progression are reduced. A positive influence on the renal haemodynamics through AI with consecutively lower loss of filtrate and higher Hb levels can not be excluded either. Prospective studies are necessary for confirming and clarifying this positive effect of AI.

Cholecystokinin ameliorates diabetic renal injuries via anti-inflammatory effects

S. Miyamoto, K. Shikata, M. Sasaki, S. Nishishita, C. Sato, H. Kataoka, R. Kodera, D. Hirota, N. Kajitani, H. Makino;
Department of Medicine and Clinical Science, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan.

Background and aims: We previously reported that blockade of inflammatory axis via ICAM-1 protects against renal injuries after induction of diabetes, suggesting that low grade inflammation, i.e. "microinflammation", plays a pivotal role in the pathogenesis of diabetic nephropathy. DNA microarray analysis revealed that cholecystokinin (CCK) is up-regulated in the kidneys of diabetic wild type mice but not increased in diabetic ICAM-1 deficient mice. CCK is a peptide with various functions including gastrointestinal homeostasis and neurotransmission, yet little is known about renal effects of CCK. Two types of CCK receptors, types A and B, have been identified in kidney tissues (glomeruli, tubules) and cultured macrophages. We have recently shown that deficiency of both CCK-A and B receptors accelerates renal injuries in streptozotocin (STZ) -induced diabetic mice. The aim of this study is to investigate the protective effects of CCK against progression of diabetic nephropathy.
Materials and methods: (1) Sprague-Dawley rats were divided into three groups: non-diabetic controls received continuous saline infusion, diabetic group received continuous saline infusion (DM), and diabetic group received continuous CCK octapeptide (CCK-8s) infusion (DM-CCK). Diabetes was induced by STZ, and CCK-8s or saline were infused subcutaneously via osmotic pumps over a two months period. Glomerular size and mesangial matrix area were assessed by morphometric analysis. Total RNA was extracted from kidneys, and expressions of proinflammatory genes in kidney tissues were examined by quantitative real-time RT-PCR. Macrophage infiltration into glomeruli and the expression of type-IV collagen were assessed by immunostaining.
(2) Cultured human macrophages (PMA-treated THP-1 cells) were treated with CCK-8s, control peptide or vehicle for 24h. Expressions of proinflammatory genes were examined by quantitative real-time RT-PCR.
Results: (1) DM-CCK showed reduced albuminuria as compared with DM (Mean value; 416 vs. 1160 μg/day, p<0.01), whereas there was no significant difference in HbA1c and systolic blood pressure between both diabetic groups. Glomerular size was similar between DM-CCK and DM, but mesangial matrix area was significantly reduced in DM-CCK than in DM (6.3 vs. 13.9 %, p<0.0001). Gene expression of ICAM-1, CD68 and TGF-β were significantly inhibited in both kidney cortex and isolated glomeruli of DM-CCK as compared with DM (p<0.05). The intensity of type-IV collagen in glomeruli was decreased in DM-CCK as compared with DM (P<0.01). The number of macrophage infiltrated into glomeruli was markedly decreased in DM-CCK than in DM (P<0.0001).
(2) Cultured macrophages treated with CCK-8s suppressed mRNA expression of TNF-α and IP-10 as compared with control peptide and vehicle (P<0.05).
Conclusion: Our results have shown that CCK-8s ameliorates inflammatory reactions and tissue injuries in diabetic kidneys, and that CCK-8s inhibits the production of proinflammatory cytokines from cultured macrophages. These findings suggest that CCK exerts protective effects against progression of diabetic nephropathy via anti-inflammatory effects. CCK may be beneficial for the treatment of diabetic nephropathy.

1067

α-linolenic acid protects against palmitic acid toxicity via inhibition of endoplasmic reticulum stress in renal proximal tubular cells

E. Katsoulieris, J.G. Mabley, I.C. Green, P.K. Chatterjee;
Pharmacy and Biomolecular sciences, University of Brighton, United Kingdom.

Background and aims: The saturated fatty acid palmitic acid (PA) causes cell death and induces endoplasmic reticulum (ER) stress in vitro. The aim of this study was to evaluate the protective effects of a polyunsaturated fatty acid, α-linolenic acid (ALA) against PA-induced ER stress and loss of renal cell viability and to examine the signaling mechanism.
Materials and methods: Cytotoxicity was assessed by measuring MTT reduction, LDH release or Hoechst-propidium iodide (HPI) staining for apoptosis and necrosis in renal proximal tubular NRK-52E cells. ER stress was evaluated by Western blotting against the markers CHOP, phosphorylated eIF2α (p-eIF2α) and the protein chaperone glucose regulated protein 78 (GRP78).
Results: Co-treatment with 100μmol/L ALA prevented palmitic acid induced cellular release of LDH and increased MTT reduction from 43.8±3.47 to 75.31±3.81% (P<0.01). α-linolenic acid (ALA) decreased palmitic acid-induced apoptosis from 17.1 ± 2.6 to 4.2 ± 0.7% and necrosis from 9.6 ± 1.7 to 2.1 ± 0.4%. Addition of wortmannin (100nmol/L), a phosphatidylinositol 3-kinase (PI3K) inhibitor, did not inhibit the protective effects of ALA against palmitic acid-induced LDH release and MTT reduction. PA (300 μmol/L) increased GRP78 expression from 0.33±0.02 to 0.41±0.01 arbitrary units (n = 3, P < 0.05), CHOP from 0.19±0.04 to 0.88±0.14 (n = 6, P < 0.05) and p-eIF2α from 0.32±0.03 to 0.70±0.03 (n = 5, P < 0.05). Expression of the latter two proteins was reduced in the presence of ALA to levels in untreated cells. In the absence of palmitic acid, but the presence of salubrinal, which maintains eIF2α in the phosphorylated state, ALA also decreased salubrinal-induced p-eIF2α and CHOP levels from 0.69±0.02 and 0.73±0.03 to 0.54±0.04 (n = 6, P < 0.01) and 0.52±0.07, respectively (n = 10, P < 0.05).
Conclusion: These results suggest that α-linolenic acid protects renal proximal tubular cells against palmitic acid induced apoptosis. This protection may involve reduction of ER stress caused by palmitic acid, at the level of eIF2α phosphorylation.

Effects of CB1 blockade in experimental diabetic nephropathy

F. Barutta, S. Giunti, R. Mastrocola, S. Pinach, L. Giardino, M.P. Rastaldi, P. Cavallo Perin, G. Gruden;
Department of Internal Medicine, University of Turin, Italy.

Background and aims: Diabetic nephropathy is characterized by increased glomerular permeability to proteins. Podocyte abnormalities have been implicated in the pathogenesis of the diabetic proteinuria, but the underlying mechanism/s remains unclear. The CB1 endocannabinoid receptor is predominantly localised in the central nervous system; however, recent studies have shown that it is also expressed by peripheral tissues and plays a role in the pathogenesis of chronic degenerative diseases. Our aim was to assess whether the CB1 receptor is expressed in the glomeruli in both normal and diabetic mice and if CB1 blockade affects expression of podocyte slit diaphragm proteins and proteinuria in experimental diabetes.
Materials and methods: Male C57Bl6 mice were made diabetic by intraperitoneal (IP) injection of streptozotocin in citrate buffer. Control mice were injected with citrate buffer alone. After the onset of diabetes both control (ND n=10) and diabetic mice (DM n=14) were treated with either AM251, a selective CB1-receptor antagonist (1 mg/kg IP daily), or vehicle. Fourteen weeks after the induction of diabetes, urine were collected to perform measurement of the urinary excretion of albumin and a blood sample taken for blood glucose and glycated haemoglobin measurements. Mice were sacrificed, kidneys removed, and both immunofluorescence and immunohistochemistry were performed to examine CB1, nephrin, synaptopodin, and zonula occludens-1 (ZO-1) glomerular expression. Quantification of the percentage area of staining of positive cells was performed in 20 glomeruli for each section in a blinded manner.
Results: Diabetic mice showed a significant increase in both plasma glucose and glycated haemoglobin levels. Within the glomeruli CB1 receptor expression localised predominantly to podocytes and was significant greater in the diabetic than in the control animals (DM: 4.32 ± 0.28 vs ND: 2.76 ± 0.45, percentage area, p<0.02). Treatment with AM251 reduced CB1 expression in the controls and normalised it in the diabetic mice (ND+AM251: 1.11 ± 0.62, DM+AM251: 2.16 ± 0.23, p=ns ND vs DM+AM251). Albuminuria was significantly (p<0.001) increased in the diabetic animals [DM: 372.34 (250.61-650.84) μg/18hrs, geometric mean (25^{th}-75^{th} percentile)] as compared to the controls [ND: 33.41 (27.48-39.06)] and ameliorated by treatment with AM251 [ND+AM251: 24.15 (15.99-38.91); DM+AM251: 167.71 (125.78-250.74); p<0.01 DM vs DM+AM251]. In the diabetic mice the increase in albuminuria was paralleled a significant reduction in nephrin expression (ND: 26 ± 6.1; DM: 12.8 ± 2.2; p<0.01). This effect was completely prevented in the diabetic mice treated with AM251 (ND+AM251: 28 ± 3.3; DM+AM251: 21.2 ± 1.9, p<0.05 DM+AM251 vs DM; p=ns DM+AM251 vs ND). Similarly, diabetes-induced ZO-1 downregulation was entirely abolished in AM251-treated diabetic mice (ND: 23.1 ± 2.2; ND+AM251: 24.3 ± 3; DM: 6.7 ± 1.4; DM+AM251: 22.9 ± 2.3, p<0.001 DM vs ND and ND+AM251; DM+AM251 vs DM). No significant changes in synaptopodin expression were observed among groups.
Conclusion: These findings demonstrate that in experimental diabetes there is CB1 receptor overexpression and that CB1 blockade ameliorate diabetic proteinuria, possibly via prevention of podocyte slit diaphragm protein loss.

Exendin-4 ameliorates renal injuries through anti-oxidative and anti-inflammatory effects in type 1 diabetic rats

R. Kodera, H. Kataoka, K. Shikata, C. Sato, M. Sasaki, S. Nishishita, S. Miyamoto, D. Hirota, N. Kajitani, D. Ogawa, H. Makino;
Department of Medicine and Clinical Science, Okayama University Graduate School of Medicine Dentistry and Pharmaceutical Sciences, Okayama, Japan.

Background and aims: We have recently shown the renoprotective effects of exendin-4 independent of blood glucose lowering actions using streptozotocin induced diabetic rats. In addition, we have demonstrated that GLP-1 receptor is expressed in glomeruli, tubular epithelium, arterioles and cultured macrophage (THP-1 cell). The aim of this study is to clarify the mechanism of protective effects of exendin-4 against diabetic nephropathy.
Materials and methods: Five-week old male Sprague-Dawley rats were divided into four groups: non-diabetic: ND, non-diabetic rats treated with exendin-4: ND+EX, diabetic rats without treatment: DM, diabetic rats treated with exendin-4: DM+EX. Rats were administered intraperitoneally with exendin-4 (10μg/kg/day, ND+EX and DM+EX) or vehicle (ND and DM) every day for 8 weeks. To examine the effects of exendin-4, we measured urinary albumin excretion and creatinine clearance and evaluated the renal histological morphometry. We also examined the expression of CD14, MCP-1, TGF-β1, ICAM-1 in kidney tissues by quantitative real-time RT-PCR and immunostaining. In addition, to clarify the locarization of GLP-1 receptor in glomerulus, we examined gene expression of GLP-1 receptor in cultured human glomerular endothelial cell, murine mesangial cell and epithelial cell. To investigate the mechanism for renoprotective effects of exendin-4, we measured the urinary 8-hydroxy-2'-deoxyguanosine (8-OHdG) and examined nonphagocytic NADPH oxidase 4(NOX4) in the kidney.
Results: Exendin-4 significantly reduced urinary albumin excretion (Mean values; DM 2,215μg/day, DM+EX 713μg/day, DM vs DM+EX: P<0.05) without change of blood glucose levels and blood pressure. Exendin-4 significantly attenuated glomerular size (glomerular size; ND: $6.7\times10^3\mu m^2$, ND+EX: $7.0\times10^3\mu m^2$, DM: $9.0\times10^3\mu m^2$, DM+EX: $7.7\times10^3\mu m^2$ DM vs DM+EX: P<0.01) and mesangial matrix expansion (mesangial matrix index; ND: 2.9%, ND+EX: 2.8%, DM: 8.0%, DM+EX: 2.9%, DM vs DM+EX: P<0.05). Exendin-4 also significantly reduced mRNA expression of CD14, TGF-β1 and ICAM-1(P<0.05) in kidney tissues. Expression of MCP-1 was reduced by exendin-4, however, there was no statistical significance. Immunohistochemical analysis revealed that exendin-4 suppressed macrophage infiltration and expression of type IV collagen and ICAM-1 in the kidney of diabetic rats. In addition, exendin-4 significantly reduced the urinary excretion of 8-OHdG and the expression of 8-OHdG in the glomeruli in diabetic rats. NOX4 was significantly reduced in the glomeruli of diabetic rats by exendin-4 treatment. GLP-1 receptor was expressed in glomerular endothelial cell.
Conclusion: The current results suggest that exendin-4 decreased the expressions of NOX4 and 8-OHdG in the glomeruli via GLP-1 receptor expressed on glomerular endothelial cell in diabetic rats. Exendin-4 also prevented the expression of ICAM-1 and macrophage infiltration in diabetic glomeruli. Exendin-4 may ameliorate diabetic nephropathy through anti-oxidative and anti-inflammatory effects.

Aldosterone blockade improves nephropathy by reducing renal NADPH oxidase induced oxidative stress in the diabetic hypertensive rats

B.S. Pessôa, F.K. Hassui, J.M. Lopes de Faria, J.B. Lopes de Faria;
Department of Internal Medicine, University of Campinas (UNICAMP), Brazil.

Background and aims: It has been shown that the blockade of aldosterone ameliorates nephropathy in patients and in animal models of diabetes mellitus (DM). Reduction of oxidative stress and/or renal inflammation had been implicated in the mechanism by which aldosterone blockade improves nephropathy. However, in these studies blood pressure reduction with aldosterone blockade could not be ruled out as a contributor to this beneficial effect. The aim of this study was to investigate the hypothesis that aldosterone blockade may improve nephropathy by reducing oxidative stress and independently of its antihypertensive effect.
Materials and methods: Spontaneously hypertensive rats (SHR), with 4 weeks of age, were rendered diabetic by intravenous injection of streptozotocin. Blood glucose levels of ≥ 270 mg/dL were considered diabetic. The diabetic animals were randomized to receive or not an aldosterone blocker, spironolactone (50mg/kg/day), in drinking water. The albumin excretion rate was determined in 24 h urine by radial immunodiffusion. After 20 days or 8 weeks of treatment, the rats were euthanized and kidneys collected. Changes induced in DNA by oxidative stress and infiltration of macrophages were evaluated by immunohistochemistry for 8-OHdG and ED1, respectively. NADPH-induced superoxide generation was assessed by lucigenin-enhanced chemiluminescence. NADPH oxidase subunit p47phox and fibronectin were assessed by Western Blot.
Results: Plasma glucose levels were significantly (p<0.0001) higher in untreated diabetic rats and it was not modified by spironolactone. Likewise, systolic blood pressure was unaltered by diabetes or by treatment with spironolactone (control=159±10, untreated diabetic=156±17, spironolactone diabetic=151±2 mmHg). Albuminuria was higher in the diabetic group compared to control (216(129-265) *vs* 625(412-752) μg/24h, p=0.0062) and it was reduced to 474(249-547), p=0.0283, with aldosterone blockade. Tubulointer-

stitial expression of 8-OHdG was higher in diabetic rats when compared to controls (292±112 *vs* 555±86 positive cells/50 high field, p=0.0008, and decreased in rats treated with spironolactone for 20 days (457±54, p=0.0143). There was no increase in the expression of ED1 in diabetic animals when compared to controls in treatment for 20 days and 8 weeks (59±18 *vs* 53±19 *vs* 55±22 positive cells/50 high field, 20 days of treatment; 113±35 *vs* 133±71 *vs* 158±31, 8 weeks of treatment). The production of superoxide induced by NADPH oxidase was higher in diabetic rats when compared to controls (3.0±0.52 *vs* 6.8±2.28 RLU/20s/mg, p=0.0143, 20 days of treatment; 4.7±2.70 *vs* 9.4±2.46, p=0.025, 8 weeks of treatment) and was reduced in 8 weeks-treated rats (4.8±1.9, p=0.0389). Western blotting analysis showed an increase in expression of the p47phox subunit of NADPH oxidase in the diabetic group *versus* control group (0.43±0.24 *vs* 1.15±0.3 arbitrary units, p=0.0004) and reduction with 20 days of treatment (0.33±0.11, p<0.0001). Fibronectin expression was enhanced in 8-week diabetic rats compared to controls (1.45±0.71 *vs* 2.54±1.27 arbitrary units, p=0.062) and the treatment reduced to normal levels (1.07±0.62, p=0.0211).
Conclusion: These results suggest that spironolactone ameliorates nephropathy in the diabetic hypertensive rats by diminish NADPH oxidase-induced oxidative stress and without affecting blood pressure.

Polymorphism in the angiotensin II type-1 receptor gene and renoprotective effect of losartan
S. Andersen[1], L. Tarnow[1], P. Rossing[1], M. Lajer[1], H.-H. Parving[2,3];
[1]Steno Diabetes Center, Gentofte, [2]Department of Endocrinology, Rigshospitalet, Copenhagen, [3]Faculty of Health Science, Aarhus, Denmark.

Background and aims: The angiotensin II type-1 receptor (AT-1) mediates the major hemodynamic and trophic actions of angiotensin II. The C allele of the 1166 A/C gene polymorphism in the AT-1 receptor has been associated with severe hypertension and previous studies have suggested that the renal and systemic responses to angiotensin-II receptor-blockers (ARB) are related to this polymorphism. We investigated whether the 1166 A/C polymorphism is related to reductions in blood pressure, albuminuria and preservation of glomerular filtration rate (GFR) during short-term and long-term treatment with losartan 100 mg in 61 hypertensive type 1 diabetic patients with diabetic nephropathy.
Materials and methods: After a 4-week wash-out period, patients received losartan (100 mg o.d.) and were followed prospectively with a mean follow-up of 36 months. After 4 months with losartan as monotherapy, other antihypertensive medication was added to achieve a blood pressure target below 135/85 mmHg. At baseline, after 4 months and every 6 months thereafter, GFR (51Cr-EDTA-clearance), albuminuria and 24 h blood pressure were determined. The 1166 A/C polymorphism was determined by standard polymerase chain reaction (PCR). Investigators and patients were masked to genotypes.
Results: The AA, AC and CC genotypes were found in 46%, 44 % and 10 % of the patients, respectively. Patients homozygous or heterozygous for the C allele were combined in one group as in previous studies. At baseline, GFR, albuminuria and blood pressure were similar in the two groups, AA vs. AC/CC: (mean (SE)), 86 (5) vs. 88 (4) ml/min/1.73m^2; geometric mean (95 % CI) 1080 (778 - 1498) vs. 1291 (940-1775) mg/24 h; mean (SE) 148/80 (4/2) vs. 154/81 (3/2) mm Hg. After 4 months, blood pressure lowering response was more pronounced in the AA compared to the AC/CC group and lowered by (mean (SE)) 13/9 (4/1) vs. 8/4 (2/1) mmHg, respectively (systolic and diastolic p < 0.05). Blood pressure reduction was comparable in both groups during long-term follow-up. Equalisation of blood pressure reduction may be explained by additional antihypertensive medication during follow-up, which was given to 53 % of patients in the AA group as compared to 76 % in the AC/CC group (p = 0.07). No significant differences between groups were seen in rate of decline in GFR (median (range)): 4 .0 (0-16) vs. 3.6 (0-16 ml/min/year (p=0.5). Albuminuria was reduced to the same extend in both groups during the initial 4 months and long-term treatment (p>0.1 AA vs. AC/CC).
Conclusion: Our study indicates that presence of the C allele of the 1166 A/C gene polymorphism in the AT-1 receptor reduces the short-term blood pressure lowering response to losartan. Additional antihypertensive medication may compensate for this and contribute to a similar long-term blood pressure lowering effect and comparable decline in kidney function in both genotype groups.

PS 96 Predictors of nephropathy

1072

Leptin is a crucial factor responsible for the relationship between abdominal obesity and microalbuminuria in patients with type 2 diabetes
K. Hanai[1], T. Babazono[1], I. Nyumura[1], K. Toya[1], T. Hayashi[1], M. Ohta[1], R. Bouchi[1], K. Suzuki[1], N. Tanaka[1], A. Ishii[1], Y. Iwamoto[2];
[1]Division of Nephrology and Hypertension, Diabetes Center, [2]Department of Medicine, Diabetes Center, Tokyo Women's Medical University School of Medicine, Japan.

Background and aims: Abdominal obesity has been implicated in the pathogenesis of microalbuminuria in patients with diabetes; however, the mechanisms remain unclear. Increased leptin secretion by adipocytes may be a candidate for responsible factors for the relationship between abdominal obesity and microalbuminuria, because increased leptin secretion has been demonstrated to contribute to renal impairment through glomerular hyperfiltration by activating sympathetic nervous system or direct injury to glomerular endothelial and mesangial cells. However, it is controversial whether serum leptin levels are associated with microalbuminuria in patients with diabetes. We, therefore, conducted a cross-sectional study to clarify the relationship between increased serum leptin levels associated with abdominal obesity and albuminuria in patients with type 2 diabetes mellitus (T2DM).
Materials and methods: We studied a total of 463 adult Japanese patients with T2DM, 212 women and 251 men, with a mean (± SD) age of 61 ± 13 years. Patients with macroalbuminuria, defined as a urinary albumin-to-creatinine ratio (ACR) ≥ 300 mg/g Cr and those with an estimated glomerular filtration rate (eGFR) < 15 mL/min/1.73 m^2 were excluded. Normo- and microalbuminuria was defined as an ACR less than 30 mg/g Cr and 30-299 mg/g Cr, respectively. Waist circumference was used as a surrogate marker of abdominal adiposity. Serum leptin levels were measured by radioimmunoassay.
Results: Geometric mean (95% confidence interval [CI]) of serum leptin levels were 5.9 (5.5 - 6.4) ng/mL, overall. Serum leptin levels in patients with microalbuminuria (N=111) were significantly higher than those with normoalbuminuria (N=352, 5.6 [5.2 - 6.1] *versus* 7.0 [6.0 - 8.2] ng/mL, p= 0.012). In the Spearman's correlational analysis, waist circumference was strongly associated with serum leptin levels (rs= 0.556, p< 0.001). Urinary ACR was significantly associated with both waist circumference (rs= 0.187, p< 0.001) and serum leptin levels (rs=0.212, p<0.001). In the multiple regression analysis adjusted for age, sex, HbA1C, presence of hypertension, presence of dyslipidemia and eGFR, the association between waist circumference and urinary ACR remained statistically significant (standardized parameter estimate= 0.167, p< 0.001). When serum leptin level was incorporated in the model as an independent variable, urinary ACR was also significantly associated with serum leptin levels (standardized parameter estimate= 0.176, p= 0.017), whereas statistical significance between urinary ACR and waist circumference disappeared (p= 0.230), indicating that effects of waist circumference on the urinary ACR may be explained by increased serum leptin levels associated with abdominal obesity.
Conclusion: Leptin may be a crucial factor responsible for the relationship between abdominal obesity and microalbuminuria in patients with T2DM.

1073

Lipid profiles predict progression of renal disease
N. Tolonen[1,2], C. Forsblom[1,2], J. Wadén[1,2], L. Thorn[1,2], M.-R. Taskinen[3], P.-H. Groop[1,2], FinnDiane Study Group;
[1]Folkhälsan Research Center, Folkhälsan Institute of Genetics, [2]Department of Medicine, Division of Nephrology, HUCH, [3]Department of Medicine, Division of Cardiology, HUCH, Helsinki, Finland.

Background and aims: Multiple lipid abnormalities have been observed in cross sectional studies and earlier small scale studies have suggested that lipid variables might be involved in the progression of diabetic nephropathy. However, whether lipid abnormalities play a true role in the pathogenesis of diabetic nephropathy is still a matter of debate. Therefore, we decided to systematically study the impact of baseline lipid variables on the progression of renal disease in a large nation-wide prospective cohort of patients with type 1 diabetes.
Materials and methods: A total of 2,304 adult patients with type 1 diabetes and centrally measured lipid profiles participating in the Finnish Diabetic

Nephropathy Study (FinnDiane). Data on progression of renal disease were verified from medical files and patients were followed for 5.4 ± 2.0 years. The lipid profile included total cholesterol, LDL-cholesterol, triglycerides, total HDL (HDL_2, HDL_3) -cholesterol, apolipoproteins (apoA-I, A-II, B) and ratios. Albuminuria status was defined based on AER in at least two out of three collections.
Results: Patients that developed microalbuminuria (100 out of 1449), had higher total cholesterol, non-HDL-cholesterol, triglycerides, ApoB, and triglyceride/HDL-cholesterol ratio at baseline than patients that did not progress (p<0.001). In a Cox regression analysis with traditional risk factors (sex, duration, HbA1c, systolic blood pressure, BMI, and smoking), ln-triglycerides [HR 1.71 (95% CI 1.17-2.50)] predicted development of incident microalbuminuria. When the combined effect of above median triglycerides and AER was studied, the risk of microalbuminuria rose from 8.97 (2.73-39.50), in patients with above median AER alone, to 14.57 (4.52-47.02), in patients with both above median triglycerides and AER. Progressors from micro- to macroalbuminuria (50 out of 303) had higher total cholesterol,non-HDL-cholesterol, triglycerides, ApoB, ApoB/ApoA-I and triglyceride/HDL-cholesterol ratio at baseline than patients that did not progress (p<0.001). In a Cox regression analysis, ln-triglycerides [2.69 (1.53-4.71)] independently predicted progression to macroalbuminuria. The risk of macroalbuminuria rose from 7.65 (1.69-34.55) in patients with above median AER alone, to 16.61 (3.96-69.71), in patients with both above median triglycerides and AER. Progressors from macroalbuminuria to end stage renal disease (ESRD, 92 out of 310) had higher total cholesterol, non-HDL-cholesterol, triglycerides, ApoB, ApoB/ApoA-I and triglyceride/HDL-cholesterol ratio than patients that did not progress (p<0.001). In a Cox regression analysis, ln-triglycerides [2.30 (1.50-3.53)] independently predicted progression to ESRD. When triglycerides were replaced with the other lipid variables separately, high total cholesterol, LDL-cholesterol, non-HDL-cholesterol as well as low HDL-, HDL_2-cholesterol and ApoA-II concentrations were also predictive of progression to ESRD.
Conclusion: Lipid abnormalities, particularly high triglyceride concentrations, increased the risk of progression of renal disease and had an additive effect beyond albuminuria.

Incidence of microalbuminuria in patients with type 1 diabetes mellitus diagnosed in childhood and adolescence
M. Vannati[1], N. Minuto[1], A. Pistorio[2], M. Haupt[1], R. Lorini[1], G. d'Annunzio[1];
[1]Department of Pediatrics, [2]Department of Biostatistics, G. Gaslini Institute, Genoa, Italy.

Background and aims: Type 1 diabetes mellitus (T1DM) is increasing worldwide and diabetic nephropathy (DN) is a life-threatening long-term complication. Microalbuminuria (MA) is a precocious marker of DN and its detection is recommended for screening even since adolescence.
Methods: We estimated the incidence of MA using overnight albumin excretion rate (AER) in 280 T1DM patients. According to ISPAD Guidelines, AER values between 20-200 μg/min/m^2 (in two of three samples in a 6 months period) were considered positive. At screening evaluation, we collected data for age, disease duration, pubertal stage, body mass index (BMI-SDS), metabolic control (HbA1c), coexistence of autoimmune thyroid and celiac disease, and retinopathy screening results.
Results: 164/280 patients were males, age at diagnosis was 1-16.5 yrs (M 7.6± SD 3.9), follow-up mean period was 10.7±7.0 yrs and mean age at the end of follow-up was 18.2 years (SD 7.6). MA was found in 22/280 patients (7.8%), with an incidence rate of 7.36/1000 pts-yr (IC 95%: 4.84-11.17). We found a relationship between MA incidence and disease duration <10 years (p = <0.0001) and coexistence of retinopathy (p=0.047). Moreover we found a relationship between MA and either mean HbA1c levels in the last year of follow-up ≥ 7.5% (p=0.04) or a high number of follow-up yrs (≥ 85%) with poor metabolic control (cut off ≥ 85% according to ROC curve analysis). In 12/22 patients MA disappeared during follow-up, therefore angiotensin converting enzyme inhibitor treatment was started in 10/22 patients with persistent MA.
Conclusion: Diabetic nephropathy is the most important cause of end stage renal disease in adulthood worldwide. DN screening is mandatory in pediatric T1DM patients to identify patients at risk because of genetic background or poor metabolic control.

Determinants of decline in glomerular filtration rate in normoalbuminuric subjects with and without diabetes
H. Yokoyama[1], H. Sone[2], K. Saito[2], H. Itoh[3], M. Haneda[3];
[1]Internal Medicine, Jiyugaoka Clinic, Obihiro, [2]Department of Internal Medicine, University of Tsukuba Institute of Clinical Medicine, [3]Division of Metabolism and Biosystemic Science, Department of Medicine, Asahikawa Medical College, Japan.

Background and aims: We investigated whether the slope of estimated glomerular filtration rate (GFR) is different between non-proteinuric subjects with and without diabetes, and what clinical factors are associated with the GFR slope.
Materials and methods: An observational cohort study was performed in 923 subjects, and the predictive value of baseline variables on the GFR slope was investigated.
Results: Based on the median 3-year follow-up and 7 measurements of GFR, GFR slope (% per year, median and interquartile range) was significantly larger in subjects with diabetes (-2.39 (-4.86- 0.15), N=729) than in those without diabetes (-1.02 (-4.28- 1.37), N=194), and this difference remained significant with or without presence of hypertension. After adjustments for confounding factors, progression promoters of GFR decline were found to be baseline high values of HbA1C, GFR, systolic blood pressure and low plasma total protein in subjects with diabetes, while the latter two were significant in subjects without diabetes. In subjects with diabetes the high GFR was accounted for by high HbA1C at baseline, and the progression promoters differed between those with and without hypertension, or with high and low baseline GFR. Any combination of the promoters showed increased risk for GFR decline.
Conclusion: GFR slope is substantially affected by multiple factors at various stages. The degree of chronic hyperglycemia is likely to play a crucial role in elevating GFR and accelerating the decline in patients with type 2 diabetes even from the normoalbuminuric stage.

***RAGE* polymorphism and serum sRAGE levels are associated with diabetic nephropathy in Japanese type 2 diabetic patients**
E. Nakashima[1,2], A. Watarai[1], T. Tsukahara[2], T. Matsuki[2], K. Naruse[2], H. Kamiya[2], Y. Kobayashi[2], T. Shibata[2], Y. Oiso[2], J. Nakamura[2];
[1]Metabolic and Endocrinology, Chubu Rousai Hospital, [2]Internal Medicine, Diabetes and Endocrinology, Nagoya University, Nagoya, Japan.

Background and aims: Diabetic microangiopathy such as retinopathy, nephropathy, and neuropathy are the major causes of lowering quality of life in diabetic patients. The ligand-receptor for advanced glycation end products (RAGE) axis has emerged as a novel pathway involved in diabetes mellitus itself and its vascular complications. As circulating soluble forms of RAGE (sRAGE) may reflect the activity of AGE-RAGE axis, it has been proposed as a potential mechanism linking hyperglycemia and diabetic microvascular complications. Also some previous papers reported the positive relationship between RAGE polymorphisms and its blood concentrations. In this cross-sectional study, therefore, we explored its single nucleotide polymorphisms (SNPs) especially *AGER*-374T/A in correlation with its blood levels and examined the *RAGE* SNPs for the possibility as a risk marker of diabetic microangiopathy in Japanese type 2 diabetic patients.
Methods: A total of 289 type 2 diabetic outpatients were enrolled in this study. Soluble RAGE was measured by an enzyme-linked immunoassay kit. Genotyping of 3 polymorphisms in *AGER* were performed by polymerase chain reaction restriction fragment length polymorphism method. Diabetic nephropathy was defined by urine albumin extraction rate (≥ 30 mg/g Cr/day). Statistical analyses were performed using the program SPSS. Data are presented as means ± SD.
Results: There were no significant differences in genotypic or allelic distribution among patients with or without diabetic retinopathy and neuropathy, but there was a significant increase in the frequency of the TA+AA genotypes at -374T/A in the patients with diabetic nephropathy (P=0.009). The serum sRAGE levels were increased in a genotype-dependent fashion only at -374T/A (TT<TA<AA, Kruskull-Wallis test, P=0.045). Also serum sRAGE levels were higher in the patients with diabetic nephropathy than in those without this disease (500±349 ng/ml vs. 417±263 p=0.026), but there were no significant differences in patients with or without diabetic retinopathy or neuropathy. In Spearman's correlations, serum RAGE levels were correlated

with fasting blood glucose (r=-0.221, P<0.01) and estimated GFR (eGFR) (r=-0.221, P<0.01). After adjustment for sex, body mass index, systolic blood pressure, diastolic blood pressure, duration of diabetes, and serum levels of triglycerides, RAGE, HbA1c and eGFR in multivariate logistic-regression analysis, individuals with the TA or TT genotypes were significantly more likely to have had a diabetic nephropathy than individuals with the TT genotype (Odds ratio 2.01, 95% Confidence Interval 1.13-3.55, P=0.017).
Conclusion: The serum sRAGE levels and its genotype were associated with the prevalence of diabetic nephropathy in Japanese type 2 diabetic patients. Our results suggest that the *AGER* gene polymorphism (-374T/A) and serum sRAGE levels might be a risk marker of susceptibility to diabetic nephropathy among those patients. Further studies are needed to determine the exact role of sRAGE between the relationship of AGE-RAGE axis and the development of diabetic nephropathy.

Association of a single nucleotide polymorphism in *KCNQ1* with diabetic nephropathy in Japanese subjects with type 2 diabetes
S. Maeda[1], S.-I. Araki[2], T. Umezono[3], M. Toyoda[3], K. Kawai[4], M. Imanishi[5], T. Babazono[6], D. Suzuki[3], Y. Iwamoto[6], A. Kashiwagi[2], Y. Nakamura[7];
[1]Laboratory for Endocrinology and Metabolism, RIKEN Center for Genomic Medicine, Yokohama, [2]Department of Medicine, Shiga University of Medical Science, Otsu, [3]Division of Nephrology and Metabolism, Department of Internal Medicine, Tokai University School of Medicine, Isehara, [4]Kawai Clinic, Tsukuba, [5]Department of Internal Medicine, Osaka City General Hospital, [6]Diabetes Center, Tokyo Women's Medical University, [7]Laboratory of Molecular Medicine, Human Genome Center, Institute of Medical Science, The University of Tokyo, Japan.

Background and aims: It has been suggested that genetic susceptibility plays an important role in the pathogenesis of diabetic nephropathy, but most of genes responsible for the development and progression of diabetic nephropathy remain to be identified. In this study we focus on the *KCNQ1* at chromosome 11p15.5, recently identified as a strong susceptibility gene to type 2 diabetes, as a plausible candidate gene for diabetic nephropathy, and examined the association of SNPs within the *KCNQ1* with diabetic nephropathy in Japanese populations.
Materials and methods: We first examined the association of 33 SNPs within the *KCNQ1* in 1,304 Japanese subjects with type 2 diabetes having diabetic retinopathy (Study 1: 747 with overt nephropathy, 557 controls with normoalbuminuria) by using a invader assay. We further examined additional 2 independent Japanese cohorts for replication studies (Study 2: 300 type 2 diabetes with end-stage renal disease, 325 type 2 diabetes with normoalbuminuria, Study 3: 6 years longitudinal study, 31 cases progressed to overt nephropathy and 168 controls).
Results: Among the 33 SNPs examined, T allele of rs2237897 was nominally associated with susceptibility to diabetic nephropathy (OR = 1.29, 95% CI 1.09 - 1.53, nominal p = 0.002, corrected p = 0.07). Subsequent haplotype analyses revealed that common haplotype consisted of 2 SNPs including rs2237897 showed nominal association with the disease, but the association was not stronger than that of rs2237897 alone. The same trend of the association of rs2237897 could be observed in two independent Japanese cohorts (Study 2; OR = 1.19, Study 3; OR = 1.16), and combined analysis for all 3 tests with a fixed model meta-analysis gave nominal p value of 0.0009 (OR = 1.26, 95% CI 1.10 - 1.44, corrected p = 0.03).
Conclusion: We have identified significant association of rs2237897 with diabetic nephropathy in 3 independent Japanese populations. The results suggest that *KCNQ1* may play some roles in the pathogenesis of diabetic nephropathy, and can be considered as a new candidate gene for conferring susceptibility to diabetic nephropathy.

Prevalence and determinants of chronic kidney diseases in a Bangladeshi population
A. Afroz[1], A. Akter[1], F. Ahmed[2], N. Awal[3], K. Fatema[1], L. Ali[4], A.K. Azad Khan[5];
[1]Department of Epidemiology & Biostatistics, Bangladesh Institute of Health Scinces, [2]Bangladesh Diabetic Shomity, [3]ORBIS International, [4]Department of Biochemistry & Cell Biology, BIRDEM, [5]Bangladesh Dibetic Somiti, Dhaka, Bangladesh.

Background and aims: Chronic kidney diseases (CKDs) are now creating substantial burden on health care resources in developing countries and it is closely linked with the epidemic of diabetes mellitus. Data on burden of diseases and its determinants in a specific population are of vital importance in designing proper management and preventive strategies. The present study aimed to explore the prevalence and determinants of CKDs in a semi-urban and rural population of Bangladesh.
Materials and methods: A total number of 803 adult subjects (male 449, female 354), aged between 25-67 years, were screened for diabetes in 3 outreach camps. Diabetes mellitus was diagnosed by OGTT following WHO criteria and nephropathy was diagnosed by urine testing through dipstick, eGFR (calculated from serum creatinine) and measurement of albumin-creatinine ratio (ACR). Anthropometric measurements were done by standardized techniques. Blood glucose was measured by glucose-oxidase method, lipids by enzymatic method, creatinine by alkaline picrate method and albumin was measured by immunonephelometry. Following a nested case-control design an age-matched control group was selected from the non-diabetic subjects to compare with cases having abnormal glucose tolerance (AGT). Data were analyzed by univariate as well as multivariate statistics.
Results: Out of 803 subjects 113 (14.1%) showed AGT (7.5% diabetes, 5.1% IGT and 1.5% IFG). The age-matched 106 cases, who were selected as control, did not show proteinuria in the dipstick method, but in the diabetic group 17 (15.1%) subjects were found to have proteinuria of verifying degrees. As judged by eGFR only 9.4% cases in the control group showed normal eGFR; the corresponding value in the Diabetic group was even lower (3.5%). Using the ACR criteria the prevalence of nephropathy (including incipient nephropathy) in the control group was about 46% (with 41% at stage 3 and 1.9% at stage 4) and that in the Diabetic group was 65% (with 51% at stage 3 and 12.5% at stage 4). On logistic regression analysis nephropathy was found to be strongly associated with diabetes even when the confounding variables were adjusted.
Conclusion: A large population of adult Bangladeshis, even in semi-urban and rural population, are suffering from nephropathy (frank and incipient), but those can not be detected by dipstick (under diagnosis) or eGFR (over diagnosis). Measurement of ACR, along with OGTT, can detect a large number of incipient diabetic nephropathy cases at the field level and this can be used as a public health tool for prevention.

Thiamine levels and transketolase genetic variants as modifiers of progression of diabetic nephropathy
L. Pacal[1], J. Tomandl[2], V. Tanhauserova[1], M. Tomandlova[2], D. Krusova[3], J. Svojanovsky[3], S. Stepankova[4], J. Belobradkova[4], J. Olsovsky[3], K. Kankova[1];
[1]Dept. of Pathophysiology, Masaryk University, [2]Dept. of Biochemistry, Masaryk University, [3]Dept. of Internal Medicine, St. Anne's University Hospital, [4]Dept. of Gastroenterology, Faculty Hospital Brno-Bohunice, Brno, Czech Republic.

Background and aims: Diabetic complications including diabetic nephropathy (DN) develop due to the complex dysregulation of cellular metabolism during hyperglycemia. Accumulation of proximal glycolytic intermediates provides substrates for several alternative metabolic pathways producing harmful moieties such as advanced glycation end-products, dicarbonyls, sorbitol, hexosamines, reactive oxygen and nitrogen species etc. Pentose phosphate pathway (PPP) represents potentially "protective" mechanism in hyperglycemia since shunting of cumulated glycolytic intermediates (esp. triosephosphates) into the PPP reactions quantitatively limits their processing elsewhere. Thiamin status (thiamine and its esters) as cofactors of transketolase (TKT) and genetic variability in the TKT locus - potentially together with other genes encoding enzymes of PPP such as transaldolase, TKT-like and glucose-6-phosphate dehydrogenase - might contribute to an interindi-

vidual variability in the onset and progression of DN. The specific aims of the study were (i) quantification of plasma and erythrocyte levels of thiamines (Th, ThMP, ThDP), (ii) haplotype-based association study of DN with TKT variability, (iii) genotype vs. phenotype correlation of TKT variability and enzyme erythrocyte activity and (iv) evaluation of prognostic value of those biochemical and genetic parameters for the progression of DN.
Materials and methods: A total of 231 diabetic subjects were included in the case (DN) - control (non-DN) study (type 1 or 2 diabetics with parallel DN and gender- and age-matched diabetics without organ complications, respectively, in ~1:1 ratio), DN cohort followed prospectively for the average period of 24 months. SNPs (total n = 15) were genotyped by means of PCR using fluorescent-labelled probes (TaqMan®, Applied Biosystems). Haplotypes were inferred using Bayesian-based algorithm (PHASE). Concentration of thiamines (plasma and erythrocyte) and TKT catalyzed reaction were determined by HPLC.
Results: P-Th, ery- and p-ThDP and ery. activity of TKT differed significantly between diabetics with and without DN (P<0.05, Mann-Whitney). There was a signif. negative correlation between fasting glycemia and ery-Th and ery-ThDP (P<0.05, Spearman) and signif. positive correlation between serum creatinin and most of the parameters of thiamine metabolism. Haplotype distribution of TKT differed significantly between DN vs. non-DN groups (P<0.05, 10 000 permutations). Common haplotype with frequency 21.3% in the whole study population (risk-haplotype) exhibited the greatest difference. Carrier state of the risk-haplotype was associated with significantly accelerated onset of DN (P<0.05) and lower thiamin concentrations but not with TKT activity.
Conclusion: Results suggest that TKT variability and thiamine status modify susceptibility and progression of DN.

The effect of alcohol consumption on nephropathy in type 1 diabetic patients
M.E. Feodoroff, V. Harjutsalo, C. Forsblom, P.-H. Groop, FinnDiane;
Folkhälsan Research Center, Helsinki, Finland.

Objective: To study the effect of alcohol consumption on the initiation and progression of diabetic nephropathy
Research design and methods: The study included 3,468 type 1 diabetic patients from the FinnDiane (Finnish Diabetic Nephropathy) study. We studied the cross sectional association between alcohol consumption and nephropathy ass well as the effect of alcohol consumption on the progression of nephropathy during follow-up. The alcohol data were collected with questionnaires during the base-line visit. The patients were divided in five different groups according to their alcohol consumption in grams per week. Because the limit of heavy drinking is classified differently for men (≥280g/week) and women (≥140g/week) also the groups were formed differently for men (0 g/week, 0-139,9 g/week, 140-279,9 g/week, ≥280 g/week and former users) and women (0 g/week, 0-69,9 g/week, 70-139,9g/week, ≥140g/week and former users). In the cross sectional analysis the women consuming more than 70g/week were pooled due to the small number of heavy consuming women. The renal status was defined according to the albumin excretion in three urine collections. Data were analysed with logistic regression analyses. In multivariate analyses the data were adjusted for duration of diabetes, $HbA1_c$, systolic blood pressure and smoking status. In the analysis of follow up data men and women were pooled and data were adjusted for sex.
Results: According to the cross sectional data ORs for the risk of nephropathy in each increasing alcohol consumption group compared with abstainers were for men 0.71 (CI 0.50-0.99), 0.61 (CI 0.38-0.98), 0.50 (CI 0.27-0.95) and for former users 1.85 (CI 1.01-3.41). Correspoding ORs for women were 0.51 (CI 0.37-0.71), 0.48 (CI 0.29-0.79) and for former users 0.87 (CI 0.41-1.84). ORs for the progression of nephropathy in the follow up data were 1.04 (CI 0.76-1.44), 0.86 (CI 0.52-1.42), 1.67 (CI 0.91-3.05) and for former users 1.85 (CI 1.04-3.31).
Conclusion: In the cross sectional data we could observe a smaller risk of nephropathy in men and women with present alcohol consumption compared with the abstainers. The follow-up data, however, showed that the progression of nephropathy was equal among alcohol consumers and abstainers. The risk of nephropathy was highest in the former alcohol users. This was seen in the cross sectional data for men and in the follow up data for both men and women. Former heavy alcohol consumption seems to be associated with a higher risk of nephropathy. However, it is unclear if alcohol consumption per se is a risk factor for nephropathy or could the increased risk of nephropathy be explaned with other factors related to higher alcohol consumption.

The association between increased urinary albumin excretion and insulin resistance in subjects at high-risk of type 2 diabetes
S. Jiang[1,2], X. Gao[1], L. Ren[1];
[1]Endocrinology & Metablism, [2]General Practice, Zhongshan Hospital, Shanghai, China.

Background and aims: Insulin resistance has been implicated in the pathogenesis of increased urinary albumin excretion (UAE) in diabetes. In the current study, we investigate the association between increased UAE and insulin resistance in a large cohort of subjects at high-risk of type 2 diabetes.
Materials and methods: A total of 471 men and 874 women from the High-risk for Diabetes Changfen Study, aged 61±10 years with at least one of the risk factors for type 2 diabetes which included positive family history of diabetes, overweight or obesity, hypertension, dyslipidemia, history of vascular disease or history of delivery a big baby(only for women) were included. Insulin resistance was derived from the hemeostasis model assessment of insulin resistance ($HOMA_{IR}$) and UAE was derived from the albumin-to-creatinine ratio (ACR) defined as increased if the value was ≥ 40 μg/mg. Abnormal glucose metabolism was defined as fasting glucose≥5.6 mmo/L or 2h post prandial glucose≥7.8mmo/L in oral glucose tolerance test.
Results: 54 men (11.5%) and 201 women (23.0%) had increased UAE. After adjusting for age, gender, overweight or obesity, hypertension, dyslipidemia and abnormal glucose metabolism simultaneously, subjects with highest $HOMA_{IR}$ (the most insulin resistance) were more often having increased UAE than those with the lowest $HOMA_{IR}$ (the least insulin resistance) [Odds ratio (OR) 1.78, 95%CI (1.08-2.92), P=0.023), highest vs. lowest quintile]. For women, subjects with highest $HOMA_{IR}$ were more often having increased UAE [OR 2.1, 95%CI 1.1-3.9, P<0.05; highest vs. lowest quintile], but for men the risk to have increased UAE was not increased [OR 1.2, 95%CI 0.5-2.9, P>0.05; highest vs. lowest quintile]. In multivariate analyses, increased UAE was associated with $HOMA_{IR}$ independent of age, gender, overweight or obesity, hypertension, dyslipidemia and abnormal glucose metabolism (OR 1.76, P=0.000). The correlation between increased UAE and $HOMA_{IR}$ was still significant in women (OR 1.66, P=0.009), but was less pronounced and non-significant in men (OR 1.06, P>0.05).
Conclusion: In subjects at high-risk of type 2 diabetes, increased UAE is strongly associated with insulin resistance. This association seems to be stronger in women than in men.

Risk of having increased UAE according to quartiles of HOMAIR in subjects at high-risk of diabetes

Quartiles of $HOMA_{IR}$ (range)	Whole population (n=1345)	Men (n=471)	Women (n= 874)

Fibrinocoagulopathy in chronic kidney disease in patients with elderly type 2 diabetes

M. Kameyama, Y. Tamura, Y. Ando, Y. Tojo;
Division of Diabetology, Toho University Ohashi Medical Center, Tokyo, Japan.

Background and aims: Chronic kidney disease (CKD) is now widely accepted as a risk factor for coronary vascular disease (CVD) and mortality. Diabetes mellitus (DM) is a leading cause of CKD in patients with established CKD in the world. Macrovascular events such as CVD, especially in elderly DM, are most likely due to thrombotic process of the large arteries. The aim of this study was to evaluate the relationships between the blood coagulation and fibrinolytic function and the degree of CKD stages in patients with elderly type 2 diabetes in terms of CKD.
Materials and methods: We studied 139 elderly type 2 diabetic outpatients of 65 to 86 years of age[73.0+/-6.7 years(mean+/-SD)]. All of subjects had no evidence of cerebral, cardiac or peripheral vascular complications. None of them received the treatment of dialysis. At overnight fast, blood pressure (BP) was measured, and blood sampling for plasma glucose (PG), HbA1c, serum lipids, creatinine, plasma thrombomodulin (TM): a marker of vascular endothelial damage, prothrombinfragment 1+2 (F1+2), a direct marker of thrombin generation, α2 plasmin-inhibitor plasmin complex (PIC), a marker of fibrinolytic activity and fibrinogen (Fbg) were performed. Urinary albumin excretion ratio (UAE) was obtained in morning spot urine sample. The estimated glomerular filtration rate (eGFR) was estimated by using the following equations: $eGFR=0.741\times175\times Cr^{-1.154}\times Age^{-0.203}\times0.742$ (for females). All patients were divided into five CKD stages based on eGFR: stage 1 (GFR> 90 ml/min/1.73m^2), stage 2 (GFR: 60-89 ml/min/1.73m^2), stage 3 (GFR 30-59 ml/min/1.73m^2), stage 4 (GFR 15-29 ml/min/1.73m^2), and stage 5 (GFR<15 ml/min/1.73m^2).
Results: Number of each CKD stage was stage 1; 13, stage 2; 68, stage 3; 37, stage 4; 12 and stage 5; 9 cases, respectively. No differences in gender and age were present among 5 CKD stages. However, the duration of DM was significantly longer in stage 4 and 5 than other three stages. There were no differences among 5 stages in BP, PG, HbA1c and serum lipids. Concentration of plasma TM in stage 4 and 5 were significantly higher than stage 1, 2 and 3 ($p<0.01$, $p<0.01$, $p<0.01$ in stage 4 and 5, respectively). Similarly, concentration of F1+2 in stage 4 was higher than stage 2 ($p<0.05$) and that in stage 5 was higher than stage 1 and 2 ($p<0.01$, $p<0.05$, respectively). PIC concentration in stage 4 was significantly higher than stage 1, 2 and 3 ($p<0.01$, $p<0.05$, $p<0.05$, respectively). Moreover, PIC in stage 5 was significantly higher than stage 1, 2 and 3 ($p<0.01$, $p<0.01$, $p<0.01$, respectively). Plasma Fbg levels in stage 4 was significantly higher than stage 2 ($p<0.05$) and that in stage 5 was higher than stage 1 and 2 ($p<0.01$, $p<0.05$, respectively). eGFR was inversely correlated with TM ($r=-0.668$, $p<0.01$), F1+2 ($r=-0.400$, $p<0.01$), PIC ($r=-0.379$, $p<0.01$) and Fbg ($r=-0.323$, $p<0.01$), respectively. Moreover, significant linear correlation was observed between log UAE and TM ($r=0.472$, $p<0.01$). Furthermore, log UAE was correlated with F1+2 ($r=0.353$, $p<0.01$), PIC ($r=0.363$, $p<0.01$) and Fbg ($r=0.443$, $p<0.01$), respectively.
Conclusion: The vascular endothelial damage was highly progressed and the thrombin generation was accelerated, and the plasma fibrino-coagulation resulted in strongly reinforced accompanied with the secondary increased of fibrinolysis in advanced CKD stages with elderly type 2 diabetes. These abnormal coagulation and fibrinolytic function may contribute to the increased cardiovascular risk in CKD patients with elderly type 2 diabetes.

1083

Change in body composition but not glomerular filtration is related to altered insulin sensitivity in type 1 diabetes patients with or without diabetic nephropathy

M.K. Svensson[1,2], J.W. Eriksson[1,3];
[1]Molecular and Clinical Medicine, Sahlgrenska University Hospital, Gothenburg, [2]Dept of Medicine, Umeå, [3]AstraZeneca R&D, Mölndal, Sweden.

Background and aims: Insulin resistance has been recognised in patients with albuminuria and in chronic renal failure. Recent studies have shown that insulin resistance is present already in mild renal impairment. It could therefore be argued that loss of glomerular filtration rate (GFR) over time could contribute to a decline in insulin sensitivity. The aim of this study was to evaluate if a decline in GFR over time is associated with changes in insulin-antagonistic hormones, cytokines and insulin sensitivity in patients with T1D with different degrees of renal impairment at baseline over time.
Patients and methods: In a prospective follow-up study 20 patients with type 1 diabetes with or without diabetic nephropathy at baseline were re-examined after 5.0±0.4 (range 4.4-6.1) years. 8/20 (40%) patients had no signs of diabetic nephropathy (DN) and 12/20 had DN at baseline defined as micro- (≥20 μg/min), or macroalbuminuria (≥200 μg/min) and no sign of any other renal disease. 14/20 (70 %) patients displayed a decline in GFR during the follow-up period. GFR was determined by ^{51}Cr-EDTA clearance. Insulin sensitivity was assessed as hyperinsulinemic (56 mU/m^2/min), euglycemic glucose uptake (M-value) at steady state during clamp and calculated per lean body mass. Body composition was determined by bioelectrical impedance analysis.
Results: In all patients taken together, a significant decline in GFR over time was found (-13±21 ml/min/1.73m^2, $p<0.01$). There was no change in BMI ($p=0.68$) but a significant change in body composition, with a decrease in lean body mass (%) and an increase in fat mass (%) (both $p<0.01$). In all patients taken together and in patients without DN at baseline there was no significant change in insulin sensitivity during the study period (M-value +0.9±3.1 mg/kg lbm/min, $p=0.18$ and -0.6±2.9, $p=0.59$). In contrast, a significant increase in insulin sensitivity was found in patients with DN at baseline (+2.0±2.9 mg/kg lbm/min, $p=0.04$). In univariate analysis no significant association was found between change in GFR and change in M-value over time in all patients taken together or in patients without DN at baseline or with DN at baseline ($r=-0.33$, $p=0.15$; $r=-0.43$, $p=0.28$ and $r=-0.39$, $p=0.21$, respectively). Instead, change in M-value was significantly associated to change in fat mass (%) and IL-6 levels ($r=-0.55$, $p=0.012$ and $r=-0.62$, $p=0.006$). When fat mass and IL-6 were included in a multivariate regression model these variables explained approx 53% (adj $r^2=0.53$, $p=0.001$) of the change in M-value, and the changes in fat mass and IL-6 both contributed significantly ($p=0.015$ and $p=0.009$) to the model.
Conclusion: In patients with type 1 diabetes a decline in GFR over five years does not influence insulin sensitivity. This may suggest that the insulin resistance found in type 1 diabetes patients with nephropathy may be genetically determined and not an effect of the reduction in GFR per se. Instead, this study indicates that increase in body fat and elevated levels of inflammatory cytokines, such as IL-6, are major determinants of insulin resistance in these patients.

1084

Acute hyperglycaemia decreases serum angiotensin converting enzyme 2 (ACE2) activity

S.-P. Aino[1], D. Gordin[1], C. Forsblom[1], M. Rosegard-Barlund[1], M. Thomas[2], P.-H. Groop[1];
[1]Department of Medicine, Helsinki University, Folkhälsan Institute of Genetics, Biomedicum Helsinki, Finland, [2]Diabetic Complications, Baker IDI Heart and Diabetes Institute, Melbourne, Australia.

Background and aims: Activation of the renin-angiotensin system (RAS) contributes to diabetic kidney and vascular injury. Angiotensin converting enzyme 2 (ACE2) is a newly identified homolog of ACE that converts angiotensin (AT) II to AT-1-7 and potentially promotes vasodilatation. ACE2 activity levels are shown to be increased in early diabetes in experimental models. However, the role of circulating ACE2 activity in human physiology and disease is unknown. The purpose of this study was to test whether ACE2 activity is modified by diabetes or hyperglycaemia in patients with type 1 diabetes, with and without microvascular complications.
Materials and methods: Quantitative ACE2 activity was measured by a fluorometric assay in 546 adult patients with type 1 diabetes participating in The Finnish Diabetic Nephropathy (FinnDiane) study and in 205 healthy control subjects. In addition, ACE2 activity was determined in 22 type I diabetic patients and 13 controls before and after a 2 hour hyperglycemic clamp.
Results: Acute hyperglycemia during a 2-hour hyperglycemic clamp resulted in an 8% reduction in the ACE2 activity with simultaneous stiffening of the arteries in diabetic patients as well as in healthy controls ($n=35$, $P<0.05$). Baseline ACE2 activity was similar in patients with type 1 diabetes and healthy control subjects (461±20 vs 494±21, P=n.s., data presented in arbitrary fluorescence units). Chronic hyperglycemia as measured by HbA1C (%) or presence of albuminuria was not associated to the ACE2 activity. Among men with diabetes, ACE2 activity level was increased in patients with increased glomerular filtration rate (GFR) ($r=0.156$, $P=0.034$).

Conclusion: Circulating ACE2 activity is modified by acute hyperglycemia, potentially contributing to the hyperglycemia-associated increased vascular tone. Chronic hyperglycemia appears to have no effect on circulating ACE2 activity levels. ACE2 is increased when the patients show signs of renal hyperfiltration, which indicates vasodilatory changes in the kidney in early diabetes.

1085

Increased urinary excretion of fibrogenic growth factors is associated with initial structural changes in the kidneys in type 1 diabetic patients

V.V. Klimontov[1], I.A. Bondar[1], A.P. Nadeev[2];
[1]Department of Endocrinology, [2]Department of Pathology, Novosibirsk State Medical University, Novosibirsk, Russian Federation.

Background and aims: Transforming growth factor beta (TGF-beta), insulin-like growth factor-1 (IGF-1) and vascular endothelial growth factor (VEGF) are believed to be involved in pathogenesis of diabetic nephropathy (DN). Recent experimental studies have shown that these factors enhance the extracellular matrix production in glomerular and tubular cells and, therefore, contribute to progression of glomerular and interstitial sclerosis in diabetes. The aim of our study was to assess the relation between urinary excretion of fibrogenic growth factors and development of nephropathy in type 1 diabetic patients.

Materials and methods: 57 patients with type 1 diabetes were examined, including 22 normoalbuminuric (group DN0), 23 microalbuminuric (group DN1) and 12 macroalbuminuric ones (group DN2). Urinary excretion of TGF-beta, IGF-1 and VEGF was determined by ELISA and compared to control (10 healthy subjects, group C). A kidney biopsy was performed in 8 normoalbuminuric and 10 microalbuminuric patients. The glomerular and tubular basement membrane (GBM and TBM) width, mesangial fractional volume [Vv(mes/glom)] and mean podocyte foot processes number was estimated by morphometric analysis.

Results: (median, percentile 25-75)**:** TGF-beta excretion was increased significantly in patients with micro- and macroalbuminuria as compared to control (DN0: 2.0, 1.2-2.5, p=0.3, DN1: 3.0, 2.1-5.1, p=0.003, DN2: 6.3, 4.0-8.2, p=0.003 vs C: 1.6, 0.9-2.2 pg/μmol creatinine). IGF-1 excretion exceeded control in micro- and macroalbuminuric patients also (DN0: 2.5, 2.1-3.2, p=0.25, DN1: 3.7, 3.0-4.6, p=0.004, DN2: 7.6, 6-13, p=0.04 vs C: 2.1, 1.7-3.5 pg/μmol creatinine). VEGF excretion was increased significantly in patients with macroalbuminuria only (DN0: 6.5, 4.4-10.8, p=0.69, DN1: 10.2, 5.8-20, p=0.06, DN2: 16.7, 7.0-45.9, p=0.02 vs C: 5.4, 3-9.7 ng/μmol creatinine). There were negative correlations between TGF-beta, IGF-1 and glomerular filtration rate (TGF-beta: r=-0.32, p=0.02; IGF-1: r=-0.43, p=0.002; VEGF: r=-0.14, p=0,3). In normoalbuminuric and microalbuminuric patients excretion of all growth factors correlated positively with the width of GBM (TGF-beta: r=0.75, p=0.0003; IGF-1: r=0.53, p=0.04; VEGF: r=0.53, p=0.04) and TBM (TGF-beta: r=0.73, p=0.0004; IGF-1: r=0.59, p=0.02; VEGF: r=0.3, p=0.29). Only VEGF excretion correlated with Vv(mes/glom) significantly (r=0.69, p=0.004; TGF-beta and IGF-1: r=0.34, p=0.19). The increased excretion of TGF-beta and IGF-1 was associated with reduction of podocyte foot processes number (TGF-beta: r=-0.5, p=0.03; IGF-1: r=-0.69, p=0.004; VEGF: r=-0.48, p=0.08).

Conclusion: In type 1 diabetic patients increased urinary excretion of fibrogenic growth factors (TGF-beta, IGF-1 and VEGF) is associated with albuminuria and initial structural changes in the kidneys.

1086

Evaluation of prognostic factors affecting urinary albumin and urinary type IV collagen in early-onset type 1 diabetes mellitus

M. Morita[1], Y. Uchigata[2], K. Hanai[2], Y. Ogawa[3], Y. Iwamoto[2];
[1]Internal Medicine 1, Shimane University Faculty of Medicine, Izumo, Shimane, [2]Diabetes Center, Tokyo Women's Medical University School of Medicine, [3]Pediatrics, Niigata University Faculty of Medicine, Japan.

Background and aims: To clarify factors affecting increases in urinary albumin/ creatinine ratio (ACR) and urinary type IV collagen/creatinine ratio (T4C) in early-onset type 1 diabetes mellitus (T1DM) by age at the start of observation.

Materials and methods: This study included 238 patients diagnosed with T1DM at <30 years old, and <40 years old and without overt diabetic nephropathy at the start of observation. Study endpoints were increased ACR (progression from normoalbuminuria to microalbuminuria or overt nephropathy; progression from microalbuminuria to overt nephropathy) and progression to elevated T4C (*multivariate Cox proportional* hazards analysis).

Results: Prognostic factors selected for increased ACR were baseline ACR in all patients along with diastolic blood pressure (BP) in ≥16 year and ≥18 year subgroups and Body mass index (BMI) in ≥20 year and ≥22 year subgroups. Prognostic factors selected for increased T4C were hemoglobin (Hb) A1c, diabetic retinopathy, and female sex in all patients, along with tobacco use in the ≥18 year subgroup only.

Conclusion: Prognostic factors for ACR and T4C differed, including differences based on age at the start of observation (baseline). T4C, as compared to ACR, may more sensitively reflect the effects of hyperglycemia itself on the kidneys. This difference in prognostic factors based on age at the start of observation suggests that T4C, in addition to ACR, may be an important marker to monitor disease status.

1087

Normalizing albuminuria using urinary-creatinine rather than measuring albuminuria alone leads to more accurate and less false positive or false negative results when screening patients with diabetes mellitus for nephropathy

C.S. Kloos, U.A. Müller, N. Müller, G. Wolf;
Internal Medicine, Klinikum für Innere Medizin III, Jena, Germany.

Background and aims: Microalbuminuria (MIA) is an early indicator of renal damage in diabetic patients. Therefore, MIA is a valuable screening tool and routinely used in quality assurance programs (e.g. the German nationwide disease management programme for diabetes). In clinical routine, for practical reasons, MIA measurements are mostly drawn from a single, "on the spot" urine specimen. A value > 20mg/l is considered pathologic. However, unstable results occur because of fluctuating urine volumes. This can lead to inaccurate diagnosis of nephropathy. We examined whether normalizing MIA to urinary-creatinine (MIA/gUCrea) ratio increases the reproducibility of the results.

Patients and methods: The electronic patient file EMIL® was used as the data source. All visits from 06/2000 to 01/2008 with a simultaneous analysis of MIA and MIA/gUCrea in patients with diabetes mellitus type 1 (DM1) and 2 (DM2) were exported. A total of 3716 data sets were retrieved (average number of visits 2.1 (span 1-14), comprising 326 patients with DM1 (age 46.1±15.6years, diabetes duration 18.3±12.8 years, BMI 26.5±4.4kg/m^2, HbA1c 8.14±1.47%, serum-creatinine 93.5±39.7μmol/l, systolic blood pressure 135.7±16.6 mmHg, diastolic blood pressure 77.0±7.4 mmHg) and 1468 patients with DM2 (age 64.6±11.4 years, diabetes duration 12.3±9.0 years, BMI 32.4±6.1 kg/m^2, HbA1c 7.80±1.53%, serum-creatinine 111.1±67.5 μmol/l, systolic blood pressure 135.2±11.2 mmHg , diastolic blood pressure 77.5±8.5mmHg). Ten patients on dialysis (DM1=1, DM2=9) were excluded from the analysis. The MIA and MIA/gCrea values per visit and the inter-visit differences were compared.

Results: Average serum-creatinine of all patients was 108.0±63.9 μmol/l. Proteinuria >1g/l was present in 58 (3.2%) patients using MIA, in 76 (4.2%) using MIA/gUCrea (p<0.001). Average MIA was significantly lower than average MIA/gUCrea (141.7±415.1 mg/l vs. 177.8±550.0 mg/g; p<0.001). MIA in the normal range and increased MIA/gUCrea occurred in 280 cases (7.5%), and increased MIA and MIA/gUCrea in the normal range occurred in 234 cases (6.3%; p=0.04). Unstable values, alternating between normal and pathological MIA or vice versa in consecutive measurements, occurred with MIA in 204 (5.5%) cases, and with MIA/gUCrea in 155 (4.2%) of the cases (p=0.010).

Conclusion: Values of urinary-creatinine normalized albuminuria (MIA/gUCrea) are, when compared to non-normalized albuminuria (MIA), significantly lower. MIA/gUCrea is less vulnerable to instability in consecutive samples because differences in urine volume and concentration are normalized. Use of MIA alone would have led to misclassification regarding the diagnosis of nephropathy in 13-14% of the cases (7.5% false negative, 6.3% false positive). In quality assurance programs where screening for renal damage plays an important role, measurement of MIA alone should be abandoned in favour of urine-creatinine normalized MIA. Quality assurance programmes, e.g. the German nationwide disease-management program for diabetes, should be adapted accordingly.

Plasma proteome analysis of patients with type 1 diabetes with diabetic nephropathy

A.J. Overgaard[1], M. Lajer[2], L. Tarnow[2], P. Rossing[2], J.N. McGuire[1], F. Pociot[1];
[1]Hagedorn Research Institute, [2]Steno Diabetes Center, Gentofte, Denmark.

Background and aims: At present microalbuminuria is used as a risk marker for development of diabetic nephropathy (DN); however, much debate exists about its sensitivity and specificity. The search for new and better biomarkers for DN has, with a few exceptions, previously focused on either hypothesis-driven studies or urinary based investigations. To date only two studies have investigated the proteome of blood in search for new biomarkers, and these studies were conducted in sera from patients with type 2 diabetes. This is the first reported study where the plasma from type 1 diabetic patients was investigated in depth with the goal of finding improved candidate biomarkers to predict DN.
Materials and methods: Plasma from a cross-sectional cohort of 123 type 1 diabetic patients previously diagnosed as normoalbuminuric, microalbuminuric or macroalbuminuric, was collected at Steno Diabetes Center. In order to reach lower concentration proteins in plasma a pre-fractionation step was performed prior to surface enhanced laser desorption/ionization time-of-flight mass spectrometry analysis (SELDI-TOF-MS). In addition to traditional statistical tools, we evaluated our spectral data with independent component analysis (ICA). ICA measures signals in complicated background and considerably increase the quality of the resulting data as well as improving the biological validity of subsequent examination.
Results: Mass spectrometry analysis gave rise to 290 peak clusters significantly different between the groups. 17 were selected for future examination as the most promising biomarker candidates with $p < 0.0001$ and component stability scores > 0.8. Two of the peaks that were discovered have been identified as transthyretin (difference in peak intensity between groups, $p < 0.0001$) and transferrin (difference in peak intensity between groups, $p < 0.0001$). Several other (e.g., m/z 6963.9, m/z 11351 and m/z 13584) have also been discovered as candidate biomarkers and are in the process of being identified. These proteins, especially when combined, are better able to define the stages of diabetic nephropathy.
Conclusion: These results demonstrate the capacity of proteomic analysis of plasma, by confirming the presence of known biomarkers as well as revealing new biomarkers for diabetic nephropathy in plasma in type 1 diabetic patients.

1089

Vascular diseases and mortality of patients on haemodialysis with type 2 or type 3 diabetes

G. Bodlaj, O. Janko, B. Schmekal, G. Biesenbach;
Second Department of Medicine, General Hospital Linz, Austria.

Background and aims: In rare cases, diabetic patients on dialysis therapy have pancreatic diabetes (PAD), also called type 3 diabetes. Aim of this study was to investigate possible differences in patient survival, prevalence of vascular diseases and incidence of vascular complications in dialysis patients with type 3 or type 2 diabetes.
Materials and methods: In a retrospective study we evaluated 96 diabetic patients, who started dialysis therapy between 1995-2003 in our dialysis centre. Type 3 diabetes was diagnosed in 12 patients and type 2 diabetes in 84 patients. In both groups we compared vascular risk factors, prevalence of vascular diseases, incidence of vascular complications and patient survival in the first 5 years after the initiation of dialysis therapy.
Results: At the beginning of dialysis therapy, patients with type 2 diabetes were significantly older than patients with type 3 diabetes (63 ± 8 vs. 56 ± 6 years, $P < 0.05$). Vascular risk factors were similar in both groups, only mean cholesterol was significantly lower in type 3 diabetic patients compared to those with type 2 diabetes (142 ± 42 vs. 196 ± 36, $P < 0.05$). In addition, mean BMI (22 ± 3 vs. 25 ± 3 kg/m^2, $P < 0.05$) and mean serum levels of fasting C-peptide (0.9 ± 0.3 vs. 1.9 ± 0.6 ng/ml, $P < 0.05$) and of albumin (2782 ± 348 vs. 3464 ± 342 mg/dl, $P < 0.05$) were significantly lower in type 3 diabetic patients compared to those with type 2 diabetes. At the beginning of dialysis therapy, the prevalence of vascular diseases was not significantly different between both groups, as well as the incidence of vascular complications (stroke, myocardial infarction and/or amputations) in the first 5 years. The frequency of malnutrition (BMI < 21 kg/m^2) was 50% in type 3 diabetic patients versus 9% in type 2 diabetics ($P < 0.05$). In type 2 diabetic patients 3-year survival was slightly higher (54 vs. 42%, n.s.), whereas 5-year survival was significantly higher (27 vs. 8%, $P < 0.05$).
Conclusion: In dialysis patients with type 3 and type 2 diabetes the prevalence of vascular diseases and the incidence of vascular complications was not significantly different in the first 5 years after the initiation of dialysis therapy. However, malnutrition was more common and survival was lower in type 3 diabetic patients compared to those with type 2 diabetes.

1090

Prorenin receptor expression in human kidneys with diabetic nephropathy

K. Takahashi[1], H. Yamamoto[1,2], K. Hiraishi[1], I. Shoji[1], T. Hirose[3], H. Sasano[4], T. Suzuki[4], K. Totsune[3];
[1]Department of Endocrinology and Applied Medical Science, Tohoku University Graduate School of Medicine, Sendai, [2]Takeda General Hospital, Aizu-Wakamatsu, [3]Department of Clinical Pharmacology and Therapeutics, Tohoku University Graduate School of Pharmaceutical Sciences and Medicine, Sendai, [4]Department of Pathology, Tohoku University Graduate School of Medicine, Sendai, Japan.

Background and aims: The renin-angiotensin-aldosterone system (RAS) plays critical roles in the progression of diabetic nephropathy. (Pro)renin receptor ((P)RR), a specific receptor for renin and prorenin, has recently been identified. It is a 350 amino-acid protein with a single transmembrane domain and widely expressed in various tissues including brain, heart and kidney. When bound to (pro) renin, (P)RR activates the angiotensin I-generating activity of (pro)renin in the absence of cleavage of the prosegment, and directly stimulates the MAPK pathway independently from the RAS. Plasma levels of prorenin are elevated in diabetic patients, and thought to play important roles in the pathophysiology of diabetic nephropathy. The aim of the present study is therefore to clarify the expression of (P)RR in the kidney with diabetic nephropathy.
Materials and methods: The present study was approved by the Ethics Committee of the Tohoku University Graduate School of Medicine. The kidney tissues were obtained at autopsy from patients with and without Type 2 diabetes mellitus (n=5 without diabetes mellitus; and n=10 with diabetes mellitus). Immunocytochemistry was performed by the ABC method using paraffin-embedded sections. The antiserum against (P)RR was raised in a rabbit by injecting the peptide fragment of human (P)RR corresponding to 224-237 a.a. conjugated with bovine serum albumin. The identity of the (P)RR immunoreactivity was confirmed by Western blot analysis, which showed a band of 39 kDa in the protein extract of rat kidney and heart. Furthermore, the preabsorption of the antibody by the antigen peptide abolished the immunostaining of (P)RR in immunocytochemistry of the human kidney.
Results: (P)RR was mainly expressed in the tubular cells and collecting duct cells of the kidney without diabetic nephropathy. (P)RR was very weakly and sporadically immunostained in the cells of glomeruli. Vascular smooth muscle cells and endothelial cells were very weakly or were not immunostained with (P)RR. Adipocytes in the adipose tissue around the kidney were positively immunostained with (P)RR. Immunostaining pattern of (P)RR in the kidney with diabetic nephropathy was similar to that without diabetic nephropathy. However, most notably, (P)RR immunostaining in the tubular cells and collecting duct cells was clearly and frequently more strongly observed in the kidney with diabetic nephropathy up to the end stage renal disease. Even the atrophied tubular cells in the kidney tissue with end stage renal disease expressed (P)RR.
Conclusion: (P)RR was expressed in tubular cells and collecting duct cells of the kidney tissue with diabetic nephropathy up to end stage renal disease. (P)RR expressed in the diabetic kidney may play a pathophysiological role in angiotensin I generation and renal fibrosis found in end stage renal disease.

Diabetic nephropathy is associated more strongly with toe-brachial index than ankle-brachial index in type 2 diabetic patients

M.-Y. Chung, J.-O. Chung, D.-H. Cho, D.-J. Chung;
Department of Endocrinology and Metabolism, Chonnam National University Medical School, GwangJu, Republic of Korea.

Background and aims: Microalbuminuria is an indicator for diabetic nephropathy. It was known that increased urinary albumin/creatinine ratio (ACR) is a risk factor for peripheral vascular disease (PVD). Ankle-brachial index

(ABI) and toe-brachial index (TBI) are a simple useful method for assessing PVD. Some data suggested that ACR is associated with PVD, and ACR is significantly correlated with ABI in an inverse pattern in the type 2 diabetic patients. But the relationship between TBI and diabetic nephropathy was not well known. The present study was undertaken in type 2 diabetic patients to investigate whether ABI or TBI was more strongly associated with markers of diabetic nephropathy such as ACR, serum creatinine levels, and estimated glomerular filtration rate (eGFR).
Materials and methods: We recruited a total of 365 type 2 diabetics: 192 men (mean age 56.1±13.7 years) and 173 women (mean age 57.3±14.8 years). Renal function was evaluated by serum creatinine levels, estimated eGFR (calculated by the Cockcroft-Gault equation) and urinary ACR. Because the distribution of ACR was highly skewed, the natural logarithm of ACR [Ln(ACR)] was used for statistical analyses. ABI and TBI measurements were performed with the subject in a supine position, and were determined as the ratio of ankle or toe systolic blood pressure to the brachial systolic blood pressure, with both determined using an automatic device.
Results: Overall, the mean age was 60.5±11.2 years, duration of diabetes 12.1±6.8 years, HbA_{1C} 7.6±2.4%, ACR 826.7±629.0 mg/gCr, serum creatinine 1.4±1.2 mg/dL, and systemic blood pressure (BP) 138.4±14.8/88.1±13.4 mmHg. Mean calculated GFR was 59.2±35.9 mL/min/1.73m^2. ABI were 1.12±0.11 (Rt.) and 1.11±0.13 (Lt.). TBI were 0.84±0.15 (Rt.) and 0.83±0.16 (Lt.). The mean difference between ABI and TBI in our population was 0.28±0.15. Among all patients there was a significant linear association (r = 0.492; p< 0.001) between ABI and TBI. Ln(ACR) was inversely correlated with ABI (r=−0.193, P<0.05) and TBI (r=−0.249, P<0.05). TBI also tended to correlate negatively with age and diabetes duration. We found no significant correlation between hemolglobin A_{1C}, fasting C-peptide, serum creatinine levels or eGFR and ABI or TBI. By Univariate linear regression, right TBI but not right ABI showed a significant negative correlation with Ln(ACR) (r=-0.215, P<0.05).
Conclusion: This study demonstrated that ABI and TBI were related to urinary ACR and especially right TBI is suggested to be the more strongly related parameter than ABI for diabetic nephropathy in type 2 diabetic patients.

1092

Renal interstitial fibrosis factors in type 2 diabetics with renal artery stenosis
K.O. Kurumova, M. Shamkhalova, M. Shestakova, I. Sitkin, A. Ilin, M. Arbuzova, N. Goncharov, G. Katsaya, S. Saveleva;
Diabetic nephropathy, Endocrinology Research Centre, Moscow, Russian Federation.

Background and aims: To estimate renal interstitial fibrosis factors in type 2 diabetics with renal artery stenosis (RAS) and without RAS.
Materials and methods: We studied 30 diabetic type 2 patients with RAS and 22 diabetic type 2 patients without RAS. All patients were invited to undergo multispiral computer tomography or selective angiography of renal arteries to define the presence of RAS (renal artery stenosis more than 60%). Transforming growth factor (TGF - β-1), vascular endothelial growth factor (VEGF), markers of endothelial dysfunctions (sICAM, VCAM), nonspecific atherosclerotic markers (C-reactive protein, homocystein), matrix metalloproteinase 9 (MMP 9), interleukin 6, angiotensin II were measured. The control group included normotensive persons of more than 45 years without diabetes (n=20). Glomerular filtration rate (GFR) was calculated by the MDRD equation.
Results: GFR was significantly lower in diabetics with RAS than without RAS [73,1 (63,3; 96,0) vs.92,5 (78,5; 114,0) ml/mines/1,73m^2, p<0,05]. TGF - β-1 level in the RAS-positive group was significantly higher than the one in the RAS-negative group [90,9 (52,2; 119,4) vs. 51,6 (25,2; 78,5) ng/ml, p<0,02]. TGF - β-1 positively correlated with MMP 9 (r=0,23; p<0,04) and VEGF (r=0,26; p <0,01). MMP 9 in a cohort of patients without RAS appeared to be paradoxically higher in comparison with persons with RAS [138,0 (109,0; 173,0) vs. 96,5 (68,0; 131,0) ng/ml, p<0,01]. Other indicators didn't differ significantly between the researched groups.
Conclusion: RAS in diabetic type 2 patients was associated with significant increase of TGF - β1, which is known to have a predictive role in the development of the tubulointerstitial expansion.

PS 98 Hypertension

Effects of telmisartan on glucose metabolism, lipid profile and adiponectin in patients with type 2 diabetes complicated with hypertension
H. Mori, Y. Okada, Y. Tanaka;
The First Department of Internal Medicine, School of Medicine University of Occupational and Environmental Health, Kitakyusyu, Japan.

Background and aims: Hypertension complicated with type 2 diabetes is a strong risk factor for cardiovascular disease. Telmisartan, a new angiotensin IItype 1 receptor blocker (ARB), is a more powerful stimulator of peroxisome proliferator activated receptor-γ (PPARγ) than the others, and is expected by in vitro studies to provide a better improvement of insulin sensitivity than other ARBs. The present study was performed to assess the effects of telmisartan at doses of 40 and 80 mg/day on glucose metabolism, lipid profile and serum adipokine levels in type 2 diabetic and hypertension.
Materials and methods: <Study 1> Fifty for patients (30 men and 24 women, mean age 64.6±10.8 years) with type 2 diabetes complicated with hypertension(systolic blood pressure ≥130 or diastolic ≥80 mmHg) were treated with valsartan (80 mg, n=20) or candesartan (8 mg, n=24) or losartan (50 mg, n=10). Then, telmisartan at 40 mg/day was administered instead of the other ARBs for 12 months. Physical examinations and blood tests were conducted at 0, 6 and 12 months after treatment in each patients. <Study 2> In a double-blind, randomized study, patients with type 2 diabetes complicated with hypertension (systolic blood pressure ≥120 or diastolic ≥70 mmHg) despite the treatment with telmisartan at 40 mg/day were switched to telmisartan 80 mg/day (n=32) or telmisartan 40 mg/day + amlodipin 5 mg/day (n=32) for 3 months. Physical examinations and blood tests were conducted at baseline and end of treatment in each patient.
Results: <Study 1> Telmisartan at 40 mg/day resulted in a significant decrease in systolic and diastolic blood pressures. Neither HbA1c nor fasting plasm glucose were significantly changed. Telmisartan tended to decrease fasting levels of serum insulin (9.6±7.2 to 8.7±6.1 mU/l) and HOMA-R (3.3±1.7 to 2.9±2.3). Serum levels of triglyceride were significantly reduced from 138.8±63.3 to 124.3±54.9 mg/dl (P<0.05) and HDL cholesterol was improved from 50.7±12.6 to 52.8±13.7 mg/dl(P<0.05) by the treatment, whereas total cholesterol and LDL cholesterol did not change. Serum adiponectin did not change, either. <Study 2> Telmisartan 80 mg, but not telmisartan 40 mg + amlodipin 5mg, significantly (P<0.05) reduced fasting levels of plasma glucose and insulin and HOMA-R. Ths change was marked (P<0.01) in patients with HOMA-R ≥2.0. In patients with total cholesterol ≥220 mg/dl, telmisartan 80 mg significantly (P<0.01) reduced total cholesterol, in patients with triglyceride ≥150 mg/dl, telmisartan 80 mg reduced triglyceride (P<0.05), in patients with LDL cholesterol ≥120 mg/dl, telmisartan 80 mg reduced LDL cholesterol (P<0.05), in patients with HDL cholesterol ≤50 mg/dl, telmisartan 80 mg increased HDL cholesterol (P<0.05) and in patients with adiponectin 4.0 ≤μg/ml, telmisartan 80 mg increased adiponectin (P<0.05).
Conclusion: Thease results suggests that telmisartan at 80 mg favorably affects glucose metabolism and lipid profile through stimulating PPARγ in patients with type 2 diabetes complicated hypertension despite the treatment with telmisartan at 40 mg.

Lipidomic profiling reveals a deficiency of ether lipids in blood plasma of men with hypertension
J. Graessler[1], D. Schwudke[2], P.E.H. Schwarz[1], R. Herzog[1], A. Shevchenko[2], S.R. Bornstein[1];
[1]Internal Medicine III, Carl Gustav Carus Medical School, [2]Mass Spectrometry, Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany.

Background and aims: Dyslipoproteinemia, obesity and insulin resistance are integrative constituents of the metabolic syndrome and major risk factors for hypertension. The objective of this study was to determine whether hypertension specifically affects the plasma lipidome independently and differently from the effects induced by obesity and insulin resistance.
Materials and methods: Plasma lipidomic screens of 19 men with hypertension and 51 normotensive male controls, covering 95 lipid species of 9 major lipid classes were analyzed by top-down shotgun profiling on a LTQ Orbitrap hybrid mass spectrometer.

Results: Obesity resulted in generally higher lipid load in blood plasma, while the content of in tri- and diacylglycerols increased dramatically. Insulin resistance, defined by HOMA-IR > 3.5 and controlled for BMI, was exclusively accompanied by a significant decrease of a single phosphatidylethanolamine metabolite. Specific alterations of the plasma lipidome in hypertensive individuals evaluated by BMI- and HOMA-IR-adjusted values indicated overall decreases in ether lipids, in particular in ether phosphatidylcholines, that comprise arachidonic (20:4) and docosapentaenoic (22:5) fatty acid moieties, as well as in free cholesterol. At the same time, conventional clinical lipid homeostasis indices (total cholesterol, LDL-, HDL-cholesterol, triglycerides) remained unaffected.
Conclusion: Top-down shotgun lipidomics demonstrated that hypertension is accompanied by specific reductions of ether lipids and free cholesterol that occur independently of lipidomic alterations induced by obesity and insulin resistance. These results may form the basis for novel preventive and dietary strategies alleviating the severity of hypertension.

Inverse relation between hypertension and FASN expression in adipose tissue

M.D. Mayas[1], F.J. Ortega[2], R. Gomez-Huelgas[3], R. Bernal[4], J.M. Fernández-Real[2], F.J. Tinahones[5];
[1]Servicio de Endocrinología y Nutrición, CIBER OBN, Málaga, [2]Servicio de Diabetes, Endocrinología y Nutrición, CIBER OBN, Girona, [3]Servicio de Medicina Interna, Hospital Carlos Haya de Málaga, [4]Servicio de Endocrinología y Nutrición, CIBER OBN, Málaga, [5]Hospital Virgen de la Victoria, Málaga, Spain.

Background and aims: There are a lot of studies that relate fatty acid synthesis enzymes, FASN (Fatty Acid Synthase) and ACC (Acetyl-CoA Carboxilase) to metabolic alterations such as obesity, insulin resistance or dyslipemia. Due to the fact that there is no literature that relates these enzymes with hypertension, the aim of this study is investigate how, in adipose tissue, FASN and ACC are related to hypertension.
Materials and methods: The study included 87 patients, with a wide range of body mass index (BMI), in order to study in their visceral adipose tissue the gene expression of FASN y ACC by RT-PCR. Anthropometric and biochemical variables (glucose, glycated hemoglobin, HOMA-IR, cholesterol, c-LDL, c-HDL, triglycerides, PCR, adiponectin, leptin, ...) were measured after getting a blood sample of the patient after an overnight fast and before the laparoscopic surgery. Patients were classified according to hypertension levels into normotensive and hypertensive groups. Hypertensive individuals were defined as those with systolic blood pressure (SBP) ≥ 130mm Hg or diastolic blood pressure (DBP) ≥ 85 nm Hg or that were on medication for this condition. Subjects were classified according to BMI, as non obese (BMI<30) and obese (BMI≥30).
Results: The main result of this work is a significant decrease of FASN expression in adipose tissue of hypertensive *vs* normotensive patients. There was an inverse correlation between FASN expression and SBP values by multiple regression analysis and there was also an inverse correlation between FASN expression and SBP. The statistical analyses and graphics were performed using the SPSS software program and values were considered statiscally significant when P≤0.05.
Conclusion: We can say that for the first time, it has been proven that a decrease of FASN expression in hypertensive individuals and the clinical significance of this work, represents an exciting challenge because it would need to be clarified if the reduced values of FASN expression led to hypertension or if this is an adaptive mechanism to the presence of hypertension. Once this aspect is clarified, it could be a new target for the treatment of hypertension.

Figure 1. Linear relationship between FASN expression and SBP was determined by Pearson's correlation coefficient test.

Glucose intolerance strongly correlates with high blood pressure in normocholesterolaemic morbidly obese women

A.R.T. Gagliardi[1], T.C. Valente[1], F.A. Savioli[1], M.I. Torres[1], A.J.F. Leal[2], L. Leal[1], M.C. Dinato[3], E.P. Heilbrun[1];
[1]Physiology and Biophysics, [2]Surgery, [3]Internal Medicine Division of Endocrinology, School of Medicine, Santos, Brazil.

Background and aims: We studied the lipid profile, glucose tolerance and the prevalence of High Blood Pressure (HBP) in morbidly obese women with body mass index (BMI) in the range 40 - 70 kg/m^2.
Materials and methods: A total of 203 morbidly obese female patients in the range from 25 to 63 years old, with normal thyroid and renal function were investigated before gastric restrictive surgery. Conventional lipid profiles, TSH, FT4, T3, fasting blood glucose (FBG) and postprandial glucose, BUN, creatinine, ALT, serum albumin and globulins, coagulation parameters, ultrasensitive PCR, bilirrubins, lipase, RBC, WBC, hematocrit, CK and hemoglobin were measured. Careful physical exam was performed and blood pressure was measured at least in three different occasions. Glucose tolerance and lipid profiles were interpreted according to ADA Clinical Practice Recommendations 2009.
Results: 37,2% of the 163 patients with normal glucose tolerance were hypertensive with an average BMI of 44,5 kg/ m^2 (SD 5,8), mean FBG of 91,4 mg% (SD 3,8) mean total cholesterol of 191,4 mg% (SD 31,2), mean LDL-cholesterol 110,2 mg%(SD 34,3), mean HDL-cholesterol 51,4 mg% (SD 16,1) and mean triglyceride 142 mg% (SD 42,3).
Fasting glucose intolerance was found in 40 patients with a mean FBG of 108,6 mg% (SD 4,1) with a prevalence of 61% of HBP and mean BMI of 47,1 (SD 6,7). LDL-cholesterol was 121,2 mg% (SD 38,5), mean HDL-cholesterol of 49,7 mg% (SD 19,5) and mean triglyceride was 165,6 mg% (SD 58,3). No patient was diagnosed as diabetic according to the OGTT. The group of patients with fasting glucose intolerance showed a significant increase in the prevalence of HBP and higher triglyceride levels.
Conclusion: Glucose intolerance is a strong predictor of high blood pressure in morbidly obese women. There is a disparity between the conventional lipid measures, higher BMI and metabolic syndrome risk factors in severely obese women, except for those with glucose intolerance that showed elevated triglycerides levels suggesting insulin resistance.

Pattern of expression of inflammatory markers in adipose tissue of untreated patients with essential hypertension

A. Solini[1], S. Madec[1], M. Chiarugi[2], E. Santini[1], C. Rossi[1], E. Ferrannini[1];
[1]Department of Internal Medicine, [2]Department of Surgery, University of Pisa, Italy.

Background and aims: Subcutaneous (SAT) and, especially, visceral adipose tissue (VAT) may contribute to hypertension by promoting endothelial dys-

function and impaired insulin sensitivity. In hypertensive patients (HT), the inflammatory network and the metallo-proteinase/tissue metallo-proteinase inhibitors (MMP/TIMP) system are important modulators of vascular structure/function.
Materials and methods: In mature adipocytes, isolated from paired samples of VAT and SAT from 30 non-diabetic, lean, never-treated HT and 20 age- and sex-matched normotensive controls (C), we measured TNFα, TGFß, IL-6, PAI-1, MMP-2, MMP-9, TIMP-1 and TIMP-2 expression (by realtime PCR, expressed as targeted/reference ratio), MMP-2 and MMP-9 activity (by zymography) and TIMP-1 and TIMP-2 protein expression (by Western blot analysis). Plasma IL-6, TGFß and PAI-1 levels were also determined.
Results: SAT MMP-9 was similarly expressed in HT and C (0.4±0.04 *vs* 0.5±0.03 in VAT and 0.9±0.05 *vs* 1.0±0.05 in SAT). In contrast, MMP-2 expression was strongly reduced in SAT of HT (2.4±0.2 *vs* 0.9±0.03, p<0.0001), but not in VAT (0.9±0.05 *vs* 0.8±0.04, p=ns). VAT TIMP-1 was similar in C and HT (1.0±0.03 *vs* 1.0±0.06), while it was reduced in SAT of HT (0.5±0.03 *vs* 0.4±0.03; p=0.0005). TIMP-2, more abundant in SAT than in VAT, was reduced in HT VAT and SAT (2.0±0.06 *vs* 1.0±0.03 in VAT, and 3.1±0.1 *vs* 1.2±0.04 in SAT, both p<0.0001). These results were confirmed at the protein level by Western blot. MMP-2 activity was reduced in HT in both VAT and SAT (4674±209 *vs* 3889±87 and 5329±113 *vs* 3965±64 AU, p=0.0008 and p<0.0001 respectively). Despite similar expression in C and HT, MMP-9 activity was markedly reduced in HT (13408±552 *vs* 1021±32 in VAT and 3398±98 *vs* 633±11 AU in SAT; both p<0.0001). IL-6 expression, abundant in both VAT and SAT, was significantly higher in HT (15.3±2.4 *vs* 186.8±21.5 in VAT and 9.8±0.8 *vs* 38.4±3.2 in SAT, both p<0.0001). TNFα was similarly expressed in VAT and SAT of C (1.2±0.04 *vs* 1.1±0.05), while its presence in VAT of HT was markedly increased (3.9±0.3 *vs* 1.4±0.2, p<0.0001). TGFß was significantly lower in VAT (1.7±0.04 *vs* 1.2±0.05) and SAT (1.4±0.05 *vs* 1.2±0.09, both p<0.0001) of HT *vs* C. Lastly, PAI-1, more abundant in VAT than in SAT in both groups, was 18-fold more represented in VAT (2.4±0.02 *vs* 35.0±4.3, p<0.0001), and 9-fold higher in SAT (2.3±0.03 *vs* 19.0±2.4, p<0.0001) of HT than C. Circulating IL-6 concentrations were 2-fold higher in HT (2.5±0.2 *vs* 5.4±0.5 pg/ml, p<0.0001), while TGFß levels did not differ between the two groups (19.0±1.3 *vs* 20.7±1.4 ng/ml). Plasma PAI-1 levels were much higher in HT than C (27.7±1.8 *vs* 49.0±1.4 ng/ml, p<0.0001). In the whole dataset, IL-6 in VAT was directly correlated with systolic and diastolic blood pressure values. Also, significant inverse relationships were observed between blood pressure levels and MMP-2 and MMP-9 activity in VAT and SAT.
Conclusion: Untreated hypertensive patients have a peculiar pattern of expression of MMP/TIMP and inflammatory molecules in isolated mature adipocytes: MMP-2, TIMP-1, TIMP-2 and TGFß expression and activity are markedly reduced, while PAI-1 and IL-6 expression is increased, as reflected in higher circulating levels. These results support an important role for adipose tissue in the pro-inflammatory and pro-thrombotic state in lean hypertensive subjects.

On the relation of visceral obesity, insulin resistance, CRP and blood pressure in a general population: the Rijswijk study
N. Tjeerdema, M.J. Van Glabbeek, J.T. Tamsma;
Vascular Medicine Dept Endocrinology / G.I.M., Leids University Medical Centre, Leiden, Netherlands.

Background and aims: Visceral obesity, insulin resistance, and low-grade inflammation are regarded as underlying pathophysiologic factors of the metabolic syndrome. The purpose of this study was to investigate blood pressure in relation to visceral obesity, insulin resistance and elevated CRP levels.
Materials and methods: In a primary health care setting, this cross-sectional study was performed in a general population. All subjects registered in the practices as patients (40-70 years) without diabetes mellitus were invited for an cardometabolic analysis. 1984 patients (response rate approx 70%) have been assessed. Laboratory assessments were performed in a representative subgroup of 1350 subjects. Access to medical records including medication use was available. Blood pressure, waist circumference, plasma glucose, insulin and hsCRP levels were measured. We used the IDF-criteria for visceral obesity (VO), HOMA-IR >2 for insulin resistance (IR) and hsCRP >2 as a marker of low grade inflammation to classify subjects.
Results: Only 20% of the subjects (CO group)were apparently healthy as defined by absence of VO, IR and normal hsCRP levels. VO was highly prevalent (73.5%). Insulin resistance was nearly always associated with VO (98.8%) and the presence of elevated hsCRP was often accompanied by visceral obesity as well (84%). In isolated form IR was observed in only 1 subject and in combination with elevated CRP in 3 subjects. These two groups were not further analysed in the present study. Blood pressure correlated with visceral obesity (r= 0.354, p= 0. 001), insulin resistance (r= 0.105, p=0.001) and slightly with CRP (r= 0.066, p= 0.013). Systolic blood pressure significantly differed between the groups (see figure for ANOVA comparisons between groups). Blood pressure increased in following order: CO, CRP+; VO+ (RR 130(19)/82(12) mmHg); VO+CRP+ (RR 133(20)/83(11) mmHg); VO+IR+ (RR 140(18)/89(9) mmHg); VO+IR+CRP+ (RR 144(23)/89(12) mmHg). For diastolic blood pressure similar results were obtained. Multiple regression analysis confirmed the independent effect of IR and VO (but not CRP levels) on blood pressure level after adjustment for age, gender and smoking. For each 10cm waist circumference respectively one unit HOMA-IR; blood pressure increased with 3,4 mmHg respectively 18,2 mmHg. Repeating analysis to subjects without blood pressure lowering medications revealed similar results.
Conclusion: Visceral obesity, insulin resistance and inflammation directly relate to blood pressure levels in a general population. Visceral obesity and insulin resistance are independent driving forces for hypertension, this was not observed for systemic inflammation measured as elevated C-reactive protein levels.

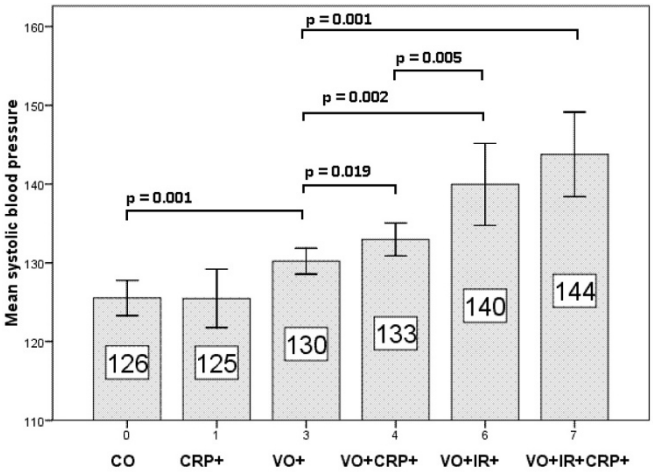

Figure: comparisons of SBP among classified groups. Vertical bars indicate mean ± s.d. Date were analysed using ANOVA. The P for trend was < 0.001. LSD P values for post hoc analysis shown.

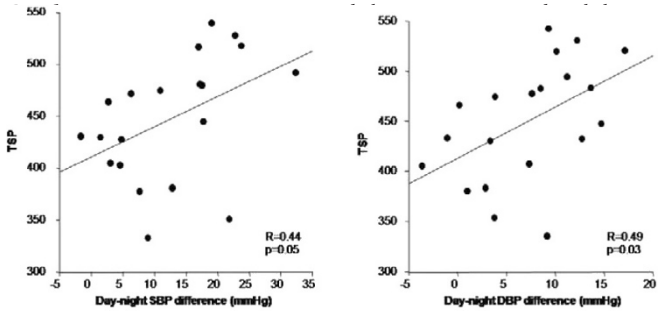
Short sleep duration is associated with blood pressure non dipping pattern in type 1 diabetes: the DIAPASOM study
A.-L. Borel[1], P.-Y. Benhamou[1], J.-P. Baguet[2], I. Debaty[1], P. Levy[3], J.-L. Pepin[3], J.-M. Mallion[2];
[1]Endocrinology, Pole digidune, [2]Cardiology, [3]Rehabilitation and Physiology, University Hospital, Grenoble, France.

Non-dipping blood pressure status is associated with an increased cardiovascular risk in type 1 diabetes. Sleep quality or duration changes may affect glucose control and perception of sleep-related hypoglycaemias.
Objective: To assess whether blood pressure dipping status in type 1 diabetes is correlated with specific sleep characteristics and differences in continuous glucose monitoring profiles.
Research design and methods: 20 type 1 diabetic patients (age 47±12 yrs, BMI 26.7±3.2 kg/m^2) underwent sleep explorations with simultaneous 24h Ambulatory Blood Pressure Monitoring and continuous nocturnal glucose monitoring.
Results: Fifty five percent of the patients exhibited blunted blood pressure dipping and did not differ from dippers for age, BMI, 24 hour systolic (SDP)/diastolic blood pressure (DBP). Total Sleep Period (TSP) (407±44 vs. 497±30 min for non dippers and dippers, respectively, p<0.001) and Total Sleep Time (TST) (356±72 vs. 425±82 min, p=0.03) were shorter in the non-dipper group. SBP and DBP day-night differences and TSP were correlated (R=0.44, p=0.05 and R=0.49, p=0.03, respectively). Subjects with the shorter TST had a higher risk to be non dipper (OR = 9.3 [1.19-7.3], p = 0.03). Periods of nocturnal hypoglycaemia (i.e. % of TSP with glycaemia<70mg/dL) were longer in dipper subjects (0.1±0.4% vs. 8.1±10.7 for non dippers and dippers, respectively, p=0.02) whereas mean nocturnal glycaemia and duration of nocturnal hyperglycaemia were similar.



Positive correlation between Total Sleep Period (TSP) and day-night Systolic and Diastolic Blood Pressure differences (SBP and DBP, respectively).

Blood pressure levels and dipping pattern are determined by insulin resistance independently from fat mass and adiponectin interaction in premenopausal obese women

J. Silva-Nunes[1,2], L. Duarte[1], L. Veiga[2], A. Melao[2], M. Brito[2], F. Malheiro[1];
[1]Endocrinology Department, Curry Cabral Hospital, Lisbon, [2]High School for the Health Technology of Lisbon, Portugal.

Background and aims: Adiponectin is an adipokine which is assumed to confer cardiovascular protection. Obesity, high blood pressure (BP), non-dipper pattern of BP variation and insulin resistance (IR) are all considered cardiovascular risk factors. The aim of our work was to evaluate the association of BP levels (mean 24 hours, daytime and nighttime levels) and its pattern of variation throughout the day with adiponectin levels and with the degree of insulin resistance, in premenopausal obese women without known hypertension.
Materials and methods: We studied 74 Caucasian premenopausal obese females not under any drug treatment (except oral contraceptives). They were characterized for BMI, waist circumference, waist:hip ratio (WHR) and a fasting blood sample was collected for adiponectin, insulin, glucose and triglycerides assessments. IR was assessed by 3 indexes: homeostatic model assessment (HOMA-IR), quantitative insulin resistance check index (QUICKI) and McAuley formula. They were submitted to a 24h ambulatory blood pressure monitoring. Nighttime was considered from 23:00 to 07:00 and non-dipper pattern was defined by less than 10% nocturnal decrease in the median BP. Statistical analysis was performed with the SPSS program, version 16.0. The established limit for statistical significance (p) was 0.05.
Results: Women were characterized by mean age=34±8.1 years, BMI=42.9±8.1 Kg/m^2, waist=117.1±14.7 cm, WHR=0.88±0.07, adiponectin=6.52±2.88 μg/ml, HOMA-IR=3.79±2.2, QUICKI=0.14±0.01 and McAuley=6.36±1.37. The 24h systolic BP=120.2±9.3 mmHg, diastolic BP=72.6±6.9 mmHg and mean nocturnal decrease=13.5±10.2 mmHg; hypertension was present is 18.9% and non-dipper pattern was present in 36.5% of patients. Dipper patients presented higher HOMA-IR (p=0.003) and lower QUICKI (p=0.001) and McAuley (p=0.032). Adiponectin correlated directly with QUICKI (p<0.001; r=0.419) and McAuley (p<0.001; r=0.468), independently from anthropometry. We also found an independent association of indexes of IR (but not adiponectin) with BP levels: daytime systolic BP with HOMA-IR (p=0.002; r=0.354), QUICKI (p=0.008; r=-0.308) and McAuley (p=0.016; r=-0.279); nighttime systolic BP with HOMA-IR (p<0.001; r=0.488) and QUICKI (p<0.001; r=-0.49); nighttime diastolic BP with HOMA-IR (p=0.001; r=0.378), QUICKI (p=0.001; r=-0.383) and McAuley (p=0.009; r=-0.304); 24h systolic BP with HOMA-IR (p<0.001; r=0.438), QUICKI (p<0.001; r=-0.404) and McAuley (p=0.004; r=-0.334); 24h diastolic BP with HOMA-IR (p=0.027; r=0.257) and McAuley (p=0.03; r=-0.253). Independently from anthropometrics, HOMA-IR was inversely related (p=0.007; r=-0.313) and QUICKI directly related (p=0.001; r=0.368) with the nocturnal decrease in BP.
Conclusion: Non-dipping pattern of BP variation is relatively common in premenopausal obese patients. Independently from the existent amount of fat mass, IR indexes contribute themselves for BP regulation and for the degree of the nocturnal decrease observed. Although lower adiponectinemia is associated with higher abdominal fat and higher IR, adiponectin itself seems not to be implicated in BP regulation or in the dipping phenomenon.

PS 99 Hypertension - clinical

1101

Blood pressure and prediction of mortality in elderly type 2 diabetic patients (ZODIAC-14)

S.T. Houweling[1,2], K.J.J. van Hateren[3], K.H. Groenier[4], G.W.D. Landman[3,5], N. Kleefstra[3,1], H.J.G. Bilo[3,5];
[1]Langerhans Medical Research Group, Zwolle, [2]General Practice Sleeuwijk, [3]Diabetes Centre, Zwolle, [4]Department of General Practice, University Medical Center Groningen, [5]Department of Internal Medicine, Isala Clinics, Zwolle, Netherlands.

Background and aims: Systolic blood pressure, diastolic blood pressure, and pulse pressure, all increase the risk of (cardiovascular) mortality. Systolic blood pressure is considered to be the strongest predictor of them. In elderly patients with type 2 diabetes mellitus (T2DM) the predictive role of the various blood pressure indices has not been assessed before. Therefore, we investigated the predictability of the various indices in elderly T2DM patients.
Materials and methods: In 1998, 881 primary care patients with T2DM aged 60 years and older participated in the ZODIAC study. The cohort was divided into two age categories: 60-75 years and older than 75 years. Life status was assessed after a median follow-up time of 5.7 years. We used a Cox proportional hazard model to investigate the relationship between the blood pressure indices and all-cause as well cardiovascular mortality in both age groups. Predictability was evaluated using Bayesian information criterion (BIC) and Harrell's C statistics. The following variables were selected as possible confounders: gender, smoking (yes or no), body mass index, duration of diabetes, serum creatinine, cholesterol-HDL ratio, macrovascular complications (yes or no), albuminuria (yes or no), the use of lipid lowering and antihypertensive drugs (yes or no) and age.
Results: All of the blood pressure indices were inversely related to all-cause mortality in the high age group (> 75 years). Predictive capability, indicated by lower BIC-values and higher Harrell's C values, was about the same for all of the indices for both all-cause and cardiovascular mortality (table 1). In the low age group (60-75 years) the associations between blood pressure and mortality were not significant.
Conclusion: Systolic, diastolic, and pulse pressures are equally strong predictors of all-cause and cardiovascular mortality in an elderly T2DM population. The predictive capability of blood pressure in the general population may not be applicable to an elderly diabetic population.

Table 1. Predictability of mortality in elderly diabetic patients

	All-cause mortality		Cardiovascular mortality	
	BIC	Harrell's C	BIC	Harrell's C
Systolic blood pressure	1934,04	0,69	965,73	0,69
Diastolic blood pressure	1942,17	0,67	965,61	0,68
Pulse pressure	1943,53	0,68	967,99	0,68

Prevalence of renal artery stenosis in diabetic patients undergoing cardiac catheterization

I.I. Klefortova[1], M. Shmkhalova[1], M. Shestakova[1], E. Tugeeva[2], U. Buziashvili[2], I. Dedov[1];
[1]Diabetic Nephropathy, Endocrinology Research Center, [2]Bakoulev Scientific Center of Cardiovascular Surgery, Moscow, Russian Federation.

Background and aims: To examine the prevalence and severity of renal artery stenosis (RAS) in patients undergoing coronary angiography.
Materials and methods: A total of 30 patients with type 2 diabetes and 26 patients without diabetes were undergone cardiac catheterization and renal angiography. Mean age was 59.1±8.3 and there was no difference in the groups. Moderate to severe arterial stenosis (>50%), was noted as significant angiographic findings. Glomerular filtration rate (GFR) was calculated by the MDRD equation.
Results: Angiographically evident RAS was present in 43.3% (30% monolateral, 13.3 % bilateral) of diabetic patients and in 30.7% of nondiabetic patients. Lipid level, GFR, ejection fraction (EF) was similar in both groups. RAS-negative and RAS-positive diabetic groups were similar in duration of diabetes and arterial hypertension, age, lipid specter, GFR. Diabetic patients with RAS had lower EF (p=0.008), lower hemoglobin level (p=0.046) and

revealed significant difference in the incidence of previous myocardial infarction (p=0.004). Multivessel coronary artery disease was more frequent in diabetic patients with RAS (73.3%) as compared with those without RAS (42.3%) (p=0.017) and that was the reason why they were more often undergone coronary stenting (p=0.027) and coronary bypass surgery (p=0.02). RAS was associated with incidence of previous myocardial infarction (RR=3.81, CI 95% (1.3; 11.4), p < 0.05), coronary stenting (RR=2.5, CI 95% (1.28; 4.88), p < 0.05) and coronary bypass surgery (RR=2.82, CI 95% (1.42; 5.61), p < 0.05).
Conclusion: The prevalence of RAS was more frequent among diabetics in comparison with nondiabetics undergoing coronary catheterization. Renal angiography should be considered particularly in diabetic patients with multivessel coronary disease with even normal renal function or mild renal insufficiency.

1103

Renal complications due to white-coat hypertension in type 2 diabetes
C. Garcia, H. Baizri, J. Le Berre, L. Bordier, O. Dupuy, H. Mayaudon, B. Bauduceau;
Endocrinology, Hôpital Bégin, Saint Mandé, France.

Background and aims: The aim of this study is to assess renal complications due to white-coat hypertension in type 2 diabetes.
Materials and methods: This study is based on the exploration of 412 patients, mean age 58.4 ± 12.7 years, followed for type 2 diabetes with mean duration 10.6 ± 9.8 years. They did not receive any cardiovascular treatment. These patients were divided into 3 groups according to the values of their clinic blood pressure (cBP) and the average of their diurnal BP (dBP), measured by ambulatory BP monitoring: patients with normal BP (cBP<140/90 mmHg and dBP<135/85 mmHg, N = 225), white-coat hypertension (WCH: cBP> dBP 140/90 mmHg and <135/85 mmHg, N = 76) and hypertension (HBP: cBP> 140/90 mmHg and dBP> 135/85 mmHg, N = 111) . The impact is assessed by renal creatinine clearance (Cockcroft formula) and the urinary albumin excretion rate (UAER, mg/24 hours).
Results: Age of patients, duration of diabetes and BMI did not significantly differ in the 3 groups. The average of diurnal BP of WCH subjects was higher than those of patients with normal BP (SBP: 124 ± 8 vs 118 ± 9 mmHg, p <0.0001 and DBP: 76 ± 6 vs 73 ± 6 mmHg, p <0.001). Creatinine clearance did not differ significantly in the 3 groups. UAER of subjects presenting WCH was higher than those with normal BP (79 ± 154 vs 40 ± 121 mg / 24 hours, p <0.05). Comparison of HBP and WCH led to the same conclusions for BP (SBP: 143 ± 11 vs 124 ± 8 mmHg, p <0.0001 and DBP: 85 ± 10 vs 76 ± 6 mmHg, p <0.0001) and for UAER (139 ± 236 vs 79 ± 154 mg / 24 hours, p <0.05). For the whole population, UAER was linked to the difference between cBP and dBP (r = 0188, p = 0.002 with SBP and r = 0145, p = 0.003 with DBP). The difference between cDBP - dDBP explained 9.1% of the UAER variance.
Conclusion: This study highlights the frequency of WCH in type 2 diabetes (18.4%) and shows that it can lead do kidney damage. Then, according to this result, patients with white-coat hypertension should be treated.

1104

Circadian blood pressure variation in patients with type 2 diabetes - relationship between dipper status and early cardiovascular organ damage
P.E. Jennersjö[1], M. Wijkman[2], A.-B. Wiréhn[3], T. Länne[2], J. Engvall[4], F. Nyström[2], C.J. Östgren[1];
[1]Department of Medical and Health Sciences, Linköping University, Division of Community Medicine, [2]Department of Medical and Health Sciences, Linköping University, Division of Cardiovascular Medicine, [3]Research and Development Unit of Local Health Care, [4]Department of Clinical Physiology, Linöping University Hospital, Linköping, Sweden.

Background and aims: The role for diurnal blood pressure pattern as cardiovascular risk assessment tool in clinical practice is unclear. The aim of this study was to explore the association between nocturnal blood pressure dipper status and measures of arterial stiffness and left ventricular mass in patients with type 2 diabetes.
Materials and methods: We analysed data from 414 patients with type 2 diabetes, aged 55-66 years, in the ongoing observational CARDIPP (Cardiovascular Risk factors in Patients with Diabetes - a Prospective study in Primary care) study. Blood samples were taken for analyses of serum lipids, serum creatinin and HbA1c. Nurses measured office blood pressure (mean values of 3 measurements in sitting position) and ambulatory blood pressure during twenty-four hours. Left ventricular mass index (LVMI) was determined with echocardiography and aortic pulse wave velocity (PWV) was measured with applanation tonometry over the carotid and femoral arteries.
Results: Dippers were defined as a ≥ 10% nocturnal reduction in systolic blood pressure. We identified 264 dippers and 150 subjects with a nocturnal non-dipping pattern. There were no differences in office systolic blood pressure (138 ± 16 vs 139 ± 16) or office diastolic blood pressure (80 ±10 vs 81 ± 11) between dippers and non-dippers, respectively. Non-dippers had higher PWV (11 ±2.2 vs 10 ± 2.2, p=0.002) and increased LVMI (127 ± 29 vs 119 ± 29, p=0.02) compared to dippers. When exploring the strength of the association between dipper status and PWV and LVMI, respectively, in a linear regression adjusted for gender, age, HbA1c, office systolic blood pressure and serum creatinin, the results remained significant for PWV (p=0.004) and LVMI (p=0.025).
Conclusion: We conclude that a non-dipping pattern in nocturnal blood pressure was associated with increased arterial stiffness and increased LVMI in middle aged patients with type 2 diabetes. The association was independent of office systolic blood pressure and serum creatinin.

Relationship of retinal vessel caliber with provoked vasodilatation under flickering light in adolescents with type 2 diabetes and hypertension
A. Mandecka[1], J. Dawczynski[2], M. Schwefer[3], W. Vilser[4], M. Blum[5], N. Müller[1], C. Kloos[1], G. Wolf[1], U.A. Müller[1];
[1]Internal Medicine III, Friedrich Schiller University Jena, [2]Department of Ophthalmology, Friedrich Schiller University Jena, [3]Department of Cardiology, Helios Klinikum, Erfurt, [4]IMEDOS, Jena, [5]Department of Ophthalmology, HELIOS Klinikum, Erfurt, Germany.

Background and aims: The assessment of retinal vessel caliber provides prognostic information regarding diabetic retinopathy. Additional information regarding retinal abnormalities may be obtained when vessels are functional challenged (dynamic vessel analysis). In response to flickering light, used as a stimulus to test vascular reactivity, the retinal vessels dilate. Reduced response to flicker is considered as a marker of endothelial dysfunction. We investigated the retinal vessel caliber (static analysis) and flicker-induced retinal vessel dilatation (dynamic analysis) in patients with type 2 diabetes and hypertension.
Materials and methods: We studied 76 healthy controls and 171 type 2 diabetic patients with known hypertension. The diameter of retinal vessels was measured with the Dynamic Vessel Analyzer. Diabetic retinopathy was classified according to the Early Treatment Diabetic Retinopathy Study criteria. Retinal vessel calibers are expressed in µm and changes in vasodilatation as percentage change over baseline value.
Results: After adjustment for age, sex, mean arterial blood pressure and blood glucose, the central retinal artery equivalent (CRAE) was significantly higher in patients without retinopathy (p<0.028) in comparison to controls. Patients with proliferative retinopathy showed significantly reduced CRAE in comparison to any other stages of retinopathy. After adjustment for age, sex, mean arterial blood pressure, blood glucose and CRAE, there was a significant trend of decreasing arterial vasodilatation after flickering light with increasing stages of retinopathy (p<0.016). Central retinal venous equivalent (CRVE) was significantly increased in diabetic patients without retinopathy (p<0.002), in mild NPDR (p<0.007) and in moderate NPDR (p<0.001) after adjustment for age, sex, mean arterial blood pressure and blood glucose. The venous vasodilatation after flickering light decreased with increasing stages of retinopathy although the trend was statistically not significant. Linear regression analysis showed a significant correlation of CRVE with HbA1c (β = 0.211, p<0.026).
Conclusion: Initial stages of retinopathy are associated with arterial and venous vasodilatation whereas the proliferative retinopathy is associated with arterial vasoconstriction. The flicker-induced arterial vasodilatation decreased significantly with increasing stages of retinopathy independent of CRAE. Static and dynamic retinal vessel analysis represent two different pathophysiological mechanisms. The implementation of both analysis may provide additional information about abnormal retinal autoregulation in diabetic retinopathy.

1106

Glycaemia and blood pressure management improves the outcome of laser coagulation in hypertensive patients with diabetes

L. Tsutskiridze, R. Kurashvili, G. Kurashvili, E. Shelestova, M. Dundua, E. Skhiladze, T. Gvaladze;
Georgian Diabetes Center, Tbilisi, Georgia.

Background and aims: Poorly controlled diabetes mellitus (DM) and high blood pressure (BP) are major risk factors for retinopathy development. Fifteen years from diagnosis, ~50% of people with Type 1 and 80% with Type 2 DM develop proliferative retinopathy (PDR). Laser coagulation (LC) is the most effective therapeutic approach to PDR and macular edema (MO). The aim of the present work was to show that LC performed when glycaemia and BP control is good, prevents PDR progression and decreases the rate of relapse.
Materials and methods: Patients with PDR (n=52, 88%) and MO (n=7,12%) were divided into 2 groups: Gr.1-(n=37), systolic BP(SBP) 160±15 mmHg and microalbuminuria (MA)-80±20 mg\l; Gr. 2-(n=22)-SBP 162±20 mmHg and MA 85±23 mg/l. At entry mean fasting (FBG) and postprandial (PBG) blood glucose and HbA1c levels in both groups were: FBG-40±15 mg\dl; PBG-230±30 mg\dl; HbA1c-12.4±2.5%; Glycaemia and ABP control was normalized in both groups before LC was performed: Gr. 1 intensive insulin therapy and aggressive antihypertensive treatment; Gr. 2 oral hypoglycemic agents and less tight ABP control. LC comprised ~2500 pan retinal burns for PDR and standard grid for MO.
Results: At 3 months glycaemia and ABP indices had improved: FBG-05±10 mg\dl; PBG-60±20 mg\dl; HbA1c-7.6±1.5%. In Gr. 1-SBP and MA were normalized (130±10 mmHg and 25±9 mg\l, respectively, p=0, 001); in Gr. 2-SBP and MA-142±15 mmHg and 38±12 mg\l, respectively, p=0, 001. At 3 months LC was successful in 49/52 PDR patients; in 3 (5.8%) cases from Gr. 2, where glycemia and ABP control was less strict, relapse occurred. Hard exudates cleared and vision improved in MO eyes.
Conclusion: In this study population strict glycaemia and ABP control resulted in better outcomes in patients with PDR and MO.

1107

Estimated GFR but not ADMA is independently associated with diabetic retinopathy in type 2 diabetes

K. Krzyzanowska[1], F. Mittermayer[2,3], G.H. Schernthaner[4], S. Brunner[5], J. Brix[1], S. Aschauer[2], M. Wolzt[2], G. Schernthaner[1];
[1]Internal Medicine I, Rudolfstiftung Hospital, Vienna, Austria, [2]Clinical Pharmacology, Medical University Vienna, Vienna, Austria, [3]Internal Medicine 5, Wilhelminen Hospital, Vienna, Austria, [4]Internal Medicine 2, Medical University Vienna, [5]Ophtalmology, Rudolfstiftung Hospital, Vienna, Austria.

Background and aims: Patients with type 2 diabetes mellitus (T2DM) and diabetic retinopathy are at increased risk for cardiovascular disease. Asymmetric dimethylarginine (ADMA) is associated with cardiovascular events in patients with T2DM. We investigated the role of ADMA in T2DM patients with and without retinopathy adjusted for prevalent cardiovascular disease.
Materials and methods: One hundred twenty seven patients with T2DM (mean age: 63 yrs.; women: n=49) were included according to a cross-sectional study design. Sixty eight of these patients had macrovascular disease. Diabetic retinopathy was present in 67 patients.
Results: Patients with diabetic retinopathy had increased ADMA, longer diabetes duration and reduced glomerular filtration rate (GFR; calculated with the MDRD formula). ADMA correlated with GFR (R=-0.35; p<0.001), diabetes duration (R=0.19; p=0.048) and age (R=0.19; p=0.033). In a crude logistic regression analysis a 1 SD log increase in ADMA was significantly associated with the presence of diabetic retinopathy (OR 1.50; 95% CI: 1.03 - 2.17; p=0.034). After adjustment for prevalent cardiovascular disease this association remained significant (OR 1.48; 95% CI: 1.02 - 2.15; p=0.039). Further inclusion of GFR into the regression analysis abolished this significant relationship (OR 1.21; 95% CI: 0.81 - 1.83; p=0.354) and revealed an independent association between GFR and diabetic retinopathy. Diabetes duration (R=-0.27; p=0.006), HbA1c (R=0.31; p=0.001) and diastolic blood pressure (R=0.25; p=0.011) correlated with GFR. A GFR decrease of 10 ml/min/1.73 m2 was associated with an OR of 1.32 (95% CI: 1.13 - 1.54; p=0.001) for the prevalence of diabetic retinopathy. After adjustment for possible confounders GFR remained significantly related to diabetic retinopathy (OR 1.25; 95% CI: 1.04 - 1.50; p=0.019).
Conclusion: These findings indicate that the prevalence of macrovascular disease does not influence the relationship between ADMA and diabetic retinopathy in patients with T2DM. However, this association seems to be caused by reduced renal function found in subjects with diabetic retinopathy. GFR was the only parameter independently related to diabetic retinopathy in this study.

1108

Diabetic retinopathy and associated conditions - what relationship? A study in patients with type 2 diabetes

J.F. Raposo[1], C.A. Nabais[2], J.A. Pereira[2], P.M. Pereira[2], R.M. Capote[2], S.M. Coelho[2];
[1]Diabetes, Portuguese Diabetes Association (A.P.D.P.), [2]Public Health Department, Medical Sciences Faculty, Lisbon, Portugal.

Background and aims: Diabetic retinopathy is the leading cause of blindness in adults in Western countries. There are few studies about this microvascular complication in the Portuguese population. The aim of the present study is to establish the relationship between diabetic retinopathy, risk factors and associated conditions, in a group of patients with type 2 diabetes mellitus.
Materials and methods: We performed a descriptive, transversal and case-control study that included 874 patients - 437 with and 437 without diabetic retinopathy, respectively, seen for the first time at the Portuguese Diabetes Association. Data were collected from informatic medical records.
Results: The group with retinopathy had significantly higher values of HbA1c, systolic blood pressure and years of diagnosis, compared with the group without retinopathy (p 6,5%) but in the subgroup with retinopathy, the percentage of patients in these conditions was higher (91,3%) compared to control group (73,2%) (p <0,05). The prevalence of hypertension in the sample was 73%. It was found that the group with retinopathy had a significantly higher prevalence of hypertensive patients (79,6% versus 66,4% - p<0,05). The prevalence of nephropathy was higher in the group with retinopathy (35,6% versus 20,8% - p<0,05).
Conclusion: There is a positive correlation between retinopathy and hypertension, glycaemic control and nephropathy. Systolic blood pressure seems more important than diastolic blood pressure for this association. With this study we reinforce the importance of blood pressure control and to educate patients about the benefits of a good glycaemic control.

Paraoxonase gene polymorphisms are associated with carotid arterial wall thickness in essential hypertensive subjects with metabolic syndrome

E. Russo[1], L. Pucci[1], D. Lucchesi[1], G. Dell'Omo[2], E. Storti[1], C. Bianchi[1], A.G. Daniele[1], G. Penno[1], S. Del Prato[1], R. Pedrinelli[2], R. Miccoli[1];
[1]Endocrinology and Metabolism, [2]Dept. of Cardio-Thorax Disease, University of Pisa, Italy.

Background and aims: Paraoxonase (PON1), a HDL-associated enzyme, is protective against LDL oxidation. Two frequent mutations of the PON1 gene, Q192R and L55M, have been associated with carotid arterial wall thickness in young adults, in type 2 diabetes, and in familial hypercholesterolemia.
Materials and methods: In this pilot study, we examined the influence of the two polymorphisms on carotid atherosclerosis in 183 newly diagnosed untreated hypertensive subjects 64 of whom (35%) had Metabolic Syndrome (MS). Distributions of the two polymorphisms were determined by PCR-RFLP analysis. High resolution B-mode ultrasound assessed carotid intima-media wall thickness (IMT). MS was defined according to the latest NCEP-ATPIII.
Results: Frequencies of the QQ and LL genotypes were 56% and 52%, respectively, with no differences between MS+ (n. 64) and MS- (n. 119). QQ and R carriers, as well as LL and M carriers did not differ for age, BMI, waist, systolic and diastolic BP (ambulatory BP monitoring), creatinine, MDRD-eGFR, total-, LDL- and HDL-cholesterol, triglycerides, apolipoprotein A1 and B, fasting- and OGTT-AUC- (Area Under the Curve) glucose, fasting- and OGTT-AUC-insulin, HbA1c. No differences by genotypes emerged after stratification by MS. Carotid IMT was higher in QQ (n. 103; 0.81±0.25 mm) than in R carriers (n. 80; 0.73±0.22 mm, p=0.02). This difference was lost in MS- (0.78±0.25 vs 0.73±0.23 mm) but persisted in MS+ (0.85±0.25 vs 0.72±0.21 mm, p=0.04). No difference in carotid IMT was observed between LL genotypes and M carriers (0.79±0.25 vs 0.76±0.23 mm) in the whole co-

hort, as well as in MS- (0.76±0.24 vs 0.76±0.25 mm) and MS+ (0.84±0.27 vs 0.77±0.20 mm). Homozygous wildtype QQ/LL (48 subjects, 26%) had the highest carotid IMT (0.85±0.27 mm) as compared to the other genotypes (combined: 0.75±0.23 mm, p=0.01). Again, this difference was present in MS+ (0.91±0.31 vs 0.77±0.20 mm, p=0.05) but not in MS- (0.81±0.25 vs 0.75±0.24 mm). Multiple regressions analysis demonstrated the QQ genotype and the QQ/LL combination of the PON1 gene to be independent risk factors for increased IMT.

Conclusion: In conclusion, our data support the view of an independent association between PON1 gene variants and carotid atherosclerosis in essential hypertensive subjects with metabolic syndrome.

Localized peripapillary optic nerve fibers deficiency (LPONFD) in diabetic patients without retinopathy

C. Vardanian[1], P. Guillot[1], S. Bernard[1], S. Charrière[1], A. Crand[1], A. Decaudain[1], M. Pugeat[1], P. Denis[2], P. Moulin[1];
[1]Endocrinology Diabetology, [2]Ophthalmology, Hospices Civils de Lyon, France.

Background and aims: Fundus photographs examination revealed that some diabetic patients have localized peripapillary optic nerve fibers deficiency (LPONFD) without glaucoma criteria. The aim of the study was to evaluate the functional impact of these defects.

Materials and methods: This case-control study enrolled 2 000 consecutive diabetic patients (without retinopathy or with minor retinopathy) between july 2007 and july 2008 : 150 LPONFD were detected (prevalence of 7,5%). A prevalence of 3% was observed in 170 controls subjects without diabetes. A complete ophthalmologic examination was made (intraocular pressure (IOP) measurement, visual field analysis (VF), retinal nerve fiber layer measurement (RNFL) by OCT) in 40 subjects with LPONFD, 30 subjects with normal tension glaucoma (NTG) et 56 diabetic controls.

Results:

	Controls (n=56)	LPONFD (n=40)	NTG (n=30)	p
Age (years)	53.5 +/-1.71	58.04 +/-1.89	62.9 +/-1.99	0.006
Diabetes duration (years)	12.9 +/-0.94	10.25 /- 1.38	8.33 +/- 1.27	0.2
HbA1C (%)	7.98 +/- 0.16	7.85 +/- 0.31	9.2 +/- 0.48	0.04
IOP	14.8 +/-0.86	16.6 +/-0.56	16.3 +/-0.53	0.26
OCT RNFL	108 +/-1.42	99.5 +/-2.31	79.7 +/-3.49	0.0001
VF MD	-0.62 +/-0.35	-1.59 +/-0.52	-4.26 +/-1.43	0.006
VF PSD	1.7 +/-0.09	3.66 +/-0.3	4.1 +/-0.53	0.017
small optic disk (%)	18	43	0	0.001

LPONFD was observed in diabetic subjects younger than those with NTG. There were no difference between groups in prevalence of cardiovascular risk factors and diabetic complications.

Conclusion: In this diabetic population, we reported LPONFD resulting in impairment of RNFL and in corresponding visual field defects. LPONFD seems not to be related with diabetes mellitus but might be associated with a constitutional or acquired small optic disk.

1111

Low prevalence of diabetic retinopathy in a geriatric population of type 2 diabetic patients

C. Kellner, A. Mandecka, W. Hunger-Battefeld, C. Kloos, G. Wolf, U.A. Müller;
Internal Medicine III, Friedrich Schiller University Jena, Germany.

Background and aims: There is just a few evidence on the prevalence of diabetic retinopathy in the geriatric population. Up to now just one study concentrated specifically on the incidence of retinopathy in patients diagnosed with diabetes mellitus after the age of 70 years. We estimated the prevalence of diabetic retinopathy in patients with type 2 diabetes mellitus diagnosed after the age of 70 years in a ambulant and hospital based German population . The prevalence of retinopathy, blood glucose and blood pressure control was examined. The incidence of retinopathy in the geriatric population was compared to the incidence of retinopathy in type 2 diabetic patients diagnosed between the age of 40 and 70 years.

Materials and methods: The study was performed on a collective of type 2 diabetic patients who were being treated in a large out- and inpatient diabetes clinic at a tertiary university hospital. A total of 136 patients with the age of diagnosis of 70 years or more (age 80y, time since diagnosis 5y, HbA1c 9%, blood pressure 146/79mmHg, BMI 28 kg/m^2) and 1551 patients with the age of diagnosis between 40 and 70 years (age 66y, time since diagnosis 13y, HbA1c 8%, blood pressure 145/82 mmHg, BMI 30 kg/m^2) were investigated. Patients with an eye examination within the last 2 years were included. Diabetic retinopathy was classified as no retinopathy (no DR), non-proliferative DR, proliferative DR and blindness.

Results: In a group of 174 patients diagnosed after the age of 70 years 13.2% had DR (8.8% non-proliferative and 3.7% proliferative retinopathy). One patient was blind. In a group of 1551 patients diagnosed with diabetes between 40 and 70 years 25.8% showed signs of DR (18.9% non-proliferative and 6.9% proliferative retinopathy). In a group of patients diagnosed at the age of 70 or more, patients with diabetic retinopathy were older (82 vs. 80 J) and had significantly longer duration of the disease (8 vs. 5J) in comparison to the patients who had no signs of retinopathy. The HbA1c, systolic blood pressure, creatinine in serum and urine albumin excretion was higher in a group with retinopathy, although the difference was not significance.
Conclusion: The prevalence of retinopathy in diabetic patients diagnosed after the age of 70 is only half as much as in diabetic patients diagnosed at the age between 40 and 70 years. The prevalence of retinopathy in the elderly group is even lower as in a similar Danish analysis (Cahill et al 1997, DR 14%) and in an American study (WESDR 1984, DR 39%). The prevalence of proliferative retinopathy in the Danish study (3,3%) was similar to our results. Therefore, older patients with late onset of the disease are less endangered to suffer from diabetic retinopathy.

1112

Results of screening for diabetic retinopathy in people with diabetes mellitus type 2 in Uzbekistan

N.S. Ibraghimova, N.M. Normatova, B.H. Shagazatova, N.M. Yuldasheva, D.M. Berdykulova;
Laboratory for Endocrine Diseases, Research Institute of Endocrinology, Tashkent, Uzbekistan.

Background and aims: Diabetic retinopathy (DR) remains to be one of the most serious complications of diabetes mellitus (DM) resulting in partial or full loss of vision and subsequent disability. Screening for DR in PDM especially in those with DM type 2 is an effective method of DR detection at various stages of its development which enables development of step by step pathogenetic therapy.
Goal: carrying out of DR screening in PDM in regions of Uzbekistan and development of methods for prevention and early diagnostics of DR.
Materials and methods: Within the framework of the WDF 07-232 project «Prevention of blindness in people with diabetes mellitus in Uzbekistan» granted to Tashkent CPA "UMID", DR screening was performed in PDM type 2 residing in the Ferghana, Bukhara regions and the Republic of Karakalpakstan. We examined 2087 people with diabetes mellitus type 2 aged 18 to 67. A level of glycaemia (a fasting one and 2 hours after meals), glycosylated haemoglobin and cholesterol were measured. Eyes were examined with a direct ophthalmoscope (after preliminary pupil dilatation), visual acuity and an intraocular tension were measured.
Results: The analysis of the results of the screening undertaken in 2087 patients demonstrated that the DR rate in PDM type 2 made 56.9%. Of them DR grade I was revealed in 32.8%, DR grade II -18.6%, DR grade III was found in 5.5%. Retinopathy was not detected in 43% of patients. Percentage of patients in who DR was diagnosed during the screening for the first time made 52%. In comparison with the date obtained by D.M. Berdykulova (Research Institute of Endocrinology 2003) epidemiological researches undertaken in the Tashkent region the frequency of DR in DM type 2 made 57.4% (grade I - 77.7%, II - 23% and III - 6.9%). The screening studies performed correspond to the data of the epidemiological research. The prevalence rate of DR in DM type 2 was reliably higher in females than in males ($p<0.05$). Studies of DR frequency in PDM type 2 of glycosylated hemoglobin (HbA1c) revealed a clear rise in prevalence of all DR stages from the HbA1c level. Prevalence of DR stages I, II and III in faces with controlled carbohydrate exchange (HbA1c<7%) made 11.3%, 3.4% and 2.0% respectively ($p<0,001$). Prevalence of DR stages I, II and III in subjects with uncontrolled carbohydrate exchange (HbA1c>8.5%) was 36.9%, 15.8% and 8.8% respectively. Mean rates of systolic and diastolic pressure in sick with DR grades II-III made 151.0±5.1 mm Hg and 90.8±2.2 mm Hg which corresponds to AH stage I. The frequency of DR in PDM type 2 depended directly on the patient's age. In PDM type 2 with DR mean rates of total cholesterol, LDL and HDL mismatched the norm having made 5.5±0.2 mmol/L, 4.14±0.22 mmol/L and 0.94±0.03 mmol/L, respectively. It should be noted that the mean LDL was reliably higher in comparison with that in patients without DR (3.65±0.07 mmol/L).
Conclusion: According to the screening performed, the frequency of DR in patients with DM type 2 made 56.9%, where the share of DR grade I was 32.8%, DR II - 18.6% and DR III- 5.5%. Advance of DR in patients with DM type 2 depends on duration of the disease and a degree of controlling carbohydrate exchange as well as AH, hypercholesteremia and dislipidemy. Screening is quite an effective method of revealing retinal lesions in PDM and promotes quality improvement of treatment and prophylactic care at early stages of DR development.
Our acknowledgement to WDF for the great contribution to improvement of diabetic service in Uzbekistan

1113

Ethnic disparities in eye care for people with diabetes

B.R. Shah[1], S. Anand[2], D.G. Manuel[1], J.E. Hux[1];
[1]Institute for Clinical Evaluative Sciences, Toronto, [2]McMaster University, Hamilton, Canada.

Background and aims: Diabetes prevalence is known to vary between ethnic groups. However, variations in diabetes microvascular complication rates between ethnic groups have been less well established, as have utilisation rates for medical services to manage these complications. The aim of this study was to compare eye care for diabetes between people of South Asian and Chinese origin versus the general Canadian population (mostly of European origin).
Materials and methods: The study used administrative data sources which provided detailed information on the health care utilisation of all residents of the province of Ontario (population=12 million). Ontario is one of Canada's most ethnically diverse provinces, with 6.6% of the population reporting South Asian origin and 4.8% reporting Chinese origin. The entire population with prevalent diabetes as of 1 July 2006 in Ontario was identified from an administrative data-derived disease registry. South Asian and Chinese ethnicity was assigned based on surname, using lists of surnames specific for each ethnic group that have been validated against self-reported ethnicity. All other people were assigned to the general population group. Through linkage with administrative data, patients who had physician claims for an eye examination, for laser photocoagulation therapy or for vitrectomy surgery in the following year were identified. Differences between groups were determined, using logistic regression to adjust for age, sex, socioeconomic status and diabetes duration.
Results: The crude prevalence of diabetes was 12.9% among people of South Asian origin, 7.2% among people of Chinese origin, and 9.1% in the general population. Compared to the general population, people of South Asian origin and of Chinese origin were less likely to have an eye examination (OR 0.86, 95% CI 0.84-0.88 and OR 0.83, 95% CI 0.81-0.85, respectively). However, people of South Asian origin were more likely to require laser photocoagulation (OR 1.46, 95% CI 1.35-1.58) whereas those of Chinese origin were less likely (OR 0.60, 95% CI 0.53-0.68). The results for vitrectomy surgery were similar, although attenuated (OR 1.12, 95% CI 0.93-1.35 and OR 0.70, 95% CI 0.55-0.90, respectively).
Conclusion: People of South Asian and Chinese origin in Ontario were less likely than the general population to receive eye examinations to screen for diabetic retinopathy. South Asians had worse clinical outcomes, with a greater need for laser photocoagulation. These findings suggest that South Asians with diabetes have an increased burden of retinopathy and/or are experiencing clinical consequences of inadequate screening.

Analysis of intraocular level of VEGF in patients with diabetic retinopathy, operated from cataract

A.G. Kuzmin[1], D.V. Lipatov[1], T.A. Tchystyakov[1], O.M. Smirnova[2], M.I. Arbuzova[3], A.V. Ilyin[3], M.V. Shestakova[4];
[1]Diabetic Retinopathy and Ophthalmosurgery, [2]Psychosocial Reabilitation and Training, [3]Laboratory of Biochemical and Hormone Analysis, [4]Institution of Diabetes, Research Centre of Endocrinology, Moscow, Russian Federation.

Background and aims: Diabetic retinopathy (DR) is the main cause of blindness among young people, suffering from diabetes mellitus (DM). DR is associated with increasing of proliferative molecules in eye, which stimulate permeability, oedema and growth of new vessels. The most established agent, leading to proliferative DR, is vascular endothelial growth factor (VEGF). The aim of our study was to determine level of VEGF in aqueous humor from patient with DM and cataract and to indentify an association between level of VEGF, glycated hemoglobin (HbA_{1C}) and visual acuity (VA) at the postoperative period.
Materials and methods: In the study were included 10 patients with DM type 1; 52 - with DM type 2 and 6 - without DM (as control group). During operation from cataract (we used ultrasound facoemulsification and following implantation the acrylic intraocular lens) the aqueous humor was obtained, the sample was prepared by prompt centrifugation (15,000 g*min) and stored at -80°C. The level of VEGF was analyzed by ELISA. All patients were examined before and after operation. The grade of DR was measured using recommendation of WHO (1999). Results of data analysis were expressed as means±SD, all tests with $p<0.05$ were considered significant. Relationship between VEGF, visual acuity and evidence of retinopathy was analyzed using multiple regression.
Results: 84 eyes (68 patients) were operated from cataract, prevalence of DR has been presented in tab.1, sings of DR were absented only in 4% of patients with DM. Laser coagulation of retina were performed on several patient from DR before operation. Level of HbA_{1C} didn't significantly different (p=0,1976) in groups of patients with DM. Corrected VA before operation in patients without DM were 0,33±0,32 and 0,26±0,23 in patients with DM, in groups of DR significant difference didn't observe. After operation VA was improve and was 0,58±0,39 in patients without DM and 0,45±0,33 in patient with DM. It progressively was worsen in patient with proliferative DR (0,25±0,26), difference was statistically significant. Level of VEGF in aqueous humor in patients without DM was 61,17±33,78 pg/ml and progressively increased in patients with DM, in patients with proliferative DR level of VEGF was 243,39±203,82 pg/ml (p=0,0175).
Conclusion: Proliferative DR was associated with worsen corrected VA after operation from cataract. Level of VEGF in aqueous humor was considerably increased in patients with proliferative DR (comparably with patients with preproliferative and nonproliferative DR). High level of VEGF may be factor, causing deterioration vision in patients with DM.

Characteristic	Non DM	DM type 1 and 2				p-value
		No DR	Nonproliferative DR	Preproliferative DR	Proliferative DR

Pregnancy-induced sight threatening diabetic retinopathy in women with type 1 diabetes

M. Vestgaard[1,2], L.R. Nielsen[1,2], C.S. Laugesen[3], P. Damm[4,2], E.R. Mathiesen[1,2];
[1]Department of Endocrinology, Faculty of Health Sciences, University of Copenhagen, [2]Center for Pregnant Women with Diabetes, [3]Department of Ophtalmology, Faculty of Health Sciences, University of Copenhagen, [4]Department of Obstetrics, Faculty of Health Sciences, University of Copenhagen, Denmark.

Background and aims: To evaluate the progression of diabetic retinopathy in pregnant diabetic women offered tight glycaemic and blood pressure control.
Materials and methods: Prospective study of 102 (87%) out of 117 consecutive pregnant women with type 1 diabetes for median 16 years (range 1-36) and HbA_{1c} 6.7 % (4.9-10.8) in early pregnancy. Fundus photography was performed at 10 and 28 gestational weeks. Diabetic retinopathy was classified in five stages. Macular oedema was classified as present in a mild form or as clinically significant macular oedema (CSME). Progression was defined as at least one stage of deterioration of retinopathy and/or development of macular oedema in at least one eye. Sight threatening progression was defined as loss of visual acuity ≥0.2 on Snellen's chart or laser treatment performed during pregnancy due to proliferative retinopathy or CSME.
Results: Diabetic retinopathy was present at inclusion in at least one eye in 64 (63%) women and proliferative retinopathy and macular oedema was present in nine and 16 women, respectively. Progression of retinopathy occurred in 28 (27%) women with sight threatening progression in six of whom three deteriorated in visual acuity and four required laser treatment. Sight threatening progression was associated with presence of macular oedema (p=0.007), impaired vision (p=0.03) and higher blood pressure in early pregnancy (p=0.016), but not with HbA_{1c}, decline in HbA_{1c} or prevalence of severe hypoglycaemia.
Conclusion: Pregnancy-induced sight threatening diabetic retinopathy is still a clinical problem and associated with presence of macular oedema, visual impairment and higher blood pressure in early pregnancy.

PS 101 Retinopathy - experimental

Angiotension II type 1 receptor blocker decreases the nitric oxide end products and inducible nitric oxide synthase preventing the early oxidative markers of diabetic retinopathy

K.C. Silva, M.A.B. Rosales, N. Martins, J.B. Lopes de Faria, J.M. Lopes de Faria;
Faculty of Ciencies Medicine, State University of Campinas, Brazil.

Background and aims: In addition to be a very frequent disease in patients with diabetes mellitus (DM), hypertension is the major risk factor associated with the development of diabetic retinopathy (DR). Oxidative stress mechanisms, renin-angiotensin system (RAS) and nitric oxide (NO) are described to be involved into the pathogenesis of DR. This investigation sought to determine whether concomitance of diabetes and hypertension exacerbates these parameters, to evaluate the potential retinal antioxidant effects of the angiotensin II type 1 receptor blocker (ARB) on retinal tissue by oral administration of losartan in diabetic hypertensive rats and to assess the mechanisms of its beneficial effects.
Materials and methods: Four-week-old spontaneously hypertensive rats (SHR) were rendered diabetic by intravenous injection of streptozotocin. Diabetic SHR rats were randomized to receive no treatment (DM-SHR) or treatment with ARB losartan (200mg/Kg, DM-SHRLos); control rats received citrate buffer. After 20 days, the rats were euthanized and the retinas collected. The results were compared by analysis of variance (ANOVA) followed by Fisher's protected least-significant difference test.
Results: As expected, the angiotensin II biodisponibility evaluated by Western blot assay was higher in retina of treated rats (p=0.02). The oxidative status, evaluated by superoxide production and NO end products levels estimated by Nitric Oxide Analyser (p=0.03) and the antioxidative systems, estimated by reduced glutathione (p=0.04) and activity of total superoxide dismutase through a colorimetric kit (p=0.002) revealed an accentuated unbalance in favor to oxidants in DM-SHR rats. As a consequence, the tyrosine nitration assessed by immunohistochemistry for nitrotyrosine (p=0.02) and DNA damage evaluated by 8-hydroxy-2'deoxyguanosine immunohistochemistry (p=0.0003) were higher. The retinal protein expression of inducible nitric oxide synthase (iNOS) was also elevated in DM-SHR rats (p=0.01). The treatment with losartan prevented all the above alterations.
Conclusion: These data demonstrate that the therapy with ARB losartan increases the reduced glutathione and total SOD activity and reduces the amount of nitric oxide end products (NO_x^-) and iNOS expression preventing the retinal nitrosative damage in a model of diabetes and hypertension. This study provides new information on understanding of the molecular basis underlying the beneficial effect observed by AT_1 blockage in the retina of patients with diabetes.

Beta2-glycoprotein I inhibits insulin and insulin-like growth factor induced angiogenesis through its amino terminal domain

P. Yu[1], D. Yu[1], S. Krilis[2], J. Qi[2];
[1]Department of Nephropathy & Dialysis, University of Tianjin Medicine, Metabolic Disease Hospital, China, [2]Department of Medicine, University of New South Wales, St George Hospital, Sydney, Australia.

Background and aims: Insulin treatment is epidemiologically known as an independent risk factor in the progression of diabetic retinopathy. Insulin elicits angiogenesis through the induction of autocrine VEGF, thereby leading to the exacerbation of diabetic retinopathy. Beta-2 glycoprotein I (beta(2)GPI) is a plasma glycoprotein which interacts with various proteins of the coagulation and fibrinolysis system. beta(2)GPI has recently been shown to have anti-angiogenic properties. We undertook this study to investigate the specific domain of beta(2)GPI involved in the anti-angiogenic function and its effect on downstream signaling of vascular endothelial growth factor (VEGF) and basic fibroblast growth factor (bFGF).
Materials and methods: Various preparations of beta(2)GPI were used on human retinal endothelial cells (HRECs) in the absence or presence of insulin and insulin-like growth factor (IGF). The effect on HRECs' proliferation, migration and tubule formation in Matrigel matrix was investigated. The effect of beta(2)GPI on the mRNA expression of VEGF receptors and phosphorylation of signaling molecules was also studied.
Results: beta(2)GPI is shown in this study to be an anti-angiogenic molecule in vitro by inhibiting insulin and IGF-induced proliferation, migration and papillary-like tubule formation of HRECs. This inhibition was achieved by native, proteolytically clipped and domain deletion mutants, domain I-IV (DI-IV) but not domain II-V (DII-V) of beta(2)GPI. Native beta(2)GPI was found to downregulate the expression of the VEGF receptor KDR/Flk-1 on endothelial cells and to block the phosphorylation of VEGF's downstream effector molecules in the MAPK/ERK and PI3K/Akt/GSK3beta pathways.
Conclusion: These results indicate that beta(2)GPI has anti-angiogenic functions which depend on the presence of domain I. This anti-angiogenic activity may have important implications for the therapeutic manipulation of angiogenesis in diabetic retinopathy especially during insulin treatment.

Exogenous superoxide dismutase mimetic tempol prevents the early markers of diabetic retinopathy through inhibition of poly (ADP-ribose) polymerase

M.A.B. Rosales, K.C. Silva, J.B. Lopes de Faria, J.M. Lopes de Faria;
Department of Internal Medicine, Faculty of Medical Sciences, State University of Campinas (UNICAMP), Brazil.

Background and aims: Hypertension is an important factor associated with development of diabetic retinopathy (DR). Oxidative pathways are proposed to explain how the hyperglycemia initiates the biochemical processes in the pathogenesis of DR. The aim of this study was to investigate the efficacy of tempol (4-hydroxy-2,2,6,6-tetramethylpiperidinyloxy) a superoxide dismutase (SOD) mimetic in preventing the early retinal changes in a model that combines hypertension and diabetes.
Materials and methods: Four-week-old spontaneously hypertensive rats (SHR) were rendered diabetic by streptozotocin (60mg/kg). Diabetic SHR rats (DM-SHR) were randomized to receive or not intraperitoneal injection of tempol (250mg/kg/day); control rats received vehicle only. After 20 days of diabetes, rats were euthanized and the retinas were collected for protein extraction and colorimetric assays or the eyes were prepared for imunohistochemistry. The results were compared by analysis of variance (ANOVA) followed by Fisher's protected least-significant difference test.
Results: The early markers of DR, glial fibrillary acidic protein (GFAP) and fibronectin (FN) evaluated by western blot assays were increased in DM-SHR compared with SHR group (p=0,0001 and p=0,02, respectively). The oxidative balance, evaluated by superoxide production (p=0,05) and nitric oxide end products levels estimated by Nitric Oxide Analyser (p=0,002), and the counterpart antioxidative defense revealed an accentuated unbalance in DM-SHR compared to CT-SHR group (p=0,01 and p=0,02 for activity and expression of SOD, respectively evaluated by colorimetric kit and western blot). As a result, the product peroxynitrite detected, by retinal immunohistochemistry for nitrotyrosine, was higher in DM-SHR rats (p=0,04). The retinal poly(ADP-ribosyl)ation (PARP) and the iNOS protein expression were found to be increased in this group (p<0,05). The treatment with tempol re-established the oxidative parameters and reduced the PARP activation thus preventing the early markers of DR.
Conclusion: Our data demonstrated that the administration of tempol inhibited the ribosylation of PARP, decreased the iNOS levels and prevented the oxidative damage in the retina of diabetic hypertensive rats. As a consequence the extracellular matrix accumulation and glial reaction, accepted as early markers of DR were prevented in tempol treated DM-SHR rats. These findings provide rational for development of PARP inhibitor/SOD mimetic compound for prevention of diabetic retinal disease.

High glucose-induced downregulation of mitochondrial connexin-43 expression triggers mitochondrial shape change and cytochrome-C release in retinal endothelial cells

K. Trudeau, A. Molina, W. Guo, S. Roy;
Department of Medicine, Boston University, United States.

Background and aims: Retinal vascular cell loss is a prominent lesion of diabetic retinopathy. While mitochondrial dysfunction has been shown to contribute to the development of pericyte loss and acellular capillaries, it remains unclear how high glucose promotes mitochondrial damage. Since de-

pletion of mitochondrial connexin 43 (Cx43) facilitates reactive oxygen species (ROS) formation, in this study, we investigated the effect of high glucose (HG) on mitochondrial connexin43 (mt-Cx43) expression and cytochrome C (CytC) release in retinal endothelial cells. Additionally, we examined whether HG-induced mitochondrial shape change was influenced by altered mt-Cx43 channel activity by inhibiting mt-Cx43-channels.
Materials and methods: Rat retinal endothelial cells (RRECs) were grown in normal (5mM) or HG (30mM) medium for 8 days, and mt-Cx43 protein level and CytC release in the cytosolic fraction was simultaneously assessed by Western Blot (WB) analysis. In parallel, mt-Cx43 immunostaining was performed using MitoTracker Red (100nm) and FITC-labeled Cx43, and overlapping Cx43 and mitochondria signals were counted to assess the number of mt-Cx43 plaques. To determine the effect of inhibition of mt-Cx43 channels on mitochondrial shape change, RRECs were plated sparsely without cell to cell contacts and grown for two days in three groups: untreated cells (control), cells treated with β-glycerrhetinic acid (β-GA), an inhibitor of Cx-channels (50uM), and cells treated with glycyrrhizic acid GZ (50uM), a chemical analog of β-GA that does not inhibit Cx-channels. Cells were then stained with tetramethylrhodamine-ethyl-ester-perchlorate (TMRE, 8nM) and assessed for mitochondrial morphology using live confocal imaging. Analysis for mitochondrial shape change was calculated using Form Factor (FF) and Aspect Ratio (AR) values of the mitochondria.
Results: Western blot analysis indicated that mt-Cx43 protein level was significantly reduced in RRECs grown in HG media compared to those grown in N media (59 ±19% of control, p=0.027), with concomitant increase in cytosolic CytC (421 ±155% of control, p=0.005). CoCl2 used as a positive control showed similar increase in CytC release (404 ±143% of control, p=0.007). Immunofluorescence data also confirmed HG-induced downregulation of mtCx43 plaques (63 ±27% of control, p=0.030). Treatment of RRECs lacking cell contacts with β-GA significantly changed mitochondrial shape to rounded forms (FF for β-GA treated RRECs: 1.71 vs. 2.60 in normal, p=0.009; AR: 1.88 vs. 2.25 in normal, p=0.010), which coincided with decreased Cx43 protein on the mitochondria (46 ±16% of control, p=0.007). Treatment with the β-GA, an inactive analog of GZ, did not significantly inhibit Cx43 protein (74% of control, p=0.081) and did not show significant shape change or fragmentation of mitochondria (FF for GZ treated RRECs: 2.14 vs. 2.60 in normal, p=0.068, AR: 1.98 vs. 2.25 in normal, p=0.079).
Conclusion: Results indicate that HG downregulates mt-Cx43 protein and triggers concomitant release of CytC. Inhibition of mt-Cx43 channel activity resulted in mitochondrial shape change, suggesting that mt-Cx43 may be important to mitochondrial shape regulation and overall homeostasis, which, when compromised under HG condition may result in the release of CytC and apoptosis. This suggests a potential mechanism for hyperglycemia-induced apoptosis in diabetic retinopathy.

Retinal pigment epithelial cells express a functional receptor for glucagon-like peptide-1
A. Puddu, A. Durante, G.L. Viviani;
Department of Internal Medicine, University of Genova, Italy.

Background and aims: Glucagon-like peptide-1 (GLP-1) is a gut-derived incretin hormone of great interest for the management of diabetes for its glucose lowering action. Treatment with GLP-1or with dipeptidyl peptidase-4 inhibitors, the enzyme that degrades GLP-1, reduces HbA_{1c} and the levels of free fatty acids, and improves insulin sensitivity. The biological effects of GLP-1 are mediated by its specific receptor GLP1R, that is expressed in a wide range of tissues, where it is responsible of the extra-pancreatic effects of GLP-1. Recently it has been reported that treatment with a long-acting agonist of GLP1R provides protection for early experimental diabetic retinopathy, suggesting an important role of GLP-1 in preventing diabetic complication. Since the retinal pigment epithelium (RPE), that forms the outer retinal barrier, has a key role in maintaining retinal homeostasis we verify the expression of GLP1R in the RPE cell line ARPE-19 and investigate the signal transduction pathway activated by GLP-1.
Materials and methods: ARPE-19 cells were cultured in DMEM/F12 supplemented with 10%FBS. A batch of cells was lysed and total protein extract were used for Western blot analysis of GLP1R. Lysates from the pancreatic insulin secreting cell line HIT-T15 were used as positive control in immunoblot analysis with specific antibody against GLP1R. Another batch of cells was cultured in serum free medium for 24 hours and stimulated for 10, 20 and 40 minutes with 10 nmol/l GLP-1. Cells were then lysed and total protein extract were used for Western blot analysis of phospho- and total extracellular signal-regulated kinases 1 and 2 (ERK1/2); phospho- and total protein kinase B (PKB). In addition a batch of cells were stimulated with 10 nmol/l GLP-1 for 20 minutes with or without pharmacological inhibitors either of the mitogen-activated protein kinase MEK1/2 (U0126) or of Phosphatydilinositol-3kinase (PI3K) (LY294002) (10 μmol/l of U0126 or 50 μmol/l LY294002 added respectively 2 hours and 30 minutes before incubation with GLP-1). Cells were then lysed and analysed as described above.
Results: Immunoblot analysis with specific antibody against GLP1R reveals a band between 60 and 70 kDaltons in protein extracts from ARPE-19 cells analogous to that detected in HIT-T15 protein lysate. Exposure of ARPE-19 cells to GLP-1 increases the protein levels of phosphorylated ERK1/2 and PKB compared to the control cells. The increment in PKB phosphorylation reaches maximum levels after 20 minutes of exposure and remains elevated after 40 minutes; whereas phosphorylation of ERK1/2 shows a progressive increase also at 40 minutes. Interestingly, inhibition of PI3K, one of the upstream activators of PKB, completely abrogates GLP-1-induced phosphorylation of PKB and of ERK1/2. Inhibition of MEK1/2, the upstream activator of ERK1/2, suppresses GLP-1-induced ERK1/2 phosphorylation, but it has not effect on GLP-1-induced PKB phosphorylation.
Conclusion: We show, for the first time, that a functional GLP1R is expressed in RPE cells. The signal transduction pathway of GLP-1 in ARPE-19 cells involves both PKB and ERK1/2, and our results suggest that it is prevalently mediated by PI3K. GLP-1, affecting RPE cells, may have a direct role in preventing RPE cell dysfunction and, consequently, diabetic retinopathy.

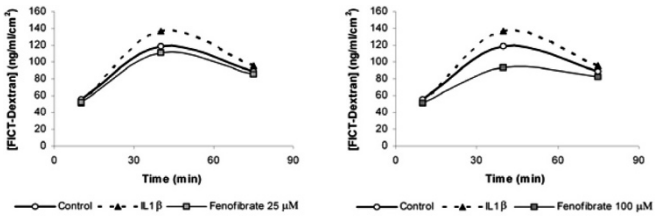
Fenofibrate restores the barrier function of human retinal pigment epithelial cells cultured under conditions mimicking the diabetic milieu
M. Villarroel, M. Garcia-Ramírez, L. Corraliza, C. Hernández, R. Simó;
CIBERDEM (Centro de Investigación Biomédica en Red de Diabetes y Endermedades Metabólicas) Instituto de Salud Carlos III and Diabetes Research Unit, Institut de Recerca Hospital Universitari Vall d'Hebron, Universitat Autònoma de Barcelona, Spain.

Background and aims: Diabetic retinopathy remains the leading cause of blindness and vision loss in adults under 40 years in the developed world. In the FIELD study on diabetic retinopathy, treatment with fenofibrate reduced the need for laser treatment for diabetic macular edema (DME) and proliferative diabetic retinopathy (PDR) by 30%. Because of this notable effect of fenofibrate in preventing DME progression, the aim of this study was to explore the effect of fenofibrate on the barrier function and the expression of tight junction proteins (occludin, ZO-1 and claudin-1) in a human retinal pigment epithelial (RPE) cell line under culture conditions mimicking the diabetic milieu.
Materials and methods: ARPE-19, a spontaneously immortalized human RPE cell line, was cultured for 18 days at 37°C under 5% CO_2 in medium (DMEM/F12) supplemented with 10% fetal bovine serum in hyperglycemic conditions (25 mM D-glucose). To study the potential protective effect of fenofibrate on the barrier function of RPE cells, two concentrations of fenofibric acid (25 μM and 100 μM) were added to the standard culture medium in the last 3 days of the experiment (days 19, 20, 21) (1 application/day). Cells were also treated with IL1β (10 ng/ml) for 48 hours until the end of the experiment in order to mimick the diabetic milieu (days 20, 21). The cells were subjected to serum starvation (1% FBS) during the treatments. Barrier function of RPE (permeability) was evaluated by measuring apical-basolateral movements of FICT-dextran (40 kDa). Occludin, zonula occludens-1 (ZO-1) and claudin-1 expression were determined by western blot analysis.
Results: Treatment of ARPE-19 cells with fenofibric acid reduced the increment of permeability induced by IL1β. This protective effect on monolayer permeability was more evident in cultures treated with fenofibric acid 100 μM than in cultures treated with fenofibric acid 25 μM, thus modulating permeability in a dose-dependent manner. No significant differences were observed in occludin, ZO-1 and claudin-1 protein content between cultures treated with fenofibric acid and untreated cultures.
Conclusion: These results indicate that fenofibric acid has a protective dose-dependent effect on RPE disruption that is unrelated to changes in occcludin, zonula occludens-1 (ZO-1) and claudin-1 expression. This protective effect on the leakage of the outer blood-retinal barrier could be involved in the beneficial effects of fenofibrate on DME. However, further investigation addressed to determining the mechanisms by which fenofibrate exerts its effects in reducing permeability is needed.



Results of 40 kDa FICT-Dextran Permeability

Beneficial effects of erythropoietin on retinal pigment epithelial cells cultured under conditions mimicking the diabetic milieu

M. Garcia-Ramírez, M. Villarroel, L. Corraliza, C. Hernández, R. Simó; CIBERDEM (Centro de Investigación Biomédica en Red de Diabetes y Enfermedades Metabólicas) Instituto de Salud Calos III and Diabetes Research Unit, Institut de Recerca Hospital Universitari Vall d´Hebron, Universitat Autònoma de Barcelona, Spain.

Background and aims: Visual loss in diabetic macular edema (DME) results from fluid accumulation due to the breakdown of the (inner and outer) blood retinal barriers (BRBs). We have previously reported that erythropoietin (Epo) is synthesized by the human retina and that its levels are increased in patients with diabetic macular edema (DME). In addition, there is growing evidence that Epo acts as a prosurvival and neuroprotective factor in the early stages of DR. Furthermore, it has been reported that Epo administration improves DME in diabetic patients with anemia and renal failure. However, there is no information regarding the mechanisms involved in this beneficial effect of Epo.

The aim of this study was to explore the effects of Epo on the outer BRB function by means of measuring permeability and transepithelial resistance (TER) in cultures of human RPE. In addition, the effects of Epo on the expression and distribution of three TJs proteins (occludin, ZO-1 and claudin-1) were also investigated.

Materials and methods: ARPE-19 cells (a spontaneous immortalized RPE cell line) were cultured in monolayer during 21 days in standard Ham´s-F12 DMEM medium supplemented with fetal calf serum (FCS 10%). Epo treatments were performed by adding Epo (50-1000 mU/mL) at the apical side of the monolayer in standard conditions (control) or after mimicking the diabetic milieu (by addition of IL-1β or VEGF at 10 ng/mL). To further clarify the Epo-induced effects, the experiments were repeated in the presence and absence of a neutralizing antibody or specific inhibitors (AG490, a JAK2 kinase Epo receptor associated inhibitor, LY294002, a PI3K inhibitor and GF109203X a PKC inhibitor). The outer BRB function was evaluated by measuring TER and the apical-basolateral movements of fluorescein isothiocyanate dextran (70 KDa). ZO-1, occludin and claudin-1 mRNA levels were assessed by Real-Time PCR and protein content by Western blot. Inmmunohistochemistry for ZO-1, occludin and claudin-1 was performed and fluorescent images were acquired by confocal microscopy

Results: Epo treatment (200 mU/mL) significantly increased TER *vs*. control ($p=0.0038$, after 6 h) and reduced permeability to 70 KDa dextran ($p=0.0062$). These effects were blocked by the neutralizing antibody (3-1.5 μg/mL) as well as by AG490. LY294002 and GF109203X also decreased the effect of Epo but did not reach statistical significance. Confocal microscopy images confirmed a positive staining of TJs at the intercellular outlining, necessary for barrier function. mRNA levels of occludin, claudin-1 and ZO-1 were significantly increased after 24 h of Epo treatment ($p<0.002$; $p<0.05$; 0.05; $p<0.0019$ *vs*. control). However, we did not find a significant increase in protein levels.

Conclusion: Epo administration reduces the hyperpermeability induced by the diabetic milieu in human RPE cells *in vitro*. This beneficial effect seems to be mainly mediated by the downstream signalling of JAK2 kinase Epo receptor protein. Overall our findings suggest that Epo could be proposed as new treatment for DME by targeting the outer BRB.

AAV-mediated PEDF gene transfer counteracts diabetic retinopathy in IGF-I transgenic mice

P. Villacampa[1,2], V. Haurigot[1,2], A. Ribera[1,2], D. Ramos[3], A. Bosch[1], J. Ruberte[3,2], F. Bosch[1,2];
[1]Center of Animal Biotechnology and Gene Therapy, Dept. of Biochemistry and Molecular Biology, Universitat Autonoma de Barcelona, Bellaterra, [2]CIBER of Diabetes and Associated Metabolic Disorders, Barcelona, [3]Center of Animal Biotechnology and Gene Therapy, Dept. of Animal Health and Anatomy, Universitat Autonoma de Barcelona, Bellaterra, Spain.

Background and aims: Diabetic retinopathy is the leading cause of loss of visual acuity and blindness in adulthood. Current therapeutic approaches for diabetic retinopathy, such as laser photocoagulation and vitrectomy, are invasive and merely palliative and repetitive local delivery of drugs is not desirable in a chronic disease. Transgenic mice overexpressing Insulin-like Growth Factor (IGF-I) in the retina have retinal alterations characteristic of non-proliferative retinopathy and, with age, mice develop alterations that mimic the proliferative stage of diabetic retinopathy such as neovascularization in the vitreous cavity and retinal neovascularization. The aim of this study was to assay new therapeutic approaches for diabetic retinopathy in IGF-I transgenic mice.

Materials and methods: AAV2 vectors expressing Green Fluorescent Protein (GFP) or Pigmented Epithelium Derived Factor (PEDF) were injected in the vitreous cavity of transgenic mice. Inmunohistochemical studies were performed to check the transgene expression. After, dextran-conjugated fluorescein injection through the mice tail vein, retinas were dissected and fixed and the vasculature was analyzed using morphometric techniques. The expression of key angiogenic factors was checked by RT-PCR or Western blot in non-treated and PEDF-treated mice.

Results: With the aim of overcoming the angiogenic process present in the transgenic mice retina, the antiangiogenic factor PEDF was overexpressed in the mice retinas using an AAV2 viral vector. PEDF is one of the most potent anti angiogenic factors and also has neuroprotective properties, making it an excellent candidate for gene transfer in diabetic retinopathy. Our studies show that AAV2 vectors have a high efficiency in the transduction of cells of the ganglionar layer and also cells in the inner nuclear layer. PEDF was detected in retinas of mice six months after intravitreal injection of AAV2 PEDF. These animals had a significant reduction of neovascularization in the retina, as measured by fluorescein angiography morphometry and also showed a decrease in retinal inflammatory molecule levels, such as Intercellular Adhesion Molecule 1 (ICAM-1).

Conclusion: PEDF overexpression was able to counteract neovascularization and reduce inflammation in TgIGF-I retinas, indicating that AAV-PEDF treatment could be a feasible therapy for diabetic retinopathy.

PS 102 Retinopathy

1125

Prevalence of diabetic retinopathy through the years 1994 to 2007

S. Karadeniz[1], T. Yilmaz[2];
[1]Ophthalmology Dept., Istanbul Bilim University, [2]Endocrinology and Metabolism Dept., Istanbul University, Turkey.

Background and aims: To assess the prevalence of diabetic retinopathy in patients with type 2 DM and duration of diabetes 5-10 years from 1994 to 2007.
Materials and methods: This study includes 303 patients (F/M 160/143) with type 2 DM with duration of DM 5-10 years. The fundus findings at their first visit to the Diabetes Outpatient Clinic were considered. Patients were grouped regarding the year of their application to the Clinic as follows: between the years 1994 and 1999 (Group 1, n: 128) and between the years 2000 and 2006 (Group 2, n:175).
Results: The mean duration of DM was 7.3±1.7 years in Group 1 and 7.7±1.8 years in Group 2 (p>0,05). The mean chronological age was 55.6±9.7 years in Group 1 and 57.5±10.0 years in Group 2 (p>0,05). In Group 1 73.4% and in Group 2 77.9% of patients had diabetic retinopathy. Nonproliferative diabetic retinopathy (NPDR) was present in 24.1% and proliferative diabetic retinopathy (PDR) in 2.5% of patients in Group 1; 21.2% and 0.9%, respectively in Group 2. Although the number of patients with no diabetic retinopathy were less this did not reach statistically significant levels. Regarding the prevalence of NPDR and PDR, there was no statistically significant difference in the severity of diabetic retinopathy between the Group 1 and Group 2.
Conclusion: Despite efforts for increasing awareness for diabetes and its complications, availability of wider range of technologies and drugs for better diabetes management in Turkey the prevalence of diabetic retinopathy seems not to be dramatically declined from 1994 to 2007.

1126

Glycated haemoglobin as a surrogate marker for the appearance and progression of retinopathy in type 1 diabetes mellitus: systematic review and meta-analysis

P. Rys[1], A. Wieczorek[1], A. Marcisz[1], I. Skrzekowska-Baran[2], M.T. Malecki[3];
[1]HTA Consulting, Krakow, [2]NovoNordisk Poland, Warsaw, [3]Department of Metabolic Diseases, Jagiellonian University, Krakow, Poland.

Background and aims: Glycated haemoglobin (HbA1c) is commonly employed in clinical trials as a surrogate marker of diabetes control and the risk for diabetic complications in type 1 diabetes mellitus (T1DM). The efficacy of many glucose-controlling agents has been characterised with respect to HbA1c, without their effects on clinically important endpoints being demonstrated. To date, several trials have examined the relationship between HbA1c level and microvascular complications in T1DM, but no systematic review has been published. We performed a systematic review and meta-analysis to examine the association between HbA1c and the appearance and progression of diabetic retinopathy (DR) in T1DM.
Materials and methods: We conducted a systematic literature search using two electronic medical databases (MEDLINE and The Cochrane Library). Observational studies and randomised, controlled trials (RCTs) of retinopathy in T1DM patients that reported HbA1c level were included in the analysis. Our chosen search strategy was highly sensitive, including over 100 terms grouped into three categories: population, e.g. "diabetes mellitus", "insulin-dependent diabetes mellitus", "IDDM"; surrogate, e.g. "glycosylated haemoglobin", "HbA1c"; and clinically important outcomes, e.g. "retinopathy". Estimates were made of the adjusted relative risk (RR) of complications for an increase in HbA1c of 1%. If there were insufficient data to calculate RR, the odds ratio (OR) was estimated instead. Weighted mean differences (WMD) in HbA1c level (mean value during the observation period) between the case group (with DR) and the control group (without DR) were also calculated.
Results: We identified 16 trials that fulfilled the inclusion criteria, involving a total of 4176 patients. Based on four RCTs (n=1597), pooled RR for progression of DR was calculated as 1.24 (confidence interval [CI]: 1.01-1.52; p=0.039) for an increase in HbA1c of 1%. Pooled data from four observational studies (n=910) showed that RR of the incidence of DR was 1.59 (CI: 1.34-1.89; p<0.0001) for an HbA1c increase of 1%. A meta-analysis of eight observational studies (n=1171) demonstrated a lower mean HbA1c level in patients without DR compared with patients with DR (WMD=0.82 [CI: 0.69-0.96]; p<0.0001). In addition, a meta-analysis of five observational studies revealed that mean HbA1c values were significantly lower in the group without progression of DR relative to the group with DR (WMD=1.05 [CI: 0.37-1.72]; p<0.001). One RCT included data on visual deterioration and macular oedema; analysis demonstrated that an increase in HbA1c level of 1% increased the risk of both macular oedema (RR=1.81 [CI: 1.17-2.81]; p=0.008) and visual deterioration (OR=2.2 [CI: 1.2-3.9]; p=0.008).
Conclusion: The results of our systematic review indicate a strong correlation between HbA1c level and appearance and progression of DR in T1DM. Thus, HbA1c may be considered an excellent surrogate endpoint for DR in T1DM.

1127

Increased clonogenic capacity of endothelial progenitor cells (EPCs) in type 1 diabetic patients with early non proliferative diabetic retinopathy

G. Zerbini[1], G. Tremolada[1], A. Maestroni[1], R. Lattanzio[1], D. Gabellini[1], M.R. Pastore[1], R. Bonfanti[1], A. Palini[1], L. Luzi[1], P. Rama[1], M. Lorenzi[2];
[1]Medicine, San Raffaele Scientific Institute, Milano, Italy, [2]Ophthalmology, Schepens Eye Research Institute, Boston, United States.

Background and aims: It has been proposed that the formation of abnormal new vessels in proliferative diabetic retinopathy (PDR) occurs through both the self-expansion of vascular endothelium and the contribution of bone marrow-derived endothelial progenitor cells (EPC). Indeed, we observed in previous work that circulating EPC from patients with type 1 diabetes and untreated PDR had a greater clonogenic capacity than EPC from patients with no signs of retinopathy. We wished to ascertain whether the EPC number and or characteristics manifest changes before the onset of PDR, and even at early stages of retinopathy.
Materials and methods: We studied type 1 diabetic patients with 25 years of diabetes and no retinopathy (n=21), and age-and gender-matched nondiabetic controls (n=18). The patients were free of any other complication of diabetes and took no medications except insulin. We measured the number of circulating EPCs (CD45dim, CD34+,VEGFR-2+) by flow cytometry; their in vitro clonogenic capacity by the Hill's assay; and plasma concentrations of VEGF and SDF-1, the two cytokines known to mobilize EPC, by ELISA. All measurements were performed when plasma glucose levels were between 70 and 200 mg/dl.
Results: The clonogenic capacity of EPCs was increased in patients with non-proliferative retinopathy when compared to those without retinopathy (p<0.002) and to nondiabetic controls (p<0.01). In contrast, the number of circulating EPCs and the plasma levels of cytokines were similar in the three groups. The difference in clonogenic capacity between the diabetic groups was not explained by different glycemic control (blood glucose and HbA1c), and no differences in clonogenic capacity were noted between patients with minimal (ETDRS 20) as compared to mild (ETDRS 35) degree of retinopathy.
Conclusion: Increased clonogenic capacity of EPCs occurs in a portion of patients with type 1 diabetes and no other complications but early non-proliferative diabetic retinopathy. This finding indicates that some type of EPCs "activation" precedes the onset of PDR, and suggests that even early stages of retinopathy signal to EPC. Longitudinal studies may help us determine whether the early EPC activation has a protective or accelerating role on the course of retinopathy.

1128

Retinopathy screening in patients with type 1 diabetes diagnosed at a young age

N. Minuto[1], V. Emmanuele[1], M. Vannati[1], N. Fratangeli[1], S. Panarello[2], A. Pistorio[3], R. Lorini[1], G. d'Annunzio[1];
[1]Department of Pediatrics, [2]Department of Ophtalmology, [3]Department of Biostatistics, G. Gaslini Institute, Genoa, Italy.

Background and aims: Up to 60% of patients with type 1 diabetes mellitus (T1DM) for more than 15 years develop diabetic retinopathy (DR). Guidelines for DR screening have been formulated, to detect DR at an early stage.
Methods: We estimated the prevalence of DR in our patients with T1DM using a Nonmydriatic Digital Stereoscopic Retinal Imaging (NMDSRI), and evaluated the role of socio-demographic and clinical variables associated with the presence of DR, using a multivariate logistic regression analysis. We

enrolled 247 patients with T1DM who underwent to fundus photography during the biennium 2006-2007. At diabetes diagnosis we considered gender, age, pubertal stage, presence of diabetic ketoacidosis, autoimmunity and HLA-DQ heterodimers of susceptibility for T1DM. At NMDSRI evaluation, we collected data for age, disease duration, pubertal stage, body mass index (BMI-SDS), insulin requirement, degree of metabolic control (mean Hb1Ac), coexisting autoimmune diseases, and other diabetic complications.
Results: Retinopathy was found in 26/247 (10.5%) patients: 25 presented background retinopathy, while only one a macular oedema and needed a laser therapy. At the bivariate analysis, we found a significant relationship between retinopathy and female gender (p=0.03), age at study visit (p<0.0001), pubertal stage at last retinal photography (p=<0.0001), age at onset ≥ 5 - 9.9 years or ≥ 10 years (p=0.037), duration of disease ≥15 years (p<0.0001), presence of microalbuminuria (p=0.036), and mean HbA1c ≥ 7.5% or >9% (p=0.015). Using a multivariate analysis, we confirmed a significant association between DR and disease duration ≥ 15 years, mean HbA1c>9%, female gender and the presence of microalbuminuria.
Conclusion: Metabolic control is the most important modifiable factor and therefore the promotion of continuous educational process in order to reach a good metabolic control is a corner stone to prevent microangiopathic complications. DR is the first cause of blindness in industrialized countries. Symptoms appear when DR is already developed; a screening program with an early diagnosis is mandatory to prevent an irreversible damage.

1129

Prevalence of diabetic retinopathy and related risk factors in diabetic patients. Results of Tirana district/Albania

F. Toti[1], V. Mema[2], G. Bejtja[3], N. Qafa[2], M. Ismaili[1];
[1]Service of Endocrinology & Metabolic Diseases, University Hospital Center "Mother Theresa", [2]Service of Ophthalmology, University Hospital Center "Mother Theresa", [3]Institute of Public Health, Tirana, Albania.

Background and aims: Diabetic Retinopathy (DR) is a serious and frequent complication of diabetes. Often it is present since the diagnosis of type 2 diabetes. It remains largely preventable with proper screening, followed when required by proper interventions' therapy. The aims of our study were: 1) To define the prevalence of diabetic retinopathy in Tirana district. 2) To analyze the clinical features associated with this complication in the examined group.
Materials and methods: As part of ALBDIAB Project, we examined all the medical records of diabetics updated during the last year. In total, we included 7226 diabetics. Male 3530 (48.8 %). 740 (10.2%) type 1 Diabetes and 6480 (89.3%) type 2. Type 1 Diabetes duration 9.7±7.8 years and T2 Diabetes duration 4.6±4.9 years. In all patients clinical and metabolical profiles were determined. Trained ophthalmologists defined the stages of retinopathy by ophthalmoscope after papillary dilatation.
Results: Diabetic retinopathy of different stages was present in 43% of T1DM and 22% of T2DM. The multivariate analyses revealed that significant predictors for diabetic retinopathy were: diabetes duration (p= 0.0001 OR= 4.36), poor metabolic control as HbA1c >8% (p= 0.0015 OR= 3.02), insulin treatment (OR=4.24, HTA >150/95mm Hg (p= 0.002 OR= 2.45) and smoking status more than 10 years (p= 0.0023 OR= 1.34) although for smoking 6-10 years OR= 0.57. We found a good correlation between retinopathy and nephropathy. The other features such as BMI, coronary artery disease and diabetes or HTA treatment were univariate predictors of diabetic retinopathy, but they lost significance in multivariate analyses.
Conclusion: Our study showed that DR remains one of the most frequent complication of Diabetes. We were able to confirm that type 2 diabetes with poor metabolic control, longer diabetes duration, nephropathy, uncontrolled HTA, and on insulin treatment are more prone to develop DR. The smoking status remains of a controversial feature.

1130

Incidence of diabetic retinopathy in type 2 diabetic subjects in a tertiary care hospital in Bangladesh

K.R. Ahmed[1], S.H. Habib[2], L. Ali[3], A. Hussain[1];
[1]Department of International Health, University of Oslo, Norway, [2]Health Economics Unit, BADAS, Dhaka, Bangladesh, [3]Department of Biochemistry & Cell Biology, BIRDEM, Dhaka, Bangladesh.

Background and aims: Diabetic Retinopathy (DR) is one of the major micro vascular complications of diabetes that imposes a huge economic burden on diabetic subjects in developing countries like Bangladesh. It is a vascular disorder affecting the microvasculature of the retina and the major cause for new cases of blindness in people with in the aged of 25-74. Therefore, it is interest to estimate the number of new cases of diabetic retinopathy in developing countries. The aim of the present study was to investigate the 5 year, 10 year and 15 year incidence rate of DR in Type 2 Diabetic Subjects (T2DM) in Bangladesh.
Materials and methods: It was a cohort study. 977 T2DM were taken randomly from the patient registry of 1993 and came for the follow up in 2008 and in between in the Out Patient Department, BIRDEM. DR was graded using the Early Treatment Diabetic Retinopathy Study. Ophthalmologist performed comprehensive eye examinations, which were reconfirmed by senior ophthalmologist.
Results: Of the 977 subjects observed, 468 were male and 509 were female (mean±SD, age 56±8 years). According to the age distribution of the study subjects the age groups were <45, 45-60 and >60 years. The number of the study subjects according to the age groups were (115/12%), (617/63%) and (245/25%) respectively. Five, ten and fifteen years after diagnosis, retinopathy was found in 115 (11.8%), 151 (17.5%) and 229 patients (32.2%). Among the study subjects 115 patients (11.8%) had mild nonproliferative DR (NPDR) in first five years from the initial stage (1993). Ten years after diagnosis the retinopathy was mild in 136 (13.9%), moderate in 14 (1.4), 1 (0.1%) patients had severe NPDR. Fifteen years after diagnosis the retinopathy was mild in 111 (11.4%), moderate in 77 (7.9), severe in 33 (3.4%), whereas 5 (0.5%) patients had very severe NPDR and 3 (0.3%) had proliferative DR (PDR). Five, ten and fifteen years the incidence of DR (Incidence per 1000 person years with 95% Confidence Interval) were 23.54 (19.61-28.26), 17.52 (14.93-20.55) and 21.47 (18.86-24.44). Compared to other age group the incidence was higher in the age group >60 years in three different time period. It was slightly higher in males 23.64 (19.80-28.23) than females 19.44 (16.08-23.49). Comparatively it was also higher 22.17 (18.94-25.96) in the 45-60 year age group in fifteen years.
Conclusion: Working age group (45-60 years) had higher incidence for the development of DR. The overall incidence of DR increased as the duration of DM and age increases. Strategies aimed at early detection and prevention of DR will reduce the incidence rate.

PS 103 Autonomic neuropathy

1131

Plasma asymmetric dimethyarginine (ADMA) is associated with autonomic neuropathy in long standing type 1 diabetes

D. Galicka-Latala[1], A. Surdacki[2], D. Fedak[3], M. Kuzniewski[4], E. Konduracka[5];
[1]Medical College, Department of Metabolic Diseases, [2]Medical College, 2nd Department of Cardiology, [3]Medical College, Medical Diagnostic Department, [4]Medical College, Department of Nephrology, [5]Medical College, Coronary Department Jagiellonian University, Kraków, Poland.

Background and aims: Decreased availability of nitric oxide (NO), which contributes to the development of diabetes vascular complications, is partially related to excessive accumulation of asymmetric dimethylarginine (ADMA), an endogenous NO synthase inhibitor. Abnormalities of the L-arginine-NO pathway have been demonstrated in type 1 diabetics without clinical evidence of vascular disease. Increased circulating ADMA had previously been associated with propensity to atherosclerosis and its complications in non-diabetic populations and with cardiovascular morbidity and early nephropathy in type 1 diabetes. Plasma ADMA has recently been identified as independent predictors of cardiovascular events and progressive renal deterioration in patients with type 1 diabetic nephropathy.
Our objective was to evaluate the relationship between plasma ADMA and diabetic autonomic neuropathy in type 1 diabetes.
Materials and methods: We studied seventy eight patients with type 1 DM without clinical evidence of macrovascular complications, defined as a positive medical history for myocardial infarction, angina, coronary artery bypass gaft and stroke, and ischemic changes in ecg. To evaluate the pattern of cardiovascular autonomic balance a standard battery of cardiovascular reflex tests and a short-term heart rate variability (HRV) analysis were performed. HRV analysis included absolute and relative (%) spectral HRV power at rest in 3 standard frequency bands: VLF: 0.01-0.05 Hz); LF: 0.05-0.15 Hz; HF: 0.15-0.5 Hz.
Results: Using computer assisted method (ProSciCard), autonomic neuropathy was diagnosed in 31 diabetics (N1), being absent in 47 patients (N0). Height, weight, body mass index (BMI), blood pressure, ADMA, fasting glucose, HbA1c, serum creatinine, CRP, total chol, HDL-chol, LDL-chol and triglycerides (Tg), were measured in all subjects. The subjects with neuropathy were significantly older than the remainder (N1 vs N0: 36.2 ± 10.3 vs 43.7 ± 9.2 years ; N1 vs N0, p=0.002). No differences were found between respective groups group with regard to diabetes duration (21.8 ± 9.2 vs 23.4 ± 9.9), total chol (4.76 ± 0.90 vs 4.85 ± 1.00 mmol/l), LDL-chol (2.44 ± 0.55 vs 2.47 ± 0.84 mmol/l), HDL-chol (1.96 ± 0.77 vs 4.85 ± 1.25 mmol/l), triglycerides (0.84 ± 0.55 vs 0.92 ± 0.41 mmol/l), CRP (1.81 ± 2.38 vs 1.69 ± 2.21 mg/l). Diabetics with neuropathy exhibited elevated plasma ADMA (N1 vs N0: 0.90 ± 0.28 vs 0.69 ± 0.39 μmol/l; p=0.01).
Conclusion: This is the first report suggesting a coincidence between elevated circulating ADMA levels and autonomic neuropathy in type 1 diabetes. Prospective studies are required to validate the concept of a cause-and-effect relationship between altered NO activity and risk of diabetic neuropathy in type 1 diabetes. The potential limitation of this study is that ADMA was measured at a single time point. Thus, it did not answer the question whether elevated ADMA levels stimulate the development of diabetic neuropathy or merely constitute its marker. Prospective studies are necessary to clarify this.

Corneal confocal microscopy: a novel surrogate marker for diabetic autonomic neuropathy

M. Tavakoli[1], P. Begum[2], J. McLaughlin[3], R.A. Malik[1];
[1]University of Manchester, [2]2GI Sciences, University of Manchester, Salford, [3]GI Science, University of Manchester, United Kingdom.

Background and aims: The accurate quantification of the severity of diabetic autonomic neuropathy (DAN) can be time consuming and challenging. At present, most clinicians undertake cardiac autonomic function tests to use as a surrogate of autonomic neuropathy of the GI tract. We undertook a range of tests of small fibre and autonomic neuropathy including the novel technique of corneal confocal microscopy (CCM) to define how they may detect and quantify the severity of DAN in patients with gastroenteropathy.
Materials and methods: 20 subjects with diabetic gastroenteropathy and 14 control subjects underwent cardiovascular and peripheral autonomic function testing to establish the Composite Autonomic Severity Score (CASS). Quantitative Sensory testing (QST) was performed to assess the severity of somatic neuropathy and corneal sensitivity and CCM were performed to quantify c-fibre dysfunction and damage.
Results: 12 patients (60%) had moderate-severe DAN (CASS 4.0 ± 2.2). Corneal Nerve Fibre Density (NFD) 17.8 ± 13.3 (95% CI 11.6-23.9) vs 48.3 ± 12.4 (95% CI 41.1-55.4), Nerve Branch Density (NBD) 8.9 ± 7.9 (95% CI 5.2-12.6) vs 30.1 ± 5.3 (95% CI 27.0-33.2) and Nerve Fibre Length (NFL) 3.6 ± 3.1 (95% CI 2.1-5.2) vs 9.7 ± 2.5 (95% CI 8.3-11.2) were all significantly reduced in DAN vs controls (p<0.0001) and corneal sensation threshold was significantly elevated 1.6 ± 0.9 (95% CI 1.2-2.1) vs 0.7 ± 0.2 (95% CI 0.6-0.8); (p <0.0004). Corneal abnormalities correlated highly significantly with the severity of DAN (CASS vs NFD [r = -0.713], NBD [r = -0.726], NFL [r = -0.786] and CS [r = 0.659]; p<0.0001).
Conclusion: Patients with DAN had significant corneal nerve abnormalities compared to healthy controls and the severity of nerve damage was very strongly associated with the severity of autonomic neuropathy. Thus CCM may act as a simple non-invasive surrogate marker for DAN in patients with diabetic gastroenteropathy.

Effects of aldose reductase inhibitor on peripheral muscle sympathetic nerve activity in streptozotocin-induced diabetic rats

M. Kusunoki[1], G. Shinzawa[2], T. Nakamura[2];
[1]Dept. of Internal Medicine, Aichi Medical Univ., Nagoya, [2]Dept. of Biomed. Information Eng., Grad. Sch. of Med. Sci., Yamagata Univ., Japan.

Background and aims: Peripheral neuropathy is one of the most common complications of diabetes mellitus. Excessive aldose reducatase activation in the polyol pathway due to high blood glucose is one of the main factors inducing the neuropathy. Therefore, aldose reductase inhibitor (ARI) was expected to prevent the neuropathy, and it has been used in clinical cases in several countries. However, the effects of ARI on small peripheral, unmyelinated nerve fibers, such as muscle sympathetic nerve ones, have not been documented well. The purpose of this study is to determine the effects of ARI on peripheral muscle sympathetic nerve activity directly measured with microneurography in streptozotocin (STZ)-induced type 1 diabetes model rats.
Materials and methods: Wistar rats were separated into three groups: normal, STZ and ARI. STZ (80 mg/kg) was administered ip to each rat at 8 weeks of age in the STZ and ARI groups. ARI (150 mg/kg) was orally given every day to rats in ARI group for 3 weeks after the STZ administration. Microneurographic technique was used for the direct measurement of the compound sympathetic nerve signal in the sciatic nerve of anesthetized, 11-week rats in the 3 groups. In the supine position, a tungsten microelectrode was inserted several times into the nerve bundle until the specific burst signal of sympathetic flow was observed. Glucose solution (50 %, 0.25 mL) was administered via the right jugular vein, and the sympathetic signal and blood pressure (BP) were recorded on DAT tape. The data were fed offline into PC after each experiment, and analyzed using Matlab. After noise reduction procedures, action potentials (APs) were manually detected and the firing rate was evaluated.
Results: The blood glucose level was transiently increased after glucose administration by about 100 mg/dL from about 60 , 400 and 400 mg/dL in the normal, STZ and ARI rats, respectively. Before glucose administration, AP firing rate in STZ rats was lower than that in normal rats (212±117 vs. 408±177 spikes/min) although the difference was not statistically significant. The rate of ARI rats (358±166 spikes/min) was higher than that of STZ rats and close to that of normal rats. In each group, the glucose administration caused little change in BP. After the glucose administration, the firing rate increased in normal rats (408±177 and 628±359 spikes/min, before and 60 min after the administration, respectively), which may imply that the sympathetic system plays some role in the glucose metabolism in peripheral tissues. In contrast, the rate in STZ and ARI rats increased little (from 212±117 to 220±73 and from 358±166 to 395±169 spikes/min in STZ and ARI rats, respectively), which may show diminished sympathetic response to the glucose administration. The results may suggest that the sympathetic functional deterioration takes place within 3 weeks under high blood glucose and low plasma insulin condition in STZ rats, and that ARI prevents the sympathetic function at least from reduction of basal activity. Further study is necessary to

evaluate the effects on dynamic response of sympathetic system because it is necessary to evaluate the condition of afferent system as well in the feedback response.
Conclusion: The sympathetic functional deterioration may bring about within 3 weeks in STZ rats, and ARI administration may be useful to prevent the sympathetic function at least from reduction of basal activity.

Blunted postprandial parasympathetic drive and its relation to blood pressure control in patients with diabetes mellitus
A. Pop, A. Stirban, S. Nandrean, D. Tschöpe;
Diabetes Center, Heart and Diabetes Center, Bad Oeynhausen, Germany.

Background and aims: The autonomic nervous system plays an important role in the regulation of metabolic and cardiovascular events following food ingestion. Postprandial hypotension, a hemodynamic abnormality in diabetes mellitus (DM), indicates a lack of cardiovascular compensatory changes to offset the fall in splanchnic vascular resistance. But data showing the relation between postprandial hypotension and the autonomic control of the heart in patients with diabetes is contradictory. Several studies have suggested blunted autonomic postprandial regulation in subjects with diabetes. The aim of our study was therefore to assess the postprandial regulation of the autonomic nervous system in relation to blood pressure control in subjects with DM without further complications.
Materials and methods: We have investigated 27 patients with type 2 DM (age: 55.7±7.7 years, diabetes duration: 7.8±4.8 years, HbA_{1c}: 7.4±1.0 % and BMI: 30.6±4.6 kg/m^2). Patients were investigated in the morning, after an overnight fast and 4 hours after the ingestion of a breakfast (590 kcal). At any time point, HRV was measured in the supine position over a period of 5 minutes, using the SUEmpathy 100 System along with measurements of systolic (sBP) and diastolic (dBP) blood pressure. The following HRV parameters were analyzed: average length of the RR interval (RRi), variance, the square root of the mean squared differences of successive RR intervals (RMSSD) as indexes of the parasympathetic drive and the LF/HF ratio as index of the sympatho-vagal balance. All results are expressed as mean ± SEM and presented under fasting conditions vs. postprandial.
Results: There was a significant decrease of the RRi (867.4±25.3 ms vs. 836.9±22.5[3] ms, [3]p<0.01) and a mild but significant decrease of both systolic and diastolic blood pressure at 4 hours postprandially (sBP: 128.0±2.4 mmHg vs. 120.8±2.8[3] mmHg; dBP: 82.2±1.8 mmHg vs. 78.0±2.0* mmHg; [3]p< 0.01 and [*]p< 0.05). We also noticed a non-significant decrease in variance (4.5±0.8 % vs. 3.2±0.3 %, p=0.09), a significant decrease in RMSSD (46.0±12.6 ms vs. 14.8±4.9* ms, [*]p< 0.05) and a significant increase of the LF/HF ratio (4.4±0.7 vs. 7.3±2.0*, [*]p< 0.05).
Conclusion: Our data suggest that:
1) patients with diabetes show a mild but prolonged postprandial fall in blood pressure, both systolic and diastolic;
2) the blood pressure fall occurs despite a statistically significant increase in heart rate;
3) since parameters reflecting the parasympathetic drive significantly decrease postprandially, the marked increase in the sympatho-vagal balance is due to a parasympathetic withdrawal;
4) overall our data suggest that in DM subjects without other complications, postprandial autonomic nervous regulation is not preserved.

Increased left ventricular torsion rate in subjects with type 1 diabetes correlates with cardiac autonomic neuropathy: a pilot study
M.K. Piya[1,2], G. Nallur Shivu[1], K. Dubb[1], A.A. Tahrani[1,2], K. Abozguia[1], T.T. Phan[1], P. Narendran[1], M. Frenneaux[1], M.J. Stevens[1,2];
[1]University of Birmingham, [2]Biomedical Unit Birmingham Heartlands Hospital, United Kingdom.

Background and aims: We have previously demonstrated that left ventricular (LV) torsion is increased in patients with Type 1 Diabetes Mellitus (T1DM) without known coronary artery disease (CAD) or heart failure. Increased LV torsion may be one of the earliest features of diabetic cardiomyopathy. Since we have previously demonstrated altered sympathetic function in these subjects, our aim was to determine the role of cardiac autonomic neuropathy (CAN) in the development of increased torsion in these individuals.
Materials and methods: A pilot cross-sectional study is being conducted in subjects with T1DM recruited from two diabetes centres in Birmingham, UK. LV function was assessed by echocardiography. LV rotation and strain was measured using a commercially available speckle tracking system in an ECHOPAC (version 4.2.0) workstation. LV torsion, torsion rate and untwist rates, were determined from the apical and basal rotation measurements. CAN was assessed using ANX-3.0 (Ansar, Inc., Philadelphia, PA). CAN was assessed by heart rate variability (HRV) and blood pressure changes during four stages: at rest, deep breathing, valsalva manoeuvre and during the stand response. We used spectral and time domain analysis. Correlation coefficient (r) was calculated using Pearson's method of correlation.
Results: So far 16 subjects with T1DM of 17±9 years duration (mean±1SD), aged 35±7 years, 63% male, HbA1c of 8±1.2% have been included. With root mean square successive difference (rmsSD) during valsalva manoeuvre, there was a significant negative correlation with LV torsion rate during systole (r= -0.52, p=0.044), and a significant positive correlation with LV untwist during early diastole (r= 0.57, p=0.025). The ratio of sympathetic to parasympathetic response (LFa/RFa) in the stand response was significantly correlated positively with intraventricular relaxation time (IVRT) (r= 0.77, p=0.001) and also negatively with inferior septum contraction rate (r= -0.57, p=0.03), both markers of diastolic dysfunction. IVRT was also significantly positively correlated with Expiration Inspiration (E/I) ratio (r= 0.56, p=0.02) and with valsalva ratio (r= 0.52, p=0.04). Radial strain of the LV was significantly negatively correlated with E/I ratio (r= -0.57, p=0.02) and valsalva ratio (r= -0.54, p=0.03).
Conclusion: Our pilot study suggests that LV torsion is related to sympathetic dysfunction in subjects with T1DM without CAD or heart failure. This suggests that CAN is possibly implicated early in the development of cardiomyopathy in patients with T1DM. Larger scale studies exploring the relation between CAN and early diabetic cardiomyopathy are ongoing.

The presence of sympathovagal abnormalities in patients with subclinical diabetic autonomic neuropathy
M.A. Oleolo, J.L.B. Marques, R. Gandhi, D. Selvarajah, S. Tesfaye;
University of Sheffield Teaching Hospital, United Kingdom.

Background: Diabetic autonomic neuropathy (DAN) is associated with a five-fold increase in cardiovascular mortality. Recognised causes of death include silent myocardial Infarction (MI) and sudden cardiac death (SCD) due to malignant arrythmias. This study involved analysis of heart rate variability (SHRV) as an early, non-invasive, test useful for detecting the presence of sympathovagal abnormalities in a group of diabetic patients with sub-clinical DAN.It is well recognised that in patients who die of sudden cardiac death, HRV abnormalities are demonstrable.These represent sympathovagal imbalance.They are seen in the five minute period preceding the event and are well characterised using a time domain parameter, the standard deviation of all normal RR interval variation (SDNN).
Aim: To assess the usefulness of HRV in demonstrating sympathovagal abnormalities associated with sudden cardiac death and myocardial infarction.
Methods: Sixteen age and sex matched, healthy volunteers (HV) and 48 patients with diabetes (type-1, n=16; type-2, n=32) underwent standard cardiovascular autonomic testing (CAT) using the O'Brien protocol, and specialised autonomic tests (baroreceptor sensitivity [BRS], and HRV). Subjects were classified as no-DAN (n=14, normal CAT and BRS), subclinical-DAN (sub-DAN, n=17,normal CAT, abnormal BRS) and established DAN (est-DAN, n=17, BRS and CAT abnormal).
Results: Analysis of HRV showed subjects with sub-DAN (12.3±5.2ms) and est-DAN (17.0±7.1ms) had significantly lower SDNN than HV (46.9±9.6ms) and no-DAN (39.9±4.5ms); ANOVA p< 0.001. Subjects in the sub-DAN had the lowest RR interval variation (677.2±73.2ms) and this was significantly lower than in HV (937.0±114.1ms) and no-DAN (880.9±138.8ms);ANOVA p<0.05.The lower RR interval variation for sub-DAN was not significant when compared to est-DAN (830.9±120.7).
Conclusion: This study suggests that SHRV can detect autonomic dysfunction in asymptomatic diabetic subjects with normal CATs and that these individuals have abnormal SDNN,which represents sympathovagal imbalance. Such imbalance, even when transient, have been shown to predispose to sudden cardiac death.Prospective studies are required to see if these patients are at risk of increased cardiovascular mortality due to sudden cardiac death.

Severe symptomatic diabetic gastroparesis and cardiovascular tests exhibit a close relationship

N. Ejskjaer, J. Fleischer;
Department of Medicine M (Endo+Diab), Aarhus University Hospital, Denmark.

Background and aims: Diabetic gastroparesis is associated with autonomic dysfunction, but the nature of this relationship remains elusive. This study presents detailed clinical data. Aim: To describe Type 1 diabetes patients suffering severe symptomatic gastroparesis.
Materials and methods: 19 consecutively recruited type 1 diabetes patients (6 males and 13 females) with delayed gastric emptying and correlating symptom scores. Age 43 years (+/- 14 years). Diabetes duration 21 years (+/- 8 years). Body mass index 26 (+/- 5). All demonstrated autonomic symptoms from more than one organ system. Cardiovascular autonomic neuropathy (CAN) was assessed by heart rate variability resting, expiration:inspiration and heart rate variability from lying to standing. A ^{13}C-octanoic breath test determined rate of gastric emptying and symptom scores by a validated questionnaire. All patients underwent through physical, paraclinical and clinical examinations including endoscopies.
Results: Gastric emptying rates were all significantly increased ($T^1/_2$ = 152 minutes (+/- 33 minutes). All patients but two were diagnosed with CAN. Of the 17 patients exhibiting CAN 7 were at an early stage of progression whereas 10 were at an endstage of CAN. Blood pressure lying down 140/82 mmHg (systolic +/- 29 mmHg and diastolic +/- 14 mmHg) and blood pressure standing 126/83 mmHg (systolic +/- 32 mmHg and diastolic +/- 15 mmHg) signifies postural hypotension. On validated questionnaires all patients demonstrated symptoms pathognomic for gastroparesis and severely so.Examination for CAN may support a gastroparesis diagnosis in Type 1 diabetes patients suffering upper gastrointestinal symptoms. The finding of CAN in a Type 1 diabetes patient may warrant a need for further investigations regarding gastric motility.
Conclusion: All consecutively recruited patients suffered symptomatic gastroparesis and all but two patients demonstrated cardiovascular autonomic dysfunction. There exists a close relationship between severe gastric motility and cardiovascular autonomic neuropathy.

Endothelial impairment and bone marrow-derived CD34$^+$/133$^+$ cells in diabetic subjects with erectile dysfunction

M. Murata, H. Tamemoto, T. Saito, A. Ikoma, H. Toyoshima, S. Ishikawa, M. Kawakami;
Department of Medicine, Jichi Medical University Saitama Medical Center, Japan.

Background and aims: The present study was undertaken to determine endothelial impairment and erectile dysfunction (ED) in subjects with type 2 diabetes mellitus.
Materials and methods: One hundred sixteen type 2 diabetic men were enrolled in the present study. Endothelial function and exercise capacity were evaluated by flow-mediated vasodilation (FMD) and cardiopulmonary exercise test (CPX). Also, endothelial progenitor cells were determined by FACS.
Results: In the ED diabetic subjects FMD and anaerobic threshold (AT) after exercise tolerance were significantly less than those in the subjects with normal erectile function (FMD: 2.8 vs. 3.8%, p=0.02, and AT: 11.1 vs. 12.8 ml/kg/min, p=0.01). Basal levels of bone marrow-derived CD34$^+$/133$^+$ cells were comparable in both the diabetic subjects with and without ED, but exercise tolerance significantly increased the number of CD34$^+$/133$^+$ cells in both groups (77 to 90 cells/100μl, p=0.006, and 73 to 101 cells/100μl, p<0.001). The diabetic subjects were subgrouped according to the development of autonomic neuropathy. In the subjects having a CVRR more than 2%, FMD was significantly reduced in the ED subjects than those without ED (2.5 vs. 3.9%, p=0.021). In response to exercise tolerance the number of CD34$^+$/133$^+$ cells increased in both the diabetic subjects with ED (78 to 93 cells/100μl, p=0.023) and without ED (99 to 134 cells/100μl, p=0.015). On the contrary, in the diabetic subjects with autonomic neuropathy (CVRR <2.0%), FMD was reduced and there was no difference in FMD between the subjects with and without ED. The exercise tolerance increased the number of CD34$^+$/133$^+$ cells in the subjects without ED (45 to 60 cells/100μl, p=0.023), but it disappeared in those with ED (76 to 88 cells/100μl, ns). Similar results were obtained with the ED diabetic subjects according to the progression of nephropathy.
Conclusion: These findings may indicate that ED diabetic subjects have endothelial impairment during the early period of diabetic complications, who concomitantly repair endothelial function by promoting bone marrow-derived endothelial progenitor cells.

PS 104 Neuropathy and wound healing - experimental

1139

Deletion of the redox enzyme p66shc promotes diabetic wound healing in mice

G. Fadini[1], M. Albiero[1], L. Menegazzo[1], E. Boscaro[2], C. Agostini[2], A. Lapolla[3], M. Giorgio[4], A. Avogaro[1];
[1]Dept Clinical and Experimental Medicine - DMM, University of Padova, [2]Dept Clinical and Experimental Medicine - Clinical Immunology, University of Padova, [3]Dept of Medical and Surgical Sciences, University of Padova, [4]European Institute of Oncology, Milan, Italy.

Background and aims: Diabetic wounds challenge patients and clinicians. Limb ischemia is the most important risk factor for the development of diabetic wounds, but the mechanisms that delay wound healing in diabetes are poorly understood. Deletion of the lifespan determinant redox enzyme p66shc protects against experimental diabetic nephropathy and endothelial dysfunction. We aim to study the effects of p66shc knock-out on skin wound healing in the presence/absence of experimental diabetes and hind limb ischemia.
Materials and methods: Excisional skin wounds were created on the dorsal surface of hind limbs in diabetic and non-diabetic wild type (w/t) and p66shc-/- mice. Diabetes was induced through intraperitoneal streptozotocin. Wound size was monitored with digital imaging. Skin concentrations of pentosidine and nytrotyrosine were also assessed. In separate sets of experiments, hind limb ischemia was induced by femoral artery excision, and wounds were created on the ischemic skin 2 weeks later. Post-ischemic skin microcirculatory blood flow was monitored with laser Doppler imaging. Sections of adductor muscles were assessed for necrosis, apoptosis and capillary density 2 weeks after ischemia. Mobilization of CD34+/Flk1+ endothelial progenitor cells (EPCs) was assessed 4 days after ischemia using flow cytometry. Dermal fibroblasts were isolated from w/t and p66shc-/- mice and used for an in vitro scratch-wound assay under 5 or 25 mM glucose and under normoxic or hypoxic conditions.
Results: There were no differences in wound healing between non diabetic w/t and p66shc-/- mice. The presence of diabetes delayed wound healing by about 34% in w/t mice but not in p66shc-/- mice. Skin pentosidine and nytrotyrosine concentrations were increased by 40% and 35% respesctively in diabetic w/t as compared to non-diabetic w/t mice, but not in diabetic versus non-diabetic p66shc-/- mice. The co-existence of hind limb ischemia and diabetes almost doubled healing time in w/t mice, while p66shc-/- mice still showed faster healing. Post-ischemic skeletal muscle damage was reduced in p66shc-/- mice as compared to w/t mice in the presence or absence of diabetes. Post-ischemic skin perfusion and muscle capillary density were significantly improved in diabetic p66shc-/- mice as compared to diabetic w/t mice (0.41±0.03 vs 0.29±0.04 units and 1.15±0.20 vs 0.87±0.1 capillaries/fiber), while there was no difference between non-diabetic w/t and p66shc-/- mice. Mobilization of CD34+/Fkl1+ EPCs was impaired in diabetic versus non-diabetic w/t mice, while p66shc-/- mice did not mobilize EPCs, independently of the presence of diabetes. Dermal fibroblasts from p66shc-/- mice showed almost complete resistance to oxidative stress induced by hydrogen peroxide (6% vs 85% cell death) and improved migration under high glucose or hypoxia, as compared to w/t fibroblasts.
Conclusion: Deletion of p66shc promotes diabetic wound healing, especially in the setting of ischemia. The mechanisms include reduced oxidative stress and accumulation of glycation end-products, improved cell migration and post-ischemic angiogenesis, which was not associated with improved EPC mobilization.

Modified epidermal growth factor(FRM-EGF) gene therapy markedly improved histologic findings of diabetic mice skin wound

J. Park[1], C. Yoon[2], H. Jung[2], J. Ko[1], H. Jun[1], T. Kim[1], M. Kwon[1], S. Lee[1], K. Ko[1], B. Rhee[1], S. Chung[3], M. Kim[4];
[1]Division of Endocrinology and Metabolism, Department of Internal Medicine, Pusan Paik Hospital, Inje University, [2]Molecular Therapy Lab, Paik Institute for Clinical Research, Inje University, [3]Department of Pathology, College of Medicine, Inje University, [4]Department of Internal Medicine, Maryknoll Medical Center, Busan, Republic of Korea.

Background and aims: Skin ulcers of diabetes mellitus are notorious for delayed healing. The clinical role of topical growth factor treatment might have been limited because of its high cost, low efficacy and short half-life of applied factor due to over-expressed non-specific proteases in the wound bed. Growth factor gene therapy into the wound tissue might be a fascinating alternative to overcome these limitations. We already have shown that human $VEGF^{165}$ gene therapy improved the healing of diabetic mice skin wound. This study was performed to see that the sonoporation gene therapy using modified human EGF DNA could improve the histologic quality of diabetic skin wound healing.
Materials and methods: Novel plasmid DNA containing FRM(furin recognition motif)-EGF for facilitating the secretion of produced EGF outside the cell driven by the ubiquitous strong chicken β-actin promoter was cloned. The competency of cloned plasmid DNA was verified using cultured HEK-293 cells. Ultrasound micro-bubble destruction method was employed to deliver plasmid DNA into the 6mm circular skin wound of streptozotocin induced diabetic C57BL/6J mice. The quality of wound healing was monitored via H&E and Mason-Trichrome stain along with the measurement of the expressed EGF in the skin tissue.
Results: Insertion of FRM prior to the EGF DNA sequence dramatically enhanced the secretion of produced EGF outside the transfected HEK293 cells. Sonoporation of EGF plasmid DNA into the skin wound of diabetic mice showed marked improvement of the histologic findings. Rapid epithelization and deposition of large amount of collagen in the healing skin tissue was nearly similar with the healing process of normal control mice skin wound. And the histologic improvements coincide with the expression pattern of EGF in the sonoporated skin.
Conclusion: In conclusion, sonoporation of modified EGF plasmid DNA into the skin wound of diabetic mice not only hasten the healing, but also normalized the microarchitectures and tissue collagen deposition.

Estrogen receptor beta modulates wound healing in diabetes

V.G. Sunkari, J. Grünler, S. Lindberg, O. Savu, I. Botusan, K. Brismar, K.R. Steffensen, S.-B. Catrina;
Karolinska Institutet, Stockholm, Sweden.

Background and aims: The impaired wound healing in diabetes represents a major medical, social and economic problem. It is therefore a high need to find new therapeutical approaches. The effects of estrogens on cutaneous wound healing are well established and explain the defective wound healing in elderly. Estrogen receptors beta (ERβ) have been linked to venous ulcers. However the effect of estrogens on diabetic wounds is still unexplored. The present study analyzed the contribution of the estrogen receptor beta (ERβ) for wound healing in diabetic mice.
Materials and methods: We studied the effect of diabetes (induced by streptozotocin) on wound healing rate in estrogen receptor-beta (BERKO) knockout mice and in wild type mice (C57BL/6). The wound model consists in full-thickness wounds made on the dorsum of the animals. The wounds were followed every other day using a digital camera. Wound granulation, dermal and epidermal regeneration were evaluated by hematoxylin and eosin staining and angiogenesis by GS-1 isolectin staining. Markers for inflammation, endothelial precursor's cell recruitment, cell migration were analyzed by qRT-PCR.
Results: Diabetic BERKO mice (50% and 90% wound closure at 3.4+/-0.3 days respectively 8.7+/- 0.2 days) have a faster wound healing rate compared with diabetic wild mice (50% and 90% wound closure at 4.7 days+/- 0.5 days respectively 10+/-0.3 days).
Conclusion: Estrogen receptor-beta modulates the wound healing rate in diabetes and suggests the need of specific ER agonists for therapeutical trials.

Effects of PKF275-055 in peripheral diabetic neuropathy

R. Bianchi[1], I. Cervellini[1], C. Porretta-Serapiglia[1], N. Oggioni[2], B. Burkey[3], G. Cavaletti[2];
[1]Molecular Biochemistry and Pharmacology, Mario Negri Institute for Pharmacological Research, Milan, Italy, [2]Department of Neuroscience and Biomedical Technologies, University of Milan "Bicocca", Monza, Italy, [3]Novartis Institute forBiochemical Research, Cambridge, United States.

Background and aims: Dipeptidyl peptidase IV (DPP IV) inhibitors exert antidiabetic effects of by potentiating the biological activity of incretin hormones like glucagon-like peptide (GLP)-1. PKF275-055, a vildagliptin analog, is a novel, selective, potent, orally bioavailable, long-acting DPP IV inhibitor. We studied the effect of chronic dosing with PKF275-055 (1-2 months) in two experimental settings.
Materials and methods: The first was aimed at testing the efficacy of PKF275-055 in preventing and/or protecting (prevention and protection schedules, respectively) peripheral diabetic neuropathy in the streptozotocin-induced (STZ) diabetes model in rats; the second at investigating therapeutic efficacy in established peripheral diabetic neuropathy in the same model (therapeutic schedule). In addition to general observations (body and muscle weight, blood glucose) several other parameters were examined including nerve conduction velocity (NCV), Na+,K+-ATPase activity, thermal and mechanical thresholds and oral glucose tolerance.
Results: Chronic PKF275-055 besides improving anabolic function, as indicated by body and muscle weight gain and supported by oral glucose tolerance test (OGTT) data, counteracted the impairment of NCV, nociceptive thresholds and Na+,K+-ATPase activity. OGTT after drug washout showed marked improvement in glucose tolerance in all the treatment schedules. In the experimental therapeutic setting, compared to non-diabetic rats NCV was 36% lower ($P<0.001$) at ten weeks in the STZ-untreated group, but only 17% lower in PKF275-055 treated animals ($P<0.01$ vs. diabetic). As expected, Na+,K+-ATPase activity was significantly reduced in diabetic nerves (by 40%) and PKF275-055 halved this decrease with a significant difference from the untreated diabetic group ($P<0.05$). Thermal and mechanical allodynia nociceptive thresholds were checked every 15 days throughout the study. Rats develop mechanical hypoalgesia within two weeks after STZ injection. PKF275-055 therapeutic schedules partially protected diabetic rats (about 50%), but had no such effect in non-diabetic controls. Hind paw thermal response latencies were significantly longer ($P<0.01$) in untreated diabetic rats than in untreated controls. Treatment had no effect on these latencies in controls, but progressively prevented the increase in diabetic rats.
Conclusion: Although further studies are needed the present data indicate PKF275-055's efficacy and highlight its potential for treating established diabetic neuropathies.

The functions of bone marrow-derived mononuclear cells and their therapeutic efficacy on diabetic polyneuropathy are affected by their age

M. Kondo[1], H. Kamiya[1], T. Shibata[1], K. Naruse[1,2], T. Himeno[1], J. Suzuki[1], J. Kato[1], Y. Kobayashi[2], A. Watarai[3], Y. Hamada[1], E. Nakashima[3], Y. Oiso[1], J. Nakamura[1];
[1]Endocrinology and Diabetes, Nagoya University, [2]School of Dentistry, Aichi Gakuin University, [3]Chubu Rousai Hospital, Nagoya, Japan.

Background and aims: Recent studies have shown that cell transplantation therapy such as endothelial precursor cells (EPCs), mononuclear cells (MNCs) and mesenchymal stem cells (MSCs), is effective on diabetic polyneuropathy (DPN) through ameliorating impaired nerve blood flow in diabetic rats. Among them, bone marrow (BM) MNCs are isolated relatively easy and collected in large quantities at one time. Moreover, it has been reported that the functions of EPCs are impaired under the diabetic condition and the number of MSCs in BM decreases with age. Although these indicate that BM-MNCs are the most suitable for clinical application in DPN, their functions in diabetes or with age has not been reported. Here, we investigated the effects of BM-MNCs transplantation on DPN by using BM-MNCs from 16-week-old 8-week-diabetic (AD), 16-week-old normal (AN) and 6-week-old normal (YN) rats.
Materials and methods: 1) Diabetes was induced by intraperitoneal injection of STZ to 8-week-old male Spraugue-Dawley rats. 2) After 8 weeks, MNCs were isolated from BM of AD, AN and YN rats. 3) bFGF, VEGF, NGF and

NT3 mRNA levels in each group of MNCs were measured. 4) Then, MNCs with saline or saline alone were injected into the right and left hindlimb muscles of normal (N) and 8-week STZ diabetic (D) rats, respectively. 5) Four weeks later, plantar test (PT), nerve conduction velocity (NCV) and nerve blood flow of sciatic nerves (SNBF) were evaluated.
Results: 1) bFGF mRNA levels in MNCs of YN rats were significantly increased compared with those of AD and AN rats. There were no significant differences between AD and AN rats. 2) Impaired thermal sensation (N: 17.0±1.4s, D: 22.4±3.9), decreased SNBF (N: 17.2±3.9 ml/min/100g, D: 8.0±2.5) and delayed NCV (N: 53.9±3.9 m/s, D: 41.8±3.7) in 8-week diabetic rats were significantly ameliorated by YN rat-derived MNCs (PT: 17.3±2.3s, SNBF: 13.4±4.1 ml/min/100g, NCV: 50.7±5.1m/s). Whereas MNCs from AD or AN rats did not show any effects on these functional tests.
Conclusion: These results indicate that cytokine production abilities of MNCs would highly depend on their age, and that this difference would explain the disparity of the therapeutic efficacy on DPN.

1144

The efficacy of methylcobalaminamin was influenced by diabetic conditions on experimental peripheral neuropathy via IGF-1
L. Jianbo[1], J. Chen[1], C. Wang[2], X. Li[3], H. Ma[4];
[1]Endocrinology & Metabolism, [2]Molecular Lab, [3]Neurology Department, [4]Pathology, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China.

Background and aims: Neurotrophic substances have been implicated in the pathogenesis of diabetic neuropathy,a degenerative defect ameliorated by exogenously administered IGF-I. Continuous treatment with methylcobalamin, one of the coenzyme forms of vitamin B(12),also has an ameliorative effect on this lesions in a neurotrophic pattern. However, little is known about potential association of methylcobalamin with IGF-1 on neurotrophic mechanism. On the basis of previous studies,we explored the link by observing dynamic changes of serum IGF-1 and it's main contributor-liver IGF-1 mRNA following exogenous methylcobalamin administration,and furthermore suggested an effective way of improving methylcobalamin effect on diabetic neuropathy.
Materials and methods: We included ninety adult male Sprague-Dawley rats in this study. Diabetes was induced in rats with STZ. Thirty rats were in normal control group(NG), thirty in a relatively good -controlled diabetic grou p(GG)(FPG:10.94±1.08mmol/L), and thirty in a relatively poor -controlled diabetic group(PG)(FPG:18.34±1.03mmol/L). Each rat of treatment groups was given methylcobalamin(500ug/kg/d, im). We measured liver IGF-1 cDNA to β-actin cDNA band density ratio and IGF-1 peptide to total protein ratio(ng/ mg)by using RT-PCR or ELISA, sciatic sensory and motor nerve conduction velocity [SNCV, MNCV(m/s)]by using evoked electromyograph, respectively.
Results: At week 2 after onset of diabetes, untreated GG and PG showed a reduced serum IGF-1 peptide and liver IGF-1 mRNA (371.0±12.5, 223.2±9.39 vs 511.2±24.7, P<0.0025,P<0.001 for serum IGF-1; 0.79±0.048, 0.53±0.023 vs1.15±0.09 ,P<0.0025,P<0.001 for liver IGF-1 mRNA). IGF-1s in methylcobalamin treated GG and PG were greater than untreated GG and PG (423.4±13.41 vs 371.0±12.5, 240.0±7.8 vs 223.2±9.39, P<0.01,P<0.025 for serum IGF-1; 0.93±0.049 vs 0.79±0.048, 0.69±0.031vs 0.53±0.023 P<0.01,P<0.05 for liver IGF-1 mRNA). Physioelectroparameters did not differ between the treated GG, PG and NG till week 8, when it showed impaired SNCV(25.70±1.59 vs 26.32±1.51 P<0.05) and MNCV(18.61±1.86 vs 20.11±1.76 P<0.05) as compared to NG. The IGF-1s and physioelectroparameters downturn progressed through week 12(end of experiment), when the IGF-1s and physioelectroparameters of the treated PG gradually dropped to that of the untreated PG, though they were more delayed to decrease in treated GG than in untreated GG (345.16±18.7, 199.25±11.41 vs 525±30.2, P<0.01,P<0.001 for serum IGF-1; 0.74±0.041, 0.48±0.017 vs 1.12±0.056 P<0.005,P<0.0001 for liver IGF-1 mRNA; 23.79±1.68 vs 21.30±1.72 P<0.05 for MNCV; 17.60±1.79 vs15.92±0.65 P<0.05 for MNCV). No effect of methylcobalamin on blood glucose was shown in any given groups.
Conclusion: The study was our pilot observation that the efficacy of methylcobalamin, at least via liver IGF-1 expression upregluation contributing to serum IGF-1 level, delayed the onset of diabetic peripheral neuropathy. The effect was influenced by diabetic status, e.g., high effectiveness was achieved in a relatively good -controlled diabetic state , especially at early stage.

Angiotensin II type-1 receptor blocker olmesartan increases neuronal expression of angiotensin II receptors in dorsal root ganglia and ameliorates diabetic peripheral neuropathy in Zucker diabetic fatty rats
K. Sugimoto[1], M. Baba[2], M. Yasujima[1];
[1]Laboratory Medicine, Hirosaki University, [2]Neurology, Aomori Prefectural Central Hospital, Japan.
Background and aims: Recent clinical studies have demonstrated that renin-angiotensin system (RAS) blockade may reduce the risk of developing type 2 diabetes and its complications. However, there has been little research on the effects of Angiotensin II type (AT)1 receptor blockers on diabetic peripheral neuropathy in type 2 diabetic animals.

Materials and methods: In the present study, 14-week-old, male, type 2 diabetic Zucker diabetic fatty (ZDF) rats were either treated orally with olmesartan (6 mg/kg/day)(n=7), an AT1 receptor blocker, or left untreated (n=7), and followed for 9 weeks. Age- and sex-matched nondiabetic lean rats served as controls (n=7).
Results: At the end of the experiment, untreated ZDF rats had higher blood glucose and HbA1c levels than control rats, and these levels were not affected by olmesartan treatment for 9 weeks. While untreated ZDF rats and control rats had comparable serum insulin and adiponectin levels, untreated rats had higher serum total cholesterol, triglyceride, free fatty acid, and leptin levels than control rats. In ZDF rats, olmesartan treatment decreased serum total cholesterol and increased serum leptin levels. Furthermore, untreated ZDF rats had increased myelinated fiber density and decreased myelin area in the distal peroneal nerve, though the densities of CD-31- and RECA-1-immunoreactive endoneurial microvessels in the sciatic nerve were comparable in untreated ZDF rats and control rats. Untreated ZDF rats developed mechanical hyperalgesia and thermal hypoalgesia, and they showed sensory and motor nerve conduction slowing in the sciatic-tibial nerves. Compared with untreated ZDF rats, olmesartan-treated ZDF rats had increased myelin area and sensory nerve conduction velocity. In dorsal root sensory neurons of untreated ZDF rats, immunoreactivities for AT1 and AT2 receptors were unchanged, but immunoreactivities for total and phosphorylated insulin receptors decreased. Olmesartan treatment increased immunoreactivities for AT1 receptors (vs. untreated ZDF rats), AT2 receptors (vs. control rats), and total insulin receptors (vs. untreated ZDF rats). The immunoreactivities for 8-OHdG, a marker of oxidative DNA damage, of dorsal root sensory neurons did not differ among the three groups.
Conclusion: These results demonstrate that olmesartan upregulates angiotensin II and insulin receptors of dorsal root sensory neurons and ameliorates sensory nerve conduction slowing and myelinated fiber pathology in ZDF rats. Further studies on the possible interaction between angiotensin II and insulin signaling systems in peripheral nerves would help elucidate the mechanisms underlying the beneficial effects of RAS blockade on diabetic peripheral neuropathy.

Loss of glyoxalase-1 promotes hyperalgesia in early diabetic neuropathy
S.B. Stoyanov[1], T. Fleming[1], P.M. Humpert[1], S. Sauer[2], N. Rabbani[3], D. Edelstein[4], P.J. Thornalley[3], P. Reeh[2], M. Brownlee[4], P.P. Nawroth[1], A. Bierhaus[1];
[1]Department of Medicine 1, University of Heidelberg, Germany, [2]Institute for Physiology and Pathophysiology, University of Erlangen, Germany, [3]Warwick Medical School, University of Warwick, United Kingdom, [4]Departments of Medicine and Pathology, Albert Einstein College of Medicine, New York, United States.

Background and aims: Formation of intracellular Advanced Glycation End Products (AGEs) is thought to contribute to the development and progression of diabetic neuropathy. Reactive intermediates of AGE formation such as glyoxal, methylglyoxal (MG) and other dicarbonyl compounds are detoxified by the rate-limiting enzyme glyoxalase-1 (GLO-1). Due to their high energy demand, neuronal cells metabolize large amounts of glucose through oxidative phosphorylation. This may explain why sciatic nerves from wildtype mice demonstrated particularly low levels of GLO-1 activity. However, this finding suggests that sciatic nerve may be particularly susceptible to high glucose-derived carbonyl toxicity. Therefore, we studied the contribution of GLO-1 and MG to functional changes in early diabetic neuropathy.
Materials and methods: Hyperalgesia was determined in healthy and diabetic mice using Hot Plate, Hargreaves, and Tail flick assays. GLO-1 was studied

on the level of transcription (quantitative Real time-PCR), expression (Western Blot and immunohistochemistry), and activity (enzyme-kinetic assay) in plasma, dorsal root ganglia (DRG) and sciatic nerve.
Results: Diabetes for 8 weeks reduced GLO-1 activity in sciatic nerve by 60%. A similar decrease occurred in non-diabetic heterozygous GLO-1-knock down mice (GLO-$1^{-/+}$)-mice. Decreased GLO1 activity in both models was associated with increased hyperalgesia, which was paralleled by a 2-fold increase in plasma and tissue MG. Application of GLO-1 inhibitors to sciatic nerve of wild-type mice also resulted in a significant increase in hyperalgesia, while overexpression of GLO-1 using somatic gene transfer reduced hyperalgesia in both diabetic and non-diabetic GLO1 knockdown mice. Finally, i. p. injection of increasing concentrations of MG into healthy mice caused a significant increase in hyperalgesia within 3h, which could be reduced by overexpressing GLO-1.
Conclusions: These data demonstrate that glycotoxic substrates of GLO-1 known to accumulate in diabetes play a central role in modulating neuropathic pain.

Exercise training retarded peripheral neuropathy symptoms with heat shock protein 72 overexpression in type 1 diabetic rats
Y.-W. Chen[1], P.-L. Hsieh[2], C.-H. Hung[2];
[1]China Medical University, Taichung, [2]National Cheng Kung University, Tainan, Taiwan.

Background and aims: Diabetic patients may suffer from many complications, and one of the complications is diabetic peripheral neuropathy (DPN). Heat shock protein 72 (HSP72) has the neuroprotective function and could be induced from normal or streptozotocin (STZ)-induced diabetic rats with exercise training. Therefore, we hypothesize that exercise may induce HSP72 overexpression in peripheral nerves and reduce the symptoms of DPN in STZ-induced diabetic rats.
Materials and methods: Male Wistar rats were randomly assigned to four groups: normal sedentary group, normal exercise group, and diabetic rats with/without exercise training group. The trained rats ran on a treadmill 5 days/week, 30-60 min/day with an intensity of 20-25m/min from day 3 after STZ-administration. DPN were tested by the withdrawal responses to heat stimuli (thermal hyperalgesia) and to light touch stimuli (tactile allodynia). In addition, HSP72 expressions in sciatic and other peripheral nerves from each group were determined by western blot.
Results: Compared with normal sedentary group, normal exercise group showed no significant changes in allodynia and hyperalgesia. Exercise training modified the development of allodynia and hyperalgesia in type I diabetic rats. HSP72 expressions in sciatic and other peripheral nerves were significantly greater in diabetic rats with exercise training than those without exercise training.
Conclusion: Exercise training performed significant lags in development of DPN and increased expressions of HSP72 in peripheral nerves.

Research about inhibition of MMP9 expression in dermal fibroblast by siRNA
X.Y. Xie, C. Yang, L. Yan;
Department of Endocrinology and Metabolism, The Second Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

Background and aims: Chronic, nonhealing skin wounds are common with significant morbidity in uncontrolled diabetes. Matrix metalloproteinases (MMPs) are zinc-dependent endopeptidases can degrade essentially all extracellular matrix components. Researches showed that MMPs activity elevated in diabetic foot, and the increased MMP9 has been confirmed to contribute to the vulnerability of diabetic skin and refractory of diabetic foot ulcer. Here to find a safe and effective way to decrease the high MMP9 expression in diabetic skin, we studied in inhibition of MMP9 expression in dermal fibroblast by siRNA in vitro.
Materials and methods: The changes of MMP9 distribution in skins of normal SD rats, STZ rats and STZ rats with skin wound were observed respectively by immunohistochemistry. Fibroblasts were obtained from the dermis of 1-day-old normal SD rats. To induce the increased MMP9 expression, the cells were cultured in the DMEM medium with high concentration of glucose and homocystein. Finally, fibroblasts were transfected with siRNA complexes or only with transfection reagents (mock) using Lipofectamine 2000 under condition with at least 75% transfection rate and 85% cell viability, which was established by transfecting FITC-labeled GAPDH siRNA, determined by inverted fluorescence microscope and MTT. 24h, 48h and 72h after transfection, RT-PCR, western blot and gelatin zymography for MMP9 were performed respectively to detect the percentages of inhibition of MMP9 mRNA, protein expression and activity.
Results: MMP9 existed extensively in epidermal layers but was not detected in dermis in the skin of normal rats. In the skin of diabetic rats, there is an increased expression of MMP9, especially around the wound. Treatment with hyperhomocysteinaemia increased the production and enzymatic activity of MMP9 in fibroblast, which was further enhanced in high glucose treatment ($p<0.05$). After a 24-h, 48-h and 72-h transfection with 40nmol/l of each MMP9-specific siRNA, significantly morphologic change of fibroblasts was not observed. RT-PCR, carried out in fibroblasts collected at different intervals, showed a remarkably reduction of MMP9 mRNA compared with

mock transfection (p<0.05), especially at 48h after that. Meanwhile, MMP9 protein abundance and activity had the same trend according to the Western blot and gelatin zymography results. Among the four MMP9 siRNAs, the sequence(5`-GGGCUUAGAUCAUUCUUCATT-3 3`-UGAAG AAUGAUCUAAGCCCAG-5) was selected out for its stable high inhibition rate.
Conclusion: The expression of MMP9 increased in the skin of diabetic rat, especially in the wound skin. MMP9 expression was inhibited remarkably after treated with MMP9 siRNA (p<0.05), especially at 48-h after transfection.

Selective inhibition of disease-related thermal hyperalgesia by tapentadol in a mouse model of diabetic neuropathic pain
T. Christoph, J. De Vry, T.M. Tzschentke;
Preclinical Research and Development, Grünenthal GmbH, Aachen, Germany.

Background and aims: Selective inhibition of pathological pain sensation without modification of normal sensory function is the primary aim of analgesic treatment in chronic neuropathic pain. Tapentadol [(-)-(1*R*,2*R*)-3-(3-Dimethylamino-1-ethyl-2-methyl-propyl)-phenol] is a novel analgesic with two modes of action, μ-opioid receptor (MOR) agonism (K_i = 0.1 μM for rat MOR binding) and noradrenaline (NA) reuptake inhibition (K_i = 0.5 μM for rat synaptosomal NA reuptake inhibition).
Materials and methods: Diabetic mice (streptozotocin-induced) and non-diabetic controls were tested by means of a 50°C hot plate to determine neuropathic hyperalgesia and normal nocifensive response.
Results: Tapentadol HCl (0.1-1 mg/kg iv) and morphine HCl (0.1-3.16 mg/kg iv) dose-dependently attenuated heat-induced nociception in diabetic animals with full efficacies attaining >80% at the highest doses tested. Tapentadol was more potent as compared with morphine on heat hyperalgesia (ED_{50} values [minimal effective dose], 0.32 (0.316) and 0.65 (1) mg/kg, respectively). Non-diabetic controls did not show significant anti-nociception with tapentadol up to the highest dose tested (1 mg/kg). In contrast, 3.16 mg/kg morphine, the dose that resulted in full anti-hyperalgesic efficacy under diabetic conditions, showed significant anti-nociception in non-diabetic controls.
Conclusion: Selective inhibition of disease-related hyperalgesia by tapentadol suggests an advantage in the treatment of chronic neuropathic pain when compared with classical opioids, such as morphine. It is hypothesized that this attractive efficacy profile of tapentadol is due to simultaneous activation of MOR and inhibition of NA reuptake.

PS 105 Diabetic foot

1150

Prevalence of undernutrition in diabetic foot unit
E. Lecornet, N. Masseboeuf, M. Baudot, C. Veyrie, F. Bouilloud, A. Grimaldi, A. Hartemann-Heurtier;
Service de Diabétologie, GH Pitié-Salpêtrière, Paris, France.

Background and aims: Patients hospitalized for diabetic foot are at risk of undernutrition because of infection, antibiotherapy, ischemia, old age (>70 years old), renal failure or dialysis, gastroparesis, multiple hospitalizations, social problems and psychiatric disease. Undernutrition is an important factor of delayed cicatrisation, nevertheless its prevalence in diabetic foot is unknown. The aim of this study is to evaluate nutritional status in patients hospitalized for diabetic foot.
Materials and methods: We studied prospectively 252 consecutive patients hospitalized in our podology unit. Patients with hemodialysis, hepatic failure and nephrotic syndrome were excluded. According to international recommendations, diagnosis of undernutrition was established by the presence of one of the following criteria:
- clinic: loss of weight more than 10% (or 5% in the last month), BMI < 17 or 20 kg/m² (respectively for people < or > 70 years old),
- biologic: albumin < 30g/l, prealbumin < 110mg/l (for patients without inflammatory syndrome defined by CRP<15mg/l)
- clinico-biological scores
o age < 70 years old: Nutritional Risk Index NRI = 1,519 x albuminemia (g/l)+0,417 x (measured weight/usual weight)/100
o age > 70 years old: Mini Nutritional assessment MNA, well validated.
Results: Our patients' caracteristics were: 74.7% male, aged 63 ± 12 years old, 35% older than 70, HbA1c=8.2 ± 2%, BMI=26 ±5 kg/m², diabetes duration: 19 ±12 years, type 2 diabetes 85%, grade 3 wound 70%, peripheral arterial disease 60%, infection 90% (osteomyelitis 70%), lower limb amputation 6%, length of staying: 25 ±16 days. Among 252 patients, 81 (32%) were malnourished, with 43 (17%) moderately malnourished and 38 (15%) severely malnourished. Patients' loss of weight before hospitalization was 2.4 ± 6.0%. This study shows that 61.5% had inflammatory syndrome (CRP>15mg/l), 8,7% had lost more than 10% of their weight, 31.3% had albumin below 30g/l. We compared malnourished patients to normal patients: they were older (69 vs 61 years old, p<0.01), hospitalization was longer (29 vs 23 days, p<0.01), they were slimmer (weight= 72 vs 83kg, p<0.01, BMI = 25 vs 28, p<0.01), albumin was lower (30 vs 33g/l, p<0.01), foot wounds were more severe (grade D: 68 vs 45%, p<0.01). There was no difference on HbA1c, diabetes duration, prealbumin, CRP, urea, proteinuria, glomerular filtration rate, weight loss during hospitalization. Moreover patients with undernutrition died more during hospitalization: 7 (8.6%) vs 5(2.9%), p=0.046.
Conclusion: The prevalence of undernutrition in our podology unit was high despite 40% of the patients received nutritional oral supplementation. Undernutrition is associated with more severe wounds and excess of mortality. Our study proves undernutrition must be considererd as an important part of treatment of diabetic patients hospitalized for foot wound.

1151

Prevalence of risk factors in the diabetic foot ulcer
R. Duarte, A.L. Costa, A. Valongo, I. Lessa, A. Recto, R. Oliveira, A. Castela, J.M. Boavida, J. Raposo;
Diabetic Foot, Portuguese Diabetes Association, Lisbon, Portugal.

Background and aims: Foot ulcers and lower limb amputations are the main consequences of diabetic foot complications. Around 85% of amputations start with foot ulcers, therefore having a significant increase on morbidity and mortality in this population.
Prevention programs on the diabetic foot can reduce the incidence of ulceration and lower limb amputations, as well as its socio- economic impact.The aim of this study was to determine the prevalence of risk factors for foot ulcers in diabetic patients that were observed in a 1st visit at the Portuguese Diabetic Association (APDP).
Materials and methods: In this observational study we evaluated the risk factors for foot ulcer, according to the clinical records of diabetic patients that required 1st time assistance at APDP, during the period of January through December 2007. All this patients were evaluated for the presence neuropathy, peripheral vascular disease, foot deformations and major nail alterations.

Results: We have studied 1048 patients, 495 (47,2%) female and 553 (52,8%) male, with an average age of 60,6 years old (Median 62 years old); 67 (6,4%) with type 1 diabetes, 925 (88,3%) with type 2 diabetes and 56 (5,3%) with other type of diabetes. 16,3% of patients had HbA1c equal or inferior to 6,5%, with a an average duration of disease of 11 years (Median 7 years of average duration of disease). We found foot deformations in 498 (47,5%) patients, hyperqueratosis in 522 (49,8%) and previous ulceration in 211 (20,1%) patients. It was also recorded an impairment in the vibratory sensibility, using 128 Hz tuning fork in 101 (9,6%) patients and using the Semmes-Weinstein monofilament, neuropathy was present in 168 (16,0%) patients. According to degree of risk using The International Consensus on The Diabetic Foot, we identified 67,5% of grade 0 patients, 16,0% with grade 1, 10,7% with Grade 2 and 5,8% with grade 3.
Conclusion: The high prevalence of patients with a risk degree 1, 2 and 3 found in the studied population stresses the importance and shows the need for the implementation of the right prevention strategies and foot evaluation programs, in the primary health care setting, therefore reducing the impact of this public health problem.

Trends in lower extremity amputations in people with and without diabetes in England, 1996-2005
E.P. Vamos[1], A. Bottle[2], A. Majeed[2], C. Millett[2];
[1]First Department of Internal Medicine, Semmelweis University, Budapest, Hungary, [2]Department of Primary Care and Social Medicine, Imperial College London, United Kingdom.

Background and aims: To examine trends in non-traumatic lower extremity amputations over a 10-year period in people with and without diabetes in England.
Materials and methods: All individuals admitted to NHS hospitals for non-traumatic amputations between financial years 1996 and 2005 in England were identified using hospital activity data. Associated postoperative and one-year mortality were examined from financial years 2000 to 2004.
Results: There was a reduction in minor and major non-traumatic lower extremity amputations during the study interval. The number of type 1 DM- and non-DM-related minor lower extremity amputations decreased by 11.4% and 32.4%, respectively, while the number of type 2 DM-related minor amputations almost doubled. For major lower extremity amputations, there was a decline in number of type 1 DM- and non-DM-related procedures by 41% and 22.4%, respectively, whereas type 2 DM-related amputations showed a consistent upward trend increasing by 83.5 %. Median length of stay decreased significantly in people with diabetes but remained considerably longer than for patients without diabetes at the end of the study period. Overall perioperative and one-year mortality rates did not significantly change between financial years 2000 and 2004 (7.7% to 7.5%, P=0.52 and 23.8 to 23.5%, P=0.70).
Conclusion: The significant increase in lower extremity amputations in people with type 2 diabetes over the past decade has important financial and health planning implications. These findings highlight the importance of achieving further improvements in preventive care and management for lower extremity amputations in people with diabetes.

Remote areas of bone marrow oedema identified by magnetic resonance imaging in feet of subjects with diabetes presenting with neuropathic lesions are common but do not predict future Charcot neuroarthropathy
J. Valabhji[1], E. Hui[1], C. Thorning[2], P.A. Tyler[2], E.A. Dick[2], W.M.W. Gedroyc[2];
[1]Department of Endocrinology, [2]Department of Radiology, Imperial College Healthcare NHS Trust, London, United Kingdom.

Background and aims: We hypothesize that the spectrum of Charcot neuroarthropathy includes a subclinical phase characterised by bone marrow oedema on MRI without the classical clinical signs. We aimed to test the hypothesis by performing a retrospective cohort study to assess the prevalence of remote areas of bone marrow oedema on MRI of feet of subjects with diabetes presenting with neuropathic foot ulceration, in whom MRI had been requested to assess for underlying osteomyelitis. MRI findings were correlated with subsequent clinical outcome.
Materials and methods: All MRI scans previously performed to look for osteomyelitis associated with neuropathic foot lesions between February 2003 and January 2009 were assessed by two independent radiologists who were not aware of subsequent clinical outcomes. A third radiologist adjudicated if there was discordance. The criteria for diagnosing osteomyelitis were hyperintense signal within the bone on T2 weighted images in continuity with abnormal high signal in the surrounding soft tissues which lead to the abnormal skin and subdermal area associated with the ulcer. Remote areas of hyperintensity in the bone not associated with the soft tissue abnormality and not in direct contiguity with areas diagnosed as osteomyelitis were recorded. Subjects in whom a diagnosis of Charcot was suspected clinically at the time of imaging were excluded.
Results: Seventy MRI studies of feet with neuropathic ulcers in 66 subjects with diabetes were assessed. A second study in the same subject was of the other foot. Of the 66 subjects (mean (standard deviation) age 64 (13) years; duration of diabetes 21 (14) years; HbA1c 8.6 (2.1) %; 48 (73%) male; 8 (12%) with Type 1 diabetes; 13 (20%) on renal replacement therapy), all had clinical evidence of a peripheral neuropathy. Of the 70 neuropathic lesions (66 forefoot and 4 hindfoot), 54 (77%) healed without any form of amputation. Osteomyelitis underlying the neuropathic lesion was present in 48 (69%). Remote areas of hyperintensity in bone were present in 21 studies (30%) (5 without and 16 with concurrent osteomyelitis); in 20, the neuropathic lesion had involved the forefoot and the remote areas of hyperintensity involved the forefoot in 1 study, the midfoot in 14, the hindfoot in 3 and the midfoot and hindfoot in 2; in 1 study, the neuropathic lesion had involved the hindfoot and the remote area of hyperintensity also involved the hindfoot. Subjects with remote areas of hyperintensity were younger (56 (13) vs. 67 (12) years; unpaired t-test $p < 0.001$), were more likely to require renal replacement therapy (43% vs. 9%; Fisher's exact test $p = 0.002$) and were non-significantly more likely to have Type 1 diabetes (24% vs. 7%; $p = 0.098$). Mean duration of follow-up post-MRI was 17 (14) months. Charcot neuroarthropathy subsequently developed in only 1 of the 70 feet studied, 19 months following the index MRI which had not demonstrated remote areas of hyperintensity or osteomyelitis.
Conclusion: Remote areas of hyperintensity on MRI consistent with bone marrow oedema in feet of subjects with diabetes and neuropathic lesions are common. While the bone marrow oedema may be consistent with a subclinical Charcot process, it did not predict future clinical Charcot neuroarthropathy.

1154

Charcot neuroosteoarthropathy in patients with pancreas-kidney transplantation and pancreas transplant alone
R. Bem, A. Jirkovská, M. Dubský, R. Kožnarová, F. Saudek, M. Adamec;
Diabetes Centre, Institute for Clinical and Experimental Medicine, Prague, Czech Republic.

Background and aims: Charcot neuroosteoarthropahy (CNO) is a deforming and destructive process of the foot that can lead to increased morbidity in patients with diabetes. Pancreas-kidney transplantation (PK) and pancreas transplant alone (PTA) could have potential both decreased by improved glycaemic control, renal function and perhaps even improved vascular complications and increased risk of by corticosteroids used in early period after transplantation or for the treatment of rejection, but also by higher level of walking activity. The role of diabetic neuropathy, bone disorders and other predisposing factors developed before transplantation may also play a key role. The aims of our study were to evaluate the presence of CNO before and after PK transplantation and PTA and to assess possible difference between those two types of pancreas transplantation.
Materials and methods: All diabetic patients, in whom PK or PTA was performed in our Institute from May 1993 to December 2008, were included into our retrospective study. The study group consisted of 318 patients (279 PK transplantation and 39 PTA) with mean age at the time of transplantation 42.5±9.0 years and mean duration of diabetes 25.6±8.0 years. The presence of CNO before transplantation was assessed retrospectively from medical records, after transplantation all patients were regularly followed in foot clinic and the diagnosis of acute CNO was based on standard criteria. The mean follow-up period was 71.4±48.4 months after transplantation.
Results: There was no significant difference between manifestation of CNO in all patients before and after transplantation - 24/318 (7.5 %) vs. 23/318 (7.2%), the recurrence of CNO was seen in 6 cases. Patients with PK transplantation and PTA did not differ significantly in the frequency of CNO either before transplantation - 20/279 (7.2%) vs. 4/39 (10.6%) or during the follow-up period after transplantation - 22/279 (7.9%) vs. 1/39 (2.6%). There

were no significant differences between PK transplantation and PTA in presence of neuropathy and levels of glycosylated hemoglobin at the latest follow-up visit.
Conclusion: The frequency of CNO did not change after transplantation either PK transplantation or PTA. It is likely that other mechanisms play an important role in manifestation of acute CNO after transplantation than not only renal function and glycaemic control. PK transplantation and PTA did not increase risk of CNO in our study.

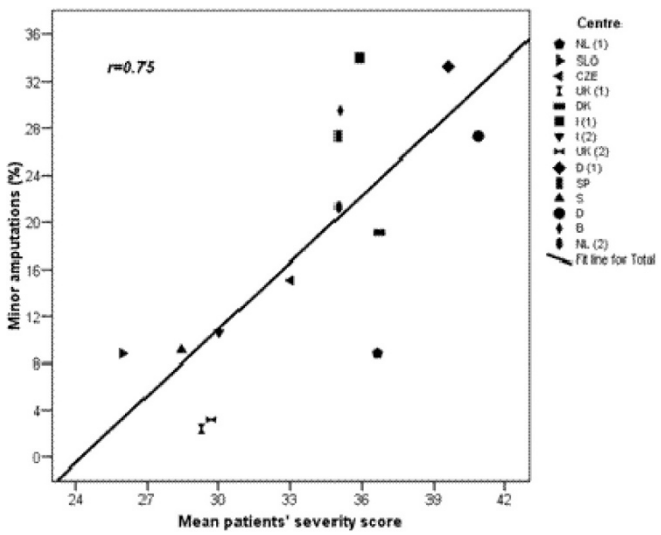
Differences in minor amputation rate in European foot centres are largely explained by differences in disease severity at presentation
P.L.H. van Battum, N.C. Schaper, L. Prompers, I. Ferreira, M.S.P. Huijberts, Eurodiale study group;
Internal Medicine, Maastricht University Medical Centre, Netherlands.

Background and aims: Minor amputation is a frequent consequence of diabetic foot ulcers. So far, determinants of minor amputation have not been studied systematically and the current literature suggests that the incidence of minor amputation may vary significantly between centres and countries. We have therefore investigated: 1) the determinants of minor amputation; 2) the differences in amputation rates between 14 centres from 11 European countries; and 3) the extent to which centre differences in amputation rates could be explained by differences in disease severity at presentation.
Materials and methods: We examined 1088 patients from the Eurodiale study, a prospective cohort study of patients with new diabetic foot ulcers who were followed, on a monthly basis, until healing, death, major amputation or up to a maximum of 1 year. Ulcers were treated according to international guidelines. Patient, foot and ulcer characteristics were obtained at baseline and data on any minor amputation were collected on a monthly basis. Multiple logistic analyses were used to ascertain the baseline characteristics independently associated with minor amputation. A severity score was then calculated, for each patient, on the basis of these characteristics. Finally, we examined the correlation between the amputation rates and the mean patient's severity scores of each centre.
Results: 194 (18%) patients underwent a minor amputation. Baseline factors independently associated with minor amputation were, depth of the ulcer (OR=6.08, CI: 4.10-9.03), peripheral arterial disease (OR=1.84, 1.30-2.60), infection (OR=1.56, 1.05-2.30) and male sex (OR=1.42, 0.99-2.04). Minor amputation rate across centres varied between 2.4% and 34% and these rates were strongly associated with the patient's severity score (figure 1: r=0.75).
Conclusion: Minor amputation is performed frequently in diabetic foot centres throughout Europe and primarily determined by depth of the ulcer, PAD, infection and male sex. Differences between the different European centres can be explained, to a great extent, by differences in patient's level of disease severity at presentation. Our findings suggest that amputation rates should not be used as an indicator of quality of care, given the large variance in patient's initial disease severity across centres, which may also be related to regional or national differences in health care organisation.



1156

Using record linkage of claims data to determine incidence of amputations in patients with and without diabetes mellitus in Austria
I. Rakovac[1], P. Beck[1], W. Habacher[1], L. Schmidt[1], G. Klima[2], A. Knopp[2], U.M. Roth[3], A. Siebenhofer[4], T.R. Pieber[1,5];
[1]Inst of Medical Technologies and Health Management, Joanneum Research, Graz, [2]Steiermärkische Gebietskrankenkasse, Graz, [3]Gesundheitsfonds Steiermark, Land Steiermark, Graz, [4]Institute for Medical Informatics, Statistics and Documentation, Medical University of Graz, [5]Department of Endocrinology and Nuclear Medicine, Medical University of Graz, Austria.

Background and aims: To determine the incidence of minor and major amputations in persons with and without diabetes mellitus in the Austrian province of Styria.
Materials and methods: Styria is a province in Austria with 1.2 million inhabitants. A record linkage was performed using claims data from the year 2005 from the local insurance fund (covering approximately 70% of the Styrian population) and all publicly financed Styrian hospitals. Persons with diabetes were identified as those with claims relating to at least one prescription for anti-diabetic medicine (ATC class A10) or those with diabetes diagnoses present in hospital claims (ICD 10 codes E10-E14). Amputations were identified by means of Austrian procedure codes for inpatient services (MELs) (Major amputation: MEL 4227 femoral amputation and MEL 4408 shank amputation; minor amputation: MEL 4549 other surgery - foot, metatarsus, toes and MEL 4551 large amputation, exarticulation not covered by other codes). Amputation was classified as traumatic, if the main ICD 10 coded discharge diagnosis was included in the groups 'S','T','V', 'W','X' or 'Y' indicating a trauma as cause for hospitalisation.
Results: In 2005, ambulatory claims from 835,403 persons were available for analysis. Crude prevalence of anti-diabetic medication prescriptions was 3.56%. 138,342 persons were admitted a total of 218,517 times to hospitals. Among persons with at least one hospital admission, crude prevalence of diabetes was 7.85%. Using both data sources, a crude diabetes prevalence of 3.84% was estimated. Mean age was 66.6 ±14.4 years and 37.7 ±22.0, for persons with and without diabetes, respectively. Crude incidence of amputations (number of persons with at least one amputation per100,000 persons) is shown in table.

	Without diabetes	With diabetes	Overall
Any amputation	38.5	742.1	65.5
Any non-traumatic amputation	33.0	723.4	59.5
Non-traumatic major amputation	6.7	243.2	15.8
Non-traumatic minor amputation	26.9	536.3	46.4
Any traumatic amputation	5.7	28.1	6.6
Traumatic major amputation	0.7	9.4	1.1
Traumatic minor amputation	5.0	18.7	5.5

Table: Incidence of amputations per 100,000 persons.

Logistic regression models, with age, diabetes status and gender as dependent variables were fitted. Males and females with diabetes had, respectively, 12.8 and 5.3 fold increased risk for any amputation, compared to males or females without diabetes.
Discussion: Record linkage of health care data can be used to assess incidence rates and quality of care. Incidence of major lower limb amputations is cumbersome high for patients with diabetes mellitus in our region of Austria. Tailored programmes for tertiary prevention with the aim to reduce major amputations in diabetic subjects are urgently needed.

Efficacy and safety of recombinant human platelet-derived growth factor gel for diabetic neuropathic foot ulcers: a systematic review
J. Shi, T. Chen, H. Tian;
West China Hospital of Sichuan University, Chengdu, China.

Background and aims: To assess the efficacy and safety of recombinant human platelet-derived growth factor (rhPDGF) gel for diabetic neuropathic foot (DNF).
Materials and methods: We electronically searched MEDLINE, EMBASE, Evidence-Based medicine Review(Cochrane DSR, ACP Journal Club, DARE, and CCTR), China National Knowledge Infrastructure (CNKI) and VIP da-

tabase to July 2008 for randomized controlled trials (RCTs). Mata-analyses were performed with the RevMan 5.0 software from Cochrane Collaboration.For numeration data, Relative risk (RR) was used as the statistic of curative effect.Each effect number was demonstrated by 95% confidence interval (CI).Heterogeneity amongst trials was assessed by both Chi-square test and I-square test with a 10% level and a 50% level of statistical significance respectively.

Results: Six randomized controlled trials involving 1181 patients were included. Meta-analysis showed that, compared with controls, patients treated with rhPDGF at 100 ug/g had a significantly increase in complete healing rate [RR 1.36, 95%CI (1.16, 1.58)], while patients with rhPDGF at 30 ug/g didn't show an increased rate [RR 1.38, 95%CI (0.76, 2.50)]. rhPDGF gel (100 ug/g) was likely to decrease the time to complete healing and reduces the size of the ulcer more effectively. Moreover, rhPDGF gel did not cause apparent adverse effects and was relatively safe for use.

Conclusion: The currently available evidence indicated that rhPDGF gel can increase complete healing rate of DNF, shorten the time of complete healing and be helpful to shrink ulcer surface. rhPDGF gel has no apparent adverse effects.

The cost of treatment of neuropathic diabetic foot ulcers to healing

B. Sørgård[1], E. Aas[2,3], O. Johansen[1];
[1]Asker and Baerum Hospital, Rud, [2]Oslo University Hospital, Aker,
[3]University of Oslo, Norway.

Background and aims: The burden of diabetic foot ulcers (DFU) is high, also in economic terms. We calculated the direct costs associated with the treatment of neuropathic DFUs.

Materials and methods: Costs for all resources used (outpatient visits, lab test, swabs, diagnostic procedures, transportation, hospitalisation, antibiotics, topical treatment, orthopaedic appliances, home care) in the treatment of DFU among 12 patients (mean/average age 65, 10 male, 10 type 2 diabetes) referred to a diabetes outpatient clinic in a tertiary hospital in southern Norway covering a population of 150000 inhabitants, was collected until healing. The total cost, unit costs and cost in relation to ulcer severity according to the University of Texas system for ulcer classification, was calculated.

Results: Average (min, max) healing time was 19 (4,61) weeks. The total direct cost for treatment of neuropathic DFU was Euro 5460. Outpatient visits accounted for 29 % of total costs whereas orthopaedic appliances 28%, hospitalisation 20 %, topical treatment 11 %, antibiotics 11% and home care 6%. Diagnostic procedures, transportation, lab tests and swabs only accounted for a marginal part of total costs (Figure 1). In relation to ulcer severity, costs where significantly higher for ulcers Texas grade B (n=5) than for those with grade A (n=7), Euro 10483 and 1871 (p=0.012) respectively. There was a strong correlation between total costs and time to healing (spearmans ρ=0.688, p=0.013)

Conclusion: The treatment of neuropathic DFU is associated with high costs, and time to healing and ulcer severity is cost raising factors. Seeing that even less severe DFU constitutes a significant economic burden, the importance of prevention is underpinned.

Infected diabetic foot: use of actovegin to accelerate wound healing

R.M. Parhimovich[1], W.T. Krivikhin[2], O.S. Ambrosimova[2], D.W. Krivikhin[2], I.J. Lazarev[2];
[1]Diabetology, Moscow Regional Research Clinical Institute, [2]Moscow Regional Center "Diabetic foot", Russian Federation.

Background and aims: Actovegin is deproteinized hemoderivative of calf blood with low-molecular peptides and nucleic acid content. It is known as antihypoxant, activator of cell metabolism and tissues regeneration.We aimed to assess clinical efficacy of actovegin use on wound healing after surgical treatment of purulent necrotising form of diabetic foot (DF).

Materials and methods: Two matched group of type 2 diabetes (mean 12,3 and 13,1 years duration) patients with infected DF and necrotising lesion were operated. Toes or forefoot (transmetatarsal) amputation were made in 80% of patients and necrectomy - in 20% in each group. The postoperative wounds were left without sutures and healed by secondary intention. Standard care including wound, diabetes and infection treatment was given to all patients. Besides, after operations for patients of the trial group ("A-group") Actovegin was administered via IV infusion 2 g \ day in 0,9% saline during 15 days with following one month oral administration 600-1200 mg\day. A-group consisted of 41 patients (mean age 60,3 years, 14 male) included: 17 patients with neuropathic DF (NDF), 15 - with neuro-ischaemic DF (NIDF) and 9 - with ischemic DF (IDF). Control group - 27 patients (mean age 54,5 years, 9 male) included: 12 patients with NDF, 11 - with NIDF and 4 - with IDF. All patients presented comorbidity: arterial hypertension, ischaemic heart disease,prevalently. Standard examination included wound healing evaluation and TcpO2 measurement on the foot on 5-7th and 14-17th days after operation.

Results: Pre-therapy mean data of TcpO2 (mmHg) in patients of control and A-group were accordingly: NDF - 61,2 - 56,8 ; NIDF - 38,4 - 42,6; .IDF - 12,8 - 14,2. On 5-7 and 14-17 postoperative days TcpO2 significant increased in A-group patients and mean data were accordingly: in NDF - 60,2 - 62,8, in NIDF 52,9 - 59,7 ; in IDF 15,7 - 20,6 mmHg. TcpO2 in control group did not change significantly during postoperative days. The inflammation markers (local swelling, infiltration, hyperemia) disappeared 2-times earlier than in control in NDF and NIDF patients from A-group; such acceleration in IDF patients was less pronounced . Granulation appeared 3-times earlier in patients with NDF and NIDF receiving actovegin; the days of granulation appearing (mean data) in control and A-group patients were accordingly: in NDF patients 9,2 - 3,02; in NIDF 12,8 - 4,6; in IDF 19,4 - 12,8th. Acceleration of the epithelialisation in A-group was not so pronounced; days of the epitelialisation beginning in control and A-group patients were accordingly: in NDF 11,6 - 8,6; in NIDF 13,2 - 9,1; in IDF 23,2 - 18,2th.

Conclusion: Actovegin administration significantly accelerates healing of wound (2- times earlier sign of inflammation disappeared and 3-times earlier granulation beginned) after operation performed in neuropathic and neuro-ischaemic diabetic foot with purulent, necrotic lesion. Effect of actovegin on

wound in ischaemic diabetic foot was less pronounced, but significant. The revealed improvement of tissue oxygenation may be one of the possible explanation for beneficial effect of actovegin on wound healing.

Use of outpatient intravenous antibiotic therapy for the treatment of diabetic foot ulcers

N. Wijenaike, H. Marath, H. Abdulla, S. Gururaj, J. Whatling;
Diabetes & Endocrinology, West Suffolk Hospital NHS Trust, Bury St Edmunds, United Kingdom.

Background: Foot ulcers complicating diabetes lead to hospital admission and prolonged length of stay. Parenteral out patient antibiotic therapy (OPAT) has been successfully used in clinical situations where protracted treatment is indicated. The experience of it's use in diabetic ulcers in United Kingdom is limited.
Methods: 18 patients requiring parenteral antibiotic therapy were identified at the diabetic foot clinic between March 2008 and March 2009. We used peripherally inserted central catheters (PICC) lines to enable intravenous therapy at home in these patients. Duration of prior oral treatment averaged 10 weeks. PICC line was inserted by a skilled technician and all patients underwent inpatient training and observation for 72 hours. Antibiotics were selected on basis of convenience and sensitivity data. Teicoplanin was used in 13 patients for ease of once daily administration and broad spectrum cover. 2 patients received Co-amoxiclav initially before changing to Teicoplanin and 3 had Ceftriaxone. Weekly review was arranged to prescribe antibiotics and monitor progress. Duration of therapy was 2 - 14 weeks with an average of 8.5 weeks.
Results: 15 (83.4 %) patients demonstrated healing following 6 - 8 weeks of therapy. 3 (16.6%) patients had minimal improvement after 6 weeks and two were referred to vascular surgeons. In 3 patients training was not feasible and received treatment at home administered by district nurse. One patient who left the area was lost to follow up. No line infections occurred.
Conclusion: PICC lines enabled safe and effective outpatient administration of intravenous antibiotic therapy for prolonged periods. There were no issues with compliance. 83.4 % percent demonstrated good progress or healing. This saved 675 hospital bed days with an estimated saving of £155,250.

Relationship between continuous variations of glucose levels and heart rate variability in patients with type 2 diabetes mellitus

F. Zaccardi[1], D. Pitocco[1], R. Nerla[2], F. Infusino[2], G.A. Sgueglia[2], G.A. Lanza[2], F. Crea[2], G. Ghirlanda[1];
[1]Diabetes Care Unit, [2]Institute of Cardiology, Catholic University, Rome, Italy.

Background and aims: Heart rate variability (HRV), a marker of autonomic dysfunction, is known to be impaired in type 2 diabetic patients and tight blood glucose control has been reported to improve HRV parameters in these patients. Recent data deriving from continuous glucose measurement in animal models of diabetes mellitus have suggested that HRV may be phasically influenced by blood glucose fluctuations. Whether this potentially relevant dynamic is present in humans is unknown.
Materials and methods: Seven type 2 diabetic subjects underwent simultaneous 24-hour ECG Holter monitoring and 24-hour continuous interstitial glucose measurements by amperometric method with a needle electrode placed subcutaneously in the abdomen and acquiring data every 5 minutes (CGM, 288 per day measurements). Then, in each patient we divided the 24h-ECG and 24h-CGM in three intervals of 8 hrs and analyzed: 1) glycemic variability indices (Standard Deviation [SD], Conga 1-5h, BG rate of change and Mean) of each interval; 2) HRV parameters (time and frequency domain) obtained from the analysis of the correspondent ECG; 3) the correlations between variability indices and HRV parameters.
Results: Data from 21 correspondent intervals evidenced that 24h-mean glucose level was significantly and positively associated with several HRV parameters (SDNN-i, r-MSSD, pNN50, Band 2, Band 3, Band 4; highest correlation with pNN50, 0.63; p=0.002), as was SD (SDNN-i, r-MSSD, pNN50, Band 1, Band 2, Band 3; highest correlation with Band 2, 0.60; p=0.004). Moreover, BG rate was positively associated with SDNN, SDNN-i, r-MSSD, pNN50, Band 1, Band 2, Band 3, Band 4 (highest correlation with Band 3, 0.66; p=0.001), while, among CONGA1-5h, the highest correlation was found between CONGA5h and Band 3, 0,62; p=0.002.
Conclusion: To our knowledge, this is the first human study that demonstrates a short-term effect of glucose level on autonomic modulation of heart function. Moreover, as glycemic variability strongly correlated with HRV, this finding could explain recent data evidencing an excess of mortality in subjects treated intensively who are more likely to experience rapid glycemic excursions.

1162

The association between sudomotor dysfunction assessed by the indicator plaster Neuropad with foot ulceration in diabetes

N. Tentolouris, S. Liatis, C. Voulgari, E. Diakoumopoulou, I. Eleftheriadou, K. Alexiadou, N. Katsilambros;
1st Department of Propaedeutic Medicine, Athens University Medical School, Laiko General Hospital, Greece.

Background and aims: To examine the relationship between sudomotor dysfunction assessed by the Indicator Plaster Neuropad (IPN) and foot ulceration (FU) in patients with diabetes.
Methods: A total of 321 patients with either type 1 or type 2 diabetes (211 without and 110 with FU; mean age: 62±10 years) were recruited in this cross-sectional study. Assessment of PN was based on neuropathy symptom score (NSS), neuropathy disability score (NDS), vibration perception threshold (VPT) and 10g-monofilament perception. Sudomotor dysfunction was assessed using the IPN.
Results: Patients with FU had significantly longer duration of diabetes, lower values of ankle-brachial pressure index, higher values of VPT, NSS, NDS and monofilament score in comparison with patients without FU. Sudomotor dysfunction, assessed by abnormal result of the IPN, was significantly more common in the FU group (94.5%) in comparison with the group without FU (50.2%). Multivariate logistic regression analysis after adjustment for gender, body mass index, duration of diabetes, glycemic control and ankle-brachial pressure index, demonstrated that the odds (OR, 95% confidence intervals) of FU increased with measures of neuropathy such as NDS >6 (12.18, 6.96-21.29), VPT >25 Volts (23.86, 11.19-50.87), monofilament score <3 (7.64, 3.88-15.02) but was also significantly increased with abnormal IPN result (17.33, 7.28-41.27) (P<0.001).

Conclusion: Sudomotor dysfunction assessed by the IPN is associated with increased risk of FU and may be included in the screening tests for identification of the diabetic patients at risk for this complication.

1163

The diabetic neuropathy in Mongolia

S. Sainbileg[1], J. Suvd[1], G. Tsagaankhuu[2], K. Altaisaikhan[1];
[1]Department of Endocrinology, [2]Department of Neurology, School of Medicine, Health Sciences University of Mongolia, Ulaanbaatar, Mongolia.

Background and aims: The aims of this study were to evaluate the diabetic neuropathy and risk factors of diabetic neuropathy among type 2 diabetic patients.
Materials and methods: This study included 285 type 2 diabetic patients (146 male, 139 female), with a mean age of 58.81±11.03 years and a mean diabetes duration of 5.06±5.68 years. The Diabetic Peripheral Neuropathy (DPN) was diagnosed by means of International Guidelines on the Outpatient Management of Diabetic Peripheral Neuropathy by Neurodiab. The DPN assessment was included brief questionnaire and clinical examination (deformities, dry skin, callus, infection and ulceration). Nerve damage examined by 128-Hz tuning fork, 10-g monofilament, pin prick, cotton wool, temperature sensation, muscle strength and achilles reflexes. The Diabetic Autonomic Neuropathy (DAN) was diagnosed by means of Position Statements from the American Diabetes Association and American Association of Neurology. The DAN diagnosed by brief questionnaire and clinical testing of Cardiovascular Autonomic Neuropathy (CAN) such as Expiration : Inspiration ratio (E:I ratio), Valsalva ratio or maneuver (VR), Heart rate response to standing (30:15 ratio) and Orthostatic Hypotension (OH).
Results: DPN and CAN were 178(68.0%) and 107(52.7%). Symptoms of genitourinary and gastrointestinal autonomic neuropathy were 72.5% and 43.7%. Sudomotor autonomic neuropathy and Impotentia in male were in 87.3% and 74.2%. diabetic patients. People with no clinical (Stages 0/1), clinical (Stage 2) and late complications of clinical (Stage 3) DPN were 84(32.1%), 138(52.7%) and 40(15.3%). Abnormal E:I ratio, VR, 30:15 ratio and OH were in 20(9.8%), 132(64.7%), 125(61.6%), and 44(21.7%) diabetic patients. Risk factors for development and progression of neuropathy such as poor glycemic control, hypertention and hyperlipidemia were 239(88.5%), 139(48.8%) and 129(52.7%). Number of cigarette smoking and alcohol consumption patients were 59(22.5%) and 61(23.3%). Mean duration of diabetes was different between groups with DPN and without DPN (5.86±6.01 vs 4.01±5.14 p<0.05). DPN related with duration of diabetes (r =0.23 p<0.01). Groups with CAN and without CAN were different for age and mean duration (63.94±9.24 vs 57.45±11.24 p<0.01), (6.36±7.31 vs 4.02±3.89 p<0.01). CAN related with age of patients and duration of diabetes (r =0.25 p<0.01 and r =0.225 p<0.01). Result of our study revealed that main differences between male and female sex were incontinence (91.4% vs. 77.4% p<0.05), sexual dysfunction (74.2% vs 26.7% p<0.01) genitourinary infections (43.1% vs. 76.5% p<0.01), dysness (20.7% vs. 47.6% p<0.01), and constipation (41.4% vs. 65.1% p<0.05).
Conclusion: The DPN and CAN in Mongolian type 2 diabetic patients were 68.0% and 52.8%. One of most important risk factors for development and progression of diabetic neuropathy poor glycemic control was in 218(87.6%) patients. DN related with diabetes duration (p<0.01).

1164

Association of serum vitamins B_{12} levels with peripheral nerve conduction abnormalities in diabetic subjects

S. Ishrat[1], S. Satter[2], F. Jebunnesa[2], N.B. Bhowmik[3], L. Ali[2];
[1]Dept of Biochemistry, [2]Dept of Biochemistry & Cell Biology, [3]Dept of Neuromedicine, BIRDEM, Dhaka, Bangladesh.

Background and aims: Diabetic neuropathy (DN) is a syndrome whose component disorders are still not adequately classified and the complex interaction of various metabolic, nutritional and morphological factors in producing the underlying disorders are not yet fully understood. Vitamin B_{12} is an important nutrient in maintaining proper nerve function and peripheral neuropathy related to its deficiency is a major confounder of diabetic polyneuropathy of somatic origin. Diabetic patients in Bangladesh with symptoms of DN are routinely given vitamin B Complex supplementation, but evidence for the association of vitamin B status with nerve conduction parameters in diabetic case are still rare. In the above context, the present study was undertaken to investigate the site and nature of nerve dysfunction in diabetic subjects and to explore the association of serum vitamin B_{12} with DN in general as well as with individual nerve conduction parameters
Materials and methods: A group of 33 type 2 diabetic subjects with DN and a control group of 22 type 2 diabetic subjects with non-DN, matched for glycemic status as determined by HbA_{1c} levels, were investigated for their NCV parameters and serum vitamin B_{12} levels. DN was confirmed by electrodiagnosis and type 2 DM was diagnosed by OGTT following WHO criteria. NCV was measured by EMG equipment and vitamin B_{12} was estimated by fluorescent based immunosorbent assay, HbA_{1c} was measured by a dedicated HPLC. Serum glucose (Glucose Oxidase) and serum lipids (Enzymetic method) were also measured. Anthropometric measurements were done by standard techniques.
Results: Compared to Non-DN subjects, the DN ones showed higher Ud Latency (msec, M± SD, 3.18±0.944 vs 5.28±2.32, p=<0.001), lower PCAMP(μV, 4.28±1.71 vs 2.20±1.40, p<0.001), lower PNCV (m/sec, 47154±3.40 vs 40.96±6.37, p<0.001), higher SUD latency (msec, 2.11±0.54 vs 2.40±0.24, p<0.05) and lower sensory UNCV (m/sec, 46.91±4.09 vs 42.92±5.94, p=0.005). The DN group had significantly higher age (yrs, M±SD, 38.88±11.19 vs 27.27±7.12; p=<0.001) and BMI (kg/m^2, M±SD, 25.30±3.74 vs 23.25± 2.12; p=0.012) compared to Non-DN groups. TG level was also higher in the DN as compared to Non-DN subjects. Serum vitamin B_{12} levels were significantly higher in the DN group as compare to the Non-DN one. On simple correlation, in the two separate groups, Vitamin B_{12} did not show any significant association with any of the nerve conduction parameters. However, there was a significant association of vitamin B_{12} with Mud Latency (p=0.016), PNCV (p=0.002), Sud Latency (p=0.037) and SSNAP (p=0.051) when all the subjects were pooled as a Diabetic group. On Logistic regression analysis the DN showed significant positive association (P<0.001) with serum vitamin B_{12} when the effects of age, BMI and TG were adjusted. On Multiple regression, vitamin B12 status was found to have significant association with Mud Latency (p=0.038), PNCV (p=0.005) and SSNAP (p=0.045).
Conclusion: a) Duration of DM (as reflected by higher age), body weight and TG are important determinants of neuropathy in type 2 DM subjects. b) Both ulnar (mainly motor function) and peroneal nerves (motor as well as sensory functions) are affected in middle aged type 2 DM patients, were as sural nerve are least affected and c) Serum B_{12} levels have an association with type 2 DM subjects and the vitamin seem to affect the ulnar and peroneal nerves.

Cerebral metabolic abnormalities in diabetes; a clue to the pathogenesis of thalamic neuronal dysfunction in diabetic neuropathy. A proton MR spectroscopic (H-MRS) study

D. Selvarajah[1], I.D. Wilkinson[2], R. Gandhi[1], C.J. Emery[1], S. Tesfaye[1];
[1]Diabetes Research Unit, [2]Academic Unit of Radiology, University of Sheffield, United Kingdom.

Background and aims: The thalamus plays an important role in somatosensory perception and H-MRS studies have demonstrated thalamic neuronal dysfunction in diabetic neuropathy (DN). Understanding the pathological changes that lead to thalamic impairment is vitally important. In this H-MRS study we explore the role of glutamine/glutamate (Glx) and astrocytes in this process. Glutamate is the primary excitatory neurotransmitter in the central nervous system, and implicated in the induction of apoptosis in neurodegenerative diseases. In neuropathic pain syndromes, long-term increase in glutaminergic signaling in nociceptive pathways has been shown to result in central sensitization. Astrocytes play a crucial role in clearance of glutamate from the synaptic cleft, thereby preventing a toxic build up. Myoinnositol (mI) an astrocyte marker can also be assessed by H-MRS.
Materials and methods: Eighteen, right-handed, subjects with type-1 diabetes (no-DN=6, painful-DN=5, painless-DN=7) and 5 healthy volunteers (HV) underwent detailed neurophysiological assessments (NIS[LL]+7 tests). H-MRS evaluation of the thalamus was performed at 1.5T. Proton spectra were obtained from a single voxel using short echo-time technique (STEAM: TE=20ms, TR=300ms. Short TE results are expressed as the areas under the Glx and mI resonances relative to that of unsuppressed water.
Results: In the full sample of subjects with diabetes, unpaired t tests revealed significantly elevated thalamic Glx in subjects with diabetes [mean(SD) 0.47(0.12)] compared with HV [0.27(0.13), p=0.001]. A one-way ANOVA revealed a main effect of group [HV, 0.27(0.14); no-DN, 0.53(0.13); DN, 0.45(0.12)] on thalamic Glx levels (p=0.002). Post hoc pairwise comparisons showed that HV had significantly lower Glx in comparison with all diabetic subgroups [No-DN (p=0.001) and DN (p=0.006)]. There was no significant difference in Glx between diabetic subgroups.

Mean mI signal of subjects with diabetes [0.38(0.16)] was lower compared with HV [0.53(0.15); p=0.67]. DN subjects had the lowest mI levels [0.36(0.16)] compared with subjects with No DN [0.42(0.17)] and HV [0.52(0.15), ANOVA p=0.14]. mI levels in subjects with DN were significantly lower compared with HV (p=0.05)

Conclusion: This cross sectional study demonstrates abnormally high levels of thalamic Glx in subjects with diabetes compared to HV. mI levels were lower in subjects with DN suggesting decreased or dysfunctional glial function. This combination may represent a susceptibility to developing thalamic neuronal dysfunction or a generalised "diabetes effect". Given the pathophysiological importance of glutamate and neuroprotective role of astrocytes, further prospective H-MRS studies are required to investigate the role of Glx and mI in DN.

Achilles tendon volume in type 2 diabetic patients with or without peripheral neuropathy: MRI study

N. Papanas[1], N. Courcoutsakis[2], K. Papatheodorou[1], G. Daskalogiannakis[2], E. Maltezos[1], P. Prassopoulos[2];
[1]Outpatient Clinic of the Diabetic Foot at the Second Department of Internal Medicine, [2]Department of Radiology and Medical Imaging, Democritus University of Thrace, Alexandroupolis, Greece.

Background and aims: There is evidence that diabetes may increase Achilles tendon (AT) thickness and stiffness, possibly predisposing to foot ulceration. Tendon thickening may be attributable to increased density of collagen fibres as a result of chronic non-enzymatic glycation. However, the association between AT pathology and peripheral diabetic neuropathy has not been adequately investigated. Therefore, the aim of the present study was to evaluate AT in type 2 diabetic patients with vs. without peripheral neuropathy using Magnetic Resonance Imaging (MRI).

Materials and methods: This study included 19 patients (group A, mean age 63.9±7.4 years) with peripheral neuropathy and 19 patients (group B, mean age 63.6±6.1 years) without peripheral neuropathy, as well as 16 healthy age-matched controls (group C, mean age 61.6±8.4 years). Diagnosis of neuropathy was based on clinical examination using the Diabetic Neuropathy Index. Neuropathy was diagnosed in patients with DNI score higher than 2. Furthermore, moderate neuropathy was defined as DNI score 2.5-4.5 and severe neuropathy as DNI score 5-8. The maximum AT thickness and AT volume were measured in sagittal T_1 weighted MRI images. AT volume was calculated by the sum of the tendon surface area of all contiguous sections multiplied by the slice thickness.

Results: Overall, diabetic patients had significantly (p<0.001) greater AT volume than controls (9742.0±2034.9 mm^3 vs. 7323.8±1918.2 mm^3). On the contrary, AT thickness did not differ between diabetic patients and controls (7.2±1.0 mm vs. 6.7±1.5 mm, p= 0.194). The difference in AT volume was observed both in men (p=0.030) and in women (p<0.001). AT volume was significantly greater in group A vs. C (9503.9±1764.8 mm^3 vs. 7323.8±1918.2 mm^3, p=0.003) and in group B vs. C (9980.2±2297.3 mm^3 vs. 7323.8±1918.2 mm^3, p<0.001), but there was no difference between groups A and B (p=0.469). Finally, in group A increased AT volume was significantly (p=0.041) associated with clinical severity of neuropathy.

Conclusion: Type 2 diabetic patients have increased AT volume as compared to controls. There is no difference in AT volume between patients with and without neuropathy. However, in neuropathic patients increased AT volume is associated with severity of neuropathy.

1167

New markers of diabetic neuropathy?

J.M. Pou[1], J. Freixa[2], J. Merce[2], J. Jurado[3], J. Ybarra[4];
[1]Dept. Endocrinology, Autonomous University, Barcelona, [2]Dept. Biochemistry Autonomous University, Barcelona, [3]IDIAP J Gol, ICS., Olot, Girona,, [4]ICAMED Centro Medico Teknon, Barcelona, Spain.

Background and aims: The plasma levels of the N-terminal fragment of brain natriuretic peptide (NT-proBNP) recently gained extreme importance as marker of myocardial dysfunction in type 2 diabetes mellitus (T2DM). In a previous work, we observed that NT-proBNP levels also display a significant association with the Diabetic Neuropathy (DPN), even after correction for age and cardiovascular disease (CVD). Scarce data is available regarding the association between diabetic polyneuropathy (DPN) and other peptides as Transforming Growth Factor Beta 1 (TGFβ1) and Tumor Necrosis factor (TNF). TGFβ1 manifested several important roles in diabetic nephropathy and TNF in insulin resistantce but its relationship to DPN is not quite understood.

Materials and methods: Hence, we set forth a cross-sectional pilot study, to assess the hypothetical relationships between NT-proBNP, TNF and TGFβ1 levels, CVD and DPN in a group of T2DM patients (N=190; W:46 %) randomly selected from the North Catalonia Diabetes Study (NCDS). CVD and DPN (clinical and neurophysiology evaluation) prevalence were assessed. NT-proBNP was measured by immunoassay, total TGFβ1 by ELISA and TNF by inmunoassay.

Results: Patients' age: 65.6±7.2, T2DM duration: 11.2±4.5 years, HbA1c: 7.3±1.7; DPN: 48.6%. Log-transformed NT-proBNP levels (logNT-proBNP) were significanlly higher in T2DM patients with CVD (*P*<0.004) and DPN (*P*<0.000) and also log-transformed TGFβ1 (Log TGFβ1) was higher in CVD (p< 0.001) and DPN (p< 0.04) patients, but no differences was observed in log-transformed TNF. Log NT-proBNP manifested an important correlation with log TGFβ1 (p<0.0001) and correlated with: age (*P*<0.001), microalbuminuria (p<0.03), CVD (*P*<0.000) and DPN (*P*<0.000) -even after correction for age and CVD (p<0.001)-. Log TGFβ1 correlated with creatinine (p<0.001), microalbuminuria (p<0.001), C-reative protein plasma levels (CRP) (p<0.02), CVD (*P*<0.006) and DPN (*P*<0.000) -even after correction for microalbuminuria, creatinine and CVD (p<0.014), but log TNFa only correlated to: age (0<01), BMI (0<0.1) and CRP (p<0.05) but not to CVD and DPN.

Conclusion: Noteworthy,TGFβ 1 and NT-proBNP plasma levels appear as important molecules for diabetic micro-angiopathic complications' development and screening although TNF could not play and important roler in diabetic neuropathy. Further prospective trials are warranted.

5% lidocaine medicated plaster vs pregabalin in patients with painful diabetic polyneuropathy (DPN): efficacy and tolerability results from a randomized, controlled trial

R. Baron[1], G. Nell[2], I. Steigerwald[3], P.D. Rogers[4];
[1]Universitätsklinikum Schleswig-Holstein, Kiel, Germany, [2]ClinPharm International GmbH, Vienna, Austria, [3]Grünenthal GmbH, Aachen, Germany, [4]St Mary's Hospital, Portsmouth, United Kingdom.

Background and aims: Comparison of efficacy, tolerability and safety of topical 5% lidocaine medicated plaster with systemic pregabalin for the treatment of neuropathic pain in patients with painful DPN.

Materials and methods: In a pan-European study, 213 patients with painful DPN were randomized 1:1 to 5% lidocaine medicated plaster or pregabalin (titrated to effect: 300 or 600mg/day). The safety set (SAF) comprised 210 patients, the per protocol set (PP) 193 patients. Responder rates were measured as a ≥2 point reduction from baseline in NRS-3 or an overall score of ≤4 after 4 weeks' treatment. Additionally change in NRS-3 values and AEs were reported.

Results: Responder rates were comparable between lidocaine plaster and pregabalin groups in patients with painful DPN (66/99, 66.7% vs. 65/94, 69.1%; PP). The NRS-3 decreased significantly by 2.5 points in both treatment groups (lidocaine plaster: 2.5+-2.0, pregabalin: 2.5+-1.8; baselines were lidocaine plaster: 6.9+-1.3, pregabalin: 6.6+-1.2). Significantly fewer lidocaine plaster patients than pregabalin patients experienced drug-related adverse events: 3.8% (4/105) versus 36.2% (38/105) (p<0.0001). Overall, only 1.9% (2/105) patients administering 5% lidocaine medicated plaster experienced drug-related adverse events leading to discontinuation, compared with 21.9% (23/105) of patients treated with pregabalin.

Conclusion: 5% lidocaine medicated plaster delivers continuous analgesic therapy of neuropathic pain symptoms associated with DPN with low frequency of drug-related adverse events and discontinuations. 5% lidocaine medicated plaster shows comparable analgesic efficacy to pregabalin with improved tolerability in patients with painful DPN.

Risk of microvascular events following initiation of insulin glargine or NPH insulin in type 2 diabetes in the US

L. Kennedy[1], A. Vinik[2], A. Chaudhuri[3], G. Rhoads[4], L. Vaur[5], V.A. Fonseca[6]; [1]Cleveland Clinic, Cleveland, United States, [2]Eastern Virginia Medical School, Norfolk, United States, [3]SUNY at Buffalo, United States, [4]University of Medicine and Dentistry of New Jersey, Piscataway, United States, [5]sanofi-aventis, Paris, France, [6]Tulane University, New Orleans, United States.

Background: It is unknown if glycemic control with different insulins is associated with differential risk for subsequent microvascular events (ME).
Methods: A database of 47 US managed care plans was analyzed to determine the incidence of ME following initiation of glargine (GLAR, n=10,667) or NPH (n=2,009) in patients treated with oral antidiabetic drugs between 2001 and early 2008. MEs were defined based on ICD9-CM codes for diabetes specific eye, kidney or nerve complications. Patients with MEs or no HbA1c value available during the 1 year period (baseline) prior to insulin initiation were excluded.
Results: Patients initiating GLAR vs NPH were older (53 vs 48 years), predominantly male (57 vs 36%), had a higher mean HbA1c (9.3 vs 8.3%), fewer specialist visits (18 vs 29%), and lower Charlson comorbidity score (0.86 vs 1.0). Initial crude, unadjusted ME incidence estimates were 225 vs 201 events/1,000 patient-years (Rate Ratio=1.12, p=0.02) with mean follow up of 15 vs 16 months from initiation of GLAR vs NPH, respectively. Unadjusted 1-year HbA1c change was similar between the groups (-1.0 vs -0.96%). Analysis adjusted for multiple confounders showed an increasing risk for ME with baseline HbA1c (Hazard ratio (HR)=1.07, p<0.001) and the risk trended slightly lower in patients achieved HbA1c < 7% vs those who did not during first year follow-up (HR=0.95, p=0.32). After accounting for substantial baseline group differences, 1:1 propensity matched comparisons (Table) showed a 15% lower risk of ME in patients who initiated GLAR (n=1,589) instead of NPH (n=1,589).
Conclusion: These provocative data suggest a lower incidence of ME following initiation of GLAR vs NPH after adjusting for important baseline confounders. This effect of GLAR appears incompletely explained by the differences in HbA1c lowering. Further well controlled studies are necessary to evaluate this hypothesis.

Comparisons on incidence of microvascular events in propensity matched (1:1) GLAR vs NPH initiator groups

Agent	N	Baseline A1C %	% Patients with ME	OR (95% CI)	McNemar S (P)
Match criterion: difference in estimated propensities between glargine and NPH < 0.1					
Glargine	1589	8.64 (p=0.49)	27.6	0.85 (0.73, 0.99)	4.12 (0.04)
NPH	1589	8.70	30.8		
Match criterion: difference in estimated propensities between glargine and NPH < 0.05					
Glargine	1523	8.66 (p=0.16)	27.8	0.83 (0.71, 0.97)	5.26 (0.02)
NPH	1523	8.77	31.6		
Match criterion: difference in estimated propensities between glargine and NPH < 0.01					
Glargine	1449	8.70 (p=0.08)	28.2	0.82 (0.70, 0.96)	6.05 (0.01)

Decreased adiponectin levels in diabetic patients with neuropathy

E. Cagiltay[1], B. Sahan[1], H.M. Terekeci[1], C. Top[1], M.G. Senol[2], E. Ulusoy[3], S. Celik[1], S. Nalbant[1], Y. Kucukardalı[1], C. Oktenli[1]; [1]Internal medicine, [2]Neurology, [3]Cardiology, GATA Haydarpasa Training Hospital, İstanbul, Turkey.

Background and aims: The mechanism underlying Diabetic peripheral neuropathy still remains unclear. Adiponectin, is an adipocytokine, having several beneficial and protective effects like anti-inflammatory, vasculoprotective and anti-diabetic effects. Little is known about the relationship between adiponectin and diabetic peripheral neuropathy. Therefore, the aim of this study is to investigate the role of adiponectin on diabetic peripheral neuropathy in type 2 diabetic subjects.
Materials and methods: Thirty-eight Type 2 diabetic patients and twenty-three non-diabetic healthy controls were included in the study. We studied EMG and neuropathy symptom score in all study subjects. All subjects underwent a plasma adiponectin level measurement by ELISA method.
Results: The level of adiponectin was found statistically different among all groups (healthy control, diabetic patients with or without neuropathy). Adiponectin levels were found lower at the diabetic patients when compared with healthy controls and the lowest levels have been measured at the diabetic patients with neuropathy. Serum adiponectin levels were found negatively correlated with neuropathy symptom score and also with the diabetes duration, serum fasting glucose, body mass index, triglyceride, hs-CRP and sedimentation rate at type 2 diabetic patients.
Pathogenetic mechanisms underlying the progressive nerve fiber loss seem to be multifactorial, including polyol pathway, reactive oxygen particles, some adipocytokines, and altered protein C kinase activity. Our data imply that adiponectin can be a protective factor against neuropaty at the diabetic patients and further studies should be made about increasing adiponectin levels for the protection of diabetic patients without neuropathy from newly developing neuropathy.
Conclusion: Pathogenetic mechanisms underlying the progressive nerve fiber loss seem to be multifactorial, including polyol pathway, reactive oxygen particles, some adipocytokines, and altered protein C kinase activity. Our data imply that adiponectin can be a protective factor against neuropaty at the diabetic patients and further studies should be made about increasing adiponectin levels for the protection of diabetic patients without neuropathy from newly developing neuropathy.

Distinct regulation of fetal adiponectin and adipo-cytokines in pregnancy complicated by maternal obesity

S. Hauguel de Mouzon, L. Laffineuse, J. Minium, L. Presley, P. Catalano;
Reproductive Biology, Case Western, Cleveland, United States.

Background and aims: Obesity in pregnancy is associated with metabolic imbalance in the fetus, leading to enhanced in utero growth and adiposity. The aim of this study was to investigate whether modifications of adipo-cytokines production by fetal tissues are associated with the fetal anabolic state.
Methods: 121 women with singleton pregnancy (53 lean ; BMI : 22.0 ± 1.9) and 68 obese ; BMI : 38.4 ± 6.3) were recruited at the time of term elective C-section delivery (38.8 ± 0.6weeks). They had no sign of infection and had normal glucose tolerance but features of chronic low grade inflammation. Umbilical blood was sampled within 10 min of delivery and neonatal anthropometrics were recorded within 24 hrs of birth. Plasma cytokines concentrations were measured by ELISA.
Results: Neonates of obese mothers had similar body weight 3217±452 vs 3320± 460 g (p=0.22) but increased fat mass 384 ±150 vs 448±175 g (p=0.04) at birth. They were insulin resistant (HOMA-IR : 1.9±0.3 vs 1.2 ±0.2). Total adiponectin (30.8 ± 10.0 vs 30.6 ± 9.7 µg/ml (p=0.94) and adiponectin index defined as the ratio of HMW/total adiponectin (0.35±0.06) were not different between groups. Plasma leptin was increased in neonates of obese women 14.7 ± 13.6 vs 8.2 ± 4.7 ng/ml (p=0.001) and so were IL-6 concentrations 3.5 ± 2.3 vs 2.4 ± 1.4 ng/ml (p=0.02). Circulating umbilical TNF-alpha and C-reactive protein concentrations were similar in both groups. When assessing the relationships between circulating adipo-cytokines and body composition only leptin displayed a positive correlation with fetal adiposity (y = 1.04 + 0.02x; r = 0.30, p=0.001).
Conclusion: These results delineate specific regulations of adipo-cytokines in fetuses of obese women. Despite the development of insulin resistance in the fetus, adiponectin concentrations remained unchanged and there were only minor signs of inflammation. Since maternal cytokines do not cross the placenta these data suggest that obese fetuses are effectively protected against maternal inflammation. However, the combination of high insulin and high adiponectin levels may have functional consequences in creating a favorable environment for enhanced fetal adiposity.

YKL-40, a biomarker of inflammation, is not increased in patients with gestational diabetes mellitus

F. Hoellerl[1,2], J.M. Brix[2], G. Placher-Sorko[2], K. Krzyzanowska[2],
G.H. Schernthaner[1], G. Schernthaner[2];
[1]Angiology, Medical University of Vienna, [2]Medicine I, Rudolfstiftung Hospital, Vienna, Austria.

Background and aims: Gestational diabetes mellitus (GDM), defined as disturbance in glucometabolism with onset during pregnancy, complicates about seven percent of all pregnancies and its prevalence is increasing. Up to now the importance of inflammatory processes during pregnancy is not fully clarified. YKL-40, a novel marker which is produced by macrophages is elevated in various inflammatory processes as well as in atherosclerotic processes. Recent studies demonstrated increased YKL-40 levels in patients with type 2 diabetes mellitus (T2DM) compared to healthy controls independent of the BMI. Thus, we were interested if inflammatory alterations being involved in T2DM might be as well associated with GDM.
Materials and methods: We performed a cross-sectional and a longitudinal study, in which 28 patients with GDM (BMI 33.1± 5.8 kg/m², mean age 33±6 years) as well as 30 pregnant women without GDM (NGDM, BMI 28.1± 5.4 kg/m², mean age 32±6 years) were included. Apart from weight and standard risk factors for GDM (Family History, BMI pre-pregnancy, GDM in previous pregnancy, high birth weight) a standard oral glucose tolerance test (75g), lipid and insulin parameters for the calculation of HOMA were assessed at 28±4 weeks of gestation as well as 8 weeks postpartum in both groups. Blood samples for YKL-40 were obtained at the same time points and were determined by a commercial ELISA.
Results: YKL-40 levels in GDM during pregnancy did not differ significantly from NGDM (74.1±62. vs 60.3±30.10 ng/ml). A non-significant decrease of YKL-40 levels postpartum in GDM (63.4±30.5 ng/ml) whereas a non-significant increase of YKL-40 levels in NGDM was observed (66.9±32.7 ng/ml). During pregnancy there were the following differences between the two groups (GDM vs NGDM): fasting glucose (74.6±9.0 vs 89.4±13.4 mg/dl; p<0.001), glucose two hours postprandial (110.4±27.3 vs 161.1±35.9 mg/dl; p<0.001), HbA1c (5.0±0.4 vs 5.5±0.6%; p<0.001), HOMA (1.5 vs 3.2; p<0.001), BMI (28.1±5.4 vs 33.1±5.8kg/m2; p<0.001). In a correlation analysis delta YKL-40 (the change of YKL-40 between pregnancy and postpartum) was associated with BMI (r= 0.423, p=0.04) and insulin one hour postprandial (r=0.511, p=0.008).
Conclusion: YKL-40 levels did not differ significantly between the groups, suggesting that the inflammatory state - as evaluated by macrophage marker YKL40 - is not different between women with or without gestational diabetes. An alternative explanation might be that the abnormal glucometabolic state in pregnancy might be too short to lead to changes in YKL-40.

Normal secretion of the glucagon-like peptide-1 (GLP-1) during gestational diabetes mellitus

C. Lencioni, R. Lupi, V. Resi, A. Bertolotto, F. Romero, A. Ghio, L. Volpe, S. Del Prato, P. Marchetti, G. Di Cianni;
Department of Endocrinology and Metabolism, Section of Diabetes, University of Pisa, Italy.

Background and aims: Gestational Diabetes (GDM) predisposes women to future development of type 2 diabetes and the two conditions share a similar spectrum of metabolic alterations. Recent observations suggest that a defective glucose stimulated insulin secretion by glucagon-like peptide-1 (GLP-1), plays a role in the pathogenesis of type 2 DM. Whether such a defect in incretin secretion is impaired in women with GDM remains to be ascertained. Therefore, we have determined GLP-1 secretion in response to oral glucose load in pregnant women with normal glucose tolerance (NGT) and with GDM.
Materials and methods: 100g-3h OGTT (evaluated according to Carpenter and Coustan criteria) was performed in 12 GDM and 16 NGT women at 27.3±4.1 weeks of gestation, for determination of plasma GLP-1, glucose, insulin and C-peptide at 0',60',120',180' min. Insulin sensitivity (ISI) and insulin secretion (first and second phase); as well as insulin sensitivity-secretion index (ISSI) were also derived from the OGTT.
Results: NGT and GDM women were comparable for age (35.2±23.2 vs 34.5± 3.2 years), pre-pregnancy BMI (23.36± 2.86 vs 25.45± 4.26 kg/m²) and weight gain (7.88±3 vs 6.45± 3.8 kg, respectively). As expected GDM women had higher value of the area under the glucose curve (AUC glyc: 27575.5±3448 vs 20685.88±2715 mg/dl min, p<0.01), but lower first phase insulin secretion (993.12±367 vs 1376.61±423 , p<0.05) and ISSI compared to Controls (3873.23±1185 vs 6232.13±1734, p<0.001). In contrast nor AUC GLP-1 did not significantly differ between the two groups (NGT 6542.01 ±2104 vs GDM 5863.5 ±1313 pmol/l min) nor mean GLP-1 values during OGTT were different in the two groups. Only plasma GLP-1 at 180' tended to be lower in GDM (NGT:37.08 ±23.4 vs GDM: 23.19 ±8.28 pmol/l; p=0.07). Univariate regression analysis showed no correlation between AUC GLP-1 and AUC glic, first phase of insulin secretion, ISSI, age and prepregnancy BMI.
Conclusion: Our data show that GLP-1 secretion in response to OGTT in GDM and NGT is not different in spite of a difference in glucose tolerance and b-cell function. Therefore our data do not support a primary role of defect in incretin-mediated insulin secretion in gestational diabetes.

1174

The expression of peroxisome-activated receptor-gamma in fat and placental tissue is not altered in patients with gestational diabetes

B. Telejko[1], M. Kuzmicki[2], N. Wawrusiewicz-Kurylonek[1], A. Nikolajuk[1], D. Zwierz-Gugala[1], J. Szamatowicz[3], P. Laudanski[2], A. Kretowski[1], M. Gorska[1];
[1]Department of Endocrinology, Diabetology and Internal Medicine, [2]Department of Pathophysiology of Pregnancy, [3]Department of Gynecology, Medical University of Bialystok, Poland.

Background and aims: Recent studies have implicated adipokines and ligand-activated transcription factors, such as peroxisome proliferation-activated receptors (PPARs), as the key regulators of lipid and glucose metabolism

that allow adaptation of the mother to the nutritional requirements of the fetus. In the present study we aimed to investigate whether there are significant differences in the expression of PPAR-gamma, transcription factor 7-like 2 (TCF-7L2) and various adipokines in subcutaneous adipose tissue (SAT), visceral adipose tissue (VAT) and placental tissue obtained from pregnant women with gestational diabetes mellitus (GDM) and normal glucose tolerance (NGT).
Materials and methods: The expression of adiponectin, leptin, visfatin, resistin, PPAR-gamma and TCF-7L2 mRNA was measured using quantitative real-time PCR Serum adipokines concentrations were estimated by RIA or ELISA.
Results: Serum adiponectin and visfatin concentrations were significantly lower in the GDM than in the NGT subjects (27.3 [23.6-40.3] vs 35.0 [28.0-45.0] μg/ml, p=0.04 and 2.75 [0.7-4.6] vs 5.2 [3.9-5.9] ng/ml, p=0.02, respectively). The patients with GDM had also lower adiponectin (p=0.008) and TCF-7L2 mRNA expression (p=0.04), as well as higher resistin mRNA expression in VAT (p=0.02) in comparison with the healthy women, whereas PPAR-gamma mRNA expression did not differ significantly between the groups studied. One-way ANOVA revealed that PPAR-gamma and TCF-7L2 mRNA expression in SAT and VAT was significantly higher than in placental tissue (p=0.0003, p=0.0009, p=0.04 and p<0.0001, respectively). Leptin mRNA expression was markedly higher in SAT than in VAT and placental tissue (p<0.0001), whilst adiponectin mRNA expression did not differ between SAT and VAT. No detectable amount of adiponectin mRNA in any of the placental tissue samples was found. There was a significant correlation between the expression of PPAR-gamma and TCF7-L2 mRNA in SAT (R=0.60, p<0.0001), VAT (R=0.64, p=0.001) and placental tissue (R=0.56, p=0.0005). There were also correlations between PPAR-gamma mRNA and adiponectin mRNA expression in SAT (R=0.77, p<0.00001), PPAR-gamma mRNA and visfatin (R=0.43, p=0.009) and leptin (R=0.64, p=0.001) mRNA expression in VAT, as well as between PPAR-gamma mRNA and visfatin (R=0.79, p<0.0001) and leptin (R=0.44, p=0.01) mRNA expression (R=0.56, p=0.0005) in placental tissue.
Conclusion: Low circulating adiponectin and visfatin, as well as decreased adiponectin and TCF-7L2 mRNA expression in VAT seem to play a pathogenic role in GDM, whereas the expression of PPAR-gamma in fat and placental tissue is not altered in GDM patients.

Plasma MR-proADM concentrations in women with gestational diabetes
A. Handisurya[1], G. Vila[1], J. Struck[2], N.G. Morgenthaler[2], K. Klein[3], A. Luger[1], M. Clodi[1], A. Kautzky-Willer[1];
[1]Department of Internal Medicine III, Division of Endocrinology and Metabolism, Medical University of Vienna, Austria, [2]Research Department, BRAHMS AG, Biotechnology Centre, Henningsdorf, Germany, [3]Department of Gynaecology and Obstetrics, Division of Feto-Maternal Medicine, Medical University of Vienna, Austria.

Background and aims: Gestational diabetes (GDM) is associated with distinct differences in placental perfusion and maternal hemodynamics. Adrenomedullin (ADM), a potent vasoactive peptide, is implicated in the regulation of vascular function and related to glucose intolerance and obesity. Previously, ADM was found to play a role in the development of gestational hypertension and pre-eclampsia. Midregional pro-ADM (MR-proADM) is secreted equimolarily with ADM but features a longer half-life. The objective of the present study was to evaluate whether GDM *per se*, i.e. uncomplicated by hypertension or pre-eclampsia, is associated with changes in circulating MR-proADM levels as compared to pregnant women with normal glucose tolerance (NGT).
Materials and methods: In a cross-selectional study, plasma MR-proADM concentrations were measured by ELISA in 101 women with GDM and 87 pregnant women with NGT at gestational week (GW) 10-23, 24-30 and 31-38 (timepoints 1-3). In a longitudinal study, changes in MR-proADM levels between timepoints 1 and 2 were evaluated in 12 NGT and 5 GDM as well as in 23 NGT and 28 GDM between timepoints 2 and 3.
Results: In the cross-selectional study, HOMA-IR was significantly increased in GDM as compared to NGT at all timepoints (p<0.05, respectively). Plasma MR-proADM concentrations were similar in GDM and NGT at GW 10-23 (0.53±0.22 vs. 0.43±0.20 nmol/l, p=0.012), however lower in GDM at GW 24-30 (0.72±0.33 vs. 0.84±0.40 nmol/l, p=0.088) and GW 31-38 (0.82±0.35 vs. 0.99±0.42 nmol/l, p=0.032). At GW 24-30 circulating MR-proADM levels correlated with midregional pro-atrial ANP levels (MR-proANP; r=0.197, p=0.043) and at GW 31-38 with HOMA-IR (r=-0.305, p=0.009) and MR-proANP (r=0.499, p<0.0001). In the longitudinal study, the increase in ΔMR-proADM between timepoints 1 and 2 as well as timepoints 2 and 3 was more pronounced in NGT than GDM (p=0.05; p=0.076) and correlated positively with Δweight (r=0.32, p=0.023) and ΔMR-proANP (r=0.46, p<0.0001) between timepoints 2 and 3.
Conclusion: Although previous studies reported on increased plasma ADM concentrations in type 2 diabetic or obese subjects, our data indicate that GDM women feature lower MR-proADM concentrations in late pregnancy as compared to pregnant subjects with NGT. Such decrease in ADM was related to an increase in insulin resistance. Thus, it might be suggested that during late pregnancy glucose intolerance might curb the physiologic increase of circulating ADM levels.

1176

The activity of lysosomal n-acetyl-beta-hexosaminidase during pregnancy in type 1 diabetes mellitus and gestational diabetes mellitus
W.J. Zarzycki[1], D. Dudzik[1], M. Skotnicki[2], M. Gorska[1];
[1]Department of Endocrinology, Diabetology and Internal Medicine, [2]Department of Perinatology, Medical University of Bialystok, Poland.

Background and aims: Hyperglycaemia causes chronic tissue damage and might influence on the activity of lysosomal N-acety-β-hexosaminidase (HEX), which catalyzes the removal of N-acetylglucosamine or N-acetylgalactosamine residues from the non-reducing end of glycoconjugates oligosaccharide chains. HEX is a sensitive marker of diabetic vascular complications. The aim of our investigation was to determine the changes in the activity of lysosomal HEX in type 1 diabetes during pregnancy and gestational diabetes mellitus.
Materials and methods: Serum and homogenates of placenta tissue of 20 women with gestational diabetes mellitus (GDM), 10 with type 1 diabetes (DM1) and 15 women in physiological pregnancy and serum of 15 non pregnant women as a control groups. The diabetic women was well controlled. HEX activity (pKat/ml of sample or μKat/kg of protein) was measured by Chatterjee *et al* method in modification by Zwierz *et al*.
Results: We observed a statistically significant increase of HEX activity in the serum in physiological pregnancy (1221,32±282,3) compared to the non-pregnant women (428,92±86,2; p=0,000000), statistically significant increase of HEX activity in the serum of GDM women (1843,64±495,86) compared to physiological pregnancy (p=0,000124). In placenta tissue we found statistically significant increase of Hex activity in GDM (321,5±135,95) as compared to non-complicated pregnancy (138,23±30,3; p=0,000021). There was no statistically differences of HEX activity in serum (p=0,477) and placenta (p=0,7) between type 1 diabetes and gestational diabetes mellitus. The activity of lysosomal HEX in serum 3 months postpartum was compared to control group non-pregnant women.
Conclusion: Our study might suggest that diabetes might have an influence on metabolism of gycoconjugates that leads to increase in their degradation. The mechanism of hyperactivity of HEX is probably the same in DM 1 and GDM. It is suggested that damage of vascular endothelium is the major source of the enzyme in diabetes.

Role of maternal iron status in the pathogenesis of gestational diabetes mellitus
N. Sultana[1], M.R. Sharker[2], F. Jebunnesa[1], T. Wahed[1], R. Helal[1], L. Ali[1];
[1]Biochemistry & Cell Biology, BIRDEM, Dhaka, [2]Food and Nutrition, Dhaka University, Bangladesh.

Background and aims: Gestational diabetes mellitus (GDM) is one of the commonest complications of pregnancy; but its pathophysiology is still not fully understand. Recently attention has been focused on the relation between iron metabolism and glucose intolerance in the genesis of GDM. The present study was conducted to investigate the association of body iron store with various covariates of metabolic syndrome.
Materials and methods: A total 100 subjects were included in this study: 43 were healthy nondiabetic and nonanemic pregnant women (Control group) and 57 were pregnant women having Gestational Diabetes Mellitus (GDM group). The subjects were investigated for glycemic (fasting & 2h ABF glucose and HbA_1c), insulinemic (fasting C-peptide) and body iron (serum iron,

ferritin & transferrin) status. Glucose level was measured by using glucose-oxidase method, fasting serum C-peptide by chemiluminescent enzyme immunoassay, HbA_{1c} by using a modified HPLC method and insulin sensitivity (HOMA%S) and insulin secretory capacity (HOMA%B) were calculated by Homeostasis Model Assessment. Serum transferrin receptor (STfR) was measured by Enzyme-Linked Immunosorbent Assay (ELISA), and serum ferritin level was assessed by Microparticle Enzyme Immunoassay (MEIA) technology. Serum iron concentration was measured by IRN method.
Results: The age of the study groups were found to be matched (p=0.522). Gestational weeks and parity of the study groups were significantly higher in GDM than Controls (p=0.004 and p=0.015 respectively). HbA_{1c} level (%, M±SD) was significantly higher in GDM group (6.09±1.1) as compared to Control (5.8±0.7, P=0.001). Serum insulin level [ng/ml, Median (range)] as assessed by C-peptide, was significantly higher in GDM group [2.5(1-6.6)] compared to Control [1.5(1-3.3), P<0.001], but the insulin secretory capacity (HOMA% B) was not different between the two groups [median (range) 144(102-270) in GDM vs 165(100-281) in Control]. HOMA%S [Median (*range*)] was significantly lower in GDM group [38(20-90)] as compared to Control [60(32-99), P<0.001]. The lipidemic status of the GDM group did not show any difference from Control . Among the marker of body iron status hemoglobin level showed no difference between GDM (11±1.25) and Control groups (10.6±0.8), but serum iron concentration [median (range)] was significantly lower in GDM group [6(2-19)] as compared to Control [12(2-36)]. There was no significant difference between the two groups in their levels of serum ferritin and STfR. On Pearson's correlation coefficient analysis Ferritin level had significantly negative correlation with HbA_1c (P=0.046). No other correlation was found among other variables.
Conclusion: From the above data it may be concluded that GDM in Bangladeshi subjects does not seem to be associated with iron less deficiency or elevated body iron store. GDM subjects may show lower serum iron, but this is probably related to chronic inflammatory state of diabetes rather than iron deficiency itself. The data also suggest that interpretation of body iron status in this condition, using the available markers (like serum iron, serum ferritin and STfR), needs to be made with caution due to the presence of concurrent factors like pregnancy and chronic inflammatory status.

Homeostatic insulin sensitivity indices in the detection of gestational diabetes mellitus

S. Hayat[1], F. Jebunnesa[2], N. Sultana[2], T. Wahed[2], R. Helal[2], L. Ali[2];
[1]Obstetrics and Gynecology, [2]Biochemistry and Cell Biology, BMRG, Dhaka, Bangladesh.

Background and aims: Early identification of GDM is strongly warranted for prevention of both maternal and fetal complications, but well known disadvantages of the present methods based on oral glucose challenge reduces the compliance and applicability of these methods in the screening of the disorder. The present study aimed to assess FBG-based insulin sensitivity indices (ISIs) regarding their suitability as alternatives of 2 hour 75-g OGTT. Other related glycemic and insulinemic indices as suitable alternatives were also explored. McNamara test was used to calculate sensitivity, specificity, PPV and NPV of various tests against the gold standard of OGTT.
Materials and methods: A group of pregnant mothers, at 24 to 32 weeks of gestation, were recruited from BIRDEM (the tertiary hospital of Diabetic Association of Bangladesh) and Dhaka Medical College Hospital were screened for GDM by adapting WHO criteria of 75-g OGTT. Out of 300 subjects, 112 had GDM. Finally 84 GDM and 82 normal mothers were analyzed through a nested case control design. Serum glucose was measured by glucose oxidase method and insulin was assayed with a chemluminescence based ELISA. Insulin sensitivity indices as well as glycemic and insulinemic indices were calculated and tested for their ability to detect GDM. Homeostatic formulas were used to quantify insulin sensitivity and B-cell function.
Results: The GDM group had higher age as compared to control (years, M±SD, 28.9±3.8, vs. 26.7±4.6, p<0.001). HOMA%B was significantly (p<0.001) lower in GDM (113.3±51.4) than their non-GDM counterparts (207.9±91.3). QUICKI of GDM was 0.52 ±.03 and that of control was 0.55±.05; the difference was statistically significant (p<0.001). HOMA%S showed no significant difference (p=0.158) between GDM and non-GDM groups. In Pearson's correlation analysis HOMA%B had a significant correlation with age, FBG, 75-g OGTT and fasting insulin level. HOMA%S showed statistically significant correlation with FBG, 75-g OGTT, fasting insulin, HOMA%B and QUICKI. Logistic regression analysis provided significant association of HOMA%B with GDM (p=0.002) after adjusting the effect of the confounders. The value of different screening markers for predicting GDM was explored. HOMA%S at optimum cut-off value of 50 showed sensitivity of 50% and specificity of 56%, with PPV and NPV 56% and 55% respectively. QUICKI had sensitivity and specificity of 28% and 31% respectively at an optimum cut-off value of 0.54. Fasting insulin showed sensitivity and specificity of 54% and 49% respectively at cut-off value of 12.9μU/ml with PPV 50% and NPV 50%. At an optimum cut- off value of 5mmol/l, the sensitivity, specificity, PPV and NPV of FBG was 82%, 78%, 79% and 81% respectively The corresponding value for combined fasting glucose and fasting insulin were 84%, 79%, 82% and 82%.
Conclusion: The data suggest that insulin sensitivity indices do not seem to be reliable alternatives for oral glucose based tests for the detection of GDM. Simple fasting blood glucose with a cut-off value of 5.0mmol/l, for Bangladeshi population, seems to be an acceptable test in the screening of GDM.

PS 108 Gestational diabetes - maternal and foetal outcome

1179

Increasing incidence of abnormal glucose tolerance in women with gestational diabetes (GDM) or mild gestational diabetes (MGH) in France: DIAGEST 2 study

P. Fontaine[1], S. Schaller[1], X. Lenne[2], V. Coliche[3], G. Montreuil[4], P. Goeusse[5], H. Pauchet[6], A. Vambergue[1], Gestational Diabetes Study Group, Diagest Group;
[1]Diabetology, CHRU Lille, [2]CRESGE LEM, CNRS 8179, Lille, [3]Diabetology, CH, Boulogne sur mer, [4]Diabetology, CH, Helfaut, [5]Gynecology, CH, Tourcoing, [6]Gynecology, CH, Saint-Omer, France.

Background and aims: Gestational diabetes (GDM) is characterized by impaired glucose metabolism during pregnancy. After pregnancy, these women do not completely normalise their metabolism and maintain an increased risk of later maternal diabetes (DM) and vascular disease. Mild blood glucose abnormalities during pregnancy may be linked to later glucose tolerance abnormalities or diabetes mellitus. Our aims were 1) to evaluate the prevalence of diabetes mellitus (DM), impaired glucose tolerance (IGT), and impaired fasting glucose (IFG) 11 years later after delivery in women with various blood glucose status during pregnancy 2) to determine the risk factors of diabetes in this population.
Materials and methods: We compared long-term outcomes among control women (n= 221), women with mild gestational hyperglycaemia (n=322) and women with gestational diabetes (GDM) (n=466). Women were recruited from 15 public maternity units in north of France wich belong to the Diagest group. Between delivery and the follow-up visit (6 years and 11 years), women with prior GDM or MGH had not received specific advice, particularly about nutrition or physical activity. Women with prior GDM or MGH and control subjects were offered a 75-g OGTT. Women who refused the OGTT contributed only a fasting plasma glucose. Rates of DM, IGT and IFG were compared between the groups (American Diabetes Association criteria).
Results: Eleven years after delivery, clinical and biological parameters were be determined in 225 GDM, 122 MGH and 76 controls. Rates of DM, IGT and IFG were respectively 3.9%, 4.5% and 1.3% in the control group. In GDM women, the rates of DM, IGT and IFG are respectively 35.6%, 8.9% and 5.3%. In MGH women, the rates of DM, IGT and IFG are respectively 12.3%, 15.7% and 10.7%. Among 178 GDM who were seen at 6 years and at 11 years, the prevalence of DM was 30.3% at 6 years IC 95% [23.6-37.1] and 42.7% at 11 years IC 95% [35.4-50.0]. At 11 years, predictors for DM are: family history of diabetes, previous GDM, BMI > 27 kg/m^2, fasting glucose during pregnancy > or = 5.5 mmol/l, the severity of hyperglycaemia during pregnancy defined by the number of abnormal blood glucose values fasting, 1, 2 and 3 h during the glucose tolerance test at diagnosis of GDM, and insulin therapy during pregnancy.
Conclusion: This study has identified a high prevalence of glucose tolerance abnormalities after GDM and MGH. Compared to GDM women, women with MGH have also a high risk of later diabetes. After 6 years, the prevalence carries on to increase. Thus, women with previous glucose tolerance abnormalities represent a high-risk group and a target for intervention to postpone or prevent the development of overt diabetes in France.

Metabolic syndrome in early pregnancy and risk of gestational diabetes mellitus

L. Chatzi[1], E. Plana[2], A. Pappas[3], D. Alegkakis[4], P. Karakosta[1], V. Daraki[5], C. Tsatsanis[6], A. Kafatos[1], A. Koutis[1], M. Kogevinas[1,2];
[1]Department of Social Medicine, Faculty of Medicine, University of Crete, Heraklion, Greece, [2]Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain, [3]Diabetic Clinic, Venizelio Hospital, Heraklion, Greece, [4]Department of Rheumatology, Clinical Immunology and Allergy, Faculty of Medicine, University of Crete, Heraklion, Greece, [5]Department of Endocrinology, Faculty of Medicine, University of Crete, Heraklion, Greece, [6]Department of Clinical Chemistry-Biochemistry, Faculty of Medicine, University of Crete, Heraklion, Greece.

Background and aims: Gestational diabetes mellitus (GDM) is a prevalent disease associated with adverse outcomes of pregnancy. The association between metabolic aberrations in early pregnancy and the development of GDM remains little explored. The purpose of this study was to determine the extent to which, maternal metabolic syndrome in early pregnancy is a risk factor for GDM.
Materials and methods: The mother-child "Rhea"study in Crete is a prospective cohort examining pregnant women (Greek and immigrants) residents at the prefecture of Heraklion that became pregnant during one year starting in February 2007 and initiated prenatal care before 15 weeks of gestation. Five hundred and eight women with sigleton pregnancies without a diagnosis of diabetes mellitus or GDM in a prior pregnancy were included in the analysis. Maternal fasting serum samples were collected and blood pressure was measured at the time of the first major ultrasound (Mean: 12 weeks, SD: 1.5). Metabolic syndrome in early pregnancy was defined according to the NHLBI/AHA criteria. Pregnant women were screened for GDM between 24 and 28 weeks of gestation, and GDM was defined by the criteria proposed by Carpenter and Coustan. Multivariable log-binomial regression models were used to estimate the effect of metabolic syndrome in early pregnancy on the risk of GDM after adjusting for confounders.
Results: Women with metabolic syndrome were in high risk for GDM (RR=3.17, 95 percent CI: 1.06, 9.50), whereas among the components of metabolic syndrome, the most significant risk factors were impaired fasting glucose (RR=4.92, 95 percent CI: 1.41, 17.23), and pre-pregnancy obesity (RR=2.65, 95 percent CI: 1.23, 5.70). An elevation of 10mmHg in systolic or diastolic blood pressure increased the relative risk for GDM by 49% (RR=1.49, 95 percent CI: 1.10, 2.02) and 34% (RR=1.34, 95 percent CI: 1.04, 1.73) respectively, while a per unit increase in the BMI pre-pregnancy increased the relative risk for GDM by 6% (RR=1.06, 95 percent CI: 1.01, 1.12).
Conclusion: These findings suggest that women with metabolic syndrome in early pregnancy had higher risk for GDM.

Undiagnosed pre-gestational diabetes among women with gestational diabetes mellitus

A.E. Lilja[1,2], E. Stage[1], C. Barfred[1], S.B. Nielsen[1], M.R. Mikkelsen[1], P. Damm[1,3], E.R. Mathiesen[1,2];
[1]Center for Pregnant Women with Diabetes, [2]Department of Endocrinology, [3]Department of Obstetrics, Rigshospitalet, Faculty of Health Sciences, Copenhagen, Denmark.

Background and aims: Among women diagnosed with gestational diabetes mellitus (GDM), a subpopulation is presumed to have undiagnosed pre-gestational diabetes. Well aware of the severe adverse pregnancy outcome in women with pre-gestational diabetes, such as malformations, preterm delivery and perinatal mortality, women with undiagnosed pre-gestational diabetes are assumed to be equally vulnerable to complications in pregnancy. This implies that GDM women with undiagnosed pre-gestational diabetes deserve intensified pregnancy surveillance, and therefore need to be identified as early as possible in pregnancy.
Materials and methods: A cohort of 215 women diagnosed with GDM in 2007 was investigated. Two women were classified as having had undiagnosed pre-gestational diabetes due to continuous need for insulin treatment after delivery. In addition, 10 women were diagnosed according to the WHO criteria of oral glucose tolerance tests performed in 141 cases (66%) two months post partum.
Results: At diagnosis of GDM, all women were instructed in diabetes diet, resulting in a restricted mean weight gain of 1.6 kg from GDM diagnosis to delivery, seven weeks (0-35) later. Sixty-one of these women (43%) were insulin treated due to insufficient glucose control on diet treatment alone.
Patients with undiagnosed diabetes in pregnancy were characterised by higher 2 hour plasma glucose value (13.8 mmol/l (SD 3.9) vs. 10.7 (SD 1.8), p<0.001), higher HbA1c value at GDM diagnosis (6.7 % (SD 1.5) vs. 5.5 (SD 0.7), p<0.001), and being diagnosed earlier in pregnancy (median 19 weeks (11-37) vs. 31 (5-39), p<0.001), while age and BMI were comparable (34.5 years vs. 33.6 and 32.6 kg/m^2 vs. 31.7). In eight cases with baseline HbA1c>6.5% and GDM diagnosis before 35 weeks, four (50%) had diabetes and four (50%) had pre-diabetes (IGT or IFG) post partum. Among women treated with insulin, 10 (16%) had diabetes, and 24 (39%) had pre-diabetes two months post partum, in comparison to two (2%) and 17 (21%) among women treated with diet alone.
Conclusion: The presence of women with undiagnosed pre-gestational diabetes among women with GDM is a significant clinical problem. These women can be distinguished among GDM patients by higher 2 hour plasma

glucose and HbA1c values, early onset of GDM, and the necessity of insulin therapy during pregnancy. Special attention should be paid to GDM patients with these characteristics in order to prevent severe pregnancy outcome due to undiagnosed pre-gestational diabetes.

Obstetrical outcomes in pregnancies with gestational diabetes: what benefits? Which patients?
N. Chevalier, S. Hieronimus, V. Giaume, F. Brucker-Davis, A. Bongain, P. Fénichel;
Pôle de Gynécologie-Obstétrique-Reproduction-Endocrinologie, Nice, France.

Background and aims: Up today, no international consensus was found for gestational diabetes mellitus (GDM) diagnosis. We have previously reported that O'Sullivan test has a low relevance for GDM screening in our Mediterranean population. Thus we adopted a universal one-step screening strategy with a 75 grams OGTT. We report here our first results of obstetrical outcomes since we apply this new screening strategy at our University Hospital.
Materials and methods: We conducted a prospective and descriptive study between 01/01/2008 and 12/31/2008. Over nine months (January to September 2008), all pregnant women (n=2014) were screened with a 75 gr OGTT between 24th and 28th week of amenorrhea (wa). When GDM was diagnosed (fasting plasma glucose (FPG) > or = 95 mg/l and/or 2h post-load (PLG) > or = 140 mg/l), women had an intensive management including dietary advice, glucose self-monitoring and insulin therapy as necessary.
Results: GDM was screened at mean term of 27 wa. Prevalence of GDM was increased from 2,98 % to 7,78 % (n = 157). Mean age was 32 years (20 - 45). Mean preconceptional BMI was 25,8 kg/m² (16,8 - 44,6) but above 27 kg/m² in 38,2 % of patients. Insulin was initiated in 21 % (n = 33). Delivery occurred at 39 wa (32-42), spontaneous in 58 %. Caesarean section rate was 26,8 % (vs 19,2% in global population). Prematurity rate (under 37 wa) was 10,8 %. Mean birth weight was 3218 gr (1640-5120). Macrosomia was present in 5,7 % (birth weight (BW) > or = 4000 gr) and in 8,3 % (BW > or = 90th percentile for a standard French population). No major neonatal event was reported.
Insulin therapy was more frequent in patients with BMI > or = 27 kg/m² and/or FPG > or = 95 mg/l (p < 0,001) and was associated with higher rates of macrosomia (RR = 5,2; p = 0,006) and caesarean section (RR = 3,5; p = 0,003). Labor induction was most frequent in insulin treated GDM and induced caesarean section in 20 %.

	GDM with insulin therapy	**GDM without insulin therapy**	p
Percentage	21 %	79 %	< 0,01
Mean BMI (kg/m²)	**30,3 ± 6,9**	**24,5 ± 4,7**	< 0,001
BMI ≥ 27 kg/m²	**66,7 %**	**30,6 %**	< 0,001
FPG (mg/l)	100 ± 21	85 ± 12	< 0,001
2h PLG (mg/l)	176 ± 45	153 ± 21	< 0,001
BW > 90th perc.	**21,2 %**	**4,8 %**	< 0,001
BW < 10th perc.	12,1 %	14,5 %	NS
Global caesarean section rate	**48,5 %**	**20,9 %**	< 0,001
Primary caesarean section rate	24,2 %	12,1 %	< 0,001
Labor induction rate	**91 %**	**29 %**	< 0,001

Preconceptional BMI above 27 kg/m² was only associated with higher rate of insulin therapy (OR = 4,48; p or = 95 mg/l was associated with higher rates of insulin therapy (OR = 4,26; p < 0,001) and caesarean section (OR = 2,43; p = 0,02); no correlation was found between FPG or preconceptional BMI and macrosomia.
34 % of patients had no risk factors for GDM and were characterized by lower glycemia levels (mean FPG 83 mg/l; mean 2h PLG 151 mg/l), lower BMI (21,2 kg/m²) and lower rates of insulin therapy (7,1 %), caesarean section (17,8 %) and macrosomia (3,6 %).
Conclusion: Intensive management of GDM is efficient but leads to a high rate of caesarean section. Preconceptional weight excess and FPG appear as prognostic factors of obstetrical outcomes. It is not obvious that intensive management of GDM impacts obstetrical prognosis of women without risk factors, who are characterized by lower glycemia levels. This should trigger reflection on diagnostic thresholds and therapeutic intervention strategy.

1183

Maternal and foetal outcomes of gestational diabetes in a tertiary hospital Sri Lanka
T.D. Hewawasam[1], P. Katulanda[2], A. Rathnapala[3], H. Senanayaka[2], S.B. Uduwerella[1], A. Fernando[1], A. Abeysinghe[1];
[1]General Hospital, Badulla, [2]Faculty of Medicine, Colombo, [3]Colombo South Teaching Hospital, Colombo, Sri Lanka.

Background: Maternal and foetal outcomes of gestational diabetes mellitus (GDM) in peripheral hospitals in Sri Lanka are not well documented.
Materials and methods: This case control study was conducted in an antenatal clinic from 1st of February 2008 to 31st January 2009. Objectives of the study are to describe the underlying socio-demographic factors of GDM and to determine the maternal and foetal outcomes of GDM at Provincial General Hospital (PGH), Badulla, Sri Lanka. Cases were women with singleton pregnancy and GDM according to the WHO criteria. Controls were age, BMI and parity matched women with singleton pregnancy with no GDM. GDM was diagnosed using a 75g OGTT when plasma glucose was >140mg/dl in 50g glucose challenge test (GCT) at one hour.
Results: 87 women out of 7934 (1.1%) had GDM. Mean age of those with GDM was 31.6 years. 65.6% of cases had a Body Mass Index over 23. There was no difference in the income between cases and controls (p=0.745).Polyhydramnios was seen in 16.9% of cases vs. 3.6% of controls (p=0.05). Caesarean sections were carried out in 67.5% of cases and in 62.5% of controls (p=0.515). Temperature more than 98.4^{0}F was seen in 3.6% of cases and 9.6% of controls (p=0.119). Vaginal candidiasis was seen in 4.8% of cases and 6% of controls (p=0.732). Urinary tract infection and pre term labour were equally present in cases and controls, 3.6% and 6% respectively. No birth traumas were reported.Neonatal hypoglycaemia was reported in 4.8% of cases but not in controls (p=0.043).Two still births were reported in the cases while one was reported in the controls (p=0.56). Birth weight more than 3.5Kg was reported in 12% of cases and 3.6% of controls (p=0.043). Congenital anomalies were reported as 1.2% both in cases and controls. Neither neonatal deaths nor shoulder dystocia were reported.
Conclusion: In this hospital based population from peripheral Sri Lanka, the prevalence of GDM (1.1%) was lower than that shown in the studies from urban or semi-urban areas (5.5 - 8.4%). Polyhydramnios, birth weight >3.5kg and neonatal hypoglycaemia were found significant in this study.Caesarean sections, Temperature >98.4F, Vaginal candidiasis, Urinary tract infection, pre term labour were not significantly associated with GDM as maternal outcomes. Congenital anomalies, shoulder dystocia, still births, neonatal deaths, were also not significantly associated with GDM pregnancies compared to the others as Foetal outcomes. These findings are useful in establishing national policies on screening for GDM.

1184

Metabolic syndrome and adiponectine in women with prior gestational diabetes
M. Carrasco, O. González-Albarrán, G. Pérez, A. Paniagua, J. Gómez, S. Calvo;
Endocrinology, Hospital Ramón y Cajal, Madrid, Spain.

Background and aims: Women with prior gestational diabetes mellitus (pGDM) are at increased risk of developing type 2 diabetes and associated vasculopathy. The relationship between insulin sensitivity, parameters of subclinical inflammation, and plasma concentrations of adipocytokines was investigated in pGDM both at 3 months and 12 months after delivery
Materials and methods: We prospectively studied 198 women with pGDM .According to OGTT, we divided into two groups: pGDM with normal glucose tolerance post-partum (NG) (66,8%) and pGDM with abnormal glucose tolerance post-partum (AG) (33,2%). Insulin sensitivity was derived using HOMA. Metabolic syndrome (MS) was defined by ATP-III We collected obstetric history, personal history of pGDM and personal and family history of cardiovascular risk factors Plasma concentrations of ultrasensitive C-reactive protein (CRP), adiponectin, and leptin were measured
Results: The mean age was 33,45 ± 4,5 yrs.; 26,25% smoking, 15,6% history of dyslipemia, 30% had history of previous abortions. 62,34% of women had first-degree relatives with type 2 DM and 59,25% had family history of hypertension The prevalence of MS was higher (32,3%) in AG group than in NG (14,7 %); p<0.005. In addition, AG group had higher values of BMI and WC vs. NG group (28,86 ± 4,5 vs 22,70 ± 3,1 Kg/m²; p<0.005 and 93,76 ± 6,1 vs 80,34 ± 4,6; p<0.05, respectively) . Fasting glucose and 2h-glucose levels

were higher in AG group than NG (98,85 ± 7,7 vs 80,2 ±5,6 mg/dl, p<0.005 and 166,57± 23 vs 119,4 ± 20 mg/dl). Fasting insulin and HOMA values were significantly higher in AG than NG; p<0.005. AG showed lower (P < 0.0001) plasma adiponectin (5.8 +/- 0.2 microg/ml) than NT (8.9 +/- 0.6 microg/ml) and a decreased (P < 0.003) but increased plasma leptin (P < 0.003) and CRP (P < 0.03). adiponectin correlated positively with HOMA (P < 0.003) and HDL cholesterol (P < 0.0001) but negatively with plasma glucose (2-h oral glucose tolerance test [OGTT]) (P < 0.0001), leptin (P < 0.01) and CRP (P < 0.007). In addition, AG group presented a higher prevalence of family history of type 2 DM (68,7% vs 48%, p<0.01)

Conclusion: Women with pGDM have a high prevalence of abnormal glucose tolerance and MS and lower values of adiponectin, particularly those with AG.. Thus women with pGDM and family history of type 2 DM may be especially suitable interventions aimed at preventing or reducing type 2 DM and probably cardiovascular events.

1185

Glycaemic variability and foetal growth in diabetic pregnancy

A. Lapolla[1], M. Dalfrà[1], G. Di Cianni[2], R. Marchetti[3], G. Sartore[1], G. Mello[4];
[1]Medical and Surgical Sciences, University of Padova, [2]Endocrinology and Metabolic Disease, University of Pisa, [3]Teseo srl, Pisa, Italy, [4]Gynecology Perinatology and Human Reproduction, University of Firenze, Italy.

Background and aims: Fetal overgrowth is the most important complication of diabetic pregnancies (gestational (GDM) and pregestational (preGDM)). Aim of the study was to evaluate the relationship between glycemic profile, detected with continuous glucose monitoring (CGM), (Glucoday, Menarini Diagnostic, Firenze, Italy) and parameters of fetal growth

Materials and methods: 80 pregnant women (32 with preGDM, 31 with G DM, 17 with normal glucose tolerance (NGT)) were evaluated. PreGDM women measured glucose profile by CGM at the first, second and third trimester of pregnancy, GDM and NGT women at the second and third trimester.As for mothers, age, prepregnancy BMI, HbA1c and glucose monitoring were recorded. As for newborn, birth weight, ponderal index (gr/cm^3), large± for gestational age (LGA) parameters were recorded.

Results: Mean age was 33± 6 yrs for preGDM, 35± 4yrs for GDM, 33±5 yrs for NGT women, prepregnancy BMI was respectively 29± 3, 26± 4, 21± 4; HbA1c were 6.8± 1.2 %, 7.2± 1.1%, 6.0± 0.8 % for preGDM at each trimester, 5.2 ± 0.5%, 5.5± 0.4%, for GDM at second and third trimester. As for fetal growth, mean birtweigth was 3096 ±583 in preGDM, 3240± 582 for GDM, 3142± 386 for NGT; ponderal index was 2.88 ± 0.9 in preGDM, 2.61± 0.6 in GDM and 2.46± 0.4 in NGT . As for glycemic variability, we took into consideration MAGE (mean amplitude of glycemic excursion) and M-value (a quantitative index od the deviation of blood glucose determination in 24 hrs period from an arbitrariluy selected standard). M-value, at the third trimester, was related to birth weigth in NGT(p=0.05), furthermore M-value was related to birth weigth and ponderal index at the second trimester in preGDM patients (p=0.04, p=0.018 respectively),MAGE at the second trimester was related to birth weigth in GDM (p= 0.05).

Conclusion: Our data show that glycemic variability evaluated by M-value and MAGE is important in determining fetal overgrowth, suggesting that the second trimester of pregnancy in diabetic women is critical for fetal growth and so a good metabolic control needs to be obtained in this period in order to normalize fetal weigth.

1186

Impact of incidental use of oral antidiabetics on pregnancy outcome

F.M.A. Fawzy, G. Saeed;
Internal Medicine, Zagazig University, Faculty of Medicine, Diabetes & Endocrinology Unit, Zagazig, Egypt.

Background and Objectives: Except for patients with Polycystic Ovary Syndrome who are continued on metformin even after getting pregnant, other oral antidiabetic agents are not advised during pregnancy. Because of obvious ethical considerations a prospective controlled study of oral antidiabetics during pregnancy can not be conducted in humans. In this pilot study we followed 93 pregnant diabetic women who continued to use their oral medications for variable periods of time before realizing they were pregnant. Once pregnancy was confirmed, they were shifted to standard therapy with diet and/or insulin.

Subjects and methods: The study included 93 diabetic ladies with type 2 diabetes mellitus.Their ages ranged from 26 to 41 years with a mean ± SD of 37±7.9 years. The mean duration of oral antidiabetic use before shift to other treatment modality ranged from 2 weeks to 2 months. The oral antidiabetic medications used were metformin in 89 patients (95.7%), one of the sulphonyl ureas (glibeneclamide, glimepride or gliclazide) in 67 patients (72%), acarbose in 4 patients (4.3%) and thiazolidinediones (TZD's) in 6 (6.5%) of the study group (4 on pioglitazone and 2 on rosiglitazone). Concomitant use of other medications was recorded in 7 patients who received antihypertensive drugs and 5 patients who received antacids for heartburn. SMBG, frequent oral and post-prandial plasma glucose measurements or glycated hemoglobin level determination were used to asses the degree of diabetes control during pregnancy.

Results: 81patients (87%) were able to reach full term, while 12 patients (13%) had abortions or miscarriages. Normal vaginal delivery was possible in 21 patients of those who completed their pregnancy (25.9%), while 60 patients (74.1%) were delivered by elective CS. Maternal complications in the form of toxemia of pregnancy was recorded in eight patients (8.6%). Regarding fetal complications, macrosomia or large for gestational age weight at birth was recorded in 23 newborn infants (28.4%) and gross fetal anomalies diagnosed immediately after birth were found in 7 of the newborn babies (8.6%).In this latter group two of them were born to mothers who used TZD's in their 1st trimester (one was using rosiglitazone and another was using pioglitazone). The majority of the newborn babies required glucose infusion post-natally to correct for hypoglycemia. Regarding the degree of control of the diabetic state, the mean glycated hemoglobin level was 8.7% on booking to the clinic, 6.3 % at the end of the 1st trimester, 7.2% at the end of the 2nd trimester and 7.1% at the end of the 3rd trimester.

Conclusion: Except for probably thiazolidinediones, the use of oral hypoglycemic agents, specially metformin and SU's may be safe during pregnancy. However cumulative experience from different centers should be collected and carefully analyzed before reaching a solid conclusion.

1187

Short acting insulin analogues versus regular human insulin in women with gestational diabetes - patient-relevant outcomes: systematic review

E. Matyas[1], K. Horvath[1,2], K. Jeitler[1,3], K. Koch[4], U. Püringer[1], S. Lange[4], A. Siebenhofer[1,5];
[1]Department of Internal Medicine, EBM Review Center, Medical University of Graz, Graz, Austria, [2]Division of Endocrinology and Nuclear Medicine, Department of Internal Medicine, Graz, Austria, [3]Institute of Medical Technologies and Health Management, Joanneum Research Forschungsgesellschaft mbH, Graz, Austria, [4]Institute for Quality and Efficiency in Health Care, Cologne, Germany, [5]Institute for Medical Informatics, Statistics and Documentation, Medical University of Graz, Graz, Austria.

Background and aims: Gestational diabetes mellitus (GDM) is associated with risks of complications during pregnancy and birth. A therapy with insulin is recommended as a therapy option for possibly lowering these risks. Short acting insulin analogue use for diabetic patients is still controversial. Therefore, possible beneficial effects of short acting insulin analogues (SA-I) compared to human insulin (HI) on maternal and perinatal patient-relevant outcomes were evaluated.

Materials and methods: To assess the effects of SA-I in gestational diabetes, a systematic literature search was conducted in 18 databases up to 10/2008 for controlled clinical trials (CCTs) and randomized controlled trials (RCTs). Trial selection and evaluation of study quality were carried out independently by two reviewers. A systematic review was performed.

Results: In 3 RCTs fulfilling our inclusion criteria 134 subjects were included. For 2 studies the intervention was a therapy with Insulin Lispro (IL) and for 1 trial with Insulin Aspart (IA), both in comparison to HI. In terms of the methodological quality all 3 studies were classified as having a high risk of bias. The differences in HbA1c-values between treatment groups were not statistically significant at any time. The incidence of a caesarean section delivery was similar in SA-I and HI. Findings on maternal hypoglycaemia, reported in 2 studies for the intervention with SA-I, were conflicting: While in one study for the HI-group they were higher, they were lower in the other trial. Maternal hyperglycaemic episodes were reported only in one study and indicated a statistically significant difference (IL: 4.0 vs. HI: 5.5, p=0.019). 1 perinatal death occurred in the IA-group and 2 children with malformations were identified in the HI-group of the same trial. In 2 studies no children were classified as being large-for-gestational-age (LGA), in the third the incidence of this outcome was not statistically significant. Data for perinatal hypoglycaemic events was found only in Jovanovic 1999 (IL: 0% vs. HI: 0%).

Conclusion: Based on this data, there is no evidence that SA-I have benefits with regard to maternal and perinatal outcomes compared to HI when it comes to the therapy of GDM. To answer this question and to evaluate safety more evidence on patient-relevant outcomes is urgently needed.

Results of SA-I vs. HI

Maternal outcomes		**Jovanovic** 1999[a] (n=42)	**Mecacci** 2003[a] (n=65)	**Pettitt** 2007[b] (n=27)

PS 109 Pregnancy - complications

1188

Pregnancy and type 1 diabetes: St Vincent declaration 20 years later, an alarming observation

M. Floriot[1], G.-A. Séry[1], C. Langbour[2], O. Ziegler[3], P. Judlin[1];
[1]Maternité Régionale, [2]Endocrinologie, Centre Hospitalier Universitaire, [3]Diabétologie - Maladies Métaboliques, Centre Hospitalier Universitaire, Nancy, France.

Background and aims: In 1989, the St Vincent's declaration stated that the outcome of diabetic pregnancy should approximate the one of non diabetic pregnancy within 5 years. What is the situation 20 years later ?
Materials and methods: We conducted a retrospective study in a French regional university maternity on the outcomes and management of 117 pregnancies between 2000 and 2007. These 117 pregnancies occurred among 85 diabetic women (maternal age = 29.6 ± 5.4 years, diabetes duration = 14.4 ± 7.0 years, pregestational BMI = 24.1 ± 4.0 kg/m^2, preconceptional HbA1c = 8.1 ± 1.7 %). The data were compared to the results of the 2003 French perinatal survey.
Results: 100 births were reported. There were 19 spontaneous abortions. A preconception care program was implemented in only 42% of the pregnancies. Gestational hypertension or pre-eclampsia occurred in 22.2% of the women (6.1% in the general population). Perinatal mortality (4.3%), severe congenital malformations (3.9%) and prematurity (37%) were above corresponding rates in the general population (respectively 0.7%, 2.2%, 7.2%). Caesarean section rate was increased 2.5-fold in diabetic women (54 vs 20%). A preconception HbA1c level < 7% (26.2% of the pregnancies), was associated with a significant reduction in preterm delivery (p=0.05). This level of blood glucose control depended mostly on the implementation of a preconception care program.
Conclusion: Twenty years after the St Vincent declaration, pregnancies in patients with Type 1 diabetes remains at high risk (perinatal mortality x 6, prematurity x 5, vascular complications x 3.6, caesarean section x 2.5, severe congenital malformations x 2).
The implementation of a preconception care program remains insufficient despite the knowledge of the risks and the availability of means to reduce the obstetrical and neonatal complications. The reasons for this insufficient preconception care remain partially unknown. Counselling women with Type 1 diabetes before conception is essential. They should be provided with a management plan that will help them to live a nice pregnancy.

1189

Prognostic importance of the intensive diabetes mellitus control prior to conception and pregnancy for mother and child

J. Taton[1,2], A. Czech[1], I. Raźna[1], M. Mironiuk[1], M. Bernas[1];
[1]Chair and Department of Internal Diseases and Diabetology, Warsaw Medical University, [2]Chair and Department of Internal Diseases and Diabetology, Warsaw, Poland.

Background and aims: Therapeutic "near normalization" of metabolism and of clinical status positively influence in a specific way many life functions of the person with diabetes mellitus. It could be assumed, that it involves also the complex factors of the reproduction in women with diabetes mellitus type 1: 1) early in the preconception and conception and 2) later during pregnancy periods. The application of the intensive therapy in the early (1) period has the preventive influence and is connected with planning the pregnancy. Intensive therapy applied during already existing pregnancy comes too late, is less effective in shaping the prognosis for mother and child. In order to examine this thesis the study involving both types of intervention time was executed.
Materials and methods: In Diabetological-Obserical Centre based on close cooperation between both sides - diabetological and obstetrical - of care the cohort at 118 women with diabetes mellitus type 1 was formed. They did not present any of organ complications of diabetes mellitus beside simple retinopathy (class B, C and D). This cohort underwent the routine clinical examination and entered the study program. The cohort was subdivided into 2 subgroups:1) 31 women planning conception and pregnancy - the preventing subgroup and 2) 88 women already pregnant in a non-planned group - the late intervention subgroup. They were similar in typical clinical parameters - age, BMI, absence of additional diseases and therapies, smoking and behavio-

ral parameters. In both subgroups the intense metabolic and clinical therapy program was applied. All women in the planning group become pregnant after - in average - 1 year of the program and continued it during pregnancy according to the study protocol.
Results: Diabetological data - mean values of HbA1c in consecutive trimesters were statistically lower in the group planning the pregnancy than in the non planning group (6,4%, 5,84%, 5,67% vs 7,0%, 6,33%, 6,28%; p<0,05, p<0,05 i p<0,001). There were also significant differences in the general clinical parameters like number of hyperglycemia episodes, blood lipids concentration and in compliance behavior. 8 put of 9 cases of the worsening of retinopathy occurred in the non-planning - late intervention subgroup. Obstetrical data.1) Late intervention (non-planning) subgroup: in 88 women occurred 2 spontaneous abortions, in 86 delivered children 8 had major congenital abnormalities. The early (1 month) death rate of children in this group was 3,4%. This was accompanied by the Hb1c average level of 8.23%. Planning, preventive subgroup: no spontaneous abortions or congenital malformations occurred. The average HbA1c level was 6,92% (p<0,01). Early death at children was not observed.
Conclusion: Planning the fertilization and pregnancy enabling the introduction of intensive metabolic and clinical therapy in average 1 year before conception significantly improves the metabolic and clinical parameters of diabetes control. It is correlated with the decrease of the risk of worsening of retinopathy, spontaneous abortion and congenital malformations. The preconceptional intensive therapy program applied in average 1 year before pregnancy is effective in improving the prognosis for mother and the child.

Pregnancy-induced increase in IGF-I is associated with progression of diabetic retinopathy
L. Ringholm Nielsen[1], M. Vestgaard[1], C.S. Laugesen[2], A. Juul[3], P. Damm[4], E.R. Mathiesen[1];
[1]Endocrinology, [2]Ophtalmology, [3]Growth and Reproduction, [4]Obstetrics, Rigshospitalet, Faculty of Health Sciences, Copenhagen, Denmark.

Background and aims: To evaluate the influence of Insulin-like Growth factor-I (IGF-I) and placental growth hormone on progression of diabetic retinopathy during pregnancy in women with type 1 diabetes.
Materials and methods: Prospective study of 94 consecutively included pregnant women with type 1 diabetes for median 16 years (range 1-36) and median HbA_{1c} 6.7% (range 5.2-10.5) in early pregnancy. At 8, 14, 21, 27 and 33 gestational weeks blood samples were drawn for IGF-I, placental growth hormone and HbA_{1c} analyses and blood pressure was recorded. Fundus photography was performed at 8 and 27 weeks. Diabetic retinopathy was classified in five stages. Progression was defined as at least one stage of deterioration of retinopathy and/or development of macular oedema on at least one eye and/or loss of visual acuity ≥0.2 on Snellen's chart.
Results: Placental growth hormone and IGF-I increased throughout pregnancy and progression of diabetic retinopathy occurred in 24 (26%) women. In a multivariate logistic regression analysis, progression of diabetic retinopathy was associated with a steeper increase in IGF-I levels from 8 to 33 gestational weeks (p=0.02) and higher systolic blood pressure at 8 gestational weeks (p=0.01) independent of placental growth hormone and HbA_{1c} levels. At 8 gestational weeks IGF-I levels were comparable in women with and without progression (p=0.40). However, the steeper increase resulted in 11% higher IGF-I levels (p=0.049) throughout pregnancy in women with progression compared with women without progression while similar levels of placental GH (p=0.70) and HbA_{1c} (p=0.74) were observed.
Conclusion: Pregnancy-induced increase in IGF-I levels is associated with progression of diabetic retinopathy independent of changes in HbA_{1c}.

1191

Prevalence and progression of diabetic retinopathy during pregnancy in women with type 2 diabetes
K.L. Rasmussen, C.S. Laugesen, L.R. Nielsen, P. Damm, E.R. Mathiesen;
Center for Pregnant Women with Diabetes, Departments of Endocrinology, Obstetrics and Ophthalmology, Rigshospitalet, Faculty of Health Sciences, University of Copenhagen, Denmark.

Background and aims: To study the prevalence and risk of progression of diabetic retinopathy during pregnancy in women with type 2 diabetes.
Materials and methods: In 80 out of 108 (74%) consecutively referred pregnant women with type 2 diabetes retinopathy status was available. Fundus photography was performed at median 10 (range 6-21) and 28 (27-37) gestational weeks. Diabetic retinopathy was classified in five stages. Progression was defined as at least one stage of deterioration of diabetic retinopathy and/or development of macular oedema on at least one eye between the two examinations. Significant loss of visual acuity was defined as a deterioration of ≥0.2 on Snellen's chart and macular oedema was defined as retinal thickening and/or hard exudates within the macula area of 1500 um in diameter. Clinical parameters were obtained from the medical records.
Results: Diabetic retinopathy was present in 11 (14%) women in early pregnancy, mainly mild retinopathy. Duration of diabetes was 3.7 years (3.3) (mean (SD)), HbA1c 6.6% (1.1), BP 121 (12) / 72 (9) mmHg in early pregnancy and 22 (28%) women were on insulin treatment prior to pregnancy. During pregnancy 74 (93%) were treated with insulin and 11 (14%) with antihypertensive treatment. At 34 weeks mean HbA1c was 5.7% (0.6%) and BP 124 (16) / 75 (9) mmHg. During pregnancy progression of diabetic retinopathy (including new-onset) was seen in 11 (14%) women. Mainly mild progression occurred (table 1), but one woman progressed in both eyes from mild diabetic retinopathy to sight-threatening proliferative retinopathy, clinical significant macular oedema and impaired vision. She had a diabetes duration of five years and became unplanned pregnant with a HbA1c of 13.2%, uncontrolled hypertension and proteinuria. Another woman developed preproliferative changes. Two cases with macular oedema in early pregnancy regressed during pregnancy. Women with progression of diabetic retinopathy during pregnancy were characterized by a longer duration of diabetes (p = 0.03), more prevalent insulin therapy prior to pregnancy (p = 0.004). At 10 weeks a higher HbA1c and a higher diastolic blood pressure in women with progression did not reach statistical significance (p = 0.13 and p = 0.12).
Conclusion: Despite a low risk of progression of retinopathy in pregnant women with type 2 diabetes, development of macular oedema with impaired vision and proliferative retinopathy did occur. Screening for diabetic retinopathy in pregnancy in women with type 2 diabetes should follow the recommendations for type 1 diabetes.

Stage of retinopathy for **every single eye** (n=160) in early and late pregnancy in 80 women with type 2 diabetes.

Eye examination at 28 weeks \ Eye examination early in pregnancy	No diabetic retinopathy	Mild NPDR	Moderate NPDR	Preproliferative NPDR	Proliferative diabetic retinopathy
No diabetic retinopathy	132	4	1	0	0
Mild NPDR	6	4	0	0	0
Moderate NPDR	7	0	3	0	0
Preproliferative NPDR	0	1	0	0	0
Proliferative diabetic retinopathy	0	2	0	0	0

NPDR = nonproliferative diabetic retinopathy.

1192

Preeclampsia; prevalence and risk factors in women with diabetes mellitus
A. Abd EL Rahman[1], A. Mc Carthy[1], R.G. Firth[1], S. Daly[2], B. Kinsley[1];
[1]Diabetes Mellitus/Endocrinology, Mater University Hospital, [2]Obstetrics & Gynaecology, Coombe Women University Hospital, Dublin, Ireland.

Background and aims: The rate of preeclampsia(PE) is 4-7% in non-diabetic subjects. The aims of this study are to determine the rate of preeclampsia in diabetic women and the association between preeclampsia and maternal age, parity, duration of diabetes and glycemic control, during the first trimester, in type 1 and type 2 Diabetes Mellitus (DM).
Materials and methods: Analysis of retrospectively collected data of 726 patients was performed. Patients were stratified according to the type of Diabetes they have. Those who are known to have hypertension or nephropathy were excluded from the analysis.
Results: A total number 619 women had type 1 DM while 107 had type 2 DM. Preeclampsia was diagnosed in 11.6%(72/619) and 13.1%(14/107)of women with type 1 and type 2 DM respectively.

PE found to be higher in younger women (P= 02), nulliparous women (P=0.0002) with type 1 DM. Women with type 2 DM were found to be older (P=0.04) and to be multiparous(P= 0.001) compared to those who did not have preeclampsia. Women with type 1 Diabetes Mellitus had higher fructoseamine (P=0.04) and higher insulin requirement (P=0.003) in the first trimester compared to those who did not have preecalmpsia. Women with type 2 DM had higher HbA1c% (P=0.03) than those who did not have preeclampsia. Duration of DM was not found to be associated with preeclampsia.
Conclusion: We concluded that the rate of preeclampsia in women with DM is double that of non diabetic women. Maternal age, parity and glycemic control, in the first trimester, are significant risk factors for the development of preeclampsia in women with DM

1193

Efficacy and safety of continuous subcutaneous insulin infusion therapy in pregnancy complicated by type 1 diabetes

K. Cyganek[1], A. Hebda-Szydło[1], B. Katra[1], T. Klupa[1], I. Kaim[2], J. Skupien[3], A. Reron[2], J. Sieradzki[1], M.T. Malecki[1];
[1]Department of Metabolic Disease, Jagiellonian University, Krakow, Poland, [2]Department of Obstetrics and Perinatology, Jagiellonian University, Krakow, Poland, [3]Joslin Diabetes Center, Harvard Medical School, Boston, United States.

Background and aims: Excellent glycemic control during pregnancy in women with type 1 diabetes (T1DM) is required to improve maternal and neonatal outcomes. Two regimes of insulin therapy are used to achieve this goal: multiple daily injections (MDI) and continuous subcutaneous insulin infusion (CSII). We report the results of a large, observational study that compared efficacy and safety of CSII and MDI in pregnant women with T1DM.
Materials and methods: From 2002 to 2008, we examined 255 women with T1DM. There were 147 subjects on MDI and 108 patients on CSII. The groups did not differ by age (mean 29.0±4.0 vs. 28.4 years±6.0; p=0.3, respectively) and duration of T1DM (mean 12.4±7.3 vs. 11.4±7.4 years; p=0.3, respectively). In 59.3% of CSII patients, pump therapy was initiated before the conception, while the rest underwent training and received the insulin pumps through the first trimester. We compared HbA1c level achieved by each treatment regimen, insulin dose, weight gain, birth weight, frequency of adverse pregnancy outcomes and number of C-sections. The estimated differences between treatment regimens were adjusted for baseline characteristics, such as age, diabetes duration, BMI and baseline HbA1c.
Results: The CSII did not differ from MDI by HbA1c in the 1st trimester (6.8% vs 6.9%, p=0.7). It similarly improved in both groups during 2nd and 3rd trimester to 5.8% (p=0.9). However, women on CSII gained more weight during pregnancy than those on MDI (14.5 vs. 12.5, p=0.002). There was no difference in duration of gestation and birth weights (38.2 weeks vs. 38.2 weeks, p=0.4; 3.46 kg for CSII vs. 3.47 kg, p=0.8, for CSII and MDI, respectively). Similarly, no difference occurred between CSII and MDI in Small for Gestational Age and Large for Gestational Age frequencies (6.7% vs. 9.0%, p=0.8 and 19.0% vs. 18.8%, p=0.3, respectively). The frequency of stillbirths and fetal malformations was similar in both groups (5.6% vs. 9.3%, p=0.7). The frequencies of C-sections did not differ significantly between the study groups (p=0.3).
Conclusion: In summary, both CSII and MDI can provide excellent glycemic control in pregnant women with T1DM, thus, limiting the risk of adverse pregnancy outcomes. This model, however, seems to predispose to a larger weight gain in mothers.

1194

Relationship between mean blood glucose values and HbA_{1c} in diabetic pregnant women

G. Papageorgiou, K. Makris, K. Economou, A. Athanasiadou, M. Alevizaki, E. Anastasiou;
Alexandra Hospital, Athens, Greece.

Background and aims: Previous studies have confirmed a close relationship between mean blood glucose (MBG) derived from self blood glucose measurements and HbA1c in patients with type 1 and 2 diabetes. Recently it was proposed (ADAG study) that HbA1c can be expressed as estimated average glucose values. The strength of this relationship during pregnancy is unclear due to various physiological changes. The aim of the study was to establish the strength of the association between MBG profiles in diabetic pregnancies and HbA1c at each trimester of pregnancy.
Materials and methods: In 42 pregnant women with type 1 DM a 7-point glycaemic profile (before and 1h after meals, and at bedtime) was performed daily throughout pregnancy with a portable glucose meter. Target BG values were: 70-90mg/dl before meals, 100-130 mg/dl after meals. To achieve this, intensified insulin therapy with frequent adjustments was applied. MBG of each trimester was correlated with HbA1c measured at the end of each trimester (HPLC Menarini-Arkray HA8160). The accuracy of self monitoring of glucose measurements was tested at hospital visits where each patient had simultaneous measurements of blood glucose by her portable meter and by the laboratory method (hexokinase). Their correlation was highly significant (r=0.9444, p<0.001).
Results: Mean HbA1c, MBG and number of self measurements at each trimester are shown in Table 1. The range of HbA1c values was 4.1-7.8%. In the 1st trimester a positive correlation was observed between MBG (y) and HbA1c (x), where: y= 12.57 x + 54.68 (r=0.522, p<0.001). In the 2nd trimester the correlation was y =14.75 x+41.41 (r=0.5834, p<0.001) and in the 3rd it was y=11.85 x+51.51 (r=0.531, p<0.001). These equations were different to the ADAG study. No correlation was found between HbA1c and MBG of pre- or post-meal measurements.
Conclusion: The relationship between MBG and HbA1c in pregnant women with pre-existing diabetes differs significantly from that of non-pregnant diabetic subjects, as observed in the ADAG study. Possible explanations were that pregnancy is not a glucose stable state, also the range of HbA1c observed in pregnancy was narrower than in non-pregnancy, and finally the physiological changes per se that occur in pregnancy.More data are needed to confirm these findings.

Table1. Mean HbA1c, MBG and Self-Measurement

	MBG (mg/dl)	BG Measurements	HbA1c (%)
	x±SD	n	x±SD
1st Trimester	129 (19.3)	343	5.9 (0.8)
2nd Trimester	120 (16.0)	686	5.3 (0.6)
3rd Trimester	114 (14.2)	441	5.3 (0.6)

1195

A real-time continuous glucose monitoring for diabetic women during the delivery

A. Ghio, C. Lencioni, F. Romero, F. Pancani, A. Bertolotto, M. Aragona, S. Del Prato, L. Volpe, G. Di Cianni;
Departement of Endocrinology and Metabolism, Section of Diabetes, University of Pisa, Italy.

Background and aims: Optimal maternal glucose control before and during delivery is recommended to avoid neonatal hypoglycaemia in newborns of diabetic mother. This can be prevented by frequent measurements of maternal glycaemia and coordinated glucose/insulin infusion. Continuous Glucose Monitoring (CGM) allows time-to-time glucose assessment and, therefore, it may provide a better opportunity for maternal glycaemic control at delivery. The aim of this study was, then, to evaluate CGM efficacy during the delivery on maternal glucose control and on the prevention of neonatal hypoglicaemia.
Materials and methods: We studied 13 diabetic women treated with intensive insulin therapy (DM1: n 8, DM2: n 2 and GDM: n 3), undergoing delivery with elective C-section (CS). In all women CGM (GUARDIAN®) was applied 24 hours before delivery. On the morning of the CS a dual channel infusion pump started for intravenous infusion of 5% dextrose and insulin (0.5 UI/ml). To achieve the glycaemic target (90-120 mg/dl), infusions were adjusted by predefined algorithms (ADA recommendations 2008) based on the glucose values registered by CGM.
Results: Average delivery time was 36±1 weeks of gestation, six women having preterm delivery. Mean glucose values at 24, 8 and 1 hours before delivery were 119±14, 115±22 and 108±11 mg/dl, respectively. At birth time maternal glycaemia was 103±19 mg/dl and 1 and 2 hours after the delivery increased to 110±29 and 143±35 mg/dl, respectively. All babies were alive with birth-weight of 3203±406 g.(3 newborns were LGA) with Apgar at 5' of 8.8. Neonatal hypoglycaemia (<30 mg/dl 1h after birth time) occurred in 2 cases (both in preterm newborns). The neonatal plasma glucose value at 60' after the birth (37±6 mg/dl) was inversely related to maternal glucose levels at 24, 8 and 1 hours before the delivery and at birth time (all the p<0.01). After multivariate analysis, only the maternal glicaemia at birth time remains independently correlated with the neonatal glycaemia (F test = 20.4%; p<0.01)
Conclusion: This observation, although limited, support the possibility that common use of CGM during the delivery may help to control maternal glycemia and prevent neonatal hypoglicaemia.

PS 110 Intrauterine development and observations in children

1196

Maternal undernutrition during the first half of gestation accelerates the age-related insulin resistance, and promotes hepatic lipid deposition in the adult offspring in a sex-specific manner

M.P. Ramos Alvarez, J. Sevillano, M. Limones, J. de Castro, J. Marciniak, E. Herrera;
Biochemistry, Molecular and Cellular Biology, Faculties of Pharmacy and Medicine, University CEU San Pablo, Madrid, Spain.

Background and aims: Epidemiological studies have linked low birth weight with the risk of a number of chronic diseases in adulthood. In this context, it has been proposed that intrauterine malnutrition enhances the risk to develop diabetes in later life. Since the accumulation of fat depots in maternal tissues takes place during early pregnancy, we hypothesized that it may play a key role in the availability of nutrients to the foetus with long-term consequences. Thus, the aim of this work was to determine whether an impairment of the mother to build up fat depots during early pregnancy would affect lipid metabolism, and alter the glucose/insulin axis in adult offspring.
Materials and methods: From mating, one group of pregnant rats was fed ad libitum (controls, C) whereas another group was allowed to eat 60% the amount fed by C until day 12 of pregnancy (underfed, U). From this time on, all the animals were fed ad libitum. During lactation, litters were adjusted to 9 pups per dam and they were weaned at 21 days of age. From this time to 19 months age (19 m), body weight and biochemical parameters were determined. At different ages, insulin sensitivity index (ISI) was quantified by means of glucose and insulin values in OGTT. Insulin-stimulated phosphorylation of the insulin receptor was analyzed in adipose tissue of 4 m old pups as index of tissue insulin sensitivity. Hepatic lipid content and the expression and activity of enzymes involved in lipid synthesis were analyzed in 19 m old pups.
Results: At 12 d of pregnancy, lumbar adipose tissue of U mothers weighed less than C. When compared to the C group, newborns of U dams had lower body weight, this effect disappeared at weaning. The ISI values appeared lower in 4 m old males than in females and whereas it was even lower in U males than in C pups, with no difference between U and C in females. At this age, the insulin-stimulated Tyr-phosphorylation of the insulin receptor in adipose tissue was also lower in male U than in C, whereas no difference was found in the females. Values of ISI declined faster with age in males than in females and at 8 m of age, in both males and females, were lower in U than in C pups. The lowest ISI was found in pups from 15 m of age, with no difference between U and C groups of either gender. At 19 m lipid accumulation in liver was higher in the females offspring of the U mother, due to a higher accumulation of TG and NEFA. By the contrary, no change, or even a decreased in Cholesterol and NEFA, was observed in the hepatic lipids in the U males. This gender-specific lipid deposition in the liver seems to be caused by the delay in the age-dependent decrease of ISI in U females vs. males, causing a differential modulation of mRNA/protein expression and activity of AMPK, ACC and other enzymes involved in hepatic lipid metabolism in males and females.
Conclusion: Maternal undernutrition during the first half of pregnancy impairs the accumulation of maternal fat depots and compromises normal foetal growth, which permanently alters insulin/glucose relationships in the offspring, accelerating the age-related deterioration of insulin sensitivity, appearing the effect earlier in males than in females. Furthermore, this nutritional alteration in the mother favours liver steatosis in female but not in male offsprings later in life.

Intrauterine milieu influences the mRNA expression and the wiring of anorexigenic POMC cells in the arcuate nucleus of offspring from diabetic and/or obese dams in mice

B. Sarman[1], Z. Liu[1], E. Borok[1], M. Shanabrough[1], J. Bruening[2], X. Gao[1], T. Horvath[1];
[1]Obstetrics, Gynecology and Reproductive Sciences, Yale University School of Medicine, New Haven, United States, [2]Mouse Genetics and Metabolism, University of Cologne and Center of Molecular Medicine, Cologne, Germany.

Background and aims: We tested how altered perinatal metabolic milieu due to maternal hyperglycemia/obesity influences 1) the phenotype of offspring and 2) the wiring and mRNA expression of POMC (pro-opio-melanocortin) cells in the arcuate nucleus.
Materials and methods: We placed 8-week old females on high fat (HF) or low fat normal diet (ND). When body weights (bw) and glucose levels were different ($p < 0.005$) females were set up as breeders. Offspring's bw, POMC-mRNA, glucose and insulin levels were monitored. At day 21, mice were processed for synaptic analysis of POMC. mRNA were collected at birth and 21 days. At weaning progeny were placed on ND and followed for 18 weeks.
Results: At birth the body weights of all groups were similar (no gender differences). After postnatal day 10, both males and females of HF mothers weighed more than those from ND during lactation. After weaning bw difference diminished and remained indistinguishable. After birth POMC-mRNA levels of HF mothers' offspring were lower than ND counterparts. Blood glucose of newborn pups of HF mothers, was significantly lower than that from ND dams, that difference diminished at day 21 however both males and females of HF mothers had significantly higher insulin levels than the ND offspring. The POMC expression did not differ significantly between male groups, but there was a significantly lower POMC mRNA expression in female newborn pups of HF mothers. Synaptic input organization of POMC neurons of 21-day-old mice from HF mothers were different from that of ND-mice: inhibitory synapses shifted towards excitatory contacts corresponding with electrophysiology. At 21 days, male mice from HF diet mothers had a higher POMC mRNA concentration, but the difference is not significant. In female mice, there seems to be no difference between the two groups, however the percentage growth of POMC mRNA from newborn age is bigger in the HF group. At day 144, POMC cells number and volume was smaller in HF mothers' offspring than in ND counterparts.
Conclusion: Synaptic input organization of the POMC cells is altered in offspring from obese, diabetic mothers, suggesting that increased excitatory input on POMC cells might be due to their altered number and function. This might contribute to diet induced obesity later in life. The body-weight changes, however, showed that overfeeding of mothers does not result in obesity of offspring while they are on ND. POMC mRNA expression is decreased in newborn female pups from HF/diabeitc mothers which may indicate a gender specific sensitivity to the intrauterine milieu and/or the different effect of female and male hormones on the development of the melanocortin system under altered intrauterine conditions. The POMC cell number and volume differences found at older age might indicate the long term effect of these early intrauterine conditions.

FTO is expressed in human placenta and is related to birth weight and placental visfatin

J. Bassols[1], A. Prats-Puig[1], M. Martínez-Pascual[2], P. Avellí[2], R. Martínez-Martínez[2], M. Gifre[2], M. Piqué[2], M. Bruel[2], J. Reid[2], L. Ibáñez[3,4], A. López-Bermejo[1];
[1]Pediatrics, Dr. Josep Trueta Hospital, Girona, [2]Obstetrics and Gynecology, Salut Empordà Foundation, Figueres, [3]Pediatric Endocrinology, Sant Joan de Déu Children's Hospital, Barcelona, [4]CIBERDEM (Center for Network Biomedical Research in Diabetes and Related Metabolic Diseases) ISCIII, Madrid, Spain.

Background and aims: The fat mass and obesity associated gene (FTO) has been found to contribute to obesity risk in adult subjects. The loss of the FTO gene in mice leads to postnatal growth retardation and to a significant reduction in fat and lean mass. Visfatin, a newly described adipokine, is strongly expressed in fetal membranes. In adipose tissue, the expression of visfatin correlates with that of FTO gene. Our aim was to assess whether the FTO

gene is expressed in human placenta and whether it correlates with fetal growth and placental visfatin.
Materials and methods: Human placentas from 83 Caucasian women with uncomplicated pregnancies were obtained at delivery after informed consent. Clinical variables of the newborns were assessed. FTO, visfatin and housekeeping genes (TATA box binding protein and Succinate dehydrogenase complex, subunit A) were quantified in placental tissue by real-time PCR using TaqMan probes. A relative quantification was used using the delta-delta Ct formula.
Results: FTO was highly expressed in human placenta and was independently and directly related to newborn's weight and length (both $p<0.001$) and to the fetal-to-placental weight ratio ($p<0.05$). FTO gene expression was also directly related to visfatin gene expression ($p<0.0001$).
Conclusion: For the first time to our knowledge, we describe that the FTO gene is expressed in the human placenta and is directly associated with measures of fetal growth and to placental visfatin expression. The role of the FTO gene in the regulation of body weight is herein suggested to include prenatal development.

Maternal fatty acid status during pregnancy and risk of type 1 diabetes in the offspring
I.M. Sørensen[1], G. Joner[1], P.A. Jenum[2], A. Eskild[3], L.C. Stene[4];
[1]Dep. of Pediatrics, Oslo University Hospital, Ullevål, Oslo, [2]Dep. of Microbiology, Asker and Bærum Hospital, Bærum, [3]Dep. of Obstetrics and Gynecology and the Medical Faculty Division, Akershus University Hospital, University of Oslo, [4]Division of Epidemiology, Norwegian Institute of Public Health, Oslo, Norway.

Background and aims: A recent prospective study found that n-3 fatty acids in the diet and in membranes of red blood cells of children predicted a lower risk of islet autoimmunity, and we have previously found an association between use of cod liver oil by the mother during pregnancy or by the child in the first year of life and lower risk of type 1 diabetes (T1D). Cod liver oil is a rich source of the long chain n-3 fatty acids eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) in the Norwegian population. We aimed to test whether maternal EPA and DHA in the phospholipid fraction of serum samples taken in pregnancy (as marker of EPA and DHA dietary intake) predicted lower risk of T1D in the offspring.
Materials and methods: In a prospective cohort of nearly 30 000 pregnant women who gave birth in Norway during 1992-94, we analyzed serum samples from 106 pregnant mothers whose child developed T1D and 125 mothers whose child did not develop T1D before 15 years of age. The sera were stored at -20°C until analysis in 2008/9. Cases were identified by record linkage to The Norwegian Childhood Diabetes Registry. Controls were randomly chosen. Fatty acid status was expressed as the proportion of EPA and DHA of the total phospholipids in serum, analyzed using solid phase extraction and gas chromatography (GC) with flame ionization detection.
Results: There was no evidence for any association between EPA or DHA in maternal serum and risk of T1D in the offspring. Odds ratio (OR) for upper vs. lower quartile for EPA: OR=0.9 (95% CI 0.4-2.0), test for trend: p=0.6, and for DHA: OR= 0.7 (95% CI 0.3-1.5), test for trend p=0.5. The median level of both EPA (0.2% in cases and 0.2% in controls) and DHA (1.1% in cases and 1.1% in controls) was similar in cases and controls.
Conclusion: There was no association between maternal EPA or DHA status during pregnancy and risk of T1D in the offspring.

Insulin resistance and secretion indexes in healthy Italian children and adolescents: a multicentre study
G. d'Annunzio[1], M. Vanelli[2], A. Pistorio[3], N. Minuto[1], L. Bergamino[1], D. Iafusco[4], R. Lorini[1];
[1]Department of Pediatrics, G. Gaslini Institute, Genoa, [2]Department of Pediatrics, University of Parma, [3]Department of Biostatistics, G. Gaslini Institute, Genoa, [4]Department of Pediatrics, 2nd University, Naples, Italy.

Background and aims: Type 2 diabetes mellitus (T2DM) is a metabolic disorder of heterogeneous etiology with social, behavioural and environmental risk factors. Studies in populations at risk of T2DM reported that insulin resistance is an early abnormality detectable in the normoglycemic, pre-diabetic state, and that the worsening of insulin resistance leads to fasting hyperglycemia, impaired glucose tolerance and clinical diabetes mellitus. We aimed to establish normal values of insulin resistance, secretion and sensitivity indexes i.e. HOMA-IR, HOMA-β% and QUICKI in healthy Italian children and adolescents, based on fasting samples.

TS 4-5	24	0.31	0.32	0.32	0.33	0.35	0.38	0.40	0.40	0.45

Methods: We determined HOMA-IR, HOMA-β% and QUICKI at baseline in 142 healthy subjects from Pediatric Centres, aged 2.7 to 19 years (10.6±3.8, Mean±SD), with different Tanner pubertal stages (TS). None had hypo/hyperglycemia (fasting plasma glucose ranging from 3.6 to 5.6 mmol/l), obesity (BMI 17.9±2.4 kg/m^2 M±SD), or family history for diabetes mellitus. The following formula were used: for HOMA-IR: fasting plasma insulin in mU/l × FPG in mmol/l/22.5; for HOMA-β%: 20 × (fasting insulin in mU/l)/(fasting glucose in mmol/l - 3.5), for QUICKI: 1/($\log_{10}$ fasting plasma insulin in mU/l + $\log_{10}$ glucose in mg/dl).
Results: The HOMA-IR index slightly increases with Tanner stage. As regards HOMA-β% and QUICKI, a weak variation throughout puberty was observed. No significant correlation was observed between HOMA-IR, HOMA-β%, QUICKI and BMI-SDS or chronologic age.
Conclusion: Normal values of HOMA-IR, HOMA-β% and QUICKI are useful tools in the clinical and epidemiological practice for baseline screening and follow-up of subjects at risk for type 2 diabetes mellitus.

Coeliac disease precedes the development of type 1 diabetes in children with both diseases
G.E. Frisk, I. Dahlbom, T. Tuvemo, T. Hansson;

Department of Womens and Childrens Health, Uppsala University, Sweden.
Background and aims: The prevalence of celiac disease (CD) is higher in patients with type 1 diabetes (T1D). It is assumed that T1D develops first accompanied by an increased risk of developing CD and other autoimmune diseases. However, we hypothesised that untreated CD may lead to the subsequent development of T1D in some children. The HLA-DQ genotype distribution in T1D has changed over time in Sweden, the risk HLA shared by both diseases has increased with 7% during a ten years period. One of the reasons for the increased incidence of T1D might be the increased consumption of gluten.
Materials and methods: Anti-tTG were measured in serum samples from 169 T1D children collected at T1D onset, 88 siblings of the T1D children, and 96 age and sex matched control children. CD was confirmed with a small intestinal biopsy showing villous atrophy. Antibodies against the islet autoantigens, GAD64 and IA-2, were also measured.
Results: In total, 17/169 T1D children, 6/88 siblings and 3/96 control children had elevated serum levels of anti-tTG. Five children had confirmed CD before T1D onset, and 12 children were diagnosed after T1D onset. Notably, 11/12 children had elevated anti-tTG levels at T1D onset, and the remaining child was positive in a follow up sample six months later. The prevalence of biopsy confirmed CD at T1D onset was 10.1%. None of the siblings had symptoms indicating CD, despite anti-tTG positivity, and so far CD has been confirmed in 4/88 (4.5%) of the siblings. Antibodies against IA-2 were detected in 70% of the T1D children and in 5% of the siblings. Against GAD65 the corresponding figures were 60% and 13.5%. There were no correlation of CD and T1D related antibodies.

Conclusion: The presence of anti-tTG at T1D onset indicates that CD precedes T1D in children with both diseases. The leaking gut syndrome with sub clinical inflammation is associated with T1D onset (Vaarala O 2008) and infections with enteric viruses such as enterovirus has for long been associated with T1D and in children with CD the spread of enteroviruses to other organs, such as the pancreas, would be facilitated with the viral receptor, a protein of the tight junction, made accessible to the virus. Moreover, the lack of correlation between the CD related and the T1D related autoantibodies implies that this is not a general autoimmunity behind these diseases. If this hypothesis is correct and inflammation of the gut precedes T1D, it would be possible to prevent the onset of the disease in children with CD by a population-based screening program.

Genetic dependence of urinary enzyme, neutral alpha-glucosidase, in diabetic nephropathy in Uzbek children and adolescents with type 1 diabetes mellitus
A.S. Sadykova;
Pediatric Endocrinology, Institute of Endocrinology, Tashkent, Uzbekistan.

Aim: To assess clinical-diagnostic value of urinary α-glucosidase activity in predicting chronic renal insufficiency in type 1 diabetes mellitus in Uzbek children and adolescents.
Materials and methods: We examined 152 children and adolescents of the Uzbek population, 122 children and adolescents with type 1 diabetes mellitus (51 male and 71 female). By proteinuria the patients were divided into 3 groups: with normoalbuminuria (NAU) (n=52), with microalbuminuria (MAU) (n=50) and marked proteinuria ((MPU) (n=20). 30 children and adolescents of matched age and sex were included into the control group. The urinary neutral α-glucosidase activity was measured by rate of glucose formation from maltose.
Results and discussion: In Uzbek children and adolescents with typ1 diabetes mellitus high incidence of D-allele was observed as diabetic nephropathy progressed. II Genotype was registered in 41.6% of cases on the MAU stage, but no cases were observed on MOU stage to be the evidence for high protection of the ACE gene genotype in chronic renal insufficiency progression and consistent with data of studies conducted in other ethnic populations. For the first time the study on interconnection between activity of urinary neutral α-glucosidase activity and ACE gene genotype was performed. It was established that urinary neutral α-glucosidase activity depended not only on diabetic nephropathy (DN) severity, but on all DN stages in persons with ID and DD genotype it was confidently higher than in those with II genotype. That is the activity of the enzyme was turned out genetically determined by ACE gene.
Conclusion: The findings broaden diagnostic opportunities in assessment of urinary neutral α-glucosidase activity not only in early diagnosing of preclinical DN in children and adolescents with type 1 diabetes mellitus, but also in predicting progression of terminal DN stages in patients with high susceptibility to chronic renal insufficiency. Registration of increase in the urinary neutral α-glucosidase in children and adolescents with type 1 diabetes mellitus on the pre-MAU stage as a marker of early pre-clinical DN stage will allow solving problem of identification of a group with confidently high DN predicting and progression risk as well as preventive therapy of the complication in question.

PS 111 Treatment in nephropathy, hypertension and macrovascular disease

1204

Treatment with lisinopril reduces E-selectin and increases adiponectin in type 1 diabetic patients with diabetic nephropathy
A.S. Astrup[1], K.J. Schjoedt[1], F. Persson[1], L. Tarnow[1], C.D.A. Stehouwer[2], C.G. Schalkwijk[2], H.-H. Parving[3], P. Rossing[1];
[1]Steno Diabetes Center, Gentofte, Denmark, [2]Academic Hospital Maastricht, Netherlands, [3]Rigshospitalet, Copenhagen, Denmark.

Background and aims: New potential treatment targets are evolving from knowledge on biomarkers and their involvement in inflammation and endothelial dysfunction. Patients with type 1 diabetes and diabetic nephropathy have a high overall risk, and potentially they could benefit from new renoprotective treatment modalities. Knowledge on how biomarkers of inflammation and endothelial dysfunction are influenced with treatment are scarce, thus we sought to examine if treatment with high doses of the ACE-inhibitor lisinopril influenced biomarkers in these high risk patients.
Materials and methods: A total of 56 type 1 diabetic patients with diabetic nephropathy were included in this double-masked randomized crossover trial consisting of three treatment periods. At inclusion, ongoing antihypertensive treatment was discontinued and replaced with slow-release furosemide in individual but fixed doses. After 2 months wash-out period, patients were treated in random order with lisinopril 20, 40, and 60 mg once daily, each dose for 2 months. The biomarkers C-reactive protein (hsCRP), soluble vascular cell adhesion molecule (s-VCAM-1), soluble intercellular adhesion molecule (s-ICAM-1), von Willebrand Factor (vWF), soluble E-selectin, and HMW adiponectin was measured after the wash-out period (baseline), and after each treatment period.
Results: Forty-nine patients completed the study. Seven patients were excluded due to mild reversible adverse events with no specific dose-relationship. All doses of lisinopril effectively reduced albuminuria and blood pressure. E-selectin was reduced 11.4% with treatment (p for change with treatment <0.001), and adiponectin increased 33.9% with treatment (p=0.008 and p<0.001). There was no correlation between change in urinary albumin excretion and E-selectin or adiponectin during treatment. There were no significant differences in levels of any biomarkers between different doses of lisinopril. Levels of sVCAM-1, sICAM-1, vWF, and hsCRP were not significantly changed with RAS-blockade.
Conclusion: E-selectin, a cell adhesion molecule that binds leukocytes to the endothelial cell during inflammation was reduced with ACE-inhibitor treatment. Finally, HMW adiponectin was significantly increased with RAS-blockade. Adiponectin is thought to have beneficial effects in regards to cardiovascular disease and the elevation may reflect a compensatory mechanism.
Adiponectin was kindly measured by Georg Hess and Dietmar Zdunek, Roche Diagnostics

1205

Renoprotective mechanism of ARB in diabetic nephropathy compared with TZD
T. Sumita, K. Inukai, K. Imai, D. Ito, T. Awata, S. Katayama;
Saitama Medical University, Japan.

Background and aims: Although two types of agents, angiotensin II receptor blockers (ARB) and thiazolidinediones (TZD), are known to reduce proteinuria in diabetic nephropathy, the precise mechanisms by which these renoprotective effects are exerted remain unclear. To clarify the differences between these two agents, we compared their biochemical and pathological effects on diabetic nephropathy.
Materials and methods: Two animal models of diabetic nephropathy were employed: 16-week old STZ mice, type 1 DM models, were administered STZ at 4-weeks of age, and 16-week old db/db genetically obese mice served as type 2 DM models. At 16 weeks of age, these mice were given pioglitazone (PGZ) or losartan (LOS)-containing chow for 2 weeks (n=4, each).
Results: Vehicle-treated diabetic mice showed early stage diabetic nephropathy: 3, 92 and 362mg albumin/gCr, in non-diabetic, STZ and db/db mice, respectively. In treated mice, albuminuria improved significantly, showing

83% (PGZ) and 62% (LOS) reductions in STZ mice, and 38% (PGZ) and 45% (LOS) reductions in db/db mice. Thus, there were no significant differences in albuminuria reduction between the two agents. On light microscopic analysis, glomeruli were significantly enlarged only in db/db mice, a finding which normalized with PGZ treatment, but not with LOS. On the other hand, scanning electron microscopy (SEM) revealed podocyte projections to be so shortened and thinned that areas in the gaps between the projections were enlarged by 22% in STZ and by 26% in db/db mice, presumably resulting in albumin leakage. Interestingly, these conformational changes of podocytes showed marked improvement in LOS-treated mice, i.e., the gap areas between projections were diminished to the size of those in control mice, while no significant changes were observed in mice given PGZ. The expressions of podocin and nephrin were not significantly changed at either the transcription or the protein level in these murine diabetic models, suggesting that podocyte destruction is not associated with albuminuria at least in the early stage of diabetic nephropathy. The extracellular matrix markers, type IV collagen and TGF-β, were both increased in diabetic mice, and both normalized with PGZ or LOS treatment. On the other hand, inflammation markers, ICAM-1 and MCP-1, were both increased in diabetic mice, and normalized with PGZ, but not LOS, treatment.
Conclusion: Taken together, these observations of renoprotective mechanisms indicate that ARB reverses podocyte conformational damage presumably through hemodynamic change, while TZD reduces mesangial expansion through an anti-inflammatory action.

1206

Optimal antiproteinuric dose of the direct renin inhibitor in type 2 diabetes: a randomized crossover trial

F. Persson[1], P. Rossing[1], H. Reinhard[1], C.D.A. Stehouwer[2], C. Schalkwijk[2], A.J. Danser[3], F. Boomsma[3], E. Frandsen[4], I. Rajman[5], W.P. Dole[6], H.-H. Parving[7,8];
[1]Steno Diabetes Center, Gentofte, Denmark, [2]Dept of Medicine, University Hospital Maastricht, Netherlands, [3]Dept of Internal Medicine, Erasmus MC, Rotterdam, Netherlands, [4]Dept of Clinical Physiology and Nuclear Medicine, Glostrup University Hospital, Denmark, [5]Novartis Pharma AG, Basel, Switzerland, [6]Novartis Institutes for Biomedical Research, Cambridge, United States, [7]Dept of Medical Endocrinology, University Hospital of Copenhagen, Denmark, [8]Faculty of Health Science, Aarhus University, Denmark.

Background and aims: The optimal renoprotective dose of the direct renin inhibitor aliskiren is not known. The aim of this study was to determine the maximum antiproteinuric dose of aliskiren in type 2 diabetic patients with albuminuria.
Materials and methods: After one month washout, 26 patients with type 2 diabetes, hypertension and albuminuria (>30 mg/day) were randomised to four consecutive, 2-month treatment periods, with aliskiren once daily:150 mg, 300 mg, 600 mg and placebo, in random order. Patients also received furosemide to control sodium retention and blood pressure (BP). The primary endpoint was change in urinary albumin excretion rate (UAER) calculated as the geometric mean of three consecutive 24h collections at the end of each treatment period. Secondary measures included change in 24h BP and glomerular filtration rate (GFR, ^{51}Cr-EDTA plasma clearance). Placebo (baseline) mean UAER was 350 mg/day, mean 24h BP was 137/81 mmHg, GFR was 87 ml/min/1.73 m^2.
Results: Treatment with aliskiren 150, 300 and 600 mg daily reduced UAER significantly by 36%, 48% and 54%, respectively (p<0.001) compared to placebo. The 600 mg dose produced a significantly larger reduction in UAER compared to 150 mg (p=0.025), but not compared to 300 mg, 8% lower during 600 mg (95% CI 29,-19) (p=0.517). 24h systolic BP was reduced by 4.5, 8.0 and 9.2 mm Hg compared to placebo, significant reductions for the 300 mg (p=0.001) and 600 mg (p<0.001) groups. 24h diastolic BP was reduced 3.0, 4.1 and 4.4 mm Hg respectively, all doses significantly different from placebo (p=0.019, p=0.001 and p<0.001). There was no difference between the 300mg and 600 mg doses of aliskiren in either systolic BP (p=0.598) or diastolic BP (p= 0.814) GFR was reduced by 3.0, 5.1 and 6.5 ml/min1.73 m^2, significant reductions compared to placebo for 300 and 600 mg (p=0.007 and p<0.001). All doses were well tolerated. No instances of hyperkalemia were observed. The most frequent side effects were dizziness without hypotension (four patients, one in each treatment group) and fatigue (two patients, one in the 300 mg and one in the 600 mg group).
Conclusion: In this small study in patients with type 2 diabetes, hypertension and albuminuria, the maximum antiproteinuric effect was obtained with aliskiren 300 mg, also the maximal antihypertensive dose approved for clinical use. Increasing the dose to 600 mg gave marginal non-significant additional gain in antiproteinuric effects and BP lowering.

Protection Against Nephropathy in Diabetes with Atorvastatin (PANDA): trial results

M.K. Rutter[1,2], R.R. Davies[2], J.K. Cruickshank[1], H.R. Prais[1], M. Gittins[3], C. Roberts[3], V. Charlton-Menys[1], A. Moorhouse[1], P. Jinadev[2], M. France[1,2], P.G. Wiles[4,5], M.J. Gibson[1,6], J. Dean[7], P.A. Kalra[1,6], P.N. Durrington[1];
[1]Cardiovascular Research Group, University of Manchester, [2]Central Manchester University Hospitals NHS Foundation Trust, [3]Statistics, University of Manchester, [4]University of Salford, [5]Pennine Acute Hospitals NHS Trust, Manchester, [6]Salford Royal NHS Foundation [7]Bolton Primary Care Trust, United Kingdom.

Background and aims: A sub-group analysis of the Treating to New Targets (TNT) study (N=9656) suggested that in patients with coronary disease high-dose atorvastatin reduces the progression of nephropathy when compared to low dose therapy. There have been no randomised controlled trials (RCT) of high- vs low-dose statin therapy to prevent renal dysfunction in diabetes.
Materials and methods: We performed a double-blind RCT of atorvastatin 80-mg/day vs 10-mg/day in 119 patients with Type 2 diabetes (T2DM) with microalbuminuria or proteinuria (albumin creatinine ratio (ACR) >5 mg/mmol). We excluded those with 24-hour protein excretion >2g or serum creatinine >200 μmol/l. We assessed renal function 3-6 monthly by several methods and compared the global progression of nephropathy between groups at these time points over 2 years using a linear mixed model for longitudinal data adjusting for differences in baseline covariates including renal function. Blood pressure was actively managed (target <130/75 mm Hg) prior to randomisation and during the trial including therapy with angiotensin II receptor blockers and/or angiotensin converting enzyme inhibitors.
Results: At baseline, mean (SD) age was 64 (10) years, 83% were male; HbA_{1c}: 7.7 (1.3) %; BP: 131/73 mm Hg. Baseline estimated glomerular filtration rate (eGFR) by the Modification of Diet in Renal Disease (MDRD) equation was 68 (24) ml/min/1.73 m^2; median (IQR) urinary albumin excretion (AER) was 77 (39-174) μg/min. Over 2-years there were 10 (8%) drop-outs and 7 deaths leaving complete follow-up data in 102 (86%) patients. During follow-up the MDRD eGFR declined by 0.84 vs 0.62 ml/min/1.73 m^2/year in the 10-mg vs the 80-mg group; the mean (95% CI) between-group difference in MDRD eGFR was not significant (2.2 (-1.1 to 5.4) ml/min/1.73 m^2, p=0.20; positive difference suggests benefit from 80-mg). Similarly, we observed no differences in Cockcroft and Gault-estimated creatinine clearance (2.5 (-2.4 to 7.3) ml/min, p=0.32); creatinine clearance from serum creatinine/24 hour urine collections (4.0 (-4.8 to 12.7) ml/min, p=0.38); cystatin C (p=0.69); log urine AER (p=0.93); log ACR (p=0.79) or 24-hour urine protein excretion (p=0.92). After adjusting for baseline levels, patients taking 80-mg atorvastatin had lower total cholesterol (mean difference 0.7 mmol/l, p=0.01); higher HbA_{1c} values (0.3%, p=0.03), and similar BP (p>0.7) compared to those taking 10-mg. We recorded no significant between-group differences in deaths or adverse events.
Conclusion: In T2DM patients with well-controlled BP and early renal disease we found no difference in the rate of renal dysfunction taking 80-mg vs 10-mg atorvastatin. We cannot rule out an effect of <1.6 ml/min/1.73m^2/year on MDRD eGFR, or an effect if BP was less well controlled. The benefits of 80-mg atorvastatin on lipoproteins, which we are currently investigating, are likely to outweigh any deleterious effect on HbA_{1c}.

Aliskiren/valsartan combination lowers blood pressure effectively irrespective of diabetic status compared to the component monotherapies: a *post-hoc* analysis

S.A. Yarows[1], S. Oparil[2], S. Patel[3], M. Wright[4], J. Zhang[3];
[1]Chelsea Internal Medicine/IHA, United States, [2]UAB Vascular Biology and Hypertension Program, Birmingham, United States, [3]Novartis Pharmaceuticals Corporation, East Hanover, United States, [4]Novartis Pharma AG, Basel, Switzerland.

Background and aims: Hypertension frequently coexists with diabetes mellitus, accounting for 75% of the added cardiovascular disease risk in such patients. Patients with diabetes often have difficulty achieving the recommended blood pressure (BP) goal (<130/80 mmHg). The aim of this post-hoc analysis was to assess the antihypertensive efficacy of aliskiren (a direct renin inhibitor)/valsartan (an angiotensin receptor blocker) combination compared to the component monotherapies in patients with and without diabetes.
Materials and methods: In this double-blind study, 1797 patients (193 with diabetes and 1604 without diabetes) with mean sitting diastolic BP [msDBP] 95 to <110 mmHg were randomized to receive once-daily aliskiren/valsartan 150/160 mg, aliskiren 150 mg, valsartan 160 mg, or placebo. After 4 weeks patients were forced-titrated to double the initial doses. At Week 8 endpoint, change from baseline in msDBP, mean sitting systolic BP (msSBP), and the proportion of patients achieving the control rates <140/90 mmHg (<130/80 mmHg if with diabetes) were assessed in the intent-to-treat population.
Results: Baseline characteristics were comparable between the subgroups except patients with diabetes had high rate of BMI ≥30 kg/m^2 (65.3% vs. 46.0%) compared to patients without diabetes. Baseline SPB was slightly higher in patients with diabetes compared to patients without diabetes in all treatment groups, as expected. At the week 8 endpoint the mean reductions from baseline in sitting BP for the aliskiren/valsartan combination were largely similar for each subgroup (Table). Blood pressure reductions and control rates in the aliskiren/valsartan group were greater compared to the component monotherapies or placebo in patients with and without diabetes. Overall rates of adverse events (AEs) were comparable across the treatment groups and were not notably affected by the presence of diabetes (with, 31.6%; without, 36.1%). The rate of AEs in diabetic patients were less for the combination group than placebo (22.7% vs. 42.5% respectively). However rate of AEs with combination were similar to placebo groups in patients without diabetes (36.3% vs. 36.1%, respectively). Headache was the most frequently observed AE. Aliskiren/valsartan combination was associated with less headache versus placebo in patients with (6.8% vs. 10.0%) and without diabetes (4.0% vs. 8.9%).
Conclusion: Combination therapy with aliskiren/valsartan reduced BP regardless of diabetic status, provided additional BP-lowering effects compared to component monotherapies and was well-tolerated.

Table

	Aliskiren/ valsartan	**Aliskiren**	**Valsartan**	**Placebo**
Patients with Diabetes (N)	44	59	49	39

Renin-angiotensin system blockade improves the inflammation and insulin resistance in patients with hypertension and metabolic syndrome

O. González-Albarrán, G. Perez, S. Calvo, M. Lahera, J. Gomez, M. Carrasco, M. Alpañés, J. Sancho Rof;
Endocrinology, Hospital Ramón y Cajal, Madrid, Spain.

Background and aims: Insulin resistance (IR) is highly prevalent in arterial hypertension, and plays a central role in the pathogenesis of the metabolic syndrome. Epidemiological evidence suggests that renin-angiotensin system (RAS) blockade may improve insulin resistance and influence on the release of proinflammatory cytokines. The aims of the present work were to evaluate the effect of olmesartan, an angiotensin receptor blocker (ARB), on insulin sensitivity and inflammatory markers in patients with hypertension and metabolic syndrome (MS)
Materials and methods: We studied 36 hypertensive patients with MS, according to NCEP-ATPIII criteria. After 4 weeks of run-in period, all patients were allocated randomly to one of the three treatment: once-daily olmesartan (40 mg), once-daily olmesartan 80 mg or placebo, and followed for a period of 20 week. If the target blood pressure was not achieved (SBP>140 mmHg or DBP >90 mmHg), diuretics agents were prescribed. We measured the BMI, waist circumference, systolic and diastolic blood pressure, lipid profile, CRP, adiponectin, and microalbuminuria. IR was assessed by Homeostasis Model Assessment (HOMA) index
Results: Mean age was 61±9,8 yrs. BMI 30,9±4,98 Kg/m^2, waist circumference (WC) 105,6± 12,3 cm and 98 ±11 cm in male and female respectively. Baseline mean SBP/DBP: 154,34±8,7/93,6±6,43 mmHg. After 24 weeks of treatment, both OLME-40 and OLME-80 significantly reduced SBP and DBP compared with their baseline values (14±8/9±3 mmHg and 18±9/16±5.3 mmHg for OLME-40 and OLME-80, respectively (p<0.01). Olmesartan treatment resulted in a significant decrease in fasting insulin (17.1±3.73 vs 9,8 ±3,9; P < 0.05), HOMA index (5,8±2,5 vs 3,9± 2,8; P < 0.05). A significant reduction of high-sensitivity C-reactive protein levels, 3.27 ±0.07 *vs* 1.8 ±0.06; p<0.05) and an increase in adiponectin (3.97 ± 0.46 vs 5,14 ± 0.51 mU/ml; p<0.05) . We observed positive correlations between abdominal obesity and insulin levels (0.47; p<0.01) and HOMA index (r=0.56;p<0.01) ; by contrast, inversely correlations were found with PCR and adiponectina (r=-0.48; p<0.01). Both OLME-40 and OLME 80 were well tolerated, without any serious adverse event reported.
Conclusion: Hypertensive patients with MS have a high prevalence of IR, and chronic inflammation. The ARB olmesartan improves IR and inflammation markers in these patients.

The beyond effects of antihypertensive drug on diabetes, using calcium channel blocker and angiotensin II receptor blocker

Y. Uno[1], H. Morita[2], T. Ikeda[2], I. Mori[2], K. Fujioka[2], H. Okada[2], T. Fujikake[2], R. Miyauchi[2], K. Kajita[2], T. Ishizuka[2];
[1]Center for Regional Medicine, Gifu University, [2]Department of General Internal Medicine, Gifu Graduate University of Medicine, Gifu, Japan.

Background and aims: It is controversial whether calcium channel blocker (CaB) or Angiotensin II receptor blocker (ARB) is superior as anti-hypertensive drug in a lot of clinical and epidemiological studies. For example, "the VALUE Study" shows ARB will decrease the appearance of disease rate in diabetes, in spite of inferior prevention in myocardial infarctions and strokes. On the contrary, "the JIKEI Heart Study" shows that ARB will decrease strokes and chronic heart failure. Our propose of this study is which drug is suitable as a view of extra-cardiovascular factor such as diabetes, atherosclerosis and endocrine factors.
Materials and methods: We randomized 22 patients to CaB (amlodipine) and ARB (valsartan) treatments, who took first therapy of hypertension. After 6 month, they were switched drug treatments each other. We performed echocardiograph, pulse wave velocity (PWV) test, biochemical examinations containing adiponectin, BNP (brain natriuretic peptide), dehydroepiandrosterone-sulfate (DHEA-S), high -sensitive C reactive protein (H-CRP) before and after treatment for 6 months and 12 months.
Results: There were no differences in blood pressure and heart rate on every 6-month period between CaB and ARB groups, also any differences in Echocardiographic measurements (Ejection Fraction, LV size, LV mass in-

dex, etc.,) and PWV. As for blood samples measurements, adiponectin, BNP, DHEA-S and serum insulin were not different between two groups. But H-CRP was significantly decreased in ARB treatments (594±108 μg/dL to 467±106 μg/dL, p<0.05) and the increment of HbA1c for 6 months in ARB treatments was lower than in CaB treatments (CaB vs ARB : 0.19±0.04 vs 0.10±0.09(mg/dL), p<0.05).
Conclusion: The treatments of ARB (valsartan) for hypertension may have prevented the development of diabetes and atherosclerosis, and it is suggested that ARB has the beyond effects on not only hypertension but also diabetes and atherosclerosis.

1211

Arterial stiffness on ramipril therapy in patients with type 2 diabetes mellitus and arterial hypertension
O.K. Vikulova, I.R. Jarek-Martynowa, M.V. Shestakova;
Diabetic Nephrology Department, Endocrinology Reseach Center, Moscow, Russian Federation.

Background and aims: Cardiovascular disease is the main cause of death in type 2 diabetes mellitus (T2DM). Increased arterial stiffness may be one important pathway linking diabetes to the increased cardiovascular risk. The aim of the study was to evaluate the arterial stiffness on ramipril therapy in high risk patients with T2DM and arterial hypertension (AH).
Materials and methods: T2DM patients with inadequately controlled blood pressure (BP) on any antihypertensive treatment were included. Inclusion criteria: systolic BP (SBP) >130 and/or diastolic BP (DBP)>80 mmHg. After 2-week wash-out period (if patients used inhibitors of angiotensin-converting enzyme (IACE) or angiotensin II receptor antagonists (ARA)) ramipril 5-10 mg per day was added. Ambulatory blood pressure monitoring (ABPM), urine albumin excretion rate (UAER) and arterial stiffness were assessed before and after 12-week treatment period. Pulse wave analysis was performed by using reactive hyperemia peripheral arterial tonometry technique. Augmentation index (Aix) - the indirect parameter of arterial stiffness was estimated from the difference between the second (P2) and first (P1) systolic peaks and expressed as a % of pulse pressure (PP) ([P2-P1]/PP)x100(%).The study was approved by local Ethical Committee and informed consent was obtained from all the patients.
Results: 30 patients with T2DM and AH were examined: median age 65.2±6.9yr, M/F 5/25, AH duration 10.1±6.9yr, mean BP 148/85 mmHg, mean HbA1c 8.1±1.8% (HbA1c>7%, 6.5-7%, <6.5%: 72%, 21% and 7% patients) with one or more additional cardiovascular risk factors: smoking 10%, microalbuminuria 20%, ischemic heart disease (IHD) 43%, familial history of cardiovascular disease 76.7%. Endothelial dysfunction by reactive hyperemia was found in 93% of patients. We observed significant decrease by ABPM in mean SBP during active period: 147/78 vs 135/74 mmHg, p<0.001, as well as maximal SBP: 183/105 vs.166/99 mmHg, p<0.001 and mean SBP and DBP during passive period: 135/74 vs. 129/65 mmHg, p<0.05. The target BP level <130/80 mmHg was attained in 44% of patients. We have also found statistically reliable differences in parameters of arterial stiffness: Aix (39.9 vs 35.3%, p<0.05) and time of ejection period (T [ED/mc]: 295.8 vs. 268.9, p<0.001).
Conclusion: We conclude that treatment with IACE ramipril in patients with T2DM and hypertension with high cardiovascular risk not only has the antihypertensive effect but can reduce arterial stiffness - the significant factor of endothelial dysfunction and cardiovascular morbidity.

PS 112 Other complications

1212

Long-term complications in newly diagnosed patients with type 2 diabetes by regions of Serbia
I. Rakocevic, S. Plavsic, D. Miljus, N. Mickovski Katalina, T. Knezevic;
Department for Prevention and Control of Noncommunicable Diseases, Institute of Public Health of Serbia, Belgrade, Serbia.

Background and aims: Diabetes and its associated complications are a major health and economic burden, particularly in developing world. Type 2 diabetes is usually recognized years after hyperglycemia develops. This delay in diagnosing the disease results in a high prevalence of chronic complications at the time of actual diagnosis. The aim of this study was to determine the prevalence of complications in newly diagnosed type 2 diabetes patients by regions of Serbia.
Materials and methods: A population-based, cross-sectional study of all newly diagnosed type 2 diabetes patients in year 2007, in 8 districts of Vojvodina and Central Serbia (n=5482) identified through a Serbian Diabetes Registry (SDR) database. Age-standardized prevalence was calculated by using a direct-method to the 2002 Serbian census data. To examine differences in variables between the two groups, Student's t-test was performed for continuous variables, the X^2 test for dichotomous variables.
Results: Over a half of the patients in both study regions (63.3% in Vojvodina and 73.5% in Central Serbia) had at least one of the studied complications by the time of diagnosis type 2 diabetes mellitus. The mean age of the patients was 61.8±11.0 years in Central Serbia and 60.7±10.6 in Vojvodina (p<0.01). Long-term complications were more common among females than males in both study groups (p<0.05). Higher age-standardized prevalence of microvascular complications was observed in Central Serbia (4.8% vs. 2.4%, p<0.01), including retinopathy (6.2% vs. 2.3%, p<0.001), and neuropathy (6.9% vs. 3.1%, p<0.001). Rates of nephropathy were similar. Although there were regional differences in the prevalence of macrovascular complications, the difference was not statistically significant.
Conclusion: The findings in this study indicate that significant proportion of newly diagnosed type 2 diabetes patients in both study regions had multiple complications at diagnosis, and were diagnosed at an older age. High prevalence of complications may be related to prevalence of undiagnosed diabetes in two regions. This underlines the importance to increase public awareness and secure earlier detection of diabetes and chronic complications by appropriate screening methods especially in high-risk groups. Also, prevention programs should focus on disproportionately affected regions (central Serbia) and disproportionately affected genders (females). This will help to prevent or delay the vascular complications and thus reduce the clinical, social and economic burden of the disease.

1213

Oral health status in type 1 and type 2 diabetes patients - results of a national multicentre survey: Teeth in Diabetes (TID) study
L. Czupryniak[1], M. Pawlowski[1], A. Szymborska-Kajanek[2], K. Strojek[2], J. Gumprecht[2], M. Szelachowska[3], B. Wolnik[4], A. Czech[5], M. Malecki[6], D. Zozulinska-Ziolkiewicz[7], B. Wierusz-Wysocka[7], D. Moczulski[8], M. Jasik[9], M. Dabrowski[10], P. Dziemidok[11];
[1]Diabetology and Metabolic Diseases Dept, Lodz, [2]Diabetology, Nephrology and Internal Diseases Dept, Zabrze, [3]Endocrinology, Diabetology and Internal Diseases Dept, Bialystok, [4]Diabetology and Hypertension Dept, Gdansk, [5]Diabetology and Internal Medicine Dept, Warsaw, [6]Metabolic Diseases Dept, Cracow, [7]Diabetology and Internal Medicine Dept, Poznan, [8]Nephrodiabetology Dept, Lodz, [9]Gastroenterology and Metabolic Diseases Dept, Warsaw, [10]Diabetology Dept, Rzeszow, [11]Diabetology Dept, Lublin, Poland.

Background and aims: Diabetes is a known risk factor for periodontal and dental diseases. However, little data on oral health in type 1 and type 2 diabetes patients are available. We conducted a nationwide cross-sectional study aiming at assessing oral health status using teeth number as a general index of thereof.
Materials and methods: During first two weeks of March 2009 diabetes patients attending 14 diabetes care centres were invited to fill in a questionnaire answering questions regarding their gender, age, diabetes duration, diabetes type, insulin treatment, smoking status, education level, number of their own teeth, and most recent HbA1c value.

Results: The study group comprised 2514 (1342 [53%] women, mean [±SD]age 56±17 years) diabetes patients: 680 (27%) with type 1 diabetes (T1D) (mean age 38±14 years, diabetes duration 14±11 years, HbA1c 7.95±1.85%, 167 [25%] smokers) and 1834 (73%) with type 2 diabetes (T2D) (mean age 63±11 years, diabetes duration 11±8 years, HbA1c 7.70±1.58%, 1057 [58%] treated with insulin, 291 [16%; p<0.0001 vs T1D patients] smokers). Mean number of teeth in T1D and T2D patients were 23±10 and 12±10, respectively (p<0.0001). T1D patients who were smokers had significantly fewer teeth (20±10 vs 24±10; p<0.0001) and higher HbA1c (8.72±1.85 vs 7.7±1.79%; p<0.0001) than non-smoking individuals. T2D patients who smoked had slightly greater HbA1c (7.91±1.6 vs 7.65±1.56%; p<0.05) than non-smokers, though no difference in teeth number was found. In T1D patients there was a statistically significant correlation between teeth number and HbA1c (r= -0.22; p<0.05), diabetes duration (r= -0.47; p<0.05) and age (r= -0.62; p<0.05) as well as education level i.e. patients who completed primary, secondary or higher education level presented with 14±11, 22±10 and 26±8 teeth, respectively (p<0.0001; after adjustment for the diabetes duration, age and HbA1c). In T2D there was also a significant correlation between teeth number and glucose control (r= -0.11; p<0.05), diabetes duration (r= -0.27; p<0.05) and age (r= -0.42; p<0.05). Patients with T2D who completed primary, secondary or higher education level had 8±9, 13±10 and 17±11 teeth, respectively (p<0.0001, adjusted). Multifactorial analysis showed that the age, diabetes duration, HbA1c, education level, and smoking status, were determinants of oral health as assessed through teeth number.
Conclusion: People with diabetes, even the young ones with T1D, present with significant teeth loss. Poorly controlled subjects with long-standing T1D, low level of education and smoking are at particularly high risk of oral cavity diseases. This group of subjects should be placed under intensive dental care so as to prevent oral health deterioration.

1214

Impaired lung function in type 2 diabetes correlates with insulin resistance and metabolic control. A case-control study

A. Lecube[1], G. Sampol[2], P. Lloberes[2], J. Mesa[1], C. Hernández[1], R. Simó[1];
[1]Endocrinology Department, Hospital Vall d'Hebron, CIBER de Diabetes y Enfermedades Metabólicas Asociadas (CIBERDEM), [2]Pneumology Service, Hospital Vall d'Hebrón, CIBER Enfermedades Respiratorias, Instituto de Salud Carlos III (ISCIII). Institut de Recerca, Barcelona, Spain.

Background and aims: In a recent case-control study we have demonstrated that type 2 diabetes (T2D) adversely affects breathing during sleep, becoming an independent risk factor for severe nocturnal hypoxemia in obese patients. However, there is little information linking the presence of insulin resistance and the blood glucose control with the severity of pulmonary function. The aim of the study was to evaluate the role of insulin resistance and the degree of glycemic control on the pulmonary function in type 2 diabetic patients.
Materials and methods: In this case-control study 30 type 2 diabetic women (fasting glucose 162.4 ± 62.9 mg/dl; HbA1c 7,7 ± 1,1 %) were compared with 60 non-diabetic women closely matched by age (43.23 ± 8.05 vs. 42.10 ± 8.0, p = 0.529), body mass index (49.18 ± 6.35 vs. 49.15 ± 6.46, p = 0.989), waist circumference (130.83 ± 12.27 vs. 129.83 ± 13.43, p = 0.746), and basal oxygen saturation. The exclusion criteria for this study were type 1 diabetes, chronic diseases others than those accompanying metabolic syndrome, and active treatment with continuous positive airway pressure. Forced spirometry and static pulmonary volume measurements were performed using a MasterLab apparatus, and values were expressed as a percentage of the predicted value. All tests were performed following the European Respiratory Society guidelines. Static pulmonary volumes were measured using the plethysmography method. Insulin resistance was evaluated as HOMA-IR. Statistical analyses: Student *t* test, Pearson linear correlation test, and stepwise multiple regression analysis.
Results: No differences in PaO_2 (82.3 ± 11,4 vs. 83.6 ± 8.1 mmHg, p = 0.574), $PaCO_2$ (39.7 ± 5.2 vs. 38.9 ± 3.9, p = 0.441), forced vital capacity (FVC, 87.3 ± 1.1 vs. 89.9 ± 13.7 %, p = 0.447), forced expiratory volumen in 1st second (FEV1, 91.2 ± 20.2 vs. 97.3 ± 14.3 %, p = 0.114), total lung capacity (TLC, 97.2 ± 14.0 vs. 94.3 ± 11.6 %, p = 0.369) were observed between diabetic and non-diabetic patients. However, in diabetic patients an almost significantly decrease in the FEV1/FVC ratio (81.4 ± 9.15 vs. 85.0 ± 5.0, p = 0.058) and a significantly increase in the percentage of RV (100.1 ± 22.8 vs. 79.7 ± 18.1, p < 0.001) were observed in comparison with non diabetic subjects. When all patients were grouped, in univariate analysis RV was positively correlated with fasting glucose (r = 0.471, p < 0.001), HbA1c (r = 0.585, p = 0.001), and HOMA-IR (r = 0.429, p = 0.001). Stepwise multiple regression analyses showed that type 2 diabetes was independently associated with RV.
Conclusion: The present study is the first to demonstrate a relationship between pulmonary function and the degree of insulin resistance or blood glucose levels. Interventional studies lowering blood glucose levels and increasing insulin sensitivity are needed to demonstrate the eventual reversibility of pulmonary dysfunction.

Study of lung function in adults with and without impaired glucose tolerance (IGT). Lung could be a target organ for diabetic complication

Y. Fukusima, M. Iwata, Y. Kamura, T. Kobasi, A. Takikawa, T. Okazawa, I. Usui, K. Yamazaki, M. Urakaze, K. Tobe;
The First Internal of Medicine, Toyama University, Japan.

Background and aims: Cross-sectional and/or longitudinal studies in the western countries have significantly demonstrated lower lung function(i.e. forced vital capacity (FVC), forced expiratory volume in 1s(FEV1)) in diabetic patients than in the non-diabetic counterparts.
In Japan, however, only a few studies on lung function in diabetic adults have been investigated . We conducted an analysis of the medical checkup data to determine whether adults with IGT have impaired lung function.
Material and methods: This cross-sectional study was carried in central Japan. 570 individuals aged ≥45 yrs (237 males and 333 females) took part in this study. None of these subjects had sustained asthma and chronic obstructive pulmonary disease (COPD). Spirometry was performed in a standard fashion using an electronic spirometer. We then investigated the relationship between the results of pulmonary function tests and glucose tolerance defined by HbA1c and fasting plasma glucose (FPG) levels. Subjects were divided into the normal glucose tolerance (NGT) group (HbA1c<5.5% and FPG<110mg/dl) and the IGT group (HbA1c≥5.5% or FPG≤110mg/dl) . FEV1% and %FVC were calculated by the measured values (i.e. FVC and FEV1). Statisitical analysis was carried out using Students t-tests and linear correlation analysis. Differences in these pulmonary functions (i.e.FVC,FEV1,FEV%) between NGT and IGT subjects were compared utilizing t tests for continuous variables. Furthermore, multivariable analyses were used to assess the comparison of NGT groups with IGT groups in the models adjusting for age, sex, BMI, height, waist circumference and so on. The subgroups of subjects divided into males and females were evaluated in the same way.
Results: We found 116 NGT men, 77 IGT men, 219 NGT women and 61 IGT women in this survey. The subjects with IGT had significantly lower %FVC (103%v.s.109%, P=0.0497) and FEV1.0% (97%v.s.103%, P=0.0081) than those without IGT. We also found that the subjects with IGT had significantly lower %FVC (P=0.0075), FVC (P=0.0439), FEV1.0% (P=0.0004) and FEV1.0 (P=0.0261) than those without IGT in the multivariable models adjusting for age, sex, BMI, height, waist circumference some parameters. While significant negative correlations were found between lung functions (%FVC and FEV1.0%) and two parameters (BMI and visceral fat) in men, a significant correlation was found between %FVC and muscular volume in women (correlate coefficient r=0.306593 , P<0.0001) .
Conclusion: Japanese people with IGT had significantly lower lung function than those with NGT. Consequently, lung could be a target organ for diabetic complication regardless of ethnicity. Additional investigation is required to reveal the processes how lung function is deteriorated as they become glucose intolerant.

1216

Direct effect of change in insulin sensitivity on bone formation

B. Literáti-Nagy[1], E. Kulcsár[1], B. Buday[1], K. Bezzegh[1], É. Péterfai[1], M. Vitai[1], J. Kiss[2], L. Korányi[1];
[1]Drug Research Center, [2]State Hospital for Cardiology, Balatonfüred, Hungary.

Background and aims: Correlation between insulin sensitivity (IS) and bone mineral density (BMD), ceasing with progression of glucose intolerance have recently been identified. Decrease in insulin esistance results in increased bone formation, however insulin sensitizer rosiglitazone increases bone fracture risk. To determine if change in IS, or a direct bone effect of rosiglitazone is responsible for increased fracture risk, the effect of a non-glitazone insulin sensitizer BGP15 on bone formation was investigated among insulin resistant volunteers. The hydroxylamine derivative BGP-15 have been shown to elevate the level of heat shock proteins and nitric oxide synthase and significantly improved insulin sensitivity in phase II clinical studies.

Materials and methods: 27 volunteers with elevated HOMA (3,8 ± 2,3) were treated with 400 mg (n=16) or placebo (n=11) for 28 days. Total body glucose utilization (M)- assessed by hyperinsulinemic -euglycemic clamps-,body composition, lumbar and femoral bone mineral density (BMD), serum N-MID osteocalcin, ß-crosslaps, total P1NP, a katepsin-K, osteoprotegerin, sRANKL, leptin, resistin, adiponectin were measured.
Results: M values increased in active group (6.6 ± 2.2 vs 7,9± 2,4, p=0.003; placebo:7,6 ± 3.1 vs. 6,8 3.1, ns), while katepsin K (4.51 ±1.4 vs 3.17 ± 1.1 ng/ml, p=0.0012) and ß-crosslaps (0.41 ± 0.18 vs 0,36 ± 0.1ng/ml,p=0.031) decreased, and P1NP increased (37± 18 vs 40,9 ± 15 ng/ml, p= 0.040).
BMU index (formation markers/resorption markers to characterize the activity of the bone metabolic units: = (OGPxP1NP) x (β-crosslaps x catepsin-K x sRANKL) $^{-1}$) was also increased in active groups (270 ± 195 vs 484 ± 392, p=0.004). The relationship between osteocalcin and M values was highly significant (r = 0.5939, p<0.001). Neither change in adipocytokines levels nor their correlation with the change in M values were observed.
Conclusion: Our data strengthened the role of osteocalcin in the energy homeostasis-bone formation axis, and suggest that improved insulin sensitivity is beneficial for bone formation. The increase in bone fracture risk observed during rosiglitazon treatment should be the direct bone effect of the drug and not related to insulin sensitivity, indicating that development of insulin sensitizer different from glitazone family would be important to save the bones of 2DM patients.

Glucose tolerance, insulin sensitivity, subclinical inflammation and endothelial dysfunction in subjects with chronic pancreatitis

M. Saryusz-Wolska[1], A. Gasiorowska[2], R. Talar-Wojnarowska[2], A. Borkowska[1], E. Malecka-Panas[2], J. Loba[1], L. Czupryniak[1];
[1]Diabetology & Metabolic Disease Dept, [2]Digestive Tract Diseases Dept, Medical University of Lodz, Poland.

Background and aims: Chronic pancreatitis (CP) is often associated with glucose intolerance or diabetes. So-called 'pancreatic diabetes' is often difficult to treat due to impaired gastrointestinal absorption and erratic food pattern caused by recurrent abdominal pains. Moreover, cardiovascular risk of subjects with pancreatic diabetes is frequently underestimated, partly because of relative young age and low body weight of these patients. We studied glucose tolerance in patients with established chronic pancreatitis aiming at identifying typical features of glucose (in)tolerance associated with CP. In addition, the aim of the study was to assess endothelial dysfunction and subclinical inflammation as early markers of cardiovascular risk.
Materials and methods: The study group was 27 non-diabetes individuals with recently diagnosed CP (mean age 46.8±10.9 years, BMI 21.5±3.2 kg/m2), 18 age- and body weight-matched healthy subjects served as controls. All subjects underwent oral glucose tolerance test (OGTT) according to WHO protocol with plasma glucose and insulin measurements. HOMA index and fasting plasma adiponectin, TNF-alfa, interleukin-6 (IL-6), interleukin-1beta (IL-1b), E-selectin, thrombomodulin, adhesion molecules ICAM and VCAM, and high-sensitive CRP were assessed.
Results: CP and control subjects plasma glucose values in OGTT were at 0 min 101±21 and 84±12 (p<0.05), 60 min - 166±44 and 93±24 (p<0.001), 120 min - 126±43 and 88±16 (p<0.001) mg/dl, and plasma insulin at 0 min - 3.3±1.3 and 8.1±5.3 (p<0.01), 60 min - 17.5±6.9 and 29.9±18.5 (p<0.01), 120 min - 16.1±9.2 and 25.3±14.4 mIU/l. CP patients presented also with significantly greater insulin sensitivity as measured with HOMA than controls (0.79±0.36 vs 1.98±1.25; p<0.01). Moreover, CP subjects as compared with controls had significantly greater plasma adiponectin (13580±6449 vs 6327±4211 ng/ml; p<0.001), TNF-alfa (45.9±48.1 vs 16.5±13.2 pg/ml; p<0.05), IL-6 (8.2±3.8 vs 3.2±1.0 pg/ml; p<0.01), thrombomodulin (1.8±0.5 vs 1.0±0.4 ng/ml; p<0.01), ICAM (586±371 vs 336±71 ng/ml; p<0.001) and VCAM (1219±505 vs 793±306 ng/ml; p<0.001) concentrations.
Conclusion: In conclusion, chronic pancreatitis is associated with elevated fasting and early post-challenge plasma glucose as well as significant insulin sensitivity. Moreover, despite absence of insulin resistance, CP subjects present with clinical markers of subclinical inflammation and endothelial dysfunction. Therefore, regular assessment of patients with CP towards glucose tolerance and level of cardiovascular risk should be recommended.

1218

Plasma levels of chemerin and adipose triglyceridelipase in newly diagnosed type 2 diabetic patients and type 2 diabetic patients with hypertension

Y. Yan[1,2], L. Li[1,2], G. Yang[3], Y. Liu[3];
[1]The Key Laboratory of Laboratory Medical Diagnostics in Ministry of Education, [2]Department of Clinical Biochemistry, [3]Department of Endocrinology, The Second Affiliated Hospital, Chongqing Medical University, China.

Background and aims: Chemerin is a chemoattractant protein that serves as a ligand for the G protein-coupled receptor CMKLR1 and showed a strong and independent association with key markers of the metabolic syndrome including obesity, plasma triglycerides and blood pressure. Adipose triglyceridelipase has an important role in TG lipolysis and energy metabolism in cultured adipocytes and weight maintenance in mice and other lower-order organisms.But Its pathophysiologic role in humans remains unknown. In this study, we have investigated whether or not plasma chemerin and adipose triglyceridelipase level were different in patients with type 2 diabetes mellitus, type 2 diabetes mellitus patients with hypertension and control subjects.
Materials and methods: 81 subjects with newly diagnosed T2DM (42 men, 39 women, age 53±12 years, T2DM group), 33 newly diagnosed T2DM patients with hypertension (18 men, 15 women, age 61±8 years, T2DMH group) and 60 normal control subjects(22 men, 38 women, age 51±12 years, NGT group) participated the study. All patients were newly diagnosed and were not treated with oral hypoglycemic agents or diet control. The body composition and metabolic parameters were assesses.Blood samples were drawn after an overnight fast and Plasma insulin, FFA, HbA1c, TG, TC, LDL-C, HDL-C were measured. Plasma chemerin and ATGL levels were determined were evaluated using a commercially available ELISA. The homeostasis model assessment of insulin resistance (HOMAIR) and the homeostasis model assessment of β-cell insulin secretion (HOMAIS) were calculated.
Results: Plasma chemerin levels were found to be markedly increased in type 2 diabetes mellitus patients with hypertension compared with type 2 diabetes mellitus and NGT (P<0.01). Multiple regression analysis showed that waist circumference, Diastolic blood pressure, 2 h plasma insulin after glucose overload and HbA_1c were independent related factors influencing plasma chemerin levels. Plasma adipose triglyceridelipase levels were significantly increased in type 2 diabetes mellitus patients with hypertension compared with type 2 diabetes mellitus (P<0.01), whereas only Diastolic blood pressure, cholesterol and homeostasis model assessment of insulin resistance were independent related factors with plasma adipose triglyceridelipase levels.
Conclusion: The present work indicates the potential link of chemerin and adipose triglyceridelipase with the pathogenesis of insulin resistance and type 2 diabetes mellitus.

Prevalence of asymptomatic coronary artery disease in type 2 diabetic patients with micro/macroalbuminuria

H. Reinhard[1], P.R. Hansen[2], F. Persson[1], L. Tarnow[1], N. Wiinberg[3], C.L. Pedersen[3], A. Kjær[3], K. Winther[4], H.-H. Parving[5], P. Rossing[1], P.K. Jacobsen[1,6];
[1]Steno Diabetes Center, Gentofte, [2]Department of Cardiology, Gentofte University Hospital, [3]Department of Clinical Physiology and Nuclear Medicine, Frederiksberg University Hospital, [4]Department of Clinical Biochemistry, Frederiksberg University Hospital, [5]Department of Medical Endocrinology, University Hospital of Copenhagen, [6]The Heart Center, Rigshospitalet, Copenhagen, Denmark.

Background and aims: Type 2 diabetic patients with albuminuria have a poor prognosis, primarily due to cardiovascular disease. Early detection of asymptomatic cardiovascular disease is essential to improve treatment and prognosis, however a valid screening strategy has not been established. The present study examines the prevalence of asymptomatic significant coronary artery disease (CAD) in type 2 diabetic patients with albuminuria and investigates possible screening strategies, including the use of NT-proBNP levels for risk stratification.
Materials and methods: In a cross-sectional study, we identified a consecutive cohort of 200 type 2 diabetic patients with elevated urinary albumin excretion rate (micro- or macroalbuminuria), but normal P-creatinine and without known cardiovascular disease. Patients with P-NT-proBNP levels above the median and/or coronary calcium scores (CCS) > 400 were stratified as high risk patients (n=133), all others as a low risk group (n=67). High risk patients were examined by myocardial perfusion imaging (SPECT) (n=108) and/or CT-angiography (CTA) (n=20) and/or coronary angiography (CAG) (n=81).
Results: Patients were 59 (SD 9) years of age, diabetes duration was 13 (7) years, BMI 33 (6) kg/m2, and 74% were males. Albuminuria was 109 mg/24h (geom. mean; range 3-8318), P-creatinine 76 (18) µmol/l and 62% had retinopathy. Medical treatment included statins (94% of patients), aspirin (90%) and RAAS blockade (98%). HbA_{1c} was 7.9 (1.3) %, total cholesterol 3.9 (0.9) mmol/l, systolic blood pressure 130 (17) mmHg, and diastolic blood pressure 75 (11) mmHg. The median P-NT-proBNP level was 43.2 (range 5.1-575.4) ng/l and the median CCS was 183 (0-4529). In 62/108 (57%) of high risk patients, SPECT showed myocardial perfusion defects and in 25/101 (25%) examined with CTA or CAG had significant CAD. In 76 out of all 200 patients (38%) or in 76/133 (57%) of high risk patients, SPECT, CTA and/or CAG demonstrated myocardial perfusion defects or significant CAD. Revascularization procedures were performed in 9 patients. Among high risk patients, those with P-NT-proBNP >100 ng/l and CCS > 800 (n=14) had more significant CAD (88%) than patients with P-NT-proBNP and CCS below these cut-off values (53%) p=0.013**.**
Conclusion: Despite optimal medical treatment, type 2 diabetic patients with albuminuria have a very high prevalence of asymptomatic significant CAD. P-NT-proBNP and CCS may provide important information for the identification of patients with significant CAD.

1220

Relation between coronary and peripheral artery disease in type 2 diabetic patients with micro/macroalbuminuria

P.K. Jacobsen[1,2], H. Reinhard[1], P.R. Hansen[3], L. Tarnow[1], C.L. Pedersen[4], H.-H. Parving[5], P. Rossing[1];
[1]Steno Diabetes Center, Gentofte, [2]The Heart Centre, Rigshospitalet, Copenhagen, [3]Department af Cardiology, Gentofte University Hospital, [4]Department of Clinical Physiology and Nuclear Medicine, Frederiksberg University Hospital, Copenhagen, [5]Department of Medical Endocrinology, University Hospital of Copenhagen, Denmark.

Background and aims: Type 2 diabetic patients with micro/macroalbuminuria have a poor prognosis, primarily due to cardiovascular and systemic macrovascular disease. Both coronary (CAD) and peripheral artery disease (PAD) results in end organ damage and therefore have very important clinical implications. It is unclear, whether atherosclerosis in diabetes progress as a universal process throughout the vasculature or show regional differences in its manifestations. This question is important for the determination of future screening and treatment strategies, particularly because both CAD and PAD also occur in asymptomatic patients. The present study examines the relation between coronary calcium score and peripheral artery disease in type 2 diabetic patients with micro/macroalbuminuria.
Materials and methods: In a cross-sectional study, we identified a consecutive cohort of 200 type 2 diabetic patients with micro/macroalbuminuria but normal p-creatinine and without known cardiovascular disease at Steno Diabetes Center. We performed clinical and biochemical evaluation, coronary calcium Agatston score (CCS) and distal systolic blood pressure measurements at toe level (PBP)(worst big toe).
Results: Patients were 59 (SD 9) years of age, diabetes duration was 13 (7) years, BMI 33 (6) kg/m2, and 74% were males. Albuminuria was 109 mg/24h (geom. mean; range 3-8318), P-creatinine 76 (18) µmol/l and 62% had retinopathy. Medical treatment included statins (94% of patients), aspirin (90%) and RAAS blockade (98%). HbA_{1c} was 7.9 (1.3) %, total cholesterol 3.9 (0.9) mmol/l, systolic blood pressure 130 (17) mmHg, and diastolic blood pressure 75 (11) mmHg. Median CCS was 183 (0-4529). Mean PBP was 121 (2) mmHg and toe:arm ratio was 88 (1.7)%. Patients with toe:arm ratio<67% (n=35) had a median CCS of 485 (0-2406), whereas patients with ratio>67% had 112 (0-4529), p=0.007. Patients with CCS >100 (n=109) had a mean toe:arm ratio of 81 (2)% compared to 98 (2)% in patients with CCS < 100, p<0.001. We found a linear correlation between CCS and toe:arm ratio (CCS = -9 x toe:arm ratio + 1276), R=0.29, p<0.001. In a multiple linear regression model, systemic systolic blood pressure and toe:arm ratio where associated with CCS (R=0.41, p<0.001), whereas albuminuria, HbA_{1c} and cholesterol level did not influence level of CCS. In a similar model CCS and cholesterol level were associated with toe:arm ratio (dependent variable).
Conclusion: Coronary calcium score and distal blood pressure are related in type 2 diabetic patients with micro/macroalbuminuria. This may help identify high risk patients with significant CAD and PAD.

1221

Contribution of body weight, glycaemic control and insulin resistance to platelet clopidogrel responsiveness in patients with non-ST segment elevation acute coronary syndrome

B. Gaborit[1], T. Cuisset[2], C. Frere[3], P. Morange[3], J. Bonnet[2], A. Dutour[1], M. Alessi[3];
[1]Department of Endocrinology, Metabolic Diseases, and Nutrition, CHU Nord, [2]Department of Cardiology, CHU Timone, [3]Laboratory of Haematology, CHU Timone, Marseille, France.

Background and aims: Poor response to clopidogrel is a risk factor for the recurrence of ischemic complications in patients with non-ST segment elevation acute coronary syndrome (NSTE-ACS) undergoing coronary stenting. However, it is still unknown whether body weight, glycemic control, inflammation or insulin resistance are implicated in this suboptimal response or not. The aim of this study was to determine the clinical and biological factors implicated in clopidogrel platelet response in patients with NSTE-ACS.
Materials and methods: 441 consecutive NSTE-ACS patients (174 diabetics and 267 non-diabetics) undergoing coronary stenting were included in this study. All patients received loading doses of 250 mg aspirin and 600 mg clopidogrel at least 12 h before percutaneous coronary intervention. Post-treatment maximal intensity of ADP-induced platelet aggregation (ADP-Ag), platelet reactivity index of vasodilator-stimulated phosphoprotein (PRI-VASP), fasting plasma glucose and insulin, HbA1c, lipid parameters, adiponectin, and high sensitive CRP were analyzed. For non-diabetic patients, a simplified homeostatic model assessment (HOMA) of insulin resistance was calculated. Clopidogrel non-responses were defined by an ADP-Ag >70% and PRI-VASP >53%.
Results: ADP-Ag and PRI-VASP were strongly associated with body mass index (BMI) (r=0.28, p<0.0001 and r=0.26, p<0.0001, respectively). Clopidogrel non-responders (ADP-Ag> 70% or PRI-VASP>53%), had a significantly higher BMI than responders: 28.2±0.5 vs. 26.5±0.2 kg/m^2, p=0.005 27.8±0.3 vs. 26±0.3 kg/m^2, p=0.0003 respectively. Obese patients also had a significantly lower response to clopidogrel than non-obese patients. High levels of CRP were significantly associated with non-response to clopidogrel (p=0.049 and p=0.003 for ADP-Ag and PRI-VASP, respectively). Clopidogrel non-responders had significantly increased levels of CRP compared to clopidogrel responders: 18.3±2.2 vs. 3.6±0.4 mg/L, p<0.0001 (PRI-VASP). PRI-VASP but not ADP-Ag was correlated with lipid parameters known as cardiovascular risk factors: HDL cholesterol (r=-0.14, p=0.01), triglycerides (r=0.14, p=0.009), and with markers of insulin resistance: fasting plasma in-

sulin (r=0.18, p=0.001) and HOMA (r=0.17, p=0.001). Clopidogrel non-responders (PRI-VASP >53%) had increased HOMA compared to responders (2.9±0.3 vs. 4.4±0.6, p=0.0003). No correlation was found between platelet tests and fasting plasma glucose or HbA1c. Diabetes mellitus was not associated with non-response to clopidogrel although there was a trend towards an association with ADP-Ag (p=0.07). After multivariate analysis, only BMI and CRP remained statistically associated with platelet tests.
Conclusion: BMI and CRP are strong predictive factors for clopidogrel non-response in NSTE-ACS. These findings indicate that clopidogrel loading dose should be weight-adjusted and reevaluated during infections to prevent ischemic events.

1222

High glucose acutely reduces the aspirin effects on platelets by impairing the aspirin-induced activation of the NO/cGMP pathway

I. Russo, P. Del Mese, L. Mattiello, M. Viretto, G. Doronzo, M. Trovati, G. Anfossi;
Department of Clinical and Biological Sciences, University of Turin, Orbassano - Torino, Italy.

Background and aims: Atherothrombotic vascular disease in type 2 diabetes recognizes as a major cause platelet hyperactivity, justifying the recommendation of antiplatelet therapy with aspirin. In intervention studies, however, the number of diabetic patients who benefit from aspirin is lower than in the general population, suggesting a resistance to aspirin in diabetes. Hyperglycaemia is known to influence platelet function: therefore, a potential role of high glucose on platelet responses to aspirin should be hypothesized. Aim of the study is to evaluate if platelet exposure to high glucose *in vitro* modifies the anti-aggregating effects of aspirin by influencing the arachidonate metabolism and the activation of the anti-aggregating nitric oxide (NO)/cyclic GMP pathway, i.e. the two mechanisms of aspirin action.
Materials and methods: We studied 45 healthy volunteers (25M and 20F; age:22.8±0.4 yrs; body mass index: 22.6±0.4 kg/m^2), non smokers, with normal glucose tolerance and insulin sensitivity (HOMA IR:1.7±0.1). In platelet-rich plasma (PRP) and washed platelets (WP) preincubated with 5 and 25 mmol/l D-glucose, we evaluated the influence of a 30-min exposure to lysine acetylsalicylate (LAS) (1-300 μmol/l) on: i)aggregation induced by sodium arachidonate (NaAA;1 mmol/l) and ADP (20 μmol/l) (Born's method); ii)thromboxane B_2 (TxB_2) synthesis (RIA); iii)NO synthase (NOS) activity (conversion of ^{3}H-arginine to ^{3}H-citrulline) and cGMP levels (RIA). Aggregations were repeated in presence of the NOS inhibitor L-NMMA (100 μmol/l). As osmotic control, mannitol was used. Data are expressed as mean±SEM.
Results: Exposure to 25 mmol/l D-glucose decreased LAS inhibition of platelet responses: in particular, LAS IC-50 (μmol/l) for NaAA-induced aggregation was 31.4±5.2 with 5 mmol/l glucose and 47.8±8.3 with 25 mmol/l glucose (p<0.01) and inhibition exerted by 300 μmol/l LAS on the ADP-induced aggregation was 43.7±3.1% with 5 mmol/l glucose and 25.5±2.9% with 25 mmol/l glucose (p<0.0001). With 300 μmol/l LAS: i)TxB_2 production (ng/ml) in WP was similar in the presence of 5 and 25 mmol/l glucose: 28.0±2.8 vs 30.0±2.5 after NaAA stimulation (n.s). and 17.6±1.4 vs 17.0±1.7 after ADP stimulation (n.s.); ii)the NOS activity increase from 0.13±0.01 to 0.24±0.02 pmol ^{3}H-citrulline/min/mg protein (p<0.0001) in the presence of 5 mmol/l glucose was blunted by 25 mmol/l glucose (0.11±0.009 vs 0.10±0.01 pmol ^{3}H-citrulline/min/mg protein, ns), iii)the intraplatelet cGMP increase from 10.2±1.8 to 25.6±4.0 pmol/10^{9}plts (p<0.003) observed in the presence of 5 mmol/l glucose was blunted by 25 mmol/l glucose (11.8±2.3 vs 13.1±1.9 pmol/10^{9}plts, ns). Pre-incubation with iso-osmolar mannitol did not modify platelet responses to LAS. The role of NO in the anti-aggregating effect of LAS was confirmed by the fact that, in the presence of 5 mmol/l glucose, L-NMMA decreased the percentage of LAS-induced inhibition on the aggregating responses to both NaAA (57.1±5.2 vs 69.4±5.2%; p<0.006) and ADP (66.4±1.7 vs 90.0±4.7; p<0.0001).
Conclusion: This study shows that a short-time platelet exposure to high glucose reduces the aspirin anti-aggregating effect, mainly inhibiting the drug action on the NO/cGMP pathway, suggesting that hyperglycaemia plays a role in aspirin resistance.

Left ventricular systolic and diastolic function in type 2 diabetic patients with cardiac autonomic neuropathy

I.A. Bondar[1], O.Y. Shabelnikova[2];
[1]Novosibirsk State Medical University, [2]Regional Diabetes Center, Novosibirsk State Clinical Hospital, Russian Federation.

Background and aims: Patients with type 2 DM appear to have an increased incidence of early subclinical left ventricular (LV) dysfunction. To assess the relationship between cardiac autonomic neuropathy and systolic and diastolic function in patients with type 2 diabetic.
Materials and methods: 139 type 2 diabetic patients (48M/91F, age 53.1±4.9 (SD) years) with arterial hypertension (duration of hypertensions 9.7±7.8 (SD) years) were examined, including 99 patients (32M/67F, age 54.0±5.3 years) with the cardiac autonomic neuropathy (group 1) and 40 patients (16M/24F, age 52.6±4.7 years) without autonomic neuropathy (group 2) and control group consisting of 30 with arterial hypertension (duration of hypertensions 10.9±8.5 years) were studied by using Doppler echocardiography. LV ejection fraction (EF) and transmitral flow Doppler parameters (early peak diastolic-Emax and late peak diastolic velocity-Amax global LV isovolumic relaxation time-IVRT) were measured. Five standard cardiovascular reflex tests, proposed by Ewing, were performed in type 2 diabetic groups.
Results: LV ejection fraction (EF) and transmitral flow Doppler parameters (early peak diastolic-Emax and late peak diastolic velocity-Amax global LV isovolumic relaxation time-IVRT) did not differ between group type 2 diabetic patients without autonomic neuropathy and control group. The difference in the early peak diastolic-Emax (0.61±0.12 m/c) and late peak diastolic velocity-Amax (0.65±0.11 m/c) was statistically significant in the patients with type 2 diabetes with cardiac autonomic neuropathy as compared to the patients with type 2 diabetes without autonomic neuropathy (0.66±0,09 m/c vs 0.69±0.09 m/c) (P<0,05) and control group (0.71±0.16 m/c vs 0.69±0.14 m/c) (P<0.05). LV ejection fraction (EF) in patients with cardiac autonomic neuropathy (63.4±7.6%) was significantly lower than in control group (66.9±4.4%) (P<0.05) and did not differ with group without autonomic neuropathy (65.1±3.6%) (P>0.05). A significant positive correlation was found between global LV isovolumic relaxation time-IVRT and HbA1c (P=0.01) in group without autonomic neuropathy. A significant correlation was recorded between the early peak diastolic-Emax and levels insulin (P=0.01) and HOMA-IR (P=0.032) in patients with cardiac autonomic neuropathy.
Conclusion: Early subclinical left ventricular dysfunction was correlated in type 2 diabetic patients without cardiac autonomic neuropathy with hyperglycemia and in patient with cardiac autonomic neuropathy with hyperinsulinemia and insulin resistance.

1224

Differential injurious effects of antihyperlipidaemic agents, statins and fibrates on mitochondrial respiratory function

K. Yamada[1], K. Tsunoda[2], K. Tazuya[3], K. Kawai[2], M. Mishima[3], K. Matsuyama[4], H. Morita[5], K. Kajita[5], T. Ishizuka[5];
[1]Diabetes and Endocrinology, Gifu Municipal Hospital, [2]Health Science, Chukyo Women's University, Ohbu, [3]Daiichi University College of Pharmaceutical Science, Fukuoka, [4]Kyoritsu University of Pharmacy, Tokyo, [5]Department of General Internal Medicine, Gifu University Graduate School of Medicine, Japan.

Background and aims: Statins and fibrates are known to reduce the risk of vascular events in type 2 diabetic patients, but they are also known to possess the adverse effects on muscle and liver. Statins, a group of antihyperlipidemic agents which arrest the cholesterol biosynthesis by inhibiting HMG-CoA reductase, have recently been demonstrated to decrease in ubiquinone 10 (UQ10) level. This suggests that mitochondrial dysfunction is concerned in the toxicity mechanism for statins. The combination of the respiration-injurious effects with the obstruction of UQ10 biosynthesis, may prominently reinforce their mitochondria toxicity. The effects of statins on mitochondrial morphological structure and respiratory function were therefore examined in the present study using isolated rat liver mitochondria (MT) and submitochondrial particles (SMP).
Materials and methods: MT were isolated from liver homogenates of Wistar albino rats. SMP were prepared from MT. Mitochondrial structural alteration (swelling) was photometrically monitored by following the absorbance decrease at 520nm. Oxygen consumption was measured by using oxygen electrode. Respiratory activity was calculated from oxygraph data according to the method of Chance and Williams.

Results: Cerivastatin, fluvastatin, rosuvastatin and simvastatin were found to elicit cyclosporineA-insensitive swelling in mitochondria, inducing the permeability transition in the inner membranes. These statins were found to strongly detract both NAD- and succinate-linked respirations in MT. The ID50 values were lower than 50 μM. Statins were found not to directly interfere with any enzymes involving in the NADH- and succinate-linked respiratory chains in SMP. Fenofibrate and bezafibrate have been substantiated to inhibit the electron transport at the rotenon-site in NADH-linked respiratory chain. These show different modes between statins and fibrates. Pravastatin showed the weakest MT toxicity among statins tested in the present study.
Conclusion: These results suggest that mitochondria toxicity of statins should be considered when we treat with antihyperlipidemic agents.

Fasting blood glucose levels and short-term beat-to-beat QT variability in subjects with normoglycaemia: is there a relationship?
C. Lengyel[1], R. Takács[1], A. Orosz[2], T.T. Várkonyi[1], A. Nemes[3], I. Baczkó[2], P. Kempler[4], T. Wittmann[1], J.G. Papp[2,5], A. Varró[2,5];
[1]1st Department of Medicine, University of Szeged, [2]Department of Pharmacology and Pharmacotherapy, University of Szeged, [3]2nd Department of Medicine and Cardiology Centre, University of Szeged, [4]1st Department of Medicine, Semmelweis University, Budapest, [5]Division for Cardiovascular Pharmacology, Hungarian Academy of Sciences and University of Szeged, Hungary.

Background and aims: Determination of short-term QT-interval variability (QTV) is an intensively investigated new and non-invasive method for assessment of proarrhythmic risk. Several studies have demonstrated that temporal QTV is a more sensitive predictor of ventricular arrhythmias than conventional QT-measurement parameters. Enhanced QTV has been observed in patients with diabetes mellitus. The aim of the present study was to evaluate the possible connections between the QTV, the fasting blood glucose level and the autonomic function in subjects with normal carbohydrate metabolism according to the WHO criteria.
Materials and methods: 32 healthy subjects (age: 38.1±11.6 years, male/female ratio: 16/16, fasting blood glucose: 4.9±0.4 mmol/l [4.2-5.9 mmol/l], $HbA1_c$: 5.6±0.4%, BMI: 25.4±4.5 kg/m^2, blood pressure: 129/74±17.0/8.5 mmHg; mean±SD) were enrolled into the study. ECGs were recorded continuously for 5 min and all leads were acquired by an ECG signal processing system. After analogue-to-digital conversion, the data were stored on hard disk and analyzed off-line using SPEL Advanced Haemosys software (v3.0). The QT intervals were measured in 31 consecutive beats. To characterize the temporal instability of beat-to-beat repolarization, Poincare' plots of the QT intervals were constructed, where each QT value was plotted against its former value. QTV was calculated using the following formula: $QTV=\Sigma|QT_{n+1}-QT_n|/(30x\sqrt{2})$. Autonomic function was assessed by means of five standard cardiovascular reflex tests.
Results: In subjects with normal carbohydrate metabolism, the QTV (3.2±0.7 ms) exhibited positive correlation with the blood glucose ($r = 0.61$, $p < 0.0005$) and the $HbA1_c$ ($r = 0.60$, $p < 0.0005$) levels. There were no significant correlations betweeen the QTV values and the parameters of the autonomic tests.
Conclusion: Our data suggest a close relationship between higher fasting plasma glucose levels within the normal range, and the enhanced short-term QTV in healthy subjects. This increase of temporal QT variability may be considered as an early indicator of the increased instability of cardiac repolarization.

Insulin resistance is associated with microangiopathy in type 1 diabetic patients treated with intensive insulin therapy from the onset of disease
A. Araszkiewicz[1], A. Uruska[1], D. Zozulinska-Ziolkiewicz[1], P. Uruski[2], B. Wierusz-Wysocka[1];
[1]Department of Internal Medicine and Diabetology, [2]Department of Hypertension, Angiology and Internal Medicine, Poznan University of Medical Sciences, Poland.

Background and aims: Chronic complications of diabetes still remain important clinical problem. Factors influencing development and progression of diabetic micro- and macroangiopathy are being searched. The aim of the study was to evaluate the relationship of indirect parameters of insulin resistance with risk of microangiopathy in patients with type 1 diabets, from the begining treated with intensive functional insulin therapy.
Materials and methods: The study group consisted of 81 patients (30 women, 51 men) in mean age 34±6.4 years with type 1 diabetes, with mean value of HbA1c (from years 1997-2007) 8.2±1.4 %, from the begining treated with intensive functional insulin therapy, who are under continous observation of the Department (for 10±1.5 years). Indirect parameters of insulin resistance were evaluated, such as: waist circumference, waist to hip ratio [WHR], body mass index [BMI], daily insulin requirement, gain of weight from the begining of the disease, lipid profile, estimated glucose disposal rate [eGDR], features of metabolic sydrome according to IDF definition. Moreover, the presence of chronic complications of diabetes (retinopathy, nephropathy, neuropathy) was assessed. Patients were divided into two groups depending on the presence or absence of any diabetic microangiopathy.
Results: In the group with microangiopathy (n=36; 44.4%) in comparison with patients without vascular complications of diabetes we found: higher weight before diabetes (77.3±17.0 vs 67.0±12.5 kg; p=0.008), larger waist circumference (88.9±11.7 vs 83.7±10.2 cm; p=0.036), higher WHR (0.90±0.08 vs 0.86±0.08; p=0.048), higher serum level of triglicerides (1.3±0.8 vs 0.9±0.3 mmol/l; p=0.002) and lower eGDR (7.17±2.4 vs 8.8±1.9 mg/kg/min; p=0.0019). Moreover, in patients with any diabetic complication features of metabolic syndrome according to IDF were stated more often [12 (33.3%) vs 4 (8.9%); p=0.006]. A significant relationship, adjusted for sex, age and duration of diabetes, between eGDR and the presence of diabetic microangiopathy was revealed [OR 0.65 (95%CI 0.49-0.86); p=0.0037].
Conclusion: The results clearly revealed that in patients with type 1 diabetes, from the begining treated with intensive functional insulin therapy, there is an independent influence of increased insulin resistance on the development of diabetic microangiopathy.

Alpha-lipoic acid prevent neointimal hyperplasia via induction of Nur77-mediated apoptosis of vascular smooth muscle cells
S.-J. Lee[1], E.-H. Koh[2], K.-U. Lee[2], H.-C. Jang[3], J.-Y. Jeong[1], B.-W. Kim[1], I.-K. Lee[1];
[1]Deparment of Internal Medicine and Biochemistry and Cell Biology, Kyungpook National University School of Medicine, Daegu, [2]Department of Internal Medicine, University of Ulsan College of Medicine, Seoul, [3]Deparment of Internal Medicine, Seoul National University Bundang Hospital, Republic of Korea.

Background and aims: Restenosis, a main obstacle in the success of balloon angioplasty or stenting, is caused by neointimal hyperplasia due to increased proliferation and decreased apoptosis of vascular smooth muscle cells (VSMCs) and restenosis rate is higher particularly in diabetic patients. This study was undertaken to verify the effect of alpha-lipoic acid (ALA), a naturally occurring antioxidant, on VSMC apoptosis and neointimal hyperplasia.
Materials and methods: Pro-apoptotic effect of ALA was examined by FACS, caspase-3 activity and TUNEL assays in VSMCs. Induction and nuclear export of Nur77 by ALA was demonstrated by Immunofluorescence and Western blotting. We confirmed the anti-restenoic effect of ALA in balloon-injured rat carotid arteries.
Results: ALA induced apoptosis of VSMCs, which is associated with intrinsic mitochondrial pathway, as evidenced by increased Bax expression, cytochrome c release and caspase-3 activation. Besides enhancement of Nur77 (NR4A1; NGFI-B/TR3) expression, ALA promoted nuclear export and interaction of Nur77 with Bcl-2, which triggers a Nur77-mediated apoptosis. Down-regulation of Nur77 by siRNA diminished the pro-apoptotic effect of ALA. Furthermore, ALA increased p38 MAPK phosphorylation, and a p38 MAPK selective inhibitor, SB203580, reduced both ALA-induced apoptosis and nuclear export of Nur77 in VSMCs. In balloon-injured rat carotid arteries, ALA increased Nur77 expression and TUNEL-positive apoptotic cells, leading to inhibition of neointima formation.
Conclusion: These results demonstrate that ALA prevents neointimal hyperplasia through induction of VSMC apoptosis mediated by Nur77 induction and p38 MAPK-dependent nuclear export of Nur77. Our results suggest that ALA can be used as a promising drug to prevent the development of vascular restenosis after angioplasty or stenting.

Glycaemic variability leads to impaired ischaemia-induced angiogenesis in diabetic mice

D. Pitocco[1], F. Biscetti[1], G. Straface[2], F. Zaccardi[1], P. Rizzo[3], S. Lancellotti[4], R. De Cristofaro[4], V. Arena[5], E. Stigliano[5], T. Musella[1], G. Ghirlanda[1], A. Flex[1];
[1]Internal Medicine, Catholic University, [2]Internal Medicine, Sapienza University, [3]Vascular Biology, Catholic University, [4]Haemostasis Research Center, Catholic University, [5]Pathology, Catholic University, Rome, Italy.

Background and aims: There is a growing epidemiological evidence that glycemic variability is an adjunctive risk factor of diabetic vascular complications. However, neither a cause-effect relation between glucose instability and vascular dysfunction, nor the molecular bases of a such dysfunction are known. Aim of our study was to investigate the role of glycemic variability on vascular complications and to explore the molecular pathways modulated by glycemic "swings".
Materials and methods: We used two mouse models: glycemic variability and chronic hyperglycemia. After induction of diabetes in 60 C57BL/6 mouse with STZ, 30 mice received once daily basal insulin administration - insulin glargine, 0.5 UI, 8 am - plus 2 oral bolus of 33% glucose solution (0.7 ml, 10 am and 2 pm) [glycemic variability group] and 30 mice once daily basal insulin only [chronic hyperglycemia]. During the treatment (30 days), we measured glycemia 4 times daily (10 am, 12 am, 2 pm, 4 pm). 30 days after induction of diabetes, we studied neovascularization in the hindlimb ischemia model in chronic hyperglycemia group, in glycemic variability group and in untreated age-matched controls.
Results: Indices of glycemic variability (MAGE, CONGA, SD) derived from about 3600 per group glucose measurements resulted significantly different (MAGE, p=0.019; SD, p=0.001; CONGA2h, p=0.006), whereas the mean of glycemic values did not (p=0.066). Laser Doppler perfusion imaging was performed before, immediately after, and on days 7, 14, 21 and 28 after hindlimb ischemia. Mean blood flow in untreated mice 28 days after hindlimb surgery reached ≈ 90% of the preischemic flow. Perfusion recovery was significantly attenuated in chronic hyperglycemia group mice compared with untreated mice on postoperative days 7, 14, 21 and 28 (respectively p=0.021, p=0.023, p=0.018 and p=0.032). Interestingly, the recovery was significantly impaired in glycemic variability group mice compared with chronic hyperglycemia group mice on postoperative days 7, 14, 21 and 28 (respectively p=0.023, p=0.026, p=0.008 and p=0.002). In addition, histological analysis revealed that the capillary density in ischemic limb was significantly increased in chronic hyperglycemia group mice whereas no such increase was noted in glycemic variability group mice (p=0.031). Finally, immunostaining and western blot analysis revealed that VEGF pathway on postoperative day 7 was altered in glycemic variability group mice compared with chronic hyperglycemia group mice.
Conclusion: Our data indicate that glycemic variability, regardless of average blood glucose levels, causes a significant impairment of ischemia-induced angiogenesis in diabetes and that this impaired collateral vessels formation is dependent on altered VEGF pathway.

1229

Immunohistochemical investigating advanced glycation end-product and its receptor expression in STZ-induced diabetic rat intestine

P. Chen, J. Zhao, H. Gregersen;
Mech-Sense, Aalborg Hospital, Denmark.

Background and aims: Gastrointestinal (GI) tract sensory motor disorders are common in patients with diabetes mellitus (DM); however, the pathogenesis is not well understood. Advanced glycation end products (AGEs) are produced during the development of DM. It is well known that AGEs relate to the morphological changes and biomechanical remodelling of arteries in DM. Therefore, the abnormal AGEs accumulation and its receptors (RAGEs) expression may also contribute to the diabetic GI dysfunction. Aims of the present study was to compare the AGE amount and RAGE expression in the mucosa, submucosa and muscle layers including ganglia (both myenteric and submucosal plexus) between normal and STZ-induced diabetic rat jejunum, ileum and colon.
Materials and methods: Twelve male Wistar rats weighing about 300 g were used in this study. Diabetes was induced in 6 rats by a single intraperitoneal injecting STZ (50 mg/kg) and survived for 56 days, and other 6 rats were served as normal control. Approval of the protocol was obtained from the Danish Committee for Animal Experimentation. The rats were anaesthetized with Hypnorm and Dormicum. The jejunal, ileal and colon segments were selected for study. The samples were fixed in 10% formalin and embedded in paraffin. Five-um thick sections were cut and AGE (N epsilon-(carboxymethyl)lysine, CML) and RAGE were detected by immunohistochemistry staining . T-test and Anova analysis were applied to statistically analyze the differences between two groups.
Results: The blood glucose concentration increased four- to fivefold in the diabetic rats (P<0.001). DM generated pronounced morphometric and histological changes; the thickness of the intestinal layers was pronounced increased during DM (P<0.01). Comparing with the normal control, the density of AGE staining was increased in the smooth muscle and epithelial cells of villi and crypt and villus of jejunal, ileal and colon segments in the diabetic rats (P<0.05), but it did not differ in the ganglia. The RAGE expression was increased in the epithelial cells of crypt and villus brush border in diabetic jejunum and ileum as well as in the ganglia (both myenteric and submucosal plexus) in all three segments of diabetic rats.
Conclusion: High density of AGE staining was found in smooth muscle, crypt and villus of diabetic intestine, and the expression of RAGE increased in ganglia, crypt and brush border of diabetic jejunum and ileum as well as in ganglia of diabetic colon. Accumulation of AGE in the villus and crypt as well as the increased expression of RAGE in brush border in diabetic jejunum and ileum may contribute to the disorders of digestion and absorption of intestine in DM. Accumulation of AGE in the muscle layers and increased expression of RAGE in the ganglia may contribute to the motor disorders of intestine and colon in DM.

ACE inhibition abolishes plaque formation in RAGE deficient diabetic apoE knockout mice

A.M.D. Watson, A. Soro-Paavonen, L. Jiaze, A. Bierhaus, M.E. Cooper, K.A.M. Jandeleit-Dahm;
Baker IDI Heart and Diabetes Institute, Melbourne, Australia.

Background and aims: Activation of the Receptor for Advanced Glycation End-products (RAGE) in diabetic vasculature is considered to be a key mediator of atherogenesis. RAGE deletion attenuates the development of atherosclerosis in the diabetic apoE knockout (KO) model of accelerated atherosclerosis. The renin angiotensin system also plays a pivotal role in diabetes associated plaque development. In the current study we have investigated the effect of additional ACE inhibitor therapy (quinapril) in diabetic RAGE/apoE double knockout (DKO) mice.
Materials and methods: ApoE KO and RAGE/apoE DKO mice were rendered diabetic with streptozotozin and followed for 20 weeks, at which time plaque accumulation (%) was assessed by *en face* analysis. Subgroups were treated with quinapril in drinking water (30 mg/kg).
Results: Diabetic RAGE/apoE DKO showed a significant reduction in plaque area (6.9± 1.4%, compared to diabetic apoE KO mice, 10.4 ± 0.8%, p<0.01). Quinapril treatment completely abolished plaque area to levels lower than those observed in non-diabetic apoE KO mice (0.6 ± 0.1, p< 0.01). This anti-atherosclerotic effect of quinapril in diabetic RAGE/apoE DKO mice was observed in all regional areas of the aorta and was independent of glycaemic and lipid parameters. However, quinapril treatment was associated with a significant reduction in blood pressure (84± 4 mm Hg compared to diabetic RAGE/apoE DKO mice (105 ± 6 mm Hg, p< 0.01).
Conclusion: The AGE/RAGE axis and the renin-angiotensin system may contribute to diabetes associated atherosclerosis via different pathways. Thus strategies that inhibit both pathways may exert superior vasculoprotection in diabetes accelerated atherosclerosis.

Changes of FGF-21 and it's receptors in high-fat diet apoE$^{-/-}$ mice

B. Sun[1,2], L. Li[1,3], G. Yang[4], Y. Chen[4];
[1]The Key Laboratory of Laboratory Medical Diagnostics in the Ministry of Education, [2]Department of Clinical Biochemistry, [3]Department of Clinical Biochemistry, [4]Department of Endocrinology, the Second Affiliated Hospital, Chongqing Medical University, China.

Background and aims: Fibroblast growth factor-21(FGF-21) has recently been characterized as a potent metabolic regulator. It exerted glucose-lowering activity in diabetic animal models, and the effects were insulin independent. FGFs bind and activate alternatively spliced forms of four tyrosine kinase FGF receptors (FGFRs 1-4). The expression of FGFs and FGFRs and the ability of specific ligand-receptor pairs to actively signal are important factors regulating FGF activity in a variety of biological processes. In our study, we investigate the effects of high-fat diet induced insulin resistance (IR) on Fibroblast growth factor-21 (FGF-21) and it's receptors levels in ApoE$^{-/-}$ mice.
Materials and methods: Healthy male ApoE$^{-/-}$ mice, eight-week-old, were randomly divided into normal-chow diet fed group (NF group, n=20) and high-fat diet fed group (HF group, n=20) differently for 16 weeks. The insulin sensitivity was evaluated by hyperinsulinemic-euglycemic clamp technique combined with 3- [^{3}H] glucose as a tracer. The mRNA expressions of FGF-21, β-klotho and FGFR1-4 were measured by quantitative RT-PCR. FGF-21 protein levels were determined by western blot.
Results: In HF group, FBG, PIns, FFA, TC, TG, LDL-C and HDL-C were significantly higher than in NF group (all P<0.01). During the steady-state of clamp, PIns was significantly higher in HF group than NF group (P<0.01), and glucose infusion rate (GIR) in HF group was significantly decreased compared with NF group (30.2±3.1*vs.*44.6±3.0 mg·kg^{-1}·min^{-1}, P<0.01). In the end of insulin clamp, glucose disappearance rate (G_{Rd}) was significantly lower in HF group than NF groups (38.2±0.8*vs.*48.0±0.9 mg·kg^{-1}·min^{-1}, P<0.01). The FGF-21 mRNA expressions of hepatic and adipose tissues in HF group were both significantly increased compared with NC group (both P<0.01), and β-klotho levels were also increased (P<0.05). In HF group, FGFR1 mRNA expressions were higher than NF group in hepatic and adipose tissues (both P<0.01), and FGFR3 mRNA were increased too (P<0.01 and P<0.05, respectively). FGFR4 mRNA levels were significantly up-regulated in HF group than NF group in hepatic tissue (P<0.05) but there were no significant differences in liver. Plasma FGF-21 protein levels were elevated in HF group compared with NF group (P<0.01), and FGF-21 protein expression of hepatic and adipose tissues were also increased (both P<0.05).
Conclusion: There is an abnormality of glucose-lipid metabolism and insulin resistance in ApoE$^{-/-}$ mice fed by high-fat diet, and FGF-21-β-klotho-FGFR1 and FGF-21-β-klotho-FGFR3 maybe the principal modes on regulating glucose-lipid metabolism.

Gene expression profiling of sulfonylureas in endothelial cells and vascular effects in diabetic ApoE null mice

N.E. Magnusson[1,2], P. Koh[2], I. Haviv[2], R.C. O'Brien[2], T.J. Allen[2], M. Olukman[2], U. Simonsen[1], M.E. Cooper[2], J. Rungby[1];
[1]Pharmacology, University of Aarhus, Denmark, [2]Diabetes Division, Baker IDI Heart and Diabetes Institute, Melbourne, Australia.

Background and aims: Sulfonylurea drugs (SU) are widely used and remain a mainstay in the treatment of type 2 diabetes. Recent research suggests that different SU may have different cardiovascular risk profiles. SU stimulate insulin secretion by closing the ATP-sensitive potassium channel (K_{ATP}) subunit SUR1 in beta-cells. K_{ATP} channels in beta cells and muscle share the common pore forming subunit Kir6.2 but vary in their sulfonylurea receptors SUR1 and SUR2. Previous studies have shown that certain SU such as glibenclamide target both SUR1/2 subunits whereas gliclazide is SUR1 specific. To evaluate the potential different vascular effects of SU firstly we assessed the impact of SU exposure on endothelial cell gene expression using microarray analysis. Secondly, we compared the effects of two SU on plaque development in a model of diabetes associated atherosclerosis.
Materials and methods: Primary HUVEC cells were exposed to 1μM of gliclazide and glibenclamide for 24 hours. Control groups received vehicle. Each experiment was performed as three biological replicates. Gene expression profiles were analyzed using GeneChip ST1.0 arrays. For each drug, gene lists were generated using the following criteria: fold change > 2 and $p < 0.05$ (test vs. ctrl) and $p > 0.05$ for the other drug. Pathways were analyzed using Ingenuity Pathway Analysis. Significant biological functions and canonical pathways were identified using Fishers exact test.
Streptozotocin diabetic Apolipoprotein E (ApoE) knockout (KO) mice were untreated or treated with either glibenclamide or gliclazide for 20 weeks. After staining lipids with Sudan IV, plaque areas were quantitated by the *en face* method for arch, thoracic, and abdominal segments of the aorta.
Results: Several networks were identified for both drugs. The major categories of these networks related to molecular transport and cell signalling. Both SU increased the expression of NOS2 and comparison of the analyses for upregulated genes showed an increased significance for gliclazide over glibenclamide of canonical pathways relating to nitric oxide signalling in the cardiovascular system as well as pathways linked to PDE5, the target of sildenafil. Analyses of plaque areas in diabetic ApoE deficient mice treated with glibenclamide showed a significant increase in total plaque area compared to untreated and gliclazide treated mice (control [non-diabetic], n=7, 1.6 ± 0.5%; untreated diabetic, n=8, 9.0 ± 1.5%; diabetic + gliclazide, n=11, 10.8 ± 0.9%; diabetic + glibenclamide, 17.5 ± 2.7%*, $p < 0.02$ vs. other groups). The increase in plaque area seen in glibenclamide treated mice was not restricted to one aortic region. No difference in plaque area was observed between gliclazide and untreated diabetic ApoE KO mice.
Conclusion: This study demonstrates that SU affect gene expression in endothelial cells. The differences in gene expression between drugs were more pronounced than the similarities suggesting a differential profile among SU in endothelial cells. The differences between SU may be relevant to the disparate vascular effects seen *in vivo* in preclinical models of diabetic atherosclerosis with glibenclamide and gliclazide. These observations are in agreement with previous findings suggesting that gliclazide is a general scavenger of radicals and this may relate to differences in SUR1/2 specificities.

Compensated and non-compensated insulin resistance induces differential cardiovascular damage in obese BATIRKO mice

M. Benito[1], A. Gomez Hernandez[1], N. De Las Hersas[2], Y. Fernandez Otero[1], O. Escribano[1], C. Guillen[1], V. Cachofeiro[2], V. Lahera[2];
[1]Bioquimica y Biologia Molecular, Facultad De Farmacia, [2]Fisiologia, Facultad De Medicina, Universidad Complutense, Madrid, Spain.

Background and aims: Endothelial dysfunction is one manifestation of the many changes induced in the arterial wall by the metabolic abnormalities accompanying insulin resistance and diabetes. Among key players of insulin resistance, insulin receptor (IR) gene plays a relevant role. We have previously generated an experimental model of inactivation of IR in brown adipose tissue (BATIRKO) using the expression of recombinase Cre under the uncoupling protein-1 promoter. Mice lacking IRs in this tissue show a decrease in intercaspular brown fat mass and a progressive decrease in glucose tolerance due to an insulin-secretion defect. The aim of this work was to study the differential cardiovascular damage in compensated and non-compensated obese BATIRKO mice showing insulin resistance.
Materials and methods: BATIRKO mice were fed on standard diet (CT group) or high-fat diet (Obese group) for 16 weeks.
Results: Obese BATIRKO mice show a significant increase of WAT/ body weight ratio, hyperlipidemia, fatty liver, glucose intolerance and insulin resistance. However, two groups of compensated insulin resistance (hyperinsulinemic) and non-compensated insulin resistance (normoinsulinemic) were observed in obese BATIRKO mice. Moreover, lipid accumulation in peripheral tissues such as liver, heart, skeletal muscle and aortic wall was much depending on the level of expression of uncoupling protein 2 (UCP-2) or 3 (UCP-3), which in fact turned out in developing secondary insulin resistance. Non-compensated obese BATIRKO mice, but not those compensated, have a reduced acethylcholine-induced relaxation, an increased of ICAM-1, MCP-1 and PAI-1 expression in aorta tissue as compared with controls. In addition, structural alterations of the vessel wall and accumulation of lipids within intima of the aortic arch were also observed in the group of non-compensated insulin resistance as compared with the groups of compensated insulin resistance or control mice.
Conclusion: These data suggest that BATIRKO mice under high-fat diet, remarkably those that non-compensate ongoing insulin resistance increasing insulin secretion, induced an endothelial dysfunction and a greater inflammatory activity and intimal thickening in the aortic arch.

Lutein and docosahexaenoic acid prevent cortex lipid peroxidation in streptozotocin-induced diabetic rat cerebral cortex

M. Miranda[1], E. Arnal[1,2], M. Muriach[1], D. Silvestre[1], F. Bosch-Morell[1], F.J. Romero[1];
[1]Fisiología, Universidad CEU-Cardenal Herrera, [2]Fundación Oftalmológica del Mediterráneo, Valencia, Spain.

Background and aims: The mechanisms underlying diabetic encephalopathy, are only partially understood. In this study, we examined whether docosahexaenoic acid (DHA) and lutein could attenuate the oxidative changes of the diabetic cerebral cortex in a rodent model of diabetes.
Materials and methods: Male, Wistar rats were used in the study. Diabetes was induced in animals by a single intraperitoneal injection of STZ (65 mg/kg) in 0.1 M citrate buffer, pH 4.5. Animals were treated with lutein or DHA for a period of twelve weeks. At the end of week 12, the rats were killed by cervical dislocation. One of the hemispheres was dissected and fixed, cryoprotected and cryosectioned. The other hemisphere was dissected; cortex was homogenized in prechilled 0.2 M potassium phosphate buffer, pH 7.0. This homogenate was used to assay GPx activity, GSH, malondialdehyde (MDA), and protein concentrations.
Results: The levels of malondialdehyde (MDA) were significantly increased and glutathione levels (GSH) and glutathione peroxidase activity (GPx) were decreased in diabetic rats. The number of 4- hydroxynonenal (4-HNE) positive cells was increased in the cortex of diabetic rats. Treatment with insulin, lutein or DHA and the combination of each antioxidant with insulin, significantly restored all markers concentrations mentioned above, as well as the increase in 4-HNE inmunofluorescence. We combined 4-HNE immunofluorescence with NeuN (Neuronal Nuclei) staining. The NeuN staining demonstrated extensive overlap with the 4-HNE staining in the cortex from diabetic rats.
Conclusion: Our findings demonstrate a clear participation of induced glucose oxidative stress in the diabetes-induced alterations in cerebral cortex, and we also demonstrate, in vivo, that the cells suffering oxidative stress are neurons. Lowering oxidative stress through the administration of different antioxidants may be beneficial for the central nervous tissue in diabetes.

Brain signalling properties of long-acting insulin analogue glargine and detemir for memory and spatial learning in mice

T. Sasaoka, N. Mori, T. Wada, H. Tsuneki;
Department of Clinical Pharmacology, University of Toyama, Japan.

Background and aims: Central insulin action plays a crucial role in spatial learning and memory in central nervous system. Thus, intranasal injection of insulin is known to ameliorate the cognitive function in human. However, the impact of long-acting human insulin analogues glargine and detemir on the brain cognitive function is unknown. Replacement of amino acids and altered binding properties in these insulin analogues might affect the functional properties in brain. The aim of the present study was to investigate the impact of glargine and detemir on the signalling properties for spatial learning and memory in mice.
Materials and methods: Intracerebroventricular (i.c.v.) injection of glargine, detemir, and human insulin was conducted in C57BL/6J, db/+m control and db/db diabetic mice. Insulin-induced phosphorylation of Akt, which is important for the neuronal function and synaptic plasticity in the hippocampus, cerebral cortex and hypothalamus, was examined by Western blotting analysis in fasting mice. The effect of i.c.v. injection of insulin analogues on spatial learning and memory was assessed by Morris water maze test.
Results: We have previously shown that glargine possesses similar signalling properties in the peripheral target tissues compared to human insulin, whereas the biological properties of detemir are different depending on the tissue and the concentration of albumin in the milieu. In the present study, i.c.v. injection of glargine, detemir, and human insulin (10 mU/mouse) induced similar time-course of phosphorylation of Akt at Ser^{473} and Thr^{308} residues peaking at 30 min in hypothalamus of db/+m mice. On the other hand, the Akt phosphorylation was peaked at 3 h after the i.c.v. injection and decreased thereafter in the hippocampus and cerebral cortex of the control mice. Interestingly, the degree of detemir-induced phosphorylation of Akt was smaller, whereas the effect of glargine was similar, compared to human insulin. In the hippocampus and cerebral cortex of db/db mice, the Akt phosphorylation lasts longer and is still remained at 6 h after i.c.v. injection of both insulin analogues. C57BL/6J mice were trained for 4 days to memorize the location of platform in Morris water maze test. Although glargine, detemir, and human insulin i.c.v. injected immediately after finishing the training (24 h before the probe trial) did not affect the spatial learning and memory, the i.c.v. injections just before the probe trial considerably enhanced the ability in mice. In addition, the ability of spatial learning and memory evaluated by probe trial 7 days after i.c.v. injection was differentially altered between insulin and insulin analogues. These alterations are not due to the change of motor activity in mice, because the swimming speed and distance during the probe trial were not changed by i.c.v. injection of these insulins.
Conclusion: These results suggest that glargine is an insulin analogue physiologically more similar to human insulin than detemir with regard to the signalling property in the hippocampus and cerebral cortex of mice. In addition, all three insulins appear to mainly promote the recall process, but not consolidation process, of memory in mice. Glargine and detemir may affect the cognitive function by influencing the memory recall process with different properties in the physiological and pathological state of diabetes.

Defective pancreas vascularisation and downregulation of soluble epoxyde hydrolase gene expression in various organs in Goto-Kakizaki (GK) foetuses

M.-H. Giroix[1], J.-C. Irminger[2], S. Calderari[3], F. Schmidlin[4], G. Lacraz[1], M. Cornut[2], J. Coulaud[1], M. Kergoat[4], F. Homo-Delarche[1];
[1]Laboratory of Biology and Pathology of Endocrine Pancreas, Unit of Functional and Adaptative Biology, Univ Paris-Diderot, Paris, France, [2]Department of Genetic Medicine and Development, CMU, University of Geneva, Switzerland, [3]Inserm u833, Collège de France, Paris, France, [4]Merck-Serono, Chilly-Mazarin, France.

Background and aims: We identified islet inflammation associated with microangiopathy in diabetic GK rats (a spontaneous model of T2D). Signs of islet microangiopathy are also present in prediabetic 1-week-old GK neonates (1-w-GK), together with islet oxidative stress (OS). In addition, GK rats, particularly females, show hypercholesterolemia. Both hyperglycemia and hypercholesterolemia trigger OS and have deleterious effects on vessels. Both also increase placental inflammation, which takes place even during normal pregnancy. Moreover, there is evidence for linking dysmetabolic conditions during pregnancy to hypertension, cardiovascular disease and diabetes in the offspring. This probably occurs via altered fœtal programming. Because endothelial signals are essential during islet development, vascular alterations might act during fœtal life to trigger T2D. In E21 GK fœtuses, β-cell mass is decreased by 80%. Our aims were to evaluate blood glucose and lipids, pancreas vascularisation and gene expression in various organs in E21 GK fœtuses, as compared to Wistar controls.
Materials and methods: 1) glycemia and lipid assays were done on sera; 2) expression of 7 genes, selected on the basis of previous studies conducted in 1-w- Wistar and GK islets, were evaluated by quantitative RT-PCR in umbilical cord, placenta, liver and pancreas; 3) pancreatic vascularisation was quantified after immunohistochemistry for nestin, a recognized endothelial marker.
Results: 1) systemic glucose, cholesterol and cholesterol/HDL ratio were significantly higher in GK fœtuses, with no difference in triglycerides, FFA and HDL levels; 2) while in 1-w-GK islets, we found a significant upregulation of genes encoding inflammatory molecules, such as caspase-1 (x9.0), IL-18 (x3.9), IL-15 (x1.4) and CXCL-1 (x3.9), the pancreatic expression of the 4 genes was variable from one E21 GK RNA preparation to another, being however more often upregulated. The same trend toward upregulation of inflammatory genes was observed in the placenta, while it was less marked in liver and umbilical cord; the expression of 2 genes encoding proangiogenic factors, neuropilin-1 and neuropeptide Y, which was significantly downregulated in 1-w-GK islets (x0.6 and x0.1, respectively), was not decreased in most E21 GK organs; nevertheless, gene encoding soluble epoxyde hydrolase (sEH), which inhibits the catabolism of epoxyeicosatrienoic acids (EETs), was found to be downregulated by 70-90 % in E21 GK fœtal organs; sEH, by increasing levels of EETs, would augment their vasodilatator, antiinflammatory, antioxidative and proangiogenic effects; 3) pancreatic vascularisation was decreased by 60 % in E21 GK fœtuses.
Conclusion: E21 GK fœtuses are hyperglycemic and hypercholesterolemic. Their reduced β-cell mass is associated with decreased pancreatic vascular-

sation, which might participate to T2D pathophysiology. The strong under-expression of sEH in various GK fœtal organs suggests a very early defence mechanism in GK rats, probably linked to maternal OS induced by carbohydrate and/or lipid disturbances.

The motility of jejunum and ileum is changed in STZ-induced diabetic rats *in vitro*
J. Zhao, H. Gregersen;
Mech-Sense, Aalborg Hospital, Denmark.

Background and aims: The symptoms related to gastrointestinal tract dysfunctions, such as diarrhoea and constipation, are common in patients with diabetes mellitus. Both intestinal hypo-motility and hyper-motility were reported in the diabetic patients and animals. Aim of the present study was to compare spontaneous, flow-induced and distension-induced contractions *in vitro* in the jejunal and ileal segments between normal and diabetic rats.
Materials and methods: Twenty-eight male Wistar rats weighing about 300 g were used in the study. Approval of the protocol was obtained from the Danish Committee for Animal Experimentation. The diabetes was induced by a single intraperitoneal injecting STZ (50 mg/kg) in 18 rats and survived for 28 and 56 days (9 rats in each group), and 10 normal rats were served as control. The rats were anaesthetized with Hypnorm and Dormicum. The motility experiments of intestinal segments were carried out in the organ bath containing Krebs solution aerated with a gas mixture of 95% O_2-5% CO_2 at pH 7.4, temperature 37 C. The pressure and outer diameter of intestinal segments were synchronically recorded during spontaneous contraction, flow (0.6 ml/min)-induced contraction with outlet open to 0, 1.5, 3 and 4.5 cmH_2O pressures and ramp distension up to pressure 10 cmH_2O with outlet closed. The frequency and amplitude of pressure and diameter changes of contraction were analyzed. The differences between the groups were statistically analyzed using t-test and Anova analysis.
Results: The blood glucose concentration increased four- to fivefold and the intestinal wall layer thickness pronounced increased in the diabetic rats ($P<0.001$). The changes of pressure and diameter can be measured during the intestinal contraction; however the diameter changes reflect the motility pattern better. For spontaneous, flow-induced and distension-induced contractions, the frequency did not differ between 28 days diabetic rats and normal rats ($P>0.05$); however the frequency was lower in 56 days diabetic rats than that in normal rats ($P<0.05$). The amplitude was higher in the intestinal segments of diabetic rats both for 28 and 56 days than that in the normal rats ($P<0.05$). During ramp distension, the threshold of pressure to induce phasic contraction did not differ between 28 days diabetic rats and normal rats ($P>0.05$); however the threshold of pressure to induce phasic contraction was lower in 56 days diabetic rats than that in normal rats ($P<0.05$). The diameter changes to induce phasic contraction was lower in diabetic rats both for 28 and 56 days than that in normal rats ($P<0.05$ and 0.01).
Conclusion: The motility patterns of jejunum and ileum differed between STZ-induced diabetic rats and normal controls. The diabetic intestine seems more sensitive to the flow and distension. These may contribute to the intestinal dysfunction, such as diarrhea seen in diabetics. Future studies should investigate the mechanism of intestinal motor disorder in diabetes, such as investigating advanced non-enzymatic glycation end products accumulation and its receptors expression at diabetic intestinal tissues and the enteric nerve function combined with the intestinal motility in the diabetic animal models.

When it comes to platelet, hypoglycaemic drugs are not all the same. Antiplatelet treatment and pharmacological treatment for type 2 diabetes
E. Mannucci[1], M. Monami[1], R. Marcucci[2], I. Iacomelli[1], C. Lamanna[1], N. Marchionni[1], G. Gensini[2], R. Abbate[2];
[1]Critical Care Medicine and Surgery, Unit of Gerontology - University of Florence, [2]Department of Medical and Surgical Critical Care, Thrombosis Centre, University of Florence, Azienda Ospedaliera Universitaria Careggi, Florence, Italy.

Background and aims: The use of antiplatet therapy for secondary prevention in patients who have experienced a cardiovascular event is well established. Diabetes has been found to be associated with ASA resistance. Since ASA resistance is associated with a higher risk of cardiovascular events, this phenomenon could be responsible for the reduced efficacy of antiplatelet therapy in diabetes suggested by some studies. Aim of this study is the identification of clinical and laboratory predictors of resistance to ASA among type 2 diabetic patients in primary prevention.
Materials and methods: A consecutive series of 80 patients were enrolled, provided that they satisfied the following criteria: 1)Established diagnosis of type 2 diabetes; 2)Current treatment with at least 100 mg ASA in the last three months; 3)Absence of other antiaggregant (ticlopidine, clopidogrel) or anticoagulant therapy; 4)Informed consent. All patients were assessed for post-treatment residual platelet reactivity (RPR) in platelet-rich plasma by 10 microM adenosine 5'-diphosphate (ADP), 1 mM arachidonic acid (AA) and 2 microg/ml collagen-induced platelet aggregation and in whole blood by the PFA-100 system. Patients were considered ASA resistant if AA levels were> 20% and ADP> 70%.
Results: Patients with ASA resistance showed a higher fasting plasma glucose, Erythrocyte Sedimentation Rate, and von Willeband factor, and a higher prevalence of renal insufficiency; furthermore, patients resistant to ASA showed a lower prevalence of treatment with statins and metformin, and a higher prevalence of insulin treatment. The association between metformin treatment and ASA sensitivity retained statistical significance at multivariate analysis, after adjusting for age, sex, and chronic renal insufficiency, whereas insulin therapy was associated with ASA resistance after adjusting for the same confounders .
Conclusion: This is the first report suggesting that hypoglycemic treatment could modulate sensitivity to antiaggregant therapy in type 2 diabetic patients.

Effect of perindopril therapy on expression of genes involved in pathogenesis of chronic complications in patients with type 1 diabetes mellitus
M. Flekac, A. Horinek, M. Jarolimkova, J. Skrha;
3rd Department of Internal medicine, General University Hospital, Prague, Czech Republic.

Background and aims: Study has focused on perindopril therapy effect on genes which products are involved in pathogenesis of chronic complications in patients with diabetes mellitus.
Materials and methods: 25 patients (14 males/11 females) with type 1 diabetes mellitus were enrolled in this study, mean age was 46±11 years, mean duration of disease was 14±6 years. Perindopril therapy started newly or after wash out period in dose 4 mg per day. Gene expression study has been carried out in time 0, 3 and 6 months after initiation. RNA has been extracted from monocytes of blood using automatic isolator (MagNA Pure Compact). Microfluid cards TLDA (TaqMan Low Density Array) and 7900HT Fast Real-Time PCR System have been used to parallel determination of gene expression in 90 studied genes.
Results: Modifications in expression level of many genes has been observed after 6 months of the study. Products of affected genes may play role in pathogenesis of both macroangiopathy [genes for endothelin 1 (ET1), fibronectin 1 (FN1), interleukin 4 (IL4), interleukin 10 (IL10), macrophage scavenger receptor 1 (MSR1), inducible NO synthase (NOS2), oxidized LDL receptor 1 (OLR1)] and microangiopathy [genes for caldesmon (CALD1), fibroblast growth factor 1 (FGF1), elongation factor 1 (EGF1), engulfment and

cell motility 1 factor (ELMO1), MAP kinase 2 (MKNK2), metaloproteinase 1 and 9 (MMP1, MMP9), inducibile cyklooxygenase 2 (PTGS2), AGE receptor (RAGE), transforming growth factor 1 (TGFB1)] and also in insulin resistence pathogenesis [membrane glycoprotein called plasma cell antigen 1 (ENPP1), estrogen receptor 1 (ESR1), PPAR γ (PPARG)]. Changes expressed as multiples of gene expression level together with significance level *p* are presented in brackets below. Gene expression increased in ELMO1 (1,5 times (T), *p<0,05*), ESR1(1,8 T, *p<0,01*), MSR1 (1,9 T, *p<0,01*), OLR1 (2,6 T, *p<0,05*) and more significantly in NOS2 (17 T, *p<0,01*), whereas decreased in CALD1 (-1,4 T, *p<0,05*), FGF1 (-1,6 T, *p<0,05*), EDN1 (-1,2 T, *p<0,05*), EGF (-2,1 T, *p<0,05*), ENPP1 (-1,9 T, *p<0,05*), FGF1 (-2,1 T, *p<0,05*), FN1 (-1,2 T, *p<0,05*), IL4 (-3 T, *p<0,05*), IL10 (-3,5 T, *p<0,01*), MKNK2 (-1,8 T, *p<0,05*), MMP1 (-2,1 T, *p<0,05*), MMP9 (-2,4 T, *p<0,05*), PTGS2 (-2 T, *p<0,05*), RAGE (-5 T, *p<0,05*), TGFB1 (-1,5 T, *p<0,05*) and more significantly in PPARG (-21 T, *p<0,01*). Surprisingly we didn´t find any modifications in expression level of genes for cytoadhesive molecules (ICAM-1, VCAM, PECAM-1, selectins), VEGF, PAI-1, genes for antioxidant enzymes.

Conclusion: The results of this study show that renin-angiotensin system blockade may positively affect various processes in the pathogenesis of chronic complications in Type 1 diabetes.

Tetramethylpyrazine protects oxidative damage and mitochondrial dysfunction in C2C12 muscle cells

X. Gao[1], X.L. Zhao[2];
[1]Endocrinology & Metabolism, Zhongshan Hospital, [2]Endocrinology, Huashan Hospital, Shanghai, China.

Background and aims: We previously reported "Qing Huo Yi Hao" (QHYH) a prescribed traditional Chinese medicine preparation could decrease urinary microalbumin excretion in type 2 diabetic patients and have an antioxidant effects on oxidative stress induced by high glucose in endothelial cells. TMP (tetramethylpyrazine) is one of the active components of QHYH, we had demonstrated it displayed comparable antioxidant and endothelial protective effects as QHYH by reverse downregulation of Akt and eNOS phosphorylation and reduction of NO generation in high glucose treated bEnd.3 cells. One of the metabolic features of diabetes or insulin resistance in skeletal muscle is an impairment of glucose utilization and insulin sensitivity that has been related to the oxidative stress induced induced by elevated plasma free fatty acids (FFA). The present study was designed to investigate whether TMP (tetramethylpyrazine) also improves free fatty acid induced muscle cell damage by reducing oxidative stress through the pathways that increase of mitochondrial biogenesis and mitochondrial fatty acid oxidation activity.

Materials and methods: Mouse C2C12 myoblasts was cultured and differentiated to C2C12 muscle cells and oxidative damage was induced by palmitate(0.2mmol/l) for 72h. Mitochondrial sources of reactive oxygen species(ROS) was measured by the MitoTracker Red method.The mitochondrial membrane potential was assessed by using the JC-1 dyes methods. mitochondrial DNA was quantified by real time PCR. The BD oxygen Biosensor system was used to detect the oxygen consumption as an indication of mitochondrial respiration activity. We also use western blot to detect the expression of mitochondrial respiratory chain complex III as an index of mitochondrial function. Uptake of 2-deoxyglucose by C2C12 myotubes was measured using glucose 3H labeled method.

Results: TMP level ranging from 50-500uM could significantly reduce palmitate induced ROS production from mitochondrial(Fig1A), and also significantly improve the mitochondrial membrane potential(Fig1B).The mitochondrial D-loop mRNA expression which reflecte the mitochondrial DNA synthesis was also significantly increased by TMP comparing with control(Fig1C).The downregulation of some key signal molecules such as PGC1α,NRF1 and Tfam that regulate the mitochondrial function and ROS production were also significantly reversed by TMP in palmitated induced state(Fig1D). The expression of mitochondrial respiratory chain complex III was upregulated by TMP compared with the palmitate induced state(Fig1E). For cell respiration the TMP could significantly reverse the reduction of oxygen consumption induced with palmitate(fig1F-G).For glucose uptake there seemed a trends that TMP might increase the uptake of glucose(fig1H).

Conclusion: Tetramethylpyrazine protects palmitate-induced oxidative damage and improves mitochondrial dysfunction in C2C12 muscle cells.

Sodium tungstate inhibits early atherothrombotic pathways in human endothelial cells

F. Hanzu[1], M. Palomo[2], P. Gomez-Abellan[3], M. Garaulet[3], M. Diaz-Ricart[2], M. Parrizas[1], R. Gomis[1];
[1]Endocrinology and Diabetes, Hospital Clinic /IDIBAPS, Barcelona, [2]Hemotherapy and Haemostasis, Hospital Clinic, Barcelona, [3]Department of Fisiology, University of Murcia, Spain.

Background and aims: Visceral abdominal obesity is a major cardiovascular risk factor. Inflammatory endothelial injury initiates and sustains atherothrombosis. This study aims to investigate the therapeutic role of sodium tungstate in the activation of early atherothrombotic inflammatory mechanisms.

Materials and methods: We obtained omental adipose tissue from morbidly obese males, without other cardiometabolic risk factors (BMI: 40-45 kg/m2, n=6) undergoing bariatric surgery. Fat pads were separated in their stromal and adipocyte cell fractions. Resulting cell types and fat pads were incubated with nonfetal medium for 24h in order to obtain the secretome. Moreover half of this samples were also coincubated with sodium tungstate (100 um). 3 different conditioned media (CM) containing the secretome of the visceral fat pad or the visceral stromal or the adipocyte cell fraction were obtained. Studies were performed on human endothelial cells (EC) monolayer. EC were incubated for 24h with 100% of each CM. Expression of adhesion molecules in EC were determined by immunogold labelling and quantitative real time PCR.

Results: Recent results from sodium tungstate treated obese patients (data not shown) indicate that sodium tungstate presents antiinflammatory and endothelial protective properties (as determined by CRP decrease and no changes in endotelial circulant cells). Exposure of EC to the CM secreted by the visceral fat pad, adipocyte and stromal cellular fraction induces a significant expression of adhesion molecules (VCAM-1, ICAM-1). EC exposed to the secretome (CM) of sodium tungstate treated samples presents a significant (OR: 2,68; p< 0,05) reduction in the expression of the named adhesion molecules at protein and at gene level (VCAM-1 and ICAM-1: decrease of 32 and 27% respectively for fat pads; 20 and 27% for stroma; 18 and 30 % for adipocytes). No effect was observed in EC treated directly with sodium tungstate and in nontreated cells.
Conclusion: These results indicate that sodium tungstate inhibits in human endothelial cells the activation of early atherothrombotic inflammatory pathways through changes in the secretion pattern of inflammatory cytokines from the adipose obese tissue. This opens for sodium tungstate, previously studied for his antiobesity actions new therapeutical perspectives in the complementary prevention of cardiometabolic risk.

BBR reduces hepatic fat content in the rats of NAFLD by decreasing the methylation of MTP promoter

X.X. Chang[1], X. Gao[1], M. Liu[1], D.R. Lu[2], J. Fei[2];
[1]Endocrinology & Metabolism, Zhongshan Hospital, [2]State Key Laboratory of Genetic Engineering, School of Life Science and Institute of Biomedical Sciences, Shanghai, China.

Background and aims: Berberine (BBR) can reduce body weight, lower serum triglyceride(TG) and cholesterol, and improve insulin sentivity in db/db mice, high-fat-fed hamsters and patients with type 2 diabetes. There is an undisputed link between high-fat diet and the development of NAFLD, and downregulation of hepatic microsomal triglyceride transfer protein (MTP) activity is associated with NAFLD. But the mechanisms of the high-fat diet(environmental factor) regulation of MTP expression in liver still remains unclear. The interaction between genes and environment could involve epigenetic factors such as DNA methylation, and MTP promoter contains rich-GpC, which is susceptible to DNA methylation. Here we investigated whether hepatic MTP transcription is effected by the methylation of hepatic MTP promoter in NAFLD rats induced by high-fat diet and whether BBR reduces hepatic fat content by decreasing the methylation of MTP promoter.
Materials and methods: Twenty-four male Sprague -Dawley(SD) rats were divided at random into two groups. The rats in the control group(normal diet ND n=8) and in the NAFLD model (high-fat diet HFD n=16) were fed ad libitum with normal chow and high-fat diet(18% lard, 10% egg yolk powder, 2% cholesterol and 0.2% Sodium Cholate)respectively. After 8 weeks, Rats in the HFD group were divided randomly into two groups, one of which were treated with berberine (BBR) orally at 200mg/(kg d)(n=8)and the other with placebo(n=8), for sixteen weeks. On the last day of the experiment, all of the rats were euthanized after overnight fast. Hepatic TG content and mRNA level of hepatic MTP were measured in three groups. The CpG methylation status was determined by bisulphite direct sequencing of the PCR amplificates of MTP promoter.
Results: The body weights of rats with high-fat diet were greater than those with normal diet(p<0.05, Fig1A). The livers of the SD rats fed the high-fat diet showed pronounced hepatic steatosis. While MTP mRNA was reduced by 70%(p<0.002,Fig1B) in livers from rats in the HFD group, high-fat feeding caused a 2-fold increase in hepatic weight(p<0.05,Fig1C) and 1.3-fold increase in liver TG content(p<0.001,Fig1D). Treatment of high-fat feeding rats with BBR for 16 weeks reduced liver weight by 21%(p<0.05,Fig1C) and hepatic TG by 14% (p<0.01, Fig1D), with a 1.9-fold increase in hepatic MTP mRNA(p<0.05, Fig1B). DNA methylation level of MTP promoter (five out of seven CpG islands) of high-fat diet rats was increased in liver compared with normal diet group (p<0.05, Fig1E), while treated with BBR, the methylation level was decreased in almost all CpG sites of MTP promoter, especially in -20 CpG site, by up to 12%(p<0.05) compared with placebo in high-fat diet rats (Fig1E).
Conclusion: DNA methylation of MTP promoter are likely to be involved in the pathogenesis of high-fat diet induced NAFLD and BBR reduces hepatic fat content partially by decreasing the methylation of MTP promoter.

1243

Effects of prescription omega-3-acid ethyl ester vs olive oil on macro- and microvascular function in subjects with type 2 diabetes mellitus

S. Nandrean[1], A. Stirban[1], A. Pop[1], C. Götting[2], R. Tamler[3], T. Gawlowski[1], B. Stratmann[1], D. Tschoepe[1];
[1]Diabetes Center, Heart and Diabetes Center NRW, Bad Oeynhausen, Germany, [2]Institute of Laboratory and Transfusion Medicine, Heart and Diabetes Center NRW, Bad Oeynhausen, Germany, [3]Division of Endocrinology, Diabetes and Bone Diasese, Mount Sinai Medical Center, New York, United States.

Background: Recent evidence supports protective effects of omega-3-acid ethyl esters on endothelial function in populations at risk. We investigated the effect of omega-3-acid ethyl ester (eicosapentaenoic acid - EPA- and docosahexaenoic acid - DHA) on postprandial vascular function in subjects with type 2 diabetes mellitus (T2DM).
Methods: We conducted a double-blind, placebo-controlled, randomized, cross-over study in 34 subjects with T2DM who received 2g/d purified EPA and DHA, or olive oil (placebo) capsules as add-on to their usual therapy and diet for 6 weeks. Macrovascular function was assessed by ultrasound measurements of flow mediated dilatation (FMD) of the brachial artery. Microvascular function was assessed using a Laser - Doppler method. We estimated the blood flow as area under the curve (AUC) following reactive hyperemia. At the beginning and the end of each 6 weeks period, investigations were performed in the fasting state (0h) as well as 2, 4 and 6 hours following a high-fat meal (600 kcal).
Results: Baseline vascular function (fasting state) did not change with EPA/DHA or placebo treatment. FMD following EPA/DHA treatment remained unchanged: 4.91±0.57% (0h), 4.26±0.51% (2h) (p=NS), 4.31±0.46% (4h) (p=NS) and 4.81±0.52% (6h) and following placebo treatment (olive oil) decreased significantly: 5.39±0.53% (0h), 4.11±0.56% (2h) (p<0.05), 3.56±0.52% (4h) (p<0.001 vs. fasting state, p<0.05 vs. EPA/DHA) respectively 4.57±0.44% (6h)
The microvascular function described by the AUC after reactive hyperemia increased postprandially following EPA/DHA (all measurements are expressed in arbitrary units - AU): 5724±617 AU (0h), 7124±506 AU (2h) (p=0.012), 6511±630 AU (4h), 6232±665 AU (6h). The AUC remained unchanged postprandially following olive oil: 7325±688 AU (0h), 7315±607 AU (2h), 7159±535 AU (4h), 7538±664 AU (6h).
Conclusion: In subjects with diabetes mellitus, a 6 weeks treatment with EPA/DHA preserves the FMD (macrovascular function) while olive oil deteriorates it. Concerning the microvascular function, EPA/DHA for 6 weeks improved blood flow following reactive hyperemia after the test meal. These observations suggest protective cardiovascular effects of omega 3 fatty acids vs. olive oil in this population.

Analogue versus human insulin therapy improves postmeal glucose and cardiac function in patients with type 2 diabetes with intensive conventional insulin therapy

T. Siegmund, H. von Bibra, M. Riemer, P.-M. Schumm-Draeger;
Dep. for Endocrinology, Diabetes and Vascular Medicine, Klinikum Munich GmbH, Munich, Germany.

Background and aims: Compared to human insulins (HI), analogue insulins (AI) lower postprandial glucose levels more effectively also in type 2 diabetes (T2D). The importance of postprandial glucose control has been shown predominantly for cardiovascular risk and sparsely for myocardial dysfunction. Accordingly, it is not known whether therapy with AI can improve myocardial dysfunction in T2D, which is known for its high prevalence and prognostic relevance. This prospective, randomized, open long-term study tested the hypothesis, that intensive conventional insulin therapy (ICT) with AI vs. HI improves postprandial glucose control associated with improved myocardial function.
Materials and methods: For 24 months, 104 T2D patients were seen at 3 monthly visits to adapt antidiabetic ICT treatment for the target fasting glucose ≤110 mg/dl and postmeal glucose ≤150 mg/dl in these two randomised groups: AI (insulin detemir + insulin aspart, n=59) and HI (NPH-insulin and regular human insulin, n=45). Systolic (S') and diastolic myocardial function (E') were assessed by tissue Doppler before and two hours after a standardized test meal, a pure carbohydrate continental type of breakfast (48g carbohydrates). Both groups were comparable with regard to demographics, cardiovascular risk factors, concomitant medication, cardiac function and metabolic control at baseline.
Results: After 24 months, HbA1c decreased in AI from 7.0±1.5 to 6.5±0.7%, p<0.02) and in HI from 7.6±1.8 to 6.5±0.8%, p<0.001. Postprandial serum glucose was reduced (p<0.001) by 38±81 mg/dl in AI but not significantly by 8±57 mg/dl in HI (p<0.04 compared to AI). Fasting serum glucose was reduced by 16±48 mg/dl in AI (p<0.02) and by 15±43 mg/dl in HI (p<0.003). In AI, S' increased significantly from 7.4±1.1 to 7.7±1.1 cm/s (p<0.04) as did E' (7.8±1.4 to 8.1±1.4 cm/s, p<0.04) associated with a parallel increase post- meal (p<0.002). In HI, however, fasting S' remained unchanged (from 7.6±1.0 to 7.7±1.2 cm/s) and so did fasting E' (from 8.2±1.7 to 8.2±2.0 cm/s) similar to the postprandial values.
Conclusion: In patients with T2D**,** 24 months ICT-therapy with AI significantly improved postprandial glucose control associated with improved cardiac function compared to ICT with HI. Given the prognostic relevance of myocardial dysfunction in T2D, this association should be taken into consideration when selecting an insulin regimen for people with T2D.

Rationale and design of the Trial Evaluating Cardiovascular Outcomes with Sitagliptin (TECOS)

M.A. Bethel[1,2], J. Green[2], R.M. Califf[3], R.R. Holman[1];
[1]Diabetes Trials Unit, Oxford Centre for Diabetes, Endocrinology and Metabolism, United Kingdom, [2]Department of Medicine, Division of Endocrinology, Duke University Medical Center, Durham, United States, [3]Department of Medicine, Division of Cardiology, Duke Translational Medicine Institute, Durham, United States.

The purpose of TECOS is to evaluate the potential impact of sitagliptin, a dipeptidyl peptidase-4 inhibitor, on cardiovascular outcomes and clinical safety in a multinational, randomized, double-blind, placebo-controlled trial. TECOS is a pragmatic, academically run trial that will recruit approximately 14,000 patients with type 2 diabetes who are at least 50 years old, have documented vascular disease, and who have an HbA_{1c} betwen 6.5% and 8% on stable doses of any one or two of three oral antihyperglycemic agents (metformin, sulfonylurea, pioglitazone). A minimum of 2000 patients will be on metformin monotherapy and 2000 patients on pioglitazone (alone or in combination). Randomization will be 1:1 to the addition of double-blind sitagliptin (100 mg/day) or matching placebo to a patient's existing diabetes care regimen in a usual care setting, with the aim of achieving glycemic equipoise in the two groups. Patients with moderate, but not severe, renal insufficiency can be included but will be given reduced doses of sitagliptin. Patient accrual, which began in December 2008, will take 2 years in around 30 countries. The primary endpoint will be the time to the first occurrence of a composite cardiovascular outcome (cardiovascular death, nonfatal myocardial infarction, nonfatal stroke or hospitalization for unstable angina). Cardiovascular events will be adjudicated by an independent committee, blinded to study therapy. In this non-inferiority trial, 1300 confirmed primary endpoints are needed to provide 90% power to yield the upper limit of the adjusted 95% CI for a hazard ratio <1.20 at a one-sided alpha level of 0.025. Follow up will be four monthly in the first year, then twice yearly for a minimum of four years or until 1300 primary endpoints have occurred. TECOS will assess the impact of sitagliptin on cardiovascular outcomes when used in addition to usual diabetes care.

Anti-inflammatory effects of cilostazole on vascular smooth muscle in *in vitro* and *in vivo*

Y. Hattori, S. Hattori, K. Kasai;
Dokkyo University School of Medicine, Mibu, Japan.

Cilostazol is classified as an antiplatelet agent because it inhibits platelet aggregation induced by collagen, 5'-adenosine diphosphate (ADP), epinephrine, and arachidonic acid. Since receiving approval in the United States for the treatment of intermittent claudication in 1999, cilostazol continues to demonstrate promise in the treatment of cardiovascular disorders. We recently reported that cilistazol restored endothelial function in diabetic rats (OLETF), showing one of the mechanisms for cilostazol to protect endothelial cells against inflammatory stimuli that cilostazol inhibits the cytokine-induced expression of pro-inflammatory and adhesion molecule genes by suppressing NF-κB activity via AMP-activated protein kinase (AMPK) activation, not via the cyclic AMP (cAMP)/ protein kinase A (PKA) pathway using cultured vascular endothelial cells. To show that this mechanism works in *in vivo* vascular vessels, we examined aortas with cilostazol-treated rats whether AMPK is associated with the protective effect of cilostazol. We found that AMPK is highly expressed in the aorta from cilostazol-treated rats compared with control rats and that AMPK expression is strongly induced in aortic smooth muscle cell layers in cilostazol-treated rats. We thus investigated whether cilostazol exerts anti-inflammatory effects on those cultured vascular smooth muscle cells (VSMC). Cilostazol was observed to activate AMPK and its downstream target, acetyl-CoA carboxylase, in VSMC. Phosphorylation of AMPK with cilostazol was not affected by co-treatment with an adenylate cyclase inhibitor, SQ 22536, and a cell-permeable cAMP analogue, pCTP-cAMP, did not induce AMPK phosphorylation and had no effect on cilostazol-induced AMPK phosphorylation, suggesting that cilostazol-induced AMPK activation occurs through a signalling pathway independent of cyclic AMP. Cilostazol also dose-dependently inhibited tumor necrosis factor alpha (TNF)-induced NF-κB activation and TNF-induced IκB kinase activity. Furthermore, cilostazol attenuated the TNF-induced promoter activation of iNOS gene and iNOS gene expression, resulting in reduction of NO production. Transduction with dominant-negative AMPK abolished the suppressive effect of cilostazol on iNOS promoter activity and mRNA expression and NO production in VSMC. Furthermore, cilostazol treatment of the LPS-treated rats reduced the induction of iNOS expression in the aorta. In the light of these findings, we suggest that cilostazole plays anti-inflammatory roles on vascular smooth muscle cells *via* induction and activation of AMPK.

Circulating neopterin and monocyte chemoattractant protein-1 are responsive to statin therapy but are poor predictors of cardiovascular events in type 2 diabetes in CARDS

H.M. Colhoun[1], D.J. Betteridge[2], P.N. Durrington[3], G. Hitman[4], H.A.W. Neil[5], V. Charlton-Menys[6], W. Bao[7], D. DeMicco[7], G. Preston[7], S. Livingstone[1], J.H. Fuller[2];
[1]University of Dundee, United Kingdom, [2]University College London, United Kingdom, [3]University of Manchester, United Kingdom, [4]Barts and The London Medical School, United Kingdom, [5]Oxford University, United Kingdom, [6]University of Manchester, United Kingdom, [7]Pfizer Ltd, New York, United States.

Background and aims: Neopterin is produced by stimulated macrophages and monocyte chemoattractant protein-1 (MCP-1) is a chemokine involved in immune cell recruitment. Both have been suggested as useful biomarkers of cardiovascular disease (CVD). Data on whether they are useful in those with diabetes and whether they are responsive to statin therapy are scarce. We assessed whether circulating levels of neopterin and MCP-1 predict future CVD events and respond to atorvastatin 10 mg daily in diabetes in the randomised trial the Collaborative Atorvastatin Diabetes Study (CARDS).
Materials and methods: We used a nested case control design sampling all those incident cases of CVD (n=210) in CARDS in whom a valid serum sample was available (n=198) and randomly selecting three controls per case from those who completed the trial without a CVD event, stratified by treatment allocation. The median follow up duration in the trial was 3.9 years. Neopterin was measured in ng/mL using an ELISA method. MCP-1 was measured in pg/ml using the Human Cytokine LINCO Plex kit. Analysis was by Cox regression and logistic regression with adjustment for treatment allocation and relevant covariates.
Results: Baseline median (interquartile range) of neopterin was 2.5ng/ml (1.9-3.4). At one year follow up neopterin had increased significantly more in the placebo group (median increase of +0.8 ng/ml) than in the Atorvastatin group (median increase +0.4 ng/ml p=0.01 for the treatment associated difference). Baseline median (interquartile range) of MCP-1 was 134 pg/mL (90-192). At one year follow up MCP-1 had risen very slightly in the placebo group (median change of 0.7 units) but on average had fallen in the Atorvastatin group (median fall -11 pg/ml p=0.015 for the treatment associated difference). However baseline levels of neopterin did not predict CVD (Hazard ratio for a doubling in neopterin adjusted for age sex and trreatment allocation= 0.99 95% CI 0.78-1.25, p=0.90) and neither did levels of MCP-1 (Hazard ratio per doubling in MCP-1 = 1.05 95% CI 0.9-1.2, p=0.60) whether adjusted for other risk factors or not. Neither were on treatment neopterin or MCP-1 levels predictive of events.
Conclusion: Atorvastatin reduces neopterin and MCP-1 levels in those with diabetes consistent with a reduction in macrophage activation. However our data do not support the use of circulating neopterin or MCP-1 as surrogate markers of CVD events in diabetes trials.
The CARDS trial was funded by Pfizer Ltd, Diabetes UK and the UK NHS R&D

Efficacy of fenofibric acid in combination with atorvastatin in patients with type 2 diabetes mellitus and mixed dyslipidaemia

D.J. Sleep[1], A.C. Goldberg[2], C.M. Setze[1], J.-C. Ansquer[3], M.T. Kelly[1];
[1]Abbott, Abbott Park, United States, [2]Washington Univ School of Medicine, St. Louis, United States, [3]Laboratoires Fournier, Daix, France.

Background and aims: Patients with Type 2 diabetes (T2DM) are at high risk for coronary heart disease and frequently have mixed dyslipidemia (high triglycerides, low HDL-C and elevated LDL-C) which may be refractory to single-agent lipid-altering therapy. This preplanned analysis of the subgroup of patients with T2DM and mixed dyslipidemia enrolled into a multicenter, double-blind, controlled phase 3 study evaluates the efficacy of the combination of fenofibric acid (FA) and atorvastatin (A) on multiple lipid parameters.
Materials and methods: A total of 613 patients with LDL-C ≥ 130 mg/dL (3.36 mmol/L), triglycerides ≥150 mg/dL (1.70 mmol/L) and HDL-C < 40 mg/dL (1.03 mmol/L) for men (< 50 mg/dL [1.29 mmol/L] for women) were randomized to either FA 135 mg, A (20, 40 or 80 mg) or combination therapy (FA + either A20 or A40 mg) and treated for 12 weeks. A total of 147 (25.5%) of the 576 patients included in the primary efficacy analysis had T2DM. The primary efficacy comparisons were mean percentage change in HDL-C and TG (FA+A v. A), and LDL-C (FA+A v. FA). Secondary endpoints included mean percentage change in non-HDL-C and apolipoprotein B (FA+A v. A).
Results: FA+A combination therapy resulted in numerically greater improvements in TG and HDL-C than the corresponding atorvastatin monotherapies and greater improvement in LDL-C than FA monotherapy in patients with T2DM (Table). After 12 weeks of treatment, FA+A resulted in mean values of LDL-C, TG and HDL-C that were within or close to ADA-recommended target values. All treatments were generally well tolerated, and no case of rhabdomyolysis was reported.
Conclusion: The combination of FA+A resulted in more comprehensive improvement of multiple lipid parameters than either monotherapy for patients with T2DM and mixed dyslipidemia.

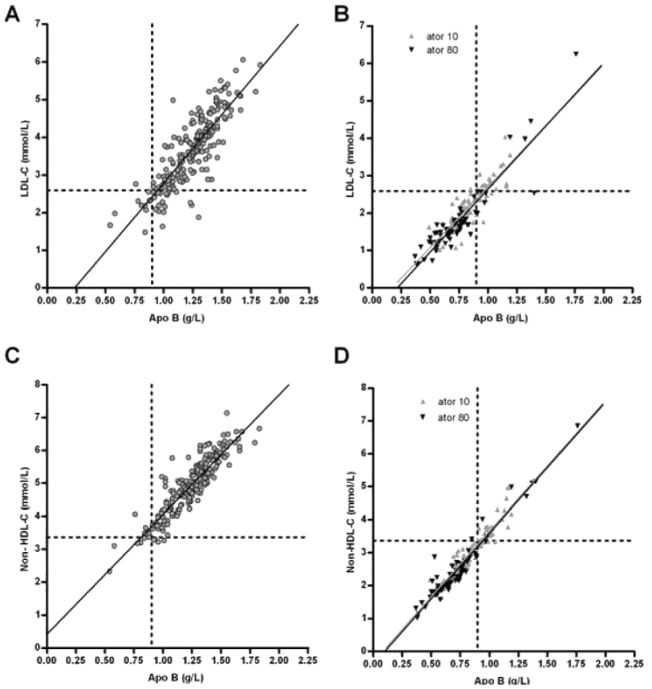
Atorvastatin treatment affects the relationships of LDL and non-HDL cholesterol with ApoB in type 2 diabetes mellitus: modification by triglycerides and CETP

P.J.W. Kappelle[1], L. Zwang[2], M.V. Huisman[3], J.D. Banga[4], W.J. Sluiter[1], G.M. Dallinga-Thie[5], R.P.F. Dullaart[1];
[1]Endocrinology, University Medical Centre Groningen, [2]Clinical Chemistry, Erasmus medical Centre, Rotterdam, [3]Endocrinology, Leiden University Medical Centre, Groningen, [4]Gelderse Vallei, Ede, [5]Laboratory of Experimental Vascular Medicine, Academic Medical Centre Amsterdam, Netherlands.

Aims and hypothesis: Current guidelines propose non-HDL-cholesterol (non-HDLC) and apolipoprotein (apo) B as treatment targets in addition to LDL-cholesterol (LDLC). The extent to which statin therapy affects the relationships of LDLC and non-HDLC with apo B was examined in type 2 diabetes.
Methods: Analyses were performed in the DALI cohort (217 moderately hypertriglyceridaemic type 2 diabetic patients). Sixty-one placebo- and 135 atorvastatin-treated patients completed 30 weeks of follow-up. LDLC was calculated by the Friedewald formula. Apo B was assayed by immunoturbidimetry. Cholesteryl ester transfer protein (CETP) mass was measured by ELISA.
Results: Baseline fasting LDLC of 2.42 mmol/l and non-HDLC of 3.69 mmol/l corresponded to the apo B guideline target of 0.90 g/L. During atorvastatin

(10 and 80 mg daily), the LDLC target was achieved more frequently than the apo B target, and lower LDLC (2.38 and 2.29 mmol/l) and non-HDLC (3.24 and 3.19 mmol/l) concentrations corresponded to this apo B goal. Decreases in LDLC during atorvastatin treatment were negatively ($p < 0.001$), but decreases in non-HDLC were positively related to changes in triglycerides ($p < 0.001$), independently from decreases in apo B ($p < 0.001$ for all). Decreases in LDLC and non-HDLC were positively associated with decreases in CETP mass ($p < 0.001$).

Conclusion and interpretation: Atorvastatin leads to a shift in the relationships of fasting LDLC and non-HDLC with apo B in type 2 diabetes towards lower LDLC and non-HDLC levels that correspond to an apo B guideline target of 0.90 g/l. Triglycerides and CETP modify these relationships.



Legends to Figure 1

The relationship between HbA_{1c} and cardiovascular disease in patients with Japanese hypercholesterolaemia and effect of low dose pravastatin

R. Nishimura[1], T. Nakagami[2], H. Sone[3], N. Tajima[1];
[1]Division of Diabetes, Metabolism and Endocrinology Department of Internal Medicine, Jikei University School of Medicine, Tokyo, [2]Diabetes Centre, Tokyo Women's Medical University, [3]Department of Internal Medicine, University of Tsukuba Institute of Clinical Medicine, Ibaraki, Japan.

Background and aims: The relationship between HbA1c and cardiovascular risk in patients with hypercholesterolemia is not well understood because of sparse data. The aim of the present study was to investigate the relationship between HbA1c and future development of cardiovascular disease in patients with hypercholesterolemia, and to evaluate the effect of pravastatin in a post-hoc analysis of the large-scale primary prevention study with pravastatin (The Management of Elevated cholesterol in the primary prevention Group of Adult Japanese (MEGA) Study).

Material and methods: The MEGA Study sought to evaluate the effect of low-dose pravastatin (10-20 mg/day, approved dose in Japan) on primary prevention of cardiovascular disease in a total of 7,832 Japanese patients (male, 40 to 70 years; female, post-menopause to 70 years) with mild to moderate hyperlipidemia without cardiovascular disease. Patients were randomized to diet alone or diet + pravastatin and followed for more than 5 years. A total of 4,002 patients with baseline and follow-up HbA1c levels were analyzed. The relationship between HbA1c and the risk of cardiovascular disease was evaluated according to sex and treatment arm, using multivariate Cox proportional hazards model with a restricted quadratic spline based on three knots for HbA1c quartiles (5.2, 5.5, 6.4 %).

Results: The spline curve in 4,002 patients continuously rose to around an HbA1c of 6%, and thereafter the curve rose more gently. cardiovascular disease risk was approximately 2-times higher in men than in women, and the shape of the curves were similar for men and women (Figure A). The curve in the diet group was consistently lower compared with that in the diet + pravastatin group, regardless of the HbA1c level (Figure B).

Conclusion: A continuous increase, up to an HbA1c of 6%, in cardiovascular disease risk was found, and thereafter a more gentle increase, in Japanese men and women with hypercholesterolemia. The beneficial effect of pravastatin is achieved regardless of the HbA1c level.

Atorvastatin lowers remnant-like particle cholesterol without affecting LDL size in type 2 diabetes mellitus: relevance for non-HDL cholesterol and apoB targets

R.P.F. Dullaart[1], P.J.W. Kappelle[1], G.M. Dallinga-Thie[2];
[1]Endocrinology, University Medical Centre, Groningen, [2]Laboratory of Experimental Vascular Medicine, Academic Medical Centre Amsterdam, Netherlands.

Background and aims: The extent to which atorvastatin treatment affects LDL size, LDL subfractions levels and remnant-like particle cholesterol (RLP-C) was determined in Type 2 diabetic patients. We also compared LDL size and RLP-C in relation to American Diabetes Association guideline cut-off values for LDL cholesterol, non-HDL cholesterol and apolipoprotein (apo) B.

Materials and methods: Changes in RLP-C (immuno-separation technique; Japan Immunoresearch Laboratories, Takasaki, Japan) and LDL size (polyacrylamide gradient gel electrophoresis) were determined in fasting plasma from Type 2 diabetic patients after 30 weeks follow-up in response to atorvastatin (10 mg daily, n=65; 80 mg daily, n=62) and placebo (n=58). In 74 participants, LDL subfractions were measured by density gradient ultracentrifugation using a six-step, discontinuous salt gradient. The patients participated in The DALI (Diabetes Atorvastatin Lipid Intervention) study, which is a randomized placebo-controlled multicentre trial that has been performed in 3 outpatient university clinics.

Results: Atorvastatin decreased LDL cholesterol, non-HDL cholesterol, triglycerides, apo B and apo E ($P < 0.001$ for each dose). Atorvastatin also lowered RLP-C ($P < 0.001$ for each dose), but LDL peak particle size remained unaffected (Table). All LDL subfractions decreased after atorvastatin ($P < 0.001$ for each dose) without a preferential shift towards LDL_3. RLP-C was lower in those patients achieving the non-HDL cholesterol (0.20 (0.17-0.30) mmol/L vs 0.35 (0.22-0.45) mmol/L, $P < 0.01$) or the apo B guideline targets (0.20 (0.17-0.30) mmol/L vs 0.39 (0.20-0.45) mmol/L, $P < 0.01$), but the LDL cut-off value failed to discriminate between lower and higher RLP-C concentrations (0.20 (0.17-0.34) mmol/L vs, 0.29 (0.20-0.40) mmol/L, $P > 0.10$).

Table (abstract 1251): Remnant like particle cholesterol (RLP-C) concentration, LDL size pattern, LDL particle size and at baseline and after placebo or atorvastatin treatment (10 mg or 80 mg daily) in type 2 diabetic patients. Data in mean ± SD or in median (interquartile range). LDL size pattern distribution by Chi-square analysis: * baseline: $P = 0.68$; **follow-up: $P = 0.63$. ***$P < 0.001$ compared to baseline. *$P < 0.01$ and **$P < 0.001$ compared to baseline. §P-value for between group difference in change by ANOVA.

	Placebo(N = 58)		**Atorvastatin 10 mg** (N= 65)		**Atorvastatin 80 mg**(N= 62)		§***P*-value**
	Baseline	Follow-up	Baseline	Follow-up	Baseline	**Follow-up**	
RLP-C(mmol/L)	0.45 (0.30-0.64)	0.37 (0.28-0.49)	0.43 (0.33-0.70)	0.25 (0.17-0.37)***	0.47 (0.32-0.64)	0.21 (0.17-0.33)***	< 0.001
LDLparticle size pattern (A/B)	41/17*	41/17**	42/23*	50/15**	38/24*	42/20**	
LDLparticle size (nm)	25.90±0.72	25.94±0.62	25.87±0.75	26.01±0.71	25.76±0.75	25.92±0.73	0.63

Conclusion: In Type 2 diabetic patients usual and high dose atorvastatin lower fasting RLP-C without affecting LDL size and changing LDL subfractions towards more boyant LDL. The proposed guideline cut-off levels for non-HDL cholesterol and apo B may be superior to the LDL cholesterol target in discriminating between higher and lower RLP-C levels.

The original Dali study was partly supported by an unrescticted grant from Parke-Davis, the Netherlands.

Long-term ezetimibe/simvastatin (E/S) + extended release niacin (N) treatment in hyperlipidaemic patients with diabetes and metabolic syndrome

S. Fazio[1], J.R. Guyton[2], J. Lin[3], J.E. Tomassini[3], A. Shah[3], A.M. Tershakovec[3]; [1]Vanderbilt University, Nashville, [2]Duke University, Durham, [3]Merck & Co, Inc., North Wales, United States.

Background and aims: Guidelines recommend combination therapy to achieve optimal LDL-C lowering and broader lipid regulation in high-risk patients such as those with diabetes (DM) and metabolic syndrome (MS). We assessed the efficacy and safety of combination *E/S+N* in hyperlipidemic patients with DM or MS.

Methods: This analysis of a double-blind, randomized 64-week study in hyperlipidemic patients assessed the effect of *E/S* (10/20 mg) +*N* (to 2 g) or *E/S* (10/20 mg) treatment for 64 weeks on lipid parameters in subjects with DM, with MS without DM (MS/nonDM), or without DM or MS (nonDM/nonMS). Safety issues including fasting glucose (FG) and new onset DM were monitored.

Results: *E/S+N* improved HDL-C, non-HDL-C, TG, ApoB (see table), ApoAI and lipid ratio levels more than did *E/S* in all subgroups. Reductions in LDL-C and hsCRP were similar for *E/S+N* and *E/S* in both DM and MS subgroups, but *E/S+N* had a greater effect than *E/S* in the nonDM/nonMS group. Changes in total cholesterol were comparable for both treatments in all groups. FG trended higher for *E/S+N*, peaked at 8 weeks above baseline (1.2 and 0.6 mmol/L [21.2 and 11.2 mg/dL] for *E/S+N* vs *E/S* respectively), then gradually declined to pretreatment levels at 64 weeks for both treatments in DM patients. New onset DM, due mostly to 2 consecutive FG increases ≥7.0 mmol/L (≥126mg/dL), was higher in the MS/nonDM than nonMS/nonDM group for either treatment (see table) and occurred predominantly during the first 24 weeks.

Conclusion: *E/S+N* improved lipid/lipoprotein profiles and was generally well tolerated in hyperlipidemic patients with DM or MS during 64 weeks. Increases in FG occurred more often in patients with DM and new onset DM in those with MS. These effects, observed mainly during the first 6 months of therapy, abated with time. These results indicate that triple combination *E/S+N* is a treatment option for dyslipidemia in patients with DM and MS, but requires monitoring of glucose changes.

Influence of metabolic syndrome factors and insulin resistance on ezetimibe/simvastatin and atorvastatin treatment efficacy in patients with metabolic syndrome and moderately high/high coronary heart disease risk

J.B. Rosen[1], C.M. Ballantyne[2], S.M. Grundy[3], W.A. Hsueh[4], H.-H. Parving[5], J.G. Robinson[6], J. Lin[7], R.S. Lowe[7], A.K. Shah[7], A.M. Tershakovec[7]; [1]Clinical Research of South Florida, Coral Gables, United States, [2]Baylor College of Medicine and Methodist DeBakey Heart and Vascular Center, Houston, United States, [3]UT Southwestern Medical Center at Dallas, United States, [4]Methodist Hospital Research Institute, Houston, United States, [5]University Hospital of Copenhagen, Denmark, [6]University of Iowa College of Public Health, Iowa City, United States, [7]Merck & Co., North Wales, United States.

Background and aims: Metabolic syndrome (MS) affects about 25% of the US population. MS associated factors (abdominal obesity, low HDL-C; and elevated triglycerides, blood pressure and fasting glucose) as well as insulin resistance (IR) may be associated with increased coronary heart disease (CHD) risk. This study assessed the influence of these factors on % change from

baseline low density lipoprotein cholesterol (LDL-C), high density lipoprotein cholesterol (HDL-C), non-HDL-C, total cholesterol (C), very low density lipoprotein cholesterol (VLDL-C), triglycerides (TG), apolipoprotein (Apo) B, Apo AI, high sensitivity C-reactive protein (hs-CRP), and lipoprotein ratios (total C:HDL-C, LDL-C:HDL-C, Apo B:Apo AI, non-HDL-C:HDL-C).

Materials and methods: Post-hoc analysis of a multicenter, 6-week, double-blind, randomized, parallel group study in over 1000 hypercholesterolemic MS patients with moderately high (MHR) or high (HR) CHD risk, treated with ezetimibe (E) 10mg/simvastatin (S) 20mg compared to atorvastatin (A)10mg or A20mg, or E10/S40mg vs. A40mg. Percent attainment of LDL-C < 1.8 mmol/L (70 mg/dL) for HR patients with atherosclerotic vascular disease (AVD) or LDL-C < 2.6 mmol/L (100 mg/dL) for MHR and HR patients without AVD was also evaluated.

Results: E/S and A efficacy were generally consistent across MS factor and IR subgroups. E/S produced greater incremental percent reductions in LDL-C (Table), non-HDL-C, Apo B, total C, and lipoprotein ratios for all subgroups and larger % increases in HDL-C and Apo AI for all but non-obese and HDL-C ≥ 40 mg/dL subgroups compared to A. TG, VLDL-C, and hs-CRP results were more variable. E/S produced greater attainment of LDL-C <1.8 mmol/L (70 mg/dL) and < 2.6 mmol/L (100mg/dL) than A for all treatment comparisons across all subgroups, except non-obese HR patients with AVD (data not shown - some sample size limitations).

Conclusion: These results suggest that efficacy of E/S and A are generally well maintained across MS and IR factors, with E/S > A for most treatment differences. Observed effects of E/S vs. A may be useful in evaluating treatment options for MS patients with moderately high/high CHD risk.

Effects of low-dose, long-term fluvastatin treatment on oxidative/antioxidative parameters in the pancreas and heart from streptozotocin-induced diabetic rats

A. Irat[1], A. Cumaoglu[2], E. Yuksel[2], T. Akhayeva[1], C. Karasu[3], A. Arıcıoglu[2], G. Ozansoy[1], N. Arı[1];
[1]Pharmacology, Ankara University, [2]Biochemistry, Gazi University, Faculty of Medicine, [3]Medical Pharmacology, Gazi University, Ankara, Turkey.

Background and aims: Statins (HMG-CoA reductase inhibitors) exert many pleiotropic effects in addition to lowering cholesterol levels. Oxidative stress is universal in diabetes, being ultimately involved with the development complications. Among various statins, fluvastatin is thougt to be the most powerful antioxidant. This study was designed to investigate cholesterol-independent antioxidative effect of chronic fluvastatin treatment in diabetic rats.

Materials and methods: Wistar male rats were made diabetic by streptozotosin (STZ: 55 mg/kg, ip). Some of them and control rats (D and C groups) were treated orally for 6 months with fluvastatin (2mg/kg/day, p.o), starting one week after STZ injection (CF and DF groups) (preventive study). In pancreas and heart homogenates, the oxidative stress markers, superoxide dismutase (SOD) and catalase (CAT) enzyme activities, malon dialdehit (MDA), protein carbonyl content (PCC) (by spectrophotometric method) and 3-nitrotyrosine (3-NT) levels (by ELISA) were measured.

Results: Body weight, hyperglycemia and dyslipidemia in D groups remained unchanged after fluvastatin treatment (p>.05, ANOVA, n:8-10 each group). Oxidative stress parameters studied in pancreas and heart tissues of diabetic animals were mostly alleviated by fluvastatin treatment (Table:Enzymes: U / mg protein; MDA, PCC: nmol / mg protein, 3-NT: mol/mg protein. Data± SEM, Sign. ≠ vs. C; * vs. D; ANOVA test, p<.05, n:5 each,).

Conclusion: Fluvastatin used in a dose too low to alter the lipid profile seems to be beneficial to reduce oxidative stress seen in diabetic state. We can speculate that early and long-term fluvastatin therapy in diabetes may lead to a progressive reduction of organ injury.

Effects of Fluvastatin treatment on oxidative stress parameters in the groups.

Role of PPARα in human white adipocyte metabolism

E. Montastier, C. Ribet, C. Valle, V. Bezaire, N. Viguerie, D. Langin; Laboratory of obesity research, Inserm U858, Paul Sabatier University, Toulouse, France.

Background and aims: Understanding of adipose tissue metabolism is important to prevent the development of obesity-associated diabetic complications. PPARs are key regulators of lipid metabolism. Among them, PPARα is predominantly expressed in tissues with a high rate of fatty acid oxidation and is known for its role in the regulation of genes involved in lipid catabolism in the liver. However, the role of PPARα in human adipocyte metabolism remains elusive. We previously showed that the activation of PPARα by its agonist GW7647 leads to enhanced expression and activity of glycerol kinase (GyK) in human white adipocytes. This probably results from a direct activation of GyK transcription by PPARα. This result suggested that PPARα could promote an energy dissipating fatty acid cycling between lipolysis and triglyceride synthesis. In order to investigate the involvement of PPARα in human white adipocyte metabolism, we compared the effects of GW7647 and of rosiglitazone, a PPARγ agonist, by a transcriptomic analysis, and we identified 80 genes differentially regulated by PPARα and PPARγ. DNA microarray data were confirmed by quantitative RT-PCR as 21 of 26 genes were differentially regulated. Study of the functions of these genes showed that part of them is involved in glycolysis and β-oxidation pathways.
Results: We next showed that GW7647 increased mRNA expression of enzymes involved in mitochondrial uptake of acyl-CoA and β-oxidation (hydroxyacyl-coenzyme A deshydrogenase α/β: HADHA/B, carnitine palmitoyltransferase 1b: CPT1b). These genes are regulated to a lesser extent or identically by rosiglitazone. Moreover, the PPARα but not the PPARγ agonist increased two fold palmitate oxidation in human white adipocytes. By silencing PPARα expression with a siRNA, we were able to confirm that palmitate oxidation was PPARα-dependent. In addition, GW7647 downregulates the expression of many enzymes of the glycolytic pathway (aldolase, glyceraldehyde-3-phosphate dehydrogenase, enolase, pyruvate kinase) and of a major regulatory protein: pyruvate deshydrogenase kinase 4 (PDK4). These genes are regulated to a lesser extent by the PPARγ agonist. This variation of gene expression is concomitant with: 1) an increase of pdk4 protein expression and 2) a decrease of glycolysis shown by reduced pyruvate and lactate accumulation in the culture medium.
Conclusion: In human white adipocytes, activation of PPARα leads to a shift in energy fuel selection. The alteration of gene expression by the PPARα agonist GW7647 is associated with a concomitant higher fatty acid oxidation level and a lower glucose utilization level, which are not observed with the PPARγ agonist. We are currently investigating the involvement of PPARα using an antagonist of the nuclear receptor.The stimulation of fatty acid consumption combined with dissipation of energy due to PPARα-induced fatty acid cycling could be envisioned as a mean to limit systemic fatty acid release, which is a crucial step in the development of insulin resistance associated with type 2 diabetes.

Serum concentrations of novel metabolic regulator FGF19 in patients with type 2 diabetes: the influence of acute hyperinsulinaemia and PPAR-α agonist treatment

M. Haluzik[1], M. Mraz[1], M. Bartlova[1], D. Haluzikova[2], I. Dostalova[1], V. Humenanska[3], Z. Lacinova[1];
[1]3rd Department of Medicine, Charles University, Prague, [2]Department of Sports Medicine, Charles University, Prague, [3]BioVendor, Brno, Czech Republic.

Background and aims: Experimental studies have identified fibroblast growth factor-19 (FGF19) as a novel endocrine and paracrine regulator with multiple effects on metabolic processes and energy homeostasis. At present, little is known about its role and regulation of its circulating levels in humans. The aim of our study was to measure serum FGF19 concentrations in patients with obesity and type 2 diabetes mellitus (T2DM) and healthy subjects (C) and to assess the changes of its circulating levels after pharmacological interventions.
Materials and methods: We measured biochemical parameters, serum FGF19, adiponectin, leptin and insulin levels by commercial ELISA and RIA kits in 21 T2DM patients and 29 control subjects. The interventions were acute hyperinsulinemia during isoglycemic-hyperinsulinemic clamp and 3-months treatment with PPAR-alpha agonist fenofibrate.
Results: Baseline serum FGF19 levels did not significantly differ between T2DM and C groups (189.24 ± 30.9 vs. 202.20 ± 16.74 pg/ml, n.s.). In a combined population of T2DM and C subjects FGF19 levels significantly negatively correlated with glycemia (r= -0,46, p<0.005) and HOMA index (r= -0.45, p=0.005). No significant relationship was found between FGF19 and BMI, cholesterol, triglyceride, insulin and leptin levels, respectively. 3 months of fenofibrate treatment significantly reduced FGF19 levels in T2DM patients (194.58 ± 26.2 vs. 107.47 ± 25.0 pg/ml, p<0.05). Acute hyperinsulinemia during isoglycemic-hyperinsulinemic clamp decreased FGF19 levels in both healthy and T2DM subjects (214.5 ± 55.2 vs. 145.7 ± 19.9 and 198.6 ± 48.6 vs. 147.2 ± 24.7 pg/ml, respectively, n.s.). 3-months treatment with fenofibrate abolished insulin-induced decrease in FGF19 concentrations during isoglycemic-hyperinsulinemic clamp in T2DM group.
Conclusion: The presence of obesity and type 2 diabetes mellitus did not influence fasting serum FGF19 levels. On the contrary, both acute hyperinsulinemia and treatment with PPAR-alpha agonist fenofibrate significantly decreased FGF19 levels. We suggest that decrease of FGF19 levels may play a role in some of positive metabolic effects of PPAR-alpha activation.

Roles of peroxisome proliferator-activated receptor delta and 4-hydroxy-dodecadienal in the regulation of glucose transport in vascular endothelial cells

S. Sasson[1], Y. Sin-Malia[1], J. Eckel[2], B. Staels[3], M. Guichardant[4], Y. Riahi[1];
[1]Department of Pharmacology, Hebrew University Faculty of Medicine, Jerusalem, Israel, [2]Clinical Biochemistry and Pathobiochemistry, The German Diabetes Center, Duesseldorf, Germany, [3]Department of Atherosclerosis, Institut Pasteur de Lille, France, [4]Insa-Lyon RMND/IMBL, University of Lyon, Villeurbanne, France.

Background and aims: Vascular endothelial cells protect their intracellular environment against deleterious effects of ambient high glucose concentrations by downregulating the rate of glucose uptake subsequent to a reduction of total cell content and plasma membrane abundance of their principal glucose transporter GLUT-1. We have discovered that high glucose levels increase the expression of the arachidonic acid metabolizing enzyme 12-lipoxygenase (12-LO) and enhance the biosynthesis of its product 12-HpETE in vascular endothelial cells (VEC). In addition, the protein calreticulin, whose expression is also increased in these cells, interacts with and destabilizes GLUT-1 mRNA, leading to a decreased expression of the transporter. The present study has aimed at ascertaining whether the peroxidation product of 12-HpETE, namely 4-hydroxy-dodecadienal (4-HDDE) activates a peroxisome-proliferator-activated receptor (PPAR) family member to induce calreticulin expression and destabilize GLUT-1 mRNA.
Materials and methods: Naïve primary cultures of bovine aortic EC or cultures expressing an ectopic hPPAR isotype (α, γ or δ) and a PPAR-response element (PPRE) driven-luciferase reporter construct were incubated at normal or high glucose levels and treated with various PPAR agonists or 4-HDDE. The rate of glucose transport, luciferase activity, mRNA and protein expression as well as the subcellular distribution of GLUT-1 and calreticulin mRNA and protein levels were determined. In addition, the amount of 4-HDDE secreted from VEC exposed to normal or high glucose was measured by HPLC.
Results: This study shows that hyperglycemia-induced production of 12-HpETE results in its excessive peroxidation to generate augmented amounts of 4-HDDE. When added to normoglycemic VEC, both 4-HDDE, at non-toxic concentrations, or the PPARδ selective agonist GW501516 mimicked high glucose-induced downregulation of glucose transport and reduced GLUT-1 mRNA and protein content while increasing calreticulin expression. 4-HDDE induced PPRE-luciferase reporter activity only in VEC that ectopically expressed hPPARδ, but not hPPARα, hPPARγ1 or hPPARγ2. In addition, partial silencing of PPARδ expression with siRNA reversed high glucose induced down and upregulation of GLUT-1 and calreticulin expression, respectively. Finally, while pharmacological inhibition of 12-LO with baicalein prevented high glucose-dependent downregulation of the glucose

transport system the presence of 4-HDDE or GW501516 restored this down-regulatory capacity.
Conclusion: This study shows that 4-HDDE is a potent physiological agonist of PPARδ. The generation of 4-HDDE is augmented in VEC under high glucose conditions due to an increased availability and peroxidation of 12-HpETE. This peroxidation product activates PPARδ, which in turn increases the expression of calreticulin that destabilizes GLUT-1 mRNA in VEC.

Preclinical safety of INT131, a selective PPARγ modulator (SPPARM), is differentiated from PPAR full agonists in chronic rodent and monkey studies
L.S. Higgins, D.M. Lanfear, U. Devanaboyina, A.M. DePaoli;
InteKrin Therapeutics, Los Altos, United States.

Background and aims: PPARγ is a validated clinical target for addressing insulin resistance, a key etiologic factor in Type 2 Diabetes Mellitus (T2DM). However, full activation of PPARγ by agents such as the thiazolidenediones (TZDs) also causes weight gain, fluid retention, CHF, and increased bone fracture risk. These effects are also observed in preclinical species, which have been predictive of clinical experience for full PPARγ agonists, including rosiglitazone and pioglitazone. In fact, cardiovascular mortality has limited full agonist exposure in chronic preclinical studies.
INT131 is a potent, novel, non-TZD selective PPARγ modulator (SPARRM) designed to minimize or eliminate the typical side effects of the full PPARγ agonists while retaining the potent effects on glucose metabolism and insulin sensitization. Pharmacology models of diabetes and a Phase 2a clinical study in T2DM have demonstrated a lack of significant weight gain and fluid retention at doses of INT131 providing similar or better anti-diabetic efficacy to rosiglitazone and pioglitazone. Six month rat and monkey studies of INT131 have shown no significant fluid retention, weight gain, cardiac effects or adipose marrow replacement at very high multiples (>400 fold for rat ,and >200 fold for monkey) of the Phase 2a exposure of INT131 that provided comparable efficacy to high dose TZDs.
Materials and methods: The safety profile of INT131 was characterized in long term studies in rodents and monkey with special attention to known cardiac and other full PPARγ agonist effects. Monkey: Groups of 4 male and female cynomolgus monkeys were administered 0, 0.3, 1.0, or 3.0 mg/kg/day INT131 for 52 weeks, with additional groups allowed a 4 week post-dosing period. A comprehensive assessment of safety was conducted. Rodent: Groups of 60 male and 60 female rats and mice were administered vehicle or one of 4 doses of INT131 (range 0.3-300 mg/kg/day) for up to 104 weeks. A safety assessment was conducted. All three studies included additional evaluations to characterize toxicity of PPAR ligands designated in FDA Draft Guidance for Diabetes Drugs.
Results: INT131 was well tolerated as determined by lack of significant effect on clinical observations, survival, weight, and food intake at anticipated exposures greater than ~130 (mouse, 2 years), ~100 (rat, 2 years), and ~40 (monkey, 1 year) fold over the Phase 2a exposure of INT131 giving similar efficacy to high dose TZDs.
Conclusion: Available nonclinical and clinical data support the potential of INT131 to function as a SPPARM to provide potent insulin sensitization and glucose reduction separate from the undesirable effects of full-agonist TZDs such as weight gain, adiposity and adipose marrow replacement, fluid retention, and CHF. Findings of interest for PPARγ ligands will be discussed, particularly those involving the cardiovascular system.

Effect of adjunct metformin treatment on levels of plasma lipids in patients with type 1 diabetes
S.S. Lund[1], L. Tarnow[1], A. Astrup[1], P. Hovind[1], P.K. Jacobsen[1], A.C. Alibegovic[1], I. Parving[1], L. Pietraszek[1], M. Frandsen[1], P. Rossing[1], H.-H. Parving[2], A.A. Vaag[1];
[1]Dep of Endocrinology, Steno Diabetes Center, Gentofte, [2]Dep of Medical Endocrinology, Rigshospitalet, Copenhagen, Denmark.

Background: In addition to its glucose-lowering effect, metformin treatment has been suggested to improve lipidaemia in patients with type-2 diabetes. In contrast, in patients with type-1 diabetes (T1DM), information about the effect of metformin treatment on lipidaemia is limited. Here we report the effect of a one-year treatment with metformin versus placebo on plasma lipids in T1DM patients and persistent poor glycaemic control.
Methods: One hundred T1DM patients and HaemoglobinA_{1c} ≥8.5% during the year before enrolment entered a one-month run-in on placebo treatment. Thereafter, patients were randomised (baseline) to treatment with either metformin (1000 mg twice-daily) or placebo for 12 months (double-masked). Patients continued ongoing insulin therapy and their usual outpatient clinical care. Outcomes were assessed at baseline and after one year.
Results: After one year, in those patients who did not start or stop statin therapy during the trial, metformin treatment significantly reduced total and LDL cholesterol by approximately 0.3 mmol/l as compared to placebo (p=0.021 and p=0.018, respectively). Adjustment for statin use or known CVD did not change conclusions. In statin users (metformin: n=22; placebo: n=13), metformin significantly lowered levels of LDL and non-HDL cholesterol by approximately 0.5 mmol/l compared to placebo (adjusted for changes in statin dose or agent: p=0.048 and p=0.033, respectively). HaemoglobinA_{1c} (previously reported) was not significant different between treatments.
Conclusion: In patients with poorly controlled T1DM, at similar glycaemic levels, adjunct metformin therapy during one year significantly lowered levels of pro-atherogenic cholesterolaemia independent of statin therapy.

Dalcetrapib safety and tolerability in high-risk patients with type 2 diabetes mellitus and/or metabolic syndrome
D. Kallend[1], A.F.H. Stalenhoef[2], R. Duttlinger-Maddux[1], A.C. Goldberg[3];
[1]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [2]Radboud University Nijmegen Medical Centre, Netherlands, [3]Washington University School of Medicine, St Louis, United States.

Background and aims: Individuals with type 2 diabetes mellitus (T2DM) and metabolic syndrome (MetSyn) are at markedly increased cardiovascular risk, even following intensive statin therapy. Low HDL cholesterol levels, characteristic of T2DM and MetSyn, constitute an independent cardiovascular risk factor. Dalcetrapib, a selective inhibitor of cholesteryl ester transfer protein (CETP) activity, effectively raises HDL cholesterol. This analysis evaluated the safety and tolerability of dalcetrapib 900 mg daily in patients with dyslipidaemia, CHD or CHD risk equivalents with and without T2DM and/or MetSyn (T2DM/MetSyn).
Materials and methods: Evaluation of the safety and tolerability profile of dalcetrapib 900 mg was evaluated in patients with T2DM/MetSyn (as defined by NCEP ATPIII guidelines) by *post hoc* analysis of a placebo-controlled Phase II trial of 24 weeks duration with 24-week extension.
Results: Overall, 107 patients with T2DM/MetSyn received dalcetrapib (n=74) or placebo (n=33) and 28 patients without T2DM/MetSyn received dalcetrapib (n=15) or placebo (n=13) for 24 weeks. Patients were of mean age 59-64 years and predominantly male (73-93%) and white (76-93%). In the T2DM/MetSyn group, the number of patients reporting ≥1 adverse event (AE) by week 24 was 61 (82%) in the dalcetrapib group and 27 (82%) in the placebo group. In patients without T2DM/MetSyn, AEs were reported in 13 (87%) and 10 (77%) patients, respectively. Most AEs were mild to moderate in intensity and considered unrelated to study drug. AEs occurring most commonly (≥10% of patients) in those with T2DM/MetSyn administered dalcetrapib or placebo were (dalcetrapib/placebo); upper respiratory tract infection (URTI [15%/9%]) and diarrhoea (14%/12%). Patients without T2DM/MetSyn showed a similar profile, commonly reported AEs (≥10%) being (dalcetrapib/placebo); URTI (13%/23%), diarrhoea (20%/8%), flatulence (7%/23%) and nasopharyngitis (7%/15%). There was no effect of treatment on blood pressure. Serious AEs (SAEs) were few. In patients with T2DM/MetSyn administered dalcetrapib or placebo, SAEs occurred in only 6 (8%) and 2 (6%) of patients, respectively. In those without T2DM/MetSyn, SAEs were reported in 3 (20%) and 2 (15%) of patients. No SAE was considered related to study treatment. The reported tolerability profile was generally sustained for up to 48 weeks. Dalcetrapib had no effect on fasting glucose or HbA_{1C}.
Conclusion: This analysis showed that dalcetrapib 900 mg was well tolerated in high-risk patients with T2DM and/or MetSyn after exposure for 24 weeks.

Dalcetrapib in high-risk patients with type 2 diabetes mellitus and/or metabolic syndrome

A.F.H. Stalenhoef[1], M.H. Davidson[2], J.G. Robinson[3], R. Duttlinger-Maddux[4], D. Kallend[4], H. Bays[5];
[1]Radboud University Nijmegen, Netherlands, [2]Rush-Presbyterian-St. Luke's Medical Center, Chicago, United States, [3]Lipid Research Clinic, The University of Iowa, United States, [4]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [5]Louisville Metabolic and Atherosclerosis Research Center (L-MARC), Louisville, United States.

Background and aims: Even with statin therapy, type 2 diabetes mellitus (T2DM) markedly increases cardiovascular (CV) risk, accounting for 70-80% of deaths. Low HDL cholesterol (HDL-C) levels often occur with T2DM and metabolic syndrome (MetSyn), and constitute an independent CV risk factor. Dalcetrapib is a selective inhibitor of cholesteryl ester transfer protein (CETP) activity that significantly raises HDL-C levels in healthy subjects and in patients with hypercholesterolaemia. This analysis evaluated the efficacy of dalcetrapib in patients with dyslipidaemia, CHD or CHD risk equivalents with and without T2DM and/or MetSyn (T2DM/MetSyn).
Materials and methods: *Post hoc* analysis of dalcetrapib 600 mg (dose used in the Phase III **dal**-OUTCOMES trial) in a total of 488 study participants, with most (~60%) having T2DM/MetSyn. Data were derived from 4 placebo-controlled Phase II trials (of up to 12 weeks' duration).
Results: Participants were predominantly male (72-88%), white or caucasian (85-95%) with a mean age 54-60 years. Overall, 296 patients with T2DM/MetSyn received dalcetrapib 600 mg (n=124) or placebo (n=172); 192 without T2DM/MetSyn received dalcetrapib 600 mg (n=90) or placebo (n=102) for 4 weeks. Mean percent changes (SE) from baseline at 4 weeks for key parameters are shown in the Table. Both groups showed similarly significant increases in HDL-C and apolipoprotein (Apo) A-I and a significant reduction in CETP activity. There was little or no change in LDL cholesterol (LDL-C) or ApoB in either patient group. Total cholesterol (TC) was significantly increased in patients with T2DM/MetSyn, presumably reflecting the increase in HDL-C. TC was also increased in patients without T2DM/MetSyn but did not reach significance. There was no significant change in triglyceride level in either patient group.
Conclusion: Dalcetrapib 600 mg had comparable lipid efficacy in patients with and without T2DM and/or MetSyn.

Parameter	With T2DM/ MetSyn	*P* (vs placebo)	Without T2DM/ MetSyn	*P* (vs placebo)

Non-alcoholic fatty liver disease increases the risk of cardiovascular disease in Korean type 2 diabetic patients with metabolic syndrome

J.-O. Chung, D.-H. Cho, D.-J. Chung, M.-Y. Chung;
Department of Endocrinology and Metabolism, Chonnam National University Medical School, Gwangju, Republic of Korea.

Background and aims: The metabolic syndrome (MS) is characterized as a cluster of risk factors that includes dyslipidemia, hypertension, glucose intolerance and central obesity. This syndrome increases the risk of cardiovascular disease. Type 2 diabetes is often associated with non-alcoholic fatty liver disease (NAFLD). Patient with NAFLD may be also at greater risk for CVD than those without NAFLD, and the relationship of NAFLD and metabolic syndrome is increasingly recognized. The aim of this study is to determine the association of NAFLD and the cardiovascular disease between type 2 diabetic patients with and without metabolic syndrome.
Materials and methods: Four hundred thirty type 2 diabetic patients (M: 226, F: 204; mean age: 60.92 ± 12.43 years) were recruited. All subjects underwent assessment for diabetes duration, the degree of obesity and cardiovascular risk factors, and measured fasting plasma glucose, fasting immunoreactive insulin, HbA_{1C}, fasting plasma C-peptide, fasting free fatty acid, high sensitivity C-reactive protein and lipid profiles. NAFLD was assessed by patient history and liver ultrasound. Metabolic syndrome was defined based on NCEP-ATP III criteria. The previous or current coronary heart disease (myocardial infarction, angina, or revascularization) was assessed. The patients were categorized as four groups according to the presence of metabolic syndrome and NAFLD; MS (-) and NAFLD (-), MS (-) and NAFLD (+), MS (+) and NAFLD (-), and MS (+) and NAFLD (+).
Results: The prevalence of coronary heart disease (CHD) in type 2 diabetic patients with MS was higher than that in patients without MS (44.8% vs. 31.2%, $P < 0.05$). The prevalence of CHD in type 2 diabetic patients with NAFLD was higher than that in patients without NAFLD (47.8% vs. 34.5%, $P < 0.01$). The type 2 diabetic patients with MS (-) and NAFLD (+) had the risk of CHD comparable to the risk of patients with MS (-) and NAFLD (-) (35.9% vs. 26.3%, P=0.364). However, the risk of CHD in patients with MS was significantly increased by the presence of NAFLD (51.6% vs. 34.1%, P = 0.001). In type 2 diabetic patients with MS (+) and NAFLD (-), diabetes duration ($r = 0.340$, $P < 0.001$), systolic blood pressure ($r = 0.197$, $P < 0.05$), and diastolic hypertension ($r = 0.333$, $P < 0.001$) were positively associated with CHD. Apo A1 was negatively associated with CHD ($r = -0.294$, $P = 0.001$). On a multivariate analysis, diabetes duration was independently associated with CHD. In type 2 diabetic patients with MS (+) and NAFLD (+), the number of components of MS ($r = 0.247$, $P < 0.001$), body mass index ($r = 0.153$, $P < 0.05$), and systolic blood pressure ($r = 0.145$, $P < 0.05$) were positively associated with CHD. HDL-cholesterol was negatively associated with CHD ($r = -0.209$, $P = 0.01$). On a multivariate analysis, the number of components of MS was independently associated with CHD.
Conclusion: This study suggested that the presence of NAFLD increased the risk of cardiovascular disease in type 2 diabetic patients with metabolic syndrome, but not the presence of NAFLD in patients without metabolic syndrome.

1264

Glucose intolerance in non-alcoholic fatty liver disease (NAFLD) subjects contributes to cardiovascular risk through increased subclinical inflammation rather than endothelial dysfunction

E. Szymanska-Garbacz[1], M. Saryusz-Wolska[1], M. Jablkowski[2], J. Bialkowska[2], A. Borkowska[1], A. Omulecka[3], M. Pawlowski[1], J. Loba[1], L. Czupryniak[1];
[1]Diabetology & Metabolic Disease Dept, [2]Infectious Diseases Dept, [3]Pathology Dept, Medical University of Lodz, Poland.

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is associated with insulin resistance and glucose intolerance. However, whether a diagnosis of NAFLD can help identify apparently healthy subjects with an increased cardiovascular risk is still unclear. The study aimed at assessing endothelial function and subclinical inflammation in subjects with NAFLD and no previously known glucose intolerance or cardiovascular disease.
Materials and methods: Study group was 46 subjects (mean age 41.5±10.0 years, BMI 30.1±8.6 kg/m2) with biopsy-confirmed NAFLD. The controls

were age- and gender-matched 13 healthy persons. All subjects had oral glucose tolerance test (OGTT) performed. Plasma lipids, insulin resistance (adiponectin, HOMA index), endothelial function (sVCAM, sICAM, sE-selectin, endothelin-1, thrombomodulin) and subclinical inflammation markers (IL-6, IL-1β) were assessed in a fasting state in all subjects.
Results: NAFLD subjects had significantly lower plasma adiponectin (2990±2883 vs 6680±4328 ng/ml, p<0.001), HDL-cholesterol (47.3±11.6 vs 59.7±14.7 mg/dl, p<0.001) and higher plasma triglycerides (240±222 vs 102±58 mg/dl, p<0.05), sVCAM (1341±833 vs 857±312 ng/ml, p<0.05), sE-selectin (60.9±32.1 vs 30.2±20.8 ng/ml, p<0.001), and thrombomodulin (1.9±0.8 vs 1.1±0.5 ng/ml, p<0.001) than controls. Upon OGTT fourteen (30%) NAFLD subjects presented with abnormal glucose tolerance (IFG and/or IGT) and 32 had normal plasma glucose. NAFLD subjects with glucose intolerance were significantly more insulin resistant than NAFLD persons with normal glucose levels (HOMA 4.2±2.2 vs 2.7±1.7, p<0.05), had similar level of endothelial dysfunction, however they had significantly greater plasma interleukin 1β levels (25.8±15.6 vs 11.3±16.5 pg/ml, p<0.05). No differences in subclinical inflammation markers were noted between NAFLD subjects with normal plasma glucose and controls.
Conclusion: In conclusion, NAFLD is generally associated with increased vascular risk due to prevalent endothelial dysfunction, which however is not related to glucose intolerance or insulin resistance. Once - whatever mild - glucose abnormalities have developed, they worsen vascular risk in NAFLD subjects by increasing subclinical inflammation.

Non-alcoholic and alcoholic fatty liver disease - two diseases of affluence associated with the metabolic syndrome and type 2 diabetes. The FIN-D2D survey
A. Kotronen[1], H. Yki-Järvinen[1], S. Männistö[2], L. Saarikoski[2], E. Korpi-Hyövälti[3], H. Oksa[4], J. Saltevo[5], T. Saaristo[4], J. Sundvall[2], J. Tuomilehto[1], M. Peltonen[2];
[1]University of Helsinki, [2]National Institute for Health and Welfare, Helsinki, [3]South Ostrobothnia Central Hospital, Seinäjoki, [4]Tampere University Hospital, [5]Central Finland Central Hospital, Jyväskylä, Finland.

Background: Non-alcoholic fatty liver disease (NAFLD) is known to be associated with the metabolic syndrome (MetS) and abnormal glucose tolerance. Whether alcoholic fatty liver disease (AFLD) is associated with similar metabolic abnormalities has not been examined in a population-based study.
Aims: To assess the prevalences of NAFLD and AFLD, and to examine to what extent these conditions are associated with MetS and abnormal glucose tolerance.
Materials and methods: Features of insulin resistance, components of the MetS, glucose tolerance status by an OGTT, liver function tests (LFTs), and daily alcohol consumption were assessed in a population-based sample of 2766 subjects aged 45-74 years from Central Finland.
Results: Subjects with NAFLD and AFLD were equally obese and had similar fasting and insulin concentrations. Alcohol consumption averaged 4±5 and 32±21 g/day in subjects with NAFLD and AFLD. The prevalences of NAFLD and AFLD were 21% and 7%. Thus, of subjects with elevated LFTs, 75% had NAFLD. The MetS was more prevalent in AFLD (73%) than in NAFLD (70%, p=0.028), and type 2 diabetes was similarly prevalent in NAFLD and AFLD (24-25%). The MetS and type 2 diabetes were more prevalent in subjects with NAFLD or AFLD compared to subjects with normal LFTs (53% and 14%, p<0.0001 for both).
Conclusion: The prevalence of NAFLD is 3-fold higher than that of AFLD. The prevalences of MetS and type 2 diabetes are, however, significantly increased in both NAFLD and AFLD compared to subjects with normal LFTs. Subjects with AFLD are thus similarly metabolically unhealthy as subjects with NAFLD.

Non-alcoholic fatty liver disease in patients with chronic plaque psoriasis
G. Targher[1], P. Gisondi[2], G. Zoppini[1], G. Girolomoni[2];
[1]Endocrinology, Ospedale Civile Maggiore, [2]Dermatology, Ospedale Civile Maggiore, University of Verona, Italy.

Background and aims: Non-alcoholic fatty liver disease (NAFLD) and chronic plaque psoriasis are both associated with the metabolic syndrome and increased risk of incident cardiovascular disease. Although it is likely that both entities may coexist in a given patient, however, there is currently a lack of information on the association between NAFLD and psoriasis. We assessed the frequency and characteristics of NAFLD in patients with chronic plaque psoriasis.
Materials and methods: We recruited 130 consecutive patients with chronic plaque psoriasis and 260 healthy controls, who were matched for age, sex and body mass index. NAFLD was diagnosed by abdominal ultrasound after excluding other secondary causes of chronic liver disease (alcohol abuse, viral hepatitis, and current use of potentially hepato-toxic medications, including also methotrexate or tumor necrosis factor antagonists).
Results: The frequency of NAFLD was remarkably greater in psoriasis patients than in matched controls (47% vs. 28%; p<0.0001). Patients with psoriasis and NAFLD (n=61) were more likely to have the metabolic syndrome (according to the Adult Panel Treatment III definition) and had higher plasma C-reactive protein levels and greater severity of psoriasis according to the Psoriasis Area and Severity Index (PASI) score (14.2±12.6 vs. 9.6±7.4; p<0.01) than those with psoriasis alone (n=69). In multivariable stepwise regression analysis, NAFLD was associated with higher PASI score independently of age, sex, BMI, psoriasis duration and daily alcohol consumption.
Conclusion: NAFLD is frequent in patients with chronic plaque psoriasis - affecting up to nearly half of these patients - and is strongly associated with the psoriasis disease severity. Early recognition of NAFLD by radiological imaging tests in this group of patients is warranted.

Liver fat associates with postprandial triglyceride-enrichment of HDL particles and endothelial dysfunction in men with type 2 diabetes and men with the metabolic syndrome
M.E. Tushuizen[1], P.G. Scheffer[2], M.H. Muskiet[1], R.P. Vermue[2], C. Rustemeijer[1], P.J. Pouwels[3], M. Diamant[1];
[1]Department of Endocrinology / Diabetes Centre, [2]Department of Clinical Chemistry, [3]Department of Physics & Medical Technology, VU University Medical Centre, Amsterdam, Netherlands.

Background and aims: Liver fat accumulation is common in type 2 diabetes (T2DM), and closely related with features of the metabolic syndrome (MetS) and increased risk of cardiovascular disease (CVD). Liver fat associates with postprandial hypertriglyceridemia, thus potentially contributing to postprandial triglyceride-enrichment of HDL (HDL-TG), and subsequent enhanced HDL particle clearance and HDL dysfunction. Low HDL cholesterol is an independent CVD risk factor and also a feature of the MetS.
Materials and methods: We assessed postprandial HDL composition changes and their association with liver fat and endothelial function, before and following 3 consecutive meals, given as breakfast (t=0h), lunch (t=4h) and diner (t=8h) during a 16h period in 12 men with uncomplicated T2DM (mean±SE: age 55±1 yrs; BMI 32±1 kg/m^2; HbA1c 7.2±0.3%), 12 normoglycemic men with the MetS, and 12 age-matched controls. Blood sampling was performed before each meal, and 12h and 16h after breakfast. Flow-mediated dilation (FMD) of the brachial artery was measured by ultrasound before each blood collection. After ultracentrifugation, TG, cholesterol, and protein content were determined in HDL. Liver fat content was measured by proton magnetic resonance-spectroscopy.
Results: Plasma TG increased significantly after the meals (P<0.001 in all groups compared to baseline), and remained elevated after diner in T2DM and MetS men only. Fasting HDL-TG was highest in T2DM, relative to MetS and controls (147.5±16, 108.3±13, 78.3±8 nmol/g, respectively; P=0.002), and increased postprandially in all groups (P<0.001). FMD correlated inversely with HDL-TG, especially after diner (r=-0.57, P<0.001). Liver fat content was highest in T2DM compared to MetS and controls (24±6, 11±3, 7±2%, P<0.02, respectively) and associated with HDL-TG-content after 3 meals (r=0.64, P<0.001), after adjustment for age, metabolic state, TG and waist.
Conclusion: We conclude that in men with T2DM and the MetS, who had the highest liver fat content, exposure to 3 consecutive meals produced exaggerated HDL-TG enrichment, which was closely associated with endothelial dysfunction.

1268

ER stress contributes to apoptosis induced by elevated fatty acids in HepG2 liver cells

X. Gu[1], K. Li[1], X. Li[1], R. Fan[1], R.D. Laybutt[2], H.-L. Zhao[1], J.C. Chan[1], G. Xu[1];
[1]Medicine and Therapeutics, The Chinese University of Hong Kong, China, [2]Diabetes and Obesity Research Program, Garvan Institute of Medical Research, Sydney, Australia.

Background and aims: Chronic elevation in plasma free fatty acid (FFA) levels is commonly associated with impaired insulin-mediated glucose uptake, and often coexists with obesity and type 2 diabetes. Studies have shown that obesity causes endoplasmic reticulum (ER) stress and, in turn, insulin resistance in liver cells. In this study, we aimed to examine the effects of FFAs on ER stress and apoptosis in the human liver HepG2 cell line and to investigate whether attenuation of ER stress could protect HepG2 cells from FFA-induced apoptosis.
Materials and methods: Human liver carcinoma HepG2 cells were exposed to varying concentrations of Sodium Palmitate (saturated fatty acid, NaPa) or Sodium Oleate (unsaturated fatty acid, NaOl) for 24 h and MTT assay was conducted to measure cell viability. Apoptosis was analyzed with flow cytometry using Annexin V surface staining and PI staining. ER homeostasis of HepG2 cells was monitored over a time course of fatty acid treatment using markers of the ER stress response pathway, including GRP78/Bip and phosphorylation of eIF2α by Western Blot. Other markers of the ER stress response pathway, including IRE1α, CHOP and Bip were measured by real time RT-PCR. An expression plasmid encoding for the ER chaperone Bip (pBip) was transfected into HepG2 cells to attenuate ER stress. Small interfering RNA siCHOP was used to knockdown the expression of CHOP in HepG2. ER stress related markers, as well as apoptosis-related markers (Bax, Bcl-2 and cleaved caspase 3) were measured by Western Blotting.
Results: The saturated fatty acid NaPa led to cytotoxicity in HepG2 cells in a dose-dependent pattern; NaPa induced significant apoptosis in HepG2 cells as measured with cell cytometry. In contrast, the unsaturated fatty acid NaOl was not cytotoxic to HepG2 cells. Incubation of HepG2 cells with NaPa (0.45 mM) was associated with the induction of ER stress as indicated by increased phosphorylation of eIF2α, as well as upregulation of IRE1α and CHOP. Bip expression levels were slightly down regulated 6 h after NaPa (0.45mM) treatment. In contrast, NaOl did not induce ER stress in HepG2 cells. Overexpression of Bip attenuated NaPa-induced ER stress and led to a significant reduction in NaPa-mediated apoptosis, indicating a requirement of ER stress for lipotoxicity in liver cells. However, siRNA-mediated reduction of CHOP did not protect against NaPa-induced apoptosis.
Conclusion: These data demonstrate that the saturated fatty acid, palmitate induces ER stress and apoptosis in HepG2 cells, whereas the unsaturated fatty acid, oleate, does not. The data indicate that while ER stress makes a necessary contribution to palmitate cytotoxicity, inhibition of CHOP alone is not sufficient to prevent palmitate-induced apoptosis.

Abnormal hepatic energy homeostasis in type 2 diabetes

J.M. Szendroedi[1], M. Chmelik[2,3], A.I. Schmid[4,5], P. Nowotny[1,6], A. Brehm[7], M. Krssak[8], E. Moser[9], M. Roden[1];
[1]German Diabetes Center, Düsseldorf, Germany, [2]Karl-Landsteiner Institute for Endocrinology and Metabolism, Vienna, Austria, [3]MR Center of Excellence, Medical University of Vienna, Austria, [4]Karl Landsteiner Institute for Endocrinology and Metabolism, Vienna, Austria, [5]MR Center of Excellence, Medical University of Vienna, Austria, [6]Dept. of Internal Medicine 3, Medical University of Vienna, Austria, [7]First Medical Department, Hanusch Hospital, Vienna, Austria, [8]Department of Radiology, Medical University of Vienna, Austria, [9]Center for Biomedical Engineering and Physics, Medical University of Vienna, Austria.

Background and aims: Increased hepatocellular lipids relate to insulin resistance and are typical for type 2 diabetic patients (T2DM). Steatosis and T2DM have been further associated with impaired muscular ATP turnover indicating reduced mitochondrial fitness. Thus, we tested the hypothesis that hepatic energy metabolism could be impaired even in metabolically well controlled T2DM.
Materials and methods: We measured hepatic lipid volume fraction (HLVF) and absolute concentrations of γATP, inorganic phosphate (Pi), phosphomono- and diesters (PME, PDE) using noninvasive $^{1}H/^{31}P$ magnetic resonance spectroscopy in T2DM (58±6 years, 27±3 kg/m^2), age- and BMI-matched (mCON, 61±4 years, 26±4 kg/m^2) and young lean humans (yCON, 25±3 years, 22±2 kg/m^2, p<0.005, p<0.05 vs. T2DM and mCON). Insulin-mediated whole body glucose disposal (M) and endogenous glucose production (iEGP) were assessed during euglycemic-hyperinsulinemic clamps.
Results: T2DM had 26% and 23% lower γATP (1.68±0.11; 2.26±0.20; 2.20±0.09 mmol.L^{-1}; p<0.05). Further they had 28% and 31% lower Pi than mCON and yCON (0.96±0.06; 1.33±0.13; 1.41±0.07 mmol.L^{-1}; p<0.05). PME, PDE and liver transaminases did not differ between groups. HLVF was not different between T2DM and mCON, but higher (p=0.002) than in yCON. T2DM had 13-fold higher iEGP than mCON (p<0.05). Even after adjustment for HLVF, hepatic ATP and Pi related negatively to hepatic insulin sensitivity (iEGP) (r=-0.665, p=0.010, r=-0.680, p=0.007) but not to whole body insulin sensitivity.
Conclusion: These data suggest that impaired hepatic energy metabolism and insulin resistance could precede the development of steatosis in T2DM.

Preβ and αHDL kinetics measured by a stable isotopic and two step electrophoresis technique

X. Li, M. Stolinski, N. Jackson, M. Umpleby;
Diabetes and Endocrinology, University of Surrey, Guildford, United Kingdom.

Background and aims: Apolipoprotein A-I (apoA-I), the main apolipoprotein of HDL is mainly secreted by the liver. Once secreted, apoA-I acquires lipid to form nascent discoidal preβHDL which are converted into spherical αHDL particles by gaining lipid. Current understanding of HDL metabolism is limited due to technical difficulties in measuring the kinetics of HDL subclasses. Traditionally, HDL is separated by ultracentrifugation (1.063<d<1.21 g/ml), however, this process may damage the integrity of certain HDL particles leading to the dissociation of apoA-I. The aim of this study was to develop a method to separate and measure the kinetics of preβHDL and αHDL apoA-I following isotopic labelling techniques.
Materials and methods: Following an overnight fast, four healthy subjects (3F+1M) undertook a 9 hour primed-constant infusion of 1-^{13}C-leucine with blood samples taken hourly. A novel two-step electrophoresis technique was developed and optimised to isolate apoA-I from αHDL and preβHDL subclasses. Briefly, preβHDL and αHDL in plasma were separated by agarose gel electrophoresis. The separated subclasses were then quantitatively isolated from the agarose and the apoA-I from each subclass isolated by SDS-PAGE. HDL_2 and HDL_3 subclasses from the same plasma samples were isolated by sequential ultracentrifugation and apoA-I separated by SDS-PAGE. ApoA-I bands were excised and hydrolyzed with 6M HCl. Amino acids were purified by cation exchange chromatography and derivatised for GC-MS. The isotopic enrichment of ^{13}C-leucine in apoA-I was measured by GC-MS in negative chemical ionisation (NCI) mode.
Results: For the four subjects, mean plasma cholesterol was 4.28 (SEM 0.23) mmol/L, triglyceride 0.62 (0.04) mmol/L, HDL cholesterol 1.17 (0.13) mmol/L and total plasma apoA-I was 1.43 (0.1) mg/ml. The fractional clearance rate (FCR) of preβHDL apoA-I was significantly higher than that of αHDL, 0.190 (0.022) vs 0.152 (0.017) pools/day respectively (*P*=0.039). There was also a significant difference between HDL2 and HDL3 FCR, 0.162 (0.018) vs 0.144 (0.017) pools/day respectively (*P*=0.003). There was no significant difference in HDL2 and HDL3 production rate (PR); 4.069 (0.610) vs 2.838 (0.374) mg/kg/day respectively.
Conclusion: This is the first time that αHDL and preβHDL have been separated and the kinetics measured using this technique. The results indicate αHDL and preβHDL kinetics can be measured by this methodology and that this technique is sensitive enough to measure significant differences in the kinetics of HDL2 and HDL3 particles. This methodology can be used to measure HDL subclass kinetics in type 2 diabetes and metabolic syndrome.

1271

Apolipoprotein C-I concentration is increased in type 2 diabetes

B. Bouillet[1], J.P. Pais de Barros[2], L. Lagrost[2], L. Duvillard[2], J.M. Petit[1,2], A. Poussier[1], M.C. Brindisi[1], B. Vergès[1,2];
[1]Service Endocrinologie,Diabetologie et Maladies métaboliques, Centre Hospitalier Universitaire de Dijon, [2]Inserm CRI 866, Dijon, France.

Background and aims: Apolipoprotein C-I (ApoC-I) is bound to Very Low Density Lipoproteins (VLDL) and High Density Lipoproteins (HDL). ApoC-I has been shown in animal models to inhibit Lipoprotein Lipase and to promote VLDL production. Mice overexpressing human ApoC-I, present moderate hypercholesterolemia and hypertriglyceridemia. Furthermore, ApoC-I has also been shown to promote inflammation and atherosclerosis. So far, ApoC-I has never been studied in type 2 diabetes (DT2). This prompted us to study ApoC-I in patients with type 2 diabetes.
Materials and methods: ApoC1 concentration was measured by a specific immunoassay (ELISA) in total plasma in 30 patients with type 2 diabetes and in 32 normolipidemic controls. Moreover the distribution of ApoC-I among lipoproteins has been studied by direct measurement of ApoC-I in the HDL fraction and determination of VLDL-ApoC-I by the difference between total Apo C-I and HDL-ApoC-I.
Results: Plasma total ApoC-I (112.8 ± 36.3 vs 89.3 ± 29.0 mg/L, p=0.007) and VLDL-ApoC-I (40.7 ± 25.3 vs 23.4 ±14.3 mg/L, p=0.002) levels were significantly higher in DT2 patients. HDL-Apo C-I level (72.1 ± 21 vs 64.9 ± 19.1 mg/L, p=0.179) was also increased in the DT2 group but not significantly. In the control group, ApoC-I was mainly bound to HDL (74.2%). In patients with DT2, ApoC-I was significantly less bound to HDL (65.9% vs 74.2%, p=0.014) and more bound to VLDL (34.1% vs 24.9%, p=0.007). In unvaried analysis, total-ApoC-I was positively correlated with total cholesterol (p=0.001), LDL-C (p=0.022), triglycerides (TG) (p<0.0001), fasting glycaemia (p=0.015), BMI (p=0.001). In multivariate analysis, total-ApoC-I was correlated with TG (p<0.0001) and LDL-C (p=0.0248), but not with HDL-C, age, BMI, sex, fasting glycemia.
Conclusion: ApoC-I concentration in plasma is increased in type 2 diabetic patients. This rise is mainly due to an increase in VLDL-Apo C-I. Apo C-I level is independently associated with triglycerides and LDL, suggesting important cross-links between ApoC-I and lipoprotein metabolism. Further studies are needed to evaluate the consequences of the increase of total ApoC-I and VLDL-ApoC-I on lipoprotein metabolism and the vascular wall, in type 2 diabetes.

1272

Isosteviol elevates plasma HDL-cholesterol level - a potential new drug for the treatment of coronary heart disease

P.B. Jeppesen, X. Chen, Z. Liu, K. Hermansen;
Dept. of Endocrinology and Metabolism C, Aarhus University Hospital, Aarhus Sygehus THG, Denmark.

Background and aims: The risk of coronary heart disease (CHD) is increased 2-4 times in type 2 diabetes (T2DM). With the epidemic growth in T2DM in recent years CHD is becoming a global problem of great importance. The last 20 years have witnessed dramatic reductions in cardiovascular risk using statins to lower LDL-Cholesterol. Epidemiological studies have identified low levels of HDL-Cholesterol, a common feature of T2DM, to be an independent determinant of CHD. In preliminary studies with isosteviol (ISV), a diterpene glycoside with proven anti-diabetic and anti-hypertensive capabilities, we found indications that it may possess beneficial effects on lipid levels. The aims of the study is to investigate the impact of ISV on the lipid profile of fat fed hyperlipidaemic Wistar rats.
Materials and methods: 44 normal wistar rats at the age of 6 weeks and a bodyweight of about 230 g were studied. Rats were randomized to 4 groups, with 11 in each. Group 1 and 2 were fed with standard chow diet ± ISV (0.03 g/kg/day). Group 3 and 4 were fed with a high cholesterol containing diet (1.63 % g cholesterol, 0.41 % g Cholic acid, 16.3 % g sunflower oil) ± ISV (0.03 g/kg/day). ISV had a purity of 99.4 %. The treatment period was 20 weeks. The fasting total plasma cholesterol level and the HDL-cholesterol were measured by an enzymatic colorimetric test, the "cholesterol CHOD - PAP" method, using commercially available test kits. For statistical analysis were used student t-tests and two way ANOVA-tests.
Results: The plasma HDL-cholesterol level increased by 9% for group 1 (- ISV) (Δ 0.13 ± 0.04 (SEM) mmol/l; p<0.004), and by 14% for group 2 (+ ISV) (Δ -0.17 ± 0.04 (SEM) mmol/l; p<0.002) from start to end of the study. The fasting total plasma cholesterol level increased by 29% for group 1 (-ISV) (Δ 0.39 ± 0.06 (SEM) mmol/l; p<0.0001) and increased by 4% for group 2 (+ ISV) (Δ 0.07 ± 0.06 mmol/l; p<0.267). The plasma HDL-cholesterol level increased by 42% in group 3 (- ISV) (Δ 0.49 ± 0.15 (SEM) mmol/l; p<0.011), and by 88% in group 4 (+ ISV) (Δ 1.11 ± 0.26 (SEM) mmol/l; p<0.002). The fasting total plasma cholesterol level increased by 145% in group 3 (- ISV) (Δ 2.2 ± 0.14 (SEM) mmol/l; p<0.0001), and by 175% in group 4 (+ ISV) (Δ 2.77 ± 0.38 mmol/l; p<0.0001). No deaths were observed for group 2 and 4 being treated with ISV, whereas two deaths occurred in group 3 on high fat diet and no ISV. The body weight was reduced by 16% during the 20 weeks for group 2 (chow diet + ISV) compared to group 1, (chow diet control).
Conclusion: ISV in addition to anti-hyperglycaemic and blood pressure lowering effects also seems to possess a putative role as HDL-Cholesterol enhancer with the potential to effectively counteract the CHD risk.

Association of ApoB and ApoA1 with the insulinaemic status in prediabetic subjects

M.G. Kabir[1], R.M. Mazumdar[1,2], S. Mohajan[1,2], I. Khan[2], Z. Hassan[2], L. Ali[3]; [1]Biochemistry & Molecular Biology, University of Chittagong, [2]Dept of Physiology and Molecular Biology, BIRDEM, Dhaka, [3]Dept of Biochemistry and Cell Biology, BIRDEM, Dhaka, Bangladesh.

Background and aims: Investigation of covariates of insulin resistance and secretory defect can be an important tool to get more insight on the interplay of genetic and environmental risk factors in the development of the diabetic state and its complications. The present study was aimed to explore the causal association of the atherosclerotic apolipoproteins (ApoB and ApoA1) and their ratio in the basic defects of pancreatic B cell dysfunction and insulin resistance in prediabetes (IGT and IFG together) and T2DM.
Materials and methods: Following standardized selection process a total number of 131 subjects consisting of 18 IFG, 56 IGT and 57 T2DM subjects were purposively recruited. Fifty-nine healthy subjects served as control. Glucose was estimated by glucose-oxidase, lipids by enzymatic colorimetric, insulin by enzyme linked immunosorbent assay (ELISA). Serum ApoB and ApoA1 were estimated by immuno-nephelometric method.
Results: Absolute insulin (μIU) level in IGT and T2DM groups was significantly higher compared to the controls (p<0.001-0.001). HOMA%B (mean±SD) was significantly lower in T2DM groups (p<0.001) and higher in IGT (p=0.008) compared to the controls although it is significantly lower in IFG (p=0.001). HOMA%S was significantly lower in IGT and T2DM group (p=0.001 and 0.002 respectively), but did not show any significant difference in IFG. Triglyceride level was significantly higher in all three groups (p=0.044 -<0.001) and total cholesterol only in T2DM group (p=0.001). Mean (±SD) ApoA1 value was 0.97±0.25, 1.05±0.27, 1.05±0.25 and 1.08±0.26 in the Control, IFG, IGT and T2DM groups respectively. Mean (±SD) ApoB value was 0.82±0.19, 0.91±0.34, 0.92±0.26 and 1.04±0.29 respectively. ApoA1 was significantly higher only in the T2DM group and ApoB was higher in IGT and T2DM group (p=0.026-<0.001). Neither ApoB nor ApoA1 showed any significant difference in the IFG group as compared to control. ApoB-ApoA1 ratio did not show significant difference among the groups. Correlation analyses revealed significant positive correlation for ApoB with both fasting and postprandial glucose in T2DM (p=0.006 and 0.040 respectively). In IGT group ApoB was positively correlated with absolute insulin (r=0.314, p=0.025) and HOMA%B (r=0.277, p=0.049) and negatively with HOMA%S (r=-0.312, p=0.026). In T2DM ApoB was negatively correlated with HOMA%B (r= -0.318, p=0.017). ApoB-ApoA1 ratio showed similar pattern of that of ApoB alone.
Conclusion: ApoB, but not ApoA1 or ApoB-ApoA1 ratio, seem to have a causal association with insulin resistance and elevation of ApoB is also modulated by obesity and atherogenic lipids. Since insulin resistance is a substantially modifiable factor through life style adjustment, the association of the atherogenic apolipoproteins with this defect can have a great public health consequence.

Genetic determinants of atherogenic dyslipidaemia in patients with type 2 diabetes mellitus

A.A. Bystrova[1], A.N. Voitovich[2], E.I. Krasilnikova[1], V.I. Larionova[2]; [1]St.Petersburg State Medical University n.a.acad.I.P.Pavlov, [2]St.Petersburg State Pediatric Medical Academy, Saint-Petersburg, Russian Federation.

Background and aims: Elevated triglycerides (TG) and reduced high-density lipoprotein cholesterol (HDL-cholesterol) levels are the main features of atherogenic dyslipidemia, which contributes to increased cardiovascular risk in patients with type 2 diabetes mellitus. The apolipoprotein A1 (apoA1) and A5 (apoA5) genes have been shown to play an important role in determination of plasma TG and HDL-cholesterol concentrations, but little is known whether polymorphic variants of these genes influence lipid disorders in type 2 diabetic patients. The aim of our study was to evaluate if there is an association between apoA1 and apoA5 gene polymorphisms and atherogenic dyslipidemia in patients with type 2 diabetes mellitus.
Materials and methods: We examined 225 patients with type 2 diabetes mellitus (161 females and 64 males, mean age 57±0,4 years), not taking lipid-lowering drugs. Serum lipids were evaluated by enzymatic method. G-75A and C83T apoA1, S19W and -1131T>C apoA5 gene polymorphisms were identified by polymerase chain reaction - restriction fragment length polymorphism method
Results: Atherogenic dyslipidemia was revealed in 115 patients (51,1%), 110 patients (48,9%) had normolipidemia (controls). The apoA5 S19W genotypes frequency was significantly higher in male patients with hypertriglyceridemia (TG above the 90th percentile for age and sex) than in patients with normolipidemia (p=0,032) and in female patients who had hypertriglyceridemia with low HDL-cholesterol level (HDL-cholesterol below the 10th percentile for age and sex) than in controls (p=0,013). The frequency of apoA1 genotypes with -75A allele was significantly higher in female patients who had hypertriglyceridemia with low HDL-cholesterol than in control patients (p=0,016). There was not significant difference in distribution of C83T apoA1 and -1131T>C apoA5 allele and genotype frequencies between patients with dyslipidemia and controls.
Conclusion: Our findings reveal an association between apoA1 and apoA5 gene variants and atherogenic dyslipidemia in patients with type 2 diabetes mellitus.

1275

Apoprotein A5 protects from atherosclerosis in mice

M. Merkel[1], D. Teupser[2], P. Gords[3], D. Müller-Wieland[1], J. Heeren[4]; [1]1. Dep. of Internal Medicine, Asklepios Klinik St. Georg, Hamburg, Germany, [2]Clinical Chemistry and Molecular Diagnostics, Institute of Laboratory Medicine, Leipzig, Germany, [3]Katholieke Universiteit Leuven, Netherlands, [4]Institute for Molecular Cell Biology, Hamburg, Germany.

Background and aims: Apoprotein A5 (apoA5) is a regulator of plasma triglycerides (TG) in patients with and without diabetes. Transgenic mice (apoA5tr) had decreased, and knock out mice 4fold increased TG. Based on human data it has been proposed that apoA5 may reduce coronary heart disease. In this study, a possible anti-atherogenic effect of apoA5 was investigated in different animal models.
Materials and methods: The apoA5tr was bred both onto the FVB-apoE deficient (apoEKO) background and on the FVB-LDL-receptor deficient (LDLRKO) backgrounds. At 22 - 26 weeks, lipoprotein profiles of individual mice were measured, and hearts and aortas were removed for quantification of atherosclerosis.
Results: ApoA5 was able to reduce atherosclerosis in both the apoEKO and the LDLRKO animal models by more than 50%. This finding was confirmed by en face preparation of whole aortas. In apoEKO mice, apoA5 dramatically reduced plasma VLDL TG by more than 70% in both genders. Here, lesion size correlated best with VLDL TG. Lipoprotein profile changes were lass pronounced on the LDLRKO background. As in wild type animals, turnover studies with different lipoprotein labels using apoE deficient VLDL showed a faster plasma TG and lipoprotein particle turnover. However, liver lipoprotein uptake was not significantly affected by apoA5. To explore the function of apoA5 for receptor mediated endocytosis at the cellular level, uptake of radiolabeled remnants in primary hepatocytes from WT and apoA5tr mice was measured. Here, preliminary data do not reveal significant differences.
Conclusion: It is concluded, that apoA5 is strongly atheroprotective in mice independent from the mouse model used.

Comparison of efficacy of pitavastatin and colestimide in Japanese patients with diabetes mellitus complicated by hyperlipidaemia and metabolic syndrome

M. Itoh[1], T. Kato[2], Y. Sawai[2], K. Inagaki[2], H. Kanayama[2], N. Katada[2]; [1]Division of Endocrinology & Metabolism, Fujita Health University, School of Medicine, Toyoake, [2]Internal Medicine, Aichi Koseiren Toyotakousei Hospital, Toyota, Japan.

Background and aims: Metabolic syndrome refers to a syndrome in which risk factors for atheroclerosis such as hyperglycemia, insulin resistance, hyperlipidemia, hypertension, and other conditions have accumulated, and is associated with a very high risk of triggering of atherosclerosis. Hyper-LDL-cholesterolemia is known to be a strong risk factor for coronary artery disease independent of metabolic syndrome. Anion exchange resin preparations have recently been attracting close attention because they exert hypoglycemic effects in addition to lipid profile-improving effects. The present study was

undertaken to evaluate the effects of pitavastatin and colestimide (a drug stimulating bile acid excretion) in patients with diabetes mellitus complicated by hyperlipidemia and metabolic syndrome.
Materials and methods: Forty-eight Japanese patients with diabetes mellitus complicated by hyperlipidemia and metabolic syndrome were randomly assigned to either a 24-week pitavastatin (1.0mg/day) treatment group or a colestimide (3.0g/day) treatment group. There were no significant differences between the two groups in demographic parameters, blood glucose level, lipid profiles, oral drugs used, or other test data at baseline. Over the 24-week period of administration, systolic and diastolic blood pressure, BMI, triglyceride(TG), HDL- and LDL-cholesterol, AST, ALT, plasma glucose, HbA1c, IRI, and high sensitivity CRP were measured. Postprandial glucose levels were evaluated after 120 min in the 75gOGTT. Pulse wave velocity (PWV) were measured with an automatic electronic sphygmomanometer.
Results: Treatment with pitavastatin significantly reduced LDL-C and TG, while that with colestimide significantly reduced waist circumference, BMI, LDL-C, HbA1c, FPG, PPG, and HOMA-R. Furthermore, hs-CRP also exhibited significant reduction with colestimide treatment (586.3 ± 352.9 vs 1016.0 ± 1063.2 μg/dl, $p<0.05$). Percent improvement in LDL-C was significantly greater in the pitavastatin group than in the colestimide group. Compared to the pitavastatin group, the colestimide group exhibited significantly greater improvement in mean change of HbA1c (-9.0 vs 0.3%, $p<0.001$), FPG (-9.7 vs 1.3%, $p<0.01$), PPG (-15.2 vs 5.4%, $p<0.05$), HOMA-R (-19.3 vs 24.0%, $p<0.05$), IRI (-11.7 vs 19.4%, $p<0.05$), and BMI (-4.3 vs 1.0%, $p<0.01$).
Conclusion: Colestimide appeared to be useful in the management of Japanese patients with diabetes mellitus complicated by metabolic syndrome, since it alleviates obesity and insulin resistance in addition to exhibiting lipid profile-improving effects, and can thus improve markers of atherosclerosis.

1277

High fat diet and chronic ethanol consumption impair the expression of key molecules in AMP activated protein kinase pathway in rat cardiac muscle

W. Xin, B. Cui, X. Lv, J. Zhang, X. Hou, L. Gao;
Scientific Centre, Provincial Hospital affiliated to Shandong University, Jinan, China.

Background and aims: Our previous work has shown that chronic ethanol consumption impairs the mRNA expression of key factors of insulin-dependent pathway, for example, IR, IRS, GLUT4 etc. in the cardiac muscle in rats. Also long-term moderate ethanol consumption reversed the adverse effects of saturated fatty acid on GLUT4 expression in adipose tissues of rats. In the present study, we investigated the combined effects of saturated fatty acid and ethanol on several signal molecules in AMP activated protein kinase(AMPK) pathway in the cardiac muscle in rats, and thus probe into the possible mechanism of these effects on the glucose metabolism in the cardiac muscle.
Materials and methods: Forty-eight male Wistar rats, randomly divided into four groups: normal diet control group (C), high fat diet group (HF), ethanol group (E) and high fat diet plus ethanol group (HF+E). The HF diet consisted of 59 % fat from lard (a representative food full of saturated fatty acid in China) whereas the normal diet contained 10% fat, and the edible ethanol dosage was 5 g·kg-1·d-1. After treatment for 22 weeks, all animals were sacrificed and the left ventricles were quickly removed and saved for later analysis. The mRNA and protein levels were determined by RT-PCR and western blotting method respectively.
Results: Compared with the control group, all mRNA and protein expression of the selected signal molecules were decreased in treatment groups. The data are as follows in table 1.

Table 1. The expression decreases of signal molecules compared to group C

		group E	group HF	group HF+E
mRNA	AMPK α1	49.50 % *	41.06 % **	33.70 %
	AMPK α2	34.50 % *	21.29 % **	15.99 %
	MEF2A	57.68 % *	15.61 %	26.14 % **
	MEF2D	35.79 % **	20.32 %	35.81 % **
	GLUT4	41.00 % *	8.27 %	18.92 %
protein	AMPK α	37.72 %	36.59 %	41.74 % **
	P-AMPK α	33.91 %	11.58 %	15.31 % **
	MEF2	21.27 % **	29.82 % **	23.71 % **
	GLUT4	33.28 % *	18.50 %	30.42 % **

* P < 0. 01 , ** P < 0. 05

Either ethanol alone intaking (group E) or high fat diet alone (Group HF) significantly decreased the expression levels of key signal molecules in the AMPK/MEF2 pathway, while in group HF+E, the mRNA decreases in both AMPK α1 and AMPK α2 subunits were not so remarkable. The protein expression of key signal molecules in the AMPK/MEF2 pathway was correspondingly reduced compared to group C. However, the P-AMPKα activity level in group HF+E showed an obvious reversion relative to the impairment in group E. This is consistent with our former reports in adipose tissues and the study of Fisher H, that is, the moderate saturated fatty acid can partly neutralize the effect of ethanol to AMPK expression.
Conclusion: High fat diet and chronic ethanol consumption impair the expression of key molecules in AMPK pathway. Moderate saturated fatty acid plus chronic ethanol intaking presents, at least at a certain extent, a benefit effect on AMPK expression in rat cardiac muscle.

High FFA-induced proliferation and apoptosis in human umbilical vein endothelial cell partly through Wnt/β-catenin signal pathway

T. You, G. Chen;
Fu jian Provincial Hospital, Fujian Medical University, Fuzhou, China.

Background and aims: Free fatty acids (FFA)-induced proliferation and apoptosis was studied in human umbilical vein endothelial cells (HUVECs).
Materials and methods: A recombinant adenovirus containing a RNAi cassette targeting the GSK-3β gene was produced and its silencing effect on GSK-3β gene was detected by Western blot analysis and immunohistochemistry assay in HUVECs. The effect of the RNAi on the protein level of β-catenin was explored by transfecting the RNAi adenovirus to inhibit the expression of GSK-3β protein. The subsequent effect on the Wnt/GSK-3β/β-catenin signal pathway and on proliferation and apoptosis of HUVECs cultured with FFAs, was analyzed by BrdU assay ,Annexin V-FITC /PI Apoptosis Detection Kit , and 4',6-diamidino-2- phenylindole(DAPI) in order to explore the possible connection between the signaling pathway and FFA-induced proliferation and apoptosis.
Results: The Western blot results showed that the expression of GSK-3β protein in HUVECs could be inhibited efficiently by the RNAi adenovirus, and that the protein level of β-catenin was increased by RNAi adenovirus transfection. The results of the BrdU assay suggested that knockdown of GSK-3β with the RNAi adenovirus may stimulate the proliferation of HUVECs. Apoptosis was observed in HUVECs exposed to FFAs (0.75 mmol/L) for 72 h, and this effect could be partly reversed when interfering with the RNAi adenovirus.
Conclusion: It may be concluded that the RNAi adenovirus specific to GSK-3β may partly protect HUVECs from apoptosis induced by FFAs. Up-regulation of the Wnt/β-catenin signal pathway can partly reverse FFA-induced apoptosis in HUVECs.

Adiponectin is an independent predictor of apolipoprotein B/A1 ratio in different grades of glucose intolerance

J. Roh[1], J. Park[1], M. Cho[1], Y. Lee[1], J. Nam[1], J. Nam[2], C. Ahn[1], B. Cha[1], E. Lee[1], S. Lim[1], K. Kim[1], H. Lee[1];
[1]Internal Medicine, Yonsei University College of Medicine, Seoul, [2]Internal Medicine, National Health Insurance Corporation Ilsan Hospital, Goyang, Republic of Korea.

Background and aims: Recent studies have reported that Apolipoprotein B/A1 ratio is a better predictor of atherosclerotic vascular disease compared to LDL-C. The aim of this study was to assess the association of serum Apolipoprotein B/A1 ratio with insulin resistance and PWV in patients with different grades of glucose intolerance
Materials and methods: According to glucose tolerance, NGT without metabolic syndrome group (N=229), IFG group (subjects with fasting plasma glucose level of between 100-125 mg/Dl, N=658), type 2 diabetes group(N=381) were divided. To minimize the possible confounding effects of glucose-lowering pharmacological treatment, included diabetic patients were not treated with insulin or thiozolidinedione, and taking lipid lowering medication(fibrate or statin) were excluded. BMI, WC, and serum concentration of apolipoprotein B, apolipoprotein A1, glucose, lipids (triglycerides,

LDL cholesterol, HDL cholesterol, and total cholesterol) were measured. Insulin resistance was estimated by the insulin resistance index of homeostasis model assessment (HOMA-IR) & serum adiponectin. PWV was evaluated to assess arterial stiffness

Results: The subjects were divided 3 groups according to glucose tolerance(NGT, IFG and T2DM group), there were significant differences in metabolic parameters among the groups, and WC, insulin, adiponectin, HOMA-IR, aortic and peripheral PWV, Apo B/A1 ratio which increased sequentially with glucose intolerance. Apo B/A1 ratio significantly correlated with total cholesterol (NGT,IFG,T2DM: γ=0.33, γ=0.21, γ=0.38, all P<0.01), TG (γ=0.28, γ=0.22, γ=0.29, all P<0.01), LDL-C (γ=0.47, γ=0.29, γ=0.39, all P<0.01), HDL-C (γ= -0.46, γ= -0.28, γ= -0.34, all P<0.01), adiponectin (γ= -0.35, γ= -0.28, γ= -0.21, all P<0.01), HOMA-IR (γ=0.20, γ=0.09, γ=0.08 , all P<0.05). Multple regression analysis showed that Apo B/A1 ratio was significantly associated with total cholesterol (β=0.50, β=0.18, β=0.27, all P<0.01), LDL-C (β=0.44, β=0.22, β=0.18, all P<0.01), HDL-C (β= -0.59 β= -0.32, β= -0.29, all P<0.01), and adiponectin (β= -0.11, β= -0.09, β= -0.13, all P<0.05)

Conclusion: The apo B/A1 ratio is significantly associated with insulin resistance according to glucose intolerance and serum adiponectin is an important independent factor associated with Apo B/A1 ratio in Koreans.

High prevalence of persistent lipid abnormalities in statin treated patients with sedentary lifestyle in Europe and Canada: results of the Dyslipidemia International Study

A.K. Gitt[1], J.-R. Gonzalez-Juanetey[2], J. Ferrieres[3], L. Leiter[4], P. Lundman[5], K.K. Thomsen[6], T. Pedersen[7], H. Drexel[8], J. Feely[9], P. Marques da Silva[10], D. Wood[11], F. Chazelle[12], C. Jünger[1], K. Bestehorn[13], J. Kastelein[14]; [1]Klinikum der Stadt Ludwigshafen, Germany, [2]Hospital Clínico Universitario, Santiago de Compostela, Spain, [3]CHU Rangueil, Toulouse, France, [4]St. Michael's Hospital, Toronto, Canada, [5]Danderyds sjukhus, Stockholm, Sweden, [6]Sydvetjysk Sygehus, Esbjerg, Denmark, [7]Ulleval University Hospital, Oslo, Norway, [8]Landeskrankenhaus, Feldkirch, Austria, [9]St. James's Hospital, Dublin, Ireland, [10]Hospital de Santa Marta, Lisbon, Portugal, [11]Charing Cross Hospital, London, United Kingdom, [12]Merck & Co Inc., Paris, France, [13]MSD SHARP & DOHME GMBH, Haar, Germany, [14]Academic Medical Center, Amsterdam, Netherlands.

Background and aims: Statins are widely used for treatment of dyslipidemia. Many patients on statin however do not reach their lipid targets. This analysis of patients from DYSIS investigated whether patients with sedentary lifestyle (SL) differ in cardiovascular disease risk factor profile (RFP) and LDL-C target achievement from patients without this risk factor. Sedentary lifestyle was considered if the patient was reported not to conduct usual physical activity (i.e. a minimum of walking 20-30 minutes 3-4 days a week or equivalent).

Materials and methods: The data originate from a large cross-sectional study in 12 countries (Europe, Canada) done in 2008 that comprise data from clinical examination as well as latest lipid values from consecutively recruited outpatients ≥45 years on chronic statin therapy. To evaluate the role of SL a stepwise logistic regression analysis adjusting for patient characteristics and lipid lowering therapy was performed.

Results: Prevalence of RFP (e.g. diabetes mellitus, metabolic syndrome, obesity, and other comorbidities) was higher in patients with SL compared to those without SL as well as LDL-C not at goal, low HDL-C, and elevated triglycerides (TG) according to ESC Guidelines. The results identified SL as independent predictor of 'LDL-C not at goal' (OR 1.19, 95%-CI 1.11-1.26).

Conclusion: Patients with SL have an unfavourable RFP and a worse lipid profile than those without. A majority of statin treated patients with SL and comorbidities in this cohort was not at lipid goal and/or had abnormal levels of HDL-C and triglycerides. These results prompt to improve life style and a more intensive and comprehensive lipid management in these patients.

Hypertriglyceridaemic waist phenotype is associated with increased severity of coronary artery disease both in type 2 diabetes and nondiabetic patients

K. Lalic[1], M. Zamaklar[1], N.M. Lalic[1], M. Ostojic[2], V. Kalimanovska[3], A. Jotic[1], N. Rajkovic[1], L. Lukic[1], T. Milicic[1], S. Singh[1], L. Stosic[1];
[1]Inst for Endocrinology, [2]Inst for Cardiovascular Diseases, [3]Faculty of Pharmacy, Belgrade, Serbia.

Background and aims: It has been previously shown that the presence of hypertriglyceridemic waist (HTgW) phenotype (waist girth ≥90 cm in men and ≥85 cm in women, and plasma triglyceride (Tg) concentration of ≥2.0 mmol/L) could identify a high-risk patient with excess visceral adipose tissue who is at high risk for development of coronary artery disease (CAD). However, the relationship between the presence of HTgW phenotype and related metabolic parameters (insulin sensitivity (IS) and cholesterol subfraction levels) and the severity of coronary artery disease (CAD) expressed as the number of stenotic coronary arteries (SCAs) in patients with Type 2 diabetes (T2D) has not yet been elucidated. Therefore, this study was aimed to analyze the (a) severity of CAD, (b) IS levels, (c) lipoprotein subfraction levels and (d) LDL particle size in the following groups of patients referred to and underwent coronary angiography for suspected CAD: (a) T2D with HTgW (group A, n=28); (b) T2D without HTgW (group B, n=12); (c) nondiabetics with HTgW (group C, n=22); (d) nondiabetics without HTgW (group D, n=38).
Materials and methods: CAD was angiographically verified in each patient included in this study and defined as a stenosis with narrowing of the lumen >50% with respect to the pre-stenotic segment in the main coronary blood vessels. The severity of CAD was evaluated based on the number of SCAs and defined as single vessel CAD (one SCA) or multivessel CAD (at least two SCAs or the stenosis of the left main artery). Insulin sensitivity levels (Si) was determined by minimal model analysis, total cholesterol (Ch), HDL-Ch, LDL-Ch and Tg levels by enzymatic methods and the LDL particle diameter by using gradient gel electrophoresis.
Results: We found that in both T2D and nondiabetic patients significantly higher percentage of patients with HTgW phenotype had multivessel CAD in comparison to patients without this phenotype (group A vs B: 83.3% vs 37.5%, p<0.05; group C vs D: 64.3% vs 33.3%; p<0.05). Also, Si values were lower in group A vs B (A: 1.47+/-0.34; B:1.91+/-0.03 $min^{-1}/mU/lx10^4$; p<0.05) and in group C vs D (C: 3.86+/-0.66; D: 6.24+/-1.12 $min^{-1}/mU/lx10^4$; p<0.05). Simultaneously, in T2D patients we found significantly lower level of HDL-Ch in group A vs B (0.92+/-0.07 vs 1.21+/-0.07 mmol/l; p<0.05) while we could not find significant differences in total, LDL-Ch and the mean LDL particle size levels between these groups. In contrast, in nondiabetic patients we did not find differences in HDL-Ch levels, while we found significantly higher levels of total Ch and LDL-Ch and smaller mean LDL particle size in group C vs D (26.02+/-0.18 vs 26.89+/-0.18 nm; p<0.01).
Conclusion: Our results signify that both in T2D and nondiabetic patients presence of HTgW phenotype is strongly associated with multivessel CAD as a more severe type of CAD. Also, the data signify that this association might be based on increased insulin resistance both in T2D and nondiabetics as well as on different lipid abnormalities involving primarily reverse cholesterol metabolism in T2D and impairments in the structure of LDL with accumulation of small dense LDL particles in nondiabetic subjects.

1282

The higher burden of small low-density lipoprotein particles is associated with profound changes in serum testosterone concentration in male adolescents

Y. Lee[1], S. Choi[2], H. Kim[3], S. Han[3], H. Lee[1], D. Kim[3];
[1]Yonsei University College of Medicine, Seoul, [2]Seoul National University College of Medicine, Seoul, [3]Ajou University School of Medicine, Suwon, Republic of Korea.

Background: Males are at higher cardiovascular risk than females from a young age. Dyslipidaemia, including a higher burden related to small low-density lipoprotein (LDL), plays an important role in precipitating atherosclerosis in both males and females. It is important to clarify which factors are related to these sex differences in cardiovascular risks from childhood, especially in males. We investigated the sex differences of atherogenic lipoprotein burden and independent predictors of LDL particle size in children and adolescents.
Methods: We measured the concentrations of total testosterone, sex hormone-binding globulin (SHBG), estradiol (E2), adiponectin, total cholesterol, triglyceride (TG), LDL cholesterol (LDL-C), HDL cholesterol (HDL-C), and LDL particle size in 135 children and adolescents (67 boys, 68 girls).
Results: Serum testosterone concentration was significantly negatively correlated with LDL particle size (r = -0.336, p = 0.016) in male adolescents, but oestrogen and LDL particle size were not related. Higher TG and lower HDL-C concentrations were independently correlated with LDL particle size in both children and adolescents. After excluding the lipid profile in the multivariate analysis, BMI (β = -0.311, p = 0.006) in children and testosterone concentration (β = -0.336, p = 0.016) in adolescents were independently associated with LDL particle size. After mid-puberty, LDL particle size declined markedly in male adolescents.
Conclusion: Serum testosterone concentration correlated significantly with LDL particle size in male adolescents, especially after mid-puberty. The prominent decrease in LDL particle size associated with the increase in testosterone concentration in males might explain why males are more likely to display atherogenic dyslipidaemia from adolescence.

1283

Elevated circulating NEFA concentration are related to cardiac dysfunction of obese rats

H. Pan, Y. Yu, H. Tan;
Endocrinology and metabolism, West China Hospital of Sichuan University, Chengdu, China.

Background and aims: Obesity is associated with cardiac hypertrophy and abnormal cardiac function, the mechanism of which is still not quite clear. Elevated circulating NEFA level may play an important role in the development of heart dysfunction. The aim of the study is to explore the effects of decreasing blood NEFA concentration on cardiac function in obese rats.
Materials and methods: 4 week aged male S-D rats were divided into three groups: control group(NC, n=16) fed normal chow, obese group(OB, n=16)and fenofibrate group (OB+F, n=16) fed high fat chow. Four weeks later, Fenofibrate(20mg/kg/d) was given to the rats in OB+F group by oral gavage. AT the end of 8 weeks and 16 weeks the maximum velocity of myocardial contraction ($+dP/dt_{max}$) and relaxation ($-dP/dt_{max}$) were tested by physiological polygraph. The concentrations of triglyceride (TG) and NEFA both in blood and in left ventricular were measured. The expressions of NF-κB and iNOS in myocardial cell were visualized by immunohistochemical

Table 1 (abstract 1283) The cardiac function and TG and NEFA concentrations in blood and myocardium

		NC		OB		OB+F	
		8w(n=8)	16w(n=8)	8w(n=8)	16w(n=8)	8w(n=8)	16w(n=8)
Weight (g)		369.5±41.3	425.9±24.1	423.9±43.9*	510.8±41.8**	411.3±26.2	534.1±60.1
TG	blood(mmol/l)	0.76±0.17	0.83±0.17	1.32±0.35*	1.57±0.37**	0.87±0.34#	1.00±0.39#
	Myocardium(mmol/g)	0.68±0.16	0.87±0.22	1.23±0.35*	1.48±0.36*	0.95±0.28#	0.99±0.31#
NEFA	blood(μmol/l)	221.9±75.9	360.7±91.8	679.3±157.6*	1247.4±227.9**	467.9±124.9#	501.4±188.3#
	myocardium(μmol/g)	433.8±146.4	518.4±151.9	682.9±201.1*	744.7±213.5*	521.0±120.5	614.8±240.3
$+dp/dt_{max}$ (mmHg/s)		4334±427	3787±544	3444±416*	2965±320*	3546±752	3448±647
$-dp/dt_{max}$ (mmHg/s)		-4174±462	-3564±440	-3267±538*	-2815±391*	-3388±667	-3223±522

* P <0.05, ** P <0.01, vs the NC group; #: P<0.05, ##: P<0.01, vs the OB group.

methods and semi-quantified by morphometric image analysis (integrated optical density, IOD)
Results: The OB group rats developed obesity and left ventricular hypertrophy. The TG and NEFA levels either in myocardial homogenate or blood were increased and the values for $+dP/dt_{max}$ and $-dP/dt_{max}$ were lower (table 1) in OB group. Fenofibrate intervention improved lipids profile and cardiac function. The expressions of NF-κB and iNOS in myocardium were higher in OB group (IOD: NFκB: 32000, vs. 55176, P<0.05; iNOS: 24949, vs. 68315, P<0.01), which was partly restored in OB+F group (IOD: NFκB: 30741; iNOS: 39525). Intramyocardial lipids deposition was associated with plasma TG and NEFA concentrations. The values of $+dp/dt_{max}$ and $-dp/dt_{max}$ were negatively correlated with the intramyocardial TG and NEFA concentration and the score of NF-κB, iNOS.
Conclusion: Elevated circulating TG and NEFC levels are associated with ectopic lipid accumulation in myocardium, which may play an important role in the development of heart dysfunction through triggering an inflammatory signaling cascade.

Prevalence of lipid abnormalities before and after introduction of lipid modifying therapy among Swedish patients with type 2 diabetes and/or coronary heart disease (PRIMULA Sweden)
B. Ambegaonkar[1], B. Pettersson[2], V. Sazonov[1], M. Martinell[3], J. Stålhammar[3];
[1]Merck and Co. , Inc., Whitehouse Station, United States, [2]Merck Sharp and Dhome (Sweden), Sollentuna, Sweden, [3]Uppsala University, Sweden.

Background and aims: Recent data on the extent of lipid abnormailities and treatments used among adults with dyslipidemia are limited; particularly among those with coronary heart disease (CHD) or type 2 diabetes mellitus (T2DM). We therefore examined the prevalence of lipid abnormalities and utilization of lipid modifying therapies (LMT) to determine any gaps in therapy in a Swedish longitudinal assessment of CHD and T2DM patients.
Materials and methods: This retrospective longitudinal study is based on primary health care electronic medical records (EMR) from the county of Uppsala, Sweden. We identified patients at least 35 years of age, experiencing CHD only (CHD without T2DM), CHD+ T2DM and T2DM only (T2DM without CHD), who initiated a LMT between May 1994-June 2007, continued treatment for 1 year and had at least 1 lipid abnormality prior to initiation of LMT. Patients selected were also required to have a complete lipid panel consisting of low-density lipoprotein cholesterol (LDL-C), high- density lipoprotein cholesterol (HDL-C) and triglycerides (TG), 13 months pre (baseline) and 1-year post (follow-up) therapy initiation. Target/normal levels for LDL-C, HDL-C and TG were specified as per NCEP ATP III Guidelines.
Results: Sample consisted of CHD only (n=337), CHD+T2DM (n=95) and T2DM only (n=1,033) patients. Mean age of the above 3 groups was 74, 75 and 67 years respectively with 57%, 60% and 54% men in the respective groups. At baseline, 91% of patients with CHD exhibited elevated LDL-C compared to 82% of those with CHD+ T2DM and 90% of those with T2DM. Low HDL-C was observed among 30%, 46% and 42% of patients with CHD, CHD+ T2DM and T2DM respectively while 31% of patients with CHD, 41% with CHD+ T2DM and 52% with T2DM had elevated TG levels. Prior to therapy, 39%, 46% and 57% of patients with CHD, CHD+T2DM and T2DM respectively experienced elevated LDL-C coupled with low HDL-C and/or elevated TG. Over 90% of patients utilized statin monotherapy. Post therapy breakdown for lipid abnormalities is shown in the table.

Lipid Abnormality Profile by Risk Status

	CHD only (n=337) (1)	CHD+T2DM (n=95) (2)	T2DM only (n=1,033) (3)	p value (1) vs. (2)	p value (1) vs. (3)	p value (2) vs. (3)
Elevated LDL-C	59%	38%	51%	<0.01	<0.05	<0.05
Low HDL-C	22%	39%	41%	0.001	<0.01	0.677
Elevated TG	18%	24%	36%	0.162	<0.01	<0.05
Elevated LDL-C + low HDL-C and/ or elevated TG	18%	17%	28%	0.828	<0.01	<0.05

Conclusion: In this longitudinal study of Swedish high CV risk patients primarily treated with statins, improvement in LDL-C level post LMT was substantial: at least one out of three patients achieved LDL-C goal, approximately additional 13-17% achieved normal TG levels while improvement in HDL-C level was small (up to 8% among CHD+ T2DM patients). Post therapy patients with CHD had significantly higher percentage with elevated LDL-C and significantly less with low HDL-C and elevated TG compared to CHD+ T2DM and T2DM groups. Despite LMT, over a quarter of T2DM patients and up to one in five patients from the other two groups, continued to exhibit elevated LDL-C coupled with low HDL-C and/or elevated TG and could potentially benefit from higher doses of statin or as recommended in the guidelines from adding another therapy to statins.

1285

High-density lipoprotein cholesterol effects of pioglitazone compared with non-TZD oral medications in a US managed care cohort
T. McCall, M. Bron, J. Liu, S. Manthena, R. Spanheimer;
Takeda Pharmaceuticals North America, Inc., Deerfield, United States.

Background and aims: Decreased high-density lipoprotein cholesterol (HDL-C) is characteristic of diabetic dyslipidemia and a risk factor for cardiovascular disease among patients with type 2 diabetes mellitus (T2DM). Nearly half of patients with T2DM in a primary care cohort had HDL-C values below normal, suggesting that strategies to raise HDL-C are not incorporated into treatment regimens. In randomized controlled clinical trials, pioglitazone (PIO), an oral antidiabetic (OAD) agent, has consistently raised HDL-C and lowered triglycerides (TG). To further explore the lipid effects of PIO, a retrospective claims analysis in a large database of United States privately-insured enrollees was conducted.
Materials and methods: The Integrated Healthcare Information Services database (01/01/00-03/31/07), a database of US managed care population was used. Analysis inclusion criteria were new-onset T2DM patients treated with PIO or non-TZD OAD monotherapy regimens. Patients using insulin were excluded. Patients were required to have at least one HDL-C, a low-density lipoprotein cholesterol (LDL-C), and TG lab value at baseline and another value during 12 months follow-up.
Results: Both treatment groups were similar in age (55 years). There was a higher percentage of women in the non-TZD OAD (47.2%) than the PIO (35.2%) group. Baseline lipid values were (mg/dL): LDL-C 117.2, TG 229.3, and HDL-C 43.2 for PIO and LDL-C 120.2, TG 220.8, HDL-C 44.4 for non-TZD OAD. While HDL-C was increased from baseline in both groups over 12 months, the magnitude of increase was greater with PIO (P<0.0001 Figure). Both PIO and non-TZD OAD treatment were associated with reductions of LDL-C and TG. After age and gender adjustments, HDL-C increases remained significant for both groups and between groups. Among patients who took statins prior to OAD treatment, HDL-C increased by 10.0% in the PIO group and 2.8% in the non-TZD group, while LDL-C decreased 1.5% and TG decreased 13.8% from baseline in the PIO group and 4.8% and 4.9%, respectively, in the non-TZD group.
Conclusion: PIO is associated with increased HDL-C and decreased TG levels compared with baseline and non-TZD OAD treatment in this database, a finding consistent with data from clinical trials and independent of statin use. Further analyses are planned to assess the economic benefit of these improvements.
Figure: Percent Change in HDL-C, LDL-C, and TG in Patients Treated with Pioglitazone or non-TZD OAD for 12 Months
* P<.0001 PIO vs. OAD

Beneficial effects of a high-fat diet on plasma HDL concentration and macrophage cholesteropl efflux in a murine model of metabolic syndrome

A.D. Kalopissis[1], S. Maïga[1], A. Gaaya[1], L. Fourchaud[1], N. Fournier[2], M. Chabert[1];
[1]UMRS 872, INSERM, Paris, [2]Faculté de Pharmacie, Châtenay-Malabry, France.

Background and aims: The metabolic syndrome (MS) is a cluster of abnormalities conferring increased risk of type II diabetes and cardiovascular diseases. We generated transgenic mice overexpressing human apo AII (hapo A-II), a major HDL apolipoprotein, which present three MS traits: postprandial hypertriglyceridemia, low plasma HDL levels and glucose intolerance. In this study our first aim was to investigate whether the low plasma HDL levels originate from decreased formation by macrophages. Macrophages in the arterial wall accumulate cholesterol following uptake of oxidized LDL (a non-regulatable process), and are thus implicated in initial steps of atherosclerosis. The cholesterol load of macrophages decreases through cholesterol efflux, stimulated by ABCA1 (ATP Binding Cassette Transporter AI), and resulting in formation of nascent HDL. Our second aim was to study the effects of a moderate high-fat (HF) diet on plasma HDL concentration and on HDL formation by macrophages.
Materials and methods: Hapo A-II transgenic mice and control C57BL/6 mice were fed for 2 months either low-fat chow diet or HF diet (20% coconut oil containg 48% lauric acid). Plasma lipoproteins were analyzed after ultracentrifugation and FPLC. Mouse peritoneal macrophages (MPM) were isolated from transgenic and control mice on both diets, and primary cultures were performed. MPM were loaded with cholesterol by incubation with acetyl-LDL and [3H] cholesterol, and treated with cAMP to upregulate ABCA1 expression. Efflux of [3H] cholesterol was measured in the absence or presence of acceptors (lipid-free apo A-I or apo A-II in equimolar concentrations). Nascent HDL were detected in the media by bi-dimensional electrophoresis.
Results: Under HF feeding, plasma HDL and apo A-I levels increased 2.5 times in transgenic mice, whereas their hypertriglyceridemia persisted.
MPM from the four groups of mice (hapo AII-transgenic and control mice, under chow or HF diet) displayed similar cholesterol efflux capacities, both in the absence of acceptors (passive efflux) and in the presence of apo A-I or apo A-II (ABCA1-mediated efflux). Of note, apo A-I and apo A-II promoted cholesterol efflux to similar extents. Nascent HDL were formed with apo A-I and apo A-II. MPM from chow and fat-fed transgenic and control mice displayed comparable capacities to synthesize nascent HDL.
Conclusion: The low plasma HDL of our murine model for MS is not due to impaired HDL synthesis by macrophages. Interestingly, the lauric acid-rich moderate HF diet improved the MS phenotype of transgenic mice by markedly increasing HDL, a protective factor against atherosclerosis. Moreover, this diet allowed an efficient cholesterol efflux from MPM, as well as an adequate HDL synthesis.

The effect of hypoxia and hyperglycaemia on migration of microvascular endothelial cells

P.C. Gadad, D. Moir, R.M. Knott;
The Robert Gordon University, Aberdeen, United Kingdom.

Background and aims: Type 1 and 2 diabetes mellitus lead to micro and macrovascular angiopathies which lead to morbidity and mortality. Furthermore, delayed wound healing is one of the leading concerns of the microvascular complications of diabetes. Hyperglycaemia and hypoxia characterise a wound environment of a person with diabetes. The aim of this work was to determine the combined effect of hypoxia and hyperglycaemia on endothelial cell migration.
Materials and methods: The radial migration assay was employed to assess the effect of hypoxia and hyperglycaemia on human endothelial cell migration. This assay was carried out using human microvascular endothelial cells of adult dermis (HMVECad). The migration was studied under normal oxygen (20%) tension (normoxia) and below normal oxygen (5%) tension (hypoxia), in either 5mmol/l or 20mmol/l D-glucose and in the presence of an anti-proliferative agent hydroxyurea (5mmol/l). HMVECad were seeded into circular rings of 4mm diameter in 6 well plates and after 5 hours of incubation, rings were removed and wells were incubated in the test conditions outlined above. Migration distance was measured by recording the radii of a defined area of cells at 0 h, 24 h and 48 h following incubation.
Results: The results were obtained by measuring 20 radii from each of 3 monolayers (n=60) within each test group and are presented in the table. The results are presented as net migration, which was defined as the difference between the measurements of 24 h or 48 h with those of 0 h. This experiment was repeated on two further separate occasions and found to be reproducible. The data was analysed using a paired *t* test (2-tailed).Migration of HMVECad was found to be significantly ($p<0.001$) higher in hypoxic conditions at 24 h and 48 h compared with normoxic conditions. High glucose concentration significantly ($p<0.001$) reduced the migration of cells at 24 h and 48 h compared to the cells incubated in 5mmol/l glucose at the same time point. Combining high glucose concentration with hypoxia attenuated ($p<0.001$) the migration of cells compared to hypoxic cells in 5mmol/l glucose. In the presence of hydroxyurea, the same relative increase with hypoxia ($p<0.001$) and decrease with high glucose concentration ($p<0.001$) were evident at 24 h.
Conclusion: Hypoxia and hyperglycaemia had opposing effect on microvascular endothelial cell migration. Hypoxia combined with high glucose decreased migration of cells in comparison with hypoxia alone. Future study will involve investigation of the molecular mechanisms underpinning the changes observed in endothelial cell migration and proliferation as a result of oxygen and glucose concentration.

Net migration of HMVECad (mean ± SEM) (in μm)

Treatment	without hydroxyurea		with hydroxyurea
	24 h	48 h	24 h
20% oxygen 5mmol/l glucose	95.74 ± 1.26	140.21 ± 1.32	87.30 ± 1.79
20% oxygen 20mmol/l glucose	56.44 ± 1.32	105.67 ± 0.89	76.53 ± 0.98
5% oxygen 5mmol/l glucose	117.55 ± 1.44	173.32 ± 1.31	114.62 ± 1.26
5% oxygen 20mmol/l glucose	81.50 ± 1.24	126.22 ± 0.86	72.61 ± 1.36

Fenofibrate suppresses microvascular inflammation and apoptosis through AMP-activated protein kinase activation

S. Hattori, A. Tomizawa, K. Kasai, Y. Hattori;
Dokkyo University School of Medicine, Mibu, Japan.

FIELD (Fenofibrate Intervention & Event Lowerig in Diabetes) showed that treatment with fenofibrate in individuals with type 2 diabetes mellitus not only reduced nonfatal coronary events but also reduced the need for laser treatment for diabetic retinopathy and inhibited the progress of diabetic nephropathy. However, the mechanism of the effect of fenofibrate on the microangiopathy is not yet clear. We here investigated the mechanism of microvascular protection by fenofibrate using human glomerular microvascular endothelial cells (HGMEC). Treatment of HGMEC with fenofibrate resulted in transient activation of AMP-activated protein kinase (AMPK), as monitored by phosphorylation of AMPK and its down-stream target, acetyl-CoA carboxylase. Fenofibrate caused phosphorylation of Akt and eNOS, leading to increased production of NO, and also caused inhibition of advanced glycated end-product (AGE)-induced NF-kB activation, leading to suppression of expression of adhesion molecule genes. Significant decreases in eNOS activity and NO production in response to fenofibrate were observed in cells treated with AMPK siRNA or with compound C, a pharmacological inhibitor of AMPK. The attenuation of fenofibrate-induced inhibition of NF-kB activation was observed in cells treated with AMPK siRNA or with compound C. Furthermore, fenofibrate dose-dependently suppressed apoptosis under high glucose culture condition, detected by the ELISA method of cell death detection and morphological assessment. Treatment with compound C abolished the suppressive effect of fenofibrate on HGMEC apoptosis. Our findings suggest that the beneficial effects of fenofibarate on microvascular endothelial cells might be attributed to the induction of AMPK activation beyond its lipid-lowering actions.

Cardiac microvascular dysfunction in diabetes and insulin treatment: role of glucose-induced PKC-βII activity

H. Wang, Z. Yin, L. Wei;
Department of Cardiology, The Fourth Military Medical University, Xi'an, China.

Background and aims: Multiple lines of evidence support the viewpoint that diabetes mellitus is an independent risk factor for cardiovascular disease. Activity of the protein kinase C (PKC) family has been well documented in diabetic myocardium for its numerous biological responses. However, little attention is addressed on PKC-βIIin cardiac microvascular dysfunction, which takes a significant role in the pathophysiological cascade of diabetic cardiomyopathy.
Materials and methods: In the animal experiment, normal Sprague-Dawley rat, streptozotocin-induced diabetic rat model,insulin-treated and physiological saline-treated diabetic rat were administrated with a serial of evaluations for 4 weeks natural course including pressure measurements, angiogenesis and permeability observations under electron microscope, histopathologic analysis for cardiac microvascular endothelium cell with CD31, terminal dUTP nick end-labeling (TUNEL), and Western blotting for PKC-βII. On the part of cell research, cardiac microvascular endothelial cells (CMECs) in three different mediums (normal medium, high-glucose concentration medium, insulin-stimulated and physiological saline-stimulated high-glucose medium) were investigated with MTT, apoptosis, quantitative permeability assessment via Vitro Vascular Permeability Assay Kit, and detailed analysis for PKC-βII.
Results: 1. Accompanied with more active expression of PKC-βII and higher apoptosis rate in diabetic model, either increased microvascular permeability or pathological angiogenesis is observed, and which is attenuated in certain extent while receiving insulin treatment. 2. At the same moment, accordant results from cell research were obtained. Compared with normal group, CMECs in high-glucose medium are demonstrated with poor proliferation, more notable apoptosis, increased permeability of cell monolayer, and augmented PKC-βII expression. As far as insulin-stimulated group concerned, it poses a midst performance between normal group and high-glucose group.
Conclusion: Increased PKC-βII activity has been implicated responsible for the pathogenesis of cardiac microvascular dysfunction in diabetes and elevated glucose is sufficient to induce these effects. Moreover, PKC-βII is indicated to occupy an important position in the whole process of insulin treatment. A thorough understanding of the pathophysiology of cardiac microvascular insufficiency and the function of PKC-βII in diabetes also leads to more efficacious suggestions for therapeutic strategies.

Elucidation of the molecular mechanisms involved in endothelial dysfunction induced by hyperglycaemia via the activation of the hexosamine pathway

T.V. Fiorentino, A. Greco, F. Andreozzi, F. Arturi, G. Sesti, M.L. Hribal;
University of Catanzaro Magna Graecia, Italy.

Background and aims: Despite intense research the molecular processes by which diabetes promotes atherosclerosis are not yet fully understood . One unexplored possibility is that hyperglycemia, acting through the glucosamine (GlcNAc) pathway may induce endothelial dysfunction promoting the misfolding of proteins in the endoplasmic reticulum (ER) and consequently ER stress. The aim of this study is to test this hypothesis and to analyze the functional consequences in endothelial cells.
Materials and methods: Human umbilical vein endothelial cells (HUVECs) were cultured in ECM medium at 37°C with 5% CO_2. Time-course experiments were carried out treating HUVECs for 24, 48, 72 and 96 hrs in the presence of 7.5mM GlcNAc. The non-metabolizable sugar mannitol was used as an osmotic control. Total RNA obtained from GlcNAc treated HUVECs and control cells were used to evaluate XBP-1 splicing and expression of BiP, Calnexin, IL-6, CRP, ICAM-1, VCAM-1 by RT-PCR. Total protein lysates were employed to assess ATF6 cleavage, Bip, Calnexin, CRP, IRE-1, pJNK and JNK levels by Western blot. All experiments were carried out in triplicate or quadruplicate, data are given as mean ± standard deviation (SD). Statistical differences were assessed by Student's t test as compared to control cells, a p value of 0.05 has been considered statistically significant.
Results: Initially, we demonstrated that GlcNAc induces ER stress assessing the expression levels of two key ER stress markers, the chaperones Bip and Calnexin. Bip mRNA levels increased by 43±20%($p \leq 0.01$), 20±14%($p \leq 0.05$), 36±10 ($p \leq 0.001$), 10±10%, while Bip protein levels increased by 40±30% ($p \leq 0.05$), 48±19% ($p \leq 0.05$), 67±10% ($p \leq 0.001$), 39±10% ($p \leq 0.05$) at 24, 48, 72 and 96 hrs respectively in GlcNAc treated HUVECs as compared to control cells. Calnexin transcription increased by 58±30% ($p \leq 0.05$), 132±42% ($p \leq 0.001$), 112±48% ($p \leq 0.01$), 386±100% ($p \leq 0.01$) and Calnexin protein levels by 50±20% ($p \leq 0.05$), 35±15% ($p \leq 0.05$), 50±30 ($p \leq 0.02$), 25±25% respectively after 24, 48, 72 and 96 hrs. Then to evaluate the impact of GlcNAc induced ER stress we investigated if the induction of ER stress was paralleled by an increase in the synthesis and release of proinflammatory cytokines and adhesion molecules. We observed that C reactive protein expression increased by 58±7% and 46±7% ($p \leq 0.05$) at mRNA and protein levels respectively in HUVECs treated with GlcNAc for 24hrs, IL-6 mRNA levels increased by 38±3%, while ICAM1 and VCAM-1 mRNA levels were increased by 36%±20 ($p \leq 0.09$) and 54%±10 ($p \leq 0.05$), respectively. We then proceeded to a detailed characterization of the activation of the different known ER stress pathways in GlcNAc treated HUVECs; we did not observe an increased cleavage and activation of the transcription factor ATF-6 or an increased alternative splicing of the transcription factor XBP-1, by contrast we detected a significant increase of IRE-1 levels ($p \leq 0.05$) as well as a significant increase in JNK phosphorylation ($p \leq 0.05$), suggesting that this may be the major pathway mediating ER stress induction in response to GlcNAc.

Conclusion: Accumulation of intracellular GlcNAc in endothelial cells, observed in diabetes, induces ER stress and promotes an inflammatory state. The increased cytokines expression can in turn exacerbate GlcNAc induced endothelial dysfunction, by independently promoting ER stress activation on one side and compromising insulin signalling on the other.

Acute administration of high polyphenol content chocolate improves endothelial function in type 2 diabetes even in the presence of hyperglycaemia
D. Mellor[1], L. Allegaert[2], A. Wakil[1], E. Kilpatrick[3], S. Atkin[4];
[1]Diabetes and Endocrinology, University of Hull, Hull, United Kingdom, [2]Innovations, Barry Callebaut, Lebbeke, Belgium, [3]Chemical Pathology, Hull and East Yorkshire Hospitals NHS Trust, Hull, United Kingdom, [4]Diabetes and Endocrinology, HYMS, Hull, United Kingdom.

Background and aims: Endothelial dysfunction has been shown to be a reliable marker of cardiovascular disease. Individuals with type 2 diabetes are known to have a higher risk of cardiovascular disease. It has been proposed that bioactive compounds in foods such as chocolate can increase nitric oxide levels; this has been associated with improved vascular health and improved ability of the endothelial tissue to manage mechanical and metabolic stressors.
Materials and methods: Ten subjects with well controlled type 2 diabetes (HbA1c 6.6±0.7%), treated with lifestyle or metformin were enrolled. Subjects following screening attended for 3 oral glucose tolerance tests (OGTT) which were 1 week apart. The study visits schedule started with subject acclimatisation to the room prior to a baseline assessment of endothelial function, measured by EndoPAT 2000 (Intamar, Israel) to give the Reactive Hyperaemia Index (RHI), then were given water alone or water plus either high polyphenol dark content chocolate (Acticoa, Barry Callebaut, Belgium) or a low polyphenol dark chocolate . The measurement was repeated at 60 minutes, immediately prior to starting the OGTT and at 180 minutes (timed at the end of the OGTT)
Results: Table 1: The RHI for each of the tests at baseline and at 60minutes

	0 minutes		60 minutes		
	Mean	SD	Mean	SD	p value Vs 0 minutes
Water	1.70	0.36	2.05	0.54	0.02
High Polyphenol Chocolate	1.68	0.47	2.32	0.81	0.01
Low Polyphenol Chocolate	1.87	0.53	1.98	0.53	0.6

When data is standardised at baseline, high polyphenol dark content chocolate showed a significant improvement in RHI compared to both low polyphenol dark content chocolate at 60 minutes (p= 0.048) and post OGTT (p =0.04) and water at 60 minutes (p= 0.028) and post OGTT (p= 0.045). In all groups the glucose challenge did not worsen the endothelial function.
Conclusion: High polyphenol dark content chocolate appears to improve endothelial function, which is sustained following a glucose challenge. High polyphenol dark content chocolate may contain bioactive compounds that increase RHI, which may be modulated through enhanced release of nitric oxide.

The effect of glucose and glucose metabolites on calcium-induced mitochondrial permeability transition (MPT)
J. Skrha jr., J. Gall, R. Buchal, E. Sedlackova, J. Platenik;
Institute of Medical Biochemistry, First Medical Faculty, Charles University, Prague, Czech Republic.

Background and aims: Mitochondrial production of reactive oxygen species (ROS) due to upregulated glucose oxidation is supposed to play a crucial, unifying role in pathogenesis of long-term diabetic complications. We investigated the effect of glucose metabolites on the mitochondrial permeability transition pore (MPT) and mitochondrial ROS production.
Materials and methods: Mitochondria were isolated from rat liver. The inner membrane potential was measured by fluorescent probe JC-1, and mitochondrial swelling (MPT) was detected as light scatter. Mitochondria were energized by succinate with rotenone (complex I inhibitor). The effects of glucose, glucose 6-phosphate, glucose+ATP+Mg, fructose 6-phosphate and glucose 1-phosphate (all at 5 mmol/l and 30 mmol/l), glyceraldehyde and methylglyoxal (1 mmol/l and 6 mmol/l) on calcium-induced MPT were investigated. Mitochondrial release of hydrogen peroxide with Amplex Red was also measured in selected conditions.
Results: From all the compounds tested only 30 mmol/l glucose, 30 mmol/l glucose 1-phosphate and 6 mmol/l methylglyoxal significantly ($p<0.05$) slowed down the calcium-induced mitochondrial swelling, methylglyoxal appeared to be the strongest MPT inhibitor. On the other hand, 30 mmol/l fructose 6-phosphate significantly ($p<0.01$) accelerated the swelling. Glucose 6-phosphate or glucose+ATP+Mg did not influence the MPT, which suggests absence of glucokinase (known to affect the pore) in our isolated mitochondria. Hydrogen peroxide production by our mitochondria respiring on succinate + rotenone was found potential independent and approximately doubled during calcium-induced MPT. Cyclosporine A not only completely prevented the MPT, but also slowed down ROS production in response to Ca. In contrast, methylglyoxal simultaneously inhibited MPT and increased ROS production in response to Ca.
Conclusion: We confirm that methylglyoxal is a potent MPT inhibitor. In addition, we describe for the first time that high glucose, fructose 6-phosphate and glucose 1-phosphate concentrations affect the MPT, too. ROS production generally raised during MPT, however, inhibition of MPT by methylglyoxal was associated with increased ROS production. This mechanism can be important in development of long-term diabetic complications.

High dose metformin therapy reduces glycation and oxidative damage to apolipoprotein B100 and may decelerate atherosclerosis in patients with type 2 diabetes
N. Rabbani, M. Varma Chittari, D. Zehnder, A. Ceriello, P.J. Thornalley;
Clinical Sciences Research Institute, University of Warwcik, Coventry, United Kingdom.

Background and aims: Formation of advanced glycation endproducts (AGEs) and oxidative damage of apolipoprotein B100 - the major protein of low density lipoprotein (LDL) - have been implicated in increased atherogenic risk of LDL in type 2 diabetes. Metformin therapy is associated with a cardiovascular protective effects and increased patient survival in
UKPDS study. As a result, metformin is the first choice of therapy in obese and diabetic patients. Metformin is already shown to reduce the concentration of dicarbonyl methylglyoxal in diabetic patients. The aim of this study, therefore, was to analyse and quantify the glycation and oxidative damage to LDL particles by methylglyoxal in diabetic patients with and without high dose metformin therapy and healthy controls.
Materials and methods: Healthy subjects as controls (HC)(n = 17), subjects with type 2 diabetes on high dose metformin (metformin dose more than 1.5 gms/d) (MD)(n = 8)
and type 2 diabetic subjects not on high dose metformin (DN) (n = 25) were recruited for this study. LDL was isolated from venous plasma, stabilised with aprotinin and collected in the fasted state, by density gradient ultracentrifugation using Iodixanol. Purified LDL was washed with argon-purged water by ultrafiltration over a 100 kDa microspin filter. The content of AGEs and oxida-

tion adduct residues in apolipoprotein B100 was analysed after de-lipidation and exhaustive enzymatic hydrolysis by stable isotope dilution analysis liquid chromatography/mass spectrometry (LC-MS/MS). The following markers of protein damage were quantified: AGEs - Nε-carboxymethyl-lysine (CML), Nε-carboxyethyl-lysine (CEL), glyoxal-derived hydroimidazolone (G-H1), methylglyoxalderived hydroimidazolone (MG-H1), 3-deoxyglucosone-derived hydroimidazolone (3DG-H) and pentosidine; oxidation markers - dityrosine and N-formylkynurenine (NFK).
Results: The AGE products, MG-H1 and 3DG-H of apolipoprotein B100 and CEL were increased in type 2 diabetes (MD and DN) compared to control subjects (HC); MG-H1(pmol/mg protein): HC (Mean ± SD) 71.6 ± 54.7, DN(Mean ± SD): 229.6 ± 48.7, MD (Mean ± SD) 55.5 ± 33.5 . (P<0.001); 3DG-H (pmol/mg protein): HC (Mean ± SD) 36.7 ± 42.6, DN(Mean ± SD): 82.8 ± 33, MD (Mean ± SD) 18.1 ± 13.5. (P<0.001); CEL(pmol/mg protein): HC (Mean ± SD) 13.9 ± 11.6, DN(Mean ± SD): 23.9 ± 15.8, MD (Mean ± SD) 4.42 ± 4.44. (P<0.01). The above results show that subjects on high dose metformin therapy have lower levels of AGE products. Protein oxidation marker: Dityrosine (pmol/mg protein): HC (Mean ± SD) 3.9 ± 7.4, DN(Mean ± SD): 19.0 ± 10.0, MD (Mean ± SD) 0.9 ± 0.6 (P<0.05). Similarly, subjects on high dose metformin therapy have lower levels of protein oxidation markers.
Conclusion: This study indicates that whilst apolipoprotein B100 of LDL suffers oxidation and glycation in type 2 diabetes, the damage seems to be significantly reduced by using high dose metformin. This could be one of the reasons by which high dose metformin therapy leads to cardiac protection.
We thank BHF for IMRF grant

Contribution of endoplasmic reticulum stress in oxidized LDL-induced beta cell dysfunction
S. Brajkovic[1,2], D. Favre[1,2], G. Niederhäuser[1,2], G. Waeber[2], A. Abderrahmani[1,2];
[1]Department of Cell Biology and Morphology, Lausanne, [2]Service of Internal Medicine, Centre Hospitalier Universitaire Vaudois - University of Lausanne, Switzerland.

Background and aims: Induction of endoplasmic reticulum stress can be detrimental and diabetogenic as it mediates beta-cell dysfunction caused by chronic hyperglycaemia and fatty acids. Evidence for a role of oxidized LDL-cholesterol particles (oxLDL) in progression and development of diabetes is growing. First, relative increase in levels of oxLDL over native LDL, often accompanied by low plasma concentration of HDL, is measured in plasma of diabetic patients. This abnormality contributes to increase the risk of patients to develop cardiovascular disease. Second, several independent studies have shown the harmful effects of human modified lipoproteins on expression and secretion of insulin as well as cell survival. At the present time, the mechanisms whereby oxLDL exert their effect are still elusive. In this study, we investigated potential role of ER stress in beta-cell failure elicited by oxLDL.
Materials and methods: Native LDL fractions were freshly prepared from plasma of human healthy donors by sequential ultracentrifugation. In vitro oxidization of LDL by copper was adjusted to obtain oxidized LDL qualitatively similar to those observed in patients. The lipoprotein preparations were dialyzed against phosphate-buffered saline and culture medium to remove copper and salts. The mouse MIN6 insulin-secreting cell line was treated with native or modified LDL and 2.5 mM of the chemical chaperone 4-phenyl butyric acid (4-PBA) was co-added to the medium to assess the role of ER stress on oxLDL-induced dysfunction. Expression of genes involved in ER stress was monitored by quantitative PCR.
Results: OxLDL triggered a rise in the expression of ER stress markers C/EBP homologous protein (CHOP) and activating transcription factor 4 (ATF4), whereas the genes expression was unchanged in response to native LDL. However, no increase in the splicing of the unfolded protein response gene XBP-1 was observed. 4-PBA co-treatment prevented oxLDL-induced ATF4 and CHOP expression. OxLDL impair insulin synthesis, secretion and cell survival. Inhibition of the ER stress with the use of 4-PBA prevented oxLDL-induced diminution of insulin expression and cell apoptosis, whereas insulin secretion was still reduced.
Conclusion: These data highlight the contribution of ER stress in the defects of the insulin synthesis and β-cell survival induced by oxLDL.

Association between FINDRISC and systemic markers of oxidative stress
S. Kopprasch[1], P.E.H. Schwarz[1], G. Siegert[2], S.R. Bornstein[1], J. Graessler[1];
[1]Department of Internal Medicine 3, [2]Institute of Clinical Chemistry and Laboratory Medicine, University of Technology Dresden, Germany.

Background and aims: Type 2 diabetes pathophysiology is causally related to increased systemic oxidative stress. The validated Finnish diabetes risk score (FINDRISC) has been successfully implemented as practical screening tool to assess the diabetes risk and to detect undiagnosed type 2 diabetes (T2D). We investigated the association between FINDRSIC and different systemic oxidative stress markers in subjects with different stages of glucose tolerance and diabetes mellitus.
Materials and methods: The cross-sectional survey included 588 participants aged 19-85 years. Individuals were examined with an oral glucose tolerance test. At baseline, FINDRISC was gathered and six different oxidative stress markers were assessed (lagtime of serum diene formation, total antioxidant capacity, oxLDL, antioxLDL antibodies, thiobarbituric acid reactive substances and paraoxonase activity)
Results: Among investigated subjects, 73% had NGT, 4% IFG, 17 % IGT, and 5% newly diagnosed T2D. The FINDRISC score varied between individuals with NGT (10.0), IGT (12.9, p<0.001) and T2D patients (15.8, p<0.001). Total antioxidant capacity was positively associated with FINDRISC score (p<0.01) as well as lagtime of serum diene formation (p<0.05). FINDRISC correlated negatively with antioxLDL antibodies (p<0.001), thiobarbituric acid reactive substances (p=0.001), and paraoxonase activity (p=0.001)
Conclusion: The significant associations between FINDRISC and oxidative stress markers underline the potential causal relationship between systemic oxidative burden and development of T2D.

Inflammation, oxidative stress and endothelial function in subjects with normal, impaired and diabetic glucose tolerance
E. Storti[1], L. Pucci[1], D. Lucchesi[1], R. Vanacore[2], M. Iorio[2], R. Bruno[3], E. Russo[1], C. Bianchi[1], A.G. Daniele[1], S. Taddei[3], G. Penno[1], L. Ghiadoni[3], S. Del Prato[1], R. Miccoli[1];
[1]Endocrinology and Metabolism, [2]Blood Bank, [3]Dept. of Internal Medicine, University of Pisa, Italy.

Background and aims: Endothelial Dysfunction (ED) and Endothelial Progenitor Cells (EPC) reduction are key factors in atherogenesis.
Materials and methods: In subjects with normal (NGT, n.26), impaired (IFG/IGT, n.34) and diabetic glucose tolerance (T2D, n.18), we studied the relation of ED (flow-mediated, FMD; nitrate-induced dilatation, NID) and EPC (CD34+/KDR+ cells) with levels of biomarkers of inflammation (fibrinogen; C-reactive protein, hsCRP; serum amyloid A, SAA), proinflammatory cytokines (interleukin-6, IL-6; tumor necrosis factor-α, TNFα; monocyte chemoattractant protein-1, MCP-1), adhesion molecules (intercellular adhesion molecule-1, sICAM-1; vascular cell adhesion molecule-1, sVCAM-1), together with markers of oxidative stress (γ-glutamyltransferase, γGT; malonildialdehyde, MDA; lipid hydroperoxide, LOOH; ferric-redicing ability of plasma, FRAP) and the antioxidative activity of paraoxonase-1 (PON-1).
Results: The groups did not differ for gender, BMI, waist, dBP, total and LDL cholesterol, apoA1 and apoB, creatinine, cistatin C, and fasting insulin. IFG/IGT and T2D were older than NGT (55±5 and 58±8 vs 45±10 years, p<0.001), had higher sBP (p=0.001), fasting-, 2h-OGTT- and AUC-glucose (p<0.0001), and HbA1c (6.0±0.4 and 6.5±0.6 vs 5.5±0.4%, p<0.0001), marginally higher triglycerides (p=0.08), and lower HDL (p=0.07). NID was comparable in the three groups. FMD (and FMD/NID ratio) was lower in T2D (Δ% 4.4±3.3, m±sd), and in IFG/IGT (Δ% 6.0±2.8%) than in NGT (Δ% 7.9±3.6%, Kruskal-Wallis, p=0.0017). EPC pool was higher in NGT (533±69 cells/ml, m±se), than in IFG/IGT (440±53) and even lower in T2D (254±51 cells/ml, Kruskal-Wallis, p=0.014). The three groups did not differ for fibrinogen and SAA, but differ for hsCRP (1.68±2.22, 3.34±2.39 and 3.62±2.10 mg/L, p=0.009); not for TNF-α, but did for IL-6 (8.7±6.1, 13.8±12.5 and 15.1±15.9 pg/ml, p=0.05) and MCP-1 (201±56, 236±57 and 236±59 pg/ml, p<0.05); not for sVCAM-1, but did for sICAM-1 (244±122, 338±147 and 424±118 mg/ml, p<0.001); not for γGT, LOOH and FRAP, but did for MDA (2.33±0.57, 2.66±1.04 and 3.27±0.84 μmol/L, p=0.003) and PON-1 activity (93±46, 77±55 and 56±39 U/L, p=0.04). FMD inversely correlated with sICAM-1 (r=-0.24, p=0.04), MDA (r=-0.30, p=0.01), and FRAP (r=-0.25, p=0.03). EPC inversely correlated with

sICAM-1 (r=-0.30, p=0.008), IL-6 (r=-0.26, p=0.02), and directly with PON-1 activity (r=0.30, p=0.008). A significant association was observed between FMD and EPC levels both stratified by median value (χ2=8.67, p=0.003). Stratification by median values of FMD and EPC allows to identifying four different phenotypes among which that with both FMD and EPC below the median had the "worst" (n. 26), and that with both FMD and EPC above the median, the "best" pro-inflammatory and pro-oxidative profile; n. 26).
Conclusion: In subjects with different degree of glucose tolerance, endothelium dependent vasodilatation and EPC reduction are closely related. Pro-inflammatory, oxidative and anti-oxidative activities are already modified in the early stages of altered glucose tolerance. Mechanisms involved in different aspects of endothelial dysfunction are multifactorial at the prediabetic and diabetic states.

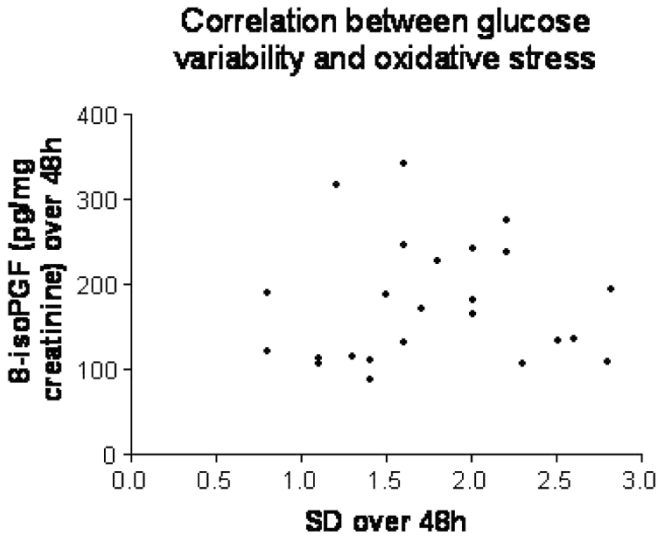
No relationship between glucose variability and oxidative stress in type 2 diabetes

S.E. Siegelaar[1], T. Barwari[1], W. Kulik[2], J.B.L. Hoekstra[1], J.H. DeVries[1];
[1]Internal Medicine, [2]Laboratory Genetic Metabolic Diseases, Academic Medical Center, Amsterdam, Netherlands.

Background and aims: A strong relationship between glycaemic variability and oxidative stress has been reported. However, this relationship could not be confirmed in type 1 diabetes. The purpose of the present study is to examine whether this discrepancy relates to the difference between type 1 and type 2 diabetes or to different methods used for the quantification of oxidative stress.
Materials and methods: 24 patients with type 2 diabetes on oral antidiabetic treatment were included. The study consisted of 72 hours of continuous glucose monitoring (CGMS® system gold; Medtronic MiniMed) while patients simultaneously collected two consecutive 24 hours urine samples for determination of 15(*S*)-8-*iso*-prostaglandin $F_{2\alpha}$ ($PGF_{2\alpha}$) using HPLC tandem mass spectrometry. Standard deviation (SD) and mean amplitude of glycaemic excursions (MAGE) were calculated as markers of glycaemic variability over the 48 hours of continuous glucose monitoring. Correlation between markers of glycaemic variability and 15(*S*)-8-*iso*-$PGF_{2\alpha}$ excretion was calculated using Spearman's correlation. Also multivariate analysis adjusted for sex, age, HbA1c and exercise was performed. Exercise was graded into sedentary, moderately active, active and fit according to the patients' history.
Results: The patient group studied consisted of 66.7% males with a mean (range) age of 59 (36-76) years and a mean (SD) HbA1c of 6.9 (0.7) %. Median [interquartile range (IQR)] urinary 15(*S*)-8-*iso*-$PGF_{2\alpha}$ excretion was 168 (114-236) pg/mg creatinine. Median (IQR) SD was 1.65 (1.33-2.20) mmol/l and MAGE 4.68 (3.07-5.88) mmol/l. Univariate regression analysis did not show a significant correlation for SD (r^2=0.001) or MAGE (r^2=0.015) with 15(*S*)-8-*iso*-$PGF_{2\alpha}$ excretion. Multivariate regression analysis adjusted for age, sex, Hba1c and exercise did not alter this observation. Spearman correlation coefficients (ρ) between 15-(*S*)-8-*iso*-$PGF_{2\alpha}$ excretion and SD and MAGE were 0.14 (p=0.53) and 0.21 (p=0.34) respectively. A significant relationship was found between 15(*S*)-8-*iso*-$PGF_{2\alpha}$ excretion and degree of exercise (r= -0.56, p=0.009) and age (r= -0.50, p=0.012).
Conclusion: In this study we did not find a relationship between glucose variability and 15(*S*)-8-*iso*-$PGF_{2\alpha}$ excretion in type 2 diabetes. The discrepancy between these and earlier data might be attributed to the superior quantification of 15(*S*)-8-*iso*-$PGF_{2\alpha}$ by HPLC MS/MS versus enzyme immunoassay that is much more open to interfering substances or to a difference in the population studied, e.g. the much better glycaemic control in our patients than in the Monnier population (mean HbA1c 6.9% and 9.6% respectively). Finally we report a negative correlation between oxidative stress formation and age and degree of exercise.



1298

Is 1,5 AnhydroGlucitol associated with malondialdehyde a marker for oxidative stress?

J. Kuenen[1], R. Borg[2], P.G. Scheffer[3], T. Teerlink[3], H. Zheng[4], D. Schoenfeld[4], E. Button[5], D.M. Nathan[4], M. Diamant[1], R.J. Heine[1];
[1]Diabetes Center, VU University Medical Center, Amsterdam, Netherlands, [2]Steno Diabetes Center, Copenhagen, Denmark, [3]Metabolic Laboratory, department of Clinical Chemistry, VU University Medical Center, Amsterdam, Netherlands, [4]Diabetes Center, Massachusetts General Hospital, Boston, United States, [5]Glycomark, Winsom Salem, United States.

Background and aims: Hyperglycaemia, and glucose excursions especially, trigger oxidative stress. Since 1,5 AnhydroGlucitol (1,5AG) levels inversely correlate with glucose fluctuations, 1,5AG is potentially also a marker of hyperglycaemia-induced oxidative stress. The objective of this study was to investigate the interrelationship of 1,5AG, the oxidative stress marker malondialdehyde (MDA) and measures of glucose variability (GV), at various levels of glycaemia in diabetes patients.
Materials and methods: Data from 83 subjects (45 T1DM and 38 T2DM) from the A1c Derived Average Glucose (ADAG) study population were included. Glucose levels were monitored with continuous glucose monitoring (CGM- four 48-h periods during 3 months) and self-monitored blood glucose (SMBG). From CGM, we calculated mean blood glucose (MBG) and Standard Deviation (SD), Magnitude of the Amplitude of the Glycemic Excursions (MAGE) and area-under-the-curve > 180mg/dl (AUC>180) as measures of GV. Post-prandial glucose (PPG) levels were obtained from SMBG results. HbA1c, 1,5AG and MDA in plasma were measured twice at an interval of 8 weeks. Pearson correlations were calculated for 1,5AG, MDA and measures of glycaemia, at different levels of HbA1c.
Results: Significant correlations were found between 1,5AG and MDA, and between these variables and the various measures of GV, HbA1c and MBG. (Table) For MDA, the strongest correlation was found with PPG and AUC>180. After adjustment for HbA1c the association between 1,5AG and MDA was lost, leaving only a significant correlation between MDA and PPG and AUC>180. Also at HbA1c < 8 % (n = 55) a significant correlation of -0.268 (p = 0.048) between MDA and 1,5AG was lost when adjusted for HbA1c. At HbA1c > 8% (n = 17) no significant correlations were found, when adjusted for HbA1c.
Conclusion: The oxidative stress marker MDA is associated with 1,5AG and variables of GV, in particular postprandial hyperglycemia and glucose levels > 180 mg/dl. However this association becomes considerably weaker when adjusted for HbA1c. As 1,5AG levels reflect glucose excursion during the previous 2 to 3 weeks, the use of this measure of glycaemia obtained during the previous 3-month period may be regarded as a limitation of this analysis. The relationship between 1,5AG and other oxidative stress markers needs to be determined.

Table: Correlation coefficients of 1,5AG and MDA with measures of glucose control and variability over a 3-month period, for patients with T1DM and T2DM, before and after adjustment for HbA1c and for different HbA1c subgroups.

	Total population				HbA1c < 8%

Whole-genome transcriptomic profile in lympho-monocytes of healthy volunteers reveals over-expression of oxidative phosphorylation and cell cycle genes in presence of increased IMT

D. Ardigò, E. Derlindati, L. Franzini, A. Dei Cas, V. Spigoni, I. Zavaroni; Internal Medicine, University of Parma, Italy.

Background and aims: Preliminary studies have been investigating gene expression profile (GEP) of circulating peripheral mononuclear cells (PBMCs) in presence of several cardiovascular (CV) risk factors in search of transcriptomic signatures of CV risk. However, no study investigated whether PBMC's GEP correlates with markers of vascular damage, such as intima-media thickness (IMT).
Materials and methods: To address this aim, IMT and GEP were evaluated in 164 apparently healthy young-adults [91M/73F, age 37±8 y], volunteering for CV risk assessment. IMT was measured by ultrasound examination with an automated edge-detection system (Carotid Analyzer, MIA-LLC, US), and transcriptomic profile investigated using whole-genome dual-color oligo-RNA-microarrays (Agilent Technologies, CA, USA). Enrolled subjects were free of diabetes, chronic inflammatory and CV diseases and not taking pharmacological medications.
Results: Subjects were stratified by IMT quartiles and clinical characteristics compared by ANOVA. Higher IMT values were significantly correlated with several established CV risk factors, including older age ($p<0.001$), male gender (0.004), greater BMI (0.011) and waist (0.006), higher fasting plasma glucose (0.008) and LDL-cholesterol concentrations (0.013). In addition to these findings, IMT values were significantly correlated with a PBMC transcriptomic profile characterized by increased expression of groups of genes involved in cell cycle and mitosis (GO terms: "Cell division" p=1.1E-9; "Cell cycle phase" p=6.7E-9; "Cell cycle process" p=1.5E-8;"Mitosis" p=3.3E-7; etc.) and mithocondrial oxidative phosphorylation ("electron transport" p=5.5E-6; "mitochondrial electron transport" p=5.4E-5). The "oxidative phosphorylation" pathway was significantly up-regulated in high IMT (p=1.8E-8), followed by the cell cycle pathway (p=3.6E-5). Since age was independently correlated with IMT by multivariate linear regression analysis, we repeated transcriptomic analysis after adjusting IMT by age. After age-adjustment, IMT values resulted significantly correlated with the same gene groups and pathways with a higher level of significance. An increase in transcription of oxidative phosphorylation genes resulted the bio-signal most strongly correlated with age-adjusted IMT values (p=6.4E-12).
Conclusion: In conclusion, the presence of vascular damage (as assessed by increased IMT) is associated with a significantly different transcriptomic profile in PBMCs of healthy volunteers. The over-expression of several genes related to the mitochondrial oxidative and cell cycling processes appears to be the main bio-signature of high IMT. An activated phenotype is therefore already visible in inflammatory cells of apparently healthy young adults in presence of high IMT values.

A novel role for p53 in the regulation of oxidative stress in vascular cells in response to glucose fluctuation

B. Schisano, C. Radford, A. Harte, G. Tripathi, P. McTernan, A. Ceriello; CSRI, University of Warwick, Coventry, United Kingdom.

Background and aims: Epidemiological data support the concept that postprandial oscillating and continuous high glucose levels represent independent risk factors for both cardiovascular and diabetic microvascular complications. Our group has recently shown that prolonged high glucose oscillation levels increases production of markers of oxidative stress in both *in vivo* and *in vitro*. However our previous data has also noted that key antioxidant enzymes (Zn-Cu SOD, MnSOD), were over expressed during exposure to chronic high glucose, whilst unaffected during chronic oscillating high glucose exposure even if we found, in this condition, higher level of nitrotyrosine, a marker of oxidative stress. Parallel to this hyperglycaemia induced stress shown also to activate the pro-apoptotic transcriptional factor p53, which has been reported to counteract the Nrf2-induced transcription of the ARE-containing promoters of key antioxidant genes. In order to explain the reported increased damage in response to oscillating as compared with continuous high glucose we investigated: (1) the activation of p53, (2) Nrf2 antioxidant response, (3) and their cross-talks in endothelial cells exposed to chronic continuous and chronic oscillating glucose levels, also by using cyclic pifitherin alpha, a p53 transcriptional inhibitor.
Materials and methods: Human endothelial cells (HUVECs) were exposed to high glucose media (30 mmol/l) with or without Cyclic Pifitherin alpha (100nM) for 12 hours (hr); for constant vs chronic oscillating hyperglycaemia experiments. HUVECs were grown for 3 weeks either in 5 mmol/l glucose, with 25 mmol/l mannitol for osmolarity normalisation (control), or in 30 mmol/l glucose or alternating 12 hr in normal glucose with 12 hr in high glucose (30 mmol/l). Protein expression analysis was conducted by Western blotting, gene expression analysis by Real Time PCR.
Results: HUVEC cells exposed to high glucose for 12 hr, with or without p53 inhibitor, significantly up-regulated p53 protein levels in a time dependent manner compared with control (Control: 1.0±0.0; p53 Protein, 6hr: 1.4±0.1ODU*; p53 Protein, 12hr: 2.0±0.2ODU*; *$P<0.05$). Similarly, findings were noted with TIGAR, a p53 induced gene product, protein expression, in absence of inhibitor; whilst TIGAR expression was unaffected with p53 inhibitor (p53 InHBr) compared to control. Whilst, in contrast, to TIGAR the antioxidant HOX-1 protein, had a pronounced up-regulation in the presence of the inhibitor at 12 hr (HOX-1/p53InHBr, 12hr: 1.5±0.2ODU↑*; Vs HOX-1, 12hr: 1.1±0.1ODU). mdm2 a p53 feedback inhibitor, mRNA levels, in the presence of high glucose, were significantly up-regulated at 9 and 12hr compared with controls (control Vs mdm2 mRNA 9hr: 2*fold increase; control Vs mdm2 mRNA, 12 hr: 3*fold increase;). Finally, TIGAR was significantly up-regulated after 3 weeks of oscillating glucose compared with constantly high glucose or control (TIGAR OSC 2.5±0.3* OD units vs TIGAR HG 1.4 ±0.2* OD units).
Conclusion: In summary, high glucose induces a p53 mediated intracellular response that limits the induction of Nrf2 antioxidant genes such as HOX-1. The delay of p53 feedback inhibiton may have a crucial role in determining the pattern of p53 regulation. As such this delay may account for p53 overactivation in oscillating glucose that may compromise Nrf2 antioxidant activity and therefore may lead to a more detrimental condition compared with constant high glucose.

Impact of glyoxalase 1 knock down on the heat shock protein expression

T. Gawlowski, B. Engelbrecht, Y. Mattern, D. Tschoepe, B. Stratmann; Diabetes Center, Heart and Diabetes Center NRW, Ruhr-University Bochum, Bad Oeynhausen, Germany.

Background and aims: Hyperglycaemia plays an important role in the pathogenesis of diabetic complications including accumulation of methylglyoxal, a highly reactive α-dicarbonyl metabolite of glucose degradation pathways and increased generation of advanced glycation endproducts (AGEs). Both AGEs and methylglyoxal contribute to the development of different pathological processes such as kidney dysfunction, retinopathy or cardiovascular disease. Methylglyoxal reacts in a non-enzymatic reaction with arginine residues of proteins to form the AGEs argpyrimidine and hydroimidazolone. In different cell lines but also in human myocardial tissue heat shock protein 27 (HSP27) was found to be the major argpyrimidine-containing protein. Furthermore, methylglyoxal is involved in regulation of different genes by modification of distinct transcription factors like mSin3A and Yap1.
Materials and methods: The rat cardiomyoblast cell line H9c2 was transfected with glyoxalase 1 (GLO1)-specific siRNA. The impact of the GLO1 knock down on the expression of HSP27 and HSP70 was analysed by immunoblotting and quantitative real-time PCR. Moreover, we investigated the effects of the knock down on the actin cytoskeleton by fluorescence microscopy and on apoptosis and oxidative stress by flow cytometry.
Results: To exclude an unspecific reaction of the siRNA we used scrambled siRNA as control and two GLO1 siRNAs, which were completely different in sequence. The GLO1 knock down using both specific siRNAs resulted in decreased expression of HSP27 on protein and mRNA level. There was no effect on the HSP70 expression. Furthermore, downregulation of GLO1 resulted in disruption of the actin cytoskeleton and increased apoptosis. It could be excluded that these observations are induced by oxidative stress, because the control siRNA also induced oxidative stress without any effects on cytoskeleton, apoptosis, and HSP27 expression.
Conclusion: It is already known that increased levels of methylglyoxal result in formation of reactive oxygen species. Results of the present study demonstrate that besides the oxidative stress, methylglyoxal induces a downregula-

tion of the anti-apoptotic and anti-oxidative protein HSP27. Further experiments are needed to explain the mechanism by which methylglyoxal affects the HSP27 expression.

Cardiovascular mortality in subjects with type 2 diabetes and in nondiabetic subjects with a first episode of myocardial infarction in southern Europe

J.A. Flores[1], J.F. Cano[1,2], J.M. Baena[3], J. Franch[4], J. Vila[2], J. Sala[5], J.J. Chillarón[1], S. Tello[2], R. Elosua[6], J. Marrugat[2];
[1]Endocrinology and Nutrition, Hospital Universitario del Mar, Barcelona, [2]Grupo de Epidemiología y Genética Cardiovascular (ULEC-EGEC), Institut Municipal de Investigació Médica, Barcelona, [3]Fundación Jordi Gol i Gurina, Primary Health Care Center La Marina, Barcelona, [4]Primary Health Care Center Raval Sud, Red GEDAPS, Barcelona, [5]Cardiologia, Hospital Josep Trueta, Girona, [6]CIBER-Epidemiología y Salud Pública, Institut Municipal de Investigació Médica, Barcelona, Spain.

Background and aims: Cardiovascular risk in type 2 diabetes (DM2) patients is still controversial. Several authors suggest that DM2 is a coronary heart disease (CHD) equivalent while others disagree. No reports on this subject have been published in southern Europe. Aims: Primary objectives: To compare mortality rates from all causes, coronary , cardiovascular and stroke, and the incidence of myocardial infarction (MI) and unstable angina between groups under study. Secondary objectives: to evaluate cardiovascular risk in diabetic subjects stratified by diabetes duration (> or < 8 years), diabetes treatment (diet, oral drugs, insulin) and baseline glycemic control (HbA1c > or <7%).
Patients and methods: A cohort study was designed with a 10-year follow-up in Catalonia, north-eastern Spain. All patients included were aged between 30 and 74. DM2 patient selection: 2260 patients were randomly recruited between 1993 and 1995 in 53 primary health care centers, serving a population of 982.567 adults. Patients with prior CHD events were excluded. Previous MI patient selection: 2150 patients were recruited between 1990 and 2003 in the population-based REGICOR study. Only non-diabetic subjects with a first episode of MI were included.
Results:

Table 1. Adjusted *Hazard ratio* (HR) at 10-year for different cardiovascular endpoints

	Type 2 Diabetes N = 2260	**Myocardial infarction N = 2154**	**HR (95% CI)**
All-cause death	289 (12.8%)	482 (22.4%)*	0.42 (0.35 - 0.50)
Coronary death	41 (1.8%)	206 (9.6%)*	0.12 (0.08 - 0.18)
Stroke death	24 (1.1%)	27 (1.3%)	0.64 (0.32 - 1.25)
Cardiovascular death	99 (4.4%)	280 (13.0%)*	0.21 (0.16 - 0.28)
Unstable angina	184 (8.1%)	145 (6.7%)	0.89 (0.68 -1.17)
Non-fatal MI	126 (5.6%)	175 (8.1%)*	0.67 (0.50 - 0.89)
Fatal or non-fatal MI	161 (7.1%)	349 (16.2%)*	0.35 (0.28 - 0.44)
Coronary Heart Disease †	296 (13.1%)	475 (22.1%)*	0.44 (0.37 - 0.53)

* $p \leq 0.001$; † Unstable angina, fatal or non-fatal MI; All models are adjusted for sex, age, and baseline dyslipidaemia, hypertension and smoking status. In the different DM2 stratified groups, risk of CV death was increased with longer diabetes duration (>8 years HR: 0,29 <8years:HR:0,19, reference: 1: MI subjects) and in insulin/oral drugs treated patients (insulin-oral drugs: HR:0,34, diet:0,13, reference: 1: MI subjects). There were no statistical differences when comparing HbA1c groups (> o < 7%).

Conclusion: Patients with DM2 showed a lower incidence of cardiovascular events than patients with prior CHD. Type 2 diabetes duration and drug therapy, but not glycemic control, proved being important prognostic factors, however, the risk of cardiovascular events remains lower than in patients with first MI.

Left-sided cardiac deterioration occurs especially in women with impaired glucose metabolism - an 8-year follow-up of The Hoorn Study

K. van den Hurk[1], M. Alssema[1], R.M.A. Henry[2], O. Kamp[3], C.D.A. Stehouwer[2], Y.M. Smulders[4], G. Nijpels[1], W.J. Paulus[5], J.M. Dekker[1];
[1]EMGO Institute for Health and Care Research, VU Medical Center, Amsterdam, [2]Department of Internal Medicine, AZM Maastricht, [3]Department of Cardiology, VU Medical Center, Amsterdam, [4]Department of Internal Medicine, VU Medical Center, Amsterdam, [5]Department of Physiology, VU Medical Center, Amsterdam, Netherlands.

Background and aims: Patients with type 2 diabetes (T2DM) have an increased risk of left-sided heart failure, but the underlying mechanisms remain controversial. Cross-sectional data of The Hoorn Study already showed signs of left-sided cardiac deterioration in T2DM, like increasing left ventricular (LV) mass and LV systolic and diastolic dysfunction. We investigated whether people with impaired glucose metabolism (IGM) or T2DM had more left-sided cardiac deterioration than people with normal glucose metabolism (NGM) over an 8-year period.
Materials and methods: In the framework of the Hoorn Study, a population-based cohort study of diabetes, 746 people, selected for glucose status, underwent a 2D echocardiogram in 2000. At follow-up in 2008, 169 individuals with NGM (62% of the baseline participants), 91 with IGM (52%), and 121 with T2DM (41%), mean baseline age 66 years had a second 2D echocardiogram. Differences in LV mass (grams), left atrial volume (ml, diastolic function) and LV ejection fraction (%, systolic function) were calculated. T-tests were performed to analyse differences compared to baseline. Linear regression analyses were performed to investigate differences in left-sided cardiac deterioration between groups of baseline glucose status, for men and women separately. Glucose status was determined by OGTT; WHO 2006 criteria were used.
Results: Left atrial volume and LV mass increased significantly in women, but not in men, with IGM (Table 1). No significant changes were found in left atrial volume and LV mass in men and women with NGM or T2DM. The LV mass increase in women with IGM remained significantly higher in IGM compared to NGM after adjustment for age, BMI, blood pressure, fasting glucose, smoking, follow-up duration, use of antihypertensive and lipid lowering medication, prior CVD, wall motion abnormalities, and baseline value of the investigated cardiac outcome, but the increase in left atrial volume lost statistical significance after adjustment for these variables. Ejection fraction decreased significantly in all groups, but no differences in change were observed between groups of glucose status.
Conclusion: Left-sided cardiac deterioration occurs especially in women with impaired glucose metabolism. The absence of more left-sided cardiac deterioration in T2DM compared to IGM and NGM, in both men and women, may be the result of selective loss to follow-up in the T2DM group, and of aggressive risk factor treatment in T2DM patients.

Association between bone mineral density and coronary atherosclerosis in patients with type 2 diabetes

S. Beer[1,2], C.H. Saely[1,3], G. Hoefle[1,4], A. Vonbank[1,3], P. Rein[1,3], J. Breuss[1], H. Drexel[1,3];
[1]VIVIT Institute, Feldkirch, Austria, [2]Private University in the Principality of Leichtenstein, Triesen, [3]Department of Internal Medicine, Academic Teaching Hospital Feldkirch, Austria, [4]Department of Internal Medicine, Hospital Hohenems, Austria.

Background and aims: The association between low bone mass and angiographically determined coronary atherosclerosis in Patients with Type 2 Diabetes is unclear.
Materials and methods: We enrolled 254 consecutive Patients with Type 2 Diabetes undergoing coronary angiography for the evaluation of established or suspected stable coronary artery disease (CAD). Type 2 Diabetes was diagnosed according to WHO guidelines. BMD was assessed by dual X-ray absorptiometry. CAD was diagnosed in the presence of any coronary artery lumen narrowing at angiography, and coronary stenoses with lumen narrowing ≥50% were considered significant.
Results: Of the total study cohort (mean age 67 ± 9 years) 36.2% (n=92) had osteopenia and 11.4% (n=29) had osteoporosis. Significant stenoses of coronary arteries were found in 65.4% (n=166). The prevalence of significant stenoses did not differ between patients with normal bone mass, osteopenia or osteoporosis (70.7%, 59.8% and 58.6%; p_{trend} = 0.173). This result did not change after multivariate adjustment for LDL cholesterol, HDL cholesterol, systolic and diastolic blood pressure, smoking, BMI, age and gender. Neither osteopenia (OR = 2.03 [95% CI 0.83-4.95], p = 0.118) nor osteoporosis (OR = 1.23 [0.50-3.00], p = 0.653) were associated with the presence of significant stenoses.
Conclusion: Low bone mass is not associated with the presence of significant coronary stenoses in patients with Type 2 Diabetes.

1305

The relationship of vascular calcification and bone mineral density with degree of albuminuria in type 2 diabetes

D.K. Singh[1], P. Winocour[2], B. Summerhayes[2], A. Viljoen[3], S. Kaniyur[4], S. Selvakumar[5], K. Farrington[1];
[1]Renal, Lister Hospital, Stevenage, [2]Diabetes and Endocrinology, QEII Hospital, Welwyn Garden City, [3]Clinical Chemistry, Lister Hospital, Stevenage, [4]Radiology, Lister Hospital, Stevenage, [5]Vascular Surgery, Lister Hospital, Stevenage, United Kingdom.

Introduction: Cardiovascular disease is the most common cause of mortality in patients with diabetes. Vascular calcification is a major cause of arterial stiffness and may contribute to the progression of vasculopathy in diabetes. Vascular calcification has been studied extensively in diabetes patients with chronic kidney disease; however there is not enough information on vascular calcification in patients with normal renal function.
Aim: To investigate the relationship of vascular calcification and bone mineral density with varying degrees of albuminuria in patients with type 2 diabetes.
Research design and methods: 65 patients with type 2 diabetes with normal creatinine levels (serum creatinine < 125 μmol/l) were studied. 25 had no

Table 1: Baseline values and mean changes (sd) in LV mass, left atrial volume and ejection fraction

		Women			Men		
		NGM	IGM	T2DM	NGM	IGM	T2DM

**Significantly more increase in IGM than NGM, in crude and adjusted analyses

albuminuria (NA), 20 had microalbuminuria (MA) and 20 had dipstick positive proteinuria (P). An x ray of the foot was carried out along with a CT scan of the femoral, posterior tibial and dorsalis pedis arteries to assess the levels of calcification along with a DEXA scan to assess the bone mineral density (BMD) of the lumbar spine, hip and left heel. In addition, routine haematology and biochemistry was carried out.
Results: The median Agatson calcification score in the left femoral artery in the NA, MA and P groups was 20, 134.5 and 260.4 respectively. The overall median score was 97.3. The proportion of patients with scores higher than the median was 32%, 55% and 65% (p = NS) in the NA, MA and P groups respectively. There was a significant correlation between calcification severity and degree of proteinuria (r = 0.251, p = 0.044). The foot x ray showed presence of calcification (based on scores of 0-4) in 36%, 30% and 45% (p=NS) in the three groups. There was a significant correlation between left femoral arterial calcification and lumbar spine BMD (r = 0.272, p = 0.034) and T score (r = 0.263, p = 0.040). The P group had longer duration of diabetes (13.4 years ±9.7: p=0.014) as compared to NA (6.6±4.9). There was no difference in calcification severity in the smoker and non-smoker groups. The groups did not differ in age, estimated creatinine clearance, serum creatinine, urea, HbA1c, Hemoglobin, serum calcium, parathyroid hormone and phosphate.
Conclusion: Vascular Calcification along with low bone mineral density is highly prevalent in Type 2 DM with normal creatinine levels. The prevalence of severe calcification increases with the degree of albuminuria.

Pre-existing macrovascular disease and glycaemic control in patients with type 2 diabetes in Europe: a matched cohort study
A.Z. Fu[1], Y. Qiu[2], L. Radican[2], D. Yin[2], P. Mavros[2];
[1]Quantitative Health Sciences, Cleveland Clinic, Cleveland, [2]Global Outcomes Research & Reimbursement, Merck & Co., Inc., Whitehouse Station, United States.

Background and aims: It is widely recognized that achieving specific glycemic goals in patients with diabetes can substantially reduce morbidity. Given that pre-existing macrovascular conditions (MVC) increase the risk of diabetes-related complications, adequate glycemic control is especially important for these high risk patients. The purpose of this study was to examine the degree of glycemic control among T2DM patients in EU.
Materials and methods: This is a matched cohort study based on a multicenter, observational study with retrospective medical chart reviews of T2DM patients in Spain, France, UK, Norway, Finland, Germany, and Poland. Included patients were aged ≥30 years at time of diagnosis of T2DM, had added a SU or a TZD to failing metformin monotherapy (index date), and had pre-existing (i.e., with onset date prior to index date) MVC. A control cohort with T2DM but without pre-existing MVC was identified using 1:1 propensity score matching. Logistic and linear regression analyses were applied to identify differences in glycemic control (HbA1c<6.5% yes/no and HbA1c level) by MVC during the follow up period, after controlling for baseline demographics, clinical information, and concurrent medication use. Robust variance estimator was used to correct for multiple observations per patient.
Results: Of the 453 patients with pre-existing MVC (cases) and eligible for inclusion, 64% were male, mean (SD) age and time from T2DM diagnosis was 64.5 (9.1) and 6.2 (5.3) years, respectively. The proportion of patients with pre-existing MVC with adequate glycemic control relative to controls during the 1st, 2nd, 3rd, and 4th years after index date was 20.7 vs. 28.2, 19.3 vs. 26.5, 18.6 vs. 26.7, and 17.7 vs. 27.8 respectively. Patients with pre-existing MVC were significantly less likely to have adequate glycemic control (Odds Ratio: 0.65; 95%CI 0.49-0.86), and had higher HbA1c levels by 0.12% (P=0.049) than controls after controlling for other potential confounding covariates. This study found that T2DM patients with pre-existing MVC tended to have poorer glycemic control than those without MVC.
Conclusion: We found that T2DM patients with pre-existing MVC tended to have poorer glycemic control than those without MVC. It may suggest that management of MVC might help reach the goal of adequate glycemic control for T2DM.

Long-term cardiovascular and non-cardiovascular mortality in women and men with type 1 and type 2 diabetes mellitus: a 30-year follow-up in Switzerland
S. Allemann[1,2], C. Saner[1], M. Zwahlen[2,3], E.R. Christ[1], P. Diem[1], C. Stettler[1,2];
[1]University of Bern, Division of Endocrinology, Diabetes and Clinical Nutrition, Inselspital, [2]Institute of Social and Preventive Medicine, Univeristy of Bern, [3]Research Support Unit at CTU Bern, University Hospital, Inselspital, Switzerland.

Background and aims: While several studies in Europe, the USA and Asia have documented an increased mortality in diabetic patients when compared with non-diabetic individuals, comparably little is known on the long-term mortality risk of diabetic patients in Switzerland. The present study assessed the 30-year mortality in a well defined cohort of type 1 and type 2 diabetic patients. A special focus was put on gender differences as well as on the time course of overall and cardiovascular mortality in diabetic patients compared with the general Swiss population.
Materials and methods: The present analysis is based on a 30-year follow-up of the 533 patients (225 with type 1, 308 with type 2 diabetes) included into the Swiss Cohort of the WHO Multinational Study of Vascular Disease in Diabetes. Standardised mortality ratios (SMRs) for the entire follow-up were calculated by dividing the observed number of deaths by the expected number of deaths based on estimates from the general population. SMRs were separately computed for all-cause and cardiovascular mortality. The time course of SMRs between 1974 and 2005 was assessed by using a poisson regression model to compute annual SMRs.
Results: The study comprised 10,349 patient-years of follow-up with a low drop-out rate (6.6%). During the entire follow-up there were 352 deaths (138 and 214 deaths in type 1 and type 2 diabetes, respectively). All-cause mortality was increased in diabetic patients compared with the general population (SMR [95% CI] 3.8 [3.5-4.3]), the standardised mortality ratio (SMR) being higher for type 1 compared with type 2 diabetic patients (4.5 [3.8-5.3] vs. 3.5 [3.1-4.0], p=0.032). For cardiovascular and non-cardiovascular deaths SMRs were 5.6 (95% CI 4.8-6.6) and 2.7 (2.3-3.1) and did not differ according to type of diabetes. SMRs for all-cause and cardiovascular mortality were significantly higher in women compared with men in type 1 ($p<0.05$ and $p<0.01$) and type 2 diabetes ($p<0.001$ and $p<0.01$). In both types of diabetes, SMRs significantly decreased during the last two decades (p=0.004 and p=0.002).
Conclusion: Patients with type 1 and type 2 diabetes had an increased long-term mortality compared with the general Swiss population. Excess mortality was higher in type 1 compared with type 2 diabetes and in women compared with men for both types of diabetes, but steadily decreased over the last two decades.

Global gene expression profiling displays a network of dysregulated genes in non-atherosclerotic arterial tissue from patients with type 2 diabetes
V. Skov[1], J.A. Funder[2], S. Knudsen[3], T.A. Kruse[1], M.L. Hansen[4], M.L. Jespersen[5], J. Aagaard[4], V.E. Hjortdal[2], L.M. Rasmussen[1];
[1]Department of Biochemistry, Farmacology, and Genetics, Odense University Hospital, [2]Department of Cardio-thoracic and Vascular Surgery, Aarhus University Hospital, [3]Medical Prognosis Institute A/S, Hørsholm, [4]Department of Cardio-thoracic and Vascular Surgery, Odense University Hospital, [5]Department of Pathology, Aarhus University Hospital, Denmark.

Background and aims: Generalized arterial alterations, such as endothelial dysfunction, medial matrix accumulations, and calcifications are associated with type 2 diabetes. These changes may render the vessel wall more susceptible to injury; however, the molecular characteristics of such diffuse pre-atherosclerotic changes in diabetes are only superficially known.
Materials and methods: To identify the molecular alterations of the generalized arterial disease in type 2 diabetes, Affymetrix high-density oligonucleotide arrays were applied to examine gene expression changes in normal-appearing, non-atherosclerotic arterial tissue (arteria mammaria interna) from 10 diabetic and 11 age-matched non-diabetic men scheduled for a coronary by-pass operation.
Results: Single gene analysis demonstrated a series of differentially regulated genes in diabetes related to endothelial and smooth muscle cell functions. In addition, global pathway analysis revealed differential expression of gene

sets representing matrix metabolism, triglyceride synthesis, inflammation, as well as hormonal and cytokine effects. Gene expression data were integrated with biological interaction networks and the results showed a significant cluster of dysregulated genes coding for both intra- and extra-cellular proteins associated with several vascular cell functions. Quantitative real-time PCR validated key findings and demonstrated differential regulation of genes associated with diabetic arteriopathy.
Conclusion: Our results identify, at the mRNA level, the diffuse arteriopathy present in non-atherosclerotic arterial tissue in patients with type 2 diabetes. These abnormalities may play a role for the arterial response to injury and putatively for the accelerated atherogenesis among patients with diabetes.

Genetic variation in cyclin dependent kinase inhibitor 2A/B is associated with the risk of coronary heart disease in type 2 diabetes in Chinese population

X. Ma[1], X. Ma[1], N. Gu[1], Y. Lin[2], X. Guo[1];
[1]Endocrinology, First Hospital, Beijing, [2]Respiratory, First Hospital, Xiamen, China.

Background and aims: Cyclin dependent kinase inhibitor 2A/B (CDKN2A/B) encode cyclin-dependent kinase inhibitors, as a cell growth regulator, playing an antiatherogenic role. This study investigated whether genetic variations in the CDKN2A/B genes mediating these effects affect the risk of coronary artery disease (CAD) in type 2 diabetes.
Materials and methods: We selected total 7 haplotype-tagged single nucleotide polymorphisms (SNPs) of CDKN2A/2B genes and genotyped 220 CAD-positive and 89 CAD-negative subjects with type 2 diabetes by the polymerase chain reaction - restriction fragment length polymorphism (PCR-RFLP) assay or directly DNA sequencing to analyze the association of all the SNPs with CAD in the given population.
Results: The major allele G of SNP rs2811708 at CDKN2A locus was protective from CAD, with the carriers of genotype GG at lower risk of CAD compared to non-carriers (OR = 0.476,*p* = 0.006,95%CI 0.281-0.808;OR* = 0.486, *p* *= 0.012, adjusted for sex, age and BMI).
Conclusion: Our findings indicated that rs2811708 at CDKN2A locus may be associated with decreased risk of CAD in type 2 diabetes in Chinese population.

Subclinical functional impairment in the community-dwelling older adults with type 2 diabetes

S. Park[1], Y. Lee[1], S. Kim[1], Y. Cho[1], K. Huh[2], J. Jeong[3], O. Ryu[3], M. Choi[3], D. Kim[3];
[1]Department of Medicine, CHA University, Sungnam, [2]Huh Diabetes Center, Seoul, [3]Hallym University, Chuncheon, Republic of Korea.

Background and aims: Type 2 diabetes is associated with a two to three fold increased risk of disability, loss of independency leading to frequent nursing home admissions in older adults. Interventions such as resistance exercise and amino acid supplementation may need to be implemented in early stages of disablement process to delay, stop or even reverse functional limitations. The aim of the study was to investigate whether community-dwelling non-disabled older adults with type 2 diabetes have subclinical functional impairments.
Materials and methods: We have examined 623 adults (men 43.3%, age; 70.6 ± 8.7 yrs) living in Chuncheon, Korea from January to May in 2007. All subjects without previous diagnosed diabetes were taken 75g-oral glucose tolerance test (OGTT). Diabetes was defined by previous diagnosis or fasting plasma glucose ≥ 7.0 mmol/l or 2-h plasma glucose ≥ 11.0 mmol/l during an OGTT. Physical function was assessed by the "Health Aging and Body Composition Study Physical Performance Battery (H-ABC PPB)" which included semi-tandem stance, tandem stance, singe leg stance, 6m usual walk, 6m narrow walk within 20cm width, and repeated chair stand tests. Each test was scored from 0 to 3 by quartiles of results and then summed as an overall physical performance score which ranged from 0 to 12 with high score represents higher function.
Results: We have identified 159 subjects (25.6%) as having type 2 diabetes including 77 (12.4%) subjects with previously undiagnosed cases. Older adults with type 2 diabetes showed lower balance score than those without diabetes (1.75 ± 0.89 vs. 2.00 ± 0.87, p=0.002) mainly due to poor performance in single leg standing test. In fact, there were no differences in the performance on the semi-tandem stance and tandem stance in regard to diabetes. Although 6m general walking speed was not slowed in older adults with diabetes (0.89 ± 0.28 vs. 0.91 ± 0.26 m/sec, p=0.290), 6m narrow walking speed was decreased in those with diabetes compared with those without diabetes (0.87 ± 0.28 vs. 0.93 ± 0.26 m/sec, p= 0.028). Performance on the repeated chair stand test was not different between older adults with and without type 2 diabetes. The overall H-ABC PPB score was decreased in older adults with type 2 diabetes (5.98 vs. 6.63, p=0.039). We have confirmed the results in gender stratified analyses as well (data not shown).
Conclusion: In community-dwelling apparently healthy nondisabled older adults, type 2 diabetes is associated with subclinical impairment in physical function. To identify those with early stage of disabling process, physical function test should include more demanding tasks such as single leg standing and narrow walking tests.

Glucose tolerance: association with high blood pressure and metabolic syndrome in Spanish population

M.T. Martínez Larrad, C. Fernández-Pérez, C. Zabena, A. Corbatón, M. Serrano-Ríos;
Diabetes and Lipids, Hospital Clínico San Carlos, Madrid, Spain.

Aim: to investigate the prevalence of high blood pressure (HBP) and its relationship to categories of glucose tolerance and the Metabolic Syndrome (MS).
Design, methods: A Cross-sectional survey: 3827 participants,.54.3% females (F), 35 - 74 yrs. Anthropometric parameters: Body mass Index (BMI), Waist Circumference (WC), Blood Pressure (BP). Laboratory parameters: glucose tolerance (75g), Lipid Profile. Additionally: plasma insulin, Insulin resistance (IR) by HOMAIR MS by IDF Criteria. HBP was classified by JNC (Joint National Committee) VII criteria: Normal Systolic Blood Pressure (SBP) <120 and Diastolic Blood Pressure (DBP) < 80 mmHg, Prehypertension SBP: 120-139 or DBP 80-89 mmHg; Stage 1 Hypertension: 140-159 or DBP 90-99 mmHg; Stage 2 hypertension ≥ 160 or DBP ≥ 100 mmHg.
Results: BP (median±SD) in the general population was systolic: 127±20 mmHg, diastolic 79±11 mmHg. Overall prevalence of HBP was 30.3%; in males: 30.2% and in females: 30.5%. Prevalence of HBP in normo glycaemic subjects: 24.4%, impaired fasting glucose (IFG): 36%, impaired glucose

tolerance (IGT) 44.4%, diabetes mellitus (DM) 50.7%. The prevalence of IR was similar in both sexes except for individuals with IFG (in men, 35.4%; in women, 43.5%; p= 0.026). Overall prevalence of obesity was in NG, IFG, IGT, IFG/IGT and DM 22.8%, 33.3%, 38.1%, 32.5% and 46.5% respectively. Obese individuals were more insulin resistant than non-obese counterparts (23.7% vs. 8.5%, p< 0.001) across all categories of glucose tolerance: IFG (56.6% vs. 30.7% (p< 0.001), IGT (37.5% vs. 19.8%, p= 0.010), and DM (72.1% vs. 60.9%, p= 0.037). In subjects with HBP the prevalence of metabolic syndrome was 54.4% and IR (HOMAIR) 34 %. The prevalence of metabolic syndrome was higher in hypertensive women than in men for all categories of glucose tolerance, adjusted by age and obesity (BMI ≥ 30 Kg/m2). In a logistical regression model metabolic syndrome was associated with HBP in all categories of glucose tolerance but the biggest impact was Stage 2 hypertension in Diabetic patients, OR: 33.35 adjusted by obesity, sex and age (p<0.001).
Conclusion: a) HBP was associated with features of metabolic syndrome in general Spanish population, the association had a higher prevalence in women in all glucose tolerance categories (BMI and age adjusted) b) worsening of glucose tolerance was associated with increased prevalence of HBP c) level of glucose tolerance, obesity, sex were significantly correlated with HBP and metabolic syndrome.

Elevated plasma homocysteine level predicts progression of atherosclerotic vascular disease in type 2 diabetic patients
M. Furuta[1], A. Yamana[1], S. Morita[1], M. Ueyama[1], H. Furuta[2], K. Nanjo[2], T. Sanke[1];
[1]Clinical Laboratory Medicine, [2]The First Department of Medicine, Wakayama Medical University, Japan.

Background and aims: Diabetes is known as the major risk factor for atherosclerotic vascular disease and it directly affects prognosis of diabetic patients. Homocysteine (Hcy) is considered to take part in the development of atherosclerosis. To examine the relationship between the severity of atherosclerotic vascular disease in type 2 diabetes and Hcy, we evaluated plasma Hcy level, and compared them with three parameters of atherosclerosis (IMT:mean intima-media thickness of common carotid artery, FMD:brachial endothelium dependent flow-mediated dilatation, BaPWV:brachial-ankle pulse wave velocity).
Materials and methods: We recruited a total of 205 type 2 diabetic patients (96 men, 109 women) were included in the study. The mean age of subjects was 63.8±10.3 years (mean±SD), BMI was 23.4±3.8 kg/m^2. Of the study population, 109 patients had hypertension (53.2%), 52 patients had atherosclerotic vascular disease (25.4%). Patients with reduced renal function (estimated GFR < 60mL/min/1.73m^2) were excluded from the study. Plasma total Hcy levels were measured by HPLC, and both IMT and FMD were assessed using B-mode ultrasonography. BaPWV was measured by a volume plethysmograph.
Results: Hcy levels were significantly elevated in patients with atherosclerotic vascular disease when compared with patients without vascular disease (10.52 vs 8.94 μmol/L, p<0.01). Hcy levels were associated with IMT (p<0.01), FMD(p<0.05), whereas not associated with BaPWV. Multiple regression analysis showed that Hcy levels were independently predicted by IMT. We also followed IMT for two years in 66 patients individually. It revealed that alteration of IMT in patients with high Hcy levels were progressively increased during two years compared with patients with normal Hcy levels (0.09 vs 0.04mm, p<0.01) respectively.
Conclusion: Our results indicate that the elevated Hcy level in Japanese patients with type 2 diabetes is characterized by vascular endothelial dysfunction and increased vascular thickness. Furthemore, IMT predicts Hcy independently on multiple regression analysis. Our results also indicate that high Hcy level could accelerate vascular thickness. These results imply that homocysteine is a reliable biomarker for atherosclerotic vascular disease of type 2 diabetic patients.

1313

Screening the asymptomatic diabetic patients for coronary artery disease. Cardiac echography and N-Terminal Pro-B-Type natriuretic peptide measurement may independently help in cardiac risk assessment
E. Cosson, I. Pham, M. Nguyen, M. Pontet, A. Nitenberg, P. Valensi;
AP-HP, Jean Verdier Hospital, Bondy, France.

Background and aims: Plasma N-terminal pro-B-type natriuretic peptide (NT-proBNP) levels are associated with cardiac function and structure, myocardial ischemia. BNP is expressed in human coronary plaques. High levels of NT-proBNP are also predictive of cardiac events (CE) and we hypothesized that resting echocardiography and plasma NT-proBNP levels could predict silent coronary artery disease (CAD) and CE in the diabetic population.
Materials and methods: Between 1998 and 2008, 517 asymptomatic patients with ≥1 additional cardiovascular risk factor but without heart failure were prospectively screened for silent myocardial ischemia (SMI), defined as an abnormal stress myocardial scintigraphy, and subsequently for significant (>70%) CAD on angiography. The 323 patients, with type 2 (n=306) or type 1 diabetes for 13±7 years, with a feasible echocardiography and for whom NT-proBNP could be measured were selected; 233 of them were followed up for CE (cardiac death, acute coronary syndrome, cardiac failure, secondary revascularization procedure).
Results: The univariate correlates of CAD as compared with no SMI or SMI without CAD were NT-proBNP (166±507 versus 47±110 pg/ml, p<0.0001),

male gender (OR 2.4 [CI 95%: 1.1-5.1]; p<0.05), retinopathy (OR 2.0 [CI 95%: 1.02-4.0]; p<0.05), peripheral occlusive arterial disease (OR 2.9 [CI 95%: 1.3-6.6]; p<0.01), left ventricular (LV) systolic dysfunction (OR 12.6 [CI 95%: 2.0-78.4]; p<0.001), dilatation (OR 3.7 [CI 95%: 1.2-11.3]; p<0.05) and hypertrophy (OR 2.8 [CI 95%: 1.3-6.0]; p<0.05), with a trend for hypokinesia (OR 2.5 [CI 95%: 0.9-7.3]; p=0.084), for lower body mass index (28.7±4.2 versus 30.6±6.2 kg/m², p=0.06) and for nephropathy (OR 1.8 [CI 95%: 0.9-3.5]; p=0.095). The following parameters were entered into a multiple logistic regression analysis including silent CAD as a dependent variable: NT-proBNP ≥38 pg/ml (third tertile), age, body mass index, gender, retinopathy, nephropathy and peripheral occlusive arterial disease, LV systolic dysfunction, dilatation and hypertrophy, and hypokinesia. NT-proBNP ≥38 pg/ml (OR 3.9 [95% CI 1.4-10.6]; p=0.008) and LV hypertrophy (OR 3.0 [95% CI 1.1-8.0]; p=0.031) were independent predictors of silent CAD. The percentage of patients with NT-proBNP ≥38 pg/ml was significantly higher in the patients with CAD than in the ones without CAD irrespective of the presence of LV hypertrophy and type 1 transmitral flow. Nine cardiac events occurred within a follow-up duration of 3.0±1.6 years. CAD (Kaplan-Meier, adjusted Log rank 77.9, p<0.0001), NT-proBNP ≥38 pg/ml (Log rank 10, p<0.01) and their combination (no, one or both criteria: Log rank 46, p<0.0001) were predictive of CE.

Conclusion: NT-proBNP and LV hypertrophy independently predict CAD in asymptomatic diabetic patients without heart failure. CAD and NT-proBNP levels are the main predictors of CE.

1314

Association of lower limb artery intima-media thickness with three-vessel or left main coronary artery disease

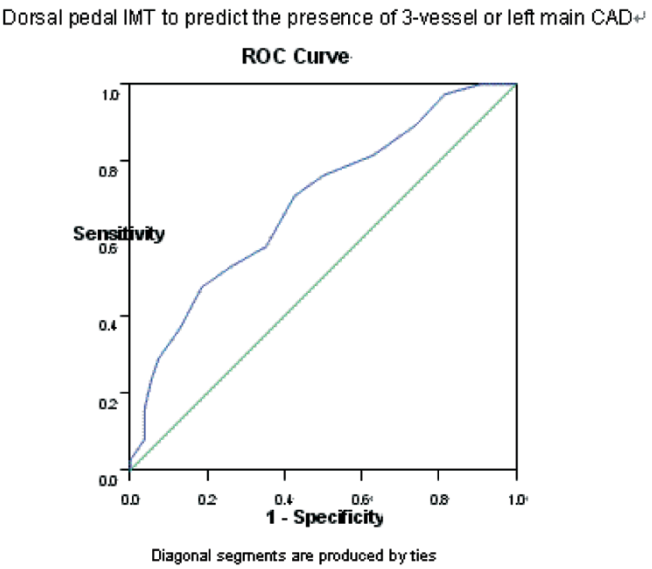
D. Zhang, Y. Mu;
Department of Endocrinology and metabolism, Chinese PLA General Hospital, Beijing, China.

Background and aims: To examine the association between carotid and lower limb artery intima-media thickness (IMT) and occurrence of three-vessel or left main coronary artery disease (CAD) in type 2 diabetic patients.

Materials and methods: 100 type 2 diabetic patients who underwent coronary angiography for suspected CAD received B-mode ultrasound scanning of the common carotid, internal carotid, external carotid, carotid bifurcation, common femoral, superficial femoral, deep femoral, popliteal, anterior tibial and dorsal pedal artery for measurement of IMT. IMT values of carotid and lower limb system were expressed as mean values of both sides. CAD extent was evaluated by the number of diseased vessels and by Gensini score, a computerized scoring system of CAD severity.

Results: Mean IMT of the superficial femoral, deep femoral, popliteal, anterior tibial, and dorsal pedal artery were significantly higher in subjects with 3-vessel or left main CAD compare control subjects (P<0.05). Also, 3-vessel CAD group has lower high density cholesterol (HDL) level (p=0.09) and more smokers (p=0.02) in univariate analysis. Mean levels of biomarkers such as C reactive protein (CRP), intercellular cell adhesion molecule-1 (ICAM-1), vascular cell adhesion molecule-1(VCAM-1), plasminogen activator inhibitor-1(PAI-1), and E-selectin were higher in 3-vessel CAD group, but did not gain statistical significance. Using multiple logistic regression analysis, two parameters were found to be independent predictors of 3-vessel or left main CAD: dorsal pedal artery IMT (OR 26.0; 95% CI 1.2 to 55.5; P=0.04), and smoking (OR 3.2; 95% CI 1.1 to 9.4; p=0.04). Dorsal pedal artery IMT predicted 3-vessel or left main CAD with cutoff value 0.93mm (sensitivity 71.1%, specifity 57.4%). In univariate analysis, dorsal pedal artery IMT (r=0.29; p=0.01) and course of diabetes (r=0.19; p=0.08) were correlated with Gensini score. The carotid bifurcation IMT had a weak correlation with Gensini score only in female patients(r=0.32; p=0.07). Dorsal pedal artery IMT was the only independent parameter for predicting Gensini score (p=0.01).

Conclusion: Dorsal pedal artery IMT, course of diabetes were correlated with severity and extent of CAD. Dorsal pedal artery IMT and smoking were independent predictors of three-vessel or left main CAD in type 2 diabetic patients.



1315

Glibenclamide-related excess in total and cardiovascular mortality risks: data from observational cohort study

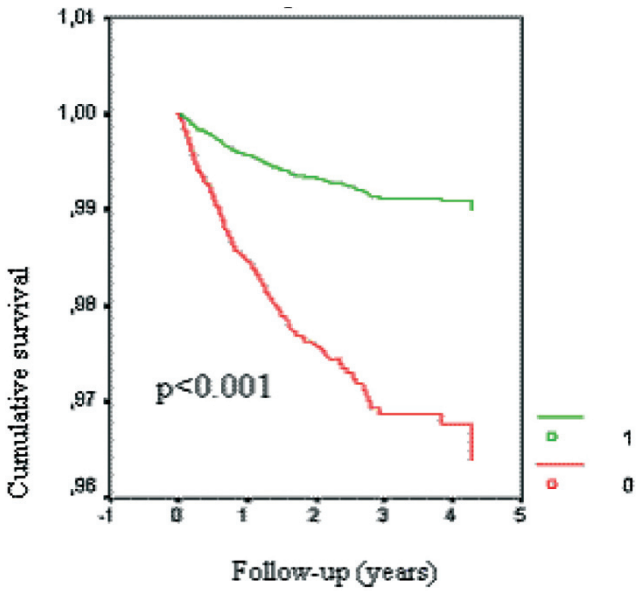
M.D. Khalangot[1], M.D. Tronko[2], V.I. Kravchenko[1];
[1]Epidemiology, [2]Institute of Endocrinology and Metabolism, Kiev, Ukraine.

Background and aims: Negative cardiovascular effects of glibenclamide have been proven on experimental models however the CVD mortality risk had not been studied sufficiently.The aim of this study was to compare mortality risks among type 2 diabetes patients (T2D) being treated with either glibenclamide or gliclazide.

Materials and methods: Cross-sectional and cohort studies of national diabetes register were carried out. Oral antidiabetic drug (OAD) structure for 2005 and 2007 was evaluated (31 569 and 164 388 T2D patients respectively). Age at the time of death among T2D in 2002 and 2007 was compared.Risk of total and cardio-vascular (CVD) mortality was evaluated in retrospective cohort of T2D that were treated with either glibenclamide (n=21 731), or gliclazide (n=3 630). Cox regression was used for multifactor evaluation. Hazard Ratios (HRs) and 95% Confidence Intervals (95%CIs) were calculated.

Results: Age at the time of death for insulin-treated T2D had increased (p<0.001) by 1.54 (95% CI 0.81-2.26), and for OAD-treated by 6.27 (95% CI 3.67-8.87) years, p<0.001. OAD structure for 2005 and 2007 had changed: the number of glibenclamide prescriptions had decreased (p<0.001):from 64.0% (95% CI 63.5-64.5) to 59.5% (95% CI 9.7-10.4), whereas the amount of gliclazide prescriptions increased (p<0.001): from 10.1% (95% CI 9.7-10.4) to 13.4% (95% CI 13.3-13.6) respectively. Age, diabetes duration and gender-adjusted total and CVD death risks were higher (p<0.001) in the glibenclamide group: HR's 2.57 (95% CI 1.73-3.82) and 2.93 (95% CI 1.83-4.71) respectively. Further adjusting (blood glucose, body mass index, and systolic blood pressure) did not influence these results.

Conclusion: Glibenclamide treatment of type 2 diabetes is associated with much greater risk of all-cause and CVD mortality, comparing to gliclazide treatment. These results comply with recent trends of OAD structure and life span of T2D.



Cardiovascular mortality among gliclazide –treated (1) and glibenclamide – treated (0) type 2 patients

Characteristics and management of diabetic patients hospitalized for myocardial infarction in France

P. Tuppin[1], A. Neuman[1], D. Simon[2], W. Alain[1], P. Ricordeau[1], N. Danchin[3], H. Allemand[1];
[1]CNAMTS, [2]Hôpital Pitié-Salpêtrière, [3]Hôpital Georges Pompidou, Paris, France.

Background and aims: To compare characteristics and management of diabetic and non-diabetic patients six months before, during, and six months after their hospitalization for a diagnosis of myocardial infarction (MI).
Materials and methods: All hospital admissions for MI in France from January to June 2006 were selected from the national hospital discharge database. Data on medications six months before and after hospitalisation for patients covered by the general health insurance scheme (70% of French population) were merged with the reimbursement information system. Diabetic patients were identified by at least two refunds for antidiabetic medications 6 months before or 6 months after hospitalisation for MI.
Results: Of the 14 007 patients included, 2 936 were diabetics (21.0%) and 86.7% of them had antidiabetic medications before MI. After adjustment for sex and age, diabetics patients more frequently had cardiovascular medications (beta blockers, antiplatelet agents, statins, angiotensin-converting-enzyme inhibitors or angiotensin-receptor-blockers) before admission (11.2% vs. 4.2%, p<0.0001) and prior hospitalisation for stent implantation (3.9% vs. 2.2%, p<0.0001) than non-diabetics, suggesting higher prevalence of cardiovascular disease history. During hospitalization and the following month, coronary angiography was used in a similar proportion of patients (32.9% vs. 32.0%), but angioplasty (58.1% vs. 61.5%, p=0.0001) and stent implantation (55.6% vs. 59.0%, p<.0001) were less frequently used, while coronary bypass surgery was more frequent (2.9% vs. 1.7%, p=0.0003) . During the six months after MI hospitalization diabetic patients had more admission for cardiovascular diagnosis (50.8% vs.43.9% p<.0001) and received more secondary prevention medications (66.4% vs. 61.2%, p<.0001). Six months after hospitalization, 93.8% of diabetic patients had anti-diabetic medications. They were more frequently treated by insulin only (16.5% 6 months before vs. 26.0% 6 months after) or associated with oral antidiabetic drugs (OAD) (12.2% vs. 17.7%). Frequency of diabetic patients treated with OAD only decreased (55.3% vs. 50.1%).
Conclusion: In keeping with current guidelines, diabetic patients sustaining an AMI get more frequent surgical revascularisation procedures, and fewer angioplasty procedures. After the acute stage, secondary prevention medications are used more often, and the use of antidiabetic medications increases with a marked rise in the use of insulin.

1317

Primary prevention medication use in patients with type 2 diabetes who present with an acute myocardial infarction in East London

P.G. Wright[1], S. Antoniou[1], R. DePalma[2], J. Robson[3], M. Rothman[2];
[1]Pharmacy, Barts and the London NHS Trust, [2]Cardiology, Barts and the London NHS Trust, [3]Tower Hamlets PCT, London, United Kingdom.

Background and aims: NICE guidance for the treatment of type 2 diabetes states that patients are considered at high risk of CVD unless all of the following criteria are meet: not overweight (with risk stratified according to ethnic group), normotensive (<140/80 mmHg in the absence of antihypertensive therapy), no microalbuminuria, non smoker, does not have a high-risk lipid profile, has no history of cardiovascular disease and has no family history of cardiovascular disease. Those at high risk of CVD should be considered for statin and aspirin therapy depending upon a patients age and additional risk factors. The aim of this study is to assess the use of cardiovascular disease (CVD) primary prevention medication in patients with established type 2 diabetes diagnosed with an acute myocardial infarction (AMI) in accordance with national guidelines.
Materials and methods: Data was collected prospectively for 8 months (1st February to 3rd October 2008). Use of statins and aspirin for primary prevention in patients with type 2 diabetes admitted to a regional angioplasty centre with a final diagnosis of AMI were assessed on admission. During the 8 month data collection period, 573 patients were admitted with a final diagnosis of AMI, 103 patients had type 2 diabetes of whom 78 had no previous history of MI. The pre-admission medication of these patients were assessed and compared to national guidance.
Results: In patients with type 2 diabetes admitted with an AMI, primary prevention with statins and aspirin therapy was used in 48/78 (61%) and 31/78 (40%) respectively. At least 1 additional risk factor for CVD was present in 74/78 (95%) of patients. Those not taking a statin had a mean of 1.6 (±1.1) additional CVD risk factors and those not taking aspirin a mean of 2.0 (±1.1) additional risk factors.
Conclusion: These data suggest under use of statin and aspirin therapy for primary CVD prevention in patients with type 2 diabetes admitted with an AMI when compared to NICE guidelines for primary prevention. Further work is required to identify barriers to prescribing and implement solutions to improve use of primary prevention medication in patients with type 2 diabetes.

1318

Specialist multidisciplinary clinics for diabetes patients with suspected and known coronary disease are effective at reducing cardiovascular risk

R.T. Lumbers[1], R. Rampat[1], S. Gallagher[1], A.C. Qureshi[2], S. Williams[1], A. Kapur[1,2];
[1]Newham General Hospital, [2]Barts and the London NHS Trust, London, United Kingdom.

Background and aims: Diabetic patients have cardiovascular mortality rates comparable to those of non-diabetic patients with prior myocardial infarction. We have established specialist diabetic coronary disease clinics providing rapid investigation and treatment of patients with known and suspected coronary artery disease (CAD). Our specialist nurse provides lifestyle advice and risk factor modification in a model similar to that established in cardiac rehabilitation. The presentation of CAD is frequently atypical, complicating risk stratification on the basis of history alone and we therefore have a low threshold for functional imaging and invasive investigation of patients.
Methods: We conducted a prospective study of patients referred to the DCD clinic with known and suspected CAD between October 2006 until October 2008. Our DCD specialist nurse provided lifestyle and risk factor modification advice under medical supervision. Follow up was provided up to a total of 3 appointments or for a maximum of one year. Patients were assessed by cardiologists and followed established pathways of investigation. The 10-year coronary heart disease risk was calculated using the United Kingdom Prospective Diabetes Study (UKPDS) Risk Engine was used as the surrogate outcome measure. The scores were recorded at the first consultation and on discharge from nurse led follow up.
Results: A total of 233 new patients attended the clinic during the study period and were followed up for up to one year. Significant (p<0.001) reductions were recorded in systolic blood pressure 137.7(±22.8) mmHg to 129.4(±19.6) mmHg, total cholesterol 4.45(±1.14) mmol/l to 4.09(±1.08) mmol/l, LDL 2.42(±0.98) mmol/l to 2.11(±0.90) mmol/l and HbA1C 8.30(±1.72)% to

7.87(±1.43)%. Smoking prevalence was reduced from 10.7% to 6.34%. Overall, 10-year predicted risk of CHD was reduced from 20.4% to 16.0% (p<0.001).
127 of the patients seen had no past cardiac history of CAD and 74% of patients presented with atypical symptoms of angina. Exercise tolerance testing was only possible in 45% (57/127) of patients and resulted in a definitive diagnosis in only 12% (15/127). Despite this a total of 41% (53/127) of patients in the study group underwent coronary angiography. 42 patients had demonstrable CAD and 24 of these had obstructive disease for which revascularisation procedures were performed in 13 patients.
Conclusion: The study demonstrates that specialist multidisciplinary clinics with nurse led risk factor and lifestyle modification are highly effective at reducing cardiovascular risk in diabetic patients with known and suspected coronary artery disease. There is a strong case for the widespread adoption of this model as part of a strategy to improve outcomes. In addition, our data highlight the limited value of exercise ECG testing and highlight the importance of having a low threshold for functional imaging or angiography.

1319

The predictive value of diabetes mellitus for the presence and severity of angiographically established coronary artery disease and correlation with specific angiographic findings

C.C. Koliaki[1], E. Sanidas[2], N. Dalianis[2], D. Papadopoulos[2], I. Kolovou[1], D. Panagiotakos[3], V. Votteas[2], N. Katsilambros[1];
[1]Eugenidion University Hospital, Medical School of Athens, [2]Department of Cardiology, Laiko General Hospital, [3]Department of Dietetics and Nutrition, Harokopio University, Athens, Greece.

Background and aims: Diabetes mellitus is a well established cardiovascular risk factor of major prognostic significance for patients with coronary artery disease (CAD). However, its exact relation to the angiographically assessed anatomic extent of coronary atherosclerosis has not been conclusively delineated. In the present study, we aimed to evaluate the association between diabetes and specific coronary angiographic findings in a large unselected population of catheterized patients.
Materials and methods: The study included 1228 subjects (290 female, 938 male, mean age 64±11 years) who consecutively underwent diagnostic coronary angiography in our Catheter Laboratory for a variety of clinical indications. We compared the prevalence of diabetes between the CAD negative group and the groups with angiographically significant (>50%) narrowing of one, two and three coronary arteries and explored the relationship between diabetes and specific angiographic characteristics of the participants, such as the number of vessels affected and the selective atherosclerotic involvement of every single major coronary artery.
Results: In our cohort, diabetes was prevalent in 348 subjects (28.3%) and increased the likelihood of positive angiographic findings by approximately two-fold (Odds Ratio=2.17, p<0.001), establishing an intermediate predictive utility between dyslipidemia (Odds Ratio=3.34) and hypertension (Odds Ratio=1.65). Comparing the prevalence of diabetes among groups with 0, 1, 2 and 3 stenosed vessels, diabetes was found to correlate well with CAD severity (p<0.001), but not as strongly as smoking and dyslipidemia. The observed differences were statistically significant, when comparing the no stenosis group with double- and triple-vessel disease groups. Diabetes was also positively associated with significant obstructive lesions in left anterior descending artery (p<0.001), left circumflex (p=0.001), right coronary artery (p=0.02) and left main coronary artery (p=0.011). Concerning left main stem, diabetes was recognised as the only conventional risk factor that could reliably and independently predict significant left main stem angiographic alterations.
Conclusion: In the considerably large cohort of our study, diabetes proved to be a less important predictor of angiographic ischemic heart disease and determinant of CAD severity, compared with other traditional risk factors such as smoking and lipid disorders. However, the superiority of diabetes in terms of predicting angiographically significant left main stem disease is strongly emphasized.

1320

Patients with systemic atherosclerosis and type 2 diabetes show elevated levels of adipocyte fatty acid binding protein compared to those with normal glucose metabolism

C. Hoebaus[1], F. Hoellerl[1], T. Hoertenhuber[1], A. Steffan[1], M. Grujicic[1], G. Schernthaner[2], R. Koppensteiner[1], G.H. Schernthaner[1];
[1]Angiology, Medical University of Vienna, [2]Medicine I, Rudolfstiftung Hospital, Vienna, Austria.

Background and aims: Peripheral arterial occlusive disease (PAOD) caused by lower-extremity atherosclerosis is found more frequently among people with type 2 diabetes mellitus (T2DM). The co-occurrence of PAOD and T2DM leads to higher complication and mortality rates. Recently, animal models revealed an involvement of adipocyte fatty acid binding protein (AFABP) in atherosclerosis. Furthermore, AFABP levels seem to predict T2DM development.
Materials and methods: In this study we investigated AFABP serum levels in 253 patients consisting of 85 female and 168 male patients with PAOD Fontaine stage I or II. An oral glucose tolerance test (oGTT) was performed to assess a possible influence of the patients' glucose metabolism on AFABP levels. AFAB was obtained by a commercially available ELISA (BioVendor Laboratory Medicine, Modrice, Czech Republic). Inter-assay coefficient of variation (CV) was 6.5%, and intra-assay CV was 2.9%. Statistical analyses were done with students' unpaired t-test, correlation analysis and multivariate regression modeling as appropriate. Left-skewed data were lg10 transformed before analysis in order to render the distribution normal for parametric tests. Normal data are given in mean±STD, non-parametric data as median (25; 75 percentile).
Results: After oGTT testing, 72 patients were classified as normal glucose tolerant (NGT), 45 patients had impaired fasting glucose, 32 patients showed impaired glucose tolerance, 103 patients had overt T2DM. AFABP levels of PAOD patients were significantly higher in the T2DM group (31 (23; 43) ng/ml) compared to the NGT group (26 (17; 37) ng/ml, p=0.006). Furthermore, female patients had significantly higher AFABP levels (36 (27; 44) ng/ml) compared to men (26 (19; 37) ng/ml, p<0.001). In univariate correlation analysis AFABP was positively associated with homeostatic model assessment - insulin resistance (beta=0.196; p=0.006), post-oGTT glucose (beta=0.150; p=0.018), body mass index (BMI) (beta=0.250; p<0.001), serum creatinine (beta=0.380; p<0.001), triglyceride (beta=0.158; p=0.012), alkaline phosphatase (beta=0.192; p=0.002), c-reactive protein (CRP) (beta=0.148; p=0.019), fasting insulin (beta=0.218; p=0.001) and post-oGTT insulin (beta=0.174; p=0.007). Multivariate regression modeling revealed a significant independent positive association of BMI (beta=0.245; p<0.001) and serum creatinine (beta=0.377; p<0.001) with AFABP levels. In addition, c-peptide was measured in a subgroup of 53 male PAOD patients. In this subgroup AFABP levels correlated with post-oGTT glucose (beta=0.280; p=0.042), diastolic blood pressure (beta=-0.314; p=0.022), weight (beta=0.359; p=0.008), BMI (beta=0.445; p=0.001), serum creatinine (beta=0.673; p<0.001), alkaline phosphatase (beta=0.288; p=0.037), CRP (beta=0.342; p=0.012), fasting insulin (beta=0.342; p=0.012), post-oGTT insulin (beta=0.491; p<0.001), fasting c-peptide (beta=0.278; p=0.044) and post-oGTT c-peptide (beta=0.493; p<0.001).
Conclusion: Higher AFABP levels were found in patients with diabetes compared to non-diabetic patients in severe systemic atherosclerosis. Furthermore, multivariate regression modeling revealed an independent association of AFABP with BMI and serum creatinine in PAOD patients.

The impact of different types of glucose metabolism disorders on long-term outcome after an acute coronary syndrome

P. Konstantinopoulos[1], A. Koutsovasilis[1], M. Stathatos[1], A. Nikolaou[1], G. Koukoulis[2], I. Skoularigis[2], S. Foussas[3], A. Melidonis[1];
[1]Diabetes Center, Tzanio General Hospital of Piraeus, [2]Cardiology, Larissa University Hospital, [3]Cardiology, Tzanio General Hospital of Piraeus, Greece.

Background and aims: Acute Coronary Syndrome (ACS) patients' glycemic profile is a crucial outcome factor while admission glucose and in-hospital hyperglycemia during the first days after admission or during the entire ACS hospitalization affect patient outcome after ACS. The aim of this study is to evaluate the impact of glucose metabolism disorders and glucose values (on admission, fasting, postprandial and mean values of glucose during hospitalization) on first year outcome.
Materials and methods: 520 patients who were admitted to the coronary care unit and discharged from February 2006 through October 2007 were included in this longitudinal, prospective, observational, unicenter study. First-year end points were: death (of cardiovascular cause), myocardial infarction, cardiac failure (clinical and echocardiographic determination) and unstable angina after hospitalization. Non-diabetic patients went through an Oral Glucose Tolerance Test (OGTT) one month after discharge and IGTs were categorized. To evaluate the impact of different types of glucose metabolism and glucose measurements on first-year complications after the ACS incidence, separate logistic regression models were performed for each measurement.
Results: Diabetes was previously diagnosed (Group A) in 152 (29.2%) patients, newly diagnosed (Group B) in 57 (10.9%) patients, an IGT (Group C) was observed in 110 (21.1%) patients while 201 (38.8%) were patients with normal glucose regulation (Group D). The incidence of one-year complications was 24.3%, 21.1%, 13.6% and 11.9% in groups A, B, C and D respectively (p=0.014). Concerning patient outcome during the first 12 months after ACS, group A showed the worst outcome (HR:2.66, 95%CI:1.234-5.135,p=0.001) followed by groups B(HR:1.84, 95%CI:1.129-4.328,p=0.022) and C(HR:1.24, 95%CI: 1.115-3.289,p=0.046), using group D as reference group after adjustment for age, gender, smoking, waist circumference, HDL, triglycerides, total cholesterol, metabolic syndrome (NCEP-ATP III criteria) and hypertension. The HR for the one-year outcome for patients with admission glucose in the top quartile was 2.32 (95%CI: 1.358-4.678, p<0.001), 2.11 (95%CI:1.277-5.023, p=0.001), 1.69 (95%CI:1.376-4.329, p=0.033) and 1.39 (95%CI:1.261-3.679, p=0.046) for Groups A, B, C and D respectively compared to those in the bottom quartile. Among other glucose measurements, a statistically significant difference in outcome between upper and lower quartile was in fasting glucose for Group A [HR=1.88 (95%CI:1.341-5.237, p=0.026)] and Group B [(HR=1.67 (95%CI: 1.461-5.673, p=0.039)], in postprandial glucose just for Group A [(HR=1.79 (95%CI:1.337-4.905, p=0.031)], and in the mean glucose values for Groups A [(HR=1.61 (95%CI: 1.218-5.892, p=0.036)] and B [(HR=1.47 (95%CI: 1.288-4.926, p=0.046)].
Conclusion: Patients with known diabetes mellitus have a worse long-term outcome after Acute Coronary Syndome compared with newly diagnosed and prodiabetes patients. Among different glucose measurements only admission glucose in ACS shows a more significant correlation with long-term outcome after an ACS even for normoglycemic patients.

1322

Impact of different glucose values during hospitalization on one-year outcome after an acute coronary syndrome

A. Koutsovasilis[1], F. Triposkiadis[2], G. Koukoulis[2], I. Skoularigis[2], M.-P. Koukouli[1], S. Foussas[3], A. Melidonis[1];
[1]Diabetes Center, Tzanio General Hospital of Piraeus, [2]Cardiology, Larissa University Hospital, [3]Cardiology, Tzanio General Hospital of Piraeus, Greece.

Background and aims: Hyperglycemia on admission is common and associated with markedly increased in-hospital complication rates in patients hospitalized with acute coronary syndrome (ACS) with and without diabetes mellitus. Admission glucose represents only a single measurement in time while in-hospital hyperglycemia during the first days after admission or during the entire ACS hospitalization period is obtained by the use of multiple glucose values. The aim of this study is to evaluate the impact of different glucose values (admission, fasting, postprandial and mean hospitalization glucose) for these patients' first-year outcome.
Materials and methods: 520 patients were admitted to the coronary care unit and discharged February 2006 - October 2007 were included in this longitudinal, prospective, observational, study. First-year end points were: death (of cardiovascular cause), myocardial infarction, cardiac failure (clinical and echocardiographic determination) and unstable angina after hospitalization. Non-diabetic patients went through an Oral Glucose Tolerance Test one month after discharge and IGTs were categorized. To evaluate the impact of different glucose measurements on first-year complications after the ACS incidence, separate logistic regression models were performed for each measurement. The accuracy of these logistic regression models in predicting complications for the predetermined time period was assessed using the Receiver- Operating Characteristic (ROC) curves, and their respective areas under the curve (AUC).
Results: Diabetes was previously diagnosed (Group A) in 152 (29.2%) patients, newly diagnosed (Group B) in 57 (10.9%) patients, an IGT (Group C) was observed in 110 (21.1%) patients while 201 (38.8%) were patients with normal glucose regulation (Group D). The incidence of one-year complications was 24.3%, 21.1%, 13.6% and 11.9% in groups A, B, C and D respectively (p=0.014). AUC of ROC curves for the probabilities of the logistic regression models (adjusted for age, gender, smoking, waist circumference, HDL, triglycerides, total cholesterol, metabolic syndrome (NCEP-ATP III) and hypertension for the admission glucose was 0.697 (95%CI:0.565-0712,p=0.001), 0.627 (95%CI:0.536-0.682,p=0.010), 0.601 (95%CI:0.524-0.679,p=0.022), and 0.578 (95%CI:0.502-0.657,p=0.049) for A, B, C and D Group respectively. AUC for the fasting glucose was 0.632 (95%CI:0.527-0.764,p=0.021), 0.581 (95%CI:0.523-0.699,p=0.033), 0.522 (95%CI:0.484-0.640,p=0.124), 0.494 (95%CI:0.414-0.574,p=0.580) for groups A, B, C and D respectively. Statistically significant AUC for the postpandial glucose was just for Group A [0.611 (95%CI:0.588-0.722,p=0.033)], while significant AUC for the mean value of the glucose during hospitalization was 0.597 (95%CI:0.532-0.691,p=0.026) and 0.533 (95%CI:0.508-0.634,p=0.097) for Groups A and B respectively.
Conclusion: Admission glucose in ACS incidents shows a more significant correlation with first-year end-points even in normoglycemic patients. Other values do not have the same impact while prolonged hyperglycemia affects newly diagnosed as well as known diabetic patients.

1323

Susceptibility to ischaemia-reperfusion injury in isolated human diabetic myocardium *versus* non diabetic

S. Lemoine, J.-L. Gérard, J.-L. Hanouz;
Departement d'Anesthésie Réanimation, Laboratoire d'Anesthésiologie Expérimentale, Caen, France.

Background and aims: Results from a number of experimental studies using animal models of diabetes are inconsistent in sensitivity of the diabetic heart to ischemia-reperfusion injury, demonstrating no change, increased or decreased sensitivity to ischemia. These controversies may be explained by important differences in experimental models of diabetes mellitus, species differences. However, important limitations of these experiments must be highlighted: it must be emphasized that glucose concentrations reported in these experimental studies are far greater (two- to three-fold higher) than those observed in diabetic patients. Consequently, the clinical relevance of experimental studies remains limited. Thus, studies on isolated human myocardium obtained from diabetic patients may have importance. The aim of the present study was, *in vitro*, to examine the sensitivity of human diabetic myocardium to simulated ischemia reperfusion in comparison to non diabetic.
Materials and methods: After the approval of local medical ethics committee, right atrial appendages were obtained during cannulation for cardiopulmonary bypass from patients (non diabetic (ND, n=9), with diabetes mellitus type 1 (insulin-dependent diabetes mellitus (IDDM), n=9) and type 2 (non-insulin-dependent diabetes mellitus (NIDDM), n=9) scheduled for routine coronary artery bypass surgery and aortic valve replacement. The force of contraction (34°C, stimulation frequency 1 Hz) of human right atrial trabeculae was recorded during 30-min hypoxia followed by 60-min reoxygenation. The results are expressed in % of baseline. The force of contraction (FoC) was compared (mean ± SD) between the groups by a variance analysis and post

hoc test. In these three groups, patient's glycemia was measured in a blood sample taken at the time of obtaining of right atrial, and their glycemic control as measured by HbA_{1C}.
Results: Hypoxia decrease the FoC in three groups; after 30 min of exposure to hypoxia the FoC is not significantly different in 3 groups: FoC was: 20 ± 13% of baseline in ND group; 31 ± 13% in IDDM group (P=0.21 vs ND), and 25 ± 14% in NIDDM group (P=0.16 vs ND; P=0.34 vs IDDM).
Reoxygenating resulted in a partial recovery of FoC, at the end of reoxygenation period, the FoC is not significantly different in 3 groups: 53 ± 5% in ND group; 54 ± 6% in group IDDM (P= 0.29 vs ND), and 52 ± 10% in the group NIDDM (P=0.78 vs ND; P=0.18 vs IDDM). The glycemia and HbA_{1C} of the patients were respectively: 5.2 ± 0.5 mM and 5.6 ± 0.5% in ND group; 8.2 ± 2.2 mM and 7.2 ± 0.7% in IDDM group; 5.7 ± 0.6 mM and 7.0 ± 1.2% in NIDDM group.
Conclusion: The present results showed that, *in vitro,* human diabetic myocardium has the same sensitivity to hypoxia-reoxygenation injury than non diabetic myocardium. However, it should be highlighted that HbA_{1C} was comparable between groups, suggesting that glycemic control was good in the diabetic patients included in the study, contrary to the experimental studies using animal models of diabetes. We hypothesized that these results could be extended to patients with diabetes mellitus.

1324

Newly diagnosed diabetes patients show worse short-term outcome compared to know diabetic and prodiabetic patients after an acute coronary syndrome
A. Kamaratos[1], A. Koutsovasilis[1], F. Triposkiadis[2], A. Sereti[1], I. Protopsaltis[1], D. Athanasopoulos[1], S. Foussas[3], A. Melidonis[1];
[1]Diabetes Center, Tzanio General Hospital of Piraeus, [2]Cardiology, Larissa University Hospital, [3]Cardiology, Tzanio General Hospital of Piraeus, Greece.

Background and aims: Patients' glycemic profile after an Acute Coronary Syndrome (ACS) is a crucial outcome factor determining complications during hospitalization as well as after discharge, with known diabetic patients showing more in-hospital complications. The impact of different categories of glucose metabolism on patient outcome after discharge varies according to elapsed time after ACS. The aim of this study is to determine the prevalence of several categories of glucose metabolism in ACS patients, as well as the correlation of these categories with the incidence of short-term complications.
Materials and methods: 520 patients mean aged 66.14±11.94 years who were admitted to the coronary care unit (CCU) and discharged from February 2006 through October 2007 were included in this longitudinal, prospective, observational, study. First 30 days end- points were: death (of cardiovascular cause), myocardial infarction, cardiac failure (clinical and echocardiographic determination) and unstable angina after hospitalization. Non-diabetic patients went through an Oral Glucose Tolerance Test (OGTT) one month after discharge and IGTs were categorized. Adjusted and unadjusted logistic regression analyses were carried out in order to find the correlation between the glycemic status of the patients and the incidence of complications during the first 30 days after their discharge.
Results: Out of the study's 520 patients, diabetes was previously diagnosed (Group A) in 152 (29.2%) patients, newly diagnosed (Group B) in 57 (10.9%) patients, an IGT (Group C) was observed in 110 (21.1%) patients while 201 (38.8%) were patients with normal glucose regulation (Group D). The incidence of the first 30-days complications was 10.5%, 12.8%, 7.3% and 5% in groups A, B, C and D respectively (p=0.031). Regarding the patient outcome after the first 30 days following ACS, group B had the worst outcome (HR:2.63, 95%CI: 1.122-4.476, p=0.001) followed by groups A (HR=2.41, 95%CI:1.354-5.783, p=0.006) and C (HR=1.41, 95%CI:1.116-3.231 p=0.026), using group D as a reference group. The correlation of glycemic status after adjustment to age, gender, smoking, waist circumference, HDL, triglycerides, total cholesterol, metabolic syndrome (NCEP-ATP III) and hypertension was similar to that of the unadjusted model, with group B still showing the worst prognosis, (HR:2.15, 95%CI: 1.109-4.156, p=0.001), followed by groups A (HR:1.87, 95%CI: 1.228-5.231, p=0.003) and C (HR:1.22, 95%CI: 0.976-2.985, p=0.112), again using group D as a reference group.
Conclusion: Disturbed glucose metabolism is common among patients with ACS. Newly diagnosed diabetic patients with ACS show a worse short-term outcome compared to known diabetic patients due to the fact that those patients have diabetes that was neither appropriately recognized nor treated before hospitalization. Insulin therapy and the achievement of nornoglycemia improve outcome but hyperglycemic patients without known diabetes are much less likely to be treated with insulin even when glucose levels are markedly elevated.

1325

Aortic stiffness as a risk factor for recurrent cardiovascular events in diabetic men with recent-onset ischaemic heart disease
D. Levisianou[1], S. Foussas[2], E. Adamopoulou[2], A. Koutsovasilis[1], E. Skopelitis[3], T. Xenopoulou[3], I. Skoularigis[4], G. Koukoulis[4], F. Triposkiadis[4], A. Melidonis[1];
[1]Diabetes center, Tzanio General Hospital, Piraeus, [2]Cardiology department, Tzanio General Hospital, Piraeus, [3]2nd department of Internal Medicine, Agios Panteleimon General Hospital, Nikea, [4]Medical School, University of Thessaly, Larissa, Greece.

Background and aims: Aortic stiffness (AS) has been shown to correlate with the possibility of recurrence of coronary events in non-diabetic patients. However, its predictive value for cardiovascular morbidity in diabetic patients with ischaemic heard disease is not yet established. The aim of this prospective cross-sectional study was to test the hypothesis that estimating AS could predict cardiovascular morbidity in diabetic patients.
Materials and methods: One hundred consecutive diabetic men with no history of cardiovascular disease, admitted to the coronary care unit between February 2006 and June 2007, were evaluated at discharge for arterial stiffness by calculating carotid-femoral pulse wave velocity (PWV). Routine biochemistry was also obtained. Follow-up telephone interviews at 12 months after discharge assessed the primary endpoints: re-hospitalisation for any cardiovascular event (unstable angina, revascularization, myocardial infarction, stroke) or death. The independent sample t-test and chi-square test were used to compare parametric and non-parametric values of risk factors for cardiovascular disease between groups of those who developed a cardiovascular event in 12 months and those who did not. Cox proportional hazard models were used to estimate cause-specific hazards of the end-points. To facilitate analysis, PWV values were divided into two halves, upper and lower. Statistical analysis was performed using SPSS 15.0.
Results: Mean age was 63.86±10.09 years, diabetes duration 11.93±9.64 years, body mass index (BMI) 28.42±4.65 Kgr/m2, waist circumference 105.81±11.77 cm, A1c glycaeted hemoglobin (HbA1c) 7.50±2.31 %, glucose at admission 166.95±52.04 mg/dl, total cholesterol (TC) 184.45±55.85 mg/dl, triglycerides 147.77±87.69 mg/dl, HDL-cholesterol 36.27±11.74 mg/dl, LDL-cholesterol 83.99±62.99 mg/dl. Frequency of smoking was 36.7%, hypertension 58.8%, dyslipidemia 44%. Overall 12 cardiovascular events (unstable angina: 6, myocardial infarction: 3, revascularization: 2, stroke: 1) and 2 deaths were recorded in the population during the 12 month period. Those in the upper compared to those in the lower half of PWV were older (68.22±7.18 vs. 58.96±10.36 years, p<0.001), had a longer diabetes duration (13.6±10.43 vs. 6.71±5.95 years, p=0.003), and had more increased TC (178.26±52.50 vs. 216.66±56.7 mg/dl, p=0.025). No statistical significant differences were detected for waist, BMI, glucose levels, troponine I, HbA1c, triglycerids, HDL-C, proportion of those receiving a lipid lowering agent, frequency of hypertension and smoking. After adjustment for age, diabetes duration, TC, and smoking, PWV was independently associated with the risk for recurrent cardiovascular morbidity (hazard ratio=2.408, 95%CI=1.313-6.88, p=0.032).
Conclusion: Increased AS was associated with increased one-year risk for recurrent cardiovascular event in diabetic men, thus representing a useful and practical measure of cardiovascular morbidity in such patients. We propose that AS could be routinely used for risk stratification in the management of diabetic men after the first coronary event.

The association between the -374T/A polymorphism of the RAGE gene and blood pressure and arterial stiffness is modified by glucose metabolism status. The Hoorn and CoDAM studies
L. Engelen[1], I. Ferreira[1], K.H.J. Gaens[1], R.M.A. Henry[1], J.M. Dekker[2], G. Nijpels[2], R.J. Heine[2], M.M.J. van Greevenbroek[1], C.J.H. van der Kallen[1], E.E. Blaak[3], E.J.M. Feskens[4], H. ten Cate[1], C.D.A. Stehouwer[1], C.G. Schalkwijk[1];
[1]Department of Internal Medicine, Maastricht University Medical Centre, [2]Institute for Research in Extramural Medicine (EMGO), VU Medical Center, Amsterdam, [3]Department of Human Biology, Maastricht University Medical Centre, [4]Division of Human Nutrition, Wageningen University, Netherlands.

Background and aims: Receptor for advanced glycation endproducts (RAGE)-ligand interaction triggers signal transduction pathways, which may lead to vascular complications. Genetic variation in RAGE has been shown

to alter expression and/or activity of RAGE. In the present study, we investigated whether RAGE single nucleotide polymorphisms (SNPs) were associated with markers of micro- and macrovascular disease among individuals without and with type 2 diabetes (DM2).
Materials and methods: Nine tag SNPs that cover the common RAGE gene variation were genotyped in 1291 individuals from 2 large population-based cohort studies in the Netherlands, aged 64.5±8.6 years, with normal glucose metabolism (NGM; 44%), impaired glucose metabolism (IGM; 23%) or DM2 (33%). We used linear regression analyses to compare levels of blood pressure, markers of atherosclerosis (i.e. carotid IMT and ankle-arm index), arterial stiffness and renal function across genotypes, and examine effect modification by glucose metabolism status.
Results: No consistent associations between RAGE SNPs and markers of micro- and macrovascular disease were found. However, the AA genotype of SNP -374 T/A (rs1800624) was consistently associated with lower systolic blood pressure (SBP) [-4.7 mmHg (95%-CI: -10.1; 0.7)], diastolic blood pressure (DBP) [-4.0 mmHg (-7.0; -1.1)] and pulse pressure (PP) [-2.2 mmHg (-6.3; 1.9)], as well as with less arterial stiffness [-0.54 SD (95%-CI: -1.02; -0.06)] in individuals with *NGM*, but with greater SBP [6.2 mmHg (0.9; 11.4)], DBP [2.0 mmHg (-0.9; 4.8)], PP [4.1 mmHg (0.5; 7.8)] and arterial stiffness [0.10 SD (-0.26; 0.47)] in individuals with *IGM* or *DM2* (p for interaction ≤0.05 in all analyses). Similar results were found for the haplotype that includes the -374A allele.
Conclusion: In individuals with NGM, the -374A allele of the RAGE gene is protectively, whereas in individuals with IGM or DM2 it is adversely associated with levels of blood pressure and arterial stiffness. These differences are currently unexplained, but may be related to differences in cellular expression of RAGE in response to hyperglycaemia.
Dr Ferreira is supported by a post-doc research grant from the Netherlands Heart Foundation

Endothelial dysfunction and arterial stiffness in subjects with type 2 diabetes mellitus
A.G. Daniele[1], L. Ghiadoni[2], R. Bruno[2], L. Pucci[1], D. Lucchesi[1], E. Storti[1], E. Russo[1], C. Bianchi[1], S. Taddei[2], R. Miccoli[1], S. Del Prato[1], G. Penno[1];
[1]Endocrinology and Metabolism, [2]Dept. of Internal Medicine, University of Pisa, Italy.

Background and aims: Arterial stiffness, recently proposed as an independent predictor of cardiovascular mortality, is regulated by a number of factors, including vascular tone. Diabetic subjects have both impaired endothelial function and increased stiffness of the large arteries. However, the relationship between endothelial dysfunction and arterial stiffness has been poorly explored in type 2 diabetic (T2DM) patients.
Materials and methods: Therefore we have tested the hypothesis that endothelial function independently affects aortic pulse wave velocity (PWV) in 39 subjects (18 men, 21 women) with T2DM (58±8 years old, diabetes duration: 12±8 years, BMI: 32.7±5.6 kg/m2, fasting C-peptide: 4.0±2.4 ng/ml, HbA1c: 8.3±0.7%).
Results: Endothelial function was measured as flow-mediated dilation (FMD) and sublingual nitroglycerin response (NTG) of the brachial artery. Carotid-femoral pulse wave velocity (PWV), and central augmentation index (Aix/HR75) were measured at rest by applanation tonometry (SphygmoCor). Time to reflection and central blood pressures were also obtained from pulse wave analysis. Central PWV correlated with age (r=0.33, p=0.04), BMI (0.53, p=0.001), waist circumference (r=0.45, p=0.05) and fasting blood glucose (r=0.41, p=0.01), but not with blood pressure parameters as estimated by 24-hour ambulatory blood pressure monitoring (ABPM). PWV was closely correlated with central BP parameters, but not with Aix/HR75 or NTG. FMD was inversely correlated with age (r=-0.46, p=0.004) and with 24-hour systolic and mean BP (r=-0.37/-0.42, p<0.05/=0.025, respectively), but not with central BP parameters, Aix/HR75 or NTG. More interestingly, FMD was significantly and inversely correlated with central PWV (r=-0.50; P<0.001). After adjusting for potential confounders, endothelial function remained independently and inversely associated with aortic PWV. On stepwise regression analysis, BMI (step 1, R2=30%), FMD (step 2, R2 change=24%), and fasting glucose (step 3, R2 change=10%), but not ABPM parameters, were independent predictors of PWV. AixHR75 and time to reflection were related only to age (R2=24% and 37%, respectively).
Conclusion: In subjects with type 2 diabetes, a decline in endothelial function seems to be independently associated with increased large artery stiffness.

1328

Increased arterial wall stiffness caused by hyperglycaemia is partially reversible in early diabetic patients
H. Sasaki, J. Ibata, H. Shimomura, Y. Nakano, H. Wakasaki, H. Furuta, M. Nishi, T. Nakao, K. Nanjo;
First Department of Medicine, Wakayama University of Medical Science, Japan.

Background and aims: Increased arterial wall stiffness (AWS) has been reported to be complicated by metabolic syndrome, impaired glucose tolerance and diabetes. The detailed relation between hyperglycemia and AWS has not been fully clarified. We investigated the influence of hyperglycemia on AWS using cardio-ankle vascular index (CAVI) which is a new method for estimating AWS.
Materials, methods and results: Three investigations were carried out in order to achieve the aim.
FIRST INVESTIGATION: We measured CAVI in 42 diabetic patients (DM) with short duration (less than 5 years) without microangipathy and 43 age-matched non-diabetic subjects (NDM), and compared the CAVI values. The CAVI of DM was significantly higher than that of NDM (7.12 vs 6.70, p<0.04). Multiple regression analysis revealed that significant risk factors for the elevation of CAVI were the presence of diabetes and age but not triglyceride (TG), HDL, LDL, systolic blood pressure (SBP) and body mass index (BMI).
SECOND INVESTIGATION: We measured CAVI in 37 DM who were hospitalized shortly with poor glycemic control. After 8 weeks, the CAVI were re-examined. In well improved DM (HbA1c improvement>1.0%, n=21), CAVI were significantly improved (8.00 to 7.44 p=0.0016). In the less improved DM (HbA1c improvement<1.0%, n=16), however, CAVI did not significantly improve (8.72 to 8.57 p=0.4793). The TG, HDL levels and SBP did not change significantly.
THIRD INVESTIGATION: We measured CAVI in 135 established DM (average duration 14.3 years) twice at interval of 18 weeks, and the change in CAVI (delta CAVI) was calculated. The clinical risk factors associated to high CAVI or CAVI elevation were evaluated by multiple regression analyses. With the multiple regression analysis using baseline CAVI as a dependent variable, age, high SBP and low BMI were significantly associated to high CAVI. On the other hand, HbA1c, lipids levels, diabetic duation and microangiopathy were not related to baseline CAVI. With the multiple regression analysis using delta CAVI as a dependent variable, no significant risk factor of CAVI elevation was detected.
Conclusion: These findings suggest that progression of AWS can be observed in the early stage of diabetes and that is partially reversible by glycemic control. The effect of glycemic control on AWS elevation may decrease in the established diabetic patients.

1329

Ambulatory arterial stiffness index and insulin sensitivity in type 1 diabetes mellitus
A. Szadkowska, I. Pietrzak, B. Mianowska, E. Czerniawska, W. Fendler, L. Walenciak, W. Młynarski;
Department of Pediatrics, Oncology, Hematology and Diabetology, Medical University of Lodz, Poland.

Background and aims: Increased arterial stiffness may predict cardiovascular mortality in patient with hypertension or diabetes. Ambulatory arterial stiffness index (AASI) has been proposed as an indirect measure of arterial stiffness. Insulin resistance is a risk factor of cardiovascular diseases. The aim of this study was to estimate the relationship between AASI and insulin sensitivity in type 1 diabetic children and adolescents without hypertension.
Materials and methods: 88 patients (36 girls and 52 boys) aged 11-19 years (mean SD: 16±2.4), with diabetes duration 0.5-17.3 years (mean SD: 4.6±3.9) were included into the study. Ambulatory arterial stiffness index was defined as 1 minus the regression slope of diastolic over systolic BP readings obtained from 24-hour recordings. Euglycemic-hyperinsulinemic clamp by de Fronzo was performed to estimate insulin resistance. Glucose disposal rate (M value) determined during the last 30 min of the test was calculated as a surrogate of insulin resistance. The height, weight and waist circumference were measured and body mass index (BMI-SDS) and waist-SDS were calculated. HbA1c was measured (HPLC).
Results: In present group AASI was 0.24±0.19 (mean±SD). There was no difference between boys and girls (p=0.97). AASI correlated with patients age (0.23; p=0.03) and BMI-SDS (0.26; p=0.014).There was no relationship with

diabetes duration, waist-SDS and actual HbA1c. The M value ranged from 2.5 to 19 mg/kg/min (6.7±2.7). The correlation between AASI and M value was also found (r=-0.27; p=0.011). In multiple regression analysis after adjustment to patient age M value still correlated with AASI (beta=-0.23; p=0.036). But the model better describing AASI included patient age and BMI-SDS (adjusted R^2:0.1; p=0.008).
Conclusion: Among type 1 diabetic children and adolescents a relationship between arterial stiffness and insulin resistance and BMI has been found.

Brachial-ankle pulse wave velocity is more correlated with visceral fat thickness measured by ultrasonography than waist circumference in type 2 diabetic patients
D.-J. Chung, J.-O. Chung, D.-H. Cho, M.-Y. Chung;
Department of Endocrinology and Metabolism, Chonnam National University Medical School, GwangJu, Republic of Korea.

Background and aims: Measurement of pulse wave velocity (PWV) is a useful non-invasive index of arterial distensibility, and predicts cardiovascular morbidity and mortality. Several studies demonstrated positive relationships between obesity and PWV in non-diabetic and type 2 diabetic patients. Although waist circumference (WC) is a fairly good indicator of the amount of total abdominal fat, it cannot distinguish the amount of visceral fat from the amount of subcutaneous abdominal fat. Ultrasound (US) measurements have been recently shown to correlate better with cardiometabolic risk factors than anthropometric measurements. We investigated the associations of PWV with obesity-related parameters including body mass index, WC, and US-measured visceral fat thickness (VFT) in type 2 diabetic subjects.
Materials and methods: 245 type 2 diabetic patients participated in the study: 131 men (mean age 58.8±12.4 years) and 114 women (mean age 60.0±13.0 years). Anthropometric, clinical, and laboratory data were measured. US procedures were performed by the same examiner using a 3.5-MHz probe. US-determined VFT was defined as the distance between the internal face of the rectus abdominis muscle and the anterior wall of the aorta. The PWV was measured between the brachial and ankle regions (baPWV), and the baPWV was measured in all patients using a waveform analyser.
Results: Strong positive correlations existed between VFT and BMI, VFT and WC, and BMI and WC ($r = 0.68$, $r = 0.79$, $r = 0.81$, respectively, $p<0.01$). The baPWV was significantly ($P<0.05$) higher in subjects with general obesity (BMI ≥ 25 kg/m^2) (1794±317 cm/s) as compared with those without general obesity (BMI < 25 kg/m^2) (1584±261 cm/s). Age ($r = 0.412$; $p< 0.01$), duration of diabetes ($r = 0.300$; $p< 0.05$), WC ($r = 0.235$; $p< 0.05$), and US-determined VFT ($r = 0.294$; $p< 0.01$) were significantly correlated with baPWV. But BMI, lipid profiles, HbA_{1C}, and systolic and diastolic BP were not correlated with baPWV. Multiple logistic regression analyses showed that the baPWV was independently associated with age ($p<0.05$) and US-measured VFT ($p<0.05$), but not WC when adjusted for various confounding factors.
Conclusion: Our data suggests that the baPWV appears to be associated with VFT measured by ultrasonography more closely than with BMI and WC in type 2 diabetic patients.

Sustained improvement of glycaemic control reduces urinary leukotriene E_4 excretion in patients with type 1 diabetes
R. Boizel[1], G. Bruttmann[1], P.-Y. Benhamou[1], S. Halimi[1], F. Stanke-Labesque[2];
[1]Endocrinology Diabetes Nutrition, [2]Pharmacology and HP2 Inserm ESPRI EA3745, CHU de Grenoble, France.

Background and aims: The development of atherosclerosis is multifactorial. The increased risk of cardiovascular disease (CVD) among patients with either type of diabetes is only partially explained by traditional risk factors, there is substantial evidence linking chronic hyperglycemia to an increased risk. Recently, the DCCT-EDIC and 10-year UKPDS follow-up support the importance of glucose lowering in reducing the risk of coronary events; indeed CVD might be more strongly glucose mediated in type 1 diabetes and intervening on blood glucose could ameliorate CVD to a greater extent in type 1 than in type 2 diabetes. Compelling evidences suggest a role of the 5-lipoxygenase pathway (5-Lox) in the pathogenesis of CVD. This pathway generates leukotrienes that possess vasoactive, chemotactic and pro-inflammatory properties. Increased urinary leukotriene E_4 excretion (LTE_4-UE) has been reported in patients with poorly controlled diabetes. Therefore the effect of an intensive glucose strategy on LTE_4-UE was investigated prospectively.
Materials and methods: Intensive therapy (education program and revised insulin dosing or insulin initiation) was decided in 20 type 1 (T1) and 19 type 2 (T2) consecutive patients with A1c > 8.5% (age 35 and 60 y, diabetes duration 14 and 11 y, retinopathy 40 and 26% respectively, 44% of T2 previously

treated with insulin). Concomitant conditions known to be associated with an increased LTE_4 production were exclusion criteria. LTE_4 and 11 dehydro TXB_2 were measured at baseline and day 90±10 (LCMS/MS, pg/mg creatinine, data shown as Inter Quartile Ranges).
Results: A1c (7.9±1.1 vs. 9,7±1.4) and LTE4-UE (IQR: 25 - 44 - 65 vs. 39 - 63 - 99, p=0.008) decreased in T1 vs baseline. The changes in A1c and LTE_4-UE were correlated with baseline A1c (r: 0.72 and 0.69, p<0.02 and <0.005). In a subset of 11 T1, an additional sampling was possible on day 5 (LTE_4 UE not different vs. baseline: 32 - 52 - 87 vs. 36 - 56 - 98). LTE_4-UE was unchanged in T2 (IQR: 39 - 64 - 94 vs. 57 - 65 - 97) despite a similar change in A1c (7.5 vs. 10.1) vs. baseline. TXB_2-UE significantly decreased in T1 (426 - 574 - 759 vs. 577 - 766 - 1123) and T2 (151 - 380 - 750 vs. 551 - 829 -1490), whereas hs-CRP (higher in T2) and s-ICAM were unchanged vs. baseline.
Conclusion: Results suggest that hyperglycemia induces a reversible activation of the 5-Lox pathway in type 1 diabetes that is consistent with CVD appearing strongly glucose-mediated in this type of diabetes. A similar 3-month improvement of hyperglycemia did not change LTE_4-UE in T2, which suggest that the activation of the cysteinyl leukotriene pathway is multifactorial in this type of diabetes associated with complex underlying inflammation (NCT00324792)

Risk factors for vulnerable plaque rupture in patients with type 2 diabetes and acute coronary syndrome with ST elevation
D. Milosz[1], L. Czupryniak[1], M. Saryusz-Wolska[1], G. Zasadzinska[1], A. Borkowska[1], E. Cieplucha[2], K. Chizynski[2], J. Loba[1];
[1]Diabetology & Metabolic Disease Dept, [2]Invasive Cardiology Department, Medical University of Lodz, Poland.

Background and aims: Type 2 diabetes is an independent risk factor for cardiovascular disease, in particular coronary artery disease. Rupture of unstable atherosclerotic plaque and thrombus formation results in the acute coronary syndrome (ACS). Risk factors for rupture of a vulnerable plaque include sudden increase in arterial blood-pressure, vasospasmus reaction and inflammatory reaction. Main destabilizers of atherosclerosis plaque are metaloproteinases - MMP-9. Vasoprotective factors include adiponectin, a cytokine with a diverse antiatherosclerotic activity. The aim of the study was to assess relationship between elevation of MMP-9 concentrations, selected inflammatory markers: visfatin, TNFα, IL6 and adiponectin in patients with type 2 diabetes and ST-elevation in acute coronary syndrome in relation to the severity of lesion in coronary arteries.
Materials and methods: 90 subjects were enrolled into the study: 55 women and 35 men with type 2 diabetes treated with sulphonylurea derivatives, diagnosed with ACS with ST-segment elevation, who underwent percutaneous coronary angioplasty. The patient were divided into two groups based on the Gensini Score (GS): the study group - 50 patients (31 women, 19 men, mean age 66±9,5 years, with severe atherosclerosis, GS>32 points [more advanced]), control group - 40 patients (24 women, 16 men, mean age 65±10 years, with less severe atherosclerosis, GS<32 points). Within 12 hours since ACS MMP-9, visfatin, TNFα, IL6, adiponectin, HbA1C were measured in the patients. Glucose and insulin levels and lipids profiles were obtained after overnight fast conditions
Results: There were no significant differences in gender, age BMI, WHR, waist, lipids profiles, HOMA-IR nor in hypertension or smoking prevalence between the two groups. The duration of type 2 diabetes was significantly longer in the study group than in the controls (6.3±2.4 vs 3.4±2.2years; p<0.05). Mean HbA1c in the study group was 7.8±1.9% vs 6,7±1,7% in the controls (p<0.05). STEMI patients with more advanced lesions presented with a significantly higher plasma MMP-9 (1112±503 vs 349±288 ng/ml; p<0.05), visfatin (187±65 vs 116±44 ng/ml; p<0,05), TNFα (62±20 vs 53±20 pg/ml; p<0.05), IL6 (17.1±14 vs 8.1±3.5 pg/ml; p<0.05) and lower adiponectin concentration (5.1±4.4 vs 8.7±3.4 mcg/ml; p<0.05) as compared to the controls.
Conclusion: Severity of inflammatory process and hypoadiponectinemia could contribute to the progression of atherosclerosis lesions in the coronary arteries in patients with type 2 diabetes.

Chemerin is associated with markers of inflammation and components of the metabolic syndrome but does not predict coronary atherosclerosis
U.C. Brödl[1], M. Lehrke[1], A. Becker[2], M. Greif[2], R. Stark[3], R.P. Laubender[4], F. von Ziegler[2], C. Lebherz[2], J. Tittus[2], M. Reiser[5], C. Becker[5], B. Göke[1], A.W. Leber[2], K.G. Parhofer[1];
[1]Department of Internal Medicine II, University of Munich, [2]Department of Internal Medicine I, University of Munich, [3]Helmholtz Zentrum, Munich, [4]IBE, University of Munich, [5]Department of Radiology, University of Munich, Germany.

Background and aims: Chemerin is a recently discovered adipokine that regulates adipocyte differentiation and modulates chemotaxis and activation of dendritic cells and macrophages. Given the convergence of adipocyte and macrophage function, chemerin may provide an interesting link between obesity, inflammation and atherosclerosis in humans. We sought to examine the relationship of 1) chemerin and markers of inflammation, 2) chemerin and components of the metabolic syndrome, and 3) chemerin and coronary atherosclerotic plaque burden and morphology.
Materials and methods: Serum chemerin levels were determined in 303 patients with stable typical or atypical chest pain who underwent dual-source multi-slice CT-angiography to exclude coronary artery stenosis. Atherosclerotic plaques were classified as calcified, mixed or non-calcified.
Results: Chemerin levels were highly correlated with hsCRP (r=0.44, p<0.0001), IL-6 (r=0.18, p=0.002), TNF-α (r=0.24, p<0.0001), resistin (r=0.28, p<0.0001) and leptin (r=0.36, p<0.0001) concentrations. Furthermore, chemerin was associated with components of the metabolic syndrome including BMI (r=0.23, p=0.0002), triglycerides (r=0.29, p<0.0001), HDL-C (r=-0.18, p=0.003) and hypertension (p<0.0001). In bivariate analysis, chemerin levels weakly correlated with coronary plaque burden (r=0.16, p=0.006) and the number of non-calcified plaques (r=0.14, p=0.02). These associations, however, were lost after adjusting for established cardiovascular risk factors (OR 1.17, 95%CI 0.97 to 1.41, p=0.11 for coronary plaque burden; OR 1.06, 95%CI 0.96 to 1.17, p=0.22 for non-calcified plaques).
Conclusion: Chemerin is strongly associated with markers of inflammation and components of the metabolic syndrome. Chemerin, however, does not predict coronary atherosclerosis.

Fibulin-1, a novel molecular marker for arterial disease in diabetes?
C. Cangemi[1], V. Skov[1], J.A. Funder[2], M.L. Hansen[3], J. Aagaard[2], V.E. Hjortdal[2], M. Olesen[1], L.M. Rasmussen[1];
[1]Department of Biochemistry, Genetics, and Pharmacology, University of Southern Denmark, Odense, [2]Department of Thoracic and Cardiac Surgery, Aarhus University Hospital, [3]Department of Thoracic and Cardiac Surgery, Odense University Hospital, Denmark.

Background and aims: Cardiovascular diseases are frequently seen in diabetes, principally because of accelerated development of atherosclerotic plaques in the arterial wall. We have recently identified a cluster of dysregulated genes at the mRNA level in non-atherosclerotic tissue from patients with type 2 diabetes using global gene expression profiling. The dysregulated genes may represent markers for pre-atherosclerotic arterial changes in diabetes and the most upregulated in diabetes was fibulin-1 (FBLN1). FBLN1 is a secreted glycoprotein of the extracellular matrix, localized in the neighbourhood of elastic fibres, but it is also a plasma protein. In this study we investigated the distribution of FBLN1 in arterial wall and the concentration in plasma from patients with diabetes *in vivo*, and in addition studied the influence of relevant factors on the production of FBLN1 *in vitro*.
Materials and methods: Patients undergoing artery by-pass graft surgery at Aarhus and Odense University Hospitals were recruited. Participants included ten men with more than 2 years known duration of type 2 diabetes, defined as known diabetes diagnosed after adolescence, and eleven non-diabetic individuals matched according to sex and age. From each subject, the waste part of the repair artery i.e. *arteria mammaria interna* was obtained and quickly dissected into intima-media and surrounding tissue. For immunohistochemistry, in total nine of the tissues from diabetic patients and eleven from non-diabetic were used. The day before operation, HbA1c, fasting glucose and lipids were measured and plasma were gathered for FBLN1 measurement (immunoassay). For *in vitro* studies, primary human vascular smooth muscle cells (HVSMCs) cultures were used as *in vitro* model of arterial physiology. HVSMCs were established from explants of healthy aortic tis-

sue obtained from excess donors' vasculature at kidney transplant operations. HVSMCs were stimulated using various substances of relevance and FBLN1 mRNA and the protein expression levels were measured *via* RT-qPCR and *via* Western blotting and ELISA respectively.
Results: Immunohistochemical studies showed a high concentration of FBLN1 in the arterial wall throughout all the tunicae with a distinct distribution in close relation with elastic fibres. Semi-quantitative analysis revealed a significantly higher amount of FBLN1 at the media/adventitia boundary, in relation to the external elastic membranes. ELISA immunoassay of serum samples showed a significant higher concentration of circulating FBLN1 in diabetic patients. *In vitro* studies, with HVSMCs, pointed at a possible up-regulation of FBLN1 at the protein level following stimulation with BMP-4 and at a possible regulatory role of progesterone on FBLN1. However we did not find influences of insulin and glucose.
Conclusion: FBLN1 occurs in higher amounts both in normal appearing arterial tissue and in plasma from patients with diabetes and therefore appears as a candidate biomarker for early changes of diabetic artery. The pathophysiological role of FBLN1 in diabetes demands further investigations.

Functional roles of transcriptional factor mafB *in vivo* assessed by siRNA technique and microarray analysis
M. Tsuchiya[1], A. Suzuki[1], A. Hayashi[1], J. Tanaka[1], K. Tsuchiya[2], A. Maeda[1]; [1]Institute of Geriatrics, [2]Department of Medicine IV, Tokyo Women's Medical Unversity, Japan.

Background and aims: Maf is a family of transcription factor proteins characterized by a typical bZip structure, and its members have been reported to regulate developmental processes, cell differentiation, and the establishment of endocrine and non-endocrine cell function in the pancreas. It is well known that mafA is a strong transactivator of insulin, whereas mafB activates glucagon gene expression. However, mafs have been speculated to have multiple functions, especially in the networking of glucose, lipid, and energy balance. Previously, we reported that mafA suppression alternated gene expression profile not only in the pancreas but also in adipose tissue and central nervous system. Since less information is available regarding mafB than mafA, the aim of this study was to elucidate the role of mafB in tissues and organs, including the pancreas.
Materials and methods: We have established an mRNA interference technique that makes it possible to modify the level of targeted mRNAs in the mouse *in vivo*. An expression vector carrying synthetic maf-siRNA was rapidly injected into the tail vein of 8-week-old-mice (n=5), and the resulting alterations of the gene profile were analyzed with a microarray system. The role of mafB and cross-talk between the mafs in the pancreas and other tissues was explored by performing a microarray analysis (Afymetrix) to characterize the gene expression profile, and the level of each transcript was confirmed by real-time PCR.
Results: The level of mafB expression in the pancreas, and in the kidney of the siRNA-treated mice was approximately 50% less than in the stop-siRNA-treated animals. Interference with the mafB mRNA level in the pancreas by siRNA resulted in changes in the level of expression of several genes, including down-regulation of the genes coding glucagon and lipocalin 2 and up-regulation of the genes coding Ddit3 and Nurpr1. MafB mRNA suppression in the kidney of the siRNA-treated mice revealed that genes related to the immune response and lipid or iron metabolism were down-regulated, that genes coding complement component C3, lipocalin2 and fibrinogen Bβ/Aα polypeptide were markedly down regulated (to~1/10), that the genes coding clusterin, serine protease inhibitor 1-1 were also down-regulated, and that the genes coding serumglucocorticoid regulated kinase (Sgk) and thioether S-methyltransferase (Temt) were up-regulated. MafB may regulate not only endocrine hormones in the pancreas, but genes coding inflammation and immune-response-related functions and lipid metabolism in the pancreas and kidney as well. Lipocalin 2, which is abundantly expressed in the kidney, Ngal, has been reported to promote insulin resistance, whose expression was likely to be regulated by mafB. The effects of mafB suppression were pancreas- and kidney-specific or unknown, so other organs, especially adipose tissue are under examination, but the overall actions of mafB in regard to glucose and lipid metabolism are in the opposite direction to those of mafA. Preliminary evidence shows that c-maf, another maf that regulates glucagon expression, tends to have effects on gene profiling similar but with some of them are not overlapping, to those observed by mafB suppression.
Conclusion: Taken together, the findings in this study suggested potential roles of mafB in glucose/lipid metabolism or inflammatory reaction in the kidney as well as in the pancreas.

Long time culture of human aortic smooth muscle cells in high glucose concentration up-regulates ERK1/2 activation and PTP1B protein expression
L.-D. Popov[1], M. Nemecz[2], M. Dumitrescu[2], A. Georgescu[2], F.D. Böhmer[3]; [1]Vascular Dysfunction in Diabetes, Institute of Cellular Biology and Pathology "N. Simionescu", Bucharest, Romania, [2]Vascular Dysfunction in Diabetes, Institute of Cellular Biology and Pathology, Bucharest, Romania, [3]Center for Molecular Biomedicine, Institute of Molecular Cell Biology, Friederich Schiller University, Jena, Germany.

Background and aims: Recent studies have provided important insights into hyperglycemia-induced signaling dysregulation in vascular smooth muscle cells (SMCs), shedding light on activated phosphorylation cascades, and on their regulation by dephosphorylation reactions exerted by phosphatases. This study aimed to investigate the effect of long time (7 days) exposure to high glucose concentration (22.5 mM and 30mM D-glucose) on multilayered human aortic SMCs with the intent to mimic situation in type 2 diabetes in which vascular wall is exposed for long term to circulating hyperglycemia; cells grown for 12 days in 5.5mM D-glucose were used as control (low glucose condition).
Methods: The level of PI3-kinase, Akt and ERK1/2 phosphorylation, as well as of PTP1B, an enzyme regulating tyrosine phosphorylation-linked signaling events were examined comparatively in oxidant (1mM H2O2, for 10 min) and insulin (1μM, for 10 min) stimulated cells. Immunoblotting and immunofluorescence techniques have been used.
Results: The results show that compared to low glucose condition, long time exposure of multilayered SMCs to high glucose induced: (i) down-regulation of PI3-kinase and Akt pathways, and (ii) up-regulation of ERK1/2 phosphorylation and of PTP1B protein expression. Cells in high glucose exposed to oxidative stress conditions displayed (vs. non-stimulated cells): (i) decreased viability, proliferation, and p-nitrophenyl phosphatase enzymatic activity that was partly recovered in the presence of reducing DTT (20 mM), and (ii) activation of PI3-kinase, Akt, and ERK1/2. Stimulated with insulin in high glucose conditions, SMCs showed (vs. non-stimulated cells): activation of PI3-kinase, Akt, and ERK1/2 and down-regulation of PTP1B protein level, while augmenting the enzymatic activity of p-nitrophenyl phosphatase in cell lysates.
Conclusion: In conclusion, increased ERK1/2 phosphorylation and PTP1B protein expression are the common events produced at long term exposure of multilayered SMCs to high glucose concentration, as well as after stimulation by oxidative stress and insulin; the latter induced activation of PI3-kinase, Akt, and ERK1/2, while down-regulating PTP1B protein level.

Vascular effects of sphingomyelinase
A. Párkányi, É. Ruisanchez, K. Fekete, B. Horváth, P. Sándor, Z. Benyó; Institute of Human Physiology and Clinical Experimental Research, Semmelweis University, Budapest, Hungary.

Background and aims: Sphingolipids, derived from sphingomyelin metabolism, have been implicated as important mediators of inflammatory processes in diabetes. The first step of sphingolipid biosynthesis is catalyzed by sphingomyelinase (SMase) enzymes which are reportedly upregulated in diabetes. In the present study we aimed to analyze the vascular effects of SMase and sphingosine-1-phosphate (S1P).
Materials and methods: The experiments have been carried out in thoracic aorta segments isolated from adult male C57Bl/6 mice. Vascular reactivity has been analyzed in vitro by isometric tension recording. After a 60-min equilibration period a reference-contraction has been induced by 124 mM K^+. Thereafter functional integrity of the endothelium has been tested by NO-mediated relaxations induced by acetylcholine after precontraction of the vessels with 10 μM phenylephrine (PE). Finally, the vascular effects of neutral SMase and S1P have been determined without and at two levels of precontraction induced by 0.1 or 10 μM PE. SMase- and S1P-induced con-

tractile and relaxant responses are presented as mean±SEM percentage of the K^+-induced reference-contraction and the PE-induced precontraction, respectively.
Results: The vascular effects of SMase and S1P were highly dependent on the level of precontraction: they induced contraction and relaxation in the absence and presence of 10 μM PE, respectively. After moderate precontraction induced by 0.1 μM PE, both SMase and S1P evoked a biphasic vascular reaction with an initial contraction and subsequent relaxation. These effects were dose-dependent and the maximal responses were induced by 0.2 U/ml SMase and 10 μM S1P. Inhibition of the final step of S1P synthesis by 10 μM sphingosine kinase inhibitor (SKI) decreased the contractile effect of 0.2 U/ml SMase from 32±7 to 14±3 % ($p<0.05$) while increased SMase-induced relaxation from 63±9 to 87±7 % ($p<0.05$). In contrast, inhibition of NO synthesis by 100 μM N^G-nitro-L-arginine methyl ester (L-NAME) increased the contractile effect of 0.2 U/ml SMase from 20±4 to 64±7 % ($p<0.001$) while decreased SMase-induced relaxation from 45±6 to 0±0 % ($p<0.01$).
Conclusion: Both SMase and S1P induce biphasic changes of the vascular tension with an initial contraction and subsequent relaxation. The contractile effect of SMase appears to be mediated by S1P. However, SMase-induced vasorelaxation is induced by a yet unidentified sphingolipid and mediated by NO. In case of diminished bioavailability of NO, like in type 2 diabetes, the vasoconstrictor effect of SMase may become dominant and contribute to the development of vascular dysfunction. SKI appears to be able to prevent the contractile effect of SMase without negatively influencing its vasorelaxant action.

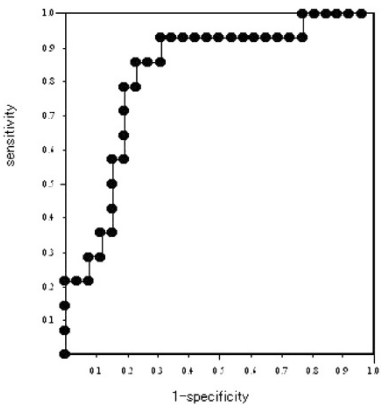
Serum levels of endothelial monocyte-activating polypeptide-II in type 2 diabetes
L. Mogylnytska;
Regional Hospital, Endocrinologist, Khmelnitsky, Ukraine.

Background and aims: Endothelial dysfunction is implicated in the pathogenesis of diabetes and atherosclerosis. Endothelial monocyte-activating polypeptide-II (EMAP-II) is a multifunctional polypeptide with proinflammatory and antiangiogenic activity. EMAP-II induces procoagulant activity on the surface of endothelial cells, increases expression of E- and P-selectins and tumor necrosis factor-1, directs migration of monocytes and neutrophils, induces apoptosis in endothelial cells. However, the role of this cytokines in diabetes is not understood. The aim of this study was to investigate serum level of EMAP-II in obese and non-obese patients with type 2 diabetes.
Materials and methods: We studied 34 obese diabetic patients (age: 50,36±1,62; BMI: 36,5±1,24); 34 non-obese diabetic patients(age: 52,9±1,69; BMI: 24,3±0,42); 22 obese non-diabetic subjects (age: 50,28±1,24; BMI: 37,95±1,8) and 22 control subjects (age: 49,4±0,4; BMI: 24,03±0,61). Serum levels of EMAP-II were determined by immunoenzyme assay. Statistical analysis was performed by use Student's test and Person's. The data were presented as means±SD.
Results: We found an increase of serum level of EMAP-II in obese diabetic patients compared to obese subjects without diabetes (4,44±0,58 and 2,41±0,47ng/ml , respectively, p=0,006), also, in non-obese diabetic patients compared to control subjects (4,23±0,94 and 1,26±0,31 ng/ml respectively, p=0,005). Moreover, it was significant elevation of serum EMAP-II in obese patients without diabetes compared to control subjects (2,41±0,47 and 1,26±0,31ng/ml respectively, p<0,02). In obese and non-obese patients with diabetes it was significant correlation between HbAc1, blood glucose and EMAP-II levels (r=0,58, r=0,69 and 0,56, r=0,67 respectively, p<0,05), also between total cholesterol, triglycerides and EMAP-II (r=0,57, 0,44 and r=0,68, r=0,29, respectively p<0,05). In obese non-diabetic patients it was significant correlation between BMI, triglycerides, total cholesterol and EMAP-II (r=0,7, r=0,39, r=0,44, respectively, p<0,05).
Conclusion: The revealed change of EMAP-II serum level reflects an endothelial dysfunction in patients with type 2 diabetes. Hyperglycemia, dyslipidemia and obesity appear to be significant factor to contributing elevation of EMAP-II.

1339

N-terminal fragment of pro-brain natriuretic peptide (NTproBNP) has a high negative predictive value to rule-out silent myocardial ischaemia (SMI) in type 2 diabetes mellitus
K. Hamano[1], M. Abe[1], R. Komi[1], J. Branch[2], S. Kobayashi[3];
[1]Diabetes and Endocrinology, [2]General Internal Medicine, [3]Nephrology, Shonan Kamakura General Hospital, Kamakura, Japan.

Background and aims: Early identification of cardiovascular risk is of vital importance for comprehensive diabetes management, since it allows early, targeted intervention. Screening for kidney and retinal complications has already been established, but there is no comparable screening for cardiac complications. Data about the significance of NT-proBNP in type 2 diabetes are limited. It is reported that NT-proBNP is elevated in type 2 diabetic patients reflecting asymptomatic left ventricular dysfunction and is also a strong predictor of the cardiovascular mortality in diabetes independent of conventional cardiovascular risk factors. With consideration to causality, we hypothesized that NT-proBNP might be a marker for SMI in diabetes.
Materials and methods: Forty type 2 diabetic subjects without evident coronary artery disease history or symptoms were consecutively recruited. There were essentially no singns of ischemia in their resting ECG. Serum NT-proBNP (ECLusys pro BNP) were measured and multislice CT (MSCT) of the coronary arteries were performed. Additional coronary angiographies were performed on subjects with positive MSCT findings.
Results: The patients' mean age, HbA1c and serum creatinine were 64.7, 8.33% and 0.78mg/dl respectively. Fourteen patients (35%) had SMI (defined as >50% significant stenosis of coronary arteries demonstrated by coronary angiographies). NT-proBNP levels were significantly higher in SMI(167.2±44.0 vs. 62.4 ±11.8 pg/ml,mean±SE, p<0.005) but HbA1c, lipid profiles and creatinine were similar in two groups. SMI subjects were older(70.4±2.0vs. 61.9±1.9,p<0.01), however, by after adjustment for age, HbA1c, creatinine, log NT-proBNP was identified as an independent predictor of SMI(p=0.025).
ROC analysis with a cut-off value of 52.06pg/ml showed 92.8% sensitivity and 69% specificity of predicting SMI (positive predictive value 61.9%, negative predictive value 94.7%).
Conclusion: As a biochemical screening tool for investigating SMI, NT-proBNP is useful because of its non-invasiveness and low cost. Its outstanding high negative predictive value in ruling out SMI enables the clinician to focus on high coronary risk patients within a large diabetic population.



PS 127 Cardiovascular disease - early detection and prevention

Role of physical activity on endothelial function of healthy subjects

L. Franzini[1], D. Ardigò[1], A. Dei Cas[1], S. Haddoub[1], S. Valtueña[1], F. Brighenti[2], I. Zavaroni[1];
[1]Internal Medicine and Biomedical Sciences, [2]Public Health, University of Parma, Italy.

Background and aims: A moderate physical activity is considered a protective factor against cardiovascular disease and a sedentary life style is associated to endothelial dysfunction, the first step to atherosclerosis. Nevertheless, it is still unclear to which extent a decreased active energy expenditure (EE) relates to the presence of subclinical cardiovascular disease, also because of the lack of reliable systems to continuously measure spontaneous EE .
The aim of our study was to evaluate the relationship between average EE, assessed by continuous monitoring with a validated wearable device (Armband, SenseWear), and endothelial function (EF), the earliest vascular abnormality related to cardiovascular disease, in a cohort of healthy young adults.
Materials and methods: To quantify endothelial function we performed a brachial artery Flow Mediated Dilatation (FMD) test, a non invasive, ultrasound-based technique, that records the endothelial vasodilatation of conduit arteries. As EE measurement we evaluated average Metabolic Equivalents (aMETS), spent over a one week period with the support of Armband SenseWear device. To evaluate the relationship between energy expenditure and endothelial function, we enrolled a population of 157 healthy volunteers (87 M; 70F, age =37 ± 8 years), after having excluded diagnosis of diabetes, previous cardiovascular events and other relevant diseases.
Results: Stratifying the study population by FMD quartiles, we observed that a worse endothelial function (lowest FMD quartiles) was significantly associated with a greater prevalence of male gender, smoking habit, and lower both average hours of sleep in the week in which armband was dressed and the number os hours of sleep the night before FMD test. Besides, a reduced endothelial vasodilatation was associated to higher values of BMI, waist circumference, and systolic blood pressure ($p< 0.05$ for all), as well as a bigger baseline Brachial Diameter ($p<0.01$) and significantly lower aMETS and average steps ($p<0.05$ for both). A multivariate linear regression analysis confirmed the presence of an independent relationship between aMETS and FMD, and a prediction model including average METS, the hours of sleeping the night before the test and brachial artery diameter was able to account for almost 20% of the variability in FMD values.
Conclusion: The spontaneous average physical activity, together with the hours of sleep and the brachial artery diameter (strictly correlated with gender) independently predicts the presence of endothelial dysfunction, a marker of subclinical atherosclerosis, in a population of apparently healthy young adults.

Effect of exercise training on cardiopulmonary functions in type 2 diabetic rats during endotoxaemia

C.-H. Hung[1], M.-C. Kao[1], Y.-W. Chen[2];
[1]Department of Physical Therapy, National Cheng Kung University,
[2]Department of Physical Therapy & Graduate Institute of Rehabilitation Science, China Medical University, Tainan, Taiwan.

Background and aims: Diabetic patients are susceptible to E. coli lipopolysaccharide (LPS) infection, resulting in endotoxemia with cardiopulmonary failure and high mortality rate. However, heat shock protein 72 (HSP72) overexpression could reduce the mortality rate and organ damage in septic shock and attenuate hemodynamic alterations due to LPS. We have demonstrated that HSP72 can be detected in various organs from normal and type I diabetic rats with exercise training. Therefore, the purpose of the current study was to characterize effects of exercise preconditioning on endotoxemia-induced cardiopulmonary dysfunction in the rat model of type 2 diabetes.
Materials and methods: Male Wistar rat fed 60% fructose-rich chow for 6-8 weeks. When loss of plasma glucose lowering response to tolbutamide were considered as type 2 diabetes with insulin resistance and randomly assigned to sedentary or exercise groups. The trained rats run gradually on a treadmill 5 days/week, 30-60 min/day with intensity 20-30m/min for 4 weeks. Twenty-four hours after the last exercise session, we compared the temporal profiles of mean arterial pressure, heart rate, cardiac output, and stroke volume of urethane-anesthetized rats after intravenous injection of LPS. At the 4th hour after LPS injection, we determined arterial blood gas, tumor necrosis factor-alpha level in serum and lavage, and lung edema. In addition, the HSP72 expression in multiple organs were determined in different groups.
Results: After exercise training, we found that HSP72 expression in multiple organs were significantly greater in rats with exercise training than sedentary rats. The survival time was significantly longer in exercised-diabetic rat than that in sedentary diabetic rats after administration of LPS (260.0 ± 23.8 min versus 712.8 ± 69.9 min, $P < 0.05$). Tumor necrosis factor-alpha level in serum were significantly lower in diabetic rats with exercise preconditioning than those in diabetic rats without exercise training (22.08 ± 14.09 pg/ml versus 0.09 ± 0.03 pg/ml, $P < 0.05$). In addition, prior exercise training could significantly diminish cardiovascular dysfunction in diabetic rats during endotoxemia.
Conclusion: Exercise training could overexpress HSP72 in multiple organs, prolong the survival time, ameliorate the survival rate and cardiopulmonary functions of type 2 diabetic rats.

Circulating endothelial progenitor cells (EPC) and endothelial function in subjects with normal, impaired and diabetic glucose tolerance

L. Pucci[1], D. Lucchesi[1], E. Storti[1], R. Vanacore[2], M. Iorio[2], E. Russo[1], C. Bianchi[1], A.G. Daniele[1], S. Taddei[3], L. Ghiadoni[3], R. Miccoli[1], S. Del Prato[1], G. Penno[1];
[1]Endocrinology and Metabolism, [2]Blood Bank, [3]Dept. of Internal Medicine, University of Pisa, Italy.

Background and aims: Endothelium is the key regulator of vascular homeostasis. Endothelial dysfunction occurs early in diabetes and reduced number and impaired function of EPC has been described even in nondiabetic hyperglycemia. Our aims were: 1. to investigate the relationship between endothelial function and circulating EPC in subjects with normal (NGT), impaired and diabetic glucose tolerance; 2. to explore the impact of the G801A gene polymorphism of the mobilizing factor SDF-1α (stromal cell-derived factor-1α) on circulating SDF-1α, EPC levels and endothelial function.
Materials and methods: Brachial artery flow-mediated dilatation (FMD) and nitrate-induced dilatation (NID) were measured in 26 subjects with NGT (13 with, NGT/Fam+, and 13 without, NGT/Fam-, first degree family history of diabetes), 34 IFG and/or IGT, and 18 with screening-diagnosed diabetes (T2D). CD34+/KDR+ cells from peripheral blood were measured by flow cytometry as phenotype for circulating EPC. SDF-1α concentration was measured by ELISA assay and the G801A SDF-1-3'A polymorphism screened by PCR-RFLP and confirmed on PCR-DHPLC. Glucose and insulin levels in response to a 75-g oral glucose load were also obtained.
Results: The groups did not differ for gender, BMI, waist, dBP, total and LDL cholesterol, apoA1 and apoB, creatinine, cistatin C, γGT, fibrinogen, hs-CRP, SAA, and serum insulin. IFG/IGT and T2D were older than NGT (55±5 and 58±8 vs 45±10 years, $p<0.001$), had higher sBP ($p=0.001$), fasting-, 2h-OGTT- and AUC-glucose ($p<0.0001$), and HbA1c (6.0±0.4 and 6.5±0.6 vs 5.5±0.4%, $p<0.0001$), marginally higher triglycerides ($p=0.08$), and lower HDL cholesterol ($p=0.07$). NID was comparable in the four groups. FMD (and FMD/NID ratio, expression of the selective alteration of the endothelium-mediated dilatation) was lower in T2D (Δ% 4.4±3.3, m±sd), and in IFG/IGT (Δ% 6.0±2.8%) than in NGT (Δ% 7.9±3.6%, Kruskal-Wallis, $p=0.0017$) with no difference between NGT/Fam+ and NGT/Fam-. EPC pool was higher in NGT/Fam- (608±87 cells/ml, m±se), similarly reduced in NGT/Fam+ (457±68) and in IFG/IGT (440±53) and even lower in T2D (254±51 cells/ml, Kruskal-Wallis, $p=0.013$). Serum SDF-1α levels were modulated by the SDF-1α-3'A G801A polymorphism (GG, n. 45: 2522±430 pg/ml; A carriers, n. 33: 2220±572 pg/ml, $p<0.01$). Both FMD and EPC showed a negative correlation with fasting glucose ($r=-0.39$, $p=0.006$; $r=-0.20$, $p<0.05$), 2h-OGTT glucose ($r=-0.31$, $p=0.009$; $r=-0.25$, $p=0.03$), AUC glucose, and HbA1c ($r=-0.40$, $p=0.001$; $r=-0.24$, $p=0.03$). Logistic regression analysis revealed the SDF-1α-3' G/A variant to be a marginally significant ($p=0.09$) predictor of EPC level independent of HbA1c ($p=0.017$) or AUC-glucose ($p=0.022$), a role that was significant in IFG/IGT ($p<0.03$).
Conclusion: Our data suggest that: 1. both FMD as well EPC count are inversely related to the degree of hyperglycemia; 2. endothelial dysfunction and impairment in endothelial repair capacity, both early markers of macrovascular disease, are present in subjects with prediabetes; 3. EPC pool seems

to be impoverished even in NGT subjects with a positive family history for diabetes; 4. 3'G/A variant of SDF-1α, a recognized mobilizing factor for EPCs, may play an independent role in regulating EPC pool.

1343

Leukocyte telomere length correlates with subclinical atherosclerosis and is independently correlated with endothelial progenitor cell number in young adult healthy subjects

A. Dei Cas[1], V. Spigoni[1], L. Franzini[1], M. Preti[1], D. Ardigò[1], E. Derlindati[1], L. Monti[2], P. Dell'Era[3], L. Gnudi[4], I. Zavaroni[1];
[1]Department of Internal Medicine and Biomedical Sciences, University of Parma, Italy, [2]Cardio-Diabetes Core-Lab, Scientific Institute San Raffaele, Milan, Italy, [3]Department of Biomedical Sciences and Biotechnologies, University of Brescia, Italy, [4]Cardiovascular Division, King's College, London, United Kingdom.

Background and aims: Leukocyte telomere length (LTL) and endothelial progenitor cells (EPCs) are putative new cardiovascular (CV) markers. Telomeres, repeats of the DNA sequence necessary for chromosomal integrity, lose repeats with self-replication and therefore LTL is considered a marker of cellular senescence. EPCs are considered to play a key role in vessel repair following endothelial damage. LTL and EPC number are reduced in conditions characterized by increased CV risk such as diabetes. No studies are available to date investigating LTL in a population with low CV risk. Aim of the study was to evaluate LTL as novel CV risk factor and the possible correlation between LTL and EPC number in a population of young healthy adults.
Materials and methods: LTL was determined in 82 healthy subjects (49M/33F; age 37±9yrs), normotensive and not taking any medication. Fasting blood samples were drawn in all subjects for the determination of lipid profile, white blood count, high sensitive C-reactive protein (hsCRP), uric acid, PAI-1 and EPC number. EPCs were identified as cells positive for CD34, CD133 and Kinase insert Domain Receptor (KDR) cell-surface antigens by flow cytometry analysis. Mean and maximum Intima Media Thickness (IMT) (B-mode ultrasound) and Framingham Risk score (FRS) were evaluated in all subjects. LTL was assessed with a specific real-time PCR reaction in DNA samples isolated from Peripheral blood mononuclear cells (PBMCs). Data were analysed with Pearson correlation test. A multivariate analysis was performed to identify variables independently correlated to LTL.
Results: LTL resulted significantly inversely correlated with age (r-0.236; p<0.05), waist circumference (r=-0.28; p<0.001), triglycerides (r=-0.25; p<0.05), PAI-1 (r=-0.28; p<0.05), hsCRP (r=-0.23; p<0.05), IMT mean (r=-0.24; p<0.05), FRS (r=-0.28; p<0.05) and directly correlated with HDL-cholesterol (r=0.35; p<0.001) and EPC number (r=0.35; p<0.001). EPC number resulted also inversely correlated with the main CV risk factors as insulinaemia (r=-0.2; p<0.05), IMT (r=-0.318;p=0.010); PAI-1 (r-=0.197; p=0.030); FRS(r=-0.273;p=0.022). At a multivariate analysis, EPC number was associated with LTL independently of the other variables considered. Subjects were divided into two CV risk groups (higher LTL/EPC number) and (lower LTL/EPC number), the latter showed lower HDL-cholesterol (p<0.05), higher IMT (p<0.05), FRS (p<0.05) and PAI-1 (p<0.05) values compared to the lower risk group.
Conclusion: These data suggest that LTL and EPC number can be considered putative markers of CV risk and subclinical atherosclerosis also in a young adult healthy population with low CV risk. The independent correlation between LTL and EPC number suggests a shared mechanism of impairment and possible pathophysiological implications. The use in combination of the two markers might be a better indicator of subclinical atherosclerosis and of cumulative CV risk.

Polymorphism for gene of connexin 37 is associated with subclinical atherosclerosis in obese women from general population and in women with diabetes type 1

J. Pitha[1], P. Pithova[2], J.A. Hubacek[1];
[1]Institute for Clinical and Experimental Medicine, [2]Teaching Hospital Motol, Prague, Czech Republic.

Background and aims: Connexin 37 (Cx37) is a key protein in gap junctions, and thus important for inter-cell communication. Potential association of genetic polymorphism of Cx37 with atherosclerotic changes is matter of controversy and the proposed association of this gene with cardiovascular disease has not been proved so far. The aim of this study was to evaluate association of Cx37 gene with preclinical atherosclerosis in population of obese women from general population and in women with diabetes type 1.
Materials and methods: Women aged 45-55 representing 5% of population sample (n=892) and 102 women with diabetes type 1 aged 22-55 were genotyped for Cx37 C1019T polymorphism. Traditional cardiovascular risk factors were analyzed. Ankle/brachial blood pressure index (ABI) was measured and calculated in both groups by standardized method. The differences between carriers of different genotypes were evaluated by non-paired t-test and by test for trend (STATA). Traditional cardiovascular risk factors including smoking were also included into analyses.
Results: The prevalence of TT, CT and CC genotype in obese women from general population (body mass index more than 30 kg/m^2; n=157) was 8.3, 48.7, and 42.9 %. Similar prevalence was found in women with diabetes type 1 (11.8, 44.1, and 44.1 %). In obese women, significantly lower ABI was found in CC than in CT/TT carriers (1.024 ± 0.07 vs. 1.056± 0.09, p=0.018, p for trend 0.03). In women with diabetes type 1 and without impaired nutrition (body mass index more than 18.5 kg/m^2; n=98) similar results were obtained (0.979 ± 0.09 vs. 1.043 ± 0.2, p=0.043, p for trend= 0.065). In non-obese women from the population sample no such differences were found.
Conclusion: The gene for Cx37 was associated with preclinical atherosclerosis expressed as ankle/brachial blood pressure index in obese women from general population. Similar but weaker association was found in women with diabetes type 1.

Early atherosclerosis and dehydroepiandrosterone sulphate in patients with type 2 diabetes mellitus

M. Vasiliadis[1,2], M. Papaioakim[2], I. Heliopoulos[2], M. Toromanidou[2], M. Nikelli[2], T. Gioka[2], A. Tsiligiris[2], A. Tavridou[3], E. Pagkalos[1];
[1]1st Department of Internal Medicine, Papageorgiou General Hospital, Thessaloniki, [2]University General Hospital of Alexandroupolis, [3]Dep. of Pharmacology, Medical School, Alexandroupolis, Greece.

Background and aims: DHEA-S, the sulphated ester of dehydroepiandrosterone (DHEA), decreases with age in both sexes. It has been shown that this prohormone can increase the levels of nitric oxide (NO), improve insulin sensitivity and inhibit accumulation of cholesteryl ester in macrophages. Moreover, DHEA exerts an antioxidant effect on LDL. In humans, some studies showed an inverse correlation between DHEA-S and CHD, DHEA-S and atherosclerosis in men with type 2 DM, as well as with progression of atherosclerosis in healthy men and women.
To our knowledge, the association between endogenous DHEA-S and ultrasonographically measured common carotid intima-media thickness (CCIMT), a marker of preclinical atherosclerosis, in type 2 DM patients of both sexes has not been evaluated.
Materials and methods: Characteristics of participants are shown in table. DHEA-S was quantified using an electrochemiluminescent immunoassay (Coat-A DHEA-S Kit, ROCHE, Europe), on a fully automated sample selective analyzer (Elecsys 2010, Roche). High-resolution real-time ultrasonography with 7,5 MHz transducer was used to measure the left and right CCIMT. Traditional cardiovascular (CV) risk factors and alcohol use were also assessed. All participants provided written informed consent and the study was approved by the Local Ethical Committee.
Results: DHEA-S were negatively correlated with age (r=-0.278, p=0.05) and CCIMT (r= -236, p=0.002). Besides DHEA-S, CCIMT was correlated with age (r=0.325, p<0.001), systolic BP (r=0.248, p=0.001), diastolic BP (r=0.166, p=0.031) and duration of DM (r=0.169, p=0.028). In multiple regression analysis between CCIMT and several CV risk factors, DHEA-S, age, and BP were the only independent predictors of CCIMT (p values and standardized beta coefficients were for DHEA-S (log10) 0.002/-0.246, for age 0.016/0.200, and for BP 0.015/0.189).
Conclusion: In this cross-sectional study, endogenous DHEA-S levels were inversely related to CCIMT. This relationship was independent of other CVD risk factors. In our study, in agreement with other reports, CCIMT was positively associated with age and both systolic and diastolic BP. The age related decline of DHEA-S is negatively associated with CCIMT in both sexes, implicating a possible atheroprotective role of DHEA-S in patients with type 2 DM.

Acute restoration of euglyacemia improves endothelial reactivity in type 2 diabetes but alters relative contribution of nitric oxide to vasodilatation

A. Basu[1], D. Nandy[1], S. Lakshmi[2], T. Curry[2], R. Basu[1], R.A. Rizza[1], M.J. Joyner[2];
[1]Endocrinology,Metabolism & Nutrition, States, [2]Anesthesiology, Mayo Clinic College Of Medicine, Rochester, United States.

Background and aims: Endothelial dysfunction commonly occurs in type 2 diabetes (DM). We wished to determine the effects of acute restoration of euglycemia on forearm endothelial function.
Materials and methods: To do so we studied ten subjects with DM (age 56.5±2.5 yrs, DM duration 6.5±1.2 yrs, BMI 29.5±2.3 kg/m^2, HbA1c 7.2±0.2%), all on metformin 2000 mg/day. Venous occlusion plethysmography was used to measure brachial artery reactivity to intra-arterial graded infusions of acetylcholine (Ach) (2, 4 and 8 µg/100 ml forearm volume/min) and sodium nitroprusside (NTP) (0.5, 1 and 2 µg/100 ml forearm volume/min) before and after intra-arterial L-NMMA infusion. Measurements were recorded after an overnight fast at ambient hyperglycemia (glucose 9.8±0.7 mM; insulin 67.0±12.8 pM) and after 3 hours of euglycemia (glucose 5.5±0.1mM; insulin 131.5±11.8 pM) obtained with an insulin infusion.
Results: Baseline forearm blood flow was higher ($p<0.05$) in the presence of euglycemia then hyperglycemia (3.7±0.5 vs. 2.2±0.3 ml/100 ml/min). Peak Ach (i.e. endothelial dependent) vasodilatation also was greater ($p<0.05$) in the presence of euglycemia than hyperglycemia (14.8±2.3 vs. 10.9±1.7 ml/100 ml/min). On the other hand peak NTP induced (i.e. endothelium independent) vasodilatation did not differ in the presence of euglycemia and hyperglycemia (16.3±1.8 vs. 14.7±1.0 ml/100 ml/min). Of note, while L-NMMA inhibited ($p<0.01$) peak Ach mediated vasodilatation in the presence of hyperglycemia (8.0±1.7 vs. 10.9±1.7 ml/100 ml/min; post vs. pre L-NMMA), it did not alter Ach mediated vasodilatation in the presence of euglycemia (15.1±2.1 vs. 14.8±2.3 ml/100 ml/min; post vs. pre L-NMMA) implying a nitric oxide mediated effect in the presence of hyperglycemia but not in the presence of euglycemia. On the other hand, L-NMMA did not alter NTP mediated vasodilatation in the presence of either hyperglycemia (15.3±1.6 vs. 14.7±1.0 ml/100 ml/min) or euglycemia (17.7±1.7 vs. 16.3±1.8 ml/100 ml/min).
Conclusion: Thus, in people with DM, acute restoration of euglycemia improves Ach mediated vasodilatation via a non-nitric oxide mediated mechanism but does not alter NTP mediated vasodilatation.

High plasma fetuin-A is associated with increased carotid intima-media thickness in a middle-aged population

N. Stefan[1], C. Thamer[1], K. Rittig[1], A. Haupt[1], J. Machann[2], A. Peter[1], B. Balletshofer[1], A. Fritsche[1], H.-U. Haring[1];
[1]Medical Clinic IV, [2] Section on Experimental Radiology, Department of Diagnostic Radiology, University of Tuebingen, Germany.

Background and aims: The secreted liver protein fetuin-A (α2-Heremans-Schmid-glycoprotein, ASHG) is increased in fatty liver and is strongly associated with insulin resistance, and the metabolic syndrome. In addition, fetuin-A promotes a state of subclinical inflammation. Therefore, fetuin-A represents a possible candidate linking fatty liver to type 2 diabetes and atherosclerosis. We investigated whether elevated plasma fetuin-A levels are associated with increased intima-media thickness (IMT) of the common carotid artery in a middle-aged population at risk for type 2 diabetes, and therefore, may serve as an early biomarker of vascular defects.
Materials and methods: We studied 315 (121 males and 194 females) non-diabetic subjects at increased risk for type 2 diabetes and cardiovascular disease. IMT was measured with high resolution ultrasound (13 MHz). Total body fat was measured using magnetic resonance imaging.
Results: In a forward stepwise multivariate linear regression analysis including gender, age, total body fat, plasma fetuin-A levels, systolic and diastolic blood pressure, HDL-cholesterol and triglycerides as independent variables only age ($p<0.0001$), gender ($p<0.0001$), plasma fetuin-A ($p=0.04$) and HDL-cholesterol ($p=0.1$) predicted IMT at significance level of $p<0.15$. In an additional multivariate regression model, plasma fetuin-A was an independent predictor of IMT ($p=0.04$) after adjustment for the independent variables age, gender and HDL-cholesterol.
Conclusion: The present study provides novel evidence that high fetuin-A levels are independently associated with early anatomical changes of the vessel wall already in middle-aged subjects without manifest cardiovascular disease. Thus, plasma fetuin-A represents an interesting candidate in the pathophysiology of atherosclerotic lesions in patients at risk for type 2 diabetes and/or cardiovascular disease.

Impaired diffusing capacity for carbon monoxide in children and adolescents with type 1 diabetes: is this the first sign of long-term complications?

M. Morelli[1], A. Scaramuzza[1], M. Rizzi[2], S. Borgonovo[1], C. Mameli[1], L. Santoro[1], G. Zuccotti[1];
[1]Paediatrics, [2]Respiratory Medicine, University of Milano - Luigi Sacco Hospital, Milano, Italy.

Background and aims: The pathogenesis of diabetic complications is still matter of debate and is thought to involve both microangiopathic process and non enzymatic glycosylation of tissue proteins. The aim of our study was to assess the presence of lung dysfunction in adolescents with type 1 diabetes, and if the alteration of the pulmonary capacity depends more on the reduction of the diffusing capacity of the alveolar-capillary membrane or of the pulmonary capillary blood volume.
Materials and methods: We evaluated 42 consecutive young patients (23 males), ages 15±3 yrs, with type 1 diabetes for 8±5 yrs (height 164±12cm, weight 59±15 kg). As controls we evaluated 30 healthy age and sex-matched peers. Both patients and controls were non smokers and didn't report any lung disease. Lung volumes and spirometric dynamic parameters were assessed by plethysmography (VMAX277 Autobox V6200), performed in accordance with European Respiratory Society and American Thoracic Society criteria. Single-breath DLCO was measured according to the recommendation above mentioned. Double measurements were accepted when estimates of DLCO and effective alveolar volume differ by 5%. The interval between measurements was 5 min and the tests were performed in the standing position. The carbon monoxide transfer coefficient (KCO) was derived. The diffusing capacity of the alveolar-capillary membrane and the pulmonary capillary blood volume were calculated using the Roughton and Foster equation
Results: Anthropometric data and pulmonary function tests of the patients and controls are shown in the Table.
Conclusion: Lung volumes, the transfer factor (TLCO), KCO and the pulmonary capillary blood volume (Vc) were significantly reduced in young patients with type 1 diabetes when compared to controls. However, when differentiat-

ing the alveolar-capillary membrane component and the pulmonary capillary blood volume component, we observed a significant impairment only about pulmonary capillary blood volume component. If this might be seen as the 'first' sign of microangiopathic involvement in patients with type 1 diabetes have to be confirmed on larger groups but is still fascinating.

Anthropometric data and respiratory function vales in diabetes patients and controls.

Insulin sensitivity, hyperglycaemia and risk of all-cause mortality and cardiovascular disease events in the general population - the AusDiab study

E.L.M. Barr[1,2], A.J. Cameron[1,2], P.Z. Zimmet[1,2], B. Balkau[1,3], T.A. Welborn[4], A.M. Tonkin[2], J.E. Shaw[1,2];
[1]Department of Epidemiology and Clinical Diabetes, Baker IDI Heart and Diabetes Institute, Melbourne, Australia, [2]Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, Australia, [3]INSERM U780, Villejuif; University Paris-Sud, Orsay, France, [4]Department of Medicine, University of Western Australia, Crawley, Australia.

Background and aims: To assess the independent associations of insulin sensitivity, glucose and HbA_{1c} with all-cause mortality and cardiovascular disease (CVD) events in individuals without diagnosed diabetes.
Materials and methods: Between 1999-2000, baseline measures of fasting insulin, plasma glucose and lipids, two-hour plasma glucose, HbA_{1c}, blood pressure, self-reported medication use, smoking and history of CVD were collected from 8533 adults aged >35 years from the Australian Diabetes, Obesity and Lifestyle (AusDiab) study. Insulin sensitivity was estimated by the homeostasis model assessment (HOMA2-%S). Five year all-cause mortality and fatal or non-fatal CVD events were ascertained through linkage to the National Death Index and adjudication of medical records.
Results: After a median 5.0 years there were 277 deaths and 225 CVD events. HOMA2-%S was not associated with all-cause mortality. However, compared to those who were most insulin sensitive, the CVD (fatal or non-fatal) HR (95% CI) for quintiles of decreasing HOMA2-%S were 1.0 (0.6-1.8), 1.4 (0.9-2.3), 1.6 (1.0-2.5), 1.9 (1.2-3.0), adjusting for age and sex (p for trend <0.01). Smoking, CVD history, hypertension, lipid-lowering medication and total cholesterol attenuated this relationship; but the association was rendered non-significant by adding HDL-C (p for trend = 0.16). Fasting plasma glucose (FPG), but neither 2hPG nor HbA_{1c}, was significantly associated with CVD independent of HOMA2-%S.
Conclusion: In individuals without diagnosed diabetes, HOMA2-%S showed no association with all-cause mortality. The significant association between HOMA2-%S and CVD disappeared after adjusting for HDL-C. FPG was a significant predictor of CVD independent of HOMA2-%S.

1350

Five-year incidence of coronary heart disease in type 2 diabetes. Comparison with the predicted risk by Framingham and UKPDS engines

A. Kofinis, A. Thanopoulou, L. Milika, E. Dimaki, M. Noutsou, E. Spanou, B. Karamanos, A. Archimandritis;
Diabetes Centre, 2nd Department of Internal Medicine, National University of Athens, Hippokration, Greece.

Background and aims: To assess the incidence of Coronary Heart Disease (CHD) in patients with type 2 diabetes mellitus (T2DM) and its relation to various risk factors, as well as to assess the predictive value of Framingham and UKPDS risk engines in a Greek population of patients with T2DM.
Materials and methods: We followed 941 consecutive patients with T2DM, who were examined for the first time at the outpatient clinic. At the 5th year of follow-up complete data was available, for 886 of them (94.2%). At baseline 658 of the patients (47.6% men) did not have macroangiopathy and were included in the present analysis. The mean age was 58.3 years and median diabetes duration 5 years. Hypertension was present in 45.6%, dyslipidemia in 41.0%, while 47.9% of the patients were current or ex-smokers. CHD was diagnosed according to UKPDS criteria, based on ECG findings, myocardial infarction, coronary angioplasty or grafting or CHD mortality. HbA1c was measured at least 15 times during the 5 years of follow-up and lipid levels at least 5 times.
Results: The 5-year incidence of CHD was 6.8%, much lower than the predicted for this population by Framingham (10.01%, p<0.05) and UKPDS (9.99%, p<0.05) risk calculators. The above risk engines did not differ between them in risk prediction. At baseline, patients who later developed CHD did not

differ in sex, age, diabetes duration, BMI, blood pressure, lipid levels, HbA1c, hypertension and dyslipidemia prevalences and smoking habits from those who did not develop CHD. During follow-up, patients without CHD showed significant improvement from baseline in HbA1c (7,5vs7,1%), in lipid levels (Cholesterol 225vs214mg%, Triglycerides 161vs149mg%, LDL 149vs138 mg%) and creatinine (1,03vs0,97 mg%), p<0,01 for all. Patients who developed CHD shoed improvement only in triglyceride levels (212vs144 mg%).
Conclusion: a) The 5-year incidence of CHD in Greek patients with T2DM is significantly lower than that predicted by Framingham and UKPDS risk engines, meaning that these engines should be used with caution in the Greek and possibly other populations b) These engines provide similar prediction of CHD in T2DM c) In spite of the short duration of follow-up, metabolic control improvement (HbA1c, lipid levels) may possibly decrease CHD incidence.

1351

Glycaemic control reduces the platelet-activating factor acetylhydrolase activity (PAF-AH activity) in type 2 diabetes mellitus

J. Cubero[1], I. Vinagre[1], J. Sánchez-Quesada[2], J. Sánchez-Hernández[3], L. Santos[1], F. Blanco-Vaca[4], J. Ordóñez-LLanos[2], A. Pérez[3];
[1]Endocrinology and Nutrition, [2]Biochemistry, [3]Endocrinology and Nutrition-CIBERDEM, [4]Biochemistry-CIBERDEM, Hospital Santa Creu i Sant Pau, Barcelona, Spain.

Background and aims: The platelet-activating factor acetylhydrolase activity (PAF-AH activity) is a phospholipase A2 associated to the lipoproteins that hydrolyzes the platelet-activating factor (PAF) and oxidizes the phospholipids. It is considered that plays an important role in the development of atherosclerosis and its complications. The aim of our study was to determine the relationship between the PAF-AH and the glycaemic control in type 2 diabetes mellitus.
Materials and methods: In a cross-sectional study, we evaluated 131 type 2 diabetes mellitus subjects and 89 healthy individuals as controls. We did a new evaluation in 54 patients after improving the glycaemic control. We determined anthropometric parameters, HbA_{1c}, lipid profile, apolipoproteins A and B, leptin and adiponectin. The PAAF-AH activity was determined using 2 thio-PAF as a substrate (Cayman Chemical).
Results: In diabetic subjects total PAF-AH was 20.7±6.9 µml/min/mL and it was 18.9±6.3µml/min/mL in healthy controls (p=0.058). In the diabetic subjects, PAF-AH had a correlation with HbA_{1c} (r=304, p<0.001) and LDL cholesterol (r=353; p<0.001) and apolipoprotein B (r=223, p<0.01) concentrations. The improvement in glycaemic control (HbA_{1c} 9.7±1.8% vs 7.6±1.1%; p<0.01) carried a reduction in PAF-AH (19.9±8.2 vs 17.2±5.6µml/min/mL, p<0.001).
Conclusion: Type 2 diabetic patients show a tendency to a better PAF-AH activity and it is related to the glycaemic control.

1352

Prevention of cardiovascular disease through glycaemic control in type 2 diabetes. A meta-analysis of randomized clinical trials

M. Monami, C. Lamanna, N. Marchionni, E. Mannucci;
Critical Care Medicine and Surgery, Unit of Gerontology - University of Florence, Italy.

Background and aims: Randomized clinical trials (RCTs) aimed at the assessment of the efficacy of lowering blood glucose in the prevention of diabetic complications have always failed to detect a significant effect on cardiovascular events. Aim of this meta-analysis is the assessment of the effects of improvement of glycemic control on the incidence of cardiovascular diseases in patients with type 2 diabetes.
Materials and methods: The RCTs were included in this meta-analysis if: a) the between-group difference in mean HbA1c during the trial was at least 0.5%, b) they had a planned duration of treatment of at least 3 years, c) if they had a cardiovascular endpoint. Data for analysis were extracted independently by two observers and potential contrasts were resolved by a senior investigator.
Results: Five studies (17,267 and 15,362 patients in the intensive and conventional therapy groups, respectively) were included. Intensive treatment, which reduced mean HbA1c by 0.9% on average, was associated with a significant reduction of incident cardiovascular events and myocardial infarction (OR 0.89[0.83-0.95] and 0.86[0.78-0.93], respectively), but not of stroke or cardiovascular mortality (OR 0.93[0.81-1.07] and 0.98[0.77-1.23], respectively). In meta-regression analysis, a higher BMI duration of diabetes, and incidence of severe hypoglycaemia were associated with greater risk for cardiovascular death in intensive treatment groups.
Conclusion: Intensified hypoglycaemic treatment in type 2 diabetic patients leads to a significant reduction of the incidence of myocardial infarction, while it does not affect the incidence of stroke and cardiovascular mortality. Hypoglycemia induced by intensified treatment could be associated with increased cardiovascular mortality.

1353

Osteoprotegerin is associated with markers of atherosclerosis in type 2 diabetes patients

B. Idzior-Waluś[1], M. Waluś-Miarka[1], B. Katra[1], D. Fedak[2], D. Czarnecka[3], M.T. Malecki[1];
[1]Department of Metabolic Diseases, [2]Department of Clinical Biochemistry, [3]Department of Cardiology, Jagiellonian University, Kraków, Poland.

Background and aims: Osteoprotegerin is a glycoprotein from the tumor necrosis factor receptor superfamily, involved in bone remodeling. In general population, osteoprotegerin levels are positively correlated with the presence and severity of coronary artery disease and progression of atherosclerosis. However it is little known about the relation of osteoprotegerin and cardiovascular disease in type 2 diabetes. The aim of this study was to determine the relationship between serum osteoprotegerin concentration and some markers of atherosclerosis and heart failure assessed by measurements of pulse wave velocity and NT-pro-BNP concentrations in a group of patients with type 2 diabetes.
Materials and methods: Material included 98 consecutive patients with type 2 diabetes from diabetes outpatient clinic, aged 40-70 years. In each subject osteoprotegerin, NT-pro-BNP, lipid profile (total, high density lipoprotein [HDL], low density lipoprotein [LDL] cholesterol and triglycerides), homocysteine, fasting glucose and glycated hemoglobin were evaluated. All subjects had bone mineral density assessed by dual-energy X-ray absorptiometry (DEXA). Total and percentage of visceral fat were assessed by DEXA. Serum lipids were measured by enzymatic methods using Roche reagents and homocysteine by enzyme-linked immunosorbent assay using R&D reagents. Osteoprotegerin was analyzed by ELISA method, NT-pro-BNP by electrochemiluminescence method (ECLIA Roche). Glycated hemoglobin was determined by high pressure liquid chromatography (HPLC). Carotid - femoral pulse wave velocity (PWV) was assessed using Complior system.
Results: Mean age of patients was 59,6±10,7 years, mean glycated hemoglobin values 7.3±1.6 %, BMI 31,2±3,8kg/m^2. Mean values of osteoprotegerin were 4.528±1.38pmol/l, in men 4.27±1.2, in women 4.83±1.36, p=ns. Mean values of serum homocysteine were 16.4+/-5.4 µmol/l, higher in men than in women (17.6+/-5.2 and 14.47+/-5.2 µmol/l, respectively [p<0.05]). Total cholesterol, LDL and HDL cholesterol and triglyceride levels were as follows: 5.4±1.74 mmol/l, 2.8±1.2 mmol/l 1.2±0.42 mmol/l and 3.4±5.4 mmol/l. Mean and median values of NT-pro-BNP were 186.6±341 and 63.2 pg/ml, higher in women than in men: 265.4±400.4, median 102.2 pg/ml vs 141.1±300, median 51.03 pg/ml, respectively (p<0.05). In the whole group of patients osteoprotegerin concentration correlated significantly positively with age (r=0.48), NT-pro-BNP (Spearman correlation coefficient R = 0.41), pulse wave velocity (r=0.43), pulse pressure (r = 0.43) and with percentage of total fat (r = 0.58). No correlation between plasma lipids, homocysteine levels, blood pressure, glycated hemoglobin or bone mineral density with osteoprotegerin levels were observed. Multiple regression analysis with osteoprotegerin as dependent variable and NT-pro-BNP, PWV and percentage of total fat as independent variables, revealed that only PWV (beta = 0.379, p = 0.02) and percentage of total fat (beta = 0.473, p = 0.005) were significantly associated with osteprotegerin level.
Conclusion: The results of this study indicate that serum osteoprotegerin is associated with arterial stiffness and percentage of fat mass in patients with type 2 diabetes.

1354

Copeptin predicts and explains the association between IGFBP-1 and cardiovascular events in patients with type 2 diabetes and myocardial infarction

S.-B. Catrina[1], L.G. Mellbin[2], N.G. Morgenthaler[3], I.R. Botusan[1], L. Rydén[2], J. Öhrvik[2], K. Brismar[1];
[1]Molecular Medicine and Surgery, Karolinska Institute, Stockholm, Sweden, [2]Cardiology Unit, Department of Medicine, Karolinska Institute, Stockholm, Sweden, [3]Research Department, BRAHMS AG Biotechnology Centre, Henningsdorf/Berlin, Germany.

Background and aims: High levels of the IGF Binding Protein-1 (IGFBP-1) are associated with impaired prognosis in patients with type 2 diabetes (DM) and acute myocardial infarction (MI). Copeptin, a surrogate marker for vasopressin, is a novel cardiovascular prognostic predictor. Infusion of vasopressin increases IGFBP-1 in humans. The present study analyzed the relation between copeptin and IGFBP-1 and their impact on the prognosis in patients with DM and MI.
Materials and methods: Copeptin and IGFBP-1 was analysed at the time for hospitalisation in 393 patients with type 2 DM and MI (a subgroup from the DIGAMI 2 trial). No patient was lost to follow and all endpoints were independently adjudicated. Multiple Cox proportional hazard regression was used to study the relation between copeptin, IGFBP-1 and cardiovascular (CV) events (cardiovascular death, reinfarction and stroke) and to adjust for a number of possible confounders of which only age was of significant importance.
Results: There was a positive correlation between the levels of copeptin and IGFBP-1 (Spearman's rank correlation r = 0.53; p<0.001). During a median follow-up of 2.1 years 95 (24%) patients died, 77 of cardiovascular causes. Fifty-nine (15%) patients had a nonfatal reinfarction and 25 (6%) a nonfatal stroke. The age adjusted Hazard Ratio (HR) for CV mortality was 1.32 (95% CI 0.99-1.74; p = 0.05) for log IGFBP-1 and 1.33 (95% CI 1.08-1.64; p = 0.008) for log copeptin. The age adjusted HR for CV events was 1.06 (95% CI 0.87-1.299; p = 0.55) for log IGFBP-1 and 1.36 (95% CI 1.16-1.59; p < 0.001) for log copeptin.
Conclusion: This study shows that copeptin, a surrogate marker for vasopressin may, at least partially, explain the prognostic impact of IGFBP-1 in patients with type 2 DM and MI. Since copeptin is an independent predictor for fatal and non-fatal cardiovascular events it becomes of interest to study agents decreasing the action of vasopressin as a possibility to improve the serious prognosis in this category of patients.

Type 2 diabetes and the coronary angiographic state are mutually independent predictors of future vascular events among angiographied coronary patients

C.H. Saely[1,2], T. Gansch[1], S. Greber[1], A. Vonbank[1,3], P. Rein[1,2], S. Beer[1,3], T. Marte[1,2], H. Drexel[1,2];
[1]VIVIT Institute, Feldkirch, Austria, [2]Department of Internal Medicine, Academic Teaching Hospital Feldkirch, Austria, [3]Private University in the Principality of Liechtenstein, Triesen.

Background and aims: Type 2 diabetes (T2DM) in cross-sectional studies is associated with coronary artery disease (CAD) and prospectively confers a strongly increased risk of vascular events. It is not certain to what extent the baseline CAD state accounts for the increased vascular risk of diabetic patients in prospective studies because angiography usually is not performed.
Materials and methods: We therefore enrolled 750 consecutive patients undergoing coronary angiography for the evaluation of stable CAD. At angiography, CAD was diagnosed in the presence of any irregularities of the vessel wall. Stenoses ≥50% were considered significant, and the extent of CAD was defined as the number of significant stenoses in a patient. Vascular events were recorded over 8 years.
Results: The prevalence of CAD (87.8% vs. 80.4%; p = 0.029) and of significant stenoses (69.5% vs. 58.4%; p = 0.010) as well as the extent of CAD (1.7 ± 1.5 vs. 1.4 ± 1.5; p = 0.014) were significantly higher in patients with T2DM (n = 164) than in nondiabetic subjects (n = 586). Prospectively, vascular events occurred in 257 patients (34.3% of the study population). T2DM after multivariate adjustment strongly predicted vascular events (adjusted hazard ratio (HR) = 1.55 [1.17-2.05]; p = 0.002). Also, the presence of CAD (HR = 3.59 [2.11-6.13]; p <0.001), the presence of significant stenoses (HR = 2.29 [1.70-3.09]; p <0.001) and the extent of CAD (standardized adjusted HR = 1.40 [1.25-1.56]; p <0.001) significantly predicted vascular events. These angiographic characteristics still predicted vascular events after additional adjustment for T2DM (HR = 3.46 [2.03-5.91], p <0.001; 2.24 [1.66-3.02], p <0.001; and 1.38 [1.24-1.54], p <0.001, respectively). Conversely, T2DM remained strongly and significantly predictive of future vascular events after adjustment for the presence and extent of CAD (HR = 1.41 [1.07-1.87]; p = 0.016).
Conclusion: Among angiographied coronary patients, the presence and the extent of CAD are higher in patients with T2DM than in nondiabetic individuals. Prospectively, T2DM and the baseline CAD state are mutually independent predictors of future vascular events.

1356

The metabolic syndrome is associated with maladaptive carotid remodeling - The Hoorn Study

H.J.B. Beijers[1], R.M.A. Henry[2], B. Bravenboer[1], I. Ferreira[2,3], J.M. Dekker[4], G. Nijpels[4], C.D.A. Stehouwer[2];
[1]Department of Internal Medicine, Catharina Hospital, Eindhoven, [2]Department of Internal Medicine, Maastricht University Medical Centre, [3]Department of Clinical Epidemiology and Medical Technology Assessment, Maastricht University Medical Centre, [4]Institute for Research in Extramural Medicine, VU University Medical Centre, Amsterdam, Netherlands.

Background and aims: The metabolic syndrome (MetS) is associated with an increased risk of ischemic stroke. The underlying pathophysiology is poorly understood. Arterial remodeling, i.e. structural changes of the arterial wall, could play an important role as maladaptive remodeling (i.e., an increase in circumferential wall stress (CWS) despite changes of the arterial wall) is a risk factor for ischemic stroke. The purpose of this study was therefore to investigate, in a population-based cohort, whether MetS is associated with maladaptive remodeling.
Materials and methods: We studied 385 (n=195 women) non-diabetic, elderly subjects. A continuous MetS *z*-score (average of the sex-specific *z*-scores of the 5 individual MetS traits) was constructed. Intima-media thickness (IMT) and inter-adventitial diameter (IAD) of the carotid artery were assessed by ultrasonography, and lumen diameter (LD) and CWS were calculated. Multiple linear regression analyses were used to investigate the associations between MetS and carotid arterial properties.
Results: After adjustment for potential confounders (i.e. sex, age, height, LDL-cholesterol, use of statins, prior CVD and smoking), the MetS z-score was independently associated with greater IAD (regression coefficient (β) per SD increase in MetS z-score (95%CI)), 0.46 mm (0.27; 0.64)), LD (0.41 mm (0.23; 0.59)) and CWS (11.17 kPa (7.17; 15.17)). No statistically significant association was found between the MetS z-score and IMT (0.025 mm (-0.003; 0.053)). In addition, the reported associations were not mediated by inflammatory, metabolic or hemodynamic factors (expressed as high sensitivity C-reactive protein, adiponectin and the homeostatic model for the assessment of insulin resistance (HOMA-IR), and pulse and mean arterial pressure, respectively).
Conclusion: MetS is associated with greater CWS, which is the result of changes in LD, IAD and, to a lesser extent, IMT of the carotid artery. This process of arterial remodeling thus seems maladaptive and may therefore explain, at least partially, the increased risk of ischemic stroke in MetS.
Dr. Ferreira is supported by a research grant from the Dutch Heart Foundation

Paraoxonase 192 Q/R gene polymorphism, enzyme activity and coronary heart disease in type 2 diabetes

M. Gorshunska, I. Karachentsev, L. Atramentova, N. Krasova, T. Tyzhnenko, A. Pochernyaev, Z. Leshchenko, G. Fedorova, A. Gladkih, N. Kravchun, O. Khizhnyak, V. Poltorak;
SI "V. Danilevsky Institute of Endocrine Pathology Problems of AMS of Ukraine", Kharkiv, Ukraine.

Background and aims: It has been known the high prevalence coronary heart disease (CHD) and dysglycaemia in Ukrainian population. Paraoxonase 1 (PON1) is a HDL-associated enzyme playing an important role in organophosphate detoxification and prevention of atherosclerosis (PON1 can protect LDL and HDL from oxidation at a certain extent). Variations in the PON1 gene (192 Q/R) which can be risk factors for CHD have been

described in different population but not in Ukrainian one. The study was undertaken to identify the PON1 Q192R polymorphism and to explore its impact on CHD in Ukrainian population including type 2 diabetes mellitus (T2D) patients.
Materials and methods: Two groups of subjects of both sexes were enrolled and compared: 123 healthy control subjects (C, M/F 86/47, age 55.3±2.5 yrs) and 96 T2D patients with CHD (T2Ds, M/F 28/68, age 56.2±1.4 yrs, diabetes duration 9.4±1.0 yrs, BMI 30.7±0.8 kg/m^2) under suboptimal or poor glycaemic control. DNA was amplified with PCR followed by restriction enzyme digestion. The products were size-separated on 2% agarose gel, stained with ethidium bromide, and pictured on an ultraviolet light box. Serum PON1 activity toward paraoxon was measured spectrophotometrically.
Results: The overall PON1 genotype distribution in C (QQ 39.0 %; QR 52.0 %; RR 9.0 %) was consistent with Hardy-Weinberg equilibrium (χ^2=2.52, p>0.05), and the allele frequencies were similar to those in other Caucasian populations. There was no gender differences in allele frequencies (F: Q/R 0.68/0.32 vs M: Q/R 0.64/0.36, p>0.05). In T2Ds allele frequencies were similar to C (F: Q/R 0.67/0.33 vs M: Q/R 0.79/0.21, p>0.05). But we observed difference in the PON1 genotype distribution between groups (χ^2=13.4, p<0.01). The genotype distributions in T2Ds were: QQ 57.0 %, QR 26.0 %, RR 17.0 %. Thus, there were more homozygous T2Ds (for both Q and R alleles) as compared to C. Relative risk (the odds ratio) of studied pathologies development in population for QQ and RR homozygote was 1.46 [95% CI 1.18 - 1.74, p<0.05] and 1.86 [95% CI 1.13 - 2.60, p=0.05], respectively, and for QR heterozygote was 0.50 [95% CI 0.12 - 0.88, p<0.05]. Serum PON1 activity was significantly decreased in T2Ds as compared to C (p<0.01), and PON1 genotype had the effect on enzyme activity level: the presence of QQ genotype was accompanied by lower (4-fold) PON1 activity than RR genotype (p<0.002).
Conclusion: The study provides first evidence for the potential role of PON1 Q192R polymorphism in protection of T2D patients from CHD in Ukrainian population and demonstrates heterosis effect at this locus, which may be due to different type of enzymatic activities of isozymes. These findings warrant further investigation to clarify their pathogenic mechanisms.

1358

Relationship between carotid intima-media thickness with plaque and brachial-ankle pulse wave velocity in patients with type 2 diabetes

B. Kim[1], Y. Jeon[1], S. Kim[1], S. Lee[1], D. Lee[1], Y. Kang[1], S. Son[1], C. Lee[2], J. An[3], I. Kim[1], Y. Kim[1];
[1]Department of Internal Medicine, Pusan National University School of Medicine, [2]Department of Internal Medicine, Busan St.Mary's Medical Center, [3]Department of Internal Medicine, Good Moonhwa Hospital, Busan, Republic of Korea.

Background and aims: Carotid intima-media thickness (IMT) and pulse wave velocity(PWV) have been shown to be good surrogate markers of clinical atherosclerosis. Recently, brachial-ankle PWV(baPWV) has been developed as a more noninvasive and convenient methods for assessment of arterial stiffness. Several studies have demonstrated a significant correlation between aortic PWV and carotid IMT. However, the interrelation between carotid IMT and baPWV in type 2 diabetes patients has not yet been fully clarified. We determined the relationship between carotid IMT with plaque and baPWV in patients with type 2 diabetes mellitus(DM)
Materials and methods: One hundred twenty two patients (56 men, 66 women, mean age 60.8±10.5 years, mean DM duration 7.0±7.3 years) were included. Subjects with type 1 diabetes, peripheral artery obstructive disease were excluded. Carotid IMT and plaque formation was assessed using B-mode ultrasonography at both common carotid artery(CCA)[10mm distal to the bifurcation], bifurcation and internal carotid artery(ICA)[10mm proximal to the bifurcation]. baPWV was measured using an automated device.
Results: Maximal baPWV was 1648±363.2 cm/sec, mean IMT of Rt. carotid artery was 0.73±0.20mm, mean IMT of Lt. carotid artery was 0.79±0.26mm, maximal IMT of carotid artery was 1.19±0.41mm, and plaque was found in 11% of subjects. In bivariate correlation analysis, maximal baPWV was significantly correlated with IMT of Rt. CCA (r=0.322, p<0.01), mean IMT of Rt. carotid artery(r=0.235, p<0.01), IMT of Lt. CCA (r=0.221, p=0.02), mean IMT of Lt. carotid artery(r=0.412, p<0.01), maximal IMT of carotid artery (r=0.409, p<0.01) and plaque (r=0.369, p<0.01). Maximal IMT of carotid artery was significantly associated with age(r=0.314, p<0.01), systolic blood pressure(SBP)(r=0.369, p<0.01) and DM duration (r=0.200, p<0.03). The existence of plaque was significantly associated with age(r=0.265, p<0.01), SBP(r=0.271, p<0.01) and DM duration (r=0.224, p=0.02). Multiple regression analysis was performed with maximal IMT of carotid artery and plaque as a dependent variable respectively. Maximal IMT of carotid artery was significantly correlated with SBP(β =0.269, p<0.01). The existence of plaque was significantly correlated with maximal baPWV (β =0.280, p=0.02).
Conclusion: baPWV was significantly correlated with carotid IMT and plaque in patients with type 2 diabetes.

1359

Impact of glycaemic control on the prognosis of diabetic patients with critical limb ischaemia

M. Takahara[1], O. Iida[2], S. Gorogawa[2], M. Ikeda[2], M. Kubota[1], H. Kaneto[1], M. Matsuhisa[1];
[1]Internal Medicine and Therapeutics, Osaka University Graduate School of Medicine, Japan, [2]Department of Internal Medicine, Kansai Rosai Hospital, Hyogo, Japan.

Background and aims: Critical limb ischaemia (CLI) has a poor prognosis for both survival and limb salvage and often requires a revascularization procedure. Diabetes mellitus is one of the major risk factors for CLI and its prevalence is considerably high in patients with CLI. Few studies have, however, examined predictive indicators for mortality and lower extremity amputation in diabetic patients with CLI, especially treated with endovascular therapy. The aim of this study was to reveal the influence of a variety of possible risk factors including poor glycaemic control on their outcome.
Materials and methods: We recruited 176 consecutive patients with diabetes mellitus, who underwent percutaneous transluminal angioplasty (PTA) for CLI between 2003 and 2008. The outcome measures were mortality and major amputation, and Cox proportional hazards regression analyses were performed. The variables in the analyses included age, gender, activity of daily living (ADL) assessmemt, history of cardiovascular disease, haemoglobin A1c (HbA1c), C-reactive protein (CRP), ejection fraction, and receiving regular haemodialysis.
Results: HbA1c levels were 7.1 ± 1.4% and follow-up period was 1.5 ± 1.2 years (mean ± SD). One hundred and sixteen patients had infrapopliteal lesions revascularized. Forty seven patients (26.7%) underwent major amputations and 54 patients (30.7%) died. In the multivariable model, HbA1c, as well as CRP and low ADL, was significantly associated with major amputation; adjusted hazard ratios (HR) of HbA1c, CRP and low ADL were 1.36 per 1% increase (p = 0.029), 1.16 per 1 mg/dl increase (p = 0.028), and 2.96 (p = 0.008), respectively. On the other hand, independent predictors for mortality were low ADL (HR 3.13; p = 0.002), receiving regular haemodialysis (HR 2.98; p = 0.009) and impaired ejection fraction (HR 1.02 per 1% decrease; p = 0.016). There was no significant association between HbA1c and mortality.
Conclusion: Poor glycaemic control, indicated by an elevated value of HbA1c, predicts major amputation, but not mortality, in diabetic patients with CLI undergoing PTA. Prognostic predictors seem somewhat different between survival and limb salvage in the population.

A proinflammatory and prothrombotic environment in young individuals with type 1 diabetes: the effects of glycaemic control

T. Koko[1,2], K. Hess, M. Mathia, K.F. Standeven, P. Holland, A.M. Carter, F. Phoenix, P.J. Grant and R.A. Ajjan;
[1]Diabetes Center, Leeds General Infirmary, [2]Department of Cardiovascular and Diabetes Research, The LIGHT Laboratories, University of Leeds, United Kingdom.

Background and aims: Raised C-reactive protein (CRP) and complement C3 plasma levels are associated with increased risk of cardiovascular events. In addition to inflammatory molecules, fibrin clot structure has been linked to cardiovascular disease, as compact clots are associated with premature and more severe atherothrombotic conditions. Although the atherosclerotic process starts at an early age, little is known about CRP and C3 plasma levels in younger individuals with type 1 diabetes (T1DM). Also, studies investigating blood clot structure in this cohort are still lacking. The present work analyses CRP and C3 plasma levels and evaluates fibrin clot structure in children with T1DM and results are compared to normal control individuals.
Materials and methods: ELISA was used to determine CRP and C3 plasma levels in 30 Type 1 DM children [14 yrs (range 11-17)] and 17 age matched controls, whereas fibrin clot structure was studied using a validated turbidimetric assay.
Results: T1DM children had higher C3 levels (mean±SEM) compared with controls (1.13±0.24 versus 0.83±0.24 mg/ml respectively; p<0.001), whereas the difference in CRP levels failed to reach statistical significance (0.85±1.36 versus 0.5±1.21 mg/l respectively; p=0.06). Clot final turbidity, an indicator of clot density, was higher in diabetes children at 0.38±0.01 au, compared with controls (0.31±0.02 au ;p<0.01). Clot final turbidity correlated positively with C3 plasma levels (r=0.39, p<0.01) but not CRP, suggesting an interaction between C3 and clot structure.
Conclusion: This is the first report describing a denser ex vivo clot structure and elevated C3 levels in children with T1DM, further confirming that the vascular inflammatory/thrombotic process starts at a young age in individuals at risk.

Vitamin D levels and mortality in type 2 diabetes

C. Joergensen[1], M.-A. Gall[1], A. Schmedes[2], L. Tarnow[1], H.-H. Parving[3], P. Rossing[1];
[1]Steno Diabetes Center, Gentofte, [2]Dept. of Clinical Biochemistry, Lillebaelt Hospital, Vejle, [3]University Hospital of Copenhagen, Denmark.

Background and aims: Low levels of vitamin D is independently associated with an increased all-cause mortality risk in the general population. This study evaluated vitamin D deficiency as a predictor of overall and cardiovascular mortality in patients with type 2 diabetes.
Materials and methods: In a prospective observational follow-up study 315 caucasian type 2 diabetic patients were followed for a median (range) of 15.5 (0.2-17.0) years. Samples available in 290 subjects, mean age 54 years, normoalbuminuria (n=173), microalbuminuria (n=73), and macroalbuminuria (n=44) at baseline. Vitamin D, 25(OH)D_3, levels were determined by high performance liquid chromatography/tandem mass spectrometry (LC-MS/MS) on stored baseline samples. Samples were available in 290 subjects, mean age 54 years. Severe vitamin D deficiency was defined as the lower 10% (<13.9 nmol/l).
Results: Median (range) vitamin D level was 35.7 (5 to 136.7) nmol/l. Vitamin D levels were not associated with age, sex, eGFR, urinary albumin excretion rate, or hemoglobinA_{1c},at baseline, but low levels were weakly associated with elevated systolic blood pressure (R=0.13, p=0.03). Of the patients, 142 died (49%), 119 of them (72%) due to cardiovascular causes. All-cause mortality was increased in patients with severe vitamin D deficiency (hazard ratio [95% CI] 2.03 [1.26 to 3.26], p=0.003). The association persisted after adjustment for urinary albumin excretion rate, glomerular filtration rate, hemoglobinA_{1c} and conventional cardiovascular risk factors (covariate adjusted hazard ratios 1.94 [1.19 to 3.16], p<0.01). Vitamin D deficiency was also associated with increased cardiovascular mortality (unadjusted hazard ratios 1.93 [1.10 to 3.39], p=0.02; covariate adjusted 1.49 [1.156 to 1.93] p=0.002).
Conclusion: In patients with type 2 diabetes, severe vitamin D deficiency is a risk factor for excess overall and cardiovascular mortality, being independent of urinary albumin excretion rate and conventional cardiovascular risk factors. Whether vitamin D substitution in type 2 diabetic patients can improve the prognosis remains to be determined.

Free fatty acids are associated with Q-T interval length in men, but not women, with type 1 diabetes

T.J. Orchard, B. Conway;
Epidemiology, University of Pittsburgh, United States.

Background and aims: Free fatty acids have been shown to be associated with ischemic heart disease in the general population and in some reports with Q-T interval lengthening. As free fatty acids are chronically elevated in type 1 diabetes and account for a significant amount of the counterregulatory response to hypoglycemia, it has been hypothesized that this, via Q-T interval lengthening, might account for some of the silent (or unrecognized) coronary artery disease observed in this population.
Materials and methods: We therefore sought to determine whether free fatty acids were associated with Q-T interval lengthening and 183 participants (87 men and 96 women) from the Pittsburgh Epidemiology of Diabetes study, a cohort of childhood onset (age < 17 years) type 1 diabetes. As we have previously noted sex-specific free fatty acid associations with pulse pressure, i.e. an association in women, but not men, we also sought to determine whether any free fatty acid association with Q-T interval length also varied by sex. Mean age and diabetes duration were 44 and 33 years, respectively, at time of investigation. Free fatty acids were measured using the colorimetric method (Wako Pure Chemical Industires, Ltd). Corrected Q-T intervals were calculated using Hogdes Formula (Corrected QT=QT+ (1.75*(vent rate-60))). Free fatty acids were naturally logarithmically transformed before analyses and all analyses were controlled for serum albumin.
Results: Mean free fatty acid levels were 0.95 mmol/l and did not vary by sex (0.93 vs 0.96 mmol/l for men and women respectively, p=0.76). Overall, age- and serum albumin adjusted free fatty acids showed no association with the Q-T interval (r=0.05, p=0.51). However, upon sex-specific examination, age- and serum albumin -adjusted free fatty acids were associated with the Q-T interval in men (r=0.22, p=0.04), but not in women (r=-0.05, p=0.62). After further allowing for systolic blood pressure, HbA_{1c}, albumin excretion rate, and HDL cholesterol, free fatty acids remained associated with the Q-T interval in men (p=0.03), but continued to show no association in women (p=0.61).
Conclusion: Free fatty acids are associated with an increased Q-T interval in men, but not women, with type 1 diabetes. Free fatty acids may contribute to the increased risk of cardiovascular disease in type 1 diabetes, albeit their effects may vary by gender.

Association between leukocyte telomere shortening and CVD in patients with type 2 diabetes mellitus

I. Testa[1], F. Olivieri[2], M. Lorenzi[3], R. Antonicelli[4], R. Testa[1], C. Sirolla[5], M. Cardelli[6], S. Mariotti[3], F. Marchegiani[6], M. Marra[1], L. Spazzafumo[5], A. Bonfigli[1], L. La Sala[2], A. Procopio[2];
[1]Diabetology Unit, Research Department, INRCA-IRCCS Hospital, [2]Dept. of Molecular Pathology and Innovative Therapies, Polytechnic University of Marche, [3]Center of Clinical Pathology and Innovative Therapies, Research Dept., INRCA-IRCCS Hospital, [4]Cardiology Unit, INRCA-IRCCS Hospital, [5]Statistical Center, INRCA-IRCCS Hospital, [6]Laboratory of Tumor Immunology, Immunology Center, Research Dept., INRCA-IRCCS Hospital, Ancona, Italy.

Background and aims: Many studies have measured leukocyte telomere length with the aim to identify associations with aging-related diseases in humans, including type 2 diabetes mellitus (T2DM). However, is unclear which biomarkers and/or T2DM complications could be significantly correlated to telomere shortening observed in these patients. We performed a cross-sectional study to examine the differences in telomere length between healthy subjects (CTR), T2DM and diabetic patients with myocardial infarction (T2DM +MI), with the aim to clarify if telomere length could be a reliable marker associated with MI in T2DM patients. Secondary end point is

the identification of possible correlations between leukocyte telomere length and selected biomarkers of pro-inflammatory status, of glycemic control and of lipidic profile.
Materials and methods: A total of 307 elderly subjects, 103 T2DM (mean age 70 ± 4 years, 59% males), 100 T2DM +MI (mean age 70 ± 7 years, 65% males), and 104 CTR (mean age 69 ± 7 years, 50% males) were studied. Telomere length, defined as T/S (Telomere-Single copy gene ratio), was determined in leukocytes by quantitative real time polymerase chain reaction (Real-Time PCR)-based assay. Moreover, we assessed: 1) high sensitive C reactive protein (hsCRP), fibrinogen and plasminogen-activator inibitor-1 (PAI-1) as inflammatory markers; 2) fasting glucose, insulin, glycated haemoglobin (HbA_1C) and waist to hip ratio as markers of glycemic control; 3) total-cholesterol, HDL-cholesterol and triglycerides as markers of lipidic profile, in all sample population. Use of statins and sulfonylurea, and presence of some relevant diabetes complications (nephropathy and retinopathy) were also assessed.
Results: The main result of the present study is that T2DM +MI patients have leukocyte telomere lengths shorter than those of T2DM patients and healthy CTR. Moreover, glucose, HbA_1C and waist to hip ratio, variables related to glycemic control, showed a significant inverse correlation with leukocyte telomeres length.
Conclusion: Our results suggest that leukocyte telomere length may be a possible reliable marker of MI, one of the most frequent and clinically relevant complication of diabetes, in elderly T2DM patients.

Morbidity and mortality associated with hepatobiliary disease in type 2 diabetes: the Fremantle Diabetes Study
T.M.E. Davis, K. Peters, W.A. Davis;
School of Medicine and Pharmacology, University of Western Australia, Fremantle, Australia.

Background and aims: There are few studies examining morbidity and mortality associated with hepatobiliary disease in type 2 diabetes. The aim of this study was to analyse detailed relevant longitudinal data collected as part of the observational community-based Fremantle Diabetes Study (FDS).
Subjects and methods: We studied the 1294 type 2 FDS participants who were recruited between 1993 and 1996 and invited to subsequent annual assessments. Additional data were obtained from the Western Australian (WA) State Government registers which record details of all deaths and hospital admissions to public and private hospitals. These data were linked to the FDS database from April 1993 to end-June 2007. All hospital admissions with ICD-9CM and ICD-10AM codes for hepatobiliary disease were extracted, as were coded causes of death.
Results: At FDS entry, the patients had a mean ± SD age of 64.1 ± 11.3 years, 48.8% were male and they had been diagnosed a median (inter-quartile range) 4.0 (1.0-9.0) years previously. The crude cumulative incidence of hospitalisation for hepatobiliary disease was i) 24.7/1000 patient-years in FDS type 2 patients during a mean of 10.3 (range 0.04-14.2) years follow-up, and ii) 5.9/1000 person-years in the general population of WA (approximately 1.7 million people) during the same period. The age-standardised incidence rate was 68% higher in the FDS type 2 cohort. By end-June 2007, 532 (41.2%) FDS type 2 participants had died, 11 (2.1%) from liver disease including cancer, alcohol-related cirrhosis, primary biliary cirrhosis, failed liver transplant, or cirrhosis/hepatic encephalopathy of unspecified cause. No death was attributed to non-alcoholic fatty liver disease (NAFLD). A history of liver disease at baseline, including viral hepatitis (13.2% hepatitis B core antibody positive, 1.8% hepatitis C positive) and at least one C282Y allele (12.2%), was not associated with all-cause mortality in a Cox proportional hazard model after adjusting for a range of significant independent predictors.
Conclusion: The incidence of hospitalisation for hepatobiliary disease is increased in community-based patients with type 2 diabetes relative to that in the local general population. However, deaths associated with liver disease are uncommon and rarely due to NAFLD. These data question the need for directed screening for NAFLD in patients with type 2 diabetes.

YKL 40 levels are elevated in patients with peripheral arterial occlusive disease and type 2 diabetes mellitus
K. Batinic[1], F. Hoellerl[1], A. Steffan[1], F. Jelic[1], D. Lorant[1], M. Grujicic[1], G. Schernthaner[2], R. Koppensteiner[1], G.H. Schernthaner[1];
[1]Angiology, Medical University of Vienna, [2]Medicine I, Rudolfstiftung Hospital, Vienna, Austria.

Background and aims: Peripheral arterial occlusive disease (PAOD) constitutes a generalized atherosclerosis of the vessels with the highest risk of cardiovascular disease (CVD) events of all its latter manifestations forms. The co-occurrence of PAOD with type 2 diabetes mellitus (T2DM) results in an even further increased CVD risk and a high risk of death within four years. YKL-40, an inflammatory protein, involved in the development of atherosclerosis, is participating in plaque rupture. In the present study we investigated the association of YKL-40, T2DM and PAOD.
Materials and methods: Our study group consisted of 132 patients with PAOD. By oral glucose tolerance testing (OGTT) 47 were identified as normal glucose tolerant and 85 as T2DM. YKL-40 levels were measured using a commercially available ELISA (Quidel Corporation, San Diego, CA). Statistical analyses were done with students' unpaired t-test, ANOVA, correlation analysis and multivariate regression modeling as appropriate.
Results: YKL-40 levels were higher in the patients with T2DM (99±68 ng/ml) versus non-diabetic PAOD patients (68±45ng/ml; p=0.002). Within one year of follow up 9 % of non-diabetic versus 25 % of the diabetic subgroup suffered a cardiovascular event. PAOD patients who developed a cardiovascular event had higher YKL-40 levels (138±77) versus those (80±55 ng/ml p=0.004) who were spared. Interestingly, YKL-40 was neither associated with insulin resistance determined by the homeostatic model assessment nor by vascular inflammation estimated by C-reactive protein in the total study population. In contrast, YKL-40 values were strongly associated with urinary albumin excretion rate (UAER; beta=0.236, p=0.007). In the 47 patients without T2DM, UAER (beta=0.388, p=0.007) and creatinine (beta=0.460, p=0.001) were associated with YKL-40 values in univariate fashion. In the 85 patients with T2DM, low-density lipoprotein cholesterol (beta=-0.232, p=0.033) and aspartate amino transferase (beta=0.327, p=0.002) were associated with YKL-40 values in univariate fashion. YKL-40 levels were higher in symptomatic PAOD (stage IIa and IIb) with T2DM (96±65 ng/ml) versus patients without T2DM (61±42 ng/m p=0.005).
Conclusion: YKL-40 levels were higher in symptomatic and asymptomatic PAOD patients with T2DM versus patients with normal glucose metabolism. Patients who had cardiovascular events during the first year of follow up had significantly higher YKL-40 levels.

Glucosepane and CML glycation modifications in human elastic arteries
K.F. Hanssen[1], T. Lund[2], A. Svindland[3], A.-B. Jensen[4], Z. Dai[5], J. Zhang[5], J.P. Berg[6], T.J. Berg[1], B. Kilhovd[1], V.M. Monnier[5];
[1]Dept. of Endocrinology, Aker University Hospital, Oslo, Norway, [2]Hormone laboratory ,Dept. of Endocrinology, Aker University Hospital, Oslo, Norway, [3]Dept. of pathology, Aker University Hospital, Oslo, Norway, [4]Hormone laboratory, Dept. of Endocrinology, Aker University Hospital, Oslo, Norway, [5]Dept. of Pathology, CWRU, Cleveland, United States, [6]Dept. of Clinical Chemistry, Ullevål University Hospital, Oslo, Norway.

Background and aims: The reason for the increased cardio-vascular disease in both type 1 and type 2 diabetes is not known in detail. However, early stiffening of arteries is central to the pathogenesis. Advanced Glycation Endproducts (AGE) are involved in the initiation and progression of atherosclerosis in diabetes and may be involved in the stiffening of arteries. We therefore studied the presence of two AGE modifications, Carboxymethyllysine (CML), a glycoxidation product, and Glucosepane, a major newly discovered lysine-arginine crosslink, in human aorta and carotid arteries .
Materials and methods: Proteins were extracted from carotid arteries and aorta from 5 diabetics and 10 non-diabetics, having different degree of atherosclerotic lesions. The extracts were analysed by one and two-dimensional electrophoresis followed by western-blotting using four different antibodies against CML and an antibody against Glucosepane. Trypsin and endopeptidase Glu-C were used to cleave proteins into peptide fragments. A Dionex Ultimate 3000 nano-LC system connected to a linear quadrupole ion trap - Orbitrap mass spectrometer (LC-MS/MS) was used to identify proteins. UltraVision ONE Detection System was used for immunohistochemical studies of tissue slices.

Results: In western-blotting the strongest signal with antibodies against CML corresponded to a molecular weight of 230 kDa. LC-MS/MS analyses showed the presence of three different myosin heavy chains and some other proteins at that position. The extracted proteins were therefore digested with trypsin and endoproteinase Glu-C, respectively. Two-dimensional electrophoresis of the digests, followed by western-blotting using antibodies against CML and the proteins identified by LC-MS/MS, showed overlapping signals with antibodies against CML and smooth muscle myosin heavy chain (SM-MHC). SM-MHC could therefore be a main target for CML-modification in human arterial walls. Immunohistochemical (IHC) studies gave strong CML-signals in smooth muscle cells that were positive for SM-MHC, compatible with the western-blotting results. Fibulin-5, vimentin and annexin IV and V were identified for the first time, by western-blotting, as arterial proteins that were modified by Glucosepane. By immunohistochemistry, Glucosepane was mainly distributed extracellularly around long fibre-like structures that probably contained elastin. Glucosepane was found associated with the internal and external elastic lamina, in the medial layer, and close to basal membranes.
Conclusion: Our results support earlier work localizing CML to smooth muscle cells in vessel wall and point out smooth muscle myosin heavy chain as a possible main target for CML modification in vivo in human elastic arteries. Putative main targets for modification by Glucosepane were also identified. CML and Glucosepane target different proteins,and both these AGE modifications may play a role in arterial stiffening.

Antibodies to oxLDL/beta(2)-GPI in type 2 diabetic subjects with and without coronary artery disease

S. Pappas[1], C. Kaliouli[2], A. Papazafiropoulou[1], P. Matsoukas[1], V. Pantiora[2], A. Fragkiadaki[2], F. Tziraki[2], E. Fwtiadou[2];
[1]3rd Department of Internal Medicine and Center of Diabetes, [2]Department of Immunology, General Hospital of Nikaia "Saint Panteleimon" – Piraeus, Nikaia, Greece.

Background and aims: High levels of oxLDL are present in metabolic disorders including type 2 diabetes mellitus (T2DM). β_2 glycoprotein 1 is an inhibitor of platelet aggregation and makes complexes with oxLDL. The complex oxLDL/beta(2)-GPI is an antigen leading to the production of autoantibodies, the activation of atherosclerotic process and, therefore, increasing the risk of cardiovascular disease. The aim of the present study was to compare the levels of IgG and IgM antibodies to oxLDL/beta(2)-GPI in T2DM subjects with and without coronary artery disease (CAN).
Materials and methods: A total of 35 with T2DM and CAN and equal number of T2DM subjects without CAN were studied [mean age ± SD: 65.1 ± 9.3 vs. 64.9 ± 12.1 years (P=0.95), duration of diabetes: 13.8 ± 8.5 vs. 12.4 ± 10.7 years (P=0.57), respectively]. A detailed medical history, current use of medications and smoking habits was obtained and a thorough physical examination was performed. Antibodies to oxLDL/beta(2)-GPI were measured by ELISA.
Results: Diabetic subjects with CAN higher levels of IgG antibodies to oxLDL/beta(2)-GPI compared with diabetic subjects without CAN (10.9 ± 12.7 vs. 7.0 ± 10.2, P=0.02). No difference was observed between the two study groups regarding the levels of IgM antibodies to oxLDL/beta(2)-GPI (16.9 ± 5.7 vs. 16.1 ± 1.2, P=0.87). Multivariate linear regression analysis in diabetic subjects with CAN demonstrated a positive relationship between IgG antibodies to oxLDL/beta(2)-GPI with HbA1c (P=0.01), plasma fasting glucose levels (P=0.04) and triglycerides, and a negative association with body mass index (P = 0.08). However, multivariate analysis, after adjustment for the above factors, showed no statistical significant relationships between antibodies to oxLDL/beta(2)-GPI and the study parameters.
Conclusion: High levels of IgG antibodies to oxLDL/beta(2)-GPI in T2DM subjects with CAN compared with T2DM subjects without CAN shows the significance of oxLDL/beta(2)-GPI to the initiation and progress of atherosclerosis as well as to the development of cardiovascular complications.
