MINUTES OF THE 44th GENERAL ASSEMBLY OF THE EUROPEAN ASSOCIATION FOR THE STUDY OF DIABETES

held in Rome, Italy on 10 September 2008 at 18:15

Present:	**E. Ferrannini**	**(President)**
	G. Spinas	**(Honorary Treasurer)**
	M. Stumvoll	**(Honorary Secretary)**
	E. Gale	**(Editor-in-Chief, Diabetologia)**
	V. Jörgens	**(Executive Director)**
	and 42 members	

The President welcomed everyone to the 44th General Assembly.

1. MINUTES 43rd GENERAL ASSEMBLY 2007

Since there were no comments, the minutes were approved unanimously and officially signed as a correct record.

2. REPORTS

a) President

The President reported on the joint project with EPA, ESC and EASD to prepare a statement concerning cardiovascular risk in diabetes in patients with severe mental illness.
The President confirmed that the Foundation was continuing to flourish. At present, 16 EFSD programmes are in place and meetings have been scheduled in Rome with potential new partners.

b) Honorary Treasurer

The Honorary Treasurer reported that the positive balance was mainly due to an increase in the number of registered delegates and an increase in the interest accrued. The expenditure in 2007 increased due to the increase in the amount spent on the salaries and the expenditure for the Annual Meeting. It had been decided to transfer 1.7 million to the Foundation. Dr. Spinas said that of the Foundation's total income more than 90% was spent on research.

Dr. Spinas expressed his thanks to Drs Grüßer and Jörgens for their support and advice and to the team in Düsseldorf in general and to Mrs Klee and Ms Deparade in particular for the precise handling of the accounts.

The President thanked the Honorary Treasurer for his diligence and asked if there were any questions. There were none.

c) Honorary Auditors

The President asked the Honorary Auditor, Dr. Tiedge, to formally discharge the accounts. He confirmed that the accounts had been checked carefully and were in perfect order. Dr. Ferrannini asked for the vote to accept the accounts.

The accounts were accepted unanimously (one abstention).

d) Honorary Secretary

Dr. Stumvoll reported that he had restructured some of the groups and the committee; there are now 40 reviewers to score 8 topics. Of the 2498 abstracts received,

1402 had been accepted. This number was then divided into 264 orals and 1138 posters. He said the Programme Committee was already in place for the Annual Meeting in Vienna and it would convene later that day.

Dr. Stumvoll closed his report by thanking all members of the EASD staff, in particular Mrs H. Goliberzuch and M. Toledo, for their outstanding help and support with the organisation of the EASD Annual Meetings.

Dr. Ferrannini thanked Dr. Stumvoll for his diligence and asked if there were any questions. There were none.

e) Editor-in-Chief, Diabetologia

Dr. Gale reported that a total of 1769 articles had been submitted to Diabetologia in 2007, which was a slight increase over 2008. The median time from receipt to first decision was 17 days. The acceptance rate for all article types combined fell to 17.4%. The impact factor rose to 5.8.

He expressed his thanks to the referees and associates and said their work was much appreciated. He also thanked his team in Bristol.

Dr. Ferrannini thanked Dr. Gale for the excellent work he had done. He said a sub-committee had been appointed by the Executive Committee to evaluate potential candidates for the position of Editor-in-Chief. There were no questions.

f) Chair, Postgraduate Education Sub-committee

Dr. Nolan reported that the usual postgraduate courses had taken place in Jena, Loipersdorf and Wroclaw. The course planned for Belgrade has been postponed until 2009. A course is being planned by Dr. Mankovsky in Ukraine.

Regarding web-based education, 2 pilot sessions on standard topics were held in Düsseldorf in 2008. Further web-casts are planned including hypertension and diabetes, diabetes and the heart and type 2 in adolescents and children.

Dr. Nolan thanked the team in Düsseldorf, especially Mrs. M. Hata and Mr. B. Carey, for their friendly assistance.

Dr. Ferrannini thanked Dr. Nolan for his valuable work. There were no questions.

3. ELECTIONS

a) President 2008-2011

The council's election of Dr. U. Smith was unanimously approved with one abstention.

b) Vice President 2008-2011

The Council's election of Dr. A.J.M. Boulton was unanimously approved with one abstention.

c) Editor-in-Chief extension 2009-2010

The extension of the Editor-in-Chief's term of office until 2010 was unanimously approved with one abstention.

d) Honorary Auditors 2008-2011

The Council's election of Drs. K. Paterson (UK) and C. Tack (The Netherlands) was approved with 1 abstention.

c) Council Members 2009-2012

The following Council Members were unanimously (1 abstention) elected by the General Assembly:
J.-M. Boavida (P), C.-G. Östenson (S), A. Pfeiffer (D) and N. Wareham (UK).

4. STUDY GROUPS

Dr. Stumvoll said that the Study Group Forum which had been held on 7 September had been well attended and no problems had arisen.

5. HONORARY MEMBERSHIP

Drs. J.-P. Assal and R. Unger were unanimously elected by the General Assembly.

6. MEMBERSHIP FEE

The General Assembly unanimously approved the proposal that applications for membership of EASD starting on 1 July would run for 1½ years.

7. ANY OTHER BUSINESS

There was no other business.

Dr. Ferrannini thanked the out-going Vice President, Dr. U. Smith, for his dedication and presented him with the Albert Renold Medal. Dr. Smith expressed his thanks for the confidence that had been shown in him when he was elected President.

Dr. Smith warmly thanked Dr. Ferrannini for his outstanding service to the EASD as President and handed over the Albert Renold medal.

Dr. Ferrannini also thanked the outgoing members of the Council:
Drs. K. Dahl Jørgensen, B. Mankovsky and S. Sasson.

Dr. Ferrannini thanked the industry for their support. He also expressed his sincere gratitude to the Local Organising Committee for their outstanding contribution to the organisation of the 44th EASD Annual Meeting. He again thanked Dr. Stumvoll and the members of the Programme Committee for their hard work with regard to the scientific programme. The President warmly thanked the EASD team in Düsseldorf for their kind and efficient help.

Dr. Ferrannini brought the General Assembly to a close at 18:35.

Agenda for the 45th General Assembly of the European Association for the Study of Diabetes

to be held in the Basch Hall at the Messe Wien, Vienna, Austria on 01 October 2009 at 18:15

1. Minutes of the 44th General Assembly, Rome, Italy 2008

2. Reports

a) President	Dr. U. Smith
b) Honorary Treasurer	Dr. G. Spinas
c) Honorary Auditors	Dr. K. Paterson Dr. C. Tack
d) Honorary Secretary	Dr. M. Stumvoll
e) Editor in Chief, Diabetologia	Dr. E. Gale
f) Chair, Postgraduate Education Sub-committee	Dr. J. Nolan

3. Elections

a) Vice President 2009-2012	in place of Dr. C. Boitard
b) Editor-in-Chief 2010-2013	in place of Dr. E. Gale
c) Honorary Treasurer Extension 2009-2010	Dr. G. Spinas
d) Chair, PGESC Extension 2009-2010	Dr. J. Nolan
e) Council Members 2010-2013	in place of Dr. F. Ashcroft (UK) Dr. F. Bosch (E) Dr. V. Petrenko (LT) Dr. A. Siebenhofer (A)

4. Study Groups

5. Honorary Membership

OP 1 GLP-1 in the treatment of type 2 diabetes mellitus

1

One-year exenatide treatment improves beta cell response in metformin treated patients with type 2 diabetes which is sustained after 5 weeks discontinuation of treatment

M.C. Bunck[1], A. Mari[2], A. Corner[3], B. Eliasson[4], R.M. Shaginian[5], Y. Wu[6], P. Yan[6], R.J. Heine[1,7], U. Smith[4], M.-R. Taskinen[3], H. Yki-Jarvinen[3], M. Diamant[1];
[1]Department of Endocrinology / Diabetes Center, VU University Medical Center, Amsterdam, Netherlands, [2]Institute of Biomedical Engineering, Padua, Italy, [3]Department of Medicine, Helsinki University Central Hospital, Finland, [4]Lundberg Laboratory for Diabetes Research, Sahlgrenska University Hospital, Goteborg, Sweden, [5]Eli Lilly, Houten, Netherlands, [6]Amylin Pharmaceuticals, Inc., San Diego, United States, [7]Eli Lilly, Indianapolis, United States.

Background and aims: Recently we reported exenatide (EX) improved hyperglycaemic clamp derived measures of ß-cell function, compared to insulin glargine (IG) in metformin (MET) treated patients with type 2 diabetes. Here we report the effect of EX treatment on the ß-cell response to a more physiological stimulus, i.e. a mixed meal.
Material and methods: In this investigator-designed study, we compared the effects of both EX and IG treatment on prandial ß-cell function during an 8 hour, high fat, double mixed meal test. Sixty-nine MET treated patients with T2D (pre-treatment (PT) age 58±8y; HbA1c 7.5±0.8%; BMI 31±4kg/m2 [mean±SD]) were randomised to EX (n=36) or IG (n=33). Meal tests were performed at PT, after 51-weeks on-treatment and again after 5-weeks off-treatment on 59 patients (EX: n=30; IG: n=29) who received a breakfast at t=0h and lunch at t=4h both containing approximately 50g fat, 75g carbohydrates, and 35g protein.C-peptide deconvolution was used to calculate insulin secretion rates (ISR), and a mathematical model to obtain the dose-response relating ISR to glucose concentrations (bGS=glucose sensitivity=dose-response slope; ISR@Gref=ISR at reference glucose level [Gref]) and a time-dependent potentiation factor expressing a relative potentiation of the dose-response relation during the meal (POT; [time]-to-basal potentiation ratio).
Results: After 1-year treatment, EX resulted in a greater upward shift in ISR-gref than IG (between group geometric LS mean ratio±SE: 1.41±0.17, P=0.007 (ISR@7.0mM); 1.32±0.16, P=0.025 (ISR@7.5mM) and 1.26±0.15, P=0.060 (ISR@8.0mM)). Additionally, EX treatment increased POT after both breakfast and lunch meals compared to IG (between group geometric LS mean ratio±SE: 1.22±0.11; P=0.026 and 1.19±0.11; P=0.054, for [170-190min]-to-basal and [240-480min]-to-basal respectively). Both Ex and IG treatment equally improved bGS (median[IQR] change from PT: EX: 7.9[2.2-27.5], P<0.001; IG: 12.8[5.6-29.3], P<0.001, between group comparison P=0.544). After the 5-week off-drug period, ISRgref remained improved in both the EX and IG treated patients without a significant difference between the two treatment groups (geometric LS mean±SE ratio to PT for EX and IG respectively: 1.52±0.18, P=0.003 and 1.47±0.19, P=0.106 (ISR@7.0mM); 1.45±0.15, P=0.004 and 1.46±0.16, P=0.053 (ISR@7.5mM); 1.41±0.14, P=0.007 and 1.45±0.15, P=0.039 (ISR@8.0mM)). All other measures returned to PT values.
Conclusion: In this study, 1-year of EX therapy, compared to IG, significantly improved both the prandial ISR over a range of glucose concentrations and the potentiation of the ISR to glucose dose-response relation. The beneficial effects on the dose-response relation were sustained after a 5-week off-treatment period in both the EX and IG treated groups.

2

A switch from twice-daily exenatide to once-daily liraglutide further improves glycaemic control in patients with type 2 diabetes on oral agents

J. Buse[1], G. Sesti[2], W.E. Schmidt[3], E. Montanya[4], Y. Xu[5], C. Chang[5], L. Blonde[6], J. Rosenstock[7];
[1]Endocrinology, University of North Carolina School of Medicine, Chapel Hill, United States, [2]Magna Graecia University of Catanzaro, Italy, [3]St Josef-Hospital, Ruhr University Medical Facility, Bochum, Germany, [4]Hospital Unversitari Bellivtge-IBIDELL, University of Barcelona, Spain, [5]Novo Nordisk Inc, Princeton, United States, [6]Ochsner Medical Center, New Orleans, United States, [7]Dallas Diabetes and Endocrine Center, Dallas, United States.

Background and aims: Liraglutide is a once-daily human glucagon-like peptide-1 (GLP-1) analogue in development for the treatment of type 2 diabetes. A 26-week randomised trial (LEAD-6) showed that, on a background of metformin and/or sulphonylurea (SU), liraglutide was more effective than exenatide in improving glycosylated haemoglobin (HbA_{1c}) and homeostasis model assessment index of beta-cell function (HOMA-B), with less hypoglycaemia. This extension compared the effect of switching from exenatide to liraglutide treatment versus continued liraglutide treatment.
Materials and methods: In total, 389 patients completing LEAD 6 entered the 14-week non-randomised extension phase (97% of these completed the extension). Patients switched from exenatide 10 µg twice daily to liraglutide 1.8 mg once daily (OD) (following 0.6 mg OD for 1 week and 1.2 mg OD for 1 week), or continued liraglutide 1.8 mg OD.
Results: Patients switching from exenatide to liraglutide further improved glycaemic control from week 26: HbA_{1c} decreased by 0.32% (p<0.0001), 57% of patients reached HbA_{1c} target <7.0% by week 40, and fasting plasma glucose (FPG) significantly decreased by 0.9 mmol/L (p<0.0001). Significant improvements in beta-cell function were seen, with HOMA-B increasing by 14.5% (p≤0.001). Also, significant additional reductions in body weight (BW) and systolic blood pressure (SBP) occurred in the exenatide-to-liraglutide group, as well as the liraglutide-to-liraglutide group (Table). Furthermore, switching from exenatide to liraglutide was characterised by a decreased rate of minor hypoglycaemia (2.6 vs 1.3 events/patient/year for Wk 0-26 and Wk 26-40, respectively). Patients continuing liraglutide treatment reported 0.7 events/patient/year during the extension phase (vs 1.9 events/patient/year; Wk 0-26). Lower rates of nausea were observed during the extension when compared to the main trial. The proportion of subjects reporting nausea reduced from 28% and 25.5% for the exenatide-to-liraglutide group and the liraglutide-to-liraglutide group, respectively, during the main trial to 3.2% and 1.5%, respectively, during the extension phase. No pancreatitis occurred.
Conclusion: Switching from exenatide to liraglutide is well tolerated and provides additional benefits in overall glycaemic control, and beta-cell function

Long-term sustained glycaemic control with liraglutide and glimepiride (both plus metformin), with added benefits of weight loss and less hypoglycaemia with liraglutide: 2-year LEAD-2 data

A. Frid[1], K. Hermansen[2], M. Nauck[3], N. Shah[4], T. Tankova[5], I. Mitha[6], M. Zdravkovic[7], D. Matthews[8];
[1]Öresund Diabetes Team AB, Lund, Sweden, [2]University Hospital, Aarhus, Denmark, [3]Diabeteszentrum, Bad Lauterberg im Harz, Germany, [4]KEM Hospital, Mumbai, India, [5]Medical University, Sofia, Bulgaria, [6]BenMed Hospital, Benoni, South Africa, [7]Novo Nordisk, Bagsvaerd, Denmark, [8]OCDEM, Oxford, United Kingdom.

Background and aims: Liraglutide is a once-daily (OD) human GLP-1 analogue. In 1091 patients with T2D, 6 months liraglutide compared with glimepiride (both combined with metformin; met) led to similar glycaemic control, but added benefits of lower weight, reduced hypoglycaemia and improved SBP with liraglutide. Here we report data from the planned 1.5-year extension.
Materials and methods: Subjects were randomised (2:2:2:1:2) to liraglutide OD (0.6, 1.2 or 1.8mg) +met, met alone [met], or met+glimepiride (4mg OD) [glim]. Met dose was 1.5-2g/day. First 6 months double-blind, double-dummy; then open-label.
Results: 89% (780 subjects) of 26-wk completers entered the extension; 529 (68%) of them completed 2 yr. Prior to trial entry, subjects were previously treated with 1 or 2 OADs. HbA_{1c} in subjects using 1 OAD before trial entry (35% of patients, baseline HbA_{1c} 8.2%) was improved and sustained for 2 yr. For these patients (ITT, LOCF) after 2 yr, HbA_{1c} was 7.38%, 7.44%, 7.74% for liraglutide 1.8, 1.2, 0.6mg, 7.49% for glim and 8.12% for met alone, respectively ($p>0.05$ for liraglutide 1.8mg vs glim) (Fig). In the total population (ITT, LOCF), the proportion reaching $HbA_{1c}<7.0\%$ after 2 yr was 31.1%, 29.9%, 19.7% for liraglutide 1.8, 1.2, 0.6mg, 23.5% for glim and 10.8% for met alone ($p<0.0001$ liraglutide 1.8mg vs glim). Providing comparable HbA_{1c} improvement to glim but bringing more subjects to target, liraglutide led to significant and sustained weight loss (1.8mg: -2.91kg; 1.2mg: -3.03kg; 0.6mg; -2.07kg) whereas glim resulted in weight gain (0.7kg, $p<0.0001$ vs all liraglutide doses). Estimated mean waist circumference was significantly reduced by 1.8-2.8cm from baseline to 2 yr with liraglutide vs an increase with glim (+0.2cm, $p\leq0.0001$). With liraglutide, hypoglycaemia incidence was similar to met alone and 10-fold less than glim (events/subj yr: 0.15 [each liraglutide dose]; 0.16 [met]; 1.60 [glim], $p<0.0001$ vs all liraglutide doses). Odds-ratio for achieving composite endpoint of $HbA_{1c}<7.0\%$+no weight gain+no hypoglycaemia for liraglutide 1.8mg was 4.9 vs glim, 3.8 vs met alone ($p<0.001$; $p=0.0002$). Although not significant between groups, visceral adipose tissue area was reduced by mean of 18 and 13cm^2 with liraglutide 1.2 and 1.8mg, respectively and increased by 9 and 2cm^2 with met alone and glim, measured by single-slice abdominal CT scan.
Conclusion: Liraglutide OD in combination with met for 2 yr brought comparable improvement in HbA_{1c} as glim in combination with met. However, hypoglycaemia with liraglutide was only a tenth of that with glim and sustained ~3kg weight loss was obtained during the 2 yr in contrast to a small weight gain with glim.

4

Liraglutide is associated with a significantly greater improvement in glycaemic control than glimepiride in patients with highest baseline beta cell function

D.R. Matthews[1], A. Falahati[2], A.D. Toft[2], J. Meier[3];
[1]NIHR Oxford Bomedical Research Centre, OCDEM, The Churchill Hospital, Oxford, United Kingdom, [2]Novo Nordisk, Bagsvaerd, Denmark, [3]Ruhr University, Bochum, Germany.

Background and aims: Treatments for T2D with beneficial effects on beta-cell function include glucagon-like peptide (GLP)-1 agonists and sulphonylureas (SUs). Liraglutide, a once-daily human GLP-1 analogue, promotes glucose-dependent insulin release and preserves beta-cell function as well as being associated with weight loss and less risk of hypoglycaemia than SUs. This report compares the efficacy (HbA_{1c}) of liraglutide (1.2 mg or 1.8 mg/day) and glimepiride in patients with T2D according to baseline beta-cell function.
Materials and methods: A meta-analysis was performed across six randomized controlled 26-week trials (3967 patients). An ANCOVA model adjusted by quartile of beta-cell function at baseline (as defined by HOMA-B and C-peptide) assessed the impact of beta cell functional capacity on response to treatment modality.
Results: After 26 weeks' treatment, liraglutide reduced HbA_{1c} from baseline significantly more than glimepiride ($p<0.01$), with reductions of 1.4%, 1.3% and 1.1% for 1.8 mg, 1.2 mg and glimepiride, respectively. Liraglutide reduced HbA_{1c} significantly across all quartiles of HOMA-B and C-peptide (≥1.3%). Reductions of HbA_{1c} with liraglutide were significantly greater than those with glimepiride in 2nd quartile (0.23% [SE=0.12], 0.28% [0.11] for 1.2 mg and 1.8 mg vs glimepiride) and 4th quartile (0.42% [0.11], 0.40% [0.11] for 1.2 mg and 1.8 mg vs glimepiride) from baseline HOMA-B ($p<0.05$), and in 3rd and 4th quartiles of baseline C-peptide (Figure). The greatest improvements in HbA_{1c} occurred in patients with the greatest baseline beta-cell function (Q4) taking liraglutide, whereas no effect of baseline quartile could be seen with glimepiride (Figure).
Conclusion: Liraglutide was effective across the continuum of beta-cell activity. Since treatment with liraglutide was even more effective in subjects with the best beta-cell function at baseline, this might imply enhanced clinical benefits when liraglutide is initiated early.

5

The DPP-4-inhibitor sitagliptin improves glucose tolerance in type 2 diabetes mellitus involving GLP-1 dependent and GLP-1 independent pathways

G. Kutscherauer, A. Bedorf, M. Nicolaus, B. Göke, J. Schirra;
Department of Internal Medicine II, Campus Großhadern, University of Munich, Germany.

Background and aims: Inhibitors of the enzym Dipeptidyl-peptidase-4 (DPP-4) are currently used for treatment of type 2 diabetes mellitus (T2DM). DPP-4-inhibitors prevent the degradation of the insulinotropic gut hormones GLP-1 and GIP, thereby enhancing plasma levels of the bioactive peptides. Both, GLP-1 and GIP are postprandially (PP) released and stimulate insulin secretion via specific receptors on the B-cell. However, the importance of the incretin hormones for the efficacy of DPP-4-inhibitors has never been demonstrated. Moreover, because several studies indicated a failure of synthetic GIP to stimulate insulin secretion in T2DM, a defect of the GIP action in T2DM has been suggested. To evaluate the contribution of endogenous GLP-1, we examined the effect of the specific DPP-4 inhibitor Sitagliptin on glucose tolerance and insulin excursions after an oral glucose tolerance test (OGTT) in patients with T2DM with and without a GLP-1 receptor blockade using exendin(9-39) (Ex-9).
Materials and methods: Double-blind, placebo-controlled, four-arm-cross-over study in 24 patients with T2DM (61±7 y, HbA1c 6.2±0.2, BMI 27.7±0.9). On four days separated by a wash-out period of at least one week blood glucose and plasma insulin concentrations were measured during the four hours after ingestion of an OGTT (75g). In a randomized cross-over fashion, oral treatment with placebo or 100 mg Sitagliptin was combined with an intravenous background infusion of saline or Ex-9 at 900 pmol/kg/min. The oral medication was given the day before and 60min before ingestion of the OGTT. The dose of Ex-9 used here blocks the insulinotropic effect of GLP-1 in human by at least 95%. The insulin-to-glucose ratio (IGR) was calculated as a measure of glucose sensitivity. Analysis of PP incremental means by two-way RM ANOVA followed by Student-Newman-Keuls multicomparison t-test (see table).
Results: Ex-9 significantly increased PP blood glucose (P=0.004 vs saline iv) and decreased PP plasma insulin excursions (P<0.001 vs saline iv) with and without Sitagliptin. Sitagliptin decreased the mean PP blood glucose excursion (P<0.001 vs placebo po) and PP glucose peak (P<0.001 vs placebo po) with and without Ex-9 iv. In spite of the lower PP glycemia, Sitagliptin increased PP plasma insulin (P=0.008), and this again was not dependent on background infusion. IGR was significantly increased under Sitagliptin during saline iv (diff. 13.4±3.5 µU/mg, P<0.001 vs placebo) and such increment of IGR under Sitagliptin, albeit lower, was detectable during Ex-9, too (diff. 7.7±2.0, P=0.012 vs placebo).

Table: Postprandial glycemia and plasma insulin excursions after an OGTT in T2DM

	Plac po + saline iv	Sita po + saline iv	Plac po + Ex-9 iv	Sita po + Ex-9 iv
Glucose, PP mean (mg/dl)	76.8±4.8	63.0±4.5*	83.9±5.2#	76.5±5.9*#
Glucose, PP peak (mg/dl)	156±5	126±6*	167±6#	158±7*#
Insulin(µU/ml)	31.7±5.5	35.2±5.6*	25.6±4.1#	28.9±4.7*#
Insulin-Glucose ratio (µU/mg)	46.2±7.3	59.6±8.5*	35.6±6.2#	43.3±7.1*#

Mean±SEM. *P<0.05 vs placebo po, same iv infusion; #P<0.05 vs saline iv., same oral treatment (2-way ANOVA followed by SNK test)
Conclusion: In patients with T2DM, endogenous GLP-1 significantly reduces postprandial glycemia by stimulating insulin secretion. Acute DPP-4 inhibition by Sitagliptin improves glucose tolerance by enhancing endogenous GLP-1 action. However, Sitagliptin is still active after blockade of the GLP-1 receptor. We suggest, that GIP accounts for the GLP-1 independent pathway of Sitagliptin.

Incidence of acute pancreatitis in exenatide initiators compared to other antidiabetic drug initiators: a retrospective, cohort study

G. Bloomgren[1], D. Dore[2], R. Patterson[1], R. Noel[3], D. Braun[3], J. Seeger[2];
[1]Amylin Pharmaceuticals, Inc., San Diego, United States, [2]i3 Drug Safety, Waltham, United States, [3]Eli Lilly, Indianapolis, United States.

Background and aims: Post-marketing cases of acute pancreatitis in patients treated with exenatide BID have been reported. Using a large, geographically diverse US healthcare insurance claims database, we conducted a retrospective, cohort study to estimate the absolute and relative risk of acute pancreatitis in patients who initiated exenatide relative to those who initiated other antidiabetic drugs. This represents an interim analysis of claims data to be further validated through medical records review.
Materials and methods: Eligible patients were enrolled in the health care plan for at least 9 continuous months (Sep 1, 2004 to Dec 31, 2007) and had no history of chronic or acute pancreatitis. Propensity scores for exenatide initiation were developed from baseline characteristics (proxies for diabetes mellitus (DM) severity, cardiovascular disease (CV), known acute pancreatitis risk factors, and empirically-derived variables), which were obtained from 9 months of claims data prior to cohort entry. Cases were patients with a primary diagnosis of acute pancreatitis (ICD-9 577.0) associated with an emergency room visit or hospitalisation during follow-up. We used multivariable Poisson regression to estimate the incidence rate (IR), rate ratio (RR), and 95% confidence intervals (CI) comparing periods of current, recent, and past use of exenatide to periods of current, recent, and past use of other antidiabetic drugs.
Results: Initiators of exenatide (N= 25,719; 80% age 40-64 y) were more likely to be female (56% vs 49%) and had a higher baseline prevalence of claims for type 2 DM (84% vs 59%), obesity (16% vs 8%), and CV risk factors (hyperlipidaemia 77% vs 54%; hypertension 64% vs 49%) than initiators of other antidiabetic drugs. In addition, exenatide initiators were more likely to use multiple DM drugs (hypoglycaemic agents: biguanides 60% vs 20%; insulin-release stimulant type 48% vs 18%; insulin-response enhancer 46% vs 13%; insulins 24% vs 9%, lipotropics 61% vs 38% , ACE inhibitors 39% vs 27%) than other antidiabetes drug initiators. Compared to other antidiabetic drugs, the RR of acute pancreatitis for exenatide was: 0.9 [CI 0.6-1.3] for current use, 0.9 [CI 0.4-2.1] for recent use, and 1.4 [CI 0.9-2.3] for past use.
Conclusion: These data suggest that use of exenatide was not associated with an increased rate of acute pancreatitis compared to other antidiabetic drugs.

OP 2 Prediction and prevention of type 2 diabetes mellitus

The diabetes risk score outperforms fasting plasma glucose and glucose tolerance tests: combined results from the Inter99 and Botnia Studies

M.P. McKenna[1], V. Lyssenko[2], M. Rowe[1], R. Gerwien[1], J. Kolberg[1], M. Urdea[1], T. Hansen[3], T. Jørgensen[4,5], O. Pedersen[5,3], K. Borch-Johnssen[3,6], L. Groop[2];
[1]Research, Tethys Bioscience, Emeryville, United States, [2]Department of Clinical Sciences/Diabetes & Endocrinology, Lund University, Malmö, Sweden, [3]Steno Diabetes Center, Copenhagen, Denmark, [4]Research Centre for Prevention and Health, Glostrup Hospital, Copenhagen, Denmark, [5]Faculty of Health Science, University of Copenhagen, Denmark, [6]Faculty of Health Science, University of Aarhus, Denmark.

Background and aims: Improved identification of subjects at high risk for development of Type 2 diabetes (T2D) would allow more aggressive preventive interventions to be targeted towards those individuals who could benefit most. The aim of this study was to validate a multi-marker panel that predicts 5 year risk of T2D on an independent population, and to compare the performance to a combined clinical model of fasting plasma glucose and glucose tolerance.
Materials and methods: The Diabetes Risk Score (DRS) was based on a 7-biomarker panel developed from the Inter99 cohort, a Danish longitudinal population-based study of middle-aged participants. The test was performed on an independent population, the Botnia cohort, a Finnish family-based study designed to identify genetic factors associated with the development of T2D. All 1993 Botnia participants with outcomes and available baseline specimens were tested. Reclassification analysis was used to consider the utility of the DRS relative to plasma glucose tests. In idealized current clinical practice, patients with impaired fasting glucose would be further stratified by 2hr OGTT. Glucose test results were categorized into Low (NFG), Medium (isolated IFG) and High (IFG/IGT) risk groups. The DRS results were applied to reclassify the glucose categories using three bins: Low (score =4=7.3). To increase the statistical power of this analysis, subjects in the Botnia cohort who converted to diabetes at any time during the study over 15.5 years were considered converters.
Results: The DRS stratified the Botnia population more accurately than glucose measures. As shown in the table, DRS identified 7% of the population as high risk, of which 30.7% converted. Using glucose measures, 6% of subjects had both IFG and IGT, of which only 19.8% converted. DRS assigned low risk to 68.4% of subjects, of which 2.1% converted; by contrast, 81.7% of subjects had normal fasting glucose of which 4.5% converted. The overall net reclassification index (NRI) was highly significant (0.341, p<0.0001). The NRI in each of the glucose strata were also significant; DRS showed the greatest improvement among intermediate risk subjects with isolated IFG.
Conclusion: DRS assigned Botnia subjects to low, medium and high risk groups with more accuracy than the combined results of fasting plasma glucose and oral glucose tolerance tests. These results provide independent validation of a panel of serum biomarkers developed in the Inter99 study for assessing the risk of developing type 2 diabetes.

Risk Group by Glucose Measures		Risk Group by DRS: Low (< 4)	Medium (≥ 4 - 7.3)	High (≥ 7.3)	All DRS Groups	NRI (p-value)

The impact of body fat distribution and ectopic fat in determining different glucose tolerance categories

K. Kantartzis[1], J. Machann[2], F. Schick[2], C. Totsikas[1], A. Fritsche[1], H.-U. Häring[1], N. Stefan[1];
[1]Department of Internal Medicine IV, University of Tübingen, Germany, [2]Section on Experimental Radiology, University of Tübingen, Germany.

Background and aims: In the pre-diabetic state impaired fasting glucose (IFG) and impaired glucose tolerance (IGT) are both risk factors for the development of type 2 diabetes and cardiovascular disease. However, they differ in their impact on these diseases. So far it is unknown whether visceral fat and ectopic fat in the liver, important determinants of type 2 diabetes and cardiovascular disease, and their humoral products, the adipokine adiponectin and the hepatokine fetuin-A, differ between these conditions and, thus, may explain the different risk.
Materials and methods: In 330 individuals at risk for type 2 diabetes we determined glucose tolerance status by means of a 2 hr 75 g oral glucose tolerance test. Total body fat and visceral fat were precisely quantified by magnetic resonance (MR) tomography. Liver fat was measured by ^{1}H-MR spectroscopy.
Results: A total of 210 individuals were found to have normal glucose tolerance (NGT), 41 IFG, 43 IGT and 36 IFG + IGT. Between the four categories of fasting glycemia and glucose tolerance total body fat was not different (p=0.51) after adjustment for age and gender. However, a small but continuous increase in adjusted visceral fat content was found from NGT to IFG+IGT (means±SE, NGT: 3.07±0.10; IFG: 3.11±0.21; IGT: 3.61±0.21; IFG+IGT: 3.84±0.23 kg, p=0.03). A large difference among the categories was found for liver fat content. There was a continuous increase in liver fat content from NGT (4.73±0.42%) to IFG (5.86±0.92%) to IGT (8.65±0.92%) and IFG+IGT (11.11±1.01%) after adjustment for age and gender (p<0.0001). Circulating levels of the adipokine adiponectin also differed among the categories, although the differences were small (NGT: 13.67±0.46; IFG: 14.47±1.00; IGT: 11.76±0.99; IFG+IGT: 10.80±1.13 μg/dl, p=0.08). In contrast, there was a larger difference in the circulating hepatokine fetuin-A among the categories (NGT: 265±3; IFG: 260±8; IGT: 284±7; IFG+IGT: 286±9 μg/dl, p=0.01). Next we investigated the predictive effect of total body fat, visceral fat and liver fat on determining the glucose tolerance categories. In a forward stepwise regression analysis liver fat was the strongest determinant of the categories (p<0.0001) followed by age (p=0.0005) and gender (p=0.11). In another analysis including age, gender, adiponectin and fetuin-A, age was the strongest determinant of the categories (p<0.0001) followed by fetuin-A (p=0.016) and adiponectin (p=0.02).
Conclusion: Among total body fat, visceral fat and ectopic fat in the liver, liver fat strongly and continuously increases when fasting glycemia and glucose tolerance move from NGT to IFG, IGT and IFG+IGT. Furthermore, liver fat is predicting the glucose tolerance category independently of total- and visceral fat. In addition, among the humoral products of fat and liver, fetuin-A was a stronger predictor of the categories than adiponectin. Thus, liver fat may represent an important target in the treatment of pre-diabetes and in the prevention of type 2 diabetes.

Use of multiple metabolic and genetic markers to improve the prediction of type 2 diabetes: the EPIC-Potsdam study

M.B. Schulze[1,2], C. Weikert[1,3], T. Pischon[1], M.M. Bergmann[1], H. Al-Hasani[4], E. Schleicher[5], A. Fritsche[5], H.-U. Häring[5], H. Boeing[1], H.-G. Joost[4];
[1]Department of Epidemiology, German Institute of Human Nutrition Potsdam-Rehbruecke, Nuthetal, [2]Public Health Nutrition Unit, Technische Universität München, Freising, [3]Institute for Social Medicine, Epidemiology, and Health Economics, Charité University Medicine Berlin, [4]Department of Pharmacology, German Institute of Human Nutrition Potsdam-Rehbruecke, Nuthetal, [5]Department of Internal Medicine, Division of Endocrinology, Diabetology, Nephrology, Vascular Disease, University of Tübingen, Germany.

Background and aims: Precise prediction of the risk of type 2 diabetes is essential for early and cost-effective prevention. We evaluated whether metabolic factors and single nucleotide polymorphisms (SNPs) can improve diabetes risk prediction in a population-based, prospective study beyond an established prediction model based on age, anthropometric, diet, and lifestyle variables (German Diabetes Risk Score).

Materials and methods: A case-cohort study within the European Prospective Investigation into Cancer and Nutrition (EPIC)-Potsdam study comprising 27,548 participants was designed. We randomly selected a subcohort of 2,500 individuals from the 26,444 participants with blood of whom 1,991 were diabetes-free at baseline and had anamnestic, anthropometrical, lifestyle, and metabolic data. Of the 801 incident type 2 diabetes cases identified in the cohort during 7 years of follow-up 582 remained for analyses after exclusions. Prediction models were compared by receiver operator characteristics (ROC) and reclassification was evaluated by the integrated discrimination improvement (IDI).
Results: Prediction by the risk score (ROC-AUC: 0.8448) was improved by inclusion of plasma glucose (ROC-AUC: 0.8636, p<0.001) and HbA1c (ROC-AUC: 0.8833, p<0.001). ROC-AUC was further improved with HDL-cholesterol, triglycerides, γ-glutamyltransferase, and alanine-aminotransferase (0.8974, p=0.0028), which was confirmed by improved risk classification (relative IDI: 5%), but additional information on adiponectin or hs-CRP resulted not in meaningful improvements. Information on diabetogenic SNPs (preliminary set of 17 variants) beyond these characteristics resulted in slight improvement in discrimination (ROC-AUC: 0.9053, p=0.0183) and risk classification (relative IDI: 4%). Parental history was associated with higher diabetes risk not explained by genetic variants evaluated, and this information provided a small improvement of risk prediction beyond the German DRS (relative IDI: 5%).
Conclusion: Metabolic markers, in particular plasma glucose and HbA1c, substantially improve risk prediction of type 2 diabetes beyond non-invasive risk factors. Seventeen SNPs slightly improved the prediction beyond these characteristics.

Prevention of type 2 diabetes development by an IKKβ inhibitor
J. Friberg[1,2], M. Thonnesen[2], F. Pociot[2], T. B. Bödvarsdottir[1], A. E. Karlsen[1];
[1]Novo Nordisk A/S, Maaloev, [2]Hagedorn Research Institute, Gentofte, Denmark.

Background and aims: High doses of anti-inflammatory drugs like aspirin and salicylates have been shown to improve insulin and glucose metabolism in insulin resistant and diabetic patients through unspecific inhibition of the IKKβ and NFkB pathways. Based on this, we have investigated the effects of a specific IKKβ-inhibitor on β-cell survival and the prevention of development of type 2 diabetes in the gerbil *Psammomys obesus* (*P. obesus*) fed a high energy diet.
Materials and methods: We investigated the development of body weight, blood glucose, HbA_1C, plasma insulin and pancreatic insulin content in P. obesus fed a high energy diet, and treated with a specific IKKβ-inhibitor (60 mg/kg; n=10) or vehicle (n=12) for one month. The effects of IKK-β inhibitor on β-cells were also studied using INS-1 cells and primary islets from *P. obesus,* exposed to interleukin-1β (IL-1β) followed by analysis of reactive oxygen species (ROS), insulin secretion and cell death.
Results: Vehicle treated animals developed diet induced diabetes during the 28 days on high energy diet with a significant increase in blood glucose (3,4±0,1mM vs. 15,5±1,3; p<0,001) and HbA_1C (4,8±0,1% vs. 6,4±0,3%; p<0,001). To compensate for the hyperglycemia the vehicle treated animals displayed a significant increase in plasma insulin until day 21 where hyperinsulinemia was declining, most likely caused by accelerated β-cell destruction (day 1: 1301±197pM vs. day 21: 6782±889; p<0,001 and day 28: 5578±708pM). Animals treated with the IKKβ-inhibitor showed no sign of diet induced diabetes during the 28 days on high energy diet. No increase in HbA_1C was observed and only a minor increase in plasma glucose and a non-significant increase in plasma insulin levels were detected. The animals treated with the IKKβ-inhibitor also had significantly lower levels of blood glucose (day 28: IKKβ-inh 5,7±0,9mM vs. vehicle 15,5±1,3mM; p<0,001), HbA_1C (day 28: IKKβ-inh. 5,0±0,2% vs. vehicle 6,4±0,3; p<0,001) and plasma insulin (day 21: IKKβ-inh. 3741±783pM vs. vehicle 6782±889; p<0,05), as compared to vehicle treated animals despite no difference in body weight (day 28: IKKβ-inh. 219±6,5g and vehicle 217±5,8g). Total pancreatic insulin was measured at day 28. The levels of pancreatic insulin stored in the IKKβ-inhibitor treated animals was more than three-fold that observed in the vehicle treated animals (day 28: IKKβ-inh. 26±7,2μg vs. vehicle 7±1,5μg; p<0,05). In primary islets and β-cells the IKKβ-inhibitor reversed IL-1β induced ROS production and diminished insulin production and β-cell death.
Conclusion: We have shown that development of diet induced hyperinsulinemia and hyperglycemia in *P. obesus* was prevented by treatment with a specific IKKβ-inhibitor. The IKKβ-inhibitor also prevented cytokine induced loss of insulin production and β-cell death in primary islets and β-cells possible by the inhibited production of ROS. This was also reflected *in vivo* since treated animals had a much larger insulin reserve compared to the exhausted β-cells in vehicle treated animals. These data support the use of anti-inflammatory drugs in prevention of type 2 diabetes. In conclusion, we have shown that an inhibitor of the NFkB pathway was able to prevent type 2 diabetes development in *P. obesus* by reversing insulin resistance and protecting β-cell function.

11

Dapagliflozin prevents the development of diabetes in male ZDF rats
B.A. Zinker[1], L. Xin[1], H. Cai[1], S. Boehm[1], M. Cap[1], J. Zalaznick[1], W.N. Washburn[2], S. Han[1], J.M. Whaley[1];
[1]Diabetes Biology, Bristol-Myers Squibb, Princeton, [2]Diabetes Chemistry, Bristol-Myers Squibb, Princeton, NJ, United States.

Background and aims: Dapagliflozin (Dapa), a potent and selective SGLT2 inhibitor, is currently under investigation as a novel agent for the treatment of type 2 diabetes. The present study was designed to examine whether treatment with Dapa for 5 weeks can prevent the development of diabetes in a model of rapid beta cell failure, the male ZDF rat.
Materials and methods: Male ZDF rats at 6 weeks of age were dosed *q.d. p.o.* for 5 weeks in the following groups: 1) age-matched lean littermates + vehicle (N=6; Lean), 2) ZDF + vehicle (N=8; ZDF), 3) ZDF + Dapa (1 mg/kg, N=8; Dapa), and 4) ZDF + rosiglitazone (10 mg/kg, N=8; Rosi) as a positive control. Oral glucose tolerance tests (OGTT, 2 g/kg) were undertaken 24 hr post final dose, after an overnight fast at the end of the 5 week treatment. Hemoglobin A1c (HbA1c) and Echo MRI were used to evaluate glycemic control and body composition, respectively, in a separate cohort (N=5) treated identically. One way ANOVA followed by Dunnett's or Tukey-Kramer test were performed for statistical analyses.
Results: In the ZDF group at 5 weeks, fasting plasma glucose (FPG) levels were 272 ± 40 mg/dL. At this time point, Dapa (80 ± 4 mg/dL; p< 0.01) and Rosi (100 ± 4 mg/dL; p<0.01) treated rats both had significantly lower FPG. HbA1c was significantly reduced with Dapa (4.6 ± 0.1%; p<0.001) and Rosi (4.1 ± 0.1%; p<0.001) compared to ZDF (7.8 ± 0.4%); both Dapa and Rosi groups were similar to Lean (4.1 ± 0.1%). In an OGTT, both Dapa and Rosi groups displayed significantly reduced glucose area under the curve (ΔAUC glucose; mg/dL*min) vs. ZDF (ZDF: 32847 ± 3995; Dapa: 11938 ± 1014, p<0.001; Rosi: 17526 ± 808, p<0.001). ΔAUC glucose in Dapa was not significantly different from Lean. Fasting insulin levels were 1.0 ± 0.1 ng/mL in Lean, and were lower in Dapa vs. Rosi (2.6 ± 0.2 ng/mL vs. 4.1 ± 0.4 ng/mL, respectively; p<0.05). Dapa fasting insulin levels were similar to ZDF (2.1 ± 0.3 ng/mL). The incremental change in insulin concentration in response to glucose challenge at 30 minutes ($\Delta Insulin_{30min}$) was greater in Dapa (7.2 ± 1.2 ng/mL, p<0.001) compared to ZDF (1.1 ± 0.4 ng/mL). Dapa $\Delta Insulin_{30min}$ was significantly different from Rosi (3.3 ± 0.9; p<0.05). Dapa treatment did not change body weight (BW, 393.4 ± 5.3 g) or fat mass (FM, 120.0 ± 3.5 g) vs. ZDF (365.2 ± 11.9 g and 111.9 ± 3.8 g, respectively), unlike Rosi treatment which increased BW (488.0 ± 15.1 g, p<0.001) and FM (219.2 ± 8.5 g, p<0.001) vs. ZDF.
Conclusion: These results suggest that once-daily dosing with Dapa prevented the development of diabetes, was body weight neutral, and preserved beta cell function in a rodent model of type 2 diabetes.

12

Liraglutide, a once-daily human GLP-1 analogue, reduces the prevalence of prediabetes in obese subjects over 20 weeks: a randomized placebo-controlled trial
N. Finer[1], M. Al Hakim[2], A. Astrup[3], A. Harper[4], M. Lean[5], L. Niskanen[6], M.F. Rasmussen[4], A. Rissanen[7], S. Rössner[8], L. Van Gaal[9], and NN8022-1807 study group;
[1]Department of Medicine, University College London, United Kingdom, [2]EB FlevoResearch, Almere, Netherlands, [3]University of Copenhagen, Frederiksberg, Denmark, [4]Novo Nordisk A/S, Bagsvaerd, Denmark, [5]University of Glasgow, United Kingdom, [6]Kuopio University Hospital, Finland, [7]Helsinki University Central Hospital, Finland, [8]Karolinska University Hospital, Huddinge, Sweden, [9]Antwerp University Hospital, Belgium.

Background and aims: Prediabetes is a strong predictor of type 2 diabetes with an estimated prevalence in Europe of 10-20%. Liraglutide reduces

HbA_{1c} by 1.0-1.5% and weight by 2-3 kg with doses up to 1.8 mg in patients with type 2 diabetes. This double-blind, placebo-controlled trial with open-label orlistat comparator was the first to investigate the effect of liraglutide in obese non-diabetic subjects. We have previously reported on body weight, the primary outcome. This abstract focuses on prediabetes status, a secondary endpoint.

Materials and methods: Subjects (18-65 years, BMI 30-40 kg/m^2), of which 175 had prediabetes based on 2003 ADA criteria, were randomized equally to 1 of 4 liraglutide doses (1.2, 1.8, 2.4 or 3.0 mg once daily s.c.), placebo once daily s.c. or orlistat (120 mg 3x daily orally) for 20 weeks. Prediabetes was defined as IGT or IFG (IGT: 2h glucose 7.8-11 mmol/L in OGTT; IFG: FPG 5.6-6.9 mmol/L). All subjects were advised and encouraged to reduce daily energy intake by 500 kcal and to increase physical activity. www.clinicaltrials.gov ID NCT00422058.

Results: In the ITT population (561 of 564 randomized subjects) with LOCF, the estimated mean placebo-subtracted weight loss from randomization was 2.1 kg [95% CI 0.6-3.6] (liraglutide 1.2 mg) to 4.4 kg [2.9-6.0] (liraglutide 3.0 mg). Mean weight loss with liraglutide 3.0 mg was 7.2 kg. Weight loss from screening, including 2-week run-in, ranged from 4.1 ± 3.9 kg with placebo to 9.1 ± 5.2 kg with liraglutide 3.0 mg (Table). Prediabetes at baseline was 31% and the incidence over 20 weeks was reduced by about 90% with liraglutide 1.8-3.0 mg. In a post hoc analysis, liraglutide-treated subjects had significantly greater odds of having normal glucose tolerance at Week 20 compared to those treated with placebo or orlistat (p<0.01 all doses, Table). The estimated odds were between 4 and 38 for liraglutide compared with 1.5 for placebo or orlistat. The number of subjects needed to be treated to prevent one case of prediabetes was 3-6 with liraglutide 1.2-3.0 mg, compared to 24 with orlistat. Compared to placebo, more events of nausea and vomiting of mild to moderate intensity occurred with liraglutide, mostly within the first 4-6 weeks.

	Liraglutide 1.2 mg	**Liraglutide 1.8 mg**	**Liraglutide 2.4 mg**	**Liraglutide 3.0 mg**	**Placebo**	**Orlistat**
Change from baseline to Week 20						
Body weight from screening (kg)[1]	**-6.7 ± 4.0**	-7.1 ± 5.8	-7.9 ± 5.0	-9.1 ± 5.2	-4.1 ± 3.9	-5.5 ± 4.3
Prediabetes to normal[2] status	**18/26 (69%)**	26/27 (96%)	23/26 (88%)	24/25 (96%)	13/28 (46%)	9/22 (41%)
Normal[2] to prediabetes status	**3/51 (6%)**	0/44 (0%)	1/46 (2%)	2/53 (4%)	11/48 (23%)	10/53 (19%)
Estimated odds ratio[3]						
Versus placebo	3.0 [1.1; 8.1]	26.1 [3.8; 181]	10.7 [2.4; 47]	12.5 [2.9; 55]	–	–
Versus orlistat	3.0 [1.1; 8.3]	26.3 [3.7; 185]	10.8 [2.4; 48]	12.6 [2.9; 56]	–	–

[1]Values are the mean +/- SD
[2]FPG <5.6 mmol/L or <7.8 mmol/L in OGTT
[3]Estimated mean OR [95% CI] for having normal glucose tolerance

Conclusion: Liraglutide 1.2-3.0 mg once daily for 20 weeks produced weight loss, reduced the incidence of prediabetes and reversed existing prediabetes in obese subjects. Treatment with liraglutide normalizes raised glucose levels and may delay the onset of type 2 diabetes.

Cost effectiveness of the DESMOND structured education programme for patients newly diagnosed with type 2 diabetes

M. Gillett[1], H.M. Dallosso[2], S. Dixon[1], A. Brennan[1], M.E. Carey[2], M.J. Campbell[1], S. Heller[3], K. Khunti[4], M.J. Davies[5];
[1]School of Health and Related Research, University of Sheffield, [2]Diabetes Research, University Hospitals of Leicester, [3]Academic Unit of Diabetes, Endocrinology and Metabolism, University of Sheffield, [4]Health Sciences, University of Leicester, [5]Cardiovascular Sciences, University of Leicester, United Kingdom.

Background and aims: DESMOND is a structured education programme for patients newly diagnosed with Type 2 diabetes. The programme meets criteria laid down by the National Institute for Health and Clinical Excellence in the UK. Previously reported results from the RCT demonstrated improvements in some bioemedical and lifestyle measures, notably smoking and body weight, and in some health scores including illness beliefs and depression scores. This analysis assesses the within-trial and long-term cost-effectiveness of DESMOND compared to usual care.

Materials and methods: The DESMOND trial was a multi-site cluster randomised controlled trial enrolling 824 people newly diagnosed with Type 2 diabetes. 12 month follow-up data including biomedical, lifestyle and NHS resource use data were collected on 749 participants. The analysis here uses the described data from the 12 month period of the DESMOND trial and the Sheffield 2 Diabetes Model to estimate the long-term outcomes, costs and benefits and cost-effectiveness of the DESMOND intervention. The estimated long-term costs and benefits of DESMOND, including its impact on use of therapies, cardiovascular events and quality-adjusted life years (QALYs) were aggregated to obtain the incremental cost per QALY. The effects of the intervention were assumed to have some sustained effect up to 3 years. Uncertainty around key parameters, such as weight changes, smoking rates and durability of effects, was explored using probabilistic sensitivity analysis (PSA) and alternative scenarios.

Results: The main drivers of the results were a 1.26 kg greater weight loss and favourable changes in smoking status with the DESMOND intervention. The resulting estimated lifetime additional costs, based on the cost of the intervention in the trial, are £218 and there is an increase in QALYs of 0.0406 and an incremental cost effectivenss ratio (ICER) of £5,369. PSA results indicate that there is an 81% likelihood that DESMOND is cost-effective compared to usual care at a UK £ 20,000 cost/QALY willingness to pay threshold. The analysis was then repeated using the current real-world cost of delivering the DESMOND intervention in a typical primary care trust which is £76 per patient compared to £203 in the trial. In this case the lifetime incremental cost is only £91 resulting in an ICER of £2,241 and the PSA indicates that there is an 87% likelihood that DESMOND is cost-effective at £20,000 cost/QALY threshold. A sensitivity analysis, based around the real world cost of DESMOND and more conservative assumptions regarding the durability of effects, resulted in an ICER of £2,647 and an 80% likelihood that DESMOND is cost effective.

Conclusion: The long-term model suggests that DESMOND, given as a one off intervention, is very cost effective even with modest assumptions around how long effects are sustained. Further model-based economic analyses can be undertaken when evidence becomes available on the effectiveness of DESMOND as an on-going intervention as recommended by NICE.

Economic impact of modular outpatient diabetes education programme

J. Pumprla[1], K. Howorka[1], N. Howorka[1], E. Perneczky[1], I. Rakovac[2];
[1]Res Group Functional Rehabilitation, Centre of Biomed. Engin. & Physics, Medical University of Vienna, [2]Joanneum Research, Graz, Austria.

Background and aims: The economic impact of a health intervention can be described by evaluation of savings with following methods: participant surveys, time value of money-analysis, extrapolation from published cost estimates, cost-benefit analyses, cost-utility studies and return on investment. Our aim was to evaluate the economic impact of our outpatient diabetes

modular education program for metabolic syndrome and diabetes, using a novel cost-utility assessment method in the context of the Austrian and German health care system and its outcomes as currently applied in diabetes treatment practice (as shown by FQSD, "Forum Qualitätssicherung Diabetes").

Materials and methods: We used the mathematical diabetes mellitus simulation model PROSIT-Danube A which is based on Markov modelling of natural course of the disease while joining cost data to the disease model. This cost-utility analysis determines the best way of spending given health care budget. It relates cost to healthy years gained (e.g. quality-adjusted life years, QALY, and/or healthy years equivalents) as benefits converted into monetary terms.

To ensure high quality epidemiological data necessary for correct input parameters, we used independent, benchmarking-based data of FQSD. Here, for benchmarking purposes 14 biggest diabetes care centres from Austria and Germany have been selected. Selection criteria for voluntarily registered centres included biggest available numbers of individuals per centre assessed with annual basic information sheets as acquired for 2 years, care for mainly adult outpatients with metabolic syndrome / type 1 and type 2 diabetes and the availability of HbA_{1c} assay reference ranges.

The simulation of effects of our diabetes structured education system was used in comparison: our subgroup treated with structured modular patient education (95 % of structured diabetes education, 35% hypertension and nephropathy prevention module), against all other patients (36% diabetes education, used data of patients with documented microalbuminuria) as found within an international benchmarking study: n = 209 / 10.325 patients, initial age 49 / 60 yrs, sex 56 / 53 % female, duration of diabetes 19 / 10 yrs, smoker 14 / 13%, HbA_{1c} 6,6 / 7,1%, blood pressure (systolic) 128 / 138 mmHg, blood pressure (diastolic) 72 / 80 mmHg, blood pressure (MAP) 91 / 99 mmHg, BMI 26 / 30 kg/m², anti-hypertensive treatment 78 / 52 %, ACE inhibitors 50 / 40%.

Results: The cost of QALY in our cost-utility calculation was 2.300 EUR while the cost per QALY in all other patients reached 2.587 EUR (both discounted values by 3.5%). Similarly, the calculated discounted cost of lifeyear was 2.277 EUR in our group versus 2.532 EUR in other centres. This finding confirms clinical findings on effective nephropathy prevention with modular diabetes education including hypertension module where necessary. Structured patient education for competent treatment proved to be cost-effective.

Conclusion: This PROSIT-based cost-utility analysis shows that structured modular ambulatory education in diabetes brings a considerable return on investment in terms of cost reduction for QALYs. Education provides benefits converted to monetary terms. Financial efficacy of patient education should be perceived by insurance and health care providers in the current health care plans of the EU.

Validating a diabetes specific quality of life measure in an English speaking population: the Irish Dose Adjustment for Normal Eating (DAFNE) Study

M. O'Hara[1], M. Byrne[2], M. Clark[3], L. Daly[4], J. Newell[4], D. Cooke[3], S. Heller[5], S. Dinneen[6], for the Irish DAFNE Study Group;
[1]Diabetes Centre, University Hospital Galway, Ireland, [2]School of Psychology, National University of Ireland, Galway, Ireland, [3]Division of Medicine, University College London, United Kingdom, [4]Clinical Research Facility, National University of Ireland, Galway, Ireland, [5]School of Medicine and Biomedical Sciences, University of Sheffield, United Kingdom, [6]Medicine, National University of Ireland, Galway, Ireland.

Background and aims: The Irish DAFNE Study is evaluating a structured education programme for people with Type 1 diabetes in Ireland. Quality of life is an important outcome of the study. We chose the Diabetes-Specific Quality of Life Scale (DSQOLS) as our main measure. The instrument was originally developed in Germany to evaluate the Düsseldorf insulin treatment and training programme. It contains 77 items including 10 individual treatment goal items, 10 satisfaction with treatment success items and 57 diabetes-related distress items (additional items were included to assess impact of hypoglycaemia on quality of life). The scale was altered slightly from the original, with input from people with diabetes, to reflect linguistic differences and more culturally appropriate scale-items. A subset of participants completed both DSQOLS and the Audit of Diabetes-Dependent Quality of Life (ADDQoL) tool. The ADDQoL was developed in England and consists of 20 items.

Materials and methods: Reliability coefficients (Cronbach's α) were computed for all psychometric subscales. Internal consistency of subscales and correlation between subscales (Pearson's correlation) were measured.

Results: A total of 42 individuals (55% female, mean age 39 years, mean diabetes duration 16 years, mean HbA1c 8.6%) completed the DSQOLS and the ADDQoL scales. The Cronbach's α for the 8 DSQOLS sub-scales were; Social relations (11 items), 0.9; Leisure time flexibility (6 items), 0.89; Physical complaints (9 items), 0.86; Worries about future (5 items), 0.87; Diet restrictions (9 items), 0.91; Daily hassles (6 items), 0.82; Fear of hypoglycaemia (11 items), 0.95 and Daily burdens and restrictions (57 items), 0.97. Cronbach's α for Average-Weighted Impact (AWI) of the ADDQoL was 0.83. In ADDQoL the overall QoL item, the future QoL item and AWI score were significantly correlated (r = .387, .341 and .324 respectively). In DSQOLS all subscales were significantly correlated to each other (r between 0.637 and 0.861). Subscales from both instruments that were significantly correlated included; Dependence (ADDQoL) and Leisure time flexibility (DSQOLS, $r = 0.363$, $p < 0.05$), Dependence (ADDQoL) and Social relations (DSQOLS, $r = 0.403$, $p < 0.01$). Holidays/ Leisure (ADDQoL) were significantly correlated to Leisure time flexibility, Physical complaints, Worries about future, Fear of hypoglycaemia and Daily burden and restrictions (DSQOLS, r = 0.393, 0.363, 0.358, 0.343 and 0.355 respectively, $p < 0.05$).

Conclusion: A high degree of internal consistency was achieved by both instruments. High inter and intra-correlations of the subscales were suitably reported. In the absence of a global QoL score from DSQOLS it was difficult to compare the 2 instruments at baseline. However future measurements within the Irish DAFNE Study will enable the responsiveness and sensitivity to change of these 2 quality of life scales to be assessed and compared.

Depression and sense of coherence are associated with food intake and compliance with dietary guidance in type 1 diabetes

A.J. Ahola[1,2], V. Mikkilä[3], S. Mäkimattila[1], M. Saraheimo[1,2], C. Forsblom[1,2], R. Freese[3], P.-H. Groop[1,2], on behalf of the FinnDiane Study Group;
[1]Folkhälsan Institute of Genetics, Helsinki, [2]Division of Nephrology, Helsinki University Central Hospital, [3]Division of Nutrition, University of Helsinki, Finland.

Background and aims: In type 1 diabetes, appropriate insulin dosing and compliance with dietary recommendations are important in achieving good metabolic control. As psychological disturbances are common in patients with type 1 diabetes, we aimed to study the associations between psychological and dietary factors. Additionally, we studied which factors are associated with compliance with dietary guidance received in health care.

Materials and methods: A total of 527 participants [46% men, mean age 47 (range 17-84) years, diabetes duration 30 (1-62) years] in the Finnish Diabetic Nephropathy Study were included in this cross-sectional study. Beck Depression Inventory (BDI) and sense of coherence test were used to study depression and sense of coherence (SOC), respectively. Data on food consumption and dietary guidance were collected using a questionnaire. Compliance with dietary guidance was assumed if patient reported following instructions always or most of the time.

Results: Overall rates of depression (score ≥16) and weak SOC (score <60) were 13% and 18%, respectively, and 9% of patients were both depressed and had weak SOC. A total of 86% of depressed and 87% of non-depressed patients had received dietary guidance (ns). These patients did not differ in compliance with dietary guidance (53% vs. 60%, p=0.27). Depressed males consumed less fresh vegetables, bread and coffee, but more fried foods compared to males without depression (p<0.05, all). Female patients with depression consumed less dairy products and fish (p<0.05, both) compared to females without depression. Of patients with weak and strong SOC, 89% and 87% had received dietary guidance (ns), but of these 48% and 61%, respectively, reported adhering to the dietary guidance often or always (p<0.05). Male patients with weak SOC consumed more soft drinks and fried foods than males with strong SOC did (p<0.05, all). Additionally, they reported more frequently using no spread on bread compared with males with strong SOC (22% vs. 5%, p<0.01). Females with weak SOC consumed less fish, cooked vegetables, and fruits and berries, but more soft drinks compared to females with strong SOC (p<0.05, all). In a logistic regression analysis, strong SOC, dietary guidance given by a physician (but not dietitian or nurse), longer diabetes duration and adherence to any special dietary regimen were associated with good self-reported compliance with dietary guidance when adjusted for gender.

Conclusion: Depression and weak SOC were associated with less prudent food choices such as infrequent consumption of fish and vegetables. Strong SOC is associated with good compliance with dietary guidance. Dietary guidance from physicians may improve the compliance. Our results suggest that

psychological well-being may play an important role in modifying dietary habits among patients with type 1 diabetes.

Effects of group-based lifestyle rehabilitation on glycaemic control, physical fitness and risk factors for cardiovascular disease in patients with type 2 diabetes

E.S. Vadstrup[1], A. Frølich[2], H. Perrild[1], E. Borg[3], M. Røder[4,1];
[1]Department of Endocrinology and Gastroenterology, Bispebjerg University Hospital, Copenhagen, [2]Department of Integrated Healthcare, Bispebjerg University Hospital, Copenhagen, [3]Health Care Centre Oesterbro, Copenhagen, [4]Department of Cardiology and Endocrinology, Hillerød University Hospital, Denmark.

Background and aims: Current guidelines recommend education, physical activity and change in diet for type 2 diabetes patients, yet composition and organization of non-pharmacological care are still controversial. We investigated the effectiveness of a new group-based lifestyle rehabilitation programme in a Health Care Centre in primary care versus conventional individual counselling in an Outpatient Clinic.
Materials and methods: We randomized 143 adult type 2 diabetes patients to either the intervention group consisting of an education programme delivered by a multi-disciplinary team, a supervised exercise programme, and a cooking course, or the control group receiving individual counselling with a diabetes nurse specialist and a dietician. Outcome measures at 6 months follow-up included HbA1c (primary outcome), blood pressure, lipid profile, anthropometric variables, and physical fitness.
Results: Baseline characteristics were comparable, 22 patients did not complete 6 months follow-up, and 121 patients were included in the intention-to-treat analysis. 64% completed 75% of the exercise programme, and 76% attended 5 of 6 education sessions. In the control group 90% completed 75% of the counselling sessions. After 6 months HbA1c decreased from 7.8 ±0.8% to 7.5% ±1.0% in the intervention group and from 7.8 ±0.8% to 7.2 ±0.9% in the control group (p=0.054). In the two groups combined the overall decrease in HbA1c was significantly lower after 6 months compared to baseline (-0.4%, p<0.01). Similarly, there was a reduction in systolic blood pressure (-5 mmHg, 95% CI (-7.8 to -3.0)), weight (-2 kg, 95% CI (-2.7 to -1.4)), and waist circumference (-2 cm, 95% CI (-2.6 to -1.3)) after 6 months in the two groups combined, but there were no differences between the groups. There was no difference in the lipid profile between the two groups although there were a small overall decrease in the level of p-cholesterol (-0.3 mmol/L, 95% CI (-0.4 to -0.1)) and p-triglycerides (-0.2 mmol/L, 95% CI (-0.5 to -0.02)). Muscle strength in legs improved by 30% during the exercise programme in the intervention group (132 to 169 kg, 95% CI (27.6 to 46.7)). No improvement in muscle strength in the control group after 6 months.
Conclusion: Despite an improvement in muscle strength the new multi-disciplinary rehabilitation programme for type 2 diabetes patients did not improve glycemic control more than the conventional individual counselling. Likewise, there were equal effects on blood pressure, lipids, weight, and waist circumference in both groups. These results suggest that a multi-disciplinary rehabilitation programme in a Health Care Centre in primary care setting is a comparable alternative to the conventional individual counselling in an outpatient setting.

Motivational enhancement therapy with and without cognitive behaviour therapy to treat type 1 diabetes: the long-term outcomes of a randomised controlled trial

K. Ismail[1], G. Lawrence-Smith[1], Y. Cheah[2], K. Winkley[1], R. Yadav[3], S. Thomas[4], J. Bartlett[5];
[1]Psychological Medicine, Institute of Psychiatry, London, [2]King's College Hospital, London, [3]Trafford General Hospital, Trafford, [4]Guy's & St Thomas' Hospital, London, [5]London School of Hygiene and Tropical Medicine, London, United Kingdom.

Background and aims: Psychological treatments can lead to improvements in glycaemic control in the short term (12 months). We conducted a follow up of a cohort from a randomised controlled trial, in which we reported that motivational enhancement therapy (MET) with cognitive behavioural therapy (CBT) improved glycaemic control in type 1 diabetes compared to usual care at 12 months by half percent reduction in HbA1c but MET alone compared to usual care did not. We aimed to test whether this beneficial effect was maintained at 36 months.
Materials and methods: In the original study, 1659 patients were screened from 8 diabetes centres in London and Manchester, United Kingdom of which 507 were eligible. The baseline sample consisted of 344 adults with type 1 diabetes with glycated haemoglobin between 8.2 and 15%, and without complications or severe comorbid disease. They had been randomised to either nurse delivered MET (4 sessions over 2 months), MET plus CBT (12 sessions over 6 months) or usual diabetes care. Participants were contacted for informed consent to the longterm follow up. The main outcome was the 36 month change in glycated haemoglobin.
Results: To date 6 diabetes centres have been followed up (n=253) and data on the primary outcome is currently available on 115 original participants, giving a preliminary response rate of 45.4%. In the preliminary analysis, the mean baseline HbA1c was 9.37%, and the mean 36 month HbA1c was 8.72%, representing an average decrease in HbA1c of 0.65% (95% CI 0.41 to 0.90, p=0.001) from baseline to 36 months (table 1). Using ANCOVA regression modelling, there was no difference between MET plus CBT versus usual care at 36 months (baseline adjusted mean difference in HbA1c 0.11% (95% confidence interval -0.42 to 0.65) and nor between MET versus usual care (baseline adjusted mean difference in HbA1c 0.03% (-0.54 to 0.61).
Conclusion: Adjusting for baseline HbA1c, the 3 groups are very similar at months. The effectiveness of MET plus CBT at 12 months had disappeared at 36 months. There may be a selection bias in early respondents as the responders on average have improved their glycaemic control.

Table 1: HbA1c at baseline and at 36 months by intervention (n=115)

Group	Baseline HbA1c % mean (SD)	36 month HbA1c % mean (SD)
Usual care (n=42)	9.32 (0.86)	8.65 (1.39)
MET (n=41)	9.28 (0.67)	8.74 (1.16)
MET plus CBT (n=32)	9.56 (1.27)	8.79 (1.33)

Myocardial function and myocardial lipid accumulation in insulin resistant and type 2 diabetic women

M. Krssak[1,2], Y. Winhofer[2], C. Göbl[2], M. Bischof[2], G. Reiter[3], A. Kautzky-Willer[2], A. Luger[2], M. Krebs[2], C. Anderwald[2];
[1]Radiology, Medical University of Vienna, [2]Internal Medicine 3, Medical University of Vienna, [3]Siemens Austria, Wien, Austria.

Background and aims: Impaired glucose metabolism is an independent risk factor for cardiovascular disease and heart failure. Non-invasive quantification of myocardial lipid accumulation by localized ^{1}H MR spectroscopy has recently revealed possible links between myocardial steatosis, myocardial function and impaired glucose metabolism in type 2 diabetic patients. Insulin resistance is associated with enhanced ectopic lipid accumulation in skeletal muscle and liver. Therefore, the aim of the present study was to assess relations between insulin resistance and myocardial lipid accumulation and function in non-diabetic women.
Materials and methods: ^{1}H magnetic resonance imaging and localized ^{1}H single voxel spectroscopy were used to measure left ventricular dynamic parameters and myocardial lipid accumulation in cardiac septum of non-diabetic insulin sensitive (IS: n=6, 50±5 years, BMI 25±2 kg/m^2) and insulin resistant (IR: n=7, 50±6 y., 26±2 kg/m^2) women as well as females with type 2 diabetes mellitus (T2DM: n= 6, 51±8 y., 28±2 kg/m^2; HbA1c 9.2±1.9%). In non-diabetic women, insulin sensitivity was assessed by oral glucose tolerance test and subsequent calculation of the Clamp-Like Index (CLIX; IR: 4.5±0.4 vs. IS: 9.7±0.7, p<0.0001). Data are given as mean±SD.
Results: As to myocardial function, we could not find any difference between the study groups regarding left ventricular ejection fraction (IS: 69.3±2.5; IR: 70.5±2.8, T2DM: 68.8±1.7%), end-systolic volume (IS: 35±12; IR: 30±13; T2DM: 27±12 ml) and cardiac output (IS: 4.9±0.8, IR: 4.8±1.2, T2DM: 4.4±0.5 l/min), whereas end-diastolic volume (IS 113±19; IR 98±28; T2DM 84±16 ml) and stroke volume (IS 79±10; IR 68±18; T2DM 56±8 ml) tended to be lower in IR (IS vs. IR: ns) and was significantly decreased in T2DM compared to IS (T2DM vs. IS: p< 0.02). Myocardial lipid content was not different between IS and IR (p= 0.7), but tended to be increased (p= 0.2) in T2DM group (IS: 0.43±0.25; IR: 0.38±0.17, T2DM: 0.68±0.36 %)
Conclusion: Our results suggest that increased myocardial lipid content and impaired myocardial function are not linked to insulin resistance per se, but might develop after the manifestation of type-2 diabetes.

Glucosamine increases hexosamine biosynthesis and O-linked N-acetylglucosamine in the heart, and leads to metabolic alterations similar to those seen in diabetic cardiomyopathy

N. Fülöp[1,2], B. Laczy[2], A. Onay-Besikci[3], C. Des Rosiers[4], R.B. Marchase[5], J.C. Chatham[2,5];
[1]Department of Nephrology, Kaposi Mór County Hospital, Kaposvár, Hungary, [2]Department of Medicine, University of Alabama at Birmingham, United States, [3]Department of Pharmacology, University of Ankara, Turkey, [4]Department of Nutrition, University of Montreal, Canada, [5]Department of Cell Biology, University of Alabama at Birmingham, United States.

Background and aims: Increased hexosamine biosynthesis pathway (HBP) flux and O-linked attachment of N-acetyl-glucosamine (O-GlcNAc) on nucleocytoplasmic proteins have both been implicated in cardiovascular complications associated with diabetes. Therefore, the goal of this study was to determine the impact of increases in HBP flux and O-GlcNAc levels - induced by glucosamine (GlcN) - on cardiac function and metabolism.
Methods: Hearts were perfused with 0; 0.05; 0.1; 1; 5 and 10 mM GlcN, metabolic fluxes were determined by using ^{13}C-NMR isotopomer analysis. UDP-GlcNAc, a product of HBP and a precursor of O-GlcNAc was assessed by HPLC and protein O-GlcNAc, AMPK and ACC phosphorylation and membrane asociated FAT/CD36 was assessed by immunoblot analysis.
Results: GlcN had no effect on cardiac function or on cardiac ATP content at any concentration; however, 0.1 mM GlcN significantly increased both UDP-GlcNAc and O-GlcNAc by 40-50% (p<0.05, Vs 0mM GlcN). This increase in O-GlcNAc was associated with a significant increase in palmitate oxidation (46±4 vs 67±2%) and a concomitant decrease in lactate (30±3% vs 14±1%; p<0.05) and pyruvate (8±2% vs 3±1%) oxidation. Higher concentrations of GlcN had no additional effect on substrate utilization; however, UDP-GlcNAc and O-GlcNAc levels reached levels ~2-fold higher than 0 mM GlcN at 1 GlcN and did not increase further. GlcN had no effect on AMPK or ACC phosphorylation. On the other hand GlcN at every concentrations increased membrane associated FAT/CD36 levels in a dose dependent manner.
Conclusion: GlcN significantly increased O-GlcNAc levels and altered fatty acid and carbohydrate oxidation in a similar manner to that seen with diabetes at least in part by increasing membrane associated FAT/CD36 levels. These data suggest that changes in O-GlcNAc levels may contribute to the shifts in cardiac substrate utilization seen in diabetes.

Rats with experimental diabetic cardiomyopathy develop diastolic heart failure that is ameliorated by the direct renin inhibitor, aliskiren

K. Connelly[1], D.J. Kelly[2], Y. Zhang[2], K. Thai[1], A. Advani[1], R.E. Gilbert[1];
[1]University of Toronto, Canada, [2]University of Melbourne, Australia.

Background and aims: Heart failure is a common cause of morbidity and mortality in diabetic patients that frequently manifests in the absence of impaired left ventricular systolic function. In contrast to the strong evidence base for the treatment of systolic heart failure, the benefit of the treatment of heart failure with preserved left ventricular function (HFPEF) with ACE inhibitors and ARBs is unclear. In the setting of recent studies demonstrating the effects of direct renin inhibition in diabetic nephropathy, we sought to determine the effectiveness of this strategy in the syndrome of HFPEF due to diabetes. Furthermore, in light of the recently described pathogenetic effects of the (pro)renin receptor [(P)RR], we assessed its expression in the hearts of diabetic animals treated with and without aliskiren.
Materials and methods: Using a hemodynamically-validated rodent model of diabetic cardiomyopathy that develops HFPEF, the diabetic (mRen-2)27 transgenic rat (Ren-2), we randomized animals to receive either vehicle or aliskiren (10mg/kg/day via osmotic mini-pump) for 6 weeks. Cardiac function was assessed by *in-vivo* cardiac catheterization with pressure-volume loop acquisition. Following this, animals were killed, and cardiac tissue was collected for histological assessment of fibrosis (picrosirius red staining) and myocyte hypertrophy (cross sectional area). (P)RR expression was assessed by real-time PCR, Western blot analysis and immunohistochemistry.
Results: Despite preserved systolic function, diabetic rats developed diastolic dysfunction in association with cardiac fibrosis, and cardiomyocyte hypertrophy. Aliskiren treated diabetic animals demonstrated improved chamber compliance (0.032 ± 0.006 v 0.057 ± 0.006 mmHg/μL) and early active relaxation (Tau, 8.75 ± 0.40 v 9.98 ± 0.29 msec) when compared to untreated diabetic counterparts (p<0.05). Aliskiren reduced collagenous matrix in diabetic animals (2.38 v 1.40 % proportional area picrosirius red staining, p<0.05), reduced LV mass by 52% (p<0.01 versus untreated diabetic rats) and normalized cardiomyocyte diameter (22.35 v 15.68 μm, p<0.01). (P)RR was predominantly localized to cardiac myocytes by immunohistochemistry. Expression of both (P)RR mRNA and protein were increased with diabetes and reduced to baseline by aliskiren (control, diabetes, diabetes+aliskiren: 1.13 ± 0.04, 3 ± 0.2, 1.15 ± 0.07 AU, respectively; p<0.01 control versus diabetes and p<0.05 diabetes+aliskiren versus diabetes).
Conclusion: Direct renin inhibition with aliskiren prevented the development of structural and functional changes of HFPEF in the diabetic Ren-2 rat. The biological significance of modulation in (P)RR expression by diabetes and aliskiren is uncertain. However, in the setting of its purported pathogenetic role in diabetic nephropathy, its upregulation in the diabetic heart suggests that it may also be involved in the development of diabetic cardiomyopathy.

Ablation of fatty acid transporter CD36 protects against western type diet-related cardiac dysfunction following pressure overload in mice: modeling diabetic cardiomyopathy

L.K.M. Steinbusch[1], R. Vlasblom[2], I. Vroegrijk[3], P. Voshol[3], J.F.C. Glatz[1], D.M. Ouwens[4], J.J.F. Luiken[1], M. Diamant[5];
[1]Molecular Genetics, Maastricht University, [2]Laboratory for Physiology, VU University Medical Centre, Amsterdam, [3]Endocrinology and Metabolic Diseases, Leiden University Medical Centre, [4]Molecular Cell Biology, Leiden University Medical Centre, [5]Endocrinology, VU University Medical Centre, Amsterdam, Netherlands.

Background and aims: An unbalance in cardiac substrate supply, with increased utilization of long-chain fatty acids (LCFA) over glucose, is regarded to contribute to the functional and structural changes in diabetic cardiomyopathy (DCM). In the hypertrophied heart an unbalance in substrate utilization develops, with increased glucose utilization over LCFA. We investigated whether manipulation of cardiac substrate utilization by i) a western-type diet (WTD) to increase LCFA supply, ii) fatty acid translocase CD36 ablation to decrease LCFA supply, or iii) a combination of both, influences the development of cardiac hypertrophy and failure during pressure overload.
Materials and methods: Twelve weeks old male wildtype (WT) and CD36$^{-/-}$ mice (KO) were started on chow or WTD (42% fat, 29% sucrose; t=0). Ten weeks after initiation of the diet, groups were subdivided in sham-operated mice and mice that underwent aortic constriction (AC) to induce pressure overload (t=10). Diet exposure was continued throughout the study. Six weeks after surgery, mice (n=5-8 for each group) were sacrificed (t=16). Using echocardiography, cardiac systolic function (fractional shortening; FS%) was determined at t=0, 10 and 16. For statistical analysis two-way ANOVA with Bonferroni post-tests were performed.
Results: WT and KO mice on either diet displayed similar cardiac function parameters at t=0 and t=10, suggesting that 10 weeks of WTD, CD36 ablation or a combination of both, does not influence cardiac function. At t=16, heart weight (HW) and FS% from sham operated mice where alike, suggesting that CD36 ablation, WTD or a combination of both, do not affect cardiac function. However, differing responses where seen in mice that underwent AC (table 1). Whereas WTD resulted in significant cardiac hypertrophy and systolic dysfunction after AC in WT mice, it had protective effects with respect to cardiac remodeling and functional changes in KO mice.

	WT		KO	
	chow	WTD	chow	WTD
	AC versus sham	AC versus sham	AC versus sham	AC versus sham
Heart weight (% alteration)	+46 % *	+ 81 % *	+ 100 % **	+ 18 %
FS% (% alteration)	no change	- 35 %	- 27 %	no change

Table 1: Effect of WTD versus chow on heart weight and function in KO and WT mice 6 weeks after aortic constriction. *: p<0.05, **: p<0.001

Conclusion: In contrast to the effects observed in WT mice, exposure of KO to a WTD protected against the adverse effects of pressure overload on cardiac remodeling and function. These data provide the first evidence of an interaction between CD36 and nutrient supply to modulate cardiac function in compromised hearts in a model for DCM. These findings may provide therapeutic targets for ameliorating cardiac outcome in patients with DCM.

Predictors of glucose lowering therapy intensification among patients with diabetes hospitalized with acute myocardial infarction

J.M. Stolker[1], J.A. Spertus[1], D.K. McGuire[2], S.E. Inzucchi[3], S.S. Rathore[4], T.M. Maddox[5], F.A. Masoudi[6], F. Tang[1], P.G. Jones[1], M. Kosiborod[1];
[1]Cardiology, Mid America Heart Institute, Kansas City, [2]Cardiology, University of Texas Southwestern School of Medicine, Dallas, [3]Endocrinology, Yale University School of Medicine, New Haven, [4]Cardiology, Yale University School of Medicine, New Haven, [5]Cardiology, Denver VAMC/University of Colorado at Denver, [6]Cardiology, Denver Health Medical Center & University of Colorado at Denver, United States

Background and aims: Poor glucose control is common among patients (pts) with diabetes (DM) hospitalized for acute myocardial infarction (AMI). Thus, AMI hospitalization may present an opportunity to modify glucose management, but rates and predictors of glucose therapy intensification (GTI) after AMI have not been described.

Materials and methods: TRIUMPH is a prospective registry of AMI pts from 26 US centers. GTI was defined as an increased dose or addition of a new oral antihyperglycemic drug, initiation of insulin, or increased total daily insulin dose by ≥20% from baseline. Changing one oral agent to another was not counted as GTI. Independent predictors of GTI were identified using hierarchical Poisson regression (with hospital as a random effect). Candidate variables were those associated with GTI in univariate analysis (p<0.1 level), or those potentially related to DM severity and management. Since practice patterns vary across institutions, we evaluated the association of hospital site with GTI using the median rate ratio (MRR), which describes how likely two identical pts would receive GTI at one hospital as compared with another.
Results: Between 2005-07, TRIUMPH enrolled 2755 consecutive AMI pts of whom 724 (26%) had type 2 DM. Of pts with DM, 505 (70%) had HbA_{1c} measured clinically: HbA_{1c} level was <7% in 177 pts (35%), 7-9% in 196 pts (39%), and >9% in 132 pts (26%). Overall, 234 pts with DM were discharged with GTI (32%); these pts had fewer DM meds (mean 0.8 vs 1.1, p<0.001) and less frequent insulin therapy (15% vs 37%, p<0.001) on admission, higher initial (272 vs 205 mg/dL, p<0.001) and average fasting glucose (171 vs 148 mg/dL, p<0.001), more HbA_{1c} assessment during hospitalization (80% vs 64%, p<0.001), and higher HbA_{1c} levels (9.1% vs 7.7%, p<0.001). Independent predictors of GTI are listed in the Figure. MRR was 1.61, suggesting significant variability in GTI prescription across institutions.
Conclusion: Nearly two-thirds of AMI pts with DM have suboptimal or poor long-term glycemic control, but only a minority have GTI prior to discharge. Key among the independent predictors of GTI are hospital-based factors (HbA_{1c} assessment and hospital site), with >60% variation in GTI across hospitals likely reflecting the lack of clinical consensus for managing DM after AMI. These findings highlight the need to determine the relationship between different strategies of post-AMI glucose management and patient outcomes.

Secretory products of epicardial fat induce insulin resistance and impair cardiomyocytes function

S. Greulich[1], D. Herzfeld de Wiza[1], H. Müller[1], H. Sell[1], Z. Ding[2], S. Preilowski[3], K. Jaquet[3], J. Eckel[1];
[1]Institute of Clinical Biochemistry and Pathobiochemistry, German Diabetes Center, Duesseldorf, , [2]Institute of Cardiovascular physiology, Heinrich Heine University, Duesseldorf, [3]Molecular cardiology, Ruhr-University, Bochum, Germany

Background and aims: Epicardial fat (EF) is a visceral adipose tissue around the heart, which is not separated by a fascia. EF is a source of inflammatory cytokines which may interact with myocardium and coronary arteries. Increasing evidence suggests that the EF may play a role in the pathogenesis of cardiovascular diseases and special forms of cardiomyopathy.
The aim of this study is to analyse the secretion of EF compared to subcutaneous fat (SF) and its impact on the function of primary rat cardiomyocytes.
Materials and methods: 7 weeks old guinea pigs were fed with a high energy (HE) diet for 6 month. As a control we used a low energy (LE) diet. At the end of the feeding study, glucose tolerance tests (GTT) and an echocardiography (Echo) were performed. After sacrifice, we collected EF and SF and generated fat explants and conditioned media (CM). For analysis of cytokine secretion antibody arrays were used.
To analyse the effects of EF and SF on cardiomyocytes we incubated primary rat cardiomyocytes with CM or control media. Subsequently, we analysed insulin-stimulated signaling at the level of Akt Ser473-phosphorylation. Furthermore, functional alteration in cell shortening and Ca2+-transient fluxes were measured using a Contractility and Fluorescence system.

Results: Animals receiving a HE diet are characterized by reduced insulin sensitivity as demonstrated by GTT. Moreover, echo tests showed that these animals were characterised by a decreased left ventricular function of the heart at the level of the ejection fraction and the fractional shortening ($p< 0.05$). Analysis of CM showed that the two diets induced a different secretion pattern of various cytokines. For example, the secretion of Activin A was 4-fold higher in CM from HE compared to LE animals. Comparing different fat depots from one animal, differences in the secretion pattern could also be found. The secretion of Activin A was 10-fold higher in EF.
Treatment of cardiomyocytes with CM (EF) from HE animals results in a significantly decreased phosphorylation of Akt after stimulation with insulin compared to CM (EF) from LE animals ($p< 0.05$). Cardiomyocytes which were incubated with CM from SF also showed a decrease in the phosphorylation of Akt, but no significant difference between HE and LE explants could be found.
Contractility and Ca2+-transient experiments showed that steady-state shortening amplitude and intracellular Ca2+ peak after incubation with CM in cardiomyocytes are reduced. Furthermore, much less cardiomyocytes which were incubated with CM are able to contract after electrical stimulus compared to control media. Long term incubation of CM showed no further impairment when compared to short term incubation.
Conclusion: In summary, HE feeding induces starting insulin resistance and impaired left ventricular function. Isolated EF from HE animals was characterized by a different secretion pattern as compared to LE but also to SF. CM generated from EF causes dysfunction of primary rat cardiomyocytes since these cells are characterized by impaired insulin signaling, reduced contractility and Ca2+-influx. Our results suggest that the secretion of various cytokines by EF with its direct effect on the myocardium might be involved in obesity-related cardiomyopathy.

OP 05 Genes, autoimmunity and type 1 diabetes

Predictors of associated autoimmune diseases in families with type 1 diabetes. Results from the type 1 diabetes genetics consortium (T1DGC)
J.C. Wiebe[1], Á. Santana[2], M. Hernández[3], J. Nóvoa[1,4], D. Mauricio[3], A.M. Wägner[1,4], T1DGC;
[1]Endocrinology Dept., Complejo Hospitalario Universitario Insular-Materno Infantil de Gran Canaria, Las Palmas de Gran Canaria, [2]Dept of Mathematics and Statistics, Universidad de Las Palmas de Gran Canaria, [3]Endocrinology Dept., Hospital Universitary Arnau de Vilanova, Lleida, [4]Dept of Medical and Surgical Science, Universidad de Las Palmas de Gran Canaria, Spain.

Background and aims: The T1DGC is an international effort aimed at the study of the genetics and pathogenesis of type 1 diabetes (T1D). Families with at least 2 affected siblings have been included in order to find genes associated with risk/protection for T1D. The aim of our study was to find predictors of the presence of associated autoimmune diseases (AAID) in the T1DGC dataset available on the 1st October 2008.
Materials and methods: Clinical information was obtained using questionnaires at each of the participating centres, anti-GAD and anti-IA2 (RIA) were measured in serum from the affected siblings (Bristol, UK; Southbank, AUS and Aurora, CO, US) and HLA-genotyping was performed (PCR-based, sequence-specific oligonucleotide probe system) centrally (Oakland, CA, US; Melbourne, Australia and Malmö, Sweden). Presence of AAID was defined by the information obtained from the questionnaires. Statistical analysis was performed using R. Differences between groups were analysed using Wilcoxon-Mann-Whitney's test and chi-squared. To assess the predictors of AAID, a multivariate logistic regression analysis was performed on the affected siblings, including age of onset, time since diagnosis, antibody positivity and risk and protective HLA haplotypes as independent variables. We describe the results obtained from the families where DRB1-DQA-DQB1 haplotypes could be unequivocally estimated. High-risk and protective haplotypes were defined as the 4 most susceptible and protective, respectively, according to a previous report from the T1DGC.
Results: Information from 3310 families was available at the time of analysis and unambiguous HLA haplotypes were identifiable in 1864 families (8327 participants). 12.9% of all the participants and 13.1% of the T1D affected siblings had at least 1 AAID. Among the latter, AAID were distributed as follows: 63.5% thyroid, 19.44% celiac, 7.13% psoriasis, 6.7% vitiligo, 5.8% rheumathoid arthritis, 3.67% inflammatory bowel and 2,37% other diseases). Age of diabetes onset was similar, but current age (23.5 vs 18.4 (mean difference 4.0-6.3) years, p= 2.2e-16) and time since diagnosis (13.0 vs 8.8, (mean difference 3.2-5.2) years, p=2.2e-16) were higher in the siblings with AAID. Anti-GAD positivity was similar whereas anti-IA2 positivity was less frequent in subjects with AAID (39.9 vs 49.6%, p=0.0001). Risk and protective DRB1-DQA1-DQB1 haplotype distributions were similar in the group of siblings with T1D with and without AAID. In the logistic regression analysis, only age of onset (p = 6.3e-6) time since diagnosis (OR: 1.05 (CI 1.04-1.06) per year, p = 2e-16) and a-GAD positivity (OR:1.35 (CI 1.09-1.67) p=0.005) were significant predictors of AAID.
Conclusion: In the current study, the older the onset of T1D and the longer the duration of follow-up, the higher the risk of AAID. Furthermore, the positivity of a-GAD was also independently associated with AAID once adjusted for duration of T1D.

Prognostic relevance of autoantibody-based screening in the general population - results from the Karlsburg type 1 Diabetes Risk Study after 14 years
A.-M. Hoss[1], H. Kenk[2], U. Walschus[1], J. Heide[1], R. Wassmuth[3], M. Schlosser[1];
[1]Department of Medical Biochemistry and Molecular Biology, Ernst-Moritz-Arndt University Greifswald, Karlsburg, [2]Institute of Pathophysiology, Ernst-Moritz-Arndt University Greifswald, Karlsburg, [3]TU Dresden, Dresden, Germany

Background and aims: The cumulative risk for progression to Type I Diabetes mellitus (T1DM) as well as the prognostic relevance of T1DM-related

autoantibodies (AAb) and genetic markers like the HLA-DQB1 has been examined in several studies in first-degree relatives of patients. The aim of the study was to assess the cumulative T1DM risk in the general population without first-degree heredity using a combined screening for established AAbs against Glutamate decarboxylase (GADA), Protein tyrosine phosphatase (IA-2A) and Insulin (IAA) as well as HLA-DQB1 genotyping.
Materials and methods: 14,742 schoolchildren (7,508 female, 7,234 male, age 6-17 years) were enrolled in the Karlsburg Type I Diabetes Risk Study and tested for GADA, IA-2A and IAA using radio-ligand binding assays. Determination of all 3 AAbs was possible in 13,165 subjects. Children who tested positive for at least one AAb in the screening (cut-off at the 98th percentile) were invited for follow-up testing (cut-off at the 99th percentile). Children which were positive in the 1st follow-up were repeatedly tested in the further study course. HLA-DQB1 genotyping was performed at 1st follow-up by PCR and DNA hybridization with specific probes. All HLA-DQB1 alleles other than the T1DM-associated alleles *0302 and *02 and the dominant protective allele *0602 were considered as neutral. Two-sided X^2 statistics and Kaplan-Meier survival analysis were used for statistical analysis (SPSS 15.0).
Results: 4.03% (530/13,165) subjects were tested positive for at least one AAb in the initial screening, with 3.6% (474/13,165) of them having singular AAbs and 0.43% (56/13,165) having multiple AAbs. At the first follow-up, 1.18% (156/13,165) schoolchildren were tested positive for at least one AAb. 0.92% (n=121) had singular and 0.27% (n=35) multiple AAbs. 65/114 HLA-DQB1-typed children with singular AAbs had at least one diabetes-associated HLA-DQB1 allele, compared to 33/35 with multiple AAbs (p<0.001). Up to now, 24 subjects (0.18%) progressed to T1DM. Two of these children were initially tested positive for one AAb but had diabetes-associated HLA-DQB1 alleles. 20/24 of these probands had multiple AAbs, of those 19/20 had diabetes-associated HLA-DQB1 alleles and 1/20 has neutral alleles. 2/24 children who became diabetic were initially AAb-negative but were found to have multiple AAb at manifestation. The cumulative 10-year-risk for progression to T1DM was 1.2% for subjects with singular AAbs compared to 65.1% for subjects with multiple AAbs (p<0.001). No child with the dominant-protective HLA-DQB1 allele *0602 became diabetic. The cumulative 10-year-risk for developing T1DM is significantly higher for subjects with diabetes-associated HLA-DQB1-alleles (30.3%) compared to children with neutral alleles (3.7%, p=0.012).
Conclusion: The results of this study demonstrate that the T1DM risk for subjects from the general population is significantly associated with multiple AAb positivity and with the detection of diabetes-associated HLA-DQB1 alleles. It can be concluded that the prognostic value of a combined testing for diabetes-associated AAbs and immunogenetic markers in the general population is comparable to results shown for first-degree relatives.

Genome-wide mapping of variants associated with type 1 diabetes nephropathy
N. Sandholm[1,2], V.-P. Mäkinen[1,2], C. Forsblom[1,3], J. Söderlund[1,3], L. Thorn[1,3], J. Wadén[1,3], P.-H. Groop[1,3], FinnDiane Study Group;
[1]Folkhälsan Institute of Genetics, Helsinki, [2]Department of Biomedical Engineering and Computational Science, Helsinki University of Technology, Espoo, [3]Department of Medicine, Division of Nephrology, Helsinki University Central Hospital, Finland.

Background and aims: Both environment and genetic factors are likely to play a role in the development of diabetic nephropathy (DN). The genetic factors related to DN have not been fully identified in earlier studies. High-throughput genomewide association methods may provide a useful tool in the determination of genetics of DN.
Materials and methods: This study uses genome-wide association (GWA) analysis in a case-control study setting. The Finnish Diabetic Nephropathy Study (FinnDiane) is a nationwide, comprehensive large-scale multi-center study of patients with type 1 diabetes (T1D). We initiated a GWA scan of 4000 T1D patients in May 2008. Our aim is to genotype altogether 1500 T1D cases with DN (micro- or macro-albuminnuria or ESRD) and 2500 normoalbuminuric controls with T1D duration of at least 16 years. So far approximately 1900 patients have been genotyped (1037 cases and 859 controls).
The GWA scan is performed on an Illumina platform (Illumina 610Quad chip) including approximately 599.000 probes targeting multiallelic SNPs, situated both within and outside of genes. To ensure high data quality, we excluded SNPs with low genotyping rate, low minor allele frequency or significant deviation from Hardy-Weinberg equilibrium within controls. Unique individuals with high genotyping rate, correct sex and no close relatives were accepted. This resulted in 950 cases and 809 controls at 551953 SNPs passing the quality control in this preliminary analysis. Plink software was used for data handling and analysis. Association was calculated for each SNP with allelic Fisher's test, which assumes the association to be additive.
Results: 8 SNPs with p-values smaller than 10-5 were found in 5 different chromosomal locations (1q, 4q, 6q, 12q, 18q with p-values 2.3x10^-7 - 9.3x10^-6). Further putative SNPs include 53 SNPs with p-value smaller than 10^-4 and 613 SNPs with p-value smaller than 10^-3.
Conclusion: These preliminary data suggest that there might be new genomic regions related to DN, although the p-values did not survive rigorous correction for multiple testing. Nevertheless, the power of GWA is known to increase rapidly with the sample size. Thus we hope that the ongoing genotyping of more patients will give more convincing results that survive also replicative analysis.

A genome-wide SNPxSNP search for epistasis identifies gene-gene interaction in type 1 diabetes
C.A. Brorsson[1], L.L. Field[2], E. Swiergala[2], J. Høiriis Nielsen[3], T. Werge[4], R. Bergholdt[1], F. Pociot[1];
[1]Hagedorn Research Institute, Gentofte, [2]University of British Columbia, Vancouver, Canada, [3]University of Copenhagen, [4]Sankt Hans Hospital, Roskilde, Denmark.

Background and aims: Common complex diseases, such as type 1 diabetes, are influenced by multiple genetic and environmental risk factors. Many new risk loci have been identified in the last two years, all with relatively small risk ratios. There is no doubt that additional risk loci with independent effects remain to be identified in order to explain the full genetic component in the susceptibility to type 1 diabetes. However there is also a possibility that gene-gene interactions may contribute to disease risk. Epistatic effects have been identified between classic loci, such as the *HLA* genes and *INS* as well as recently *PTPN22*. However, so far no genome-wide search for epistatic effects has been conducted. Using genome-wide association data we conducted a SNPxSNP search for epistasis in order to address the question of gene-gene interactions that affect the risk of type 1 diabetes.
Materials and methods: In phase 1 of the study 600 Danish cases and controls were analysed for 50,000 SNPs genotyped on Affymetrix 50K arrays. Logistic regression was used to analyse all pair-wise combinations of SNPs for deviation from a log-additive risk model. SNP pairs with lowest p-values were prioritised for replication in phase 2 and genotyped using TaqMan assays in a larger case-control material consisting of 1500 Danish cases and 1850 blood donor controls. All pair-wise combinations were again analysed for epistasis using logistic regression. Expression profiles of selected transcripts were analysed using low density arrays (Applied Biosystems) in a preparation of human islets from 9 donors before and after cytokine stimulation, and in lymphocytes from 9 male type 1 diabetic patients and 8 healthy male controls. Relative expression was analysed using the ΔΔCt method and significance of expression level differences was evaluated using paired t-tests in islets and f- and t-tests in lymphocytes.
Results: In phase 1 we identified three SNP pairs that were prioritised for replication (p<3e-08). One of the interactions was replicated in phase 2 using the same log-additive model (p=0.02, OR=1.23). The two interacting SNPs are located in an intron of *IRF2* on chromosome 4 and downstream *XCL1* on chromosome 1. None of the SNPs identified through epistasis were significant in a single marker analysis. IRF2 was found to be significantly upregulated after cytokine stimulation in human islets (p=0.002). Furthermore a trend towards a lower expression of XCL1 was found in lymphocytes from diabetic individuals compared to healthy controls (p=0.07).
Conclusion: We have identified and replicated an epistatic effect of two SNPs that were associated with the risk of type 1 diabetes. Furthermore functional effects of the corresponding gene IRF2 was demonstrated in a model system of human type 1 diabetes. IRF2 and XCL1 have previously been implicated in human immune-mediated diseases. Their exact genetic and functional involvement in the pathogenesis of type 1 diabetes remains to be elucidated and replicated in independent studies.

Strong association between *SLC30A8* gene variant and ZnT8 autoantibody specificity during disease progression in two independent cohorts of children with newly diagnosed type 1 diabetes

L.B. Nielsen[1], F.V. Sani[2], M.-L.M. Andersen[1], S. Pörksen[1], J. Svensson[1], R. Bergholdt[3], F. Pociot[3], J.V. Jørgensen[4], J. Thomsen[5], T. Hertel[6], P. Hougaard[7], Å. Lernmark[2], H.B. Mortensen[1], L. Hansen[1];
[1]Pediatrics, Glostrup University Hospital, Glostrup, Denmark, [2]UMAS, Malmø, Sweden, [3]Steno Diabetes Center, Gentofte, Denmark, [4]Skejby Hospital, Århus, Denmark, [5]Kolding Hospital, Kolding, Denmark, [6]Odense Hospital, Odense, Denmark, [7]University of Southern Denmark, Odense, Denmark.

Background and aims: The zinc transporter, ZnT8, is newly established as a major autoantigen in type 1 diabetes and the common non-synonymous variant, rs13266634, of the SLC30A8 gene was recently found to determine the ZnT8 autoantibody (ab) specificity in a Caucasian and Japanese type 1 diabetes population. The aim of this study was to explore the association between the rs13266634 variant and the ZnT8 autoantibody specificity (arginine versus tryptophan consisting epitope) during the first year after disease diagnosis in two independent cohorts of children with newly diagnosed type 1 diabetes. Furthermore, we investigated the association of ZnT8 autoantibodies with age of onset and with disease progression (loss of residual beta-cell function).
Materials and methods: The Hvidøre cohort consists of 275 children aged<16 years from 22 paediatric centres in 18 countries; the Danish cohort consists of 130 children aged<16 years from 4 paediatric centres. All patients were newly diagnosed with type 1 diabetes. A 90-minutes Boost-test was carried out in each patient at 1, 6, 12 months to characterize the residual beta-cell function. Genotyping was done at Steno Diabetes Center. ZnT8_arg and trp ab determination was done by RIA assay at UMAS, Malmø.
Results: The CC genotype of the rs13266634 variant was highly associated with ZnT8-arg ab 1, 6 and 12 months after onset in both cohorts (with TT as ref group: log est.:1.5, 1.5, 1.3 corresponding p-values: <0.0001, Hvidøre cohort; log est.:1.9, 1.8, 2.2 corresponding p-values: 0.003, 0.004, 0.0002, Danish cohort). By contrast the TT genotype was associated with ZnT8-trp ab 1, 6 and 12 months after onset in both cohorts (with CC as ref group: log est.:1.6, 1.5, 1.5 corresponding p-values: <0.0001, Hvidøre cohort; log est.:2.2, 2.2, 1.4 corresponding p-values: <0.0001 for 1 and 6 months and p=0.006 for 12 month, Danish cohort). We found an allele dosage effect on the ZnT8 ab titers; CC carriers presented app. twice the level of ZnT8-arg ab compared to CT carriers (1 mth est.:1.6 vs 0.9, respectively) and TT carriers presented also higher level of ZnT8-trp ab compared to CT carriers (1 mth est.:1.6 vs 0.6, respectively). The youngest age group (0-4 yrs) had significantly lower ZnT8-arg ab level compared with the older age group at 1 month and at 12 months (12 mth: est.:-0.7 p=0.02). Loss of beta-cell function did not associate significantly with ZnT8 ab levels.
Conclusion: The strong genetic determination of the ZnT8 ab specificity is sustained the first 12 months of disease progression in two independent cohorts of children with new onset type 1 diabetes. Furthermore, there was a clear allele dosage effect on the ZnT8 ab titer which was maintained during the progression of the disease. The youngest patients continued to exhibit the lowest level of ZnT8-arg ab during first year after disease diagnosis but ZnT8 ab did not associate with loss of beta-cell function. These data strongly suggest a humoral involvement of ZnT8 ab in the progression of type 1 diabetes with no direct effect on the residual beta-cell function.

30

Gene expression differences in pancreas and brain between diabetes-prone BB/OK rats and their diabetes protected congenic BB.6S derivatives

I. Klöting[1,2], B. Wilke[1];
[1]Laboratory Animal Science, University of Greifswald, Karlsburg, [2]Internal Medicine III, University of Leipzig, Germany.

Background and aims: Congenic BB.6S rats are characterized by a drastically reduction of diabetes frequency by 94% compared with their parental BB/OK rat strain. To increase the chance of identification of the appropriate protective gene(s), the expression of 31,000 genes in pancreas and brain of BB/OK and BB.6S rats was studied using GeneChip microarray analysis.
Materials and methods: For the hybridization of Affymetrix GeneChips we use pooled samples of 20 individual rats (BB/OK 10M:10F; BB.6S 10M:10F) with an age of 8 days following the protocol described in the Affymetrix GeneChip Expression Analysis Technical Manual at the Interdisziplinäres Zentrum für klinische Forschung Leipzig (IZKF), Medizinische Fakultät der Universität Leipzig. In addition one gene was sequenced.
Results: By pair-wise comparisons between BB/OK and BB.6S rats, a set of 35 genes was identified in brain and pancreas representing genes whose level of expression importantly differed between BB/OK and BB.6S rats. The genes were located on 14 chromosomes (2, 3, 6, 7, 8, 9, 11, 12, 13, 15, 16, 18,19). Only one gene mapped on chromosome 6q32 within the region which was exchanged in the congenic strain BB.6S by that of SHR rats. According to the function of genes, 8 out of 36 were involved in ion binding, 8 in protein binding, 6 were enzymes, 5 hypothetical proteins 3 were involved in cell communication, 2 in protein transport and particularly 1 gene plays a role in cancer, one in ion transporter and one was unknown protein. The gene on chromosome 6q32 was a hypothetical protein which was sequenced. A SNP was found between BB and SHR as well as their congenic BB.6S.
Conclusion: The data clearly show that the chromosomal exchange in BB.6S rats led to gene expression differences between BB/OK and BB.6S rats which were mainly located on other chromosomes than 6. Only one gene on chromosome 6 characterized as hypothetical protein was differently expressed between BB/OK and BB.6S. The sequence of this gene was different between BB/OK and BB.6S so that it could be a candidate for diabetes protection.

Mice lacking lipocalin-2 are protected from developing insulin resistance associated with aging and obesity

I.K.M. Law[1], A. Xu[1,2], K.S.L. Lam[2], T. Berger[3], T.W. Mak[3], J.T.C. Liu[1], G. Sweeney[4], M. Zhou[1], Y. Wang[1];
[1]Department of Pharmacology and Pharmacy, University of Hong Kong, [2]Department of Medicine and Research Center of Heart, Brain, Hormone, and Healthy Aging, University of Hong Kong, [3]The Campbell Family Institute for Breast Cancer Research and the Ontario Cancer Institute, University Health Network, Toronto, Canada, [4]Department of Biology, York University, Toronto, Canada.

Background and aims: Obesity is characterized as a low-grade inflammation of the adipose tissue and increased circulating concentrations of pro-inflammatory cytokines. The "inflamed" adipose tissue can secrete a large amount of pro-inflammatory adipokines / cytokines that act as mediators for obesity-related metabolic syndrome. Previous studies have shown that the expression and production of lipocalin-2, a pro-inflammatory adipokine, are elevated in obese animal and human subjects. In this study, we aim to evaluate whether lipocalin-2 deficiency can protect the mice from developing systemic insulin resistance.
Methods and results: C57 wildtype and lipocalin-2 deficient mice (Lcn2-KO) were given free access to high fat diet from the age of 4 weeks for the induction of dietary obesity. In addition, genetic obesity was induced by cross-breeding male C57BL/6J db/+ mice with female Lcn2-KO mice to generate the leptin receptor $(Lepr)^{-/-}$/lipocalin-$2^{-/-}$ double knockout mice (DKO). Deficiency of lipocalin-2 in mice prevents age-associated decline in insulin sensitivity and the development of insulin resistance induced by high fat diet and genetically obesity. In diet-induced obesity, lower fasting blood glucose was consistently observed in Lcn2-KO mice (5.6±1.18 mmol/L vs that in C57 wildtype mice, 8.4±1.51 mmol/L, $p<0.05$). HOMA-IR index was increased by 77.93% in C57 wildtype after 18-weeks high fat diet feeding. On the other hand, in mice under normal diet, at the age of 21-week, the fasting glucose levels of Lcn2-KO mice were significantly lower than those of C57 mice (3.62±0.35 mmol/L in Lcn2-KO mice vs 5.05±0.3 mmol/L in C57 wildtype). Both fasting serum insulin levels and HOMO-IR indexes were largely reduced in 24-week old Lcn2-KO mice, by 44.6% and 79.35% respectively comparing to those of the control mice. Similar phenomena were observed in DKO mice, which did not develop hyperinsulinemia as in the leptin receptor $(Lepr)^{-/-}$ (db/db) counterparts (516.778.421±73.225 μU/ml in wildtype db/db mice, 97.67±35.63 μU/ml in DKO mice, $p<0.05$). Lipocalin-2 deficiency attenuated peripheral insulin resistance and macrophage infiltration in adipose tissue. Further analysis revealed that obesity- and lipopolysaccharide-induced expressions of TNFα, a pro-inflammatory cytokine, were completed blocked by lipocalin-2 deficiency in epididymal adipose tissue as revealed by quantitative PCR analysis On the other hand, increased expression of IκB found in Lcn2-KO mice while incubation of lipocalin-2 in differentiated 3T3-L1 adipocytes lowered IκB expression and increased NFκB activity.
Conclusion: Lipocalin-2 plays critical roles in causing obesity-induced insulin resistance through regulating TNFα expressions, which might account for its systematic metabolic and pro-inflammatory activities.

Chronic apelin treatment effects on lipid metabolism in wild type and insulin-resistant mice

C. Attane[1], R. Guzman-Ruiz[2], S. Le Gonidec[3], V. Bézaire[1], D. Daviaud[1], C. Dray[1], M. Ruiz-Gayo[4], P. Valet[1], I. Castan-Laurell[1,5];
[1]INSERM I2MR U858, Toulouse, France, [2]Departamento de Farmacologia, Madrid, Spain, [3]Université Paul Sabatier, IFR31, Toulouse, France, [4]Departamento de farmacologia, Madrid, Spain, [5]Université Paul Sabatier, Toulouse, France.

Background and aims: We have recently shown that apelin stimulates glucose utilization in skeletal muscle through an AMP-activated protein kinase (AMPK) dependent pathway. Since AMPK is also involved in lipid metabolism, we studied apelin chronic treatment effects on lipid plasma parameters, fatty acid oxidation and storage in the muscle of normal and insulin resistant mice.
Materials and methods: Chow fed or high fat fed C57bl6/J mice were ip injected with apelin (0,1μmol/kg/day) during 28 days. Total [1-^{14}C] palmitate oxidation was determined in soleus muscle as the sum of $^{14}CO_2$ release (corresponding to complete fatty acids oxidation) and acid-soluble metabolites (corresponding to the incomplete oxidation). Respiratory quotient (carbon dioxide production to oxygen consumption ratio) was measured by in vivo indirect calorimetry. Intramuscular triglycerides (IMTG) content was measured after extraction of muscle lipids. Plasma level of triglycerides (TG) and free fatty acids (FFA) were measured at the end of the treatment using commercial kits.
Results: In chow-fed mice, apelin treatment didn't change adipose tissue weight and body weight. TG plasma levels were significantly decreased in apelin treated mice and no change in plasma FFA concentration was observed. Palmitate oxidation was increased in soleus muscle (control 224 ± 42 vs apelin 456 ± 33 nmol/g of proteins, $p<0.001$) and IMTG content was decreased by 52% ($p<0.01$) in apelin-treated mice. In insulin resistant mice, apelin treatment didn't change neither adipose tissue and body weight or TG and FFA plasma levels. Moreover, total palmitate oxidation was increased (control 379 ± 40 vs apelin 642 ± 132 nmol/g of proteins, $p<0.05$). Of note, apelin increased complete fatty acid oxidation while no variation of incomplete fatty acids oxidation was observed. Apelin treatment decreased respiratory quotient which confirms in vivo a better fatty acid utilization in apelin treated mice.
Conclusion: Intramuscular triglycerides and incomplete fatty acid oxidation intermediates are known to be involved in insulin resistance development. Thus, by decreasing deleterious lipid accumulation and by stimulating fatty acid oxidation in muscle, apelin chronic treatment could improve insulin sensitivity.

33

Circulating visfatin levels reduced in patients with non-alcoholic fatty liver disease irrespective of type 2 diabetes mellitus status

K.C. McGee[1], A.L. Harte[1], M.J. Hill[1], A.D. Burt[2], S. Kumar[1], C.P. Day[2], P.G. McTernan[1];
[1]Unit for Diabetes and Metabolism, University of Warwick Medical School, Coventry, [2]Hepatology Department, School of Clinical Medicine, Newcastle upon Tyne, United Kingdom.

Background and aims: Visfatin/PBEF/Nampt, primarily produced by the liver, represents a novel adipokine with diabetogenic and immunomodulatory properties implicated in insulin resistance (IR) pathophysiology in patients with obesity and type 2 diabetes mellitus (T2DM). The influence of visfatin may be further exacerbated in non-alcoholic fatty liver disease (NAFLD), where several adipocytokines have been implicated in its pathogenesis. This study aimed to examine the influence of visfatin in NAFLD patients with/out T2DM; as such, we investigated (1) whether normal liver function impairment influenced visfatin production/expression, and (2) the relationship between serum visfatin levels and other adipocytokines, markers of IR and inflammation, in NAFLD patients with/out T2DM.
Materials and methods: Fasting human serum samples were collected from 104 patients (Age: 49.6±12.46years; BMI: 34.2±5.61kg/m^2; 69 males, 35 females) with biopsy confirmed NAFLD (71: Non-Diabetic (ND), 33: T2DM) and an additional 23 ND control patients without NAFLD (Age: 44.6±9.85years; BMI: 26.4±4.52kg/m^2; 8 males, 15 females). Serum visfatin, TNF-α, sCD14, leptin, adiponectin, resistin and insulin levels were assessed. Fasting glucose levels were analysed via a glucose oxidase method and IR calculated via HOMA. Inter-group comparisons were assessed via student's t-test. Correlations were calculated via a Pearsons Correlation Coefficient test. The significance threshold was $p<0.05$.
Results: Comparison between patients with NAFLD and ND controls without NAFLD revealed a significant increase in BMI ($p<0.001$), HOMA-IR ($p<0.05$) and circulating resistin ($p<0.01$) and insulin ($p<0.05$) concentrations, whilst circulating visfatin and TNF-α ($p<0.001$) levels were reduced with NAFLD. Visfatin concentrations remained similar following sub-division into level of NAFLD severity (FL, $p<0.001$; NASH, $p<0.001$; cirrhosis, $p<0.05$), although an increase was observed in serum visfatin levels from FL to NASH ($p<0.05$). Serum visfatin concentrations negatively correlated with BMI and insulin, dependent upon T2DM status. T2DM patients with NAFLD had more advanced levels of fibrosis (42%) than ND NAFLD subjects (11%). Further comparison between NAFLD patients with/out T2DM identified that serum visfatin was elevated in NAFLD T2DM patients however, these levels

were significantly lower than noted in the ND controls (ND, $p<0.001$; T2DM, $p<0.01$, respectively). Furthermore, a significant increase was exhibited in serum insulin ($p<0.05$), leptin (p<0.05), glucose ($p<0.001$), HOMA-IR ($p<0.01$) and sCD14 ($p<0.01$) levels in T2DM NAFLD vs. ND NAFLD patients.
Conclusion: The present study determined circulating visfatin concentration to be reduced in NAFLD, irrespective of T2DM status independent of severity of liver disease or fibrotic damage. In addition, this study illustrated a clear positive association between human NAFLD, increased IR, hyperresistinemia, hyperinsulinemia and adiposity. Taken together, these findings suggest that decreased circulating visfatin may be a potential biomarker of impaired liver function in NAFLD, whilst resistin shows a positive correlation with NAFLD pathogenesis.

Chemerin as an adipokine related to insulin resistance: chemerin decrease after bariatric surgery in morbidly obese patients
H. Sell[1], A. Divoux[2], K. Clément[2], J. Eckel[1];
[1]Institute of Clinical Biochemistry and Pathobiochemistry, German Diabetes-Center, Duesseldorf, Germany, [2]INSERM Nutriomique U872, University Pierre et Marie Curie-Paris 6, France.

Background and aims: Adipose tissue is a secretory and endocrine active organ producing a variety of bioactive proteins including the newly described adipokine and chemokine chemerin. We could recently demonstrate that chemerin induces insulin resistance in skeletal muscle cells in vitro. Conversely, a recent report suggests that there is a correlation of chemerin levels with BMI but not with insulin resistance in normal weight patients. The role of chemerin in obesity and type 2 diabetes remains unclear and has not been investigated after bariatric surgery.
Materials and methods: Chemerin plasma levels were measured in 60 morbidly obese female patients (BMI 50.0±1.0, age 43.1±1.5) before surgery as well as 3, 6 and 12 months after surgery. In a subgroup of 27 patients, chemerin levels were monitored for 2 years. At all time points blood levels of insulin, glucose, HbA1c, cholesterol, HDL, triglycerides, CRP, leptin, adiponectin and IL-6 were assessed in addition to weight and BMI.
Results: Chemerin concentrations are substantially elevated in obese patients compared to concentrations for normal weight persons (353.8±18.0 ng/ml compared to approximately 250 ng/ml described in the literature). Preoperatively, chemerin levels are correlated positively with body weight, BMI, CRP, IL-6 and insulin sensitivity (HOMA). Furthermore, chemerin is correlated negatively with HDL levels. After bariatric surgery, chemerin decreased significantly (275.6±17.9 ng/ml after 3 months, 255.9±12.0 ng/ml after 6 months and 253.0±14.9 ng/ml after 12 months) in parallel to leptin levels, but different from IL-6 that only displayed a marked reduction 12 months after surgery and adiponectin that was significantly increased after 6 and 12 months. In the subgroup of patients studied for 2 years, chemerin levels significantly decreased between 1 year and 2 years after surgery (preoperative 381.7±28.0 ng/ml, after 1year 290.7±26.9 ng/ml, after 2 years 215.1±14.7 ng/ml). 3 months after surgery chemerin levels only positively correlate with triglycerides, a correlation that was remaining apparent after 6 and 12 months. The prominent decrease of chemerin in the first 3 months after surgery was significantly associated with the increase in insulin sensitivity (HOMA) for this period. Analyzing diabetic patients (n=20) separately, a correlation of chemerin levels could be found with HOMA and HDL before surgery and with triglycerides 3 and 6 months after surgery. Differently in non-diabetic patients (n=37), chemerin correlates with BMI and IL-6 before surgery but not with HOMA or HDL.
Conclusion: This is the first study to demonstrate decreased chemerin plasma levels after bariatric surgery. The observed decrease in chemerin after bariatric surgery indicates together with our previous in vitro findings that chemerin might be a factor contributing to insulin resistance in obesity and the improvement of insulin sensitivity and other obesity-related morbidities after surgical intervention.

Adipokines induce degradation of IRS-1 in megakaryocytes resulting in insulin-resistant platelets
A.J. Gerrits[1], E. Gitz[1], C.A. Koekman[1], F.L. Visseren[2], H.W. de Valk[3], J.-W.N. Akkerman[1];
[1]Department of Clinical Chemistry and Haematology, University Medical Center Utrecht, [2]Department of Vascular Medicine, University Medical Center Utrecht, [3]Department of Internal Medicine, University Medical Center Utrecht, Netherlands.

Background and aims: Type 2 diabetes mellitus (T2DM) patients have a 2-8 fold higher risk for cardiovascular disease (CVD) and suffer from thrombotic complications. We demonstrated previously in normal platelets that insulin signals through IRS-1 and inhibits Ca^{2+} mobilization by interfering with Gi α-mediated suppression of cAMP, a platelet inhibitor. T2DM platelets are insulin-resistant and hyperactive which enhances the risk for thrombotic occlusion. In the present project we searched for the cause of insulin resistance in T2DM platelets. Since most of the properties of platelets are determined by the megakaryocyte and obese subjects are prone to develop insulin resistance, we investigated whether adipokines change the control of Ca^{2+} mobilization by insulin in the megakaryocyte.
Materials and methods: In megakaryocytic CHRF-288-11 cells incubated with adipokines and plasma from obese individuals and in T2DM platelets we measured (i) inhibition by insulin of thrombin-induced Ca^{2+} mobilization, (ii) phosphorylation of IRS-1 [Ser307] and protein kinase Bα [Ser473] as indicators of insulin signaling, (iii) expression of Suppressor Of Cytokine Signaling (SOCS) proteins which is under control of adipokines and, (iv) insulin signaling proteins.
Results: Leptin, resistin, PAI-1 and RBP-4 but not IL-6, TNFα and visfatin made cells resistant to Ca^{2+} suppression by insulin. Short contact with adipokines (2 h) aborted insulin signaling through IRS-1 illustrated by suppression of insulin-induced phosphorylation of IRS-1 and protein kinase Bα. The Ser/Thr phosphatase inhibitor cantharidin restored responses to those seen prior to adipokine addition demonstrating reversible insulin-resistance. Prolonged contact with adipokines (72 h) made cells unresponsive to phosphatase inhibition and revealed up-regulation of SOCS3 and IRS-1 degradation, demonstrating irreversible insulin resistance. Inhibition of adipokine signaling with the JAK2 inhibitor AG490 prevented cells from developing irreversible insulin-resistance. Poly-ubiquitination of IRS-1 by the proteosome inhibitor MG-132 was increased in leptin-treated cells (2 h). Indeed, incubation with leptin and resistin, but not IL-6 (24 h) resulted in decreased IRS-1 levels, whereas expression of insulin receptor, Giα2 and IRS-2 was unchanged. T2DM platelets but not platelets from healthy controls showed reduced levels of IRS-1. Plasma from metabolic syndrome subjects but not from matched controls mimicked the induction of insulin-resistance by adipokines in megakaryocytes. Insulin sensitivity was -13 ± 23% (2 hr) and -11.7 ± 20% (72 hr) compared with 61 ± 20% (2 hr) and 56 ± 16% (72 hr) in cells treated with obese and control plasma respectively (mean ± SEM, n=9). Leptin levels were increased in plasmas from the metabolic syndrome group compared to controls, whereas resistin levels were not different between groups.
Conclusion: This is a first report of insulin resistance induced by adipokines in the precursor of platelets, the megakaryocyte. The findings suggest that the increased CVD risk in T2DM patients is caused by synthesis of hyperactive platelets due to abnormal adipokine release.

Acceleration of the interleukin-1 receptor antagonist (IL-1Ra) trajectory precedes the diagnosis of type 2 diabetes by 6 years: the Whitehall II prospective cohort study
M. Carstensen[1], C. Herder[1], M. Kivimaki[2], M. Jokela[2], M. Roden[1], M. Shipley[2], D.R. Witte[2,3], E.J. Brunner[2], A.R. Tabak[2,4];
[1]Institute for Clinical Diabetology, German Diabetes Center, Düsseldorf, Germany, [2]Department of Epidemiology and Public Health, University College London, United Kingdom, [3]Steno Diabetes Center, Gentofte, Denmark, [4]Semmelweis University, Budapest, Hungary.

Background and aims: The proinflammatory cytokine interleukin-1ß (IL-1ß) inhibits beta-cell function and promotes beta-cell apoptosis, whereas IL-1 receptor antagonist (IL-1Ra), a naturally occurring inhibitor of IL-1ß, has been shown in a clinical trial to improve beta-cell function and glycaemic control in patients with type 2 diabetes (T2D). We recently reported high

levels of IL-1Ra to be associated with an increased risk of incident T2D, but this analysis was limited to a single serum sample from each individual. The present study exploits data from repeated measurements of IL-1Ra (i) to examine how serum IL-1Ra concentrations change during years preceding the manifestation of diabetes and (ii) to compare these trajectories with those from individuals who did not develop T2D.
Materials and methods: This is a case-cohort study within the Whitehall II cohort with a total of 2809 participants without T2D at baseline, 27.2% women, mean age at baseline 49.3 (SD 5.9) years and average BMI 25.3 (SD 3.5) kg/m^2. The study included 335 cases with incident T2D during the follow-up period and 2474 non-cases who remained T2D-free. Serum levels of IL-1Ra were measured at up to three time points for each participant (phase 3, the baseline: 1991-94; phase 5: 1997-99; and phase 7: 2003-04). Year 0 of the observation period was the year of diabetes diagnosis for cases and a randomly selected time point during follow-up for non-cases to approximate the follow-up time distribution of cases. IL-1Ra levels were traced backwards to participants' first participation in clinical screening. Multilevel models adjusted for age, sex and ethnicity were fitted to the data to assess changes in IL-1Ra during the preceding 13 years based on 755 serum samples in cases and 5095 serum samples in non-cases.
Results: Serum IL-1Ra levels were already higher in cases than non-cases 13 years before year 0. Mean (95% CI) levels were 404 (384-425) pg/ml in cases and 326 (314-339) pg/ml in non-cases. From 13 to 6 years before year 0, serum IL-1Ra levels increased only marginally in both cases and non-cases (1.5-2 pg/ml per year). From about 6 years before the manifestation of T2D, serum IL-1Ra concentrations of the cases showed a steep linear increase of about 20 pg/ml per year until the diagnosis, whereas the slope of the trajectory of the non-cases remained unaltered (P<0.0001 for the different slopes during the final 6 years). Adjustment for BMI and waist circumference as time-varying predictors had almost no impact on these trajectories.
Conclusion: IL-1Ra levels were already elevated more than 10 years before the manifestation of T2D and showed an accelerated increased during the last 6 years preceding the diagnosis (i.e., during a period also characterised by increases in plasma glucose levels and decreases in beta-cell function). These data provide support for the hypothesis of IL-1Ra upregulation to counterbalance metabolic and immunological disturbances preceding T2D.
IL-1Ra measurements were funded by a Medical Research Council (UK) New Investigator Award

OP 7 Beta cell regeneration and loss

Perinatal survivin expression is essential for the establishment of pancreatic beta cell mass
X. Wu[1,2], L. Wang[3], S. Schroer[2], D. Choi[2], P. Chen[3], H. Okada[4], M. Woo[2,3];
[1]Department of Endocrinology, First Affiliated Hospital of Nanjing Medical University, China, [2]Institute of Medical Science, Ontario Cancer Institute, University of Toronto, Canada, [3]Department of Medical Biophysics, Ontario Cancer Institute, University of Toronto, Canada, [4]Division of Signaling Biology, Ontario Cancer Institute, Toronto, Canada.

Background and aims: The deficiency of functional β-cell mass is the common denominator in all forms of diabetes. Because new β-cells are primarily formed from the replication of mature pre-existing β-cells during adulthood, the establishment of adequate β-cell mass early in life is therefore critical in determining β-cell mass expansion in respond to metabolic alterations throughout the life of the organism. From late embryogenesis and neonatal periods, pancreatic β cells undergo dynamic remodeling to establish the normal β-cell mass with enhanced neogenesis, proliferation and apoptosis. The molecular mechanisms responsible for these processes are elusive. Survivin is an inhibitor of apoptosis, first described to be expressed exclusively in tumour and embryonic tissues with regulatory functions in mitosis and apoptosis. Our aim was to define the essential physiological role of survivin in the pancreas.
Materials and methods: Survivin expression profile was assessed in the mouse pancreas and we generated mice harboring a conditional deletion of survivin in pancreas using mice with a PDX-1 promoter-driven survivin knockout mouse by the Cre-loxP recombination system to determine the essential physiological function of survivin in the pancreas.
Results: Survivin was expressed within the pancreatic islets of mice from the second wave of pancreatic endocrine development at E15.5 to the postnatal 3 weeks. Targeted deletion of survivin in the pancreas resulted in a significant decline in β-cell mass throughout the perinatal period, leading to decreased insulin levels and glucose intolerance in adult. Survivin-deficient islets showed significantly decreased cell proliferation due to a delay in cell cycle progression with perturbations in cell cycle proteins such as phosphor RB, Cyclin-E, CDK2, p21, p27, Caspase-3 and Aurora B kinase. Islet development, islet architecture, microvasculature, and apoptosis were not affected by the absence of survivin in the pancreas.
Conclusion: Survivin expression in the pancreatic islets during the perinatal remodeling period is essential for the establishment of β-cell mass through cell cycle regulation. Survivin deficiency in the pancreas leads to defects in β-cell mass establishment early in life, resulting in a permanent decrease in β-cell expansion and glucose intolerance in adult.

Regulation of beta cell mass during early life in somatostatin-deficient mice
C.C. Richardson[1], K. To[1], V. Foot[1], E. Shamil[1], W. Jefferson[1], D. Carmignac[2], I.C.A. Robinson[2], M.R. Christie[1];
[1]Division of Reproduction & Endocrinology, King's College London, [2]Division of Molecular Neurophysiology, National Institute for Medical Research, London, United Kingdom.

Background and aims: Early postnatal life represents a critical period when remodelling of the endocrine pancreas occurs, including proliferation of islet cells and their precursors, transient increases in apoptosis, and maturation of insulin secretory responses to glucose. Factors that regulate these processes are poorly understood. Somatostatin-secreting delta cells are abundant in the fetal and neonatal pancreas and since somatostatin acts to inhibit growth factor secretion and cell proliferation and promote apoptosis, the hormone may play a role in regulating islet expansion in early life. The aim of this project was to investigate the effect of somatostatin-deficiency on proliferation, apoptosis and beta cell expansion in the first three weeks of life in mice.
Materials and methods: Pancreases from wild-type or somatostatin-knockout (SST-/-) mice at 2, 7, 14, 21 days and 1 year of age were analysed for total pancreas, beta and alpha cell volumes by morphometry, and for cell proliferation and apoptosis by BrdU incorporation and TUNEL labelling, respectively. Activation of signalling pathways associated with proliferation and apoptosis was studied by Western blotting of tissue extracts.

Results: Significant decreases in pancreatic and beta cell volume were observed in pancreases from SST-/- mice in the first three weeks of life. Reduced beta cell volume (0.68±0.26 vs 2.95±0.7 mm^3, p<0.05) persisted to one year of age, whereas there were no significant differences in alpha cell or pancreatic volumes. BrdU incorporation into pancreatic cells was significantly reduced in SST-/- animals at 2 days (40.8±4.8 vs 117±19.5 BrdU-positive cells/mm^2, p<0.01) and TUNEL-positive cells increased at 14 days (235.7±58 vs 28.3±6.1 cells/mm^2, p<0.05). TUNEL positive nuclei were seen in all pancreatic cell types but were particularly abundant in pancreatic ducts. Decreased beta cell mass in SST-/- animals was not a consequence of impaired growth factor signalling through the Akt pathway, since Akt phosphorylation was increased 2.6-fold (p<0.01) and nuclear cyclin D2 increased 1.8-fold (p<0.05) in the SST-/- pancreas. However, levels of TGF-beta 1, a growth factor that stimulates apoptosis in epithelial cells and is implicated in tissue remodelling, were increased 2.5-fold (p<0.001) in the SST-/- pancreas. TGF-beta signalling is mediated by phosphorylation and nuclear translocation of SMAD proteins and SMAD phosphorylation was increased in the SST-/- pancreas.
Conclusion: Despite somatostatin being a negative regulator of growth, expansion of pancreatic beta cell mass was impaired in SST-/- mice as a consequence of reduced proliferation and increased apoptosis of beta cells and their precursors. Reduced expansion of beta cell mass was associated with increased TGF-beta 1 levels in the SST-/- pancreas and TGF-beta 1 may represent an important regulator of beta cell mass in early life.

IGF-II reexpression in adult mice is essential for beta cell regeneration *in vivo*

L. Zhou[1], S. Pelengaris[2], S. Abouna[1], J. Young[2], D.B.A. Epstein[3], M. Khan[1];
[1]Biological Science, [2]Medical School, [3]Mathematics Institute, University of Warwick, Coventry, United Kingdom.

Background and aims: Identifying factors which can support beta cell regeneration and or prevent death is a key objective in diabetes research. The insulin-like growth factor (IGF) signaling system is well know in regulating growth and development of many tissues. Both IGF-1 and insulin have been shown to play important roles in adult adaptive increases in beta cell mass and in regeneration. Conversely, Insulin-like growth factor II (IGF-II), plays a critical role in fetal cell division and differentiation, but is generally believed to play no role in the adult pancreas under normal physiological conditions.
Materials and methods: We have employed the 'switchable' pInsMycERTAM mouse, which exhibits Myc-induced beta cell ablation, and is followed by complete beta cell regeneration over 3 months once Myc is deactivated. By crossing with IGF-II knockout mice we tested the hypothesis that IGF-II re-expression is important for beta cell regeneration in adult mice. Beta cell quantitative analyses were determined by immunohistochemistry and all results are expressed as means±SD and significance of differences are evaluated with Student's t test or ANOVA.
Results: Here we show for the first time that IGF-II is re-expressed early in the adult pancreas following beta cell ablation. Following subtotal beta cell ablation, subsequent regeneration was followed. By 4 days after Myc deactivation in pInsMycERTAM we already see some expansion of beta cell mass as determined by increasing cross-sectional area of insulin staining (0.00102±0.0002 to 0.00175±0.0003; p=0.0277). Whereas, in pInsMycERTAM /IGF-II KO mice this is completely prevented (0.00125±0.0011 to 0.00083±0.00013, p > 0.05). This was confirmed by cell counting- beta cell numbers increased by 1.5±0.3 folds, whereas in pInsMycERTAM /IGF-II KO mice cell numbers did not increase at all (0.8±0.2 fold change; p=0.0364). This early delay in beta cell regeneration is also seen at 3 months of recovery. At 96 days beta cell mass and numbers have returned to pre-ablation levels- in itself interesting given the fact that blood glucose levels were essentially normal from around 4 weeks and yet beta cell mass continues to increase until pre-ablation numbers are re-achieved. In pInsMycERTAM /IGF-II KO mice beta cell mass has also returned to similar levels to pre-ablation, but cell numbers remain substantially reduced suggesting that hyperplasia is compensating for impaired beta cell regeneration in IGF-II KO mice.
Conclusion: Our results demonstrate that early beta cell regeneration in adult mice depends on re-expression of IGF-II, suggesting the possibility that reactivation of an embryonic pathway contributes to this in adult mice. Moreover, full recovery of beta cell numbers is substantially impaired even after 3 months, though this is in part compensated by beta cell hypertrophy. This also suggests that IGF-II may be a novel potential target in treatment of diabetes.

Islet cell proliferation is increased in human recent onset type 1 diabetes

A.J. Willcox[1], S.J. Richardson[1], A.J. Bone[2], A.K. Foulis[3], N.G. Morgan[1];
[1]Institute of Biomedical and Clinical Science, Peninsula College of Medicine and Dentistry, Plymouth, [2]School of Pharmacy and Biomolecular Sciences, University of Brighton, [3]Department of Pathology, Glasgow Royal Infirmary, United Kingdom.

Background and aims: Type 1 diabetes (T1D) is a disease in which the β-cells of the islets of Langerhans are killed selectively by autoimmune-mediated attack. Very little information is available about the β-cell response to this immune assault in humans and, in particular, it is unclear whether endocrine cell proliferation can be re-initiated during this phase of the disease. Therefore, the aim of the present study was to assess the extent of islet endocrine cell proliferation in recent-onset T1D patients and to compare this with age-matched control patients.
Materials and methods: Paraffin-embedded sections from autopsy pancreases of 10 recent-onset T1D patients (mean age 14±3.8 years; range 1-42 years) and 12 non-diabetic controls (mean age 17.8±6 years; range 2-53 years) were employed. An antibody directed against Ki67, a protein expressed selectively during mitosis, was used to detect proliferating cells. Multiple antigen staining was performed with antibodies against insulin, glucagon and somatostatin to identify the islet cell subtypes which were Ki67-positive. Sections were examined using brightfield and fluorescence microscopy and islet morphometry was analysed using Adobe Photoshop CS4 software.
Results: The number of Ki67-positive ($Ki67^+$) endocrine cells within the islets of non-diabetic control patients was very low, such that only 1.1±0.3% of the islets contained any $Ki67^+$ cells in a given pancreatic section. By contrast, the percentage of islets containing $Ki67^+$ endocrine cells was increased markedly in recent-onset T1D patients (to 10.88±2.5%; p<0.005) The average number of $Ki67^+$ endocrine cells per islet section in those islets with $Ki67^+$ cells was also increased significantly, from a mean of 1.14±0.09 cells/islet section in controls to 1.91±0.12 cells/islet section in T1D patients (p<0.001). Dual-labelling studies revealed that the increase in $Ki67^+$ staining occurred in both α- and β-cells whereas the absolute numbers of $Ki67^+$ δ-cells were insufficient to allow firm conclusions to be drawn about their proliferative potential. In controls, a total of 3466 islets were studied (mean cell number = 124 cells/islet section) and these yielded labelling indices of 0.008% for β-cells and 0.006% for α-cells. In the T1D patients, the $Ki67^+$ labelling index (measured in a total of 1280 islets, of which approximately 75% were insulin positive) was raised to 0.070% for β-cells and to 0.066% for α-cells Thus, the $Ki67^+$ labelling index was increased by approximately 10-fold for both α- and β-cells in recent-onset T1D. $Ki67^+$ α-cells were present in both insulin-positive and insulin-negative islets.
Conclusion: This study reveals that both α- and β-cells cells undergo a marked increase in proliferation during the progression of T1D in humans, suggesting that endocrine cell proliferation is re-initiated in response to the autoimmune attack associated with T1D. Identification of the stimulus mediating this increase may provide a means for therapeutic intervention to restore β-cell numbers in patients who are newly diagnosed with T1D.

Human islets contain a population of mesenchymal stem cell capable of differentiation toward the endocrine lineage

F. Carlotti[1], A. Zaldumbide[1], C.J. Loomans[2], M. Engelse[2], E. van Rossenberg[2], E.J. de Koning[2], R.C. Hoeben[1];
[1]Molecular Cell Biology - Virus and Stem cell Biology lab, Leiden University Medical Center, [2]Nephrology, Leiden University Medical Center, Netherlands.

Background and aims: Islet transplantation is a promising treatment strategy in type-1 diabetes, but the scarcity of donors limits its widespread application. *In vivo* islet (re)generation would be the best therapeutic approach, although it is unclear whether this approach is possible. *In vitro* islet generation from adult stem cells represents an attractive alternative. So far, embryonic stem cells as well as mesenchymal stem cells from different origins such as bone marrow and adipose tissue have been evaluated for their ability to form beta cell-like cells. However, most of the studies showed an incomplete differentiation process leading to a low and often unregulated insulin production. In this study we describe the isolation and characterization of a mesenchymal stem cell (MSC) population from islets from human donors, here called islet-

derived cells (IDC). In contrast to bone marrow-derived MSC, human IDC have the capacity to aggregate, form clusters, and to induce the expression of insulin, glucagon and somatostatin. However, their origin still has to be clarified.
Materials and methods: Gene expression was analyzed and quantified by RT-PCR and Real-time PCR, respectively. Flow cytometry and immunofluorescence coupled to confocal microscopy were used to characterize and identify the cells of interest.
Results: After expansion, hIDC isolated from human donors express the mesenchymal stem cells markers CD105, CD90, CD73, CD44, CD29, and CD13 on their surface, synthesize nestin and vimentin, and can differentiate to adipocytes and osteocytes. Also, hIDC were found to express the pericyte markers CD146, NG2, αSMA and PDGF-Rβ. However, von Willebrand Factor, CD31, CD34 and CD45 are not expressed, demonstrating that hIDC are neither of hematopoietic nor of endothelial origin. Remarkably, and in contrast with other pancreatic progenitors, hIDC do not express the ductal markers CK19 and CA19.9. Using the combination of surface markers CD90 and CD105 for immunoflowcytometry we demonstrate that human islets contain 2.0±0.8 % CD105/CD90 double-positive cells. Confocal microscopy on freshly isolated islets positioned these cells within the islets.
Conclusion: From our data we conclude that human islets contain a population of mesenchymal stem cells with the unique capacity to differentiate toward the endocrine pathway. The identification of stem cells in human islets offers new avenues that can be explored for *ex vivo* and potentially *in vivo* islet regeneration.

Islet autoantibodies in patients receiving pancreas transplantation alone
M. Occhipinti[1], V. Lampasona[2], R. Giannarelli[1], F. Vistoli[3], A. Coppelli[1], S. Bonicchio[2], D. Campani[4], G. Amorese[3], E. Bazzigaluppi[2], L.E. Pollina[4], M. Del Chiaro[3], U. Boggi[3], P. Marchetti[1], E. Bosi[2];
[1]Endocrinology and Metabolism of Organ and Cellular Transplantation, University of Pisa, [2]Diabetes Research Institute, San Raffaele Scientific Institute, Milan, [3]General Surgery and Transplantion in Uremia and Diabetes, University of Pisa, [4]Transplant Pathology, AOUP, Pisa, Italy.

Background and aims: Pancreas transplantation alone (PTA) in subjects with type 1 diabetes (T1D) and preserved kidney function is an established clinical procedure able to restore an endogenous and self-regulating insulin secretion and normalize blood glucose levels. In previous studies, post-transplant reappearance or titre increase of islet autoantibodies (Ab) was associated with transplant failure in a proportion of patients after islet or simultaneous pancreas and kidney transplantation. No data are available on PTA. Aim of this study was to investigate islet Ab in T1D patients undergoing PTA.
Materials and methods: Antibodies to the major autoantigens glutamic acid decarboxylase (GADA), protein tyrosine phosphatase IA-2 (IA-2A) and zinc transporter-8 (ZnT8A) were measured before and after PTA in 25 T1D patients (age: 36.9±7.8 yrs; males/females: 9/16; BMI: 23.7±2.7 kg/m^2; duration of T1D: 25.0±8.2 yrs; post-PTA follow-up: 38.8±14.4 mo). All patients underwent pancreas transplantation with portal-enteric drainage and received mycophenolate, tacrolimus and low-dose steroid as immunosuppressive treatment.
Results: Before transplantation, one or more Ab were detected in 12 (48%) patients: of them, 1 had all 3, 4 had 2 and 7 had 1 Ab only. After transplantation, all patients became insulin independent with normal blood glucose control. During follow-up, 5 patients lost pancreas function and resumed insulin therapy at 8, 15, 28, 55 and 77 months. The pre-transplant Ab status did not influence pancreas graft outcome. Out of patients with continuing graft function, only one showed Ab changes, defined as either appearance of previously undetectable Ab or doubling or more the titre of pre-existing Ab. Substantial changes in Ab levels were observed in 4 out of 5 patients whose transplant failed, and failure occurred after a mean of 18.5±22.0 mo from Ab changes detection. Pancreas biopsies were performed in 3 patients with failing pancreas graft and with Ab changes: immunohistochemistry showed CD3$^+$ and, to a less degree, CD20$^+$ infiltration in the exocrine tissue, with no pictures of selective insulitis or β-cell loss.
Conclusion: In conclusion, in T1D patients receiving PTA the pre-transplant islet Ab status is not predictive of graft outcome, while Ab reappearance or major titre increase is associated with transplant failure; the underlying immune pathogenetic processes remain to be clarified.

OP 8 Diabetic nephropathy and blood pressure

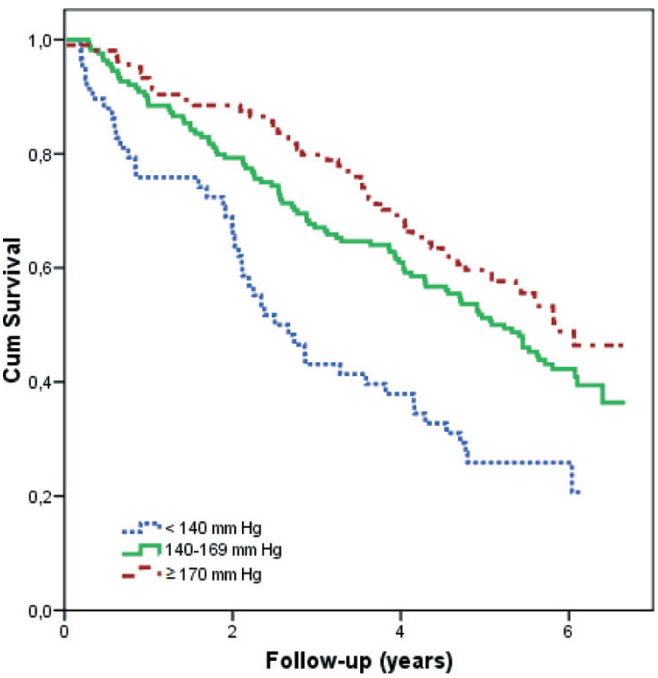
Higher blood pressure associated with lower mortality in elderly type 2 diabetic patients (ZODIAC-12)
K.J.J. van Hateren[1], G.W.D. Landman[1,2], N. Kleefstra[1,3], K.H. Groenier[4], A.M. Kamper[2], S.T. Houweling[3,5], H.J.G. Bilo[1,2];
[1]Diabetes Centre, Zwolle, [2]Department of Internal Medicine, Isala Clinics, Zwolle, [3]Langerhans Medical Research Group, Zwolle, [4]Department of General Practice, University Medical Center Groningen, [5]General Practice Sleeuwijk, Netherlands.

Background and aims: Hypertension is considered to increase the already high risk of cardiovascular disease in patients with type 2 diabetes mellitus (T2DM). However, the precise relationship between blood pressure and mortality in elderly T2DM patients remains unclear. The aim of this study was to investigate the relationship between blood pressure and pulse pressure over time and mortality in elderly T2DM patients.
Materials and methods: In 1998, 881 primary care patients with T2DM aged 60 years and older participated in the ZODIAC study. The cohort was divided into two age categories: 60-75 years and older than 75 years. After a median follow-up time of 5.7 years, updated means for systolic blood pressure, diastolic blood pressure and pulse pressure were calculated, and used, as time dependent covariates, in a Cox proportional hazard model. This analysis was used to evaluate the association between the different blood pressure measures over time and (cardiovascular and all-cause) mortality. The following variables were selected as possible confounders: gender, smoking (yes or no), body mass index, duration of diabetes, serum creatinine, cholesterol-HDL ratio, macrovascular complications (yes or no), albuminuria (yes or no), the use of lipid lowering and antihypertensive drugs (yes or no) and age.
Results: The mortality rate for the elderly patients (> 75 years) with a systolic blood pressure < 140 mm Hg was 76% compared to 50% in the group with a blood pressure ≥ 170 mm Hg (figure 1). All of the blood pressure measures were inversely related to all-cause mortality in this age group. An increase of 10 mm Hg in systolic blood pressure, diastolic blood pressure and pulse pressure led to a decrease of the hazard of mortality [95% confidence interval] of 19% [11%-27%], 27% [12%-43%] and 19% [9%-29%] respectively. For cardiovascular mortality the hazard ratios were 0,88 [0,77-1,00] for systolic blood pressure and 0,86 [0,72-1,00] for pulse pressure. In the low age group (60-75 years) the associations between blood pressure and mortality were not significant.
Conclusion: Blood pressure is a marker for mortality in elderly T2DM patients; however, the relationship is inverse. Known risk factors might have different consequences when assessed in different subgroups; in this case the elderly population.



44

Allelic variations in the SOD1 gene are associated with development and progression of nephropathy in type 1 diabetic subjects

K. Mohammedi[1], S. Maimaitiming[2], N. Bellili[2], N. Emery[3], R. Roussel[1], S. Hadjadj[4], F. Fumeron[2], G. Velho[2], M. Marre[1];
[1]Endocrinologie Diabétologie et Nutrition, Assistance publique des hôpitaux de Paris, [2]Faculté de médecine Xavier Bichat, INSERM U695, Paris, [3]Faculté de médecine Xavier Bichat, Université Paris 7- Paris Diderot, [4]Médecine Interne, Hôpital Universitaire de Poitiers, France.

Background and aims: Oxidative stress is involved in the pathophysiology of diabetic nephropathy (DN), and the enzyme superoxide dismutase 1 (SOD1) is essential for reactive oxygen species detoxification. In this study, we tested the impact of SOD1 allelic variation in the development and progression of DN in subjects with Type 1 Diabetes Mellitus (T1DM).
Materials and methods: Seven SNPs (rs2173962, rs9974610, rs10432782, rs2070424, rs1041740, rs17880135 and rs202449), giving information on ~90% of the allelic variation of the haplotypic block containing SOD1 gene were analyzed in 1278 subjects from three independent T1DM cohorts: the SURGENE prospective study, GENEDIAB and GENESIS studies. Genotypes were determined by an Assay by Design kit from Applied Biosystems. Genotype associations with DN were assessed by logistic regression analyses. Associations with DN severity were assessed by ordinal logistic regression analyses, with stages of DN coded as ordinal polytomic dependent variables: absence (1), microalbuminuria (2), macroalbuminuria (3), reduced renal function (4) and end stage renal failure (5). A renal event was defined as progression to a further stage of nephropathy. Survival analyses without renal events were assessed by Cox's proportional hazards model.
Results: The rs1041740 SNP was associated with DN in the prospective SURGENE study both at baseline (odds ratio: 3.1, 95% CI: 1.3-7.9, p=0.01) and at 6 years follow-up (odds ratio: 5.22, 95% CI: 1.9-16.9, p=0.002). Associations were also observed with DN severity (p=0.009). Genotype tends to be associated with renal event incidence (Hazard ratio: 1.33, 95% CI: 0.97 - 1.84, p = 0.08). The rs17880135 variant was associated with DN in GENEDIAB (odds ratio: 2.5, 95 % CI: 1.1-6.0, p=0.03) and GENESIS (odds ratio: 2.0, 95% CI: 1.04 - 3.8, p=0.03) cohorts. Significant association with DN severity was also observed in both cohorts (p=0.05 and p=0.04, respectively). Associations of both SNPs with albuminuria were observed in the 3 cohorts. Associations with arterial hypertension were also observed.
Conclusion: We have observed associations of SOD1 allelic variations with nephropathy, its severity and intermediate phenotypes in subjects with T1DM. We are currently performing haplotypic studies in the 3 cohorts and analysis of 10 year follow-up data of SURGENE.

45

Different sets of risk factors for the development of albuminuria and renal impairment in type 2 diabetes - the Swedish National Diabetes register (NDR)

H. Afghahi[1], J. Cederholm[2], B. Eliasson[3], P.M. Nilsson[4], K. Eeg-Olofsson[3], S. Gudbjörnsdottir[3], M.K. Svensson[5];
[1]Department of Medicine, Kärnsjukhuset, Skövde, [2]2Department of Public Health and Caring Sciences, Family Medicine and Clinical Epidemiology, Uppsala University, [3]Department of Medicine, Sahlgrenska University Hospital, Gothenburg, [4]Department of Clinical Sciences, Cardiovascular Group, Malmö University Hospital, Lund University, Malmo, [5]Dept of Nephrology, Sahlgrenska University Hospital, Gothenburg, Sweden.

Background and aims: Type 2 diabetes (T2D) is one of the leading causes of end stage renal disease (ESRD) but not all patients with T2D develop renal dysfunction (albuminuria and/or renal impairment). The aim of this study was to identify clinical risk factors associated with development of renal dysfunction in T2D patients.
Materials and methods: 3677 patients with type 2 diabetes with age 30-74 years with no signs of renal dysfunction at baseline (no micro- or macroalbuminuria and eGFR >60 ml/min//1.73m^2 according to MDRD (Modified Diet in Renal Disease) were followed for 5 years (2002 to 2007). Clinical and biochemical variables were reported at baseline and renal outcomes, development of albuminuria and/or renal impairment (eGFR <60 was ml/min/1.73m^2 MDRD or eCrCl <60 ml/min according to Cockcroft-Gault; C-G) were assessed at follow-up. Univariate logistic regression analyses for baseline variables with renal outcomes as dependent variables and then adjusted odds ratios, 95% confidence intervals, Wald X^2 and p-values in stepwise logistic regression analyses were calculated. In addition, two significant models for adjusting the odds ratios for BMI as a predictor of development of albuminuria or renal impairment were created.
Results: 20 % of patients developed albuminuria (16 % micro- and 4 % macroalbuminuria) and 11 % (MDRD) or 7 % (C-G) developed renal impairment. Among patients who developed albuminuria 16 % (MDRD) or 10 % (C-G) developed renal impairment. 29% (MDRD) or 32% (C-G) of patients who developed renal impairment also developed albuminuria. Development of albuminuria or renal impairment was independently associated with high age (all p<0.001), high systolic BP (all p<0.02), and elevated triglycerides (all p<0.02). Additional independent risk factors for albuminuria were high BMI (p<0.01), high HbA1C (p<0.001), smoking p<0.001), HDL (p<0.05) and male sex (p<0.001), and for renal impairment elevated plasma creatinine at baseline and female sex (both p<0.001). High BMI was an independent risk factor for renal impairment when defined by MDRD (p<0.01), but low BMI was when defined by C-G (p<0.001). Adverse effects of BMI on HbA1C, blood pressure and lipids accounted for approx 50% of the increase risk for albuminuria, and for 41% of the increased risk for renal impairment (MDRD).
Conclusion: Distinct sets of risk factors were associated with the development of albuminuria and renal impairment consistent with the concept that they are not entirely linked in type 2 diabetes. Interestingly effects of BMI accounted for a substantial proportion of the increased risk for both development of albuminuria and renal impairment. The equations used to define renal function (MDRD vs C-G) have an impact on interpretation of data.

46

Age at onset and sex influence the risk of developing end-stage renal disease in young patients with type 1 diabetes

A. Möllsten[1], M. Svensson[2], Y. Berhan[3], S. Schön[4], L. Nyström[5], H. Arnqvist[6], G. Dahlquist[1], The Swedish Childhood Diabetes Study Group, The Diabetes Incidence Study in Sweden, The Swedish Renal Register;
[1]Dept. of Clinical Sciences, Paediatrics, Umeå University, [2]Dept. of Nephrology, Sahlgrenska University Hospital, Gothenburg, [3]Paediatrics, Sunderby Hospital, Luleå, [4]Dept. of Internal Medicine, Ryhov County Hospital, Jönköping, [5]Dept. of Public Health and Clinical Medicine, Epidemiology and Public Health Sciences, Umeå University, [6]Dept. of Clinical and Experimental Medicine, Linköping University, Sweden.

Introduction: Young age at onset of type 1 diabetes (T1D) can postpone the development of diabetic nephropathy (DN) and end-stage renal disease (ESRD). It has been suggested that puberty could promote the development of diabetic complications. If puberty is associated with increased risk of ESRD, the cumulative incidence of DN and ESRD for subjects with diabetes onset after puberty should be similar to that of pre-pubertal T1D cases. The aims of this study were to assess the cumulative risk of ESRD due to DN in a large population-based prospective T1D cohort and to study the effects of sex and age at onset of T1D on this risk.
Study population: Since 1977 all incident cases of T1D in the ages 0-14 years are recorded in the Swedish Childhood Diabetes Register (SCDR) and since 1983 all incident cases in the age-group 15-34 years are recorded in the Diabetes Incidence Study in Sweden (DISS). The Swedish Renal Registry (SRR) started in 1991 and collects data on all patients with active uraemia treatment, ESRD. Patients with >13 years duration of T1D were entered in the analyses since these patients would have equal chance of entering the SRR. In total, 6788 patients from the SCDR and 4847 patients from the DISS were included.
Results: The median time of follow up was 21.2 years for SCDR and 18.9 years for DISS (range 13-30 years), 125 patients had developed ESRD due to DN. At 25 years of T1D duration the cumulative incidence was 3.0% in males and 1.9% in females. Among patients developing T1D before the age of 15 there was no difference between males and females. Female patients developing T1D at 15-34 years had a similar risk of ESRD as the 0-9 year age-group and lower risk than the 10-14 years age-group (Table 1). In contrast, developing diabetes after 15 years of age doubled the risk for males as compared with females, hazard ratio (HR) 2.4, 95% CI=1.2-4.8. Among male patients with T1D development at 15-34 years the ESRD risk was four times higher than the 0-9 years age-group but not significantly different from the 10-14 years age-group.

Table 1: Hazard ratios and 95% CI comparing different age at onset of T1D.

Age at onset (years)	**Males**	**Females**
15-34 vs. 0-9	4.0 (2.0-8.0)	1.8 (0.7-4.7)
15-34 vs. 10-14	1.4 (0.8-2.4)	0.5 (0.2-0.99)

Conclusion: The cumulative risk of ESRD due to DN in Sweden at 25 years of diabetes duration is low. In females, pubertal age at onset was associated with an increase in risk that disappeared in post-pubertal onset patients but males had a continuing risk increase with older age at onset. The findings suggest a role for age at onset/puberty and sex hormones in the development of diabetic renal complications.

47

Efficacy and safety of long-acting nifedipine (GITS) in patients with diabetes and symptomatic stable angina pectoris: insights from the ACTION trial

P.A. Meredith[1], H.L. Elliott[2];
[1]Medicine & Therapeutics, University of Glasgow, [2]Institute of Pharmaceutical & Medical Sciences, University of Strathclyde, Glasgow, United Kingdom.

Background and aims: In the ACTION (A Coronary disease Trial Investigating Outcome with Nifedipine GITS) trial, the benefits of adding nifedipine GITS to the treatment of patients with stable symptomatic coronary artery disease were particularly apparent in those with concomitant hypertension. This further analysis has assessed whether or not the addition of nifedipine GITS is particularly beneficial in the treatment of patients with the combination of diabetes mellitus and chronic stable angina.
Materials and methods: Of the 7665 randomised patients in the ACTION study, 1113 (14.5%) had diabetes. In addition to their existing "best practice" cardiovascular (CV) treatment, all patients were randomised to receive either nifedipine GITS 60 mg once daily or placebo. The primary endpoint for efficacy was the combined rate of death of any cause, myocardial infarction, refractory angina, new overt heart failure, debilitating stroke or peripheral revascularisation.
Results: There were significant treatment-related differences between diabetic and non-diabetic patients: for example, diabetics were more likely than non-diabetics to receive drugs blocking the renin-angiotensin system (RAS blockade) both at baseline (36 v 20%) and during the study (68 v 43%). Despite the use of RAS blockade, 60% of the diabetic patients were uncontrolled with BP>140/90mmHg and 15% with BP > 130/80 mmHg. After 4 years treatment, 56% of diabetics treated with nifedipine were controlled at < 140/90 compared to 45% in the placebo group and at <130/80 mmHg the respective figures were 25 and 18%. With respect to endpoint analysis, there was an overall consistency whereby nifedipine treatment tended to be superior to placebo across all the parameters. Furthermore there was a trend towards a greater magnitude of benefit in the diabetic versus non-diabetic patients. Although there was no difference in the occurrence of the primary end-point, nifedipine treatment resulted in a statistically significant reduction (p=0.001) in the combined endpoint of death, any cardiovascular event or cardiac procedure by 21% in the diabetics compared to 9.8% in the non-diabetic patients.
Evolution of blood glucose and serum creatinine measurements was not affected by nifedipine treatment: fewer diabetics assigned nifedipine required increased anti-diabetic medication.
Conclusion: Despite the well-recognised high level of CV risk in patients with established coronary artery disease and diabetes mellitus, BP control was poor and well short of recommended target levels, even although the majority of patients were receiving some form of RAS blockade. The addition of nifedipine to "best practice" CV treatment was not only safe in diabetic patients with stable symptomatic coronary artery disease but it led to improved BP control, reduced CV risk and a reduction in "hard" CV end-points (cardiovascular events and interventions.)

48

Impact of baseline renal function on the efficacy and safety of aliskiren added to losartan in patients with type 2 diabetes and nephropathy

H.-H. Parving[1,2], F. Persson[3], J.B. Lewis[4], E.J. Lewis[5], N.K. Hollenberg[6];
[1]Dept of Medical Endocrinology, Copenhagen University Hospital, Denmark, [2]Faculty of Health Science, Aarhus University, Denmark, [3]Steno Diabetes Center, Gentofte, Denmark, [4]School of Medicine, Vanderbilt University, Nashville, United States, [5]Medical Center, Rush University, Chicago, United States, [6]Brigham and Women's Hospital and Harvard Medical School, Boston, United States.

Background and aims: Patients with low GFR are at high risk of renal disease progression and treatment-related adverse events (AEs). This *post hoc* analysis assessed the efficacy and safety of aliskiren (ALI) or placebo (PBO) added to losartan (LOS) according to baseline renal function (estimated GFR [MDRD equation] <60, ≥60-<90 and ≥90 mL/min/1.73 m^2) in the Aliskiren in the EValuation of PrOteinuria In Diabetes (AVOID) study.
Materials and methods: In AVOID, 599 patients aged 18-85 years with hypertension and diabetic nephropathy received 6 months' ALI (150 mg force titrated to 300 mg after 3 months) or PBO added to LOS 100 mg and optimal antihypertensive therapy. Exclusion criteria included eGFR <30 mL/min/1.73 m^2 and serum potassium >5.1 mmol/L.
Results: Baseline characteristics were similar between treatment arms in all eGFR subgroups. In the overall population, adding ALI to LOS reduced urinary albumin:creatinine ratio (UACR) by 20% (p<0.001). The antialbuminuric effects of ALI were consistent across eGFR subgroups (19%, 22% and 18% reduction, respectively). Overall, eGFR declined by 2.4 mL/min/1.73m^2 with ALI but by 3.8 mL/min/1.73 m^2 with PBO (p=0.07 vs ALI); numerically smaller eGFR reductions were also observed with ALI vs PBO in all eGFR subgroups. In the eGFR <60 subgroup, baseline serum creatinine levels were equal (ALI 129.3 μmol/L vs. PBO 133.9 μmol/L) but renal dysfunction prespecified as a post randomization serum creatinine level >176.8. μmol/L (2.0 mg/dL) occurred more frequently in PBO vs. ALI (30.1% vs. 16.4%, p=0.02). Serum potassium elevations >5.5 mmol/L on a single measurement were more frequent with ALI (22.5% vs 13.6%), while the occurrence was equal in the two other groups. AE rates were highest in the eGFR <60 subgroup (68.1-72.9%) and lowest in the eGFR ≥90 subgroup (59.4-60.8%); there were no differences between ALI and PBO in each subgroup.
Conclusion: ALI added to LOS preserved renal function, reduced prespecified renal dysfunction and UACR vs. add-on PBO and was well tolerated, except for hyperkalemia, independent of baseline renal function in patients with type 2 diabetes, hypertension and nephropathy.

Defects in the dynamic control of beta cell function and in glucose effectiveness underly the initial decline in intravenous glucose tolerance of obese European children

M. Trombetta[1], L. Boselli[1], C. Banzato[2], M. Surano[2], M. Muggeo[1], E. Bonora[1], C. Maffeis[2], R.C. Bonadonna[1];
[1]Department of Biomedical and Surgical Sciences, Section of Endocrinology and Metabolism Disease, University of Verona, [2]Department of Mother and Child, Biology and Genetics, Section of Pediatrics,, University of Verona, Italy.

Background and aims: Europe Europeans are thought to be less vulnerable to obesity induced type 2 diabetes. Detailed study of the main components of the glucose (G)-insulin (I) system were never performed in Europe European obese children. We aimed at assessing the main determinants of G levels in Italian obese children with normal G regulation (NGR).
Materials and methods: Sixty-five Italian obese children (age: 10.3±1.8 yrs, mean±SD; BMI: 28.1±3.2 Kg/m^2) with NGR underwent a frequently sampled intravenous G tolerance test (IVGTT) [12 g/m^2 of body surface area] lasting 200'. G/C-peptide curves and I/G curves were analyzed with state-of-art mathematical models to quantify the sensitivity of beta-cell to both the rate of increase of G (DC: dynamic or derivative control; units: [pmol·m^{-2}] per [mM·min^{-1}]) and to G concentration (PC: static or proportional; analyzed as I secretion rate at G=4.0,5.5, 8.0, 11.0 mmol/L; units:pmol·min^{-1}·m^{-2}) and the routes of G utilization [global, i.e. liver+periphery, insulin sensitivity, SI, presented as G utilization rate at G=5 mM and I=420 pM; units: mmol·min^{-1}·m^{-2}; G effectiveness, SG units: ml·min^{-1}·m^{-2}]. Acute I response (AIR) was calculated as the AUC under I concentration between 0' and 10' of the IVGTT. Median FPG (4.6 mM) and median G level at 60' during the IVGTT (1h-PG: 5.3 mM) were used to classify children in one of 4 groups: low (below median) FPG and low 1h-PG (LowLow, n=20, FPG:4.4±0.16 mM, 1h-PG: 4.4±0.47 mM), high (above median) FPG and low 1h-PG (HighLow, n=13, FPG: 4.9±0.23 mM, 1h-PG: 4.4±0.58 mM), low FPG and high 1h-PG (HighHigh n=13, FPG: 4.3±0.25 mM, 1h-PG: 7.1±0.10 mM), and high FPG and high 1h-PG (HighHigh, n=19, FPG: 5.0±0.22 mM, 1h-PG: 6.5±0.7 mM).
Results: Worsening of G regulation was associated with increasing age (from 9.3±1.7 to 10.5±1.8 yrs, p<0.05) and BMI (from 26.6±2.4 to 28.8±3.2 kg/m^2, p<0.05). AIR was similar across the 4 groups (4.9± 2.9, 4.6± 1.6, 3.4± 2.1 and 5.2± 5.2 in the LowLow, HighLow, LowHigh and HighHigh group, respectively, p=0.31). Both SI and SG were lower (p<0.05-0.01) in the LowHigh and HighHigh groups (SI: 0.95± 0.27 and 0.96± 0.31; SG: 102± 45 and 99± 23) than in the 2 Low 1h-PG groups (SI: 1.5± 0.4 and 1.3± 0.4; SG 137±33 and 152±50). SI, but not SG, was inversely related to both DC and PC of beta-cell function (r=-0.44 and -0.43, respectively, p<0.01 for both). PC, but not DC, of beta-cell function, was higher in the LowHigh (p=0.02) and HighHigh (p=0.03) groups than in the LowLow group, but after adjusting for SI these differences disappared. After adjusting for both SG and SI, the DC of beta-cell function was lower by~47% (p<0.01) in the LowHigh and HighHigh groups than in the other two groups.
Conclusion: In Europe European (Italian) obese children with NGR: 1. elevated 1h-PG is associated to decline in DC of beta-cell function and in both SI and SG. 2. SI, but not SG, is accompanied by an apparently compensatory increase in PC of beta-cell function, 3. hence, the fall in DC of beta-cell function and the uncompensated decline in SG play primary roles in determining the initial decline in i.v. G tolerance.

Tracking insulin secretion and sensitivity in children who subsequently develop diabetes: a seven year study

A.N. Jeffery[1], B.S. Metcalf[1], J. Hosking[1], L.D. Voss[1], M.J. Murphy[2], T.J. Wilkin[1];
[1]University Medicine, Peninsula Medical School, Plymouth, [2]University of Dundee, Division of Pathology and Neuroscience, Dundee, United Kingdom.

Background and aims: Blood glucose is controlled by the interaction between insulin secretion and insulin action, which constantly adjust to maintain optimal glucose levels, and whose vector can be plotted over time. We tracked the vector plots of three children who developed diabetes in the context of age-matched children who did not.
Materials and methods: Participants: 258 healthy children from the Early-Bird cohort (recruited from randomly-selected schools in 2000/1), studied annually from 5-12y. Girls A and B were diagnosed diabetic at 12.2y and 11.9y, boy C at 8.1y. Measures: BMI (sds), glucose, insulin-sensitivity (HOMA-%S), insulin-secretion (HOMA-%B).
Results: The table shows trends in cohort and diabetic children over time. The path traced by the mean vector was biphasic in the cohort as a whole, and in children A, B and C. While glucose rose throughout (change 5-12y p<0.001), HOMA-B first fell and HOMA-S increased in compensation (changes 5-7y both p<0.001). At 7-8y, however, the vector switched direction towards lower HOMA-S and higher HOMA-B (changes 8-12y both p<0.001). The inflexion occurred at 7y in Girl-A, 8y in Girl-B, and 6y in Boy-C. In contrast to that of the remaining cohort, their insulin secretion never recovered.
Conclusion: There is limited data on pre-diabetes in children. The inflexion we describe is novel, and may reflect early strain on beta-cell reserve in contemporary children. The children who developed diabetes were distinguishable from their peers, not by higher BMI or insulin resistance, but by early beta-cell failure which was apparent up to 12 months pre-diagnosis. Vector plotting may help better understand which children are at risk of beta cell failure, and why.

Paediatric ONSET-Study: impaired QoL in children and depressed mood in mothers at onset of diabetes mellitus type 1 in children

B. Rami[1], K. Lange[2], R. Coutant[3], T. Danne[4], B. Aschemeier[4], S. Bläsig[4], R. Hartmann[4], E. Marquardt[4], K. Walte[4], N. Krug[2], T. Kapellen[5], E. Pankowska[6], O. Kordonouri[4];
[1]Medical University of Vienna, Austria, [2]Medizinische Psychologie, Medizinische Hochschule Hannover, Germany, [3]Département de Pédiatrie, Centre Hospitalier Universitaire, Angers, France, [4]Kinderkrankenhaus auf der Bult, Hannover, Germany, [5]Universitätsklinik und Poliklinik für Kinder und Jugendliche, Leipzig, Germany, [6]Medical University of Warsaw, Poland.

Background and aims: The diagnosis of diabetes mellitus type 1 (DMT1) is a significant psychological burden for a child affected and the future of the whole family. The acute psychological implications of the diagnosis, as well as their determinants in children and their mothers are investigated during the first year after the diagnosis. This is a part of the pediatric ONSET-Study, a study comparing sensor augmented pump therapy with pump therapy without continuous subcutaneously glucose monitoring in children. Data on mother's well-being and children's quality of life following the diagnosis of DMT1 will be presented.
Materials and methods: This is a prospective study with children (aged 1-16 years), randomised within 4 weeks of DMT1-diagnosis. 160 children (age: 8,7 ± 4,4 J.; 47,5% girls) were included. The psychological wellbeing of the mothers or other primary caregivers of the child was assessed a few days after the diagnosis with a questionnaire (WHO-5, a well-being index). The QoL was evaluated in children (>/= 8yrs) via KIDSCREEN-27- and in parents via KIDSCREEN-27-proxy-questionnaires.
Results: The mean sum-score of mothers in the WHO-5 questionnaire (negative - positive: 0-100) was 46,3 ± 22,8, with 55,3% of mothers with a sum-score ≤ 48 indicating poor well-being / depressed mood. The mothers of the children below 6 years were significantly more affected than those of children aged 6 to 11 yrs. (52,1 ± 21) or 12 - 16 yrs. (46,0 ± 21) (p< .05). 69% of mothers with children < 6 yrs. showed symptoms of a depressed mood. The T-Values of the children's Quality of life scores (parents' perspective) were 39.4 ± 9,8 for physical wellbeing, 40,1 ± 10,7 for psychological wellbeing, 49,9 ± 9,5 for parents and autonomy, 44,7 ± 13,9 for social integration and 46,3 ± 12,7 for school. Compared with the representative European norm data of the Kidscreen the quality of life was significantly lower in all dimensions except "parents and autonomy"(each p < .01). The children (>/=8yr.) rated their quality of life according their parents' assessments (T-values on the five dimensions: 41,5 ± 8,9; 44,4 ± 10,7; 49,7 ± 9,1; 45,3 ± 11; 46,1 ± 11). Mainly their physiological and psychological wellbeing were significantly impaired compared to European norm data of the Kidscreen. After adjusting the data according to age of the children there were no significant differences between the five diabetes centres.
Conclusion: The high psychological burden of mothers, especially of those with young children and the impaired wellbeing of children diagnosed with diabetes underline the importance of an integrated medical and psychosocial care in the first phase of coping with the chronically illness. Psychotherapeutic interventions for mothers to cope better with affective disorders should become a standard of care.

A new model of therapeutic education in pre-school and school-aged children with type 1 diabetes

T. Bufacchi, C. Paolo, P. Ippolita Patrizia, S. Riccardo, P. Lia, M. Antonella, C. Marco;
Children Hospital Bambino Gesù, Rome, Italy.

Background and aims: Therapeutic Diabetes Education is a key aspect of diabetes care, underlining the importance of psycho educational programs in type 1 diabetic child, adolescents and their family. For effective results, such programs need to focus on physical and psychological outcomes of every single phase of the child developmental stage. There are a number of studies on educational programs for school aged children and adolescence but very few of them concern the psychological adjustment and the Diabetes Education of very young children affected by diabetes mellitus type 1 (DM1).
The aim of this project is to implement a new education curriculum for children with DM1 (4-12 yrs old) and their families and to assess its effectiveness to obtain a good diabetes control, to increase knowledge about diabetes and moreover to help them developing the skills necessary to identify, confront and resolve problems with confidence.
It will use a progressive modular-based structure to improve self-management in children with DM1, following the criteria of EASD and IDF and the methodology of the Service of Children Hospitals Bambino Gesù (Rome, Italy) .
Materials and methods: A randomized control study (N=83) was designed to assess the effect of psycho-education and its relationship with HbA1c. A knowledge test and some psychometric (projective personality tests) and and pediatric quality of life measures were administered using a pre and post test design. A special psycho educational program was developed using the methodology of Childen Hospital Bambino Gesù, adapted for age (4-7 and 8-12 yrs old). A group of 43 children (standard diabetes education- Group B) matched by age and gender was considered as control.
Results: The study is still ongoing but preliminary findings in Group A, when compared to the control group, at week IV, XII and week XXIV showed: 1) a significant improvement in the overall scoring of PedsQL and in the mean scores of diabetes self efficacy scale; 2) an increase in dietary and diabetes knowledge; 3) at school, the need to speak of their condition to the classmates, instead of hide it. Morevoer a preliminary analysis of children's draws evidenced a typical structure in the family of a child with diabetes type 1; 4) HbA1c values were significant lower at 6 months (p<0.005).
Conclusion: we observed a better comprehension and acceptance of DM1 in the intervention group (especially for preschoolers) and a significant difference in HbA1c. Furthermore data obtained from Personality Projective tests offer important cues for the study of familiar functioning in diabetes.

HbA1c during the study

patients	Age 6.7±1.6	HbA1c at DM1 onset	3 months	6 months
Group A n.40	6.7±1.6	12.8±1.4	7.5±0.4	7.2±0.3
Group B n.43	7.0±1.8	13.1±1.1	7.6±0.3	7.7±0.5

Diabetes-related quality of life and glycaemic control among youth with type 1 diabetes

J.M. Lawrence[1], A. Anderson[2], G. Imperatore[3], E.J. Mayer-Davis[4], M. Seid[5], B. Waitzfelder[6], J. Yi-Frazier[7];
[1]Kaiser Permanente, Pasadena, [2]Wake Forest University, Winston-Salem, [3]Centers for Disease Control and Prevention, Atlanta, [4]University of North Carolina at Chapel Hill, [5]Cincinnati Children's Hospital and Medical Center, [6]Pacific Health Research Institute, Honolulu, [7]Seattle Children's Hospital, United States.

Background and aims: Glycemic control is a key measure of diabetes (DM) management and risk for long term DM complications. We hypothesized that poor glycemic control would be associated with poorer DM-related quality of life (QoL) among youth with type 1 diabetes (T1DM).
Materials and methods: These cross-sectional analyses included 2,601 youth ages 5-23 years (mean 13.6 yrs.) with T1DM duration of ≥ 12 months who completed a child self-report pediatric quality of life-diabetes (PedsQL-DM) module and had glycated hemoglobin (A1c) measured by SEARCH, a population-based study of youth with DM onset <20 yrs. Glycemic control was categorized using age-specific cut-points based on American Diabetes Association target values for good and intermediate control. Poor control was defined as A1C ≥9.5% regardless of age. Demographic and DM treatment variables were self-reported.
Results: Of these youth, 75% were non-Hispanic white; 80% were privately insured; 50% were female; mean T1DM duration was 5.2 years; 29% received insulin < 3 times/day, 49% ≥ 3 times/day, 22% were on a pump. Mean A1c was 8.0% for youth aged <6 years (n=167), 8.3% for 6-12 yrs. (n=1011), 8.7% for 13-18 yrs. (n=1134), and 8.7% for ≥ 19 yrs (n=289). Glycemic control was poor in 20.1% and intermediate in 47.6% of participants. In unadjusted linear regression models, PedsQL-DM total score and all five subscale scores were associated with glycemic control (p<0.0001) (Table). After adjustment for age, race/ethnicity, sex, duration, insulin regimen, and insurance status, these associations remained (p<.0001). The strongest association with glycemic control for both the unadjusted and adjusted models was for the treatment barriers subscale. In the adjusted model, youth with good control had a mean score that was 9.95 points higher (fewer barriers) than those in poor control; those with intermediate control were 6.24 points higher on the scale,

while the weakest association was for the worry subscale. Additionally, girls and those without private insurance had significantly lower (worse) PedsQL-DM scores in all models.

	Outcomes for the Six Unadjusted and Adjusted Linear Regression Models					
	PedsQL-DM Total score	**DM Symptoms Subscale**	**Treatment Barriers Subscale**	**Treatment Adherence Subscale**	**Worry Subscale**	**Communication Subscale**
Cronbach's alpha	0.85	0.78	0.56	0.59	0.71	0.90
Mean ± 1 SD score	74.1 ± 13.4	65.7 ± 15.9	79.8 ± 17.9	81.9 ± 16.1	74.0 ± 22.5	79.5 ± 22.3
Unadjusted Model						
Good Control β coefficient*	8.37	6.08	12.64	8.66	10.93	8.14
Intermediate Control β coefficient*	4.86	3.28	8.27	4.49	5.35	6.44
Adjusted Model**						
Good control β coefficient*	6.91	6.06	9.95	6.31	5.77	8.47
Intermediate control β coefficient*	3.78	3.12	6.24	3.15	2.31	5.57

*Reference = Poor Glycemic Control, A1C ≥9.5% ** Linear regression models are adjusted for age category, race/ethnicity, sex, DM duration, insulin regimen, and insurance status.

Conclusion: In this large racially/ethnically diverse sample of youth with T1DM, our analysis showed that youth in good or intermediate glycemic control have significantly better diabetes-related QoL than those in poor control. While the causal direction of the association cannot be established from cross-sectional data, these findings suggest that poor glycemic control, in addition of being a strong risk factor for long-term DM complications, is negatively associated with QoL for young people with T1DM.

Tracking of metabolic control from pediatric onset until adulthood: metabolic control during the first year of type 1 diabetes predicts HbA_{1c} during adulthood: DPV-analysis on 6578 patients from 300 centers

R.W. Holl[1], E. Schober[2], J. Rosenbauer[3], A. Herbst[4], J. Wolf[5], C. Vogel[6], A. Dapp[7], A. Thon[8], M. Borkenstein[9], German competence network diabetes and DPV initiative;
[1]Epidemiology, University of Ulm, Germany, [2]Department of Pediatrics, University of Vienna, Austria, [3]German Diabetes Center, Düsseldorf, Germany, [4]Department of Pediatrics, Leverkusen, Germany, [5]Childrens Hospital, Paderborn, Germany, [6]Children's Hospital, Chemnitz, Germany, [7]General Hospital, Spaichingen, Germany, [8]Pediatrics, Medical University, Hannover, Germany, [9]Pediatrics, University of Graz, Austria.

Background and aims: The importance of metabolic control is well established in type-1-diabetes. However, most studies address patients in a cross-sectional manner, rather than following patients longitudinally over prolonged periods of time. In this analysis we tried to answer the question, whether tracking of metabolic control is present in patients with T1DM of pediatric onset, followed continuously over the pubertal period until adulthood under routine care.

Materials and methods: The DPV initiative is based on a multicenter, standardized electronic documentation of patients with diabetes in Germany and Austria. Data are recorded at the participating institutions, anonymized and transmitted for central analysis. Inconsistent data are reported back to the centers for confirmation or correction. Until March 2009, a total of 41797 patients with T1DM of pediatric onset (prior to age 15) are included in the database. 300 institutions (294 from Germany and 6 from Austria) participate. 6578 patients from 185 centers were followed longitudinally from the first year of diabetes until adulthood (age > 16 years). The mean time of follow-up was 6.0 ± 0.4 years. Preschool onset (below 6th birthday) of T1DM was present in 505 patients (mean follow-up 12.8 ± 0.07 years), 2210 patients showed an elementary school onset (6.1 - 11.0 years; mean follow-up 7.9 ± 0.03 years) and 3863 patients had a high school diabetes-onset (11.1 - 15.0 years; mean follow-up 4.0 ± 0.02). Data were analyzed using SQL and SAS 9.13. A mixed hierarchical model with treatment center as random variable was applied.

Results: HbA1c during the first year of diabetes (3 - 12 months after onset) averaged 6.99 ± 0.02 %, compared to 8.35 ± 0.02 % during adulthood. In the whole group, after adjustment for age at onset, diabetes duration, insulin therapy and BMI during adulthood, gender, migration background, treatment center and center characteristic, HbA1c during the first year of diabetes was a strong, significant predictor of HbA1c during adulthood: ß = +0.3418, $p < 0.001$. This relationship was already significant in patients with a preschool onset of diabetes (ß= +0.12, $p<0.05$), as well as in patients with elementary school onset (ß=+0.28, $p < 0.0001$) and with high school onset of diabetes (ß = +0.41, $p < 0.0001$).

Conclusion: This study on a large, multicenter group of patients with T1DM of pediatric onset provides convincing evidence for longterm tracking of metabolic control. This result is in agreement with the importance of an early focus on metabolic control, even during the first months of diabetes (remission phase). Alternatively, disease heterogeneity or different personal traits in diabetes management might be responsible for the longterm stability of HbA1c levels in individual patients with pediatric diabetes onset, despite the considerable variability observed during puberty.

HbA_{1c} and fasting plasma glucose are predictors of retinopathy at ten years: the French desir study

P. Massin[1], C. Lange[2], J. Tichet[3], M. Rosilio[4], S. Vol[3], A. Erginay[1], M. Cailleau[3], E. Eschwège[2], B. Balkau[2], The DESIR Study Group; [1]Ophthalmology, Hôpital Lariboisière, Paris, [2]INSERM U780-IFR69, Villejuif, France, [3]IRSA, La Riche, [4]Lilly, Suresnes, France.

Aims: To evaluate the predictive values of HbA_{1c} and fasting plasma glucose (FPG) for retinopathy ten years after baseline examinations.
Methods: 700 men and women from the D.E.S.I.R. study were evaluated for retinopathy using a non-mydriatic digital camera: 235 had diabetes (treated, FPG≥7.0mmol/l at least once over preceding nine years), 227 had an impaired fasting glucose (IFG:6.1-6.9 mmol/l) at least once, 238 always had normal glucose (<6.1mmol/l).
Results: The 44 participants with retinopathy at ten years had higher baseline mean (SD) FPG and HbA_{1c} than those without retinopathy, 7.24 mmol/l (2.72) vs 5.90 mmol/l (1.22) mmol/l and 6.4% (1.6) vs 5.7% (0.7) (both p<0.0001). The frequency of retinopathy at ten-years, standardized over the entire D.E.S.I.R. population was 3.6%, and over 16% for FPG≥6.5 mmol/l and HbA_{1c}≥6.5%. The positive predictive value for retinopathy increased more rapidly for higher values of HbA_{1c} than for FPG. In our population, FPG of 6.0 mmol/l and 6.5 mmol/l had positive predictive values of 8.6% and 17.4% respectively for retinopathy at ten years, while HbA_{1c} of 6.0% and 6.5% had positive predictive values of 6.8% and 15.9%. After ten years of follow up, retinopathy was equally frequent (95%CI) in diabetes 7.9% (4.4-11.3) and in IFG 8.6% (5.0-12.2).
Conclusion/interpretation: In this population, baseline HbA_{1c} had better profile of positive predictive values for retinopathy than baseline FPG ten years later. The ten-year frequency of retinopathy in individuals with IFG (at least one value in the abnormal range during follow-up) - was as high as for those with diabetes.

Retinal microaneurysm count predicts progression and regression of diabetic retinopathy

A.K. Sjølie[1], R. Klein[2], M. Porta[3], T. Orchard[4], J. Fuller[5], H.-H. Parving[6], R. Bilous[7], N. Chaturvedi[8];
[1]Ophthalmology, University of Southern Denmark, Odense, Denmark, [2]Ophthalmology and visual science, University of Wisconsin, Madison, United States, [3]Internal Medicin, University of Turin, Italy, [4]Epidemiology, University of Pittsburgh, United States, [5]Epidemiology and Public-Health, University College London, United Kingdom, [6]Medical Endocrinology, University of Copenhagen, Denmark, [7]Audrey Collins Teaching Unit, South Cleveland Hospital, Middlesbrough, United Kingdom, [8]Internationa centre for Circulatory Health, National Heart and Lung Institute, Imperial College, London, United Kingdom.

Background and aims: To examine whether the number of microaneurysms (MAs) predicts progression and regression of retinopathy in type 1 and type 2 diabetes.
Materials and methods: 893 type 1 and 526 type 2 diabetic patients with microaneurysms only (ETDRS levels 20/20 or 20/10) were subjected to yearly 7-field stereo retinal photographs for a mean of 4.6 years as part of the Diabetic Retinopathy Candesartan Trials (DIRECT) Programme. Retinopathy progression was defined as a 2 step increase on the ETDRS scale for the patient, regression as a 2 step decrease. For the latter, analysis was restricted to those 441 type 1 and 217 type 2 patients with sufficient potential to regress, i.e. ETDRS level 20 in both eyes. MAs were counted and summed for both eyes. Mean age (+/-SD) and duration (+/-SD) of diabetes was 31.2 (8.4) and 9.8 (4.3) years in type 1, 56.2 (8.0) and 7.2 (4.5) in type 2 patients, respectively.
Results: In type 1 diabetes, we found a significantly increased risk of 2-step progression of retinopathy with increasing MA count at baseline (Hazard Ratio (HR) 1.08 per MA, 95% CI 1.05-1.12, p< 0.0001), adjusted for diabetes duration, systolic blood pressure and HbA_{1c}. Conversely, people with higher MA counts at baseline were less likely to regress (HR 0.79, 95% CI 0.73-0.86, p<0.0001). Similarly, in type 2 diabetes there was a significantly increased risk of progression of retinopathy (HR 1.07, 95% CI 1.01-1.13, p< 0.02), adjusted for diabetes duration, systolic pressure, $HbA_{1c,}$ urinary albumin excretion rate and use of antihypertensive therapy with increasing MA count, and a lesser likelihood of regression (HR 0.85, 95% CI 0.77-0.93, p<0.0009,).
Conclusion: In both type 1 and type 2 diabetic patients a greater MA count significantly predicted a greater risk of retinopathy progression, and a lesser likelihood of retinopathy regression. As clinical trials need to focus on earlier stages of disease, our findings support the use of MA counts as a possible surrogate clinical endpoint for progression and regression of retinopathy.

Effectiveness of diabetic retinopathy screening in primary health care. Agreement with the ophthalmological service

M.D. Montañés[1], C.R. Gas[1], S. Hernàndez[1], M. Torres[1], O. Simón[1], P. Romero[1,2], J.M. Hernández[1], R. Segarra[1];
[1]EAP Reus 1, Institut Catala de la Salut, Reus [2]Ophthalmology service, Sant Joan Hospital, Reus, Tarragona, Spain.

Background and aims: To assess the effectiveness of diabetic retinopathy screening using the non-mydriatic camera and to estimate the specificity and sensitivity of referrals from general to specialist services.
Scope: A Basic Care Unit of 15885 inhabitants
Materials and methods: Observational study
A non-mydriatic retinography was performed on patients with type 1 and 2 Diabetes Mellitus (except for those already suffering from retinopathy) visited in the Primary Health Care Office in the period November 2007 to December 2008.
329 patients were selected to undergo this exploration. 46 retinographies were considered pathological in the Primary Health Care Offices. They were sent to be revalued by the ophthalmological service in the reference hospital where the diagnosis was communicated to the family doctors.

Before the study was carried out, the general practitioners were intensively trained on funduscopic examination.
In parallel with this study a statistical analysis was carried out in a sample of 879 cases, including other Basic Care Units in our territory as well as the 329 cases of our center. This analysis tried to determine the reliability (sensitivity and specificity) in detecting retinal pathology in the Primary Health Care.
Results: Number of retinographies: 329
Number of non-pathological retinographies: 283 (86,02%)
Retinographies assessed by the ophthalmologist: 46 (13,98%)
Pathological retinographies: 15 (4,55%)
Slight Diabetic retinopathy (DR): 3 (0,91%)
Moderate DR: 3 (0,91%)
Severe DR: 1 (0,30%)
Age-related *macular degeneration:* 1 (0,30%)
Others: 7 (2,13%)
Non-assessable: 3 (0,91%)
Conclusion: 4,55% of the screened showed pathological retinography , of which 46,67% due to DM. Using non-mydriatic retinography in diabetic patients offers the possibility of an early diagnosis in primary care, with a sensitivity and specificity of over 90%. Its easy access and application allow the quality improvement of the diabetic patient assistance and the rationalization of the referral system to the hospital.

Thiamine and benfotiamine counter apoptosis induced by intermittent high glucose exposure in human retinal pericytes
E. Berrone, E. Beltramo, S. Tarallo, M. Porta;
Internal Medicine, University of Turin, Italy.

Background and aims: Human retinal pericytes are more vulnerable to fluctuating than stable high glucose exposure, showing great differences with bovine pericytes, used so far as models for diabetic retinopathy. For this reason, we created an immortalized human retinal pericyte line (Bmi-HRP), with the same morphology and metabolic characteristics of the wild-type cells from which it was derived. Thiamine and benfotiamine are well-known protective agents against the damaging effects of high glucose in vascular cells. Our aim was to verify if thiamine and benfotiamine are able to counter intermittent high glucose-induced damage in human retinal pericytes.
Materials and methods: Wild-type and immortalized pericytes were kept intermittently at 48h intervals in high (28 mmol/l) or physiological (5.6 mmol/l) glucose for 8 days, with or without the addition of 50 or 100 μmol/l thiamine or benfotiamine. Control cells were cultured in stable physiological or high glucose for the whole period. DNA fragmentation (ELISA and TUNEL), Bcl-2 and Bax mRNA expression and protein concentration, as markers of glucose-induced apoptosis, were determined.
Results: DNA fragmentation measured through ELISA showed a dramatic increase in apoptosis in intermittent HG only ($p<0.001$ vs NG in both cases), which was completely prevented in both wild type and Bmi-HRP by the addition of thiamine and benfotiamine at both concentrations throughout the whole period. Results obtained with the ELISA were confirmed by *in situ* TUNEL staining. Intermittent exposure to high glucose resulted in both cell types in a 50-60% decrease in Bcl-2 to Bax ratio, for both expression and concentration ($p<0.005$). Addition of thiamine and benfotiamine at both concentrations to intermittent high glucose completely reverted this damaging effect.
Conclusion: The hypothesis that daily blood glucose fluctuations play a major role in the development of diabetic retinopathy is reinforced by the confirmation that apoptosis in human pericytes is increased following intermittent high glucose exposure only. Bmi-HRP show the same behaviour of wild-type pericytes when exposed to fluctuating glucose levels, making this cell line a promising candidate model to study pathogenic mechanisms and therapeutic applications in diabetic retinopathy. Thiamine and benfotiamine are able to prevent pericyte apoptosis, suggesting once again that this vitamin could be an inexpensive approach to the prevention and/or treatment of diabetic vascular complications.

Safety and efficacy of ranibizumab treatment in patients with diabetic macular oedema: 12-months results of the RESOLVE study
K. Engelmann, on behalf of the RESOLVE study group;
Klinikum Chemnitz, Germany.

Background and aims: Evaluate safety and explore effect of ranibizumab in diabetic macular edema (DME).
Materials and methods: Multi-center, double-masked study involving 151 DME patients treated over 12 months with 6 mg/ml ranibizumab (n=51), 10 mg/ml ranibizumab (n=51), or sham injection (n=49). Three initial monthly injections followed by re-treatment based on success, futility, or safety criteria. Injection volume doubled as of Month 1 if central retinal thickness (CRT) was >300 μm or >225 μm and reduction from prior assessment <50 μm. Laser photocoagulation as rescue medication allowed from Month 3 onwards. Best-corrected visual acuity (BCVA; Early Treatment for Diabetic Retinopathy Study charts) and CRT (optical coherence tomography) were assessed monthly.
Results: Injection volume doubled in 92% sham and 73/65% ranibizumab patients (6/10 mg/ml). Rescue treatment in 33% sham and 9% ranibizumab patients.Over 12-months, most frequent ocular adverse events (AEs): conjunctival hemorrhage (14% sham, 23% ranibizumab); eye pain (20% sham, 18% ranibizumab). Serious ocular AEs: 1 sham patient (retinal detachment), 4 ranibizumab patients (endophthalmitis, transient retinal artery occlusion, peripheral retinal ischemia). Non-ocular arterial thromboembolic events: 2 sham and 3 ranibizumab (10 mg/ml) patients. Mean BCVA increased and mean CRT decreased continuously over time in ranibizumab patients. Mean change in BCVA from baseline to Month 12 was -1.4 letters (sham) +11.8 letters (6 mg/ml), +8.8 letters (10 mg/ml), and +10.3 letters (pooled ranibizumab groups).
Conclusion: Safety of ranibizumab in DME was comparable to previous studies of neovascular age-related macular degeneration. Ranibizumab treatment demonstrated superior efficacy to sham treatment in DME and was associated with continuous improvement in BCVA and CRT throughout 12 months.

OP 11 Fatty acids and lipids

61

Serum and adipose tissue adipokine concentrations are affected by non-esterified fatty-acids in healthy individuals

E.-M. Pichler[1], D. Ikeoka[1], C. Pachler[1], J.K. Mader[1], G. Bock[1], E. Krusinova[1], F. Feichtner[2], G. Koehler[1], T. Pieber[1,2], M. Ellmerer[1];
[1]Internal Medicine, Medical University Graz, [2]Joanneum Research, Graz, Austria.

Background and aims: Non-esterified fatty acids (NEFA) are implicated both in the development of insulin resistance and initiation of inflammatory pathways in different tissues. To the moment, the hypothesis of an interaction between NEFA and adipose tissue-derived cytokines in the genesis of insulin resistance was not tested *in vivo*. The aim of the present study was to investigate the effect of experimentally elevated NEFA concentrations on cytokines measured in circulation and in interstitial fluid effluent from subcutaneous tissue of healthy volunteers.
Materials and methods: Ten healthy volunteers were randomly assigned to two subsequent experiments, either receiving continuous venous lipid-heparin infusion or saline during 28 hours. Two open-flow microperfusion (OFM) catheters were inserted in the subcutaneous adipose tissue (SAT) of each volunteer for continuous sampling of interstitial fluid effluent. Blood samples were withdrawn concordantly. Effluent, plasma and serum samples were analyzed using a multiplexed ELISA system to measure the concentrations of interleukins (IL) 6, 8, 10, tumor-necrosis factor alpha (TNF-alpha), adiponectin, C-reactive protein (CRP), plasminogen activator inhibitor-1 (PAI-1) and macrophage chemoattractant protein-1 (MCP-1). NEFA, triglycerides, glucose and insulin concentrations in blood were measured by validated methods in parallel.
Results: Plasma concentrations of triglycerides and NEFA were higher in the lipid-heparin infusion group. High levels of insulin (saline: 2.69±1.30μU/mL vs. lipid-heparin: 4.78±3.2μU/mL; p<0.05), glucose (saline: 86±8mg/dL vs. lipid heparin: 94±8mg/dL; p<0.05) and the calculated HOMA-R index (saline 0.40±0.06 vs. lipid-heparin 0.57±0.09; p=0.03) indicated lower insulin sensitivity during lipid infusion. Distinct time-profiles were observed for cytokines measured in SAT effluent samples. IL-10 concentrations were higher in the control intervention in comparison to lipid infusion during the last 4 hours (saline: 449.2±105.9 vs. lipid-heparin: 65.4±15.4pg/ml; p=0.02). PAI-1 (saline: 67.8±15.6ng/mL vs. lipid-heparin: 77.2±15.1ng/mL; p<0.01) and MCP-1 (saline: 160.1±40.2pg/mL vs. lipid-heparin: 211.7±48.8; p<0.001) were substantially higher during the lipid experiment in serum. Adiponectin also presented a slight increase during lipid-heparin infusion (treatment effect: p=0.03; saline: 7.9±0.8 vs. lipid-heparin: 8.5±1.0mg/l). No additional differences in terms of cytokine concentrations were observed.
Conclusion: Elevated concentrations of NEFA promote a systemic pro-inflammatory response and a depressed anti-inflammatory response in SAT. These effects might contribute for the development of insulin resistance in conditions where NEFA is elevated in plasma, such as in obese and type-2-diabetic patients. The increase of adiponectin in serum might be interpreted as a counter-regulatory response.

Skeletal muscle fatty acid handling in the pre-diabetic state

C.C.M. Moors[1], G.H. Goossens[1], N.J. van der Zijl[2], M. Diamant[2], E.E. Blaak[1];
[1]Human Biology, University of Maastricht, [2]Endocrinology/Diabetes Center, VU University Medical Center, Amsterdam, Netherlands.

Background and aims: Already in the pre-diabetic state, fat storage in non-adipose tissues, such as skeletal muscle, is increased and associated with insulin resistance ("lipid overflow" hypothesis). When the uptake of free fatty acids (FFA) or triacylglycerol (TAG) exceeds the capacity or the need to oxidize fat in skeletal muscle the fatty acids are stored, leading to ectopic fat accumulation. Therefore, the aim of the present study was to examine fasting and postprandial skeletal muscle fatty acid handling in subjects with impaired fasting glucose (IFG), impaired glucose tolerance (IGT) (combined or not combined with IFG), compared to normal glucose tolerance (NGT).
Materials and methods: 6 NGT (age 55.0±3.0yrs, BMI 32.3±0.9 kg/m^2), 14 IFG (age 60.3±1.5yrs, BMI 29.5±1.0 kg/m^2), 12 IGT (age 58.0±1.9yrs, BMI 32.0±1.2 kg/m^2) male and female subjects were included. During fasting and after ingestion of a standardized high fat mixed meal (2.6 MJ,61% of total energy content of fat), skeletal muscle fatty acid handling was examined by measuring arterio-venous differences across forearm muscle in combination with measurements of forearm blood flow using venous occlusion plethysmography. Insulin sensitivity (IS) was determined using the hyperinsulinemic-euglycemic clamp.
Results: IS was lower in IFG and IGT compared to NGT (4.3±0.5, 4.2±0.6 and 10.7±0.9 mg·kg^{-1}·min^{-1} respectively, ANOVA p<0.001; Bonferroni p<0.001 for IFG and IGT vs NGT). Arterial TAG concentrations increased more in the early postprandial state (0-2h) in IFG (iAUC=265.5±32.3 mmol·L^{-1}·min^{-1}) and IGT (iAUC=294.1±58.9 mmol·L^{-1}·min^{-1}) compared to NGT (iAUC=82.6±13.8 mmol·L^{-1}·min^{-1}), (ANOVA p=0.02; Bonferroni p=0.06 and p=0.03 respectively). Furthermore, despite the consistently higher insulin concentrations in IFG and IGT compared to NGT (ANOVA p=0.03; Bonferroni p=0.03 and p=0.08 respectively), net forearm muscle glucose uptake was not significantly different between groups, suggesting skeletal muscle insulin resistance in pre-diabetic subjects. In addition, postprandial FFA uptake across the forearm muscle was less suppressed in IFG compared to IGT (ANOVA p=0.04; Bonferroni p=0.04) in the mid postprandial state (2-4h). TAG extraction across the forearm muscle in the early postprandial state (0-2h) was increased in IFG (AUC=57.7±11.2 nmol·100ml^{-1}·min^{-1}) and IGT (AUC=70.7±20.0 nmol·100ml^{-1}·min^{-1}) compared to NGT (AUC=3.8±15.4 nmol·100ml^{-1}·min^{-1}), (ANOVA p=0.06; Bonferroni p=0.04 and 0.07 respectively).
Conclusion: No differences between IFG and IGT were found in whole body and skeletal muscle IS (when compared to NGT). Postprandial TAG extraction across the forearm muscle was higher in subjects with IFG and IGT compared to NGT subjects, which may lead to fat accumulation in skeletal muscle and consequently, decreased insulin sensitivity in the pre-diabetic state.

63

Non-esterified fatty acids dynamics during an oral glucose tolerance test in women with a history of gestational diabetes

A. Tura[1], G. Di Benedetto[2], U. Morbiducci[2], Y. Winhofer[3], F. Montevecchi[2], G. Pacini[1], M. Roden[4], A. Kautzky-Willer[3];
[1]Institute of Biomedical Engineering, CNR, Padova, Italy, [2]Department of Mechanics, Politecnico di Torino, Italy, [3]Clinic of Internal Medicine III, Medical University of Vienna, Austria, [4]Institute for Clinical Diabetology, German Diabetes Center, Düsseldorf, Germany.

Background and aims: Elevation in non-esterified fatty acids (NEFA) has been shown to modulate insulin secretion and to be a risk factor for the development of type 2 diabetes. Since women with former gestational diabetes (fGDM) are at increased risk of diabetes, in this population we studied NEFA kinetics and its relationships with insulin during an oral glucose tolerance tests (OGTT).
Materials and methods: We analyzed 122 3h-OGTT of non-diabetic fGDM women (age=34.9±0.4 years (mean±SE); body mass index, BMI=26.6±0.5 kg/m^2, fasting glucose, G_b=5.13±0.09 mmol/l), compared to those of 19 healthy women after normal pregnancy, CNT (age=28.8±1.1, BMI=22.7±0.8, G_b=4.55±0.07). Glucose, insulin and NEFA were frequently measured during OGTT. We computed the OGTT area under the curve of insulin (AUC_{INS}) and NEFA (AUC_{NEFA}). Through mathematical modeling, we assessed parameters of NEFA kinetics: the sensitivity of lipolysis inhibition to suprabasal insulin variations, S_{NEFA}, and the fractional NEFA turnover rate, K_{NEFA}. Univariate regression analysis was performed between some parameters. ANOVA on log-transformed parameter values was used to assess differences in the two groups (P<0.05 statistically significant).
Results: fGDM women were slightly older and had higher BMI than CNT women. Glycemic levels were higher in fGDM, both at basal and at 120 min (not shown). NEFA at basal, $NEFA_b$, was not different in the two groups (538±19 μmol/l fGDM, 508±44 CNT), while basal insulin was higher in fGDM (I_b=62.4±2.7 pmol/l *vs.* 45.2±4.1 of CNT, P<0.008). After the glucose load, AUC_{NEFA} was higher in fGDM (29.3±1.4 mmol/l min *vs.* 22.0±1.6 of CNT, P<0.04). NEFA curves during the OGTT are reported in the Figure (solid line: fGDM; dashed line: CNT). Also insulin levels were higher in fGDM (AUC_{INS}=57.5±3.1 nmol/l min *vs.* 31.6±3.4 of CNT, P<0.0001). NEFA kinetic parameters were lower in fGDM: S_{NEFA}=2.3±0.3·10^{-2} ml/μU *vs.* 2.9±0.6 of CNT, P<0.04; K_{NEFA}=4.9±0.2·10^{-2} min^{-1} *vs.* 7.6±1.3 of CNT, P<0.005. In fGDM women regression analysis showed a significant but very weak relationship between $NEFA_b$ and I_b (R=0.25, P<0.005), as well as between AUC_{NEFA} and AUC_{INS} (R=0.19, P<0.03).

Conclusion: A limited number of investigations assessed NEFA in fGDM women and no study performed detailed analysis of NEFA kinetics during an OGTT based on sophisticated modeling. NEFA levels were found higher in fGDM than in CNT, despite the fact that insulin, which has an inhibitory effect on NEFA production, was higher in fGDM: in fact, these women exhibited lower sensitivity to insulin of lipolysis inhibition (S_{NEFA}) and lower NEFA turnover (K_{NEFA}), which can be further signs of early metabolic derangements in a population at risk for diabetes.

Ursodesoxycholic acid (UDCA) promotes the hepatic oxidation of free-fatty acids in Zucker fatty rats

P.M. Nunes, J.G. Jones, C.M. Palmeira, R.A. Carvalho;
Center for Neurosciences and Cell Biology, Coimbra, Portugal.

Background and aims: Ursodesoxycholic Acid (UDCA) is a natural bile acid commonly used to improve liver function in diseased livers by protecting mitochondrial membranes and avoiding their functional disruption. Its beneficial effects include decrease of hepatic triglyceride (HTG) levels hence it may have potential for treatment of non alcoholic fatty liver disease (NAFLD). On the basis that UDCA improves several aspects of mitochondrial function, we hypothesized that it reduces HTG accumulation by promoting the mitochondrial oxidation of non-esterified fatty acids (NEFA).
To test this hypothesis, we quantified mitochondrial oxidation of NEFA relative to non-fat substrates (pyruvate/lactate) and endogenous sources in Zucker Fatty Rats - a model of NAFL. UDCA action was studied either in Zucker and normal Wistar Rats.
Materials and methods: Male Zucker rats were maintained on a standard diet with (ZF+UDCA) or without (ZF) the UDCA (15mg/Kg) daily treatment for 4 weeks. Control groups were also maintained under the same conditions with (Ctrl+UDCA) or without the UDCA treatment. After 24h of fasting, livers were isolated and perfused with a Krebs-Henseleit buffer containing 0.2mM of [U-13C]long-chain fatty-acids bound to albumin, 0.1 mM [3-13C]pyruvate and 1mM [3-13C]lactate for 30 minutes. Oxidation of these exogenous 13C-labeled substrates and unlabeled endogenous sources were assessed by determining their fractional contributions to the mitochondrial acetyl-CoA pool. For this, livers were freeze clamped and soluble metabolites extracted with perchloric acid. 13C-enrichment of the hepatic Krebs cycle and acetyl-CoA pools were determined by 13C NMR analysis of hepatic glutamate 13C isotopomers and the fractional contributions of exogenous and endogenous substrates to the mitochondrial acetyl-CoA pool was determined by a metabolic model relating 13C-isotopomer distributions to acetyl-CoA sources. With this model, acetyl-CoA sources are resolved as follows: [1,2-13C]acetyl-CoA, reflecting the oxidation of exogenous [U-13C]fatty acids; [2-13C]acetyl CoA, reflecting oxidation of exogenous pyruvate/lactate, and unlabeled acetyl-CoA, reflecting the oxidation of unlabeled endogenous substrates.
Results: ZF rats exhibited a weaker capacity for NEFA oxidation, with only 23 ± 5% of acetyl-CoA derived from NEFA compared to Ctrl rats with 44 ± 3%. The contribution of exogenous pyruvate/lactate was residual in both control and ZF (3 ± 1% and 4 ± 1%, respectively) reflecting low PDH activity of the fasted liver. For the ZF rats, UDCA treatment caused a significant increase in the fraction of acetyl-CoA derived from oxidation of exogenous NEFA (46 ± 6% in UDCA-treated rats vs 23 ± 5% for untreated rats, $p < 0.05$). UDCA also increased acetyl-CoA recruitment from NEFA in Ctrl rats (53 ± 6% UDCA vs 44 ± 3% untreated, p=0.06). These increases were not accompanied by significant changes in exogenous pyruvate/lactate contributions but were related to significant reduction in the contribution of endogenous sources to acetyl-CoA (45± 8% ZF+UDCA vs 71 ± 4% in ZF; 40± 5% Ctrl+UDCA vs 53 ± 3% in Ctrl).
Conclusion: UDCA promoted the recruitment of NEFA for mitochondrial β-oxidation in a rat model of NAFLD. UDCA increased the recruitment of acetyl-CoA from NEFA over endogenous triglycerides suggesting that its site of action is downstream of lipolysis at the level of mitochondrial fatty acid oxidation.

Osteopontin deficiency prevents obesity-associated hepatic steatosis and insulin resistance

F.W. Kiefer[1], M. Zeyda[1], S. Neschen[2], K. Gollinger[1], B. Pfau[1], A. Neuhofer[1], T. Weichhart[3], L. Kenner[4], T.M. Stulnig[1];
[1]Dept. of Internal Medicine III, Clin. Division of Endocrinology and Metabolism, Medical University of Vienna, Austria, [2]Institute of Experimental Genetics, German Research Center for Environmental Health, Munich, Germany, [3]Dept. Internal Medicine III, Medical University Vienna, Clin. Division of Nephrology and Dialysis, Vienna, Austria, [4]Dept. of Pathology, Medical University of Vienna, Austria.

Background and aims: Obesity is a major risk factor for the development of hepatic steatosis and insulin resistance. The chronic low grade inflammation associated with obesity as evidenced by increased systemic concentrations of inflammatory markers probably represents a crucial link between obesity and insulin resistance. Osteopontin (OPN) is an inflammatory cytokine, the expression of which is strongly upregulated in adipose tissue and liver upon obesity. OPN has recently been linked to diet-induced adipose tissue inflammation but the role of OPN in hepatic inflammation and insulin sensitivity is still elusive. This study aimed at investigating the impact of OPN in obesity-associated alterations of the liver.
Materials and methods: OPN deficient mice (OPN-/-) and wild-type (WT) littermates were fed a high-fat diet (HF) for six months to induce obesity followed by euglycemic-hyperinsulinemic clamp testing. Hepatic triglyceride content, alanine aminotransferase and gene expression were measured by enzymatic tests and quantitative real-time PCR, respectively.
Results: Obese OPN-/- mice displayed markedly improved insulin sensitivity and suppression of hepatic glucose production compared with WT controls. Hepatic steatosis was significantly reduced in obese OPN-/- compared to WT mice as assessed by histological analysis and liver triglyceride content. Moreover, plasma alanine aminotransferase concentrations were lower in mice lacking OPN compared to WT animals. Hepatic gene expression of the lipogenic transcription factor sterol regulatory element-binding protein-1c, of the inflammatory cytokines TNF-α and TGF-β and of the gluconeogenic enzyme glucose-6-phophatase was significantly downregulated by OPN deficiency.
Conclusion: These findings indicate a critical role of OPN in the pathogenesis of obesity-induced hepatic steatosis and insulin resistance. Hence, targeting OPN could provide a novel therapeutic approach to prevent obesity-associated metabolic disorders including hepatic steatosis and type 2 diabetes.

Contribution of intra-abdominal and liver fat to components of the metabolic syndrome

K. Sevastianova[1], A. Kotronen[1], H. Yki-Järvinen[1], R. Bergholm[1], A. Hakkarainen[1], K.H. Pietiläinen[1], L. Juurinen[1], N. Lundbom[1], T.I.A. Sorensen[2];
[1]University of Helsinki, Finland, [2]Copenhagen University Hospitals, Denmark.

Background and aims: The contribution of liver vs. intra-abdominal (IA) fat to components of the metabolic syndrome cannot be studied invasively in humans. IA fat could be important independent of liver fat. Second, it might be merely an innocent bystander playing little or no role, while liver fat would

be the critical factor. Third, IA and liver fat could contribute to variation in components of the metabolic syndrome independent of each other. We explored these three possibilities in a large group of subjects in which IA and liver fat were determined by state-of-the-art techniques.
Materials and methods: We studied 356 subjects (mean age 42 yrs, mean BMI 29.7 kg/m2) in whom liver fat (proton magnetic resonance spectroscopy), IA fat (MRI), and features of insulin resistance were measured.
Results: IA and liver fat contents were closely correlated (r=0.65, p<0.0001). In multivariate linear regression analyses, liver fat explained variation in fasting serum (fS) triglyceride, fS-HDL cholesterol, fasting plasma (fP) glucose, fS-insulin, and liver enzyme concentrations (alanine and aspartate aminotransferaces) independent of age, gender, subcutaneous fat, and/or lean body mass (LBM). The same was true when liver fat was replaced by IA fat. In multivariate linear regression analyses including both liver and IA fat, liver and IA fat independent of each other explained variation in fS-triglyceride, fS-HDL cholesterol, and fS-insulin concentrations independent of age, gender, subcutaneous fat and LBM. In similar models, only liver fat was an independent predictor of fP-glucose and liver enzymes. Subcutaneous fat, i.e. overall obesity, and age explained variation in blood pressure.
Conclusion: Both IA and liver fat independently contribute to variation in serum triglyceride, HDL cholesterol, and insulin concentrations, thus supporting the idea that both fat depots independently contribute to components of the metabolic syndrome. Liver, but not IA fat, also independently explained variation in fasting glucose and liver enzyme concentrations. Age and overall obesity but neither liver not IA fat explained variation in blood pressure.

Evaluation of the effect of GLP-1 receptor activation on ER stress mediated beta cell damage in Akita mice
S. Yamane[1], Y. Hamamoto[1], N. Harada[1], K. Toyoda[1], Y. Seino[2], N. Inagaki[1];
[1]Department of Diabetes and Clinical Nutrition, Kyoto University Graduate School of Medicine, [2]Kansai Electric Power Hospital, Osaka, Japan.

Background and aims: Recent studies have revealed that the ER stress is one of the causes of β-cell damage in diabetes. On the other hand, several researchers have reported the cytoprotective effect of exendin-4(Ex-4) on β-cell. Last year, we have shown in vivo effects of Ex-4 on pancreatic β-cell in Akita mice, an animal model of ER stress-mediated diabetes. In this report, we further investigated the underlying mechanism by which Ex-4 treatment can attenuate ER stress-mediated β-cell damage.
Materials and methods: To exclude the possibility that the effects of Ex-4 on β-cell is through the decreased blood glucose level, we made three groups of animals treated with Ex-4, PBS, and phlorizin, a sodium-coupled glucose transporter inhibitor which decreases blood glucose levels without increasing insulin. The mice were given twice daily intraperitoneal injections of Ex-4 (24nmol/kg), phlorizin (0.3g/kg), or PBS for 2 weeks (from 3 to 5 weeks of age). Plasma glucose levels were measured every third day and pancreas samples from each animal groups were then obtained at 5 weeks of age for the histological evaluation, and islets were also isolated for RNA extraction. The differences of insulin-immunopositive areas and the numbers of cells exhibiting both nuclear CHOP and cytoplasmic insulin immunopositivity between the groups were determined by the staining with anti-CHOP and with anti-insulin antibodies,respectively. We also evaluated the effect of Ex-4 treatment on β-cell replication and apoptosis histologically by Proliferating cell nuclear antigen (PCNA) staining and TdT-mediated dUTP-biotin nick-end labeling (TUNEL) staining, respectively. Additionally, mRNA expression level of the CHOP was assessed by real-time quantitative RT-PCR.
Results: Ex-4 treatment significantly reduced blood glucose levels, but there was no significant difference in body weight between Ex-4-treated group and PBS-treated group. Immunohistochemical examination indicated an increase in insulin-positive areas in the islets in Ex-4-treated group compared with PBS-treated group. In contrast, we could not find any difference in insulin-positive areas between PBS-treated group and phlorizin-treated group whose glucose levels were identical to those of Ex-4-treated group. Furthermore, treatment of Akita mice with Ex-4 resulted in significant decrease in the number of CHOP-positive β-cells and TUNEL-positive β-cells adjusted by β-cell area,while there was no significant difference in the number of CHOP-positive or TUNEL-positive β-cells between PBS-treated group and phlorizin -treated group. In PCNA staining, we could not find significant difference in proliferation of β-cells between the three groups but Ex-4 treatment considerably increased the number of PCNA-positive β-cells compared to the other two groups. Ex-4 treatment significantly lowered the mRNA expression levels of CHOP, whereas there was no significant difference in the mRNA expression levels of CHOP between phlorizin-treated group and PBS-treated group.
Conclusion: Our data suggest that Ex-4 treatment can attenuate ER stress-mediated β-cell damage through the reduction of apoptotic cell death, partially through the promotion of β-cell replication, and the in vivo effect of Ex-4 on pancreatic β-cell is independent of the decreased blood glucose levels.

68

The once-daily human GLP-1 analogue liraglutide increases the beta cell mass in normoglycaemic mice by directly accelerating cell differentiation and proliferation
M. Shimoda;
Kawasaki Medical School, Okayama, Japan.

Background and aims: GLP-1 increases pancreatic β-cell mass by stimulating cell proliferation and inihibiting apoptosis. Previously, we demonstrated that liraglutide (LIRA) increases pancreatic β-cell mass in diabetic *db/db* mice through not only regulating cell kinetics as an acute effect but also suppressing oxidative stress and endoplasmic reticulum (ER) stress by ameliorating glucolipotoxicity as a chronic effect. In this study, to further clarify the

proliferative effect of GLP-1 on pancreatic β-cell by eliminating the influence of dysmetabolism, we assessed the mode of action of LIRA on β-cell function and cell mass in the normoglycemic *m/m* mice model.
Materials and methods: Ten week-old male BKS.Cg-m +/m +/Jcl (*m/m*) mice recieved LIRA (0.2mg/kg twice daily *s.c.*) or vehicle (control) for 2 weeks. Body weight (BW), fasted blood glucose (FBG), insulin (FIRI), and triglyceride (TG) were measured before and after LIRA intervention. The β-cell mass and cell proliferation/apoptosis was assessed by histological analysis including proliferating cell number antigen (PCNA), 4-hydroxynonenal modified protein (4-HNE) immunostaining, and TUNEL assay of the islet tissue. Gene expressions specific for the core area of the pancreatic islets were analyzed by Laser Capture Microdissection method and real time RT-PCR. Primer pairs encoding genes associated with pancreatic hormones, cell proliferation, apoptosis, cell cycle, ER and oxidative stress were prepared, and real-time PCR with Sybr Green was applied. Gene expression was quantified by the comparative Ct method with each result corrected by 18SrRNA quantity. Glucose stimulated insulin secretion (GSIS) and the insulin content in islets were assessed after 2 weeks of intervention.
Results: Although food intake and BW were significantly lower in the LIRA group than in the control (food intake: 21.1±0.7 vs. 27.0±0.8 g, n=6 for each, $p < 0.05$, BW: 21.1±0.2 vs. 23.2±0.5 g, $p < 0.01$) after 2 weeks intervention, FBG, FIRI, and TG levels were similar between LIRA group and control group (glucose: 48±1.6 vs. 51±2.6 mg/dl, insulin: 0.4±0.1 vs. 0.3±0.1 ng/ml, TG: 142±5.2 vs. 156±10.9 mg/dl). The pancreatic β-cell mass was greater in LIRA treated mice than in the control (1.0±0.1 vs. 0.7±0.1 mg , $p < 0.05$, n=3 for each). The PCNA-positive cells were increased in number by LIRA treatment, but, there was no difference in 4-HNE immunostaining and TUNEL assay between two groups. The mRNA levels of Hlxb-9, NeuroD and ERK-1 associated with cell differentiation/proliferation were significantly higher in LIRA treated mice than in controls. Gene expression of Hes-1 related to anti-cell differentiation was down-regulated in LIRA-treated mice compared with controls. Gene expression of ER stress related XBP-1, anti-oxidative stress related catalase and GSHPx, and lipid synthesis associated SREBP-1c and FAS were not affected by 2 weeks of treatment with LIRA. The islet insulin content was greater in LIRA group than in controls (59.0±3.7 vs. 44.4±3.9 ng/ islet, $p < 0.05$). Furthermore, GSIS with 16.7mM glucose was greater in LIRA group than in controls (1.7±0.1 vs. 1.2±0.03 ng/ml/ islet, $p < 0.01$).
Conclusion: Liraglutide increases pancreatic β-cell mass through directly regulating cell differentiation and cell proliferation, and promotes β-cell responsiveness to glucose stimulation in normoglycemic model *m/m* mice.

Gene profiles of islets after combined treatment with sitagliptin and metformin in Zucker diabetic fatty rats
S. Han, S.-E. Choi, J. Jung, H. Kim, K. Lee, Y. Kang, D. Kim;
Ajou University school of medicine, Suwon, Republic of Korea.

Background and aims: The combination of dipeptidyl peptidase IV (DPP-IV) inhibitor and metformin has been shown to be an efficient, safe and tolerable therapy for type 2 diabetes. However, the detailed mechanism of this combination therapy compared with mono therapy on beta cell was less known. The aim of this study was to investigate genes regulated after treatment with one of DPP-IV inhibitors, sitagliptin and its combination with metformin by using c-DNA microarrary, when treatment begins before the development of overt diabetes.
Materials and methods: Nine-week-old ZDF rats which were randomly chosen were divided into 4 groups and treated; control group, sitagliptin group (450mg/kg), metformin group (520mg/kg), and sitagliptin plus metformin group (300mg/kg+450mg/kg). After 5 weeks of treatment, oral glucose tolerance test and insulin tolerance test were performed; plasma active GLP-1 level and c-DNA microarrary were assessed.
Results: Sitagliptin plus metformin group showed significant improvement in glucose tolerance test compared to sitagliptin group. As for insulin sensitivity, there was no difference between combination group and either metformin group or sitagliptin group. Plasma active GLP-1 level was increased in sitagliptin plus metformin group compared to sitagliptin group. Sitagliptin plus metformin group upregulated genes involved in anti-apoptosis and proliferation compared with sitagliptin or metformin group (Table 1).
Conclusion: We identified upregulated genes after combined treatment with sitagliptin and metformin compared with either metformin or sitagliptin treatment. These genes may be associated with additive effect of glucose control of combined treatment with sitagliptin and metformin.

The direct effects of DPP-4 inhibition on isolated human islets include protection from glucotoxicity
V. D'Aleo[1], S. Del Guerra[2], F. Filipponi[3], U. Boggi[4], P. Marchetti[5], R. Lupi[2];
[1]Department of Endocrinology and Metabolism, Metabolic Unit, [2]Department of Endocrinology and Metabolism, Metabolic Unit "Renzo Navalesi", [3]Department of Liver Transplantation, General Surgery and Liver Transplantation Unit, [4]Department of Oncology, Transplantation and Advanced Technologies in Medicine, Division of Surgery in Uremic and Diabetic Patient, [5]Department of Endocrinology and Metabolism, Division of Endocrinology and Metabolism of organ and cellular transplantation, Pisa, Italy.

Background and aims: Glucagon-like peptide-1 (GLP-1) is an important physiological incretin secreted from the intestinal L-cells after pro-glucagon cleavage by pro-convertase (PC)-1/3 and rapidly degraded by DPP-IV. We have recently observed that GLP-1 is present in human pancreatic islets, with differences in the case of type 2 diabetes. The aim of the present study was to evaluate the direct effects of DPP-IV inhibition on several features of isolated human islets.
Materials and methods: Islets were prepared from the pancreas of 6 multiorgan donors (4 females/2 males; age, 56±20 yrs; body mass index, BMI, 25.6±3.3 kg/m2) and then incubated for 24h in M199 culture medium, in the presence of 5.5 (g) or 22.2 (G) mmol/l glucose, without (g- and G-) or with (g+ and G+) the addition of 0.1 nmol/l DPP-IV inhibitor (ILE-PRO-ILE, replaced after 12 h). Then, GLP-1 active form was measured in islets incubation medium by radioimmunoassay, insulin release in response to acute glucose stimulation was assessed by IRMA and expressed as stimulation index (SI), and gene expression studies were performed by quantitative RT-PCR.
Results: Active GLP-1 peptide was detected in islets incubation medium, and co-culture with the DPP-IV inhibitor significantly (p2-fold), in particular at G+ culture condition. SI was 3.2±0.35 at g- and decreased to 1.6±0.07 at G- ($p<0.01$). The presence of the inhibitor ameliorated SI in G+ (2.15±0.06, $p<0.01$ vs G-). Gene expression studies showed that G- caused a marked reduction of insulin, GLUT2 and glucokinase transcription and no major change of GLP-1 receptor. At G+, and in comparison with G-, DPP-IV inhibition significantly ($p<0.01$) increased insulin (+356±76%), GLUT2 (+334±86%), glucokinase (+342±45%) and GLP-1 receptor (+423±82%).

Conclusion: In conclusion, these results show that DPP-IV inhibition exerts a protective effect directly on islets exposed to high glucose, possibly mediated by an increased availability of intact GLP-1.

71

Prevention of islet of Langerhans degeneration with rosiglitazone: demonstration of a novel automated image analysis approach with dual insulin and collagen immunohistochemistry

H.B. Jones, A.L. Bigley, K.J. Randall;
Pathology Department, Astrazeneca Pharmaceuticals, Macclesfield, United Kingdom.

Background and aims: The search for small molecule therapies of diabetes often involves an understanding of their potential for reducing the islet of Langerhans degeneration rate. Following Rosiglitazone administration to male obese ZDF rats, islet degeneration is substantially reduced. We used this model to validate a technique of dual insulin/ collagen immunohistochemistry (IHC) with automated image analysis to assess drug-induced islet alterations.
Materials and methods: Obese ZDF rats were randomised prior to either daily gavage dosing with 3 mg/kg/day Rosiglitazone for 24 days or given vehicle only. Lean ZDF rats received vehicle only. Animals were terminated, the pancreas fixed in formalin, processed into paraffin wax and sections stained with either H&E for histopathological assessment or dual IHC stained with insulin or collagens1 and 3 antibodies using peroxidase and alkaline phosphatase techniques respectively and imaged on the Aperio scanscope. Stored images were automatically analysed by an in-house designed rule set using Definiens Developer software. The programme created subsets of islets from a reduced resolution image of the pancreatic sample, followed by high resolution analysis of islet subsets to assess relative numerical data representative of morphological changes observed in size and shape of islets and associated distribution of beta cell insulin and fibrosis. Parameters measured included: area of insulin, islet-associated collagen and islet area, the number of beta cell and islet cell nuclei, intensity of insulin and an islet shape factor.
Results: Lean ZDF islets were comparable to those of non-diabetic rat strains. Obese ZDF rat islets showed β cell vacuolation, degeneration and apoptosis with associated mononuclear inflammatory cell infiltration and fibrosis. Dual insulin/collagen IHC revealed brown-stained β cells in centrally located clusters within islets and red-stained collagen adjacent to blood vessels, exocrine ducts and within and around islets. Insulin staining was heterogeneous and pale compared with lean ZDFs. Islets of obese ZDF Rosiglitazone treated rats resembled more those of lean ZDFs and showed reductions in both β cell degenerative changes and inflammation/fibrosis. When compared to obese control rats, reductions in collagen (506±991 vs 769±1588 pixels^2 p<0.0008) and islet cell areas (42790±30570 vs 71800±75130 pixels^2 p<0.003) were seen in Rosiglitazone treated rats. Beta cell numbers remained unchanged in the **3** groups. The islet cell population was reduced in Rosiglitazone treated rats compared to obese controls (total islet nuclei, 303±191 vs 480±437 p<0.002) due to reduced interstitial tissue. The degree of insulin and collagen staining varied between groups and individual islets depending on animal strain and drug treatment.
Conclusion: Islets of lean and obese ZDF rats were characterised using combined β cell and collagen IHC. Lean ZDF islets showed intense insulin staining and minimal collagen whilst obese ZDFs had increased β cell separation, heterogeneous insulin staining and increased fibrosis. Islets of obese ZDFs given Rosiglitazone for 24 days resembled more those of lean ZDFs. Future applications will focus on reparative effects of novel anti-diabetic therapeutic agents.

72

The SGLT2 inhibitor dapagliflozin prevents the disruption of pancreatic islet morphology in the high fat-fed-female ZDF rat

J.E. Peel[1], R.F. Macdonald[2], L. Westgate[2], H.B. Jones[2], S.M. Poucher[2], R.M. Mayers[2], J. Whaley[3];
[1]Advanced Science and Technology, AstraZeneca, Loughborough, United Kingdom, [2]CVGI Discovery and Pathology, AstraZeneca, Cheshire, United Kingdom, [3]Diabetes Drug Discovery, Bristol-Myers Squibb, Princeton, United States.

Background and aims: Dapagliflozin is a potent, selective inhibitor of the renal sodium-glucose co-transporter 2. Previous studies have demonstrated dapagliflozin reduces blood glucose in rodent models of hyperglycaemia in association with urinary glucose excretion. We have investigated whether improved glycaemic control with dapagliflozin can prevent the disruption of pancreatic islet morphology observed in obese female Zucker diabetic fatty (ZDF) rats following high fat feeding.
Materials and methods: Following randomisation on body weight and blood glucose, ZDF rats (7-8 weeks of age) were placed on a high-fat diet (48% kcal), and dosed with either dapagliflozin (1mg/kg/day, p.o, n=14) or vehicle (n=14) for up to 34 days. Lean, chow fed ZDF rats (n=14) were vehicle dosed. On day 34, 48 hours after the final dose of dapagliflozin, paraffin embedded formalin fixed pancreatic sections were fluorescently labeled from a cohort of animals (n=7 / group). Automated imaging systems and Definiens analysis software were used to image and measure β-cell mass and islet morphological changes. Islet morphological changes were measured by calculating the degree of scattering of β-cells within islets and normalising this to the total area of insulin staining within the image.
Results: On day 24, blood glucose (BG) and glycated haemoglobin (GHb) levels in the dapagliflozin treated group were significantly reduced compared with obese vehicle controls (BG, 8.7±0.46mM vs 13.4± 1.34mM p<0.005; GHb, 3.4±0.17% vs 4.8±0.4% p<0.01). This is consistent with the improvement in glucose homeostasis seen in previous studies. By day 34 fasting plasma insulin (I) and triglyceride (TG) concentrations were also reduced in obese dapagliflozin treated animals compared to obese vehicle controls (I, 483±81pM vs1101±134pM, p≤0.001; TG, 7.1±0.2mM vs 10.8±1.1mM,p≤0.01 respectively). The β-cell mass in the lean, obese vehicle and dapagliflozin obese groups were 0.68+/-0.11%, 1.15+/-0.33% (ns vs lean) and 1.49+/-0.16% (P<0.002 vs lean) of total cell count, respectively. Dapagliflozin resulted in marked, quantifiable improvement of islet morphology assessment by 2.3 fold+/-0.45 (p<0.05) compared with the obese vehicle control group. The insulin staining intensity of islets post dapagliflozin treatment was also elevated (2.2 fold+/-0.2 p<0.05) relative to obese vehicle animals to the extent that there is no observable difference between these and the lean animal group. Histopathological assessment of pancreatic sections also showed islet characteristics in obese dapagliflozin groups similar to those seen in lean vehicle controls ie. substantial reductions in β-cell degeneration, vacuolation and islet inflammation/fibrosis.
Conclusion: These data suggest that, by inducing renal glucose excretion, dapagliflozin treatment not only improved glycaemic control, it also prevented the marked disruption of pancreatic islet morphology affecting β-cells, which is a characteristic of ZDF rats.

OP 13 Type 2 diabetes mellitus genetics and genomics

73

Genome-wide association meta-analysis and replication involving 141,547 individuals of European descent identifies further loci influencing type 2 diabetes risk

M.I. McCarthy, for the Diabetes Genetics Replication And Meta-analysis (DIAGRAM) Consortium;
University of Oxford, Headington, United Kingdom.

Background and aims: Genome-wide association (GWA) studies have provided novel insights into the biology of T2D and glucose homeostasis, with close to 20 confirmed T2D-susceptibility loci to date. The DIAGRAM consortium has extended previous GWA meta-analyses and replication efforts to identify additional loci influencing T2D susceptibility in European-descent samples.
Materials and methods: We combined high-density GWA data from 8 studies: DECODE (Iceland), DGDG (French), DGI (Sweden/Finland), ERGO (Netherlands), EUROSPAN (isolates from UK; Croatia; Netherlands; Italy); FUSION (Finland), KORA (Germany) and the WTCCC (UK) using standard meta-analysis approaches. These stage 1 samples included 8,130 cases and 38,987 controls (effective sample size 22,570). After setting aside 17 previously-proven associations, lead SNPs representing the 25 next strongest associations (all $p<10^{-5}$ on meta-analysis) were followed-up through de novo genotyping in 13 studies (Steno [Denmark], DGDG2 [French], DGI_GCIP [Poland], DGI_GCIUS [US], DGI_MALMO [Sweden], DUNDEE [UK], ERGO_DIAGENE [Netherlands], KORA [Germany], ULM [Germany], W2C_UKBS [UK], HUNT [Norway], METSIM [Finland] and FUSION2 [Finland]) and in silico analyses in ARIC and NHS [both US]. The maximum effective sample size of the stage 2 samples was 82,364.
Results: Of the 25 signals for which replication was attempted, 23 (binomial $p=1.6x10^{-6}$) showed consistent direction of effect in the follow-up samples, and 18 stage 2 association p values were nominally-significant as well as directionally-consistent ($p<0.05$). When stage 1 and stage 2 data were combined (fixed-effects meta-analysis), 9 SNPs generated association P-values consistent with genome-wide significance (p-values from $1.9x10^{-8}$ to $6.7x10^{-17}$). Three of these represent signals (near *MTNR1B*, *IRS1* and *KCNQ1*) for which there is already overwhelming evidence of T2D-susceptibility effects. One (rs243021 in *BCL11A*) has been the subject of previous reports of association but now reaches genome-wide significance for the first time ($1.1x10^{-13}$). The remaining five signals (which map to chromosomes 5, 7, 8, 11, and 12) represent entirely novel T2D-susceptibility loci (point estimates of effect size ranging from 1.07-1.13). The recombination intervals within which these 5 novel signals lie encompass the coding regions of at least 25 genes (range 1-9) encoding multiple members of the phosphodiesterase and carboxypeptidase gene families and other proteins of potential relevance to diabetes pathogenesis.
Conclusion: Our findings provide compelling evidence for six novel T2D-susceptibility loci and bring the number of regions known to confer risk for T2D in European populations to 26. The ongoing efforts of the DIAGRAM consortium are directed towards systematic follow-up of these data, including deeper follow-up, fine-mapping to identify the causal variants and functional studies to develop insights into the pathophysiology of diabetes. We also plan to extend these meta-analyses and replication efforts to non-European-descent populations.

Genome wide analysis of African American type 2 diabetes

D.W. Bowden[1], N.P. Allred[1], M.C. Ng[1], C.D. Langefeld[2], B.I. Freedman[3];
[1]Center for Diabetes Research, [2]Biostatistical Sciences, [3]Internal Medicine, Wake Forest University School of Medicine, Winston-Salem, NC, United States.

Over 3.2 million African Americans have type 2 diabetes (T2DM). This represents approximately 13.3% of the African American population and a significant proportion of the 20.8 million Americans believed to be living with diabetes. On average, an African American is twice as likely to have T2DM as a European American peer. We have carried out both gene-targeted and Genome Wide Association Studies (GWAS) of African American T2DM genetics in samples of T2DM-affected cases and non-diabetic controls recruited from the southeastern portion of the United States. African Americans are an admixed population and admixture in these studies was estimated based on 70 Ancestry Informative Markers genotyped on all DNA samples. Taking advantage of the LD structure of African-derived chromosomes, we have localized TCF7L2 association with T2DM to a 4kb LD block. With resequencing of this block in 96 African American DNAs we identified 35 novel and 14 known SNPs which were genotyped in 1033 cases and 1106 controls along with the T2DM-associated microsatellite DG10S478. The SNP rs7903146 was by far the most strongly associated (admixture adjusted, additive $P=1.59x10^{-6}$; OR 1.39, CI 1.21-1.60) suggesting this is a functional polymorphism. In contrast to TCF7L2, other SNPs associated with T2DM in European-derived samples showed little or no evidence of association with T2DM even in an enlarged sample of 2841 cases and 1964 controls. Only SNPs in CDKAL1, rs10946398 and rs7754840, showed even nominal evidence of association (P=0.06). Evaluation of these SNPs in the Human Genome Diversity Panel, however, suggests some of these SNPs may be fixed in the African population since Yoruba are monomorphic for the risk allele observed in Europeans. We have carried out a GWAS analysis on 966 cases and 1033 controls using with the Affymetrix 6.0 chip. After extensive quality control 835,042 SNPs were evaluated in admixture-adjusted association analysis focusing on the additive model. Approximately 40 SNPs had P-values $< 10^{-6}$. In addition, SNPs in two previously identified T2DM genes from studies of European-derived populations were among the top hits. SNPs rs17703228 ($P=7.42x10^{-5}$) in "juxtaposed with another zinc finger gene 1" (*JAZF1*) and rs10906180 ($P=6.38x10^{-5}$) in the calcium calmodulin-dependent protein kinase 1D (*CAMK1D*) were associated with T2DM in African Americans. These SNPs are different from SNPs previously observed to be associated with T2DM in Europeans. Replication studies of high scoring African American SNPs are underway in a two stage replication analysis totaling over 4,000 cases and 4,000 controls, and evaluation of imputed SNPs and copy number variation is also in progress.

Genome-wide meta-analysis identifies novel genetic loci associated with OGTT-induced post-challenge glucose

C. Langenberg[1], R. Saxena[2,3], M.-F. Hivert[3], T. Tanaka[4], J.S. Pankow[5], V. Lyssenko[6], N. Boutia-Naji[7], W.H.L. Kao[8], A. Jackson[9], J. Dupuis[10], P. Vollenweider[11], R.M. Watanabe[12], for MAGIC;
[1]MRC Epidemiology Unit, Cambridge, United Kingdom, [2]Broad Institute of Harvard and MIT, Cambridge, United States, [3]Massachusetts General Hospital, Boston, United States, [4]Medstar Research Institute, Baltimore, United States, [5]University of Minnesota, Minneapolis, United States, [6]Lund University, Malmo, Sweden, [7]CNRS-UMR-8090, Pasteur Institute, Lille, France, [8]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [9]University of Michigan, Ann Arbor, United States, [10]Boston University School of Public Health, United States, [11]Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland, [12]University of Southern California, Los Angeles, United States.

Background and aims: Two-hour post-load glucose measured during the oral glucose tolerance test (OGTT) defines glucose tolerance, reflects insulin resistance and influences cardiovascular risk - yet common genetic determinants of two-hour glucose are largely unknown.
Materials and methods: To identify genetic factors influencing 2h-glucose levels, we combined results from nine genome-wide association studies (GWAS) involving 15,234 non-diabetic individuals of European descent through collaborative MAGIC (Meta-Analyses of Glucose and Insulin-related traits Consortium) efforts and followed up 10-29 signals in up to 27,922 replication samples from 15 studies.
Results: Compelling genome-wide significant evidence of association with 2h-glucose was observed for SNPs at the *ADCY5* ($P = 8.6 \times 10^{-14}$), *TCF7L2* ($P = 4.7 \times 10^{-10}$), *GCKR* ($P = 4.0 \times 10^{-10}$), *GIPR* ($P = 1.5 \times 10^{-13}$) and *VPS13C* ($P = 4.3 \times 10^{-08}$) loci. These associations were independent of body mass index and fasting glucose levels, indicating a specific role of these loci for the post-challenge rise in glucose levels. Detailed physiological investigation showed that individuals carrying the GIPR risk allele displayed lower glucose stimulated insulin secretion early, at 2h and during the course of the OGTT (insulinogenic index ($P = 2.8 \times 10^{-10}$), 2h-insulin adjusted for 2h-glucose ($P = 8.1 \times 10^{-10}$), and AUC insulin to glucose ratio ($P = 6.9 \times 10^{-12}$) as well as exhibiting a lower incretin effect ($P = 0.007$).

Conclusion: The discovery of common genetic variants that are specifically and robustly associated with 2-hour glucose levels in diabetes free individuals provides novel insight into the pathogenesis of hyperglycaemia, type 2 diabetes and related metabolic disorders.

76

Novel genetic loci implicated in fasting glucose homeostasis and their impact on related metabolic traits

I. Prokopenko[1,2], J. Dupuis[3,4], C. Langenberg[5], R. Saxena[6,7], N. Soranzo[8,9], A.U. Jackson[10], E. Wheeler[8], N.L. Glazer[11], R. Mägi[1,2], N. Bouatia-Naji[12], J.C. Florez[6,7], I. Barroso[8], for the MAGIC investigators;
[1]WTCHG, Oxford, United Kingdom, [2]OCDEM, Oxford, United Kingdom, [3]Boston University School of Public Health, United States, [4]National Heart, Lung, and Blood Institute's Framingham Heart Study, Framingham, United States, [5]MRC Epidemiology Unit, Cambridge, United Kingdom, [6]Broad Institute of Harvard and Massachusetts Institute of Technology, Cambridge, United States, [7]Massachusetts General Hospital, Boston, United States, [8]Wellcome Trust Sanger Institute, Cambridge, United Kingdom, [9]King's College London, United Kingdom, [10]University of Michigan School of Public Health, Ann Arbor, United States, [11]University of Washington, Seattle, United States, [12]CNRS-UMR8090, Lille, France.

Background and aims: Genetic analyses of continuous glycaemic traits can offer insights into the regulation of physiological processes, and have previously led to the discovery of *MTNR1B*, a novel locus influencing type 2 diabetes (T2D) risk.
Materials and methods: To identify additional glycaemic trait loci and investigate their metabolic impact, we performed meta-analyses of 21 genome-wide associations studies informative for fasting glucose (FG, N=46,263), fasting insulin, and indices of β-cell function (HOMA-B) and insulin resistance (HOMA-IR) (N=38,413). Follow-up genotyping of 25 loci was carried out in 61,219 independent samples.
Results: We discovered nine new loci for FG (in or near *ADCY5*, *MADD*, *ADRA2A*, *CRY2*, *FADS1*, *GLIS3*, *SLC2A2*, *PROX1* and *FAM148B*) and a novel genome-wide significant ($P<5\times10^{-8}$) association with fasting insulin and HOMA-IR (*IGF1*). Also associated with FG were T2D-associated loci *TCF7L2* and *SLC30A8,* and previously reported loci *GCK*, *GCKR*, *G6PC2*, *MTNR1B* and *DGKB/TMEM195*; *GCKR* also achieved genome-wide significant association with fasting insulin and HOMA-IR. The impact of FG loci on T2D and related metabolic traits suggests shared genetic determinants: *DGKB/TMEM195*, *ADCY5* and *PROX1* with T2D and *FADS1/FADS2* and *MADD* with lipid levels.
Conclusion: Within the associated loci the most likely biological candidate genes influence signal transduction, development, glucose-sensing and circadian regulation. The wealth of novel FG loci contrasts with the sole fasting insulin/HOMA-IR novel finding and suggests a different genetic architecture for β-cell function and insulin resistance. Our findings demonstrate considerable divergence between the genetic variants influencing glucose levels in healthy populations, those altering T2D-predisposition and other influencing related metabolic traits highlighting the complex relationships that may exist between continuous endophenotypes and the disease states to which they relate.
Replication genotyping was supported in part by Diabetes UK

77

Decreased TCF7L2 protein levels in type 2 diabetes mellitus correlated with downregulation of GIP and GLP-1 receptors and impaired beta cell function

L. Shu[1], A.V. Matveyenko[2], J. Kerr-Conte[3], J.-H. Cho[4], C.H.S. McIntosh[5], K. Maedler[1];
[1]Centre for Biomolecular Interactions Bremen, Bremen, Germany, [2]Department of Medicine, Larry L. Hillblom Islet Research Center, Los Angeles, United States, [3]Thérapie Cellulaire du Diabète, INSERM /Université de Lille, France, [4]4Department of Endocrinology, Kangnam St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea, [5]Department of Cellular and Physiological Sciences, University of British Columbia, Vancouver, Canada.

Background and aims: Recent human genetics studies have revealed that common variants of the TCF7L2 gene are strongly associated with type 2 diabetes mellitus (T2DM). We have shown that TCF7L2 expression in the β-cells is correlated with function and survival of the insulin producing pancreatic β-cell. In order to understand how variations in TCF7L2 influence diabetes progression, we investigated its mechanism of action in the β-cell.
Materials and methods: RNA and protein were extracted from isolated islets from three diabetic animal models, the *db/db* mouse, the high fat diet fed mouse and the VDF Zucker rat, and RT-PCR and western blot analysis for TCF7L2 were performed subsequently. TCF7L2 expression in pancreatic sections from 8 healthy controls and from 8 patients with T2DM were analyzed by immunofluorescence staining. For transfection experiments, isolated human islets were exposed to TCF7L2 small interfering RNA or pCMV-TCF7L2 plasmids and cultured with or without GLP-1/GIP. Beta cell function was assessed by glucose-, GLP-1-/GIP-, KCl- or cAMP- stimulated insulin secretion assays in static incubations and islet perifusions.
Results: We show robust differences in TCF7L2 expression between healthy controls and models of T2DM. While mRNA levels were ~2-fold increased in isolated islets from the diabetic *db/db* mouse, the VDF rat and the high fat/ high sucrose diet treated mouse compared to the non-diabetic controls, protein levels were decreased. A similar decrease was observed in pancreatic sections from patients with T2DM. In parallel, expression of GLP-1 and GIP receptors was decreased in islets from humans with T2DM as well as in isolated human islets treated with siRNA to TCF7L2 (siTCF7L2). Also, insulin secretion stimulated by glucose, GLP-1 and GIP, but not KCl or cAMP was impaired in siTCF7L2 treated isolated human islets. Loss of TCF7L2 resulted in decreased GLP-1 and GIP stimulated AKT phosphorylation, and AKT mediated Foxo-1 phosphorylation and nuclear exclusion.
Conclusion: Our findings suggest that β-cell function and survival are regulated through an interplay between TCF7L2 and GLP-1R/ GIP-R expression and signaling in T2DM.

78

The impact of differential splicing of TCF7L2 on target gene expression in human islet of Langerhans

Y. Zhou, S. Lang, J. Taneera, E. Renström, L. Groop, O. Hansson;
Endorinology and diabetelogy, Lund University Clinical Resarch Center, Malmö, Sweden.

Background and aims: Variants in *TCF7L2* have been shown to be highly associated with type 2 diabetes. We have previously reported that the risk allele rs7903146 does not significantly influence the overall amount or splicing pattern in human islets of Langerhans, however, the expression level of the exon4-containing-TCF7L2 transcript correlates positively with plasma HbA1c levels (r = 0.758; p = 0.018). The aims of this study are identify *TCF7L2* target genes and to investigate the effect of TCF7L2 exon 4 splicing on these genes in human islets of Langerhans.
Materials and methods: All samples were from non-diabetic individuals (6 female, 11 male, aged 26-73 years, BMI 17.7-29 kg/m^2). Total RNA was isolated using the AllPrep DNA/RNA Mini Kit (Qiagen) and analyzed using Gene 1.0 ST whole transcript based assays (Affymetrix). The percentage of the exon4-containing-TCF7L2 transcripts was measured with QPCR using absolute quantification. Statistical analyses were performed using non-parametric Spearsman correlation (SPSS 16.0). Candidate genes were analysed using Gene Set Analysis Tool kit (http://bioinfo.vanderbilt.edu/).
Results: The TCF7L2 binding motif (A-C/G-A/T-T-C-A-A-A-G) was investigated in the promoter region (5 kb upstream and 1 kb downstream of transcriptional start site) of all annotated genes and regions in the human genome using a bio-informatics approach. All together, 2759 annotated genes were found to contain the motif. Genes not represented on the array and genes with expression below the detection level were excluded. 205 genes correlated significantly (p = 0.05), with exon4-containing-TCF7L2 transcript expression. Using pathway analysis, several pathways were found to be significantly enriched, including protein transport (p = 8.69 x 10e-4) and intracellular transport (p = 1.15 x 10e-2). In order to select a suitable model system to replicate these findings, the splicing pattern in the INS-1 cell line was established and was found to resemble the human pattern. Currently, the functional consequences of reduced expression of a number of the correlated genes are being investigated using siRNA.
Conclusion: Based on our results, intronic variation in *TCF7L2* could potentially perturb the binding of splice factors and thereby influence the splicing pattern. Differential splicing, e.g. exon 4 inclusion/exclusion, could then affect target gene expression and propagate the increased risk of type 2 diabetes. Future studies are obviously necessary to fully elucidate the mechanism/s whereby genetic variation in *TCF7L2* leads to increased risk of the disease and the role of differential splicing.

***MiR-217* regulates aging and angiogenic functions in human endothelium via SirT1**

R. Menghini[1], V. Casagrande[1], M. Cardellini[1], E. Martelli[2], A. Terrinoni[1], F. Amati[3], A. Ippoliti[2], G. Novelli[3], G. Melino[4], R. Lauro[1], M. Federici[1]; [1]Dept. of Internal Medicine, [2]Dept. of Surgery, [3]Dept. of Biopathology, [4]Dept. of Experimental Medicine, University of Tor Vergata, Rome, Italy.

Background and aims: Increasing evidence indicates that premature senescence contributes to endothelial dysfunction, a pivotal step in development of diabetes and metabolic syndrome. Molecular targets relevant for this process remains to be clarified. To this aim we have performed a microarray analysis of MicroRNAs (miRNAs), crucial post transcriptional modulators of gene expression, in an endothelial aging model in vitro, comparing young (Population doubling levels, PDLs8) to old (PDLs44) HUVEC.
Materials and methods: To this aim we have performed a microarray analysis of MicroRNAs (miRNAs), crucial post transcriptional modulators of gene expression, in an endothelial aging model in vitro, comparing young (Population doubling levels, PDLs8) to old (PDLs44) HUVEC.
Results: We found a progressive induction of *miR-217* during aging. Bioinformatic analysis and a promoter reporter assay revealed that SirT1, a NAD^+-dependent hystone deacetylase playing a critical role in stress resistance, longevity and metabolism, is a potential target of *miR-217*. Transfection of young HUVEC with an oligonucleotide that decreases *miR-217* (Anti-miR-217) increased SirT1 expression. Conversely, overexpression of the *miR-217* precursor decreases SirT1 expression in young HUVEC. In young HUVECs overexpressing *miR-217,* senescent cells were increased up to 30% of the control ($p< 0.0005$) in a Senescence Associated-β-gal activity assay. On the contrary, in old HUVEC transfection with Anti-miR-217 decreased the percentage of senescent cells approximately to 30% compared with the control ($p< 0.005$), indicating that *miR-217* plays a role in endothelial premature senescence in vitro. SirT1 controls endothelial angiogenic functions via deacetylation of forkhead transcription factor FoxO1. In young endothelial cells, *miR-217* overexpression significantly impaired tube forming activity ($p< 0.0005$) and induced a marked FoxO1 acetylation. Conversely, Anti-miR-217 in old HUVECs significalntly increased tube formation ($p< 0.005$). Next, we compared, by real time PCR, the mRNA expression of targets coordinately regulated by Sirt1 and of Foxo1, such as GADD45, Flt1 and eNOS, in young and old HUVEC transfected with miR-217 or Anti-miR-217, respectively. Our results confirmed that *miR-217* is involved in FoxO1 targets modulation. Functional changes in senescent endothelial cells in vivo may play an important role in the pathophysiology of age associated vascular disorders. Therefore we performed real time PCR experiments in plaques from patients who underwent carotid endarterectomy for symptomatic disease and we confirmed in vivo a negative correlation between *miR-217* and Sirt1 expression and FoxO1 acetylation state; similarly, we observed a positive correlation between Sirt1 and FoxO1 targets GADD45, Flt1 and eNOS.
Conclusion: These data suggest that miR-217, via regulation of SirT1/FoxO1, can regulate senescence and angiogenesis in endothelial cells thus providing a molecular explanation to age-related endothelial dysfunction.

Endothelial and endocrine alterations in diabetic pancreas. Role of angiopoietin-2 and thrombospondin-1

S. Calderari, C. Chougnet, M. Clemessy, H. Kempf, P. Corvol, E. Larger; INSERM U833, Paris, France.

Background and aims: In the events leading to type 2 diabetes, inadequate compensatory increase of the beta cells mass could be a direct consequence of vascular disease, either by endothelial dysfunction or secondary to defective secretion of angiogenic peptides by beta cells. To dissect the role of angiogenic process in the maintenance and growth of islets, we studied pancreatic chimeras, consisting of endocrine chick cells and murine endothelial cells, obtained by grafting embryonic chick pancreas in SCID mice. We analyzed angiogenesis during development of the pancreatic chimera and examined the impact of hyperglycemia on the vasculature of the pancreas. We then used an avian-specific retrovirus, the RCAS system, to over-express VEGF during pancreatic development.
Materials and methods: Seven-week-old female SCID mice were made diabetic by a single intra-peritoneal injection of streptozotocin (160mg/kg). Embryonic chick pancreases (E14) were grafted under the kidney capsule of SCID mice and collected 14 days later. Pancreatic vasculature was analyzed by immunohistochemistry using nestin, a mouse-specific endothelial marker, and in situ hybridization with both mouse- and chick-specific VEGFR-2 probes. Expression of angiopoïetin-2 (Ang2), thrombospondin-1 (Tsp1) and VEGF was analyzed by in situ hybridization. To over-express VEGF, an avian-specific retrovirus RCAS carrying the gene encoding the VEGF (RCAS-VEGF) was prepared. Chick pancreases were infected in vitro with the RCAS-VEGF for 1 hour before graft. Mammalian cells were not susceptible to the RCAS infection. All analyzes were performed on n=5 animals. This study was carried out along the principles of laboratory animal care.
Results: As compared to normoglycemia, hyperglycemia increased beta-cell density ($p<0.05$). Pancreatic vasculature was disorganized with large blood-filled spaces and vessels discontinuities. Vessel density was decreased as evidenced by quantification of nestin- and VEGFR-2-positive cells ($p< 0.05$). Expression of two anti-angiogenic factors, Tsp1 and Ang2 was increased in grafts ($p<0.05$), whereas no clear difference was observed for VEGF.
In order to correct the vascular defects, we over-expressed VEGF in pancreas. In normoglycemic condition, number of both beta- and endothelial-cells was not altered by VEGF over-expression. In hyperglycemic conditions, number of both beta- and endothelial-cells was increased by VEGF over-expression ($p<0.05$). Ang2 and Tsp1 determinations are pending.
Conclusion: Hyperglycemia induced major defects of the pancreatic vasculature associated with Ang2 and Tsp1 over-expression. These two anti-angiogenic growth factors have been associated with vasculopathy in diabetes. We demonstrated for the first time up-regulation of Ang2 expression in the pancreas in hyperglycemic conditions. In normoglycemic condition, there was no change after VEGF over-expression, whereas in hyperglycemic condition, VEGF over-expression increased both endocrine and endothelial cells.

Tissue Factor pre-mRNA splicing in platelets from healthy subjects and type 2 diabetes mellitus patients

J.-W.N. Akkerman[1], C.A. Koekman[1], H.W. de Valk[2], A.J. Gerrits[1]; [1]Department of Clinical Chemistry and Haematology, [2]Department of Internal Medicine, University Medical Center Utrecht, Netherlands.

Background and aims: Type 2 diabetes mellitus (T2DM) patients have a 2-8-fold higher risk of cardiovascular disease than healthy individuals and eighty percent will die of thrombosis-related disorders. T2DM induces a prothrombotic state caused by imbalance of the hemostatic mechanism characterized by hypercoagulation and platelet hyperaggregability. Patients with T2DM have increased plasma Tissue Factor (TF), the starter of coagulation. Recent findings suggest a new source for TF expression. Platelets contain Splicing Factor 2 (SF2), a regulator of constitutive and alternative splicing, together with pre-mRNA with message for TF. Splicing of TF pre-mRNA results in TF protein and the capacity to initiate coagulation. We investigated whether abnormal platelet TF production was the cause of the hypercoagulant state in T2DM patients.
Materials and methods: Platelets form T2DM patients and matched controls were depleted from leukocytes by a double incubation with anti-CD14/CD45 antibody-coupled beads and magnetic separation. RT-PCR for CD14 was negative in 30 cycles RT-PCR. Platelets were adhered to different surface-coated proteins (0.5 - 4 hrs, 37°C) and phosphorylation of SF2, TF-pre-mRNA splicing, TF protein and TF procoagulant activity (Xa assay) were measured. Numbers of adhered platelets were based on alkaline phosphatase content.
Results: Adhered platelets showed adhesion-induced Ser phosphorylation of SF2 and TF pre-mRNA splicing (blocked by the splicing inhibitor Tg003) and translation-dependent TF activity (blocked by the protein synthesis inhibitors puromycin and cycloheximide). Collagen induced TF-pre-mRNA splicing started at 30 min. and was optimal after 4 hrs. Collagen-adhered platelets produced 600 fold more TF than suspensions (0.17 ± 0.09 and 0.0003 ± 0.0001 ng TF/ $2.0 \cdot 10^8$ platelets, mean +/- SEM, n=3). Compared with fibrinogen (100%), TF production on horm collagen, collagen I, thrombin, collagen III and von Willebrand Factor was 143 ± 42, 132 ± 29, 126 ± 20, 71 ± 10 and 38 ± 14%. Incubation with AR-C699331 MX and indomethacin, which mimic the action of clopidogrel and aspirin respectively, inhibited collagen-induced TF activity, which was almost zero when co-incubated with both inhibitors. Pharmacologic blockade showed signaling through cAMP (increased by iloprost, forskolin) and PI3-kinase/protein kinase B (inhibited by wortmannin,

LY and ML9). In normal platelets, insulin (1-100 nM, 5 min) interfered with cAMP regulation, inhibited collagen-induced TF-pre-mRNA splicing and reduced TF procoagulant activity by 63 ± 10 % at 100 nM (n=5). The inhibition was two-fold lower in T2DM platelets and reached 30 ± 7% (n=4).
Conclusion: These results demonstrate that in normal platelets TF synthesis is inhibited by insulin through interference with cAMP. T2DM platelets have become partially resistant to this inhibition leading to upregulation of TF synthesis. We conclude that the hypercoagulant state in type 2 diabetics might be caused by increased platelet TF production.

Absence of fibronectin EDA exon increases endothelial dysfunction and oxidative stress in diabetic mice aortas
G. Gortan Cappellari[1], M. Boschelle[1], V. Spadotto[1], R. Barazzoni[1], L. Cattin[2], F.E. Baralle[3], G. Guarnieri[1], A.F. Muro[3], M. Zanetti[1];
[1]DSCMT, University of Trieste, [2]DSCMT, UCO III Medica and Diabetes Center, Trieste, [3]International Centre for Genetic Engineering and Biotechnology, Trieste, Italy.

Background and aims: Fibronectin (FN) pre-mRNA undergoes alternative splicing at three positions, in a tissue and develomental-specific manner generating up to 20 different protein isoforms. One of the alternatively spliced exons is the Extra Domain A (EDA). EDA exon inclusion is normaly low in adult tissues but it is upregulated in several injure-repair processes. Hyperglycemia induces overexpression of selected vascular extracellular matrix proteins, including FN. In addition, FN is known to modulate endothelial nitric oxide synthase (eNOS) activation and the absence of regulated splicing of EDA reduces atherosclerosis in mice. The precise role of the EDA segment in vascular oxidative stress and endothelial dysfunction in diabetes needs further clarification. The aim of this study was, therefore, to assess endothelial function and oxidative stress in diabetic mice constitutively expressing ($EDA^{+/+}$) or lacking ($EDA^{-/-}$) the EDA exon of the FN gene.
Materials and methods: Three months old $EDA^{+/+}$ (n=18), $EDA^{-/-}$ (n=16) and C57/BL6 (wild type, WT: n=14) mice were treated by multiple streptozotocin injections to induce diabetes. After 20±2 weeks aortas were harvested and endothelial function immediately assessed in organ chamber vasorelaxation experiments. The remaining aortic rings were frozen for RNA extraction. eNOS, Nox4 and p22phox gene expression analysis was performed by labelled-probe real-time RT-PCR. Normalisation was performed by ratio to 28S rRNA expression. Statistical analysis was performed by one-way ANOVA or Student's t-test as appropriate.
Results: Streptozotocin resulted in diabetes induction as demonstrated by increased ($p<0.01$) blood glucose levels in all genotypes (pre- vs. post treatment: $EDA^{+/+}$: 163.3±5.9 vs. 411.3±12.1 mg/dl; $EDA^{-/-}$: 168.1±3.7 vs. 474.7±8.5 mg/dl; WT: 141.9±5.0 vs. 429.3±21.0 mg/dl). Acetylcoline (10^{-6} mol/l) mediated endothelium-dependent vasorelaxation was lower in $EDA^{-/-}$ mice compared to control aortas (36.5±5.7% vs. 52.4±4.4%, $p<0.05$) and to $EDA^{+/+}$ (52.7±2.9%, $p<0.05$). Endothelium-independent vasorelaxation to DEA-NONOate was not different among groups. To investigate the mechanisms of impaired endothelial-dependent vasorelaxation in $EDA^{-/-}$ mice, we analysed eNOS, Nox4 and p22phox gene expression. eNOS mRNA was significantly reduced in $EDA^{-/-}$ samples compared to control ones (0.145±0.105 vs. 0.456±0.094 a.u., $p<0.05$). In contrast, both Nox4 and p22phox mRNA levels were significantly higher in $EDA^{-/-}$ aortas than in control vessels (Nox4: 1.167±0.320 vs. 0.226±0.038 a.u., $p<0.01$; p22phox: 0.444±0.118 vs. 0.099±0.004 a.u., $p<0.01$). Nox4 mRNA was also significantly higher in $EDA^{-/-}$ than in $EDA^{+/+}$ (1.167±0.320 vs. 0.340±0.052 a.u., $p<0.01$).
Conclusion: These data demonstrate that constitutive absence of fibronectin EDA exon increases endothelial dysfunction in diabetes and suggest an important role for this exon as a modulator of eNOS and oxidative-stress related gene expression.

Intracellular methylglyoxal levels explain hyperglycaemia-induced impaired endothelium-dependent vasorelaxation in an oxidative stress-dependent pathway
O. Brouwers[1], P.M.G. Niessen[1], T. Miyata[2], M. Brownlee[3], C.D.A. Stehouwer[1], J.G.R. De Mey[4], C.G. Schalkwijk[1];
[1]Internal Medicine, Maastricht University, Netherlands, [2]Centre for Translational and Advanced Research, Tohoku University, Japan, [3]Medicine and Pathology, Albert Einstein College of Medicine, New York, United States, [4]Pharmacology and Toxicology, Maastricht University, Netherlands.

Background and aims: In hypergglycaemic conditions, increased formation of the glycolysis-derived reactive dicarbonyl compound methylglyoxal (MGO) and MGO-derived advanced glycation endproducts (AGEs) are thought to be implicated in endothelial dysfunction and, subsequently, in the development of diabetic vascular complications. A common feature of endothelial dysfunction is an impaired nitric-oxide (NO)-dependent vasodilatation. We now investigated the effect of hyperglycaemia on impaired vasoreactivity and a putative role of MGO and glyoxalase-I (GLO-I), i.e. the enzyme detoxifying MGO, therein.
Materials and methods: Isolated mesenteric arteries from wild type and transgenic GLO-I rats were mounted in a myograph. The effects of hyperglycaemia and MGO on NO-dependent vasodilatation were tested with acetylcholine (ACh; 0.01 - 10μM) in the presence of indomethacin (10μM) during contraction with potassium (65mM). AGE formation was determined by immunohistochemistry with an antibody against the major MGO-adduct 5-hydro-5-methylimidazolone (MG-H1). Reactive oxygen species (ROS) formation was measured with a DCF-probe and an antibody against nitrotyrosine.
Results: Treatment of wild type mesenteric arteries with high glucose (30mM for 2-hours) resulted in reduced acetylcholine-induced vasorelaxation. Impairment of dilatation by hyperglycaemia was not observed in mesenteric arteries of GLO-I transgenic rats compared with their wild type littermates, indicating a specific intracellular MGO effect. Direct exposure of mesenteric arteries to 0.1, 0.33 and 1.0mM MGO (for 1-hour) significantly reduced the acetylcholine-induced vasorelaxation, as indicated by decreased potency (log EC50 was -6.33, -6.21, -6.17 and -5.94 M, respectively) and efficacy (Emax was 71; 58; 51 and 49 % dilatation, respectively). This effect was endothelium-dependent as indicated by unaltered relaxing responses to the NO donor Na-nitroprusside. Impairment of dilatation by MGO was not observed in mesenteric arteries of GLO-I transgenic rats indicating a specific intracellular MGO effect. Pre-incubation of healthy mesenteric arteries with MGO increased staining of MG-H1 in endothelial cells and adventitia accompanied by an increase in the oxidative stress marker nitro-tyrosine. The MGO-induced impaired vasoreactivity was normalized by preincubation of the vessels with the antioxidants N-Acetyl Cysteine, EUK-134 and Mn(III)TMP.
Conclusion: We found that hyperglycaemia-induced impairment of endothelium-dependent NO-mediated vasodilatation could be prevented by GLO-I overexpression. In addition, exposure to MGO decreased NO-mediated dilatation due to an increase in oxidative stress. These data implicate that elevated MGO leads to impaired endothelial function in diabetes and that GLO-I may prevent this.

Relations between endothelial function and peripheral microcirculation and cardiac autonomic neuropathy in type 2 diabetic patients
A.H. Belhadj-Mostefa[1,2], M.K. Bourahli[3], F. Touati[1], M. Nguyen[4], D. Roula[1], P.E. Valensi[4];
[1]Medicine, CHU Constantine, Algeria, [2]ANDRS, Oran, Algeria, [3]Physiology, CHU Constantine, Algeria, [4]Medicine, CHU Jean Verdier, Bondy, France.

Background and aims: Peripheral endothelial function is impaired in patients with coronary disease. Endothelial dysfunction and autonomic neuropathy may alter peripheral microcirculation. The aim of this study was to examine in type 2 diabetic patients whether endothelial dysfunction or a reduction of peripheral microcirculation might be markers of coronary disease and the role of autonomic dysfunction in these disorders
Materials and methods: We included 116 patients without any cardiac history or symptom. Silent myocardial ischemia (SMI) was assessed using an ECG stress test and if SMI was found, coronary stenoses were assessed by coronary angiography. Endothelial function and peripheral microcirculation were examined by measuring forearm post-ischemic hyperemia (echo-dop-

pler), through the changes in humeral artery diameter (D2/D1) and blood flow (F2/F1), respectively. CAN was assessed using Ewing' tests which mainly estimate cardiac parasympathetic activity.
Results: SMI was found in 34 patients and was associated with significant coronary stenoses (SCS) (>70%) in 18 of them, and CAN was present in 82 patients. D2/D1 and F2/F1 did not correlate with age, BMI and HbA1c, and did not differ in the patients with or without hypertension. D2/D1 did not differ in the patients with or without SMI or CAN, but was significantly lower in patients with SCS (p=0.04). F2/F1 was significantly lower in patients with CAN (p= 0.002) and decreased with CAN severity (p = 0.02), and was lower in patients with SCS (p=0.01). In multivariate analyses F2/F1 levels were associated independently with CAN and its severity (p< 0.001 and < 0.005).
Conclusion: These data suggest that neither endothelial function nor peripheral microcirculation may be considered as markers of silent coronary disease but that a defect in vagal activity and a relative excess of sympathetic activity may play a role in the alterations of microcirculation in type 2 diabetic patients

OP 15 Glucose monitoring

85

Effect of self-monitoring of blood glucose in patients with type 2 diabetes treated with oral medication on quality of life parameters: a 1-year randomised controlled trial
S.J.J. Logtenberg[1], N. Kleefstra[1,2], J. Hortensius[1], J.J. van der Bijl[3], K.H. Groenier[4], S.T. Houweling[2,5], R.O.B. Gans[6], H.J.G. Bilo[6,1];
[1]Diabetes Centre, Isala Clinics, Zwolle, [2]Medical Research Group, Langerhans, Zwolle, [3]Department of Nursing Science, University Medical Center, Utrecht, [4]Department of General Practice, University of Groningen, [5]General Practice Sleeuwijk, Sleeuwijk, [6]Department of Internal Medicine, University Medical Center Groningen, Netherlands.

Background and aims: Self-monitoring of blood glucose (SMBG) improves glycemic control in patients using insulin. Apparently, in patients with type 2 diabetes mellitus (T2DM) not using insulin SMBG does not result in improvement of glycemic control. In previous studies, either no effect on health related quality of life (HRQoL) was found, or, like in the ESMON trial, SMBG resulted in more depressive symptoms. Our aim was to investigate the effect of SMBG (postprandial values) on HRQoL and treatment satisfaction in patients with T2DM not using insulin who are in persistent moderate glycemic control.
Materials and methods: Patients were eligible when between 18 and 70 years of age, with an HbA1c between 7 and 8.5% at the start of the study (at annual check-up) and at the previous annual check-up, using 1 or 2 different oral blood glucose lowering drugs without regimen change during the preceding 3 months, and without use of SMBG in the preceding 6 months. Forty patients were randomly assigned to receive either SMBG added to usual care or to continue with usual care during 1 year. SMBG was performed using the Accu-check Aviva blood glucose meter. Twice a week (including either Saturday or Sunday), a fasting glucose value and 3 postprandial glucose values were measured. All participants were instructed about acceptable glucose values (fasting: 4-8 mmol/L, postprandial: 4-10 mmol/L) and no specific (dietary) advice was given. HbA1c was measured every 3 months. Blood glucose lowering therapy was intensified when HbA1c was ≥ 8.5%. At baseline, after 6 and after 12 months, HRQoL and treatment satisfaction were assessed using the short form 36 questionnaire (SF-36), the Type 2 Diabetes Symptom Checklist (DSC-type 2), the Diabetes Treatment Satisfaction Questionnaire (DTSQ) and the WHO-wellbeing index (WHO-5).
Results: Recruitment took place between March 2006 and October 2007. At baseline, mean age was 59 years, median diabetes duration was 6.0 years, mean HbA1c was 7.6%, and mean BMI was 31 kg/m^2. At the end of the study, there were no significant changes between groups on the DTSQ, the DSC-type 2, the WHO-5 or on the physical and mental component summary scores of the SF-36. The SF-36 dimension 'health change' was lower in the SBMG-group (mean difference: -12 (95%CI: -20.9, -3.1; p=0.008)).
Conclusion: Tablet-treated T2DM patients rating their health over a 1 year period experienced a worsening on the dimension 'health change' when performing SMBG. On top of the absence of a clinical benefit, we conclude that there is no evidence for a positive impact of SMBG on HRQoL or treatment satisfaction in T2DM patients not on insulin. We argue therefore, that the use of SMBG in this patient group should be reconsidered.

A randomized, controlled trial of blood-glucose self-monitoring in type 2 diabetic patients receiving conventional insulin treatment
M.A. Nauck[1], L. Heinemann[2], M. Gutzeit[1], B. Haastert[3], S. Petrick[1], C. Trautner[4], M.A. Nauck[5];
[1]Diabeteszentrum Bad Lauterberg, [2]Profil Institut für Stoffwechselforschung, Neuss, [3]mediStatistica, Neuenrade, [4]Fachhochschule Braunschweig/ Wolfenbüttel, Wolfenbüttel, [5]Laboratoriumsmedizin, Uni-Klinikum Greifswald, Germany.

Background and aims: Blood-glucose self monitoring (SMBG) is necessary and cost-effective within intensified insulin regimens. Whether SMBG helps obtaining better glycaemic control in type 2-diabetic patients on conventional insulin regimens (premixed insulin twice daily or basal insulin once daily, with or without OAD) is not known. Our randomized, controlled, multicentric study aimed at clarifying potential improvement in glycaemic control with a once-weekly glucose profile (SMBG) in such patients.

Materials and methods: 244 patients participated (300 patients randomized, 56 early drop-outs). All patients were instructed to use urinary glucose monitoring once daily (after breakfast). 125 were randomly selected not to perform SMBG (- SMBG), 119 were instructed to use once-weekly 4-point glucose profiles (+ SMBG). Baseline age was 66 ± 8 vs. 65 ± 8 years, 64.0 vs. 56.3 % were male, premixed insulin was used in 52.8 vs. 58.0 %, HbA_{1c} was 7.3 ± 1.2 vs. 7.3 ± 1.3 %, BMI was 30.8 ± 5.4 vs. 30.0 ± 4.6 kg/m^2, and diabetes duration was 12 ± 9 vs. 12 ± 8 years for the - SMBG and + SMBG groups (mean ± SD, all not significant). Patients were seen (at least) at 3-monthly intervals to evaluate any necessity for therapy intensification (adding antidiabetic agents or increasing their doses) and for the determination of HbA_{1c} (HPLC, normal values 4.0-6.2 %). Primary endpoint was HbA_{1c} after 12 months (adjusted ANCOVA with baseline HbA_{1c} as covariate). Secondary analyses determined the probability of therapy intensification with increasing percentage of glucose-positive urine tests (all patients), with increasing HbA_{1c} values, and with increasing glucose concentrations as determined by SMBG (only those assigned to this arm), estimated by logistic regression (generalized linear mixed models) using corresponding quintiles as independent class variables, adjusted for visit, treatment group (fixed effects) and repeated measurement.
Results: Adherence to urinary glucose control was 90.7-98.4 % in both groups. 95.7-98.3 % of those assigned to + SMBG performed glucose profiles vs. 6.5-8.1 % in the - SMBG group. HbA_{1c} was reduced in both groups, to 7.0 ± 1.0 (- SMBG) vs. 7.0 ± 1.2 % (+ SMBG; $p = 0.93$ for a difference between groups). The frequency of therapy intensification was similar in both groups. The odds ratios for therapy intensification rose with increasing proportions of urines testing positive for glucose ($p = 0.0007$; $n = 235$). The odds ratios for therapy intensification, likewise, rose with increasing HbA_{1c} values ($p < 0.0001$; $n = 134$), increasing fasting glucose (as determined by SMBG; $p = 0.0007$; $n = 117$), and increasing postprandial glucose ($p = 0.0004$; $n = 116$).
Conclusion: On a background of urinary glucose testing, additional 4-point glucose profiles once weekly did not further improve glycaemic control in type 2-diabetic patients receiving conventional insulin treatment. However, in those patients performing SMBG, therapy intensification was significantly more likely with higher values measured, indicating a clear association to SMBG. The magnitude of therapy intensification introduced may have been too small to finally affect overall glycaemic control.

Exploring patient beliefs about blood glucose monitoring
W.H. Polonsky[1], L. Fisher[2], Z. Jelsovsky[3], C.G. Parkin[4], B. Petersen[5];
[1]Behavioral Diabetes Institute, San Diego, [2]University of California San Francisco, [3]Biostat International, Inc., Tampa, [4]CGParkin Communications, Inc., Carmel, [5]Roche Diagnostics Corporation, Indianapolis, United States.

Background and aims: Self-monitoring of blood glucose (SMBG) is a cornerstone of personal diabetes management. However, recent evidence suggests that many people with diabetes do not check blood glucoses regularly and/or do not use SMBG data to adjust their own care. A variety of psychosocial factors may contribute to low SMBG, but few studies have explored these potential relationships. We examined the impact of affective factors (depressed mood, diabetes-related distress) and specific attitudinal factors (personal beliefs about the value of SMBG) on SMBG frequency (number of SMBG tests/week) and personal use of SMBG results (number of SMBG tests/week that were then used to adjust therapy) in type 2 diabetes (T2DM).
Materials and methods: Four hundred and three poorly-controlled ($HbA_{1c} \geq 7.5\%$), insulin-naive T2DM subjects were drawn from a large, multicenter study in the United States. Subjects completed a questionnaire that included five sets of variables: demographic information; diabetes status (e.g., HbA_{1c}, BMI); diabetes self-care behaviors; affective status (e.g., depressed mood, diabetes-related distress); and SMBG-related attitudes (7 newly created items; e.g., "I just find the SMBG results to be discouraging", "there is no rhyme or reason to the results I see"). The variables were included in multiple regression equations predicting frequency of SMBG and use of SMBG results.
Results: Sixty-four percent of subjects were white and they were evenly divided by gender (53.0% male). Mean age, HbA_{1c}, BMI, and duration of diabetes were 56.0 years (± 10.7), 8.9% (± 1.2), 34.5 (± 7.2) and 7.6 years (± 5.9), respectively. Many subjects evidenced negative SMBG attitudes; e.g., approximately one-quarter or more agreed that their own SMBG results were typically discouraging (31.7%), confusing (19.5%), and/or that they could do nothing to influence the results (20.6%). The seven SMBG items were submitted to a Principal Factor Analysis with Promax rotation, yielding a single coherent factor accounting for 52% of the total variance (alpha=0.84). We therefore computed a total SMBG beliefs score, with higher numbers indicating a more negative attitude towards SMBG. Negative SMBG attitude was associated with depression ($r = 0.15$; $p < 0.05$) and diabetes-related distress ($r = 0.33$; $p < 0.05$). Multiple regression analysis indicated that, adjusted for demographic variables, negative SMBG attitude, but not depressed mood or diabetes-related distress, was independently associated with lower SMBG frequency ($p < .02$) as well as less personal use of SMBG results ($p < .05$).
Conclusion: Beliefs about SMBG are linked to actual SMBG frequency and use of test results, independent of all other study variables. We found that negative beliefs about SMBG are common and are associated with depressed mood and diabetes-related distress, but neither depressed mood nor distress are associated with SMBG use. This suggests that patients may not follow recommendations for regular SMBG use because they do not understand how to interpret and/or make use of their results. This underscores the importance of HCPs and patients working collaboratively to make effective use of SMBG data.

Glucose concentrations at the site of subcutaneous insulin delivery in patients with type 1 diabetes
W. Regittnig[1], S. Lindpointner[1], S. Korsatko[1], G. Köhler[1], R. Kaidar[2], O. Yodfat[2], H. Köhler[3], M. Ellmerer[1], T.R. Pieber[1,3];

Background and aims: Type 1 diabetes is presently treated by self-administration of insulin, either by subcutaneous bolus injection or by continuous subcutaneous infusion. Type 1 diabetic patients furthermore separately self-monitor glucose levels in blood obtained by finger-pricking to guide the adjustment of insulin dosage. In order to simplify and improve the treatment of type 1 diabetes, we propose to use the site of subcutaneous insulin administration for the measurement of glucose. The aim of the present study was to test the feasibility of estimating blood glucose concentrations from the glucose levels directly measured at the site of subcutaneous insulin delivery in diabetic subjects.
Materials and methods: Three 24-gauge microperfusion (MP) catheters were inserted into the subcutaneous adipose tissue of ten type 1 diabetic subjects (2 females, 8 males; age 39.8 ± 2.9 years; BMI 25.3 ± 1.0 kg/m^2; HbA_{1C} 7.6 ± 0.3 %, all C-peptide negative). One MP catheter was perfused with rapid-acting insulin (100 U/ml, Aspart), and used for insulin delivery and simultaneous glucose sampling during an overnight fast and after ingestion of a standard glucose load (75 g). As controls, the other two MP catheters were perfused with an insulin-free perfusate (5 % mannitol), and used for glucose sampling only. Blood glucose was measured frequently at the bedside. Tissue glucose concentrations were calculated from glucose and conductivity levels determined in the effluent samples of the MP catheters.
Results: Insulin delivery with the MP catheter was adequate to achieve normoglycemia during fasting and to restore normoglycemia by ~5 hours after glucose ingestion. Furthermore, tissue glucose concentrations derived with the insulin-perfused probe agreed well with glucose levels measured in blood plasma. Bland & Altman analysis revealed a median residual 2SD value of 31.6 % (interquartile range: 26.4 - 34.6 %), and error grid analysis indicated that the percentage number of the tissue values falling in the clinically acceptable range is 99.6 %. Comparable analysis results were obtained for the two mannitol-perfused MP catheters.
Conclusion: Our data suggest that estimation of plasma glucose concentrations from the glucose levels directly observed at the adipose tissue site of insulin delivery is feasible and its quality is comparable to that of estimating plasma glucose concentrations from the glucose levels measured in insulin-unexposed adipose tissue.

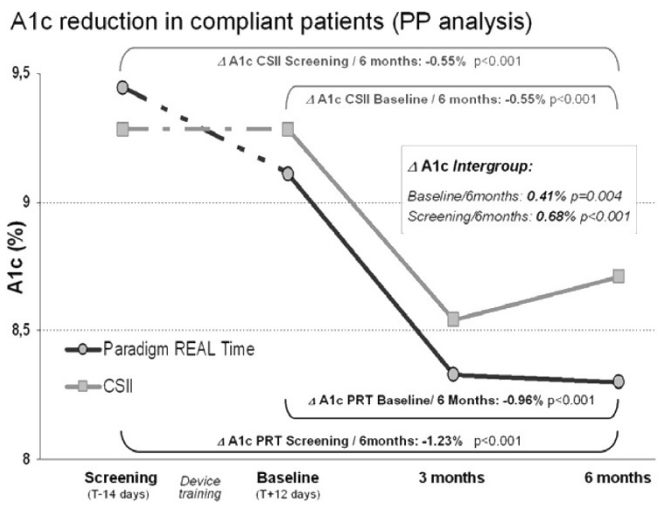
The RealTrend study: effect of continuous glucose monitoring on metabolic control in addition to pump therapy in poorly controlled type 1 diabetic patients

D. Raccah[1], V. Sulmont[2], Y. Reznik[3], B. Guerci[4], E. Renard[5], H. Hanaire[6], N. Jeandidier[7], M. Nicolino[8];
[1]University Hospital Sainte Marguerite, Marseille, [2]University American Memorial Hospital, Reims, [3]University Cote de Nacre Hospital, Caen, [4]University Hospital Jeanne d'Arc, Nancy, [5]University Hospital Lapeyronie, Montpellier, [6]University Hospital Rangueil, Toulouse, [7]University Hospitals, Strasbourg, [8]Pediatric Endocrinology, University Hospital Debrousse, Lyon, France.

Background and aims: Efficacy of insulin pump augmented with continuous glucose monitoring (CGM) versus Continuous Subcutaneous Insulin Infusion with standard self-monitoring of blood glucose has not yet been determined.
Materials and methods: In this randomized, controlled, multi-center trial, 132 adults and children with type 1 diabetes, insufficiently treated with multiple daily insulin injections (A1c≥ 8%) were assigned to a 6 months treatment in one of 2 study arms: PRT arm, fitted with the Paradigm REAL Time System (Medtronic insulin pump with integrated CGM), or CSII arm, fitted with an insulin pump and conventional blood glucose self-monitoring. In the PRT arm, patients wore glucose sensors for 9 training days prior to baseline HbA1c. HbA1c change between baseline and study end served as a primary endpoint in the 2 study arms. Secondary endpoints included hyper- and hypoglycemia parameters measured by CGM: average glucose, time spent above and below hyper- and hypoglycemia limits, and respective area under the curve.
Results: HbA1c was analyzable for 115 patients (46 children, 69 adults) of the full analysis population (FAS) and improved between baseline and study end in the two groups (PRT, n=55, -0.81%±1.09; CSII, n=60, -0.57%±0.94; p=0.087). A per protocol (PP) analysis of 91 patients (35 children, 56 adults) who wore sensors over 70 % of the time (as required by the inclusion criteria) showed a significant difference in A1c reduction between groups (PRT; n=32; -0.96%±0.93, CSII, n=59; -0.55%±0.93, p=0.004). Ancillary analyses revealed a significant decrease in HbA1c levels between the screening visit and the end of the study (PRT -1.14±1.21, p<0.001; CSII group -0.57±0.91, p<0.001), as well as a significant difference in favor of the PRT group (p=0.006) for the entire study population as well for the per protocol population (PRT -1.23±1.08, p<0.001; CSII -0.55±0.90, p<0.001; inter-group comparison: p<0.001). In PRT group, CGM hyperglycaemia parameters decreased in line with HbA1c, without increased hypoglycaemia.
Conclusion: In both FAS and PP populations HbA1c decreased in both study arms after treatment was changed from MDI to CSII or PRT, but improved significantly more in the PRT group when patients wore the CGM more than 70% of the time versus CSII.



90

Sensor augmented pump therapy substantially lowers HbA_{1c}; a randomized controlled trial

J. Hermanides[1], K. Nørgaard[2], D. Bruttomesso[3], C. Mathieu[4], A. Frid[5], C.M. Dayan[6], P. Diem[7], C. Fermon[8], I.M.E. Wentholt[1], J.B.L. Hoekstra[1], J.H. DeVries[1];
[1]Academic Medical Centre, Amsterdam, Netherlands, [2]Hvidovre Hospital, Denmark, [3]University of Padova, Italy, [4]Catholic University Leuven, Belgium, [5]Malmö University Hospital, Sweden, [6]University of Bristol, United Kingdom, [7]University of Bern-Inselspital, Bern, Switzerland, [8]Lille University Hospital, France.

Background and aims: An insulin pump augmented with a continuous glucose monitor (CGM) and mealtime insulin dose advisor is the first step towards a closed-loop system. This is the first randomized trial to investigate efficacy of this integrated system as compared to multiple daily injection therapy with SMBG.
Materials and methods: In an investigator-initiated multinational multicenter controlled trial (Eurythmics trial ISRCTN22472013), we randomized 83 diabetes type 1 patients, age 18-65 years and HbA1c ≥ 8.2%, to receive either 26 weeks of continuous treatment with a sensor augmented insulin pump (SAP) (Paradigm® REAL-Time) or standard care with multiple daily injection therapy (MDI). In both arms, treatment was preceded by 6 days of retrospective CGM use and treatment was optimized based on this information. A blinded six day CGM recording was taken in the MDI group at 13 and 26 weeks. HbA1c at 13 and 26 weeks was measured and the occurrence of severe hypoglycaemia (requiring third party assistance) was scored. Analyses were performed using ANCOVA models, adjusting for baseline values and centre.
Results: Baseline characteristics in the SAP group (n=44) and MDI group (n=39) were: mean age (± SD) 39 ± 12 and 37 ± 11 years; diabetes duration 17 ± 11 and 21 ± 9 years and 50% and 46% female, respectively, while 43/44 (98%) and 35/39 (90%) patients completed the trial. Mean HbA1c (± SD) in the SAP group decreased from 8.46 ± 0.95% to 7.23 ± 0.65% after 26 weeks. In the MDI group mean HbA1c was 8.59 ± 0.82% at baseline and 8.46 ± 1.04% after 26 weeks.
The mean difference in HbA1c change after 26 weeks was -1.10% (95% CI -1.41 to -0.71, *P*<0.001) in favour of the SAP group (Figure). The proportion of patients reaching EASD/ADA HbA1c target of <7.0% was 34.1% in the SAP group and 0.0% in the MDI group, *P*<0.001. Neither the difference in number of severe hypoglycemia episodes (4 in the SAP group versus 1 in the MDI group, *P*=0.22) nor the difference in change in sensor mean area under the curve (AUC) for hypoglycaemia (<72 mg/dl) (-0.20 mg/dl*min 95% CI-0.52 to 0.11, *P*=0.20) was statistically significant.
Conclusion: Sensor augmented pump therapy effectively lowers HbA1c in poorly regulated type 1 diabetes patients without increase in hypoglycaemia. The magnitude of the difference in HbA1c change of -1.10% suggests an additive and possibly synergistic effect of the insulin pump, mealtime insulin dose advisor and CGM.

Effect of laparoscopic ileal interposition on beta cell function and insulin sensitivity in non-obese patients with type 2 diabetes mellitus

S. Vencio[1], A. DePaula[1], A. Macedo[2], A. Halpern[3], A. Mari[4], E. Muscelli[5], E. Ferrannini[5];
[1]Hospital de especialidades, Goiania, Brazil, [2]Hospital Albert Einstein, São Paulo, Brazil, [3]Universidade Estadual de São Paulo, Brazil, [4]CNR Institute of biomedical Engineering, Padova, Italy, [5]Internal medicine, Università di Pisa, Italy.

Background and aims: Bariatric surgery is very effective in achieving weight loss and improving type 2 diabetes mellitus (T2DM) in obese patients. Our aim was to evaluate T2DM in patients with a BMI below 30 kg/m2 the impact of two versions of laparoscopic ileal interposition and sleeve gastrectomy: one in which the duodenum is kept in continuity with the stomach (II-SG) and another in which a diversion of the second portion of the duodenum is applied (II-DSG).:
Subjects and methods: Twenty-two (13M/9F; 58±2 years; BMI=26.0±0.7 kg/m2) and 20 (10M/10F; 60±2 years; BMI=27.3±0.3 kg/m2) T2DM patients underwent II-SG and II-DSG, respectively. A standard OGTT (75 g) was performed before and 8-15 months after surgery; C-peptide deconvolution and mathematical modelling were used to reconstruct insulin secretion rates and beta cell function. In particular, beta cell glucose sensitivity (b-GS, slope of the insulin secretion/glucose concentration dose-response curve) and total insulin output in response to oral glucose (TIR) were calculated. Insulin sensitivity was estimated from the plasma glucose and insulin responses by the OGIS (Oral Glucose Insulin Sensitivity) index.
Results: Mean A1c decreased from 8.15 +- 2.1% to 6.06 +- 1.19 %. With II-SG, BMI fell to 21.3±0.3 kg/m2 ($p<0.05$). Fasting plasma glucose (9.4±0.7 vs 6.6±0.3 mmol/l, $p<0.001$), 2-hour glucose (20.0±1.1 vs 9.3±1.0 mmol/l, $p<0.001$) and incremental glucose area-under-curve (AUGC) (902±59 vs 643±76 mmol.1-1.h-1, $p<0.05$) were lower after surgery. Similar effects were seen after II-DSG (BMI to 22.3±0.6, $p<0.0001$, fasting plasma glucose, 11.3±1.1 vs 6.3±0.5mmol/l, $p<0.001$; 2-hour glucose, 19.8±1.2 vs 10.1±1.1 mmol/l, $p<0.001$). TIR increased from 36.8±4.3 to 55.0±6.5 nmol/m2 ($p<0.05$) with II-SG and from 41.3±3.4 to 53.6±3.4nmol/m2 ($p<0.05$) with II-DSG, while b-GS rose from 18±4 to 47±7 pmol.min-1.m-2.mM-1 ($p<0.001$) with II-SG and from 24±5 to 42±6 pmol.min-1.m-2.mM-1 with II-DSG ($p<0.05$). Insulin sensitivity rose from 265±37 to 410±20 ml.min-1.m-2 ($p<0.001$) with II-SG and from 218±23 to 428±19 ml.min-1.m-2 ($p<0.001$) with II-DSG. In the pooled data from both groups, the changes in 2-hour-glucose concentration were independently related to the changes in BMI (standardised r=-0.20), b-GS (standardised r=-0.36) and OGIS (standardised r=-0.59), with a total explained variance of 72%, $p<0.0001$.
Conclusion: In non-obese (BMI<30) T2DM, laparoscopic ileal interposition/sleeve gastrectomy, with or without diversion, effectively improves glucose tolerance by augmenting both beta cell function and insulin sensitivity. These findings lend support to the concept that the terminal ileum releases neuroendocrine signals in response to feeding which favourably impact on glucose tolerance (hindgut hypothesis).

Early effects of biliopancreatic diversion on beta cell function in morbidly obese subjects with type 2 diabetes mellitus

L. Briatore, B. Salani, G. Andraghetti, D. Maggi, G. Adami, R. Cordera; University of Genova, Italy.

Biliopancreatic diversion (BPD) normalizes glucose tolerance in morbid obese subjects with type 2 diabetes (T2DM) improving insulin sensitivity and restoring acute insulin response to glucose (AIRg). Since other secretagogues, such as arginine, stimulate insulin secretion acting on cellular pathways different from those activated by glucose, we investigated whether arginine stimulated insulin secretion was affected by BPD. We studied 13 morbid obese subjects (5 male), 6 with and 7 without T2DM, before and 1 month after BPD. We measured body weight (BW), BMI, plasma fasting glucose, HOMA-IR, insulin secretion after arginine test (5 gr of arginine were infused IV in 45 sec at basal glucose concentrations and after infusion of 20% glucose solution to reach a glucose concentration of 14 mmol/L). The acute insulin response to arginine was calculated as the mean insulin concentration in the first 5 min of test minus the value at fasting glucose (AIRa1) and at 14mmol/L glucose concentration (AIRa2). The Slope of the AIRa [(AIRa2-AIRa1)/Δplasma glucose] was calculated as a measure of glucose potentiation of β cell insulin secretion. Preoperatively T2DM were different from controls (NFG) for higher fasting glucose (9.8±0.9 vs. 4.9±0.2mmol/L,$p<0.001$), lower AIRa1 (243±111 vs. 502±86pmol/L,$p<0.01$), AIRa2 (420±179vs.1395±149 pmol/L,$p<0.001$), slope of AIRa (18.5±18.6 vs. 181.9±41.6,$p<0.001$). Insulin sensitivity, measured as HOMA-IR, was not different between T2DM and NFG. One month after BPD, in both groups, BW was reduced by 13% but all subjects were still morbid obese (mean BMI 40.8). In T2DM fasting glucose returned to normal values and HOMA-IR was improved in both groups (2.0±0.3 in T2DM,2.1±0.5 in NFG,$p<0.01$ vs.pre BPD). AIRa1 was reduced in T2DM (163±45 pmol/L) and NFG (502±86 pmol/L), probably in relation to the reduction of insulin resistance and fasting glucose. Post BPD any significant difference in AIRa2 and slope AIR disappeared due to an increase in T2DM (AIRa2 668±338 pmol/L, slope AIR 110.4±18.0) and a reduction in NFG (AIRa2 1032±123 pmol/L, slope AIR 88.8±45.8,p=ns vs.T2DM). These findings were not correlated with BW changes. The present data show that BPD induces an improvement of β function at least partially independent by weight loss, acting both on glucose- and not-glucose stimulated insulin secretion. The mechanisms underlying the improvement of β cell function after BPD are still unknown.

Cholesterol absorption decreases after Roux-en-Y gastric bypass but not after gastric banding

J.A. Pihlajamäki[1], S. Grönlund[2], M. Pääkkönen[2], L. Moilanen[1], E. Pirinen[2], M. Kolehmainen[3], M. Uusitupa[3], E. Alhava[2], T.A. Miettinen[4], H. Gyllling[3];
[1]Department of Medicine, University of Kuopio, [2]Department of Surgery, University of Kuopio, [3]Department of Clinical Nutrition, University of Kuopio, [4]Department of Medicine, University of Helsinki, Finland.

Background and aims: Cholesterol synthesis is increased and cholesterol absorption is decreased in obese and insulin resistant humans. Dietary weight loss changes this balance towards decreased synthesis and increased absorption. Of the different forms of obesity surgery Roux-en-Y gastric bypass (RYGB) is superior to gastric banding (GB) in the treatment of diabetes. Our aim was to compare effects of RYGB and GB on cholesterol metabolism in morbidly obese subjects.
Materials and methods: Fifty-five obesity surgery patients, 29 RYGB and 26 GB, were examined at baseline and 1 year after surgery. Levels of serum cholesterol precursors cholestenol, desmosterol and lathosterol (markers of whole-body cholesterol synthesis), and serum plant sterols campesterol, sitosterol and avenasterol (markers of cholesterol absorption) were measured preoperatively and at 1 year follow-up.
Results: Weight decreased by 25% and 17% in RYGB and GB groups ($p<0.001$ in both groups), respectively. As expected both operations decreased serum levels of cholesterol synthesis markers by 10-25% (all $p<0.001$), without a significant difference between the groups. However, the expected increase in cholesterol absorption markers in response to weight loss was only observed after GB and not after RYGB. The ratio of sitosterol to cholesterol, reflecting fractional cholesterol absorption, increased by 18% in GB group and decreased by 22% in RYGB group ($p=2x10^{-6}$ for difference between the groups). Although fasting insulin levels improved significantly more after RYGB than GB (-59% vs -29%, $p<0.001$), reflecting more improvement in insulin sensitivity after RYGB, the difference in sitosterol ratio between the groups remained significant after adjustment for BMI and fasting insulin levels ($p=2x10^{-4}$), indicating a specific effect of RYGB on cholesterol absorption. In both groups the change in serum sitosterol levels correlated positively with the change in serum cholesterol levels ($r=0.464$ and 0.537, $p<0.05$ in both groups), suggesting that cholesterol absorption has a role in the regulation of serum cholesterol levels after obesity surgery. However, serum total cholesterol decreased significantly only after RYGB (-9%, $p=2x10^{-3}$).
Conclusion: Decrease in cholesterol absorption post RYGB, in addition to rapid improvement in blood glucose, is a novel beneficial effect of RYGB in comparison to dietary weight loss or GB. More detailed analysis of lipid metabolism in response to different forms of bariatric surgery is required.

Mechanisms of improvement of glucose tolerance in type 2 diabetes mellitus after bariatric surgery: gastric bypass vs sleeve gastrectomy

M. Nannipieri[1], M. Anselmino[2], A. Mari[3], B. Astiarraga[1], D. Guarino[1], R. Bellini[2], S. Tramontano[2], M. Rossi[2], E. Ferrannini[1];
[1]Internal Medicine, University of Pisa, [2]Surgery, Azienda Ospedaliera Universitaria of Pisa, [3]Bio-Engineery, CNR of Padua, Italy.

Background and aims: In morbidly obese patients with T2DM, gastric bypass (GBP) restores euglycaemia early after surgery, but data on the effectiveness of sleeve gastrectomy in resolving or improving type 2 diabetes mellitus are scarce. Aims of this study were to investigate extent and mechanisms of recovery of ß-cell function and insulin sensitivity in severely obese patients with type 2 diabetes mellitus (T2DM) undergoing Roux-en-Y gastric by-pass (RYGB, predominantly restrictive) or sleeve gastrectomy (SLV, restrictive).
Materials and methods: 14 obese T2DM subjects (8 subjects treated with RYGB and 6 with SLV) were studied before, 15 and, 45 days after surgery. The early effects of surgery were assessed by comparing the response to a Mixed Meal Test (MMT) (before and 15 days after surgery, in both cases following a week of constant, low caloric intake). Insulin sensititvity was assessed by the MMT-derived OGIS index and ß-cell function by modelling analysis of the C-peptide response to MMT. An OGTT (75 g) was also performed before and 45 days after surgery (under conditions of free caloric intake).
Results: At 15 days post-surgery, BMI decreased to the same extent in RYGB and SLV subjects (from 46.6±7.8 to 44.3±7.5 kg.m-2 in RYGB and from 46.4±5.2 to 43.9±5.6 in SLV, mean±SD, p<0.0001). Glucose tolerance improved in both groups 15 days after surgery (mean glucose during the MMT: from 8.2±1.9 to 7.4±2.1 in RYGB and from 8.0±1.0 to 6.4±0.4 mmol/l in SLV, p=0.02). Mean insulin during MMT decreased in both groups (from 166±67 to 111±46 in RYGB and from 346±115 to 233±55 pmol/l in SLV, p=0.001). ß-cell glucose sensitivity (i.e., the slope of the dose-response curve of insulin secretion rates and plasma glucose concentrations) improved after surgery in both groups (from 23.2±23.7 to 46.7±38.8 in RYGB and from 44.8±45.3 to 77.2±83.0 pmol.min-1.m-2.mM-1 in SLV subjects, p=0.05). At baseline, insulin sensitivity was similar in RYGB and SLV (299±54 vs 287±16 ml.min-1.m-2, p=ns). Following surgery, insulin sensitivity tended to improve in all subjects (to 314±51 in RYGB and 358±44 ml.min-1.m-2 in SLV, p=0.05). Forty-five days after surgery, BMI decreased similarly in both groups and insulin sensitivity improved in both groups (from 302±67 to 330±44 in RYGB and from 263±20 to 320±49 ml.min-1.m-2, p=0.015).
Conclusion: Glucose tolerance, ß-cell function and insulin sensitivity are all improved within 2 weeks of bariatric surgery under conditions of constant calorie intake. These effects, which are stabilised 45 days after surgery, are equivalent with gastric bypass and sleeve gastrectomy.

Early metabolic effect of Roux-en-Y gastric bypass on insulin-resistance in morbidly obese type 2 diabetic subjects

S. Camastra[1], S. Bonuccelli[1], A. Gastaldelli[2], G. Scartabelli[3], E. Muscelli[1], D. Ciociaro[2], E. Barsotti[1], B. Astiarraga[1], F. Santini[3], A. Mari[4], M. Anselmino[5], E. Ferrannini[1];
[1]Department of Internal Medicine, University of Pisa, [2]Institute of Clinical Physiology, CNR, [3]Department of Endocrinology, University of Pisa, [4]Institute of Biomedical Engineering, CNR, Padua, [5]IV Surgery, Bariatric Surgery Division, Santa Chiara Hospital, Pisa, Italy.

Background and aims: Weight loss after bariatric surgery improves insulin resistance (IR). Recent evidence has shown that biliopancreatic diversion, a predominantly malabsorptive procedure, restores peripheral insulin sensitivity early after surgery before important weight loss. Roux-en-Y gastric bypass (RYGB), a predominantly restrictive surgery, also has been associated with hormonal changes and improved HOMA-IR prior to substantial weight loss. However, there are no data regarding the early effect of RYGB on directly measured insulin sensitivity, endogenous glucose production (EGP) and acute insulin response to intravenous glucose (AIR).
Materials and methods: We studied eleven (3m/8f) morbidly obese type 2 diabetic (T2DM) subjects (age 49±2 years, BMI=49±2 $kg \cdot m^{-2}$) before and 19±1 days after RYGB with the use of the euglycaemic hyperinsulinaemic (240 $pmol \cdot min^{-1} \cdot m^{-2}$) clamp technique in combination with tracer infusion (6,6-$^2H_2$-glucose and 1-^{2}H-glycerol) to measure EGP and whole-body lipolysis, respectively. AIR was measured following an intravenous glucose bolus with the use of C-peptide deconvolution.
Results: After surgery, body weight had decreased by 7% (133±9 *vs* 123±8 kg, p=0.003). At this time, fasting plasma glucose (7.9±0.6 *vs* 6.8±0.4 mmol/l, p=0.01) and insulin levels (162±26 *vs* 92±13 pmol/l, p=0.003) were significantly reduced. On the clamp, peripheral insulin sensitivity was increased (M/I=46±6 *vs* 33±7 $\mu mol \cdot min^{-1} kg_{FFM}^{-1} pM^{-1}$, p=0.03). EGP was not significantly modified (HGP=12.6±0.7 *vs* 11.4±0.7 $\mu mol \cdot min^{-1} \cdot kg_{FFM}^{-1}$, p=ns) but the hepatic insulin resistance index (EGP x basal plasma Insulin) was significantly reduced (from 2.26±0.36 to 1.25±0.12 $mmol \cdot min^{-1} \cdot kg_{FFM}^{-1} \cdot pM$, p=0.04) as was whole-body lipolysis (as indexed by the rate of systemic glycerol appearance), from 494±51 to 267±43 $\mu mol \cdot min^{-1}$, p=0.02. AIR, on the other hand, did not change significantly (65±19 *vs* 67±20 ($pmol \cdot min^{-1} m^{-2} \cdot mM^{-1}$, p=ns).
Conclusion: We conclude that in morbidly obese T2DM subjects, a mostly restrictive bariatric operation such as RYGB is associated with an early improvement in glycaemia due to increased peripheral, hepatic and adipose tissue insulin sensitivity, while beta cell function is unchanged. As weight loss at this time postsurgery is minimal, these metabolic changes are likely to be the result of calorie restriction.

96

Variation in M1/M2 macrophage balance and HDL-C phenotype in obese subjects before and after gastric bypass induced weight loss

J. Aron-Wisnewsky[1], J. Tordjman[2], C. Poitou[1], M. Guerrin[3], D. Hugol[4], N. Veyrie[5], K. Clement[1];
[1]Department of Nutrition and Endocrinology, [2]Centre de Recherche des Cordeliers, INSERM, U872 team 7, [3]INSERM, U551, [4]Anatomopathology Department, [5]Surgery Department, Paris, France.

Background and aims: Macrophages accumulate in adipose tissue in obesity and most likely participate to inflammatory related metabolic complications. Macrophage amounts vary with adipose tissue amount, site and weight modification but it is unknown whether this is accompanied by phenotypic changes in humans. Furthermore macrophages infiltration in visceral adipose tissue is negatively associated with HDL-Cholesterol concentrations. HDL-C subspecies profiles and functions have not yet been precisely characterized in obesity and after weight loss. Our aim was to characterize the activation state of adipose tissue macrophages in obese subjects, before and after gastric bypass surgery and establish a link with HDL-C phenotype variation.
Materials and methods: We performed a single center prospective study. 36 premenopausal obese women (Body mass index = 44 ± 6 kg/m^2) were followed before (T0) and three months (T3M) after a laparoscopic gastric by-pass. Quantitative HDL subspecies were evaluated at T0 and T3M as well as their qualitative features on cellular free cholesterol efflux through SR-BI and ABCG1 pathways. Paired surgical biopsies of subcutaneous and visceral adipose tissue were obtained during gastric surgery in a subgroup of 16 women. A surgical subcutaneous adipose tissue biopsy was obtained in the same obese individuals at T3M, and in 10 normal weight individuals during programmed surgery. The number of CD40 (M1 cell marker) and CD163 or CD206 (M2 markers) positive cells was determined by immunochemistry. Differences between before and after surgical weight loss were tested with a Student t test.
Results: Gastric by-pass induced a 15% weight loss and a significant improvement in insulin resistance, triglyceride and total cholesterol levels. We observed a significant 18% increase in large HDL-C subspecies concentrations (p=0.004) and a significant 25% enhancement in large HDL-C capacity to mediate free cholesterol efflux (p=0.0015). These improvements result mainly from a decreased CETP activity after weight loss. In the adipose tissue (AT), the number of CD40+ cells significantly increased with obesity and in omental AT of obese subjects, while the number of CD163+ or CD206+ cells was marginally changed. A 2-fold decrease in the ratio of CD40/CD206 cells number in subcutaneous adipose tissue of obese subjects was observed 3 months after gastric surgery (p< 0.001). This was due to the concomitant increase of CD40+ and decrease of CD206+ cells counts. Interestingly, the improvement of HDL capacity to mediate free cholesterol efflux was strongly associated with the increased in M2 macrophage in subcutaneous adipose tissue.
Conclusion: In morbidly obeses women, we observe a relationship between the variation in M1/M2 macrophage balance and the improvement of HDL-C antiatherogenic properties after gastric by-pass induced weight loss.

Glycaemic control and perinatal outcomes of pregnancies complicated by type 1 diabetes: multiple daily injections vs continuous subcutaneous insulin infusion

I. Saigí[1], A. Chico[1], L. Santos[1], A. Aulinas[1], J. Adelantado[2], G. Ginovart[3], A. Garcia-Patterson[1], R. Corcoy[1];
[1]Endocrinology, [2]Obstetrics, [3]Neonatology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain.

Background and aims: Several studies have demonstrated the superiority of continuous subcutaneous insulin infusion (CSII) compared to multiple daily injections (MDI) for improving metabolic control of type 1 diabetes (T1DM) subjects**,** but in pregnancy this remains unclear. Recent publications have reported an increased risk of ketoacidosis associated with the use of CSII.
The aim is to compare the degree of metabolic control and maternal and perinatal outcomes obtained in pregnancies of women with T1DM, treated with CSII or MDI.
Materials and methods: We analyzed 308 singleton pregnancies in women with T1DM consecutively attended at our centre. A total of 213 were treated with MDI (NPH insulin twice a day plus regular or lispro insulin before meals), and 95 were treated with CSII (using regular or lispro insulin). All patients were in the same modality of treatment before and throughout pregnancy.
Patient characteristics, variables of glycemic control and perinatal outcomes were analyzed using Chi-square test for categorical variables and non-parametric tests for quantitative variables.
Results: Patients in the CSII group were older and had a longer diabetes duration than those treated with MDI. The rate of prepregnancy consultation was also higher in the CSII group (92.9% vs 61.9%; p<0.05). Weight gain (14 vs 13.6 kg), incidence of hypoglycaemic comas (MDI 10% vs CSII 9.5%) and ketoacidosis (MDI 1.4% vs CSII 0%) were comparable between both groups. Mean blood glucose (MBG) and HbA1c levels were slightly higher at the 3 trimesters in the CSII-treated group (p<0.05). Perinatal outcomes as prematurity, large for gestational age infant (LGA), small for gestational age infant (SGA), macrosomia, major malformations, stillbirth, perinatal and neonatal mortality and neonatal hypoglycaemia, were comparable between groups.
Conclusion: Perinatal outcomes in women with T1DM treated with CSII or MDI were comparable, although the patients treated with CSII showed worse baseline characteristics and a slightly worse glycemic control. In our series, the use of CSII is not related with the presence of acute complications.

98

Prediabetes is associated with similar risks during pregnancy and delivery as obesity and overweight

U. Moll[1], H. Olsson[2], M. Landin-Olsson[1];
[1]Department of Endocrinology, [2]Department of Oncology, Institution of Clinical Sciences, Lund University, Lund, Sweden.

Background and aims: Diabetes that occurs during pregnancy (gestational diabetes GDM) can result in diabetic fetopathy, which is characterized by high birth weight and postnatal complications. In addition to GDM, obesity is an increasing problem. Obesity is associated with higher risk for complications during pregnancy and higher frequency of miscarriage, instrumental delivery and macrosomic births. Our aim was to study if the prediabetic women differed in characteristics during pregnancy and delivery from the women without diabetes who were over weighted, since obesity is a risk factor for developing gestational diabetes and type 2 diabetes
Materials and methods: The Swedish Birth Registry (Medicinska födelseregistret MFR) started 1973 and contains data regarding the health of the mothers during pregnancy and peri- and postnatal status of the infants. In a population based large cohort study including 23 524 women aged 35-75 yrs from the southern part of Sweden we have identified 802 women with diabetes. In the MFR we identified 30 559 pregnancies related to the women in our cohort. Using MFR and the cohort we could retrospectively identify the pregnancies of diabetic women, women developing diabetes later in life and women without diabetes. Overweight was defined as BMI >25. We compared characteristics between the prediabetic women (n=1008) and women without diabetes who were over weighted (n=2466). Normal weighted women without diabetes were considered a control group (n=42043).
Results: The prediabetic women were significantly younger compared to over weighted women (29.4 vs 31.5 years old; p<0.05).
Weight-gain: Prediabetic women and over-weighted women had a similar weight gain during pregnancy (13.3 vs. 13.1 kg; p=ns). This weight gain was significantly lower compared to controls (14.2 kg; p<0.05 and p<0.001). There was an inverse correlation between pre-pregnancy weight and the weight gain in both groups. For controls there was a positive correlation.
Weight of the infant: There was no difference regarding the mean weight between the infants of prediabetic women and over weighted women (3602 vs. 3659g; p=ns), but the infants were larger compared to controls (3493g; p=0,001 and p<0,001 respectively). The prediabetic women had a shorter gestational length (39.6 vs. 39.8 weeks; p<0.05) and the frequency of LGA-infants was higher in the group of prediabetic women (10.5% vs 7.1%; p=0.015).
Sectio: the prediabetic women had significantly lower frequency of caesarean deliveries than the over weighted women (4.8% vs. 8.2%; p=0.014). Both groups had a higher frequency compared to controls (2.2% p=0,001 and p<0,001 respectively).
Apgar: The infants of the prediabetic women had lower mean Apgar scores at 5 (9.5 vs. 9.7; p<0.001) and 10 minutes (9.6 vs. 9.8; p<0.001) compared to the infants of the over weighted women. Controls had significantly higher Apgar scores for 1, 5 and 10 minutes compared to both study groups (p<0,005).
Conclusion: Both prediabetic women and over weighted women without diabetes had less weight gain than controls. Despite this their infants had higher birth weight. The Apgar scores were lower and the frequency of caesarean section was higher in both groups, indicating that the deliveries were more complicated. Prediabetes seems to be associated with similar risks during pregnancy and delivery as over weight and obesity.

99

Phenotypic and metabolic characteristics of women with isolated hyperglycaemia in pregnancy

E. Anastasiou, K. Papageorgiou, A. Athanasiadou, K. Economou, V. Vasileiou, M. Alevizaki;
Alexandra Hospital, Athens, Greece.

Background and aims: Although ADA defines Gestational Diabetes Mellitus (GDM) by two abnormal values on a 3-h oral glucose test (OGTT), there are few studies that have shown that pregnant women with one abnormal value (OAV) in the OGTT present features different from those of normal women. The aim of this study is to examine in a large cohort of Greek pregnant women the phenotypic and metabolic characteristics of OAV women compared to normals and GDM, and also to test if the timing of the observed hyperglycaemia is related to any difference in their phenotype.
Materials and methods: 6671 pregnant women without known DM underwent a 100g OGTT in the third trimester of pregnancy. For GDM diagnosis the ADA 2000 criteria were used. Among these, 3384 (50.7%) were found with 4 normal values in the OGTT (Group NGT), 1107(16.6%) had one abnormal value (Group OAV), and the remaining 2180 (32.7%) had two or more abnormal values and were diagnosed as GDM (Group GDM). Further we subdivided the OAV group into three subgroups according to the time of hyperglycaemia: 315 had fasting OAV (28.5%), 471 had 1h OAV (42.5%) and 321had 2 or 3h OAV (29%). Age, height, pre-pregnancy weight and BMI, as well as family history of DM were recorded. Insulin sensitivity was measured using the insulin sensitivity index (ISI) of Matsuda and DeFronzo. For beta-cell function the index HOMA-B and the Stumvoll formulas for first and second phase insulin secretion were used. Finally the product of the first phase Stumvoll index and the ISI was calculated to obtain the insulin secretion-sensitivity index (ISSI).
Results: The characteristics of the three main groups NGT, OAV and GDM are shown in Table 1(superscripted a,b,c indicate difference from preceding group).There was also a significant difference among the three groups with regard to family DM history: mother's (NGT 7.6%, OAV 11.3%, GDM 18.2%, p<0.01), father's (9.6%, 12.9%, 14.7%, p<0.01 respectively).Regarding the three OAV subgroups: OAV-Fasting was heavier than the other two; there were no differences in ISI among them. On the other hand, the OAV-1h subgroup had the lower Stumvoll first and second phase compared to the others, and also the lowest ISSI.
Conclusion: In this large cohort of pregnant women studied the OAV group is clearly in- between the normal and GDM group in all examined parameters. Furthermore, isolated hyperglycemia seems to be heterogeneous. Fasting hyperglycemia is mainly characterized by impairment in basal insulin secretion, while OAV at 1-h presented significantly diminished stimulated insulin secretion. These data suggest that women with OAV need further attention during as well as after pregnancy.

Table 1

	NGT (n=3384)	OAV (n=1107)	GDM (n=2108)	p value
Age	30.0±5.5[a]	31.6±5.5[b]	33.1±5.3[c]	<0.01
BMI	24.7±4.5[a]	25.9±5.2[b]	27.3±6.0[c]	<0.01
Weight	64.4±12.8[a]	66.8±14.2[b]	69.8±16.3[c]	<0.01

Diet and weight gain characteristics of pregnant women with gestational diabetes

M. Salmenhaara[1], L. Uusitalo[1], U. Uusitalo[1], C. Kronberg-Kippilä[1], H. Sinkko[1], S. Ahonen[2], R. Veijola[3], M. Knip[4], M. Kaila[5], S.M. Virtanen[1]; [1]Department of Lifestyle and Participation, National Institute for Health and Welfare, Helsinki, [2]Tampere School of Public Health, University of Tampere, [3]Department of Paediatrics, University of Oulu, [4]Hospital for Children and Adolescents, University of Helsinki, [5]Paediatric Research Centre, Tampere University Hospital, Finland.

Background and aims: The prevalence of gestational diabetes (GD) has increased worldwide in recent years. Nutritional therapy is the main treatment option for GD. The aim of the study was to compare food and nutrient intake of women with GD to unaffected women in the 8th gestational month and to examine the use of dietary supplements. Additionally the study illustrates associations of background characteristics with the risk of GD and weight gain during pregnancy.
Materials and methods: Food and nutrient intake in a series of 3732 pregnant women (70% of the women eligible to the study) was studied using food frequency questionnaires (FFQ).
Results: GD was reported in 4.7% of the participating women. The weight gain during pregnancy was smaller in women with GD compared to unaffected women (mean 9.4 kg vs. 12.6 kg, p<0.001). Women with GD had more milk products (84 vs. 76 g/MJ, p=0.002), cereal products (21 vs. 18 g/MJ, p<0.001), vegetables (32 vs. 22 g/MJ, p<0.001), meat (16 vs. 14 g/MJ, p<0.001) and fish (2.6 vs. 2.2 g/MJ, p<0.001) than unaffected women. The intake of total energy (10.8 vs. 11.6 MJ, p=0.012) and fat (8.8 vs. 9.3 g/MJ, p<0.001) was smaller while intake of protein (10.6 vs. 9.5 g/MJ, p<0.001) and fibre (3.1 vs. 2.4 g/MJ, p<0.001) was higher in women with GD. The quality of fatty acids in the diet was better as well in women with GD. The nutrient density was higher in women with GD regarding vitamin A, D and E, folate, calcium and iron.
Conclusion: The diet during late pregnancy in women with GD differed profoundly from the diet in unaffected women. Women with GD had larger BMI at the beginning of pregnancy but they gained less weight during pregnancy. These findings indicate that abnormal glucose tolerance during pregnancy encourages women to shape their dietary habits towards healthier food choices.

101

Pregnancy outcomes in women with hyperinsulinaemia with impaired glucose tolerance prophylactically treated with metformin. A case control study

K.N. Todorova - Ananieva[1], E.I. Konova[2], A.L. Emin[2]; [1]High-risk Pregnancy Department, Specialized Hospital of Obstetrics and Gynecology, Sofia, [2]Clinical Institute of Reproductive Medicine, Pleven, Bulgaria.

Background and aims: To evaluate the effect of metformin on maternal and neonatal outcomes in pregnant women with hyperinsulinemia with normal and pathologic glucose tolerance.
Materials and methods: A prospective one year case-control study among 66 pregnant women with one unsuccessful pregnancy without previous glucose intolerance. 75 grams OGTTs were performed in all women during the second pregnancy at 12. gestational week (gw) and at 36. gw. The levels of blood glucose and immunoreactive insulin were measured at 0 min. 60 min. and 120 min. Women were divided into three groups according to results of initial OGTT: n_1 = 21 with normal OGTT without hyperinsulinemia, n_2 = 24 with impaired OGTT (IGT) with hyperinsulinemia and n_3 = 21 with gestational diabetes mellitus (GDM) with hyperinsulinemia. Women with IGT and GDM were placed on metformin (0.75 - 1.5 g/day) according to levels of immunoreactive insulin after glucose loading. Participants were matched for age, BMI, number of previous pregnancies with abortions. Maternal and neonatal complications were recorded. Statistical methods: ANOVA - with multiple comparison and chi square test have been used.
Results: No statistically significant difference in mean values for age and BMI. The blood glucose levels in early pregnancy measured before and during glucose loading were significantly higher in pregnant with GDM. No difference was observed in initial levels of insulin in early pregnancy (0 min. n_1 = 11.4 ± 8.5 mIU/ml, n_2 = 13.6 ± 4.5 mIU/ml, n_3 = 15.8 ± 9.8 mIU/ml, P=0.06), but stimulated insulin levels after glucose loading were higher in second and third groups (60 min. n_1 = 56.8 ± 20.8 mIU/ml, n_2 = 70.1 ± 41.9 mIU/ml, n_3 = 74.8 ± 44.1 mIU/ml, P=0.04). BMI in late pregnancy was statistically lower in pregnant with normal OGTT (BMI n_1 = 26.8 ± 3.6 kg/m^2 n_2 = 28. 3± 3.6 kg/m^2, n_3 = 29.5 ± 4.2 kg/m^2, P=0.001). There was statistically difference in mean levels of BMI compared in early and late pregnancy in all groups. The level of blood glucose in late pregnancy was lowest in second group [(basal: (n_1 = 5.9 ± 0.5mmol/l, n_2 = 5.6 ± 0.4mmol/l, n_3 = 5.8 ± 0.4mmol/l, P=0.04; (60 min. n_1 = 8.1 ± 0.8mmol/l, n_2 = 7.3 ± 0.7mmol/l, n_3 = 7.4 ± 0.7mmol/l, P=0.01); (120 min. n_1 = 7.4 ± 0.9mmol/l, n_2 = 6.5 ± 0.3mmol/l, n_3 = 6.7± 0.7mmol/l, P=0.01)]. The both initial and stimulated levels of insulin were highest in the first group [(0 min. n_1 = 20.2 ±11.5 mIU/ml, n_2 = 17.4 ± 5.8 mIU/ml, n_3 = 14.9 ± 6.1 mIU/ml, P=0.03); (60 min. n_1 = 88.4 ± 11.5 mUI/ml, n_2 = 66.2 ± 34.7 mIU/ml, n_3 = 69.6 ± 24.0 mIU/ml, P=0.01)] in late pregnancy. The levels of insulin in late pregnancy were statistically lower in n_2 and n_3 groups compared to same insulin levels in early pregnancy. No maternal complications and birth defects can be attributed to metformin. The newborns' body weight was similar in all groups (n_1 =3500.9 ± 443.5 g, n_2 = 3560.3 ± 408.9 g, n_3 = 3381.7 ± 267.2 g, P=0.6). Rate of spontaneous abortion was 13.6% (9/66). The frequency of miscarriages was highest in the first group 28.5% (6/21). The evaluation of risk factors established relationship between the high insulin levels in early pregnancy and abortions.
Conclusion: Metformin use during pregnancy improved metabolic markers and reduced spontaneous miscarried rates in women with hyperinsulinemia and impaired OGTT.

102

Osteocalcin in gestational diabetes mellitus (GDM): does bone cope with pancreatic beta cell dysfunction?

Y. Winhofer[1], A. Handisurya[1], A. Tura[2], C. Bittighofer[1], K. Klein[3], B. Schneider[4], G. Pacini[2], O. Wagner[5], A. Luger[1], A. Kautzky-Willer[1]; [1]Department of Internal Medicine 3, Division of Endocrinology and Metabolism, Medical University of Vienna, Austria, [2]Institut of Biomedical Engineering, National Research Council, Padova, Italy, [3]Division of Obstetrics and Feto-Maternal Medicine, Medical University of Vienna, Austria, [4]Institute of Medical Statistics, Medical University of Vienna, Austria, [5]Clinical Institute of Medical and Chemical Laboratory Diagnostics, Medical University of Vienna, Austria.

Background and aims: Osteocalcin, an osteoblast derived protein involved in bone formation, was reported to exert endocrine function by increasing insulin secretion as well as insulin sensitivity, thereby preventing the development of diabetes mellitus in experimental animals. Furthermore, patients with type 2 diabetes (T2DM) were shown to have decreased levels of osteocalcin suggesting that osteocalcin deficiency could in fact play a role in the pathogenesis of T2DM. Since gestational diabetes (GDM) serves as a model for early changes in the pathophysiology of T2DM and since beta-cell dysfunction seems to be an essential feature of GDM, the aim of this investigation was to study osteocalcin in GDM pregnancy.
Materials and methods: 37 women with gestational diabetes (GDM) were compared to 37 women with normal glucose tolerance during pregnancy (NGT) matched for age and BMI (GDM: BMI:29±5,3 kg/m², age:34,4±6,3a; NGT: BMI:29,2±5,4 kg/m², age:32±5,4a). All women underwent an oral glucose-tolerance-test (oGTT) between 24-28 gestational weeks. Plasma

concentrations of osteocalcin, lipids, HbA1C were measured at fasting and glucose, insulin and c-peptide were assessed at 0, 30, 60, 90 and 120 minutes after ingestion of 75g glucose to calculate metabolic parameters (i.e.for insulin secretion, insulin sensitivity) by mathematical modeling. 12 GDM and 12 NGT were also restudied 8-10 weeks postpartum.
Results: Osteocalcin was significantly increased in GDM compared to NGT (15,6±5,6 vs. 12,8±4,3 ng/ml, p=0,0165) during pregnancy. We found a weak but significant correlation between osteocalcin and insulin secretion (p<0,02) as well as areas under the curve of glucose and c-peptide during oGTT. Furthermore, the adaptation index (OGIS*Total insulin secretion), which describes the capacity of the beta-cell to release increasing amounts of insulin to compensate for rising insulin resistance, was positively correlated with osteocalcin (p<0,02). At 8-10 weeks postpartum osteocalcin, as shown previously, was significantly increased, but was not different between NGT and GDM, who had already regained normal glucose tolerance.
Conclusion: Our data extend previous findings in women with GDM that osteocalcin could be involved in regulation of glucose metabolism potentially via stimulation of insulin secretion by an endocrine pathway. The fact that osteocalcin is elevated in GDM might suggest a compensatory mechanism in these women to cope with pancreatic beta-cell dysfunction.

OP 18 Molecular mechanisms of type 2 diabetes mellitus and obesity

103

Signatures of selection at the *FTO* (fat mass and obesity associated) locus in human populations
K. Dietrich[1], K. Schröck[2], D. Schleinitz[1], B. Enigk[1], I. Müller[1], K. Krohn[1], M. Stumvoll[3], P. Kovacs[1], A. Tönjes[3], T. Schöneberg[2];
[1]Interdisciplinary Centre for Clinical Research, [2]Institute for Biochemistry, Department of Medicine, [3]Department of Medicine, University of Leipzig, Germany.

Background and aims: Polymorphisms in the first intron of *FTO* (rs9939609) were identified in genome-wide association studies as a risk factor for obesity. In the Sorbs, a population resident in Eastern Germany, we verified this association. However, a SNP (single nucleotide polymorphism) in the third intron of *FTO* (rs17818920) showed even stronger effects on BMI in the Sorbs. This may indicate population genetic-relevant variants of *FTO* alleles. Since comprehensive data regarding *FTO* evolution are lacking, we initiated studies searching for signatures of selection in mammals and human populations.
Methods: First, we analysed the coding region of 13 mammalian *FTO* orthologs with Phylogenetic Analysis by Maximum Likelihood (PAML, $\omega=d_N/d_S$) to screen for signatures of selection between species. Second, in 34 non-related subjects of the Sorbian cohort 307 SNPs of the *FTO* locus (1 Mb) were extracted from the data obtained by genome-wide scans using 500K/6.0 Affymetrix GeneChips®. Additionally, phased (Phase version 2.1) SNP data of the HapMap (Europeans/CEU, Yoruba/YRI, Chinese/CHB, Japanese/JPT) and the Sorbs were analysed for signatures of selection with DnaSP version 4.5 and the Haplotter/PhaseII.
Results: The d_N/d_S analyses revealed that the *FTO* gene is highly conserved among the species analysed ($\omega<1$), hence being subjected to an overall purifying selection. Population genetic analyses provide significant evidences ($p<0.02$) for non-neutral evolution of *FTO* alleles in all investigated populations. Sliding-window analyses of phased SNP data show highly significant ($p<0.001$) signatures for recent selection specifically in the third intron of *FTO* in the Sorbs and other cohorts (Tajima's D in Sorbs: 2.77, CEU: 3.60, CHB: 2.73, JPT: 3.08, YRI: 3.46).
Conclusion: Population genetic analyses revealed signatures of recent selection at the *FTO* locus in Sorbs and other human populations. The strongest signal is observed in the third intron, a genomic region where the strong association with BMI in the Sorbs was found. Data provide some evidence to support the thrifty-gene theory where *FTO* variants were selected to accumulate energy more efficiently.

104

Association between fat intake, physical activity and mortality depending on genetiv variation in FTO
E. Sonestedt, B. Gullberg, E. Wirfält, B. Hedblad, M. Orho-Melander;
Department of Clinical Sciences, Lund University, Malmö, Sweden.

Background and aims: Genetic variation in the fat mass and obesity associated gene (FTO) has been associated with obesity, appetite regulation and mortality. We recently observed interactions between FTO genotype and fat intake or physical activity on risk of obesity. The increase in BMI across genotypes was mainly restricted to individuals reporting high fat intake or low level of leisure-time physical activity. The aim was to examine the association between total mortality and FTO genotype and to examine the association between fat intake or physical activity and mortality depending on FTO genotype.
Materials and methods: In the population-based Malmö Diet and Cancer study 4,839 individuals were genotyped for the rs9939609 in FTO, and had information on dietary intake (from a modified diet history method), leisure time physical activity (from duration participants spent on 18 different physical activities) and direct anthropometric measures. Vital status during a mean follow-up of 12.5 years until 31 December 2005 was recorded. We used Cox proportion hazard regression model to estimate total mortality for FTO genotype and gender-specific tertiles of fat intake (energy percentage) or leisure-time physical activity. The analyses were adjusted for sex, age, BMI, diabetes status at baseline, alcohol habits, smoking, education, and fat intake or leisure-time physical activity. Interaction was assessed by introducing a multiplicative factor.

Results: A total of 462 deaths occurred during the follow-up time. The FTO genotype was not significantly associated with mortality (HR, 1.01; 95% CI, 0.83-1.22 for A-allele carriers compared to TT-carriers). However, among A-allele carriers, higher fat intake was associated with increased mortality (HR, 1.42; 95% CI,1.06-1.99; P-trend, 0.02 for highest compared to lowest tertile), whereas fat intake was not related to mortality among TT-carriers (P=0.80). A tendency of interaction between fat intake and FTO genotype on mortality was observed (P=0.16). The interaction was stronger (P=0.04) when excluding individuals reporting a substantial dietary change in the past (approximately 25 % of the study population). High leisure-time physical activity was associated with decreased mortality among TT-carriers (HR, 0.62; 95% CI, 0.42-0.93; P-trend, 0.02 for highest compared to lowest tertile), whereas the level of physical activity was not related to mortality among A-allele carriers (P=0.75). A significant interaction between physical activity level and FTO genotype on mortality was observed (P=0.05).
Conclusion: Our results indicate that FTO genotype may modify the association between fat intake or physical activity and mortality, and propose that risk genotype carriers may benefit from restriction of fat intake.

Amino acid variants in the melatonin receptor type 1B associate with increased risk of obesity
E.A. Andersson[1], B. Holst[2], T. Sparsø[1], K. Banasik[1], J. Holmkvist[1], T. Jørgensen[3,4], K. Borch-Johnsen[5,6], K.L. Egerod[2], T. Lauritzen[7], A. Sandbæk[7], T.W. Schwartz[2], O. Pedersen[1,3], T. Hansen[1,8];
[1]Hagedorn Research Institute, Gentofte, [2]Laboratory for Molecular Pharmacology, Copenhagen, [3]Faculty of Health Sciences, Copenhagen, [4]Research Centre for Prevention and Health, Glostrup, [5]Steno Diabetes Center, Gentofte, [6]Faculty of Health Sciences, Aarhus, [7]Department of General Practice, Faculty of Health Sciences, Aarhus, [8]Faculty of Health Sciences, Odense, Denmark.

Background and aims: Common variants in the Melatonin Receptor type 1B (*MTNR1B*) locus increase fasting plasma glucose (FPG) and the risk of type 2 diabetes (T2D). The aim of this study was to evaluate if coding variation in *MTNR1B* associates with measures of T2D and obesity.
Materials and methods: The coding regions of *MTNR1B* were sequenced in 47 Maturity-Onset Diabetes of the Young (MODY) probands and in 51 probands with early-onset (<40 years) familial T2D. Six non-synonymous variants (L60R, V124I, rs8192552 (G24E), rs61746674 (R138C), rs8192553 (R231H) and rs61747139 (K243R)) were genotyped in the population-based Inter99 (n=6,000), T2D patients from the Danish ADDITION study (n=1,567) and additional non-diabetic individuals (n=618) and T2D patients (n=1,643) from the Steno out-patient clinic.
Results: Three novel non-synonymous variants (V124I, Y141C, R248Q) were identified in three unrelated probands with familial early-onset T2D. R248Q and Y141C did not co-segregate with diabetes in the families and were not detected in 384 Danish control individuals. V124I was identified in one obese (BMI 35 kg/m^2) T2D patient (age at diagnosis 36yrs). Among all genotyped individuals, the frequency of 124I was 0.4%. 124I associated with increased risk of overweight (OR=2.4 [1.3-4.5], *P*=0.006), obesity (OR=2.4 [1.2-4.9], *P*=0.02) and increased BMI (β = 1.9kg/m^2 [0.7; 3.1], *P*=0.002), weight (β = 5.2kg [1.5; 8.9], *P*=0.006) and waist circumference (β = 4.0cm [0.8; 7.1], *P*=0.01). No association with T2D was observed. Codon 24E associated with increased risk of overweight (OR=1.2 [1.1-1.3], *P*=0.004), obesity (OR=1.3 [1.1-1.5], *P*=0.0008) and with increased BMI (β = 0.4kg/m^2 [0.1; 0.7], *P*=0.004), weight (β =1.1kg [0.3; 2.0], *P*=0.006) and waist circumference (β = 0.9cm [0.3; 1.6], *P*=0.007). No association with T2D was observed. However, 24E associated with increased insulin response after an oral glucose load (BIGTT-AIR: β = 4% [0.9; 6.5], *P*=0.01) and decreased FPG (β = -0.032mmol/l [-0.063; -0.0017], *P*=0.04), an association that was strengthened when adjusting for the difference in BMI (*P*=0.003). L60R was only present in 6 of all genotyped individuals. 60R associated with decreased BMI (β = -4.5 kg/m^2 [-8.8;-0.3], *P*=0.04). Non-diabetic carriers of 60R had decreased acute insulin response, as measured by BIGTT-AIR (β = -60% [-106; -14], *P*=0.01) and the insulinogenic index (β = -85% [-151; -18], *P*=0.01). No associations with T2D or measures of obesity were observed for R138C, R231H, and K243R.
Conclusion: We demonstrate that non-synonymous variation in *MTNR1B* modulates the risk of obesity. 124I and 24E associate with increased the risk of overweight and obesity and associate with quantitative measures of obesity, while 60R associates with decreased BMI.

Genome-wide expression profiling of human subcutaneous and visceral adipose tissue precursor stromal cells
S. Perrini, R. Ficarella, A. Cignarelli, A. Peschechera, A. Conserva, M. Barbaro, M.C. Carreira, A. Natalicchio, L. Laviola, F. Giorgino;
Endocrinology & Metabolic Diseases, University of Bari, Italy.

Background and aims: Multipotent precursor cells can be isolated from the stromal-vascular fraction (SVF) of adipose tissue specimens by collagenase digestion. In addition, it has been recently observed that mature adipocytes possess the ability to divide asymmetrically and produce progeny cells (Adipocyte-Derived Precursors, ADP), which share the same morphological, fibroblast-like appearance with the SVF-derived stem cells. The objective of this study was to investigate the biological features of these two different precursor cell populations.
Materials and methods: SVF and ADP were isolated from paired subcutaneous (SC) and visceral (V) fat biopsies of 4 subjects (1F/3M, age 65±1 years, BMI 24.9±1.4) with normal glucose tolerance, cultured up to 4th passage, and then studied. A DNA microarray-based, genome-wide differential gene expression analysis was performed on SVF and ADP obtained from SC and V human adipose tissue. The expression of specific differentiation markers was assessed by real-time RT-PCR.
Results: Both types of cells resulted to be positive for the adipogenic lineage markers CD105, CD44, CD49d, whereas they were negative for the endothelial and macrophage markers CD106, CD44, CD31 and CD11b, respectively. Of 25,000 genes assessed, microarray analysis identified 254 genes that were differentially expressed between SC-SVF and V-SVF (p<0.001), including members of the insulin-like growth factor binding protein family and of the sterol regulatory element binding transcription factors, and 188 genes that were found to be differentially expressed between SC-ADP and V-ADP (p<0.001), including phosphodiesterase 3B, cGMP-inhibited and signal transducer and activator of transcription 3 (STAT3). Interestingly, when the two precursor cell populations from the same fat depot were compared (SC-SVF vs SC-ADP and V-SVF vs V-ADP), the pairwise comparison yielded correlation coefficients ranging between 0.704 and 0.756, indicating a significant biological difference between SVF and ADP cells. Indeed, microarray analysis identified 191 genes differentially expressed between V-SVF and V-ADP (p<0.001), including the fat mass and obesity associated (FTO) gene, and 272 genes differentially expressed between V-SVF and V-ADP (p<0.001), including the wingless-type MMTV integration site family (WNT) gene.
Conclusion: These data demonstrate for the first time the existence of genetically heterogeneous fat-derived precursor cell populations, which additionally exhibit intrinsic depot-related gene expression profiles. These differences in fat cell progenitors may be relevant for the specific biological properties of SC and V adipose tissues in humans.

Gene expression analysis demonstrates presence of a non-coding RNA (*ANRIL*) in human islets and FACs sorted beta cells which has a potential regulatory role on *CDKN2B* expression
A. Pal[1], T. Kyriakou[2], L.J. McCulloch[1], P.R. Johnson[1,3], H. Watkins[2], M.I. McCarthy[1,2], A.L. Gloyn[1];
[1]Oxford Centre for Diabetes, Endocrinology and Metabolism (OCDEM), [2]Wellcome Trust Centre for Human Genetics, [3]Nuffield Department of Surgery, University of Oxford, United Kingdom.

Background and aims: Genome-wide association studies have identified a 200Kb region on chromosome 9 which hosts at least 2 independent signals for type 2 diabetes (T2D) [susceptibility being mediated through beta-cell dysfunction]. The closest protein-coding genes, *CDKN2A* & *CDKN2B* are tumour suppressors with primary actions as cyclin-dependent kinase inhibitors. In rodents, *Cdkn2a* over expression leads to islet hypoplasia and recapitulates the T2D phenotype, supporting a model whereby T2D-susceptibility in humans is mediated by variants which increase *CDKN2A/B* expression. Discovery of a large antisense noncoding RNA (ncRNA), *ANRIL,* transcribed from the region of maximal T2D association, and with the potential to regulate *CDKN2A/B*, raises the possibility that the T2D risk variants have primary effects on *ANRIL* expression or function, leading to tissue- & variant-specific effects on the magnitude and balance of *CDKN2A/B* transcripts. The aims of this study were to (i) determine the relative expression profiles of *CDKN2A*, *CDKN2B* and *ANRIL* in human islets & beta-cells (ii) determine the *ANRIL* transcripts present in human islets & (iii) investigate a potential regulatory role for *ANRIL* on *CDKN2A/B* expression.

Materials and methods: Relative gene expression profiles of *CDKN2A*, *CDKN2B* & *ANRIL* were determined in 22 human tissues including pancreatic islets and FACS sorted beta cells using a QRT-PCR approach on an ABI 7900HT platform. A combination of rapid amplification of cDNA ends (RACE), PCR and capillary sequencing on an ABI 3700 were used to determine the *ANRIL* transcripts present in human islets. *ANRIL* knockdown was performed using a custom designed siRNA against *ANRIL* exon 5 which was transfected into HuVec cells using Dharmafect. Transfection efficiency was determined using an siRNA to *GAPDH* and appropriate controls including a scrambled siRNA were used.
Results: *ANRIL*, *CDKN2A* and *CDKN2B* are widely expressed across a panel of 22 human tissues with high expression of all 3 in pancreatic islets and FACS sorted beta cells. RACE and direct sequencing of amplified transcripts demonstrated a single alternatively spliced *ANRIL* transcript of~1000bp consisting of 7 exons is present in human islets. Preliminary data demonstrates that a 60% [48.7%, 71.3%] *ANRIL* siRNA mediated knockdown leads to a 1.7 fold increase [1.3, 2.2; n=12] in *CDKN2B* expression with no detectable effect on *CDKN2A* expression levels.
Conclusion: Our data demonstrate that *CDKN2A*, *CDKN2B* and *ANRIL* are widely expressed with high levels of expression in human pancreatic islets and FACS sorted beta-cells. We have identified a single~1000bp *ANRIL* transcript which is present in human islets. Furthermore our data provide preliminary evidence for a regulatory role of the ncRNA *ANRIL* on *CDKN2B* expression supporting our hypothesis that T2D susceptibility may be mediated through *ANRIL*.

Hyperactivity in adrenergic signalling via alpha2A receptors contributes to human type 2 diabetes
A. Rosengren, R. Jokubka, D. Tojjar, C. Granhall, J. Tuncel, L. Eliasson, P. Rorsman, A. Salehi, L. Groop, V. Lyssenko, H. Luthman, E. Renström; Lund University Diabetes Centre, Malmo, Sweden.

Background and aims: Sequence variations in several genes have been demonstrated to contribute to the strong heredity of type 2-diabetes (T2D), but the exact pathogenic mechanisms remain largely unknown. Here we undertake a translational approach to couple genetic variations to detailed mechanistic studies.
Materials and methods: The GK rat is a model of T2D that harbours naturally occurring genetic variations that predispose to hyperglycemia. The major diabetes susceptibility locus in the GK rat, the *Niddm1* locus, is homologous to an important diabetes locus on human chromosome 10. Through repeated back-crossing of the GK rat with normoglycemic F344 rats we established congenic strains harbouring small segments of GK-derived Niddm1. These rats were investigated by insulin release measurements, high-resolution single-cell capacitance measurements of exocytosis, gene expression studies, and pharmacological and RNAi-mediated rescue experiments. 6000 individuals from the Botnia Study well-characterized for insulin secretion were genotyped. We also measured insulin secretion from human pancreatic islets.
Results: From investigations of congenic strains with different extent of GK genome we identified a 1.4 Mb locus within *Niddm1* that confers impaired insulin secretion *in vivo* and *in vitro* through defective pancreatic β-cell exocytosis. This locus contains five genes, one of which is *Adra2a* that encodes the alpha2A-adrenergic receptor. *Adra2a* was overexpressed by 59% ($P<0.01$) on the mRNA level and by 100% ($P<0.001$) on the protein level in congenic rats exhibiting impaired insulin secretion. Adra2a mediates adrenergic suppression of insulin secretion. Pharmacological receptor antagonism with yohimbine or silencing of receptor expression both led to complete normalization of insulin secretion in congenic islets. Blockade of the down-stream effector (calcineurin) of Adra2a signalling rescued β-cell function. Importantly, our results are not confined to rats. Thus, genotyping of 19 SNPs covering 500 000 bp upstream and downstream of the human *ADRA2A* gene in 6000 individuals identified a SNP rs553668 for which risk A allele carriers exhibited reduced fasting insulin secretion ($P=0.0004$), 30% decrease in insulin release in response to intravenous glucose ($P<0.001$) and 10% reduction in response to oral glucose ($P<0.01$), as well as increased risk of T2D. Moreover, human pancreatic islets from risk allele carriers secreted less insulin in response to glucose, an effect that was rescued by pharmacological inhibition of Adra2a.
Conclusion: The present study demonstrates that overexpression of the alpha2A-adrenergic receptor, due to variations in the *ADRA2A* gene, is an important mechanism for naturally occurring T2D and that this novel disease pathway is of significance for impaired insulin release and T2D in humans. In fact, this represents one of the first detailed pathogenic mechanisms for human T2D. Interestingly, rs553668 has previously been associated with increased stress sensitivity and high blood pressure in humans, which points to a possible common mechanism for components of the metabolic syndrome and T2D. The findings could open up exciting possibilities for specific diagnosis and therapeutic interventions tailored to the individual patient.

Role of p66Shc in the modulation of oxidative stress in human liver cells

F. De Stefano, S. Perrini, A. Natalicchio, F. Tortosa, A. Peschechera, M. Melchiorre, S. Martemucci, F. Losurdo, L. Laviola, F. Giorgino;
Endocrinology & Metabolic Diseases, University of Bari, Italy.

Background and aims: Oxidative stress plays an important role in the pathogenesis of non-alcoholic and alcoholic fatty liver disease. The p66 Shc protein isoform (p66Shc), through its phosphorylation on Ser36, modulates the intracellular oxidative balance in part by regulating the expression of antioxidant genes via Forkhead transcription factors. Interestingly, p66Shc was shown to be overexpressed in human type 2 diabetes. In this study, the role of p66Shc in cellular responses to oxidative stress was studied in human HepG2 liver cells.
Materials and methods: Wild-type p66Shc and mutant p66Shc, in which Ser36 had been replaced by Ala (p66Shc-Ala36), were selectively overexpressed following infection with recombinant adenoviruses (HepG2/p66Shc and HepG2/p66Shc-Ala36, respectively). Expression and phosphorylation levels of specific signaling molecules were assessed by immunoblotting techniques. Intracellular ROS generation, in the presence of the DHE probe, was evaluated by fluorimetric analysis. Subcellular FoxO3a localization was investigated by confocal microscopy.
Results: Overexpression of wild-type p66Shc was associated with increased p66Shc phosphorylation on Ser36, both under basal conditions and following exposure to H_2O_2 (by 8.0- and 10-fold, respectively; $p<0.001$ vs mock-infected or non-infected control cells). HepG2/p66Shc cells showed increased ROS synthesis, both basally and after H_2O_2 exposure ($p<0.005$). In addition, Erk-1/2 and Akt phosphorylation was increased, and FoxO3a also showed increased phosphorylation levels and consequently reduced nuclear localization both basally and after H_2O_2 exposure ($p<0.001$ vs controls). Pretreatment of HepG2/p66Shc cells with the MEK inhibitor UO126 significantly reduced Erk-1/2 phosphorylation as well as p66Shc phosphorylation on Ser36 ($p<0.001$ vs controls), and this was associated with reduced basal and H_2O_2-stimulated ROS synthesis ($p<0.005$ vs controls). Then, HepG2 cells were examined following overexpression of mutant p66Shc, in which Ser36 had been replaced by Ala (HepG2/p66Shc-Ala36). In HepG2/p66Shc-Ala36 cells, the responses to oxidative stress were blunted, since following H_2O_2 exposure phosphorylation of Erk-1/2, Akt and FoxO3a was markedly reduced, and ROS synthesis was completely abolished ($p<0.001$ vs. HepG2/p66Shc cells).
Conclusion: p66Shc overexpression in HepG2 cells leads to inactivation of FoxO3a and an increase in intracellular oxidative stress both under basal conditions and following exposure to oxidants. This largely occurs via the Erk signaling pathway, which also feeds back to promote p66Shc phosphorylation and activation. Thus, the p66Shc/Erk/Foxo3a pathway represents a novel modulator of oxidative stress-induced injury in liver cells, which might be relevant for the development of liver abnormalities in the metabolic syndrome and type 2 diabetes.

Endoplasmic stress is induced by lipopolysaccharides and high glucose and is alleviated by salicylates in cultured primary human adipocytes

S. Alhusaini, K. Lois, K. McGee, P. McTernan, S. Kumar, G. Tripathi;
CSRI, University of Warwick, Coventry, United Kingdom.

Background and aims: Obesity and type 2 diabetes mellitus (T2DM) are closely associated with chronic inflammation. Adipose tissue may have a significant role in obesity associated inflammation but, the mechanisms underlying the pathogenesis of obesity induced inflammation remains unclear. Recent findings indicate that endoplasmic reticulum (ER) stress is critical to the initiation and integration of pathways of inflammation and insulin action. The ER stress occurs when there is an accumulation of unfolded/misfolded proteins, in addition to other factors. This results in activation of the unfolded protein response (UPR) to restore functional integrity which, leads to upregulation of genes such as PERK, IRE1α, ATF6 and other protein chaperones. In turn, PERK and ATF6 interlink the JNK/NFkB pathways, known to be key mediators in obesity induced inflammation. To date, no study has examined the relationship between ER stress and inflammation in human adipocytes. Therefore, our aims were to determine the existence and causes of ER stress in human adipose tissue and primary human adipocytes along with therapeutic interventions.
Methods: Human abdominal subcutaneous (AbSc) adipose tissue (AT) was obtained from a Caucasian non-diabetic population (BMI: 27.9±7.3 kg/m^2: age 36-49 yrs; n=40; all female subjects) that underwent elective liposuction surgery, as part of the well established AT collection program. The human preadipocytes were isolated from stromal fraction, grown and fully differentiated into human adipocytes (n=5). Well differentiated adipocytes were then treated with LPS (100ng/ml to 10μg/ml), tunicamycin (750ng/ml), high glucose (30mM) and in combination with 20mM salicylate, salicylate alone and with and without DMSO (controls). To characterise protein expression of the key markers relevant to ER stress, inflammation and insulin signalling pathway, total protein and RNA was extracted from adipose tissue and cultured adipocytes using standard protocol. Western blots and Real-Time RT-PCR were performed to examine protein and RNA expression levels.
Results: The expression of ER stress proteins Calnexin1, BiP1, Ero-1α, PDI, IRE1α and Phospho-PERK were significantly increased in AbSc AT from obese compared to lean subjects (n=4; $p<0.05$ to $p<0.001$). Additional data has identified upregulation of inflammation markers NFκB, TRAF6 and myd88 in AbSc AT of obese compared to lean individuals. ER stress proteins phospho-eIF2α (n=5; $p<0.005$) and calnexin (n=5; $p<0.02$) were both significantly induced by LPS, tunicamycin and high glucose proving the existence of ER stress in differentiated human adipocytes. In the same adipocytes ER stress was significantly reduced when treated with anti-inflammatory compound salicylate. Similarly, phospho-Akt (S473) (n=5; $p<0.002$), which is an important member of insulin signalling pathway was also activated when ER stress was down-regulated by salicylate.
Conclusion: Our findings highlight, for the first time, ER stress in human AbSc AT from obese subjects as compared with lean subjects. From this study we also conclude that salicylates improve insulin sensitivity and alleviate ER stress induced by LPS and high glucose in cultured primary human adipocytes. Our future aim is to investigate the mechanisms of ER stress pathways and ER stress induced inflammation pathways in fully differentiated human adipocytes.

ASK1 specifically in adipocytes is constituent of adipose tissue stress response in central obesity: potential role of oxidative stress and inflammatory cytokines

A. Maissel[1], M. Blüher[2], T. Tarnovscki[1], I. Shai[1], I. Harman-Boehm[1], M. Stumvoll[2], N. Bashan[1], A. Rudich[1];
[1]Ben Gurion University, Beer Sheva, Israel, [2]University of Leipzig, Germany.

Background and aims: Ask1 is a MAP3K known in certain cells to mediate the activation of p38MAP kinase and JNK in response to oxidative stress, inflammatory signals (TNF-R, Toll-like receptors) and endoplasmic reticulum stress. We previously reported that in human obesity omental fat exhibits activation of JNK and p38MAP kinase in correlation with the degree of obesity-related cardio-metabolic risk. The aim of the present study was to assess the possible role of Ask1 specifically in adipocytes in adipose tissue stress response.
Materials and methods: We utilized two independent cohorts, in Leipzig, Germany, and in Beer-Sheva, Israel, from whom paired omental (OM) and subcutaneous abdominal (SC) fat samples were obtained. The protein expression and phosphorylation of Ask1 and its mRNA levels were assessed. To investigate Ask1 activation specifically in adipocytes we separated adipocytes from the stromal-vascular fraction (SVF) by collagenase digestion, and utilized 3T3-L1 adipocytes.
Results: Obesity was associated with elevated expression of Ask1 in OM at both the mRNA (~1.5-fold, $p<0.05$) and protein levels (~2-fold, $p<0.05$), as compared to the paired SC depot, and as compared to OM fat from lean people. Ask1-mRNA levels correlated in OM more strongly than in SC with fasting insulin levels and the glucose infusion rate during euglycemic-hyperinsulinic clamp ($r=0.349$ and $r=-0.510$, respectively, both $p<0.001$, n=196), and with triglycerides and non-esterified fatty acid levels. Moreover, Ask1 phosphorylation on its auto-phosphorylation site, which confers activation, was elevated 2-2.5 fold in OM of obese women, and correlated with the phosphorylation of the MAP2K MKK4 ($r=0.474$, $p<0.01$, n=19) and that of p38MAP kinase ($r=0.596$, $p<0.01$, n=19). To verify the specific contribution of adipocytes to the increased OM Ask1, collagenase digestion of fat biopsies was performed, and Ask1-mRNA was assessed separately in OM adipocytes versus OM SVF. Whereas in lean persons SVF had 6-fold higher expression of Ask1, persons with predominantly subcutaneous obesity (determined by CT) had ~2.5-fold higher expression in the adipocytes, with no change in the SVF.

In persons with predominantly intra-abdominal obesity Ask1 mRNA levels increased 4.3-fold and 1.5-fold in adipocytes and SVF fraction, respectively (both $p<0.05$) compared to the lean group. Furthermore, the Ask1-MKK4-p38MAPkinase cascade could be activated in 3T3-L1 adipocytes by TNFα, IL-1β and by exposure to H_2O_2.
Conclusion: Ask1, specifically in adipocytes, is a MAP3K activated in intra-abdominal fat in human obesity, being regulated at both the expression and phosphorylation levels. In cultured adipocytes it can be activated by pro-inflammatory cytokines and by oxidants, potentially reflecting on the stress-type and stress response developing in intra-abdominal fat in obesity.

Skeletal muscle oxydative capacity is increased in Erk1 deficient mice
V. Corcelle[1], J. Jager[1], G. Pages[2], J. Pouysségur[2], Y. Le Marchand Brustel[1], J. Tanti[1], F. Bost[1];
[1]Physiopathologie Cellulaire et Moléculaire du Diabète et de l'obésité, INSERM U895, [2]Université Nice Sophia Antipolis, CNRS UMR 6543, Nice, France.

Background and aims: Skeletal muscle exhibits metabolic flexibility. Under fed condition muscle uses glucose whereas during fasting it oxidizes lipids. In type 2 diabetic patients, the failure of a such switching is associated to intramuscular triglyceride accumulation (lipotoxicity) and insulin resistance. Some members of the MAPK family are implicated in the downregulation of insulin action and signaling. We have shown that Erk1-/- mice are resistant to high fat diet-induced obesity and protected from insulin resistance. Moreover, these mice display a higher post-prandial metabolic rate and are protected against lipotoxicity. Here, we investigate Erk1-/- skeletal muscle oxydative capacity to determine whether Erk1 invalidation could protect from lipotoxicity.
Materials and methods: Ten weeks old Erk1-/- and WT mice are sacrified after 16h of fasting. Protein expression is determined by Western Blotting and enzymatic activity with commercial kits. Electron microscopy and immunofluorescence studies were performed on isolated muscles in order to investigate mitochondria phenotype and muscular fiber composition, respectively.
Results: Under fasting, a situation rising fatty acid flux, Erk1-/- muscles display a higher expression of proteins involved in fatty acid oxidation (M-CPT1, LCAD, MCAD) and in oxydative phosphorylation (complexes 1, 2, 4; cytochrome C; UCP3). Mitochondrial complex activity and expression of transcription factors regulating fatty acid oxidation steps (PGC1, PPARa, ERRa, MEF2, FOXO1) as well as some of their targets (TFAM, MHC1) are also increased in Erk1-/- muscles. Furthermore, mitochondrial content and fiber composition are modified in Erk1-/- mice. AMPK is an important energy sensor which activation promotes fatty acid oxidation by phosphorylating Acetyl CoA Carboxylase (ACC). Phospho AMPK and phospho ACC expression is increased in Erk1-/- muscles as compared to WT mice muscle.
Conclusion: Erk1 invalidation seems to induce an increased oxidative capacity that could explain that Erk1 deficient mice are protected from lipotoxicity and display an improveed insulin sensitivity. Thus, targeting specifically Erk1 may represent a new pharmacological strategy to fight obesity and insulin resistance.

113

The Tpl2 kinase is up-regulated in adipose tissue in obesity and mediates IL-1beta and TNFalpha effects on ERK activation and lipolysis
J.-F. Tanti[1], J. Jager[1], T. Grémeaux[1], S. Bonnafous[2], H. Vidal[3], P. Gual[2], M. Cormont[1], Y. Le Marchand-Brustel[1];
[1]INSERM U 895, Team: Molecular and Cellular Patophysiology of Obesity and Diabetes, Nice, [2]INSERM U 895, Team: Hepatic complications of Obesity, Nice, [3]INSERM U 870, Lyon, France.

Background and aims: Cytokines impair insulin action, increase lipolysis and alter adipocytes biology taking part in the development of insulin resistance and diabetes. Activation of the ERK pathway in adipocytes by inflammatory cytokines such as TNF-α and IL-1β could be an important component in the development of the alterations of adipose tissue function that participate in the insulin resistance. Thus, the identification of regulatory proteins that govern the activity of ERK specifically in response to inflammatory cytokines may provide important insights into mechanisms that promote metabolic diseases.MAP kinase and IKK/NFkappaB pathways often act synergistically to mediate cytokine action. It is thus possible that in adipocytes proteins that control cytokine-induced ERK activation are regulated by IKK/NFkappaB pathway. One interesting candidate could be MAP kinase kinase kinases (MAP3K) that regulate ERK through the phosphorylation and activation of MEK. Therefore, the aim of present study was to identify upstream kinase specifically involved in ERK activation by inflammatory cytokines and to address its implication in the alteration in adipocytes biology.
Materials and methods: Pharmacological inhibitors were used to inhibit IKKβ or Tpl2 activation and small interfering RNA (siRNA) was used to silence Tpl2 in 3T3-L1 adipocytes. Kinase activation and expression were analyzed by Western Blot. Gene expression was measured by real-time PCR in 3T3-L1 adipocytes and in adipose tissue of obese and morbidly obese patients and of obese mice. Lipolysis was monitored through the glycerol release in cells medium.
Results: IKKβ inhibition prevented MEK and ERK1/2 activation in response to IL-1β and TNFα, suggesting that IKKβ regulates a MAP kinase kinase kinase (MAP3K). We found that the MAP3K8 Tpl2 is expressed in both 3T3-L1 and human adipocytes and is activated by IL-1β and TNFα and that IKKβ inhibition prevented its activation in adipocytes.Both in 3T3-L1 adipocytes or in human adipocytes pharmacological inhibition of Tpl2 or its silencing prevented MEK/ERK1/2 activation by IL-1β and TNFα but not by insulin highlighting its involvement in ERK1/2 activation specifically in response to inflammatory cytokines. Prolonged treatment of 3T3-L1 adipocytes with IL-1β or TNFα markedly up-regulated the expression of Tpl2 via an IKKβ dependent-pathway, and Tpl2 mRNA level is increased in adipose tissue of obese mice and obese patients and is correlated with TNFα level. Finally, Tpl2 silencing or its pharmacological inhibition reduced lipolysis in adipocytes.
Conclusion: Our results identify Tpl2 as an inflammatory kinase specifically involved in inflammatory cytokines-induced ERK activation in adipocytes and reveal its deregulated expression in human obesity. Our data also raise the possibility that pharmacological targeting of Tpl2 could prevent the deleterious effect of cytokines on adipocytes biology.

Adiponectin and skeletal muscle: pathophysiological implications during metabolic stress
J. Jortay[1], M. Senou[2], L. Noel[1], M.-C. Many[2], S. Brichard[1];
[1]Unit of endocrinology and metabolism, [2]Université Catholique de Louvain, Brussels, Belgium.

Introduction: Adiponectin (ApN) is a hormone exclusively secreted by adipocytes under normal conditions. This adipokine exhibits insulin-sensitizing and anti-inflammatory properties as well as modulatory effects on oxidative stress thereby thwarting several disorders belonging to the metabolic syndrome. We have recently shown that ApN was paradoxically induced in skeletal muscle of obese and insulin-resistant *ob/ob* mice and related to oxidative stress. We hypothesized that this paradoxical upregulation of muscular ApN in obese mice could be viewed as a local protective mechanism to counteract oxidative damage.
Objective: To test this hypothesis, ApN-knockout (ApN-KO) mice and wild-type (WT) mice were rendered obese and insulin-resistant by administration of a western diet (WD; high-fat/high sucrose). We examined whether muscles of ApN-KO mice exhibited higher degree of oxidative stress, inflammation and apoptosis than those of WT mice when challenged by a WD and whether these abnormalities could be corrected by local administration of ApN.
Methods: ApN-KO mice (with virtually undetectable circulating ApN) and WT mice were fed with a WD or a standard laboratory diet (SD) for 6 wks. Next, mice were killed and *tibialis anterior* muscles were collected for immunohistochemistry. In additional experiments, after 2 wks on WD, muscle transfer of ApN gene was performed in anesthetized ApN-KO mice by injection of ApN cDNA containing-plasmid followed by electroporation in one *tibialis anterior*, the contro-lateral muscle being electroporated by a control plasmid. Mice were maintained on the WD for 4 additional wks. ApN was overexpressed only in the muscle injected with ApN cDNA without any rise in circulating levels of the adipokine.
Results: We first extended our data in *ob/ob* mice and showed that WT mice rendered obese by the WD diet, unlike those receiving the SD, displayed a positive labelling for ApN in myocytes. When challenged by the WD, ApN-KO mice were more obese and insulin-resistant than WT mice. Muscles of ApN-KO exhibited myotube degeneresccence when compared to WT mice,

especially after the WD-induced challenge. We searched for the underlying mechanisms. Even in basal conditions (SD), myotubes of ApN-KO mice already displayed a positive immunolabelling for 2 markers of oxidative stress (peroxiredoxin 3/5) as well as for a lipid peroxidation product (hydroxynonenal). The pro-inflammatory cytokine (TNF-alpha) and a marker of apoptosis (caspase-6) were also already present in muscle of these mice, but not in those of WT mice. After the WD challenge, immunoreactivity for these markers was much stronger in muscle of ApN-KO mice, while being detected at a lesser extent in WT mice. When compared to WT mice (whatever the diet), nuclear immunolabelling for NF-kB doubled in myocytes of ApN-KO fed the SD and further increased when these mice were on the WD. Eventually, transfer of ApN gene prevented muscle stress in ApN-KO mice challenged by the WD (reduction of oxidative stress and inflammatory markers compared to the contro-lateral untreated muscle).
Conclusion: Induction of muscular ApN may be triggered by conditions associated with obesity and insulin resistance. This induction in muscle appears to be crucial to counteract locally oxidative stress, inflammation and subsequent apoptosis. These results may have repercussions in the pathophysiology of the metabolic syndrome.

Fluorescence based real-time analysis of stimulus-secretion coupling in mouse beta cells

M.T. Kaminski[1], H. Schmitt[1], S. Lenzen[1], S. Baltrusch[1,2];
[1]Institute of Clinical Biochemistry, Hannover Medical School, [2]Institute of Medical Biochemistry and Molecular Biology, University of Rostock, Germany.

Background and aims: Glucose is the main stimulus of insulin secretion in pancreatic beta cells. Expression of the high capacity GLUT2 glucose transporter in beta cells facilitates glucose uptake close to the extracellular concentration. Glucokinase (GK) phosphorylates glucose in the first and rate limiting step of glycolysis and plays the pivotal role of a glucose sensor in beta cells. Thus, glucose recognition by cooperative action of GK and GLUT2 is vital for the subsequent machinery of insulin secretion. Recently we could establish a fluorescence resonance energy transfer (FRET) based glucose specific nanosensor (FLIPglu) to monitor the intracellular glucose concentration. Therefore the aim of this study was to characterize in real-time glucose uptake and metabolism in primary mouse beta cells in comparison to insulin-secreting MIN6 cells and with respect to insulin secretion.
Materials and methods: FLIPglu expression in primary mouse beta cells was achieved by transduction with a recombinant adenovirus. In addition an insulin-secreting MIN6 cell clone stably expressing FLIPglu was used. Using fluorescence microscopy, the dynamic changes in the intracellular glucose concentration were analyzed in a perifusion chamber in the absence and presence of glucose and selective inhibitors of glucose uptake and metabolism, respectively. FRET calculations as an enhanced yellow fluorescence protein (EYFP)/enhanced cyan fluorescence protein (ECFP) emission intensity ratio upon ECFP excitation were performed offline. Insulin was analyzed in the perifusion medium by ELISA.
Results: Glucose homeostasis in primary mouse beta cells could be depicted by calculating the rates of uptake and metabolism. Glucose uptake in mouse beta cells was significantly higher than in MIN6 cells upon addition of Krebs Ringer medium containing 10 mM glucose. However, the increase of the EYFP/ECFP ratio was accompanied by a subsequent increase in insulin secretion. Interestingly, glucose consumption which was calculated as a decrease of the EYFP/ECFP ratio after glucose removal was comparable in primary beta cells and MIN6 cells. Incubation of cells in medium supplemented with 10 mM 3-O-methylglucose caused in the presence of 10 mM glucose a significant decrease in the glucose uptake compared to incubation at 10 mM glucose alone. While the glucose uptake capacity was reduced by 50 % in mouse beta cells, the reduction was 80 % in MIN6 cells. When mouse beta cells and MIN6 cells were perifused with a mixture of 10 mM glucose and 10 mM mannoheptulose glucose metabolism was reduced by 50 % due to inhibition of GK.
Conclusion: Glucose metabolism mediated by GK in MIN6 cells is comparable to that in primary mouse beta cells, while glucose uptake is altered possibly due to a lower expression of the GLUT2 glucose transporter. The adenoviral FLIPglu sensor construct is a useful tool to analyze in future studies glucose homeostasis of primary beta cells in type 2 diabetes. This may provide new insights into the defects in the beta cell stimulus-secretion coupling in the diabetic state.

Disruption of TFB1M impairs insulin secretion in beta cells

T. Köck, M. Dekker Nitert, A. Olsson, O. Kotova, J. Stamenkovic, V. Lyssenko, L. Groop, H. Luthman, C. Ling, H. Mulder;
Clinical Sciences in Malmö, Lund University, Malmö, Sweden.

Background and aims: The nucleus encoded mitochondrial transcription factor B1 (TFB1M), a protein homologous to bacterial di-methyltransferases, has recently been shown to be crucial for mitochondrial translation. Using gene microarray analysis, we previously found that TFB1M gene expression is reduced in whole pancreatic extracts from diabetic GK compared to non-diabetic Fisher rats. This suggests a possible role for TFB1M in insulin secretion, given that maintenance of the mitochondrial proteome is essential for mitochondria-based stimulus secretion coupling. Here, we examined gene expression of TFB1M in islets from GK rats, and the effects on insulin secretion and mitochondrial ATP production following TFB1M knock down in INS-1 832/13 clonal beta-cells.

Materials and methods: RNA expression of TFB1M was analysed in pancreatic islets from GK and Fisher rats and in clonal 832/13 β-cells, using TaqMan qRT-PCR. Knock down was achieved by RNA interference. TFB1M was detected by immunoblotting. Insulin secretion was determined by RIA. ATP levels were detected by luciferase assay.
Results: Islets from the GK rat strain, a diabetic rat mode, showed a 50 % reduction in TFB1M mRNA expression compared with the normoglycemic F344 rat (P = 0.006). qRT-PCR analysis and detection of TFB1M by immunoblotting confirmed knock down of TFB1M by RNA interference in INS-1 832/13 beta-cells. TFB1M knock down resulted in a significant decrease in basal and glucose-stimulated insulin secretion (GSIS; 175 vs. 114 ng/mg/h; P<0.05). Impaired GSIS was accompanied by a decrease in mitochondrial and increase in glycolytic ATP production.
Conclusion: We show reduced expression of TFB1M in islets from the diabetic GK rat strain. Reduced expression of TFB1M in INS-1 832/13 clonal beta-cells impairs insulin secretion and alters ATP production. These findings indicate that: (1) TFB1M knock down causes profound changes in mitochondrial function/structure and metabolism in INS-1 832/13 cells; (2) the knock down of TFB1M in INS-1 832/13 cells represents a suitable model to study the cellular mechanisms causing impaired insulin secretion. Studies of TFB1M in relation to mitochondrial function and structure also opens a new avenue for research in pancreatic islet cell biology.

Metabolite profiling of clonal (832/13) beta cells after glucose stimulation
P. Spégel, A. Danielsson, C. Nagorny, H. Mulder;
Lund University Diabetes Centre, Unit for Molecular Metabolism, Malmö, Sweden.

Background and aims: The pancreatic beta-cell secretes insulin in response to elevated blood sugar levels. Two different pathways, the triggering and the amplifying pathways, have been identified as responsible for this stimulus-secretion coupling. Whereas signaling in the triggering pathway has been well studied, the identity of the signals in the amplifying pathway has remained essentially unresolved. Here, we have profiled the beta-cell metabolome following glucose stimulation. By monitoring the dynamics of beta-cell metabolism, we aimed for an unbiased identification of possible metabolic signals.
Materials and methods: INS-1 832/13 cells were starved for two hours at 2.8 mM glucose, followed by a 16.7 mM glucose stimulation. The cell cultures were subsequently quenched at different times in the interval of 0 to 30 min. Metabolites were extracted, derivatised, and subsequently analysed by gas chromatography/mass spectrometry (GC/MS). Orthogonal projection to latent structures (OPLS) was used to correlate the metabolic profile with the time of quenching.
Results: Three OPLS models were calculated to account for metabolic alterations during the first 15 min, the last 15 min and the whole time interval. The corresponding loading plots showed that proteolytic amino acids, exemplified by hydroxyproline, were continuously down-regulated, whereas serine, being an important precursor of many amino acids, purines, and pyrimidine was up-regulated. Several amino acids also showed an initial decrease followed after 15 min by a clear stagnation, which probably indicated a switch from protein catabolism to anabolism. Also ribose-5-phosphate, a pentose phosphate pathway intermediate, was up-regulated during the last 15 min investigated, which indicates increased biosynthesis. Succinate exhibited a late rise, which could reflect a higher level during starvation due to the entrance of amino acids proximal to succinate in the TCA cycle. All other glycolytic and TCA cycle intermediates were strongly up-regulated during the whole interval. The model was confirmed by raw data analysis and t-tests.
Conclusion: We suggest that a putative metabolic coupling signal should have a response curve that is correlated or inversely correlated with the insulin secretion profile. In the present investigation, several metabolites were identified with levels which were tightly coupled to the extracellular glucose level. Experiments are in progress to investigate the stimulation response during a shorter time span, as well as the alterations evoked by a drop in glucose levels.

Expression and possible roles of NOX family NAD(P)H oxidases in pancreatic islets of NOX-specific knockout mice
N. Li[1], B. Li[2], K.-H. Krause[2], P. Maechler[1];
[1]Department of Cell Physiology and Metabolism, [2]Department of Pathology and Immunology, University of Geneva, Switzerland.

Background and aims: Elevated production of reactive oxygen species (ROS) has been proposed to contribute to pancreatic beta-cell impairment in diabetes. Although the presence of phagocyte-like NOX family NAD(P)H oxidases, a potential source of ROS, has been studied in rat pancreatic islets and beta-cell lines, their role in islet function remains poorly characterized due to lack of specific inhibitors and reliable antibodies. Here, functional analysis of NOXs in islets was carried out using NOX isoform-specific knockout mice.
Materials and methods: Expression of NAD(P)H oxidase components in C57BL/6J mouse and human islets was tested by RT-PCR. Next, islets isolated from wild-type (WT) and knockout mice for specific NOX isoforms (koNOX-1, -2 and -4), were used to establish correlation between glucose-stimulated insulin secretion (measure by RIA) and NOX-derived superoxide generation (measured by NBT). In koNOX-2, islet morphology, beta-cell mass and insulin contents were determined (immunostaining) and glucose homeostasis was examined by ipGTT, plasma insulin levels (ELISA) and HOMA test. Additionally, effects of non-selective NOX inhibitor DPI on glucose-stimulated insulin secretion was evaluated on WT and koNOX-1, -2 and -4 mouse islets to test for specificity.
Results: Both mouse and human pancreatic islets expressed membrane-associated NOX-2 and -4, NOX-2 being the predominant isoform. NOX-1 and cytosolic components, such as p22phox, p40phox, p47phox, p67phox, NOXO-1, NOXA-1 were also detected in mouse islets. A negative correlation (r=-0.96, p<0.05) was found between glucose-induced insulin secretion and NOX-derived superoxide generation comparing WT and koNOX-1, -2 and -4 islets. Compared to WT, koNOX-2 islets stimulated with 22.8 mM glucose exhibited potentiated insulin release (+213%, p<0.005) associated with lower superoxide production (-37%, p<0.05). No differences in islet organisation, beta-cell mass and insulin contents were observed. The NOX inhibitor DPI exhibited a general inhibitory effect on insulin secretion in WT and all koNOX islets, showing the lack of specificity of this inhibitor. Mice deficient for NOX-2 exhibited glucose intolerance (p<0.05) associated with slightly higher plasma insulin levels, suggesting insulin resistance. This was corroborated by the observed elevated HOMA index (+62%, p<0.01).
Conclusion: NOX-2 is the most abundant NAD(P)H oxidase in human and mouse islets. NOX knockouts represent a valuable experimental model for the study of NAD(P)H oxidases and show that studies using non-specific NOX inhibitors might be misleading. NAD(P)H oxidases positively contribute to glucose-induced ROS generation and negatively regulate insulin secretory function.

Characterization of the insulin secretory profile in islets isolated from beta cell specific glutamate dehydrogenase knockout mice
L. Vetterli[1], S. Carobbio[1], R. Martín-del-Río[2], J. Tamarit-Rodriguez[2], P. Maechler[1];
[1]Department of Cell Physiology and Metabolism, University of Geneva, Switzerland, [2]Department of Biochemistry, Complutense University, Madrid, Spain.

Background and aims: Glutamate dehydrogenase (GDH) is a mitochondrial enzyme that catalyses the reversible transformation of glutamate to alpha-ketoglutarate. GDH might play a role in glucose-induced amplifying pathway through generation of glutamate and/or as an amino acid sensor triggering insulin release upon glutamine stimulation in conditions of GDH allosteric activation. Here, we investigated the role of GDH in a beta-cell specific GDH knockout mouse model, named ßGlud1-/-, recently generated in our laboratory.
Materials and methods: Islets were isolated from wild type (WT) and beta-cell specific GDH null mice (ßGlud1-/-), cultured overnight and used for perifusion experiments or static incubations to measure insulin secretory responses. Reintroduction of GDH expression was achieved using the adenovirus AdGDH. Amino acids levels were measured in islet extracts by HPLC and gene expression analysed by quantitative RT-PCR.
Results: In perifusion experiments, islets from WT mice increased insulin secretion 2-fold in response to 11.8 mM glucose and 3-fold upon 22.8 mM

glucose stimulation. Islets isolated from ßGlud1-/- beta-cell specific GDH knockout responded normally to 11.8 mM glucose, but the response to 22.8 mM glucose was reduced by 56%. The secretory response to glucose could be significantly rescued (p=0.01) when GDH knockout islets were simultaneously exposed to 22.8 mM glucose and 5mM dimethyl-glutamate, added as a cell permeant glutamate precursor. When testing the amplifying pathway by combination of KCl (30 mM) / diazoxide (0.25 mM) plus 22.8 mM glucose, the sustained insulin release observed in WT islets was inhibited by 75% in beta-cell GDH knockout islets. Glutamine stimulation is strictly GDH dependent and elicits insulin release only upon GDH allosteric activation, for instance using BCH. In accordance with this model, ßGlud1-/- islets were totally unresponsive to glutamine (5 mM) / BCH (10 mM) stimulation. The response to glutamine/BCH was partially rescued in GDH knockout islets transduced with an adenovirus encoding for GDH (50% of the WT response, p=0.02). Amino acids related to glutamate pathways were reduced in GDH knockout islets stimulated with 22.8 mM glucose (glutamate -38%, glutamine -49%, aspartate -40%, and alanine -37%, all p<0.05). Moreover, in ßGlud1-/- islets we measured decreased expression of the mitochondrial glutamate carrier GC1 responsible for glutamate transport across the mitochondrial membrane (-41%, p=0.05).

Conclusion: The present study took advantage of a unique model of beta-cell specific GDH knockout to question the role of this enzyme in islet function. Data show that GDH is essential for sustained insulin secretion at optimal glucose concentration. In these conditions, lower glutamate concentrations seem to be responsible for reduced secretory response as provision of cell permeant glutamate restored the secretory response. The lack of GDH also impacted on related glutamate pathways, pointing to GDH as a master switch linking glucose and amino acid metabolisms.

On role of transglutaminase 2 in insulin secretion: sub-cellular localization in human endocrine pancreas and identification of transamidation substrates in INS1E

O. Massa[1], L. Russo[1], C. Placidi[2], G. Nardo[3], T. Massignan[3], E. Piermarini[4], S. La Rosa[2], G. Finzi[2], V. Bonetto[3], P. Maechler[5], M. Alessio[6], F. Bertuzzi[7], C. Capella[2], G. Bottazzo[1], F. Barbetti[1,8];
[1]Bambino Gesù Pediatric Hospital - IRCCS, Rome, Italy, [2]Department of Human Morphology, University of Insubria, Varese, Italy, [3]Dulbecco Telethon Institute, Mario Negri Institute for Pharmacological Research, Milan, Italy, [4]Tor Vergata University Hospital (PTV), Rome, Italy, [5]Department of Cell Physiology and Metabolism, Geneva University Medical Centre, Switzerland, [6]DIBIT, San Raffaele Scientific Institute IRCCS, Milan, Italy, [7]Diabetes Unit, Mediterranean Institute for Transplantation and Advanced Specialized Terapies, Palermo, Italy, [8]San Raffaele Biomedical Park Foundation, Rome, Italy.

Background and aims: Transglutaminase 2 (TG2) is a multifunctional and ubiquitous enzyme that belongs to the transglutaminase family. Mutational analysis of human TG2 gene in subjects affected by familial forms of type 2 diabetes led us to the identification of three different missense mutations, M330R, I331N and N333S, that determine a reduced TG2 transamidation activity in vitro. Hence, to better investigate the role of TG2 transamidation activity in insulin secretion, we labeled INS1E rat insulinoma cells in vivo with a biotinylated TG2 specific substrate and studied transamidation activity before and after (2', 5', 8' and 15') the application of a 15.5 mmol/L glucose stimulus, in order to mimic first-phase insulin secretion.

Materials and methods: TG2 transamidation kinetics in INS1E (basal condition versus glucose-stimulated) was studied by labeling cells with 1 mM EZ Link 5 (biotinamido) pentylamine and following the appearance/disappearance of specific biotinylated substrate/s. Bi-dimensional (2D) polyacrylamide gel electrophoresis followed by Western blot, performed with streptavidin HPRT, was employed for kinetic experiments. For substrates identification, TG2 biotinylated proteins were purified on avidin sepharose column before 2D gel separation followed by MALDI MS/MS.

Results: Our data indicate that 2' after glucose stimulus, corresponding to the highest intracellular Ca2+ concentration, TG2 transamidation function is fully activated as demonstastrated by 2d gel analysis of INS1E proteins. By MALDI MS/MS, we then identified some TG2 natural substrates, and among them: cytoplasmic actin 1 and 2, GRP78, HSP90, mitogen activated protein kinase 1, tropomyosin alpha 4 and gamma 3 chain. All these proteins are involved either in insulin secretion or in glucose metabolism, or both. Western blot with an anti-cytoplasmic actin 1 polyclonal antibody showed that actin is indeed one of the biotinylated protein spots identified with 2D. In addition, we also demonstrated that cytoplasmic actin co-immunoprecipitates with TG2. Ultrastructural microscopy indicated that in normal human pancreas TG2 is localized in the cytoplasm and 2D electrophoresis showed that TG2 stays in INS1E cytoplasm during the entire period of glucose stimulus (2'-15') and beyond (up to 30').

Conclusion: We conclude that TG2 transamidation activity has a direct role in insulin secretion. This action is probably mediated by cytoplasmic actin 1 and 2 which are known to be involved in the remodeling of cytoskeleton, one of the fundamental events in insulin exocytosis.

OP 21 Insulin action - animal models

Adenoviral gene transfer of PLD1-D4 results in enhanced insulin sensitivity in skeletal muscle of *ped/pea-15* transgenic mice

A. Cassese[1,2], I. Castanò[3], L. Pastore[3], A. Ilardi[1,2], C. Nigro[1,2], C. Urbani[1,2], R. Buonomo[1,2], C. Miele[1,2], P. Formisano[1,2], F. Beguinot[1,2];
[1]DBPCM, University of Naples Federico II, [2]IEOS-CNR, University of Naples, [3]CEINGE-Biotecnologie Avanzate, University of Naples Federico II, Italy.

Background and aims: Ped/pea-15 is a gene commonly overexpressed in tissues from type 2 diabetic individuals and in First Degree Relatives. Indeed, overexpression of the ped/pea-15 gene in mice impairs glucose tolerance and leads to diabetes in association with high-fat diets. Several studies demonstrated that PED/PEA-15 binds phospholipase D1 (PLD1), stabilizing and enhancing its activity in the cell. This effect is mediated by the C-terminal D4 domain of PLD1. Both in cells and in skeletal muscle tissue from PED/PEA-15 transgenic mice (TgPED), the increase of PED/PEA-15/PLD1 interaction induces insulin-resistance, at least in part, by impairing PKC signal transduction. Indeed, PLD1 stabilization induces the constitutive activation of PKCα, determining the inhibition of insulin-induced activation of PKCζ, an important kinase involved in insulin-induced glucose uptake. In this work, we sought to test the hypothesis that D4 overexpression could represent a potential tool to rescue insulin-sensitivity and glucose tolerance in TgPED.
Materials and methods: We generated a recombinant adenoviral vector containing D4 cDNA (Ad-D4) to induce D4 expression in TgPED. 6-months old TgPED and control mice were intravenously injected with 1x1011 viral particles of either control Ad-GFP or Ad-D4. The effects of Ad-D4 were evaluated after 7-10 days of infection.
Results: After infection, D4 is efficiently expressed in skeletal muscles of TgPED and control mice. In TgPED skeletal muscles, D4 expression decreases PED/PEA-15/PLD1 interaction. This is accompanied by a decrease of PKCα constitutive activity and the recovery of insulin effect on PKCζ activation. In TgPED, Ad-D4 infection restores insulin sensitivity (ITT. AUC control mice Ad-GFP: 7930±4062.3, control mice Ad-D4: 8408±779.6; TgPED Ad-GFP: 11155±2893.8, TgPED Ad-D4: 6532,8±2683.3, p<0.001 vs TgPED Ad-GFP) and ameliorates glucose tolerance (GTT. AUC control mice Ad-GFP: 20155±5040, control mice Ad-D4: 18676±3046; TgPED Ad-GFP: 31127±6617, TgPED Ad-D4: 15619±2490, p<0,0001 vs TgPED Ad-GFP). Furthermore, D4 expression in TgPED decreases fasting insulin levels (TgPED Ad-GFP: 1.04±0.29 ng/ml, TgPED Ad-D4: 0.44±0.04 ng/ml, p<0.01), FFA (TgPED Ad-GFP: 0.87±0.28 mmoles/l, TgPED Ad-D4: 0.57±0.14 mmoles/l, p<0.01) and tryglycerides (TgPED Ad-GFP: 22.2±0.16 mg/dl, TgPED Ad-D4: 15.9±0.10 mg/dl, p<0.01). Finally, D4 expression in TgPED increases insulin-induced glucose uptake in skeletal muscles.
Conclusion: In conclusion, adenoviral delivery of PLD1-D4 rescues insulin sensitivity and glucose tolerance in vivo. Thus, interfering with PED/PEA-15/PLD1 interaction represents a major strategy for developing new molecules for the treatment of type 2 diabetes.

SIRT1 deacetylase activity is essential for calorie restriction-induced enhancement of skeletal muscle insulin sensitivity

S. Schenk[1], C.E. McCurdy[2], M.Z. Chen[1], G. Bandyopadhyay[1], S. Talukdar[1], J.M. Olefsky[1];
[1]Medicine, University of California, San Diego, La Jolla, [2]Pediatrics, University of Colorado, Denver, United States.

Background and aims: Calorie restriction (CR) manifests numerous metabolic and physiological benefits including enhanced insulin sensitivity and increased longevity. The NAD^+-dependent protein deacetylase, sirtuin 1 (SIRT1), is induced by CR, and pharmacological activation of SIRT1 mimics many of the beneficial health outcomes of CR, including improved insulin sensitivity. However, the precise role of SIRT1 in regulating insulin sensitivity in skeletal muscle is unclear. The purpose of the present study was to determine whether SIRT1 is essential for the CR-induced enhancement in skeletal muscle insulin sensitivity.
Materials and methods: Mice with knockout of SIRT1 deacetylase activity in skeletal muscle were generated using Cre recombinase methodology. Similar to their floxed/wildtype (WT) littermates, the SIRT1 protein is still present in the knockout (KO) mice, however, exon 4 of the SIRT1 gene (which encodes the catalytic domain responsible for deacetylase activity) is deleted. At 13 wks of age, we measured insulin-stimulated 2-deoxyglucose uptake (2DGU) in isolated extensor digitorum longus (EDL) and soleus muscles, as well as isolated epididymal adipocytes after ad libitum (AL) or CR (20 d at 60% of AL) feeding. We also measured the gene expression of SIRT1, protein tyrosine phosphatase 1B (PTP1B) and cytochrome c oxidase (COXIV) in skeletal muscle.
Results: Insulin-stimulated 2DGU at a physiological insulin concentration (60uU/mL) was not different in EDL and soleus muscles in WT vs. KO mice after AL feeding. After 20 d of CR, insulin-stimulated 2DGU was significantly enhanced ~3-fold in EDL and soleus muscles from WT mice. Interestingly, in KO mice, CR did not enhance insulin-stimulated 2DGU in EDL, and only partially increased (70%) insulin-stimulated 2DGU in the soleus. Importantly, these effects were muscle specific, as CR significantly enhanced (~3-fold) insulin-stimulated 2DGU in isolated adipocytes equally in KO and WT mice. Preliminary data suggests that the gene expression of PTP1B, COXIV and SIRT1 in skeletal muscle was unaffected by genotype or diet.
Conclusion: These results demonstrate that, 1) loss of SIRT1 deacetylase activity does not impair skeletal muscle insulin sensitivity and 2) SIRT1 deacetylase activity is essential for the full effect of CR to enhance skeletal muscle insulin sensitivity.

Hepatic inflammatory gene expression and the development of insulin resistance in IL-1 receptor 1 (IL1-R1) knockout mice

O. Finucane[1], M. Claessens[2], E. Oliver[1], K. Harford[2], K.H.G. Mills[3], H.M. Roche[2];
[1]Trinity College Dublin, [2]Nutrigenomics Research Group, University College Dublin, [3]Immune Regulation Research Group, Trinity College Dublin, Ireland.

Background and aims: The Metabolic Syndrome (MetS) is characterised by obesity, insulin resistance and a sub-actute chronic pro-inflammatory state. It is well known that impairing different components of the inflammatory system (TNFα, NF-κB, IKK, JNK, etc) either due to genetic or dietary manipulations can reduce the risk of the MetS. Relatively little is known in relation to IL-1RI signaling and the MetS. Preliminary work has demonstrated that IL-1R deficient ($IL\text{-}1R1^{-/-}$) mice are protected against diet-induced obesity-related insulin resistance. In addition obese $IL\text{-}1R1^{-/-}$ mice also had improved lipid profiles wherein plasma TAG and NEFA are significantly lower. Elevated TAG are another characteristic of the MetS. Therefore the present study sought to elucidate how lack of IL-1R1 improves hepatic lipid metabolism.
Materials and methods: Detailed hepatic gene expression analysis of key markers of lipid metabolism and insulin sensitivity was preformed using real time PCR and western blot.

Results: An 8 week high-fat diet induced a phenotype characteristic of the MetS, with insulin resistance and elevated TAG and NEFA concentrations in WT compared to $IL\text{-}1R1^{-/-}$ mice. Gene expression analysis showed a reduction in hepatic SREBP-1c mRNA expression in $IL\text{-}1R1^{-/-}$mice ($P<0.05$)(fig 1). SREBP-1c is a key transcription factor that regulates both lipid and glucose metabolism. In terms of understanding the role of adipokines in hepatic insulin resistance and inflammation we focused on adiponectin, which is secreted from WAT but mediates peripheral insulin sensitivity. Plasma levels of adiponectin decrease the in $IL\text{-}1R1^{-/-}$mice. In the liver the expression of the receptor adipoR1 was equally increased in both WT and $IL\text{-}1R1^{-/-}$mice, however there was a marked increase in adipoR2 in $IL\text{-}1R1^{-/-}$mice only. As expected, inflammatory marker TNFα mRNA expression showed a significant reduction in $IL\text{-}1R1^{-/-}$mice only ($P<0.05$). Finally, western blot analysis demonstrated that JNK and NF-κB p65, critical regulators of insulin action, were significantly lower in $IL\text{-}1R1^{-/-}$mice ($P<0.05$) which might partially confirm the anti-diabetic phenotype in reference to the high-fat diet.
Conclusion: The observed results underlie the link between inflammation and metabolic deregulation. Our study provides further, but not conclusive evidence that IL-1 is a crucial mediator pro-inflammatory and abrogation of its receptor may have potential therapeutic benefits.

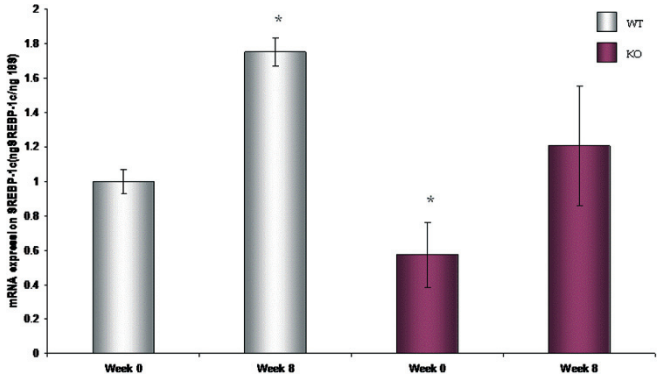

Figure 1. mRNA expression hepatic SREBP-1c was significantly increased in WT mice at week 8 compared to week 0 (P value= 0,0001). Hepatic SREBP-1c mRNA expression was significantly higher in WT mice at baseline compared KO mice at week 0 (P=0,05). Values represent means ±SEM. Significantly different *p<0.05 mRNA expression was normalised to 18S and expressed relative to WT mice at week 0

FAAH$^{-/-}$ are metabolically flexible despite whole body insulin resistance
B. Vaitheesvaran[1], S. Glaser[2], Y. Stephen[2], I.J. Kurland[1];
[1]Medicine, [2]Neurobiology and Behavior, State University of New York, Stony brook, United States.

Background and aims: Endocannabinoid (eCb) signaling is pivotal in modulating several physiological processes including: feeding, obesity, fertility, inflammation and pain. Fatty acid amide hydrolase (FAAH), a 63 kDa integral membrane enzyme, is responsible for degrading eCbs, such as anandamide and 2-arachidonoly glycerol. FAAH$^{-/-}$ mice are obese, and obesity in general is usually associated with insulin resistance and metabolic inflexibility. This study characterized metabolic flexibility and tissue-specific insulin resistance for the FAAH$^{-/-}$ mouse.
Materials and methods: FAAH-/- mice, generated from a C57BL6 strain and C57BL6 mice (C57 wt) were used for the study. Glucose disposal was assessed with a stable isotope GTT (SiGTT) using [6,6-^{2}H]-glucose. Hepatic glucose production (HGP) in the fasted state and in vivo lipolysis was determined by constant infusion of [U-$^{13}C_6$]-glucose, 2-^{13}C-glycerol by Alzet minipump respectively. Metabolic inflexibility was assessed by indirect calorimetry, using an 8-chamber Oxymax system (Columbus Instruments, Columbus, OH).
Results: FAAH $^{-/-}$ mice were obese (35±3.4 *vs.* 29±1.6 grams, p<0.002, at 4 months of age) and their food consumption/day was higher than C57 wt (4.4 *vs.* 3.5 g, p<0.01). FAAH$^{-/-}$ mice have hepatic insulin resistance, as fasting insulin (15h overnight fast) was 1.351±0.3 *vs.* 0.474±0.3 ng/ml for FAAH$^{-/-}$ *vs.* C57 wt (p<0.001). There was no difference in basal glucose levels, or HGP. FAAH$^{-/-}$ mice have adipose insulin resistance because glycerol production, reflecting *in vivo* lipolysis, was increased by 42% (p<0.01) in fasted FAAH$^{-/-}$ mice, despite increased fasting insulin. FAAH$^{-/-}$ mice have skeletal muscle insulin resistance, as measured during the SiGTT. The insulin AUC was 3 fold higher for FAAH$^{-/-}$ mice (p≤0.05). The AUC for D2 glucose (which mainly reflects glucose disposal by muscle during the GTT), however, was similar to the C57 wt, reflecting insulin resistance. Indirect calorimetry showed no difference (p>0.05) in substrate utilization during a diurnal cycle. Thus, metabolic flexibility was preserved, even though FAAH$^{-/-}$ mice have lower activity in the fed state (p<0.05).
Conclusion: Despite obesity, and flux analysis indicating hepatic, skeletal muscle and adipose insulin resistance,, FAAH$^{-/-}$ mice still have normal metabolic flexibility. Since decreases in metabolic flexibility are thought to accompany the progression of insulin resistance in the development of Type 2 DM, endocannabinoid signaling, may play a complex role on the whole body level in the linkage, as well as compensation, of insulin resistance and metabolic flexibility.

The *PED/PEA-15* diabetogene as a potential thiazolidinedione target
P. Mirra[1,2], F. Oriente[1,2], R. Teperino[1,2], M. Ciccarelli[1,2], M. Longo[1,2], P. Ungaro[1,2], F. Beguinot[1,2];
[1]DBPCM, University of Naples "Federico II", [2]IEOS-CNR, Naples, Italy.

Background and aims: Thiazolidinediones (TZDs) represent a class of insulin-sensitising drugs currently used for treating type 2 diabetes (T2D); however, resistance to TZDs sometimes occurs. The TZD target is PPARγ, a nuclear hormone receptor able to modulate gene expression upon ligand binding. Ligand-mediated activation of PPARγ has been linked to glucose homeostasis.
The phosphoprotein enriched in diabetes/phosphoprotein enriched in astrocytes (*PED/PEA-15*) gene is over-expressed in tissues from T2D subjects and from first-degree relatives of T2D subjects. Furthermore, transgenic mice ubiquitously over-expressing *ped/pea-15* feature impaired glucose tolerance and insulin resistance. In cultured cells and *in vivo*, *ped/pea-15* over-expression impairs insulin activation of protein kinase C zeta (PKCζ) and glucose disposal. Recently, we have obtained evidence that TZDs down-regulate *ped/pea-15* expression. This study aims at investigating whether and how TZDs ameliorate insulin sensitivity by modulating *ped/pea-15* gene expression.
Materials and methods: *ped/pea-15* expression was analyzed by real-time quantitative polymerase chain reaction (PCR) and Western blotting in tissues from C57BL/6J mice and in L6 myotubes, used as a cellular model system of skeletal muscle. L6 myotubes were also used for glucose transport assays. Gene Reporter Assays, Electrophoretic Mobility Shift Assays (EMSA) and Chromatin Immuno-Precipitation Assays (ChIP) were performed in HeLa cells.
Results: In L6 skeletal muscle cells, rosiglitazone (RGTZ) decreased both *ped/pea-15* mRNA and protein levels. Consistent with the *in vitro* data, muscle tissue from mice treated with RGTZ for 10 days showed a 40% decrease of ped/pea-15 protein levels.
We obtained evidence that *PED/PEA-15* expression is modulated by AP-1 activators, such as 12-O-tetradecanoyl-phorbol-13-acetate (TPA). In fact, when treated with TPA, HeLa cells showed an increase in *PED/PEA-15* mRNA levels; TPA also induced the activation of *PED/PEA-15* promoter activity. Interestingly, the TPA effect was almost completely reverted by RGTZ in a concentration dependent-manner and *via* PPARγ. Specifically, the CRE-like site within the 200bp regulatory region of *PED/PEA-15* was involved in both TPA and RGTZ effects. EMSA and ChIP assays further demonstrated that TPA caused an increase in the binding of c-JUN to the CRE-like site (a putative AP-1 binding site) on the *PED/PEA-15* promoter, and the binding was reduced by 50% in presence of RGTZ. Taken together, these results indicated that AP-1 induces *PED/PEA-15* transcription by the binding to the CRE-like site. The AP-1 activity is interfered by PPARγ and it might be due to a physical interaction between activated PPARγ and c-JUN. In addition, in L6 skeletal muscle cells the down-regulation of *ped/pea-15* expression by TZDs was associated with an increase in PKCζ activation and in glucose up-take.
Conclusion: The results of this study identified *PED/PEA-15* gene as a potential target of TZDs in T2D treatment. More interestingly, the down-regulation of *ped/pea-15* expression represents a direct effect of TZDs on skeletal muscle, in addition to the first TZD action on adipose tissue. Therefore, *PED/PEA-15* gene might represent a potential marker for resistance to TZDs in T2D treatment.

Cox6a2 deficient mice are protected against high fat diet-induced obesity and insulin resistance
R. Quintens[1], S. Singh[2], K. Lemaire[1], K. De Bock[3], A. Schraenen[1], B. Van Hoef[4], I. Vroegrijk[5], P. Van Noten[6], M. Granvik[1], L. Van Lommel[1], R. Lijnen[4], P.J. Voshol[5], P.P.A. Mammen[2], F.C. Schuit[1];
[1]Molecular Cell Biology, KU Leuven, Belgium, [2]Internal Medicine, UT Southwestern Medical Center, Dallas, United States, [3]Vesalius Research Center, VIB - KU Leuven, Belgium, [4]Center for Molecular and Vacular Biology, KU Leuven, Belgium, [5]Endocrinology and Metabolic Diseases, Universiteit Leiden, Netherlands, [6]Biomedical Kinesiology, KU Leuven, Belgium.

Background and aims: Mitochondrial dysfunction has repeatedly been associated with the etiology of obesity and type 2 diabetes. Therefore, we investigated the metabolic profile of mice deficient in the respiratory chain gene *Cox6a2*. Cox6a2 is a subunit of the cytochrome c oxidase, and it is believed to play a role in thermogenesis at rest and in protection against the formation of reactive oxygen species (ROS).

Materials and methods: Glucose tolerance (2.5 mg glucose/g body weight) was assessed in mice of 14 weeks of age and after 9 and 22 weeks of high fat diet (HFD) feeding. Insulin sensitivity was measured using hyperinsulinemic, euglycemic clamps. To investigate energy expenditure, mice were monitored in metabolic cages for three consecutive days. Affymetrix Mouse 1.0 ST Gene Arrays as well as qRT-PCR were used to assess differences in gene expression. ROS levels in skeletal muscle were measured using the fluorescent probe dihydroethidium and quantified using fluorescence microscopy. To study skeletal muscle fiber type composition, muscle sections were stained for myosin ATPase. Resistance to fatigue of isolated muscles was examined by repetitive stimulation for 12 min with decreasing rest intervals of muscles which were mounted on a force transducer and placed in oxygenated Krebs-Henseleit buffer.
Results: Glucose tolerance was comparable in wild type and knockout mice on regular diet, although fasting blood glucose was lower in Cox6a2$^{-/-}$ mice ($p < 0.001$). Cox6a2$^{-/-}$ mice were completely resistant to body weight gain after HFD feeding, in contrast to WT mice which became progressively obese and glucose intolerant. Weight gain in WT mice was mainly due to increased adiposity, and adipocytes were smaller in Cox6a2$^{-/-}$ mice ($p < 0.02$). Better glucose tolerance in Cox6a2$^{-/-}$ mice on HFD was explained by higher sensitivity to insulin ($p < 0.01$). Protection against obesity could be explained by increased energy expenditure and thermogenesis in Cox6a2$^{-/-}$ mice, which was independent of circulating thyroid hormone levels, but correlated with elevated expression of uncoupling proteins in metabolically active tissues such as skeletal muscle, heart, and white and brown adipose tissue. This upregulation was associated with increased ROS formation in skeletal muscle of Cox6a2$^{-/-}$ mice. Furthermore, we found a compensatory coordinated increase in expression of respiratory chain genes and a fiber type switch of skeletal muscles of Cox6a2$^{-/-}$ mice to a more oxidative fiber profile. These changes resulted in improved resistance to fatigue of isolated skeletal muscle. Finally, we found that female Cox6a2$^{-/-}$ mice lost more body weight during a short period of fasting ($p < 0.005$), suggesting that *Cox6a2* may be a thrifty gene which helps to efficiently store and utilize energy.
Conclusion: We conclude that Cox6a2 is involved in whole-body energy metabolism and thermogenesis. This may indicate that genetic variations in the human *COX6A2* gene could influence the susceptibility to develop insulin resistance and obesity.

OP 22 Responses to GLP-1-based therapy

127

A pilot study examining the effect of *GLP1R* polymorphisms on insulin secretion in response to glucose and GLP-1 infusion in non-diabetic subjects
A. Vella[1], A. Sathananthan[1], F. Micheletto[2], C. Dalla Man[2], G. Toffolo[2], C. Cobelli[2], A.R. Zinsmeister[1], M. Camilleri[1], R.A. Rizza[1];
[1]Mayo Clinic, Rochester, United States, [2]University of Padua, Italy.

Background and aims: Glucagon-Like Peptide-1 (GLP-1) interacts with its transmembrane receptor (encoded by *GLP1R*) to produce insulin secretion in a glucose-dependent manner. The effect of genetic variation at *GLP1R* on the response to GLP-1 is unknown. Variation in response may affect the response to incretin-based therapy. We therefore assessed the effect of *GLP1R* polymorphisms on insulin secretion in response to glucose and GLP-1 infusion in non-diabetic subjects.
Materials and methods: We studied 81 healthy individuals (48 females and 33 males, age=26.1±0.6 years, BMI=24.9±0.4 kg/m^2, fasting glucose < 4.82 ± 0.03 mmol/L) using a hyperglycemic clamp. A variable infusion maintained peripheral glucose concentrations at 150 mg/dl for 240 minutes. At 120 minutes an intravenous infusion of GLP-1 was started and maintained till the end of the study (0.75pmol/kg/min from 121-180 minutes, 1.5pmol/kg/min from 181-240 minutes). Insulin secretion was measured using a C-peptide minimal model modified to account for the effect of GLP-1 on secretion. This assumes that insulin secretion is made up of a dynamic component, proportional to rate of glucose change through the dynamic responsivity index, Φ_d (10^{-9}), and a static index, proportional to glucose through the static responsivity index, Φ_s (10^{-9} min^{-1}). Genotyping of 21 tag single nucleotide polymorphisms (tag SNPs) and 4 non-synonymous SNPs (nsSNPs) in the extended *GLP1R* locus was undertaken and their relationship with insulin secretion indices examined.
Results: The nsSNP, rs6923761, altered insulin secretion indices (Φ_{Total}, Φ_d and Φ_s) and early insulin secretion in response to GLP-1 infusion ($P < 0.05$). The tag SNPs rs4714210 and rs13202369 were also weakly associated with a blunted response to intravenous GLP-1.
Conclusion: In young, healthy subjects variation in *GLP1R* alters response to intravenous GLP-1. It remains to be determined whether these observations are replicated in a larger cohort and in diabetic subjects with impaired insulin secretion.

Impact of endogenous and exogenous GLP-1 on glucagon secretion in type 1 diabetic patients with and without residual beta -cell function
U. Kielgast[1], S. Madsbad[1], J. Holst[2];
[1]Department of Encrinology, Hvidovre Hospital, [2]University of Copenhagen, Institute of Biomedicines, Copenhagen, Denmark.
Background and aims: Effect of secreted and infused GLP-1 on glucagon secretion and glucose excursions during a mixed meal was investigated in type 1 diabetic patients with and without residual insulin secretion.

Materials and methods: Eight diabetic patients with stimulated C-peptide concentration of 0.46 ± 0.1 nM and eight without residual insulin secretion

underwent three mixed meal tests with infusion of either the GLP-1 receptor-antagonist, exendin 9-39 (ex 9-39) (300 pmol/kg/min), GLP-1 (1.2 pmol/kg/min) or saline. Eight healthy matched (age, sex and BMI) subjects with normal glucose tolerance were included as controls. Infusions were started 30 minutes prior to the meal and patients injected half of their usual fast acting insulin-dose shortly before ingesting the meal. To assess gastric emptying rate, we added 1 g of acetaminophen to the meal. Postprandial glucose, glucagon, insulin secretion and gastric emptying rate were evaluated from incremental area under the plasma concentration curves from -30 to 180 minutes and presented as mean ± SEM.

Results: The injected dose of insulin tended to be lower in the C-peptide positive compared with the C-peptide negative subjects: 2.6 ± 0.5 vs. 3.9 ± 0.3 IE, p=0.06. Ex 9-39 increased glucagon levels in the three groups compared with saline: 2,541 ± 249 vs. 566 ± 179 and 3,244 ± 470 vs. 696 ± 213 and 1,824 ± 122 vs. 644 ± 196 pmol/l x min for the C-peptide negative, positive and the control subjects respectively, p<0.01. GLP-1 decreased glucagon concentrations in the three groups compared with saline: -409 ± 119 vs. 566 ± 178, -152 ± 109 vs. 696 ± 213 and -590 ± 114 vs. 644 ± 196, p<0.05. Glucose excursions were strongly decreased with GLP-1 compared with saline: -137 ± 141 vs. 930 ± 184, -273 ± 105 vs. 731 ± 137 and -7 ± 27 vs. 84 ± 31 mM x min, p< 0.01. In both diabetic groups, postprandial glucose levels with GLP-1 did not differ from control subjects receiving saline. Ex 9-39 increased glucose levels in the C-peptide positive group: 1,072 ± 103 vs. 731 ± 137, p=0.02, but the increment did not reach statistical significance in the C-peptide negative or control subjects: 1,168 ± 132 vs. 930 ± 184 and 141 ± 25 vs. 84 ± 31, p=NS. However, in the diabetic subjects as a whole group, ex 9-39 did significantly increase blood glucose levels (p=0.002). Compared with saline, GLP-1 decreased gastric emptying rate in both diabetic groups (p<0.01), whereas ex 9-39 increased gastric emptying rate in the diabetic subjects (p<0.05). In the C-peptide positive subjects, insulin secretion was significantly lower with both GLP-1 and ex 9-39 compared with saline: 40.6 ± 17.9 and 56.4 ± 22.0 vs. 69.8 ± 25.6, nM x min p=0.02 and 0.05 respectively, but with GLP-1, C-peptide was transiently increased from the beginning of the infusion until start of the meal.

Conclusion: Infusion of GLP-1 is able to control blood glucose excursions during a mixed meal in patients with type 1 diabetes regardless of residual beta-cell function. This is probably due to decreased glucagon levels and slowed gastric emptying. Blocking the endogenous GLP-1 action strongly increases glucagon levels leading to increased postprandial glucose excursions in type 1 diabetic patients.

129

The effect of LY2189265 (GLP-1 analogue) once weekly on HbA_{1c} and beta cell function in uncontrolled type 2 diabetes mellitus: the EGO study analysis

G. Umpierrez[1], T. Blevins[2], J. Rosenstock[3], C. Cheng[4], E. Bastyr[4,5], J. Anderson[4];
[1]Emory University School of Medicine, SE Atlanta, [2]Texas Diabetes & Endocrinology, Austin, [3]Dallas Diabetes & Endocrine Center, Dallas, [4]Lilly Research Laboratories, Indianapolis, [5]Indiana University School of Medicine, Indianapolis, United States.

Background and aims: LY2189265, a novel, long-acting glucagon-like peptide 1 (GLP-1) analog, consists of a dipeptidyl peptidase-IV (DPP-IV)-protected GLP-1 analog covalently linked to a human IgG4-Fc heavy chain by a small peptide linker. This randomized, placebo-controlled, double-blind study investigated the effect of dose titration of LY2189265 in overweight/obese patients with type 2 diabetes mellitus (T2DM) taking 2 classes of oral antihyperglycemic agents (OAH). The impact of LY2189265 on metabolic outcomes and measures of physiologic function of β-cell function and insulin sensitivity was evaluated.

Materials and methods: Following a 2-week placebo run-in, 262 patients (49% female) with T2DM (mean duration 8.3±6.4 years) and elevated BMI (mean 33.9±4.1 kg/m^2) and HbA1c (mean 8.2±0.9%) were randomized to once-weekly subcutaneous injections of either placebo (16 weeks), 1 of 2 titrated doses of LY2189265 (0.5 mg for 4 weeks followed by 1.0 mg for 12 weeks; or 1.0 mg for 4 weeks followed by 2.0 mg for 12 weeks), or LY2189265 1.0 mg (16 weeks). Patients were stratified with similar numbers randomized across the strata to the 4 treatment arms. The primary measure was glycemic control, as measured by HbA1c change from baseline at 16 weeks. Secondary measures were fasting serum glucose (FSG); solid mixed meal test postprandial glucose (PPG) excursion; body weight; and β-cell function (%B), insulin sensitivity (%S) and insulin resistance (IR), as measured by the Homeostasis Model Assessment (HOMA2) using c-peptide concentrations.

Results: Statistically significant decreases in glycemic and weight measures and increases in β-cell function were observed compared to placebo in response to LY2189265 treatment, as shown in the following table:

Outcome Measures (units)	Change from Baseline***			
	Placebo	LY2189265		
		0.5/1.0 mg	1.0/1.0 mg	1.0/2.0 mg
HbA1c (%)	-0.27	-1.28**	-1.29**	-1.52**
FSG (mmol/L)	-0.49	-2.09**	-2.04**	-2.64**
Test Meal PPG AUC	36.36	30.71**	32.21**	28.24**
Test Meal PPG AUC Excursion	10.94	8.85*	9.92*	8.16*
Weight (kg)	-0.07	-1.58*	-1.40*	-2.51**
HOMA%B	1.04	39.20*	44.26**	45.61**
HOMA%S	2.46	0.46	-1.65	3.58
HOMA-IR	-0.23	-0.20	0.01	-0.23

*p<0.05 vs placebo
**p<.0.001 vs placebo
***HbA1c, FBG, and weight reported as Least-Squares Mean; HOMA%B, %S, and IR reported as Mean; Test Meal PPG AUC and Test Meal PPG AUC Excursion reported as Mean for test meal at endpoint.

The incidence of hypoglycemic episodes was not statistically significantly different across treatment groups. Nausea (13%), diarrhea (8.8%) and abdominal distension (8.0%) were the most frequently recorded treatment-emergent adverse events.

Conclusion: In conclusion, in patients with T2DM sub-optimally controlled by OAHs, adjunctive administration of once-weekly LY2189265 resulted in significant reduction of HbA1c, fasting and postprandial glucose and an improvement in β-cell function with a favorable effect on body weight.

130

The long-acting GLP-1-receptor agonist albiglutide improves glycaemic control in type 2 diabetes: time-course analysis

F. Yang[1], J.E.B. Reusch[2], J. Rosenstock[3], M.A. Bush[4], M.W. Stewart[1];
[1]GlaxoSmithKline, King Of Prussia, [2]Denver VAMC, Denver, [3]Dallas Diabetes and Endocrine Center at Medical City, Dallas, [4]GlaxoSmithKline, Research Triangle Park, United States.

Background and aims: To assess early responses to pharmacologic therapies, fasting plasma glucose (FPG) is a more accurate reflection of immediate glucose control than is HbA_{1c}, and variations in FPG levels may in part be due to underlying pharmacokinetics (PK). Albiglutide is a GLP-1-receptor agonist with a half-life of ~5 days, having the potential for weekly or less-frequent dosing. Accordingly, in a Phase 2 study designed to determine optimal dosing and scheduling of albiglutide, a time-course analysis was conducted to examine optimal effects on key measures of glycemic control. Exenatide was included as a clinical reference for twice-daily GLP-1-receptor agonist therapy.

Materials and methods: A randomized, multicenter, double-blind, parallel-group study in 356 subjects (mean age 54 years, BMI 32.1 kg/m^2) with type 2 diabetes (mean duration 5 years) previously treated with diet and exercise or metformin (mean baseline HbA_{1c} 8.0%) was conducted. Patients received subcutaneous placebo, albiglutide [weekly (4, 15 or 30 mg), every other week (biweekly; 15, 30 or 50 mg) or monthly (50 or 100 mg)], or non-blinded exenatide twice daily (per label, in metformin-treated patients) over 16 weeks. FPG was assessed throughout the study so that the time course of these effects could be evaluated.

Results: Improvements in FPG were seen as early as the first assessment (2 weeks) in all albiglutide groups. Among top doses within each schedule, the lowest FPG fluctuations were seen for 30 mg weekly albiglutide, followed by 50 mg biweekly dosing. The 100 mg monthly albiglutide dose produced the greatest FPG fluctuations between dosing, with attenuated FPG reductions as albiglutide exposure decreased. PK/PD modelling showed a clear relationship between albiglutide exposure and FPG. Despite greater fluctuations in FPG for monthly dosing, similar HbA_{1c} improvements were observed with the highest dose of each albiglutide regimen at week 16 (-0.87, -0.79 and -0.87% by 30 mg weekly, 50 mg biweekly and 100 mg monthly dosing, respectively, vs PBO -0.17%, p < 0.005. Exenatide reduced HbA_{1c} by -0.54%).

Conclusion: Albiglutide at all doses and schedules improved HbA_{1c} in a stable manner in patients with type 2 diabetes over 16 weeks. The 30 mg weekly dose generated the least fluctuation in FPG, followed by 50 mg biweekly albiglutide. The stability of the FPG profile over time among patients in the

weekly and biweekly albiglutide groups may have important therapeutic benefits and is likely related to the reduced PK fluctuations compared with monthly administration.

131

Post-meal pharmacodynamic profile of AVE0010, a once-daily GLP-1 receptor agonist, in patients with type 2 diabetes inadequately controlled on metformin

R.E. Ratner[1], J. Rosenstock[2], G. Boka[3], L. Silvestre[3];
[1]MedStar Research Institute, Hyattsville, United States, [2]Dallas Diabetes and Endocrine Center, Dallas, United States, [3]sanofi-aventis R&D, Antony, France.

Background and aims: AVE0010 is a new GLP-1 receptor agonist under development for the treatment of type 2 diabetes mellitus (T2DM). In a 13-week, double-blind, placebo-controlled study, AVE0010 given once- (QD) or twice-daily (BID) provided dose-dependent improvements in HbA_{1c} (-0.5% to -0.8% from a baseline of 7.5%), reductions in body weight of approximately 2-4 kg, and was well tolerated. Here, we report the results of a post-meal pharmacodynamic (PD) evaluation carried out in a subset of patients from that study.
Materials and methods: Patients (n=542) inadequately controlled on a stable dose of metformin for at least 3 months (1.6-1.9 g/day; HbA_{1c} ≥7%) were randomised to subcutaneous AVE0010 at doses of 5, 10, 20, and 30 µg QD or BID, or matching placebo. At selected sites, patients (n=201) received a standardised breakfast meal challenge 30 min after drug administration to evaluate fasting, 2-h post-meal, and $AUC_{[0\text{-}4h]}$ values of plasma glucose, serum insulin, proinsulin, proinsulin/insulin ratio, C-peptide, and glucagon levels, at baseline and Week 13.
Results: Dose-dependent decreases in mean 2-h post-meal glucose and glucose $AUC_{[0\text{-}4h]}$ from baseline were seen for both QD and BID dosing. Insulin $AUC_{[0\text{-}4h]}$, 2-h C-peptide, 2-h insulin, and 2-h proinsulin were also dose-dependently reduced with QD dosing (Table). Glucagon levels at 2 h and glucagon $AUC_{[0\text{-}4h]}$ were significantly decreased at all doses (except the 2-h value at 5 µg QD), but no dose-response relationship was evident. The 2-h proinsulin/insulin ratio was unchanged with AVE0010, but the fasting ratio was significantly reduced by -0.4 to -1.4 relative to placebo at higher doses (20 and 30 µg QD and 10 to 30 µg BID), suggesting improved β-cell function.
Conclusion: AVE0010 given QD or BID was associated with dose-dependent improvements in post-meal glucose levels, and this was accompanied by reduced glucagon and insulin levels, consistent with a glucose-dependent effect on insulin secretion. These results highlight the promising post-meal glucose control profile of this new once-daily GLP-1 receptor agonist in T2DM.

132

Once-daily saxagliptin added to metformin is well tolerated and provides sustained glycaemic control over 102 weeks in patients with type 2 diabetes

S. Ravichandran[1], R. DeFronzo[2], A.J. Garber[3], J.L. Gross[4], M.N. Hissa[5], R.Y. Duan[1], R. Chen[1];
[1]Bristol-Myers Squibb, Princeton, NJ, United States, [2]Dept. of Medicine/Diabetes, University of Texas Health Science Center, San Antonio, United States, [3]Baylor College Of Medicine, Houston, United States, [4]Hospital de Clinicias de Porto Alegre - Centro De Pesquisa Em Diabetes, Porto Alegre, Brazil, [5]University Federal do Ceará Medical School, Fortaleza, Brazil.

Background and aims: Saxagliptin (SAXA) is a potent selective dipeptidyl peptidase-4 (DPP-4) inhibitor specifically designed for extended inhibition of the DPP-4 enzyme. The long-term efficacy and safety of SAXA added to metformin (MET) were assessed in patients with type 2 diabetes (T2D) and inadequate glycemic control (HbA_{1c} ≥7.0%–≤10.0%) on MET alone.
Materials and methods: For the double-blind (DB) short-term (ST) treatment (tx) period, 743 patients (baseline HbA_{1c} 8.0%) were randomized and treated 1:1:1:1 to SAXA 2.5, 5, 10mg or PBO od+stable MET dose (1500–2500mg/day) for 24wks. Patients who met prespecified glycemic rescue criteria during the ST tx period received open-label pioglitazone (pio) 15–45mg+blinded study medication and entered the DB 42mo long-term extension (LTE). Patients completing the ST tx period without rescue were also eligible to enter the 42mo LTE; pio rescue therapy was also available during the LTE based on prespecified glycemic criteria. Efficacy analyses (ANCOVA, LOCF) reflect data before rescue; safety analyses reflect data regardless of rescue.
Results: At 102wks PBO-subtracted HbA_{1c} changes from baseline (n/N) for SAXA 2.5, 5, and 10mg were −0.62 (181/192; 95%CI: −0.84, −0.40), −0.72 (184/191; 95%CI: −0.94, −0.50), and −0.52 (177/181; 95%CI: −0.74, −0.30), respectively. The proportion of patients (n/N) discontinued for lack of glycemic control or rescued for meeting prespecified glycemic criteria was lower for SAXA 2.5- (58.3% [112/192]), 5- (51.8% [99/191]), and 10mg (56.9% [103/181]) vs PBO+MET (71.5% [128/179]). SAXA+MET was generally well tolerated; AE frequencies for SAXA 2.5, 5, and 10mg were 89.6%, 78.0%, and 86.7%, respectively, vs 78.8% for PBO+MET. The proportions of patients with hypoglycemia events (all) were 10.4%, 8.9%, and 11.0% for SAXA 2.5, 5, and 10mg vs 10.1% for PBO+MET. Confirmed hypoglycemia (symptoms with glucose ≤50mg/dL) was infrequent (≤1.1%, all tx groups). Small decreases in mean body weight at wk102 (before rescue, LOCF) vs baseline were observed in all tx groups.
Conclusion: In patients with T2D inadequately controlled on MET alone, SAXA added to MET provided sustained, clinically meaningful glycemic improvements over 102wks vs control and was generally well tolerated with no increase in hypoglycemia or weight.

Prediction of coronary heart disease in a general, prediabetic and diabetic population during 10 years of follow-up: accuracy of the Framingham, SCORE and UKPDS functions. The Hoorn Study

A.A.W. van der Heijden[1], M.M. Ortegon[2], L.W. Niessen[3,4], G. Nijpels[1], J.M. Dekker[1];
[1]The EMGO Institute for Health and Care Research, VU University Medical Center, Amsterdam, Netherlands, [2]Rosario University, Bogota, Colombia, [3]Department of Health Policy and Management, Erasmus University, Rotterdam, Netherlands, [4]Department of International Health, John Hopkins Bloomberg School of Public Health, Baltimore, United States.

Background and aims: Risk of coronary heart disease (CHD) can be estimated using prediction formulas that combine values for different risk factors. We compared the validity of the Framingham, SCORE and UKPDS risk function in the prediction of risk of first or fatal CHD in populations with normal glucose tolerance (NGT), intermediate hyperglycemia (IH) and diabetes mellitus (DM).
Materials and methods: We used prospective data of 1482 Caucasian men and women, 50 to 75 years of age, who participated in the Hoorn Study. The predictive accuracy of the three risk functions was estimated using calibration (the ability to predict the number of observed events during follow-up) and discrimination appraisals (the ability to distinguish between those who experience a CHD event during follow-up from those who do not). Calibration of the models was visually checked by plotting the predicted probabilities against the observed proportion of CHD events. The discriminatory ability of the models was assessed by calculating the area under the receiver operating characteristic curve (AUROC) using the 10-year risk estimates predicted by the three models. The discriminatory power of the models is graded as low for an AUROC between 0.5-0.7, moderate between 0.7-0.9 and high if >0.9. All analyses were stratified for glucose status.
Results: During 10 years of follow-up, a total of 197 CHD events of which 43 were fatal, were observed in this population, with the highest percentage of CHD events in the diabetes group. The Framingham and UKPDS prediction models overestimated the risk of first CHD in the NGT, IH and DM sub-group. Overall, all prediction models had a low to moderate discriminatory capacity, showing better discrimination when fatal CHD was used as the predicted outcome. The SCORE risk function was the best predictor of fatal CHD events in the NGT group (AUROC=0.79 (95% CI, 0.70-0.87)), whereas the UKPDS performed better in the IH group (0.84 (0.74 (95% CI, 0.56-0.93) when estimating fatal CHD risk. In the diabetic sub-group all prediction models had low discriminatory ability when estimating the risk of first CHD.
Conclusion: The use of the Framingham function for prediction of first CHD is likely to be inappropriate due to the overestimation of persons' absolute CHD risk. In CHD prevention, the application of the SCORE risk function in diabetic patients and application of the SCORE and UKPDS risk functions in persons with normal glucose metabolism or intermediate hyperglycemia might prove useful to estimate relative changes in the absence of a more valid tool.

Discriminatory ability of the Framingham, SCORE and UKPDS risk functions: AUROC (95% CI))

	Normal glucose tolerance	Intermediate hyperglycemia	Type 2 diabetes mellitus
First CHD			
Framingham	0.68 (0.63-0.74)	0.60 (0.47-0.74)	0.63 (0.50-0.76)
SCORE	0.71 (0.66-0.76)	0.70 (0.60-0.79)	0.66 (0.54-0.79)
UKPDS	0.71 (0.66-0.75)	0.70 (0.60-0.80)	0.66 (0.56-0.78)
Fatal CHD			
Framingham	0.71 (0.61-0.82)	0.76 (0.65-0.88)	0.61 (0.37-0.86)
SCORE	0.79 (0.70-0.87)	0.70 (0.50-0.89)	0.74 (0.56-0.93)

Comparison of the impact of glycaemic status, HbA_{1c}, fasting and 2-hour glucose on aortic stiffness: a 5-year follow-up from The Whitehall II study

D.R. Witte[1,2], R. Aakaer Jensen[1], C.M. McEniery[3], E.J. Brunner[2], I.B. Wilkinson[3], M. Kivimäki[2], A.G. Tabák[2,4];
[1]Steno Diabetes Center, Gentofte, Denmark, [2]Department of Epidemiology and Public Health, University College London, United Kingdom, [3]Clinical Pharmacology Unit, University of Cambridge, United Kingdom, [4]1st Department of Medicine, Semmelweis University, Budapest, Hungary.

Background and aims: HbA_{1c} is being considered as a diagnostic tool for diabetes. Direct evidence regarding its association with early stages of atherosclerosis is essential, however compared to fasting or 2-hour glucose is scarce. Our aim was to compare the relation between glycaemic status, HbA_{1c}, fasting and 2-hour glucose with aortic stiffness 5 years later in a middle-aged, non diabetic population, accounting for potential confounders.
Materials and methods: We examined 1818 participants (1214 men) of the Whitehall II cohort without known diabetes (mean age: 60.8 years, SD:5.8; mean BMI: 25.9, SD:3.8), who had a clinical assessment including a 75g oral glucose tolerance test and HbA_{1c} measurement at study phase 7 (2003-2004, baseline for the current analysis) plus measurement of carotid-femoral pulse wave velocity (PWV) as an indicator of aortic stiffness at study phase 9 (2007-2009). We present results from linear regression models adjusted for age, sex and mean arterial pressure (MAP), and the degree of attenuation on further adjustment for cardiovascular risk factors.
Results: Mean PWV was 8.3 m/s (SD:2.0). PWV did not differ between those with isolated Impaired Fasting Glycaemia (IFG) and the reference group with normoglycemia (β:-0.02 m/s; 95%CI:-0.5;0.5). Those with isolated Impaired Glucose Tolerance (IGT), combined IFG/IGT and newly detected diabetes had higher PWV [β (95%CI): 0.9 (0.3;1.5), 0.5 (0.2;0.7) and 0.7 (0.3;1.2) respectively], indicating stiffer arteries. Figure 1 shows age, sex and MAP adjusted differences in PWV by quintile of HbA_{1c}, fasting and 2-hour glucose, compared to the lowest quintile. Further adjustment for cardiovascular risk factors (smoking, HDL cholesterol, triglycerides, statin therapy, antihypertensive therapy) attenuated the differences by up to 23, 27 and 33% for HbA_{1c}, fasting and 2-hour glucose respectively. Differences in the upper two HbA_{1c} quintiles and the upper quintile of fasting and 2-hour glucose remained statistically significant. Across the range of values, PWV increased by 0.19 m/s (95%CI: 0.11;0.28), 0.19 m/s (0.11;0.27) and 0.25 m/s (0.17;0.33) per standard deviation increase in HbA_{1c}, fasting and 2-hour glucose respectively, adjusted for age, sex and MAP.
Conclusion: Our findings show similar impact of HbA_{1c}, fasting, and 2-hour glucose levels on aortic stiffness (an early marker of systemic atherosclerosis). Although 2-hour glucose has a stronger impact on PWV in the highest ranges, its overall effect is explained to a larger degree by other cardiovascular risk factors. HbA_{1c} may therefore be expected to perform at least as well as direct glucose measures in the prediction of cardiovascular events.

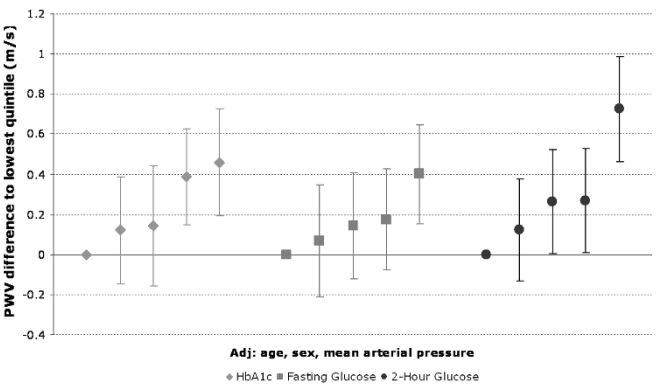

Figure 1.

Central obesity markers, but not BMI, are associated with cardiovascular risk in type 2 diabetic patients: results from the ADVANCE study

S. Czernichow[1,2], R. Huxley[1], A.-P. Kengne[1], B. de Galan[1,3], A. Pillai[1], S. Zoungas[1], D. Batty[1,4], M. Marre[5], B. Neal[1], J. Chalmers[1], on behalf of the ADVANCE Collaborative Group;
[1]The George Institute for International Health, Sydney, Australia, [2]Avicenne Hospital; University of Paris 13, Bobigny, France, [3]Radboud University Nijmegen Medical Centre, Netherlands, [4]MRC Social & Public Health Sciences Unit, Glasgow, United Kingdom, [5]Bichat Hospital & Paris 7 University, Paris, France.

Background and aims: The relative importance of anthropometric markers [body mass index (BMI), waist circumference (WC) and waist-to-hip ratio (WHR)] for cardiovascular risk in people with type 2 diabetes (T2D) has not been well established. These analyses examine the strength of the associations between baseline anthropometric markers and cardiovascular risk in T2D patients participating in the ADVANCE (Action in Diabetes and Vascular Disease: PreterAx and DiamicroN MR Controlled Evaluation) Study.
Materials and methods: 11,140 patients followed-up for 5 years were included in the present report. Cox proportional hazard models were used to determine the hazard ratios (HR) and 95% confidence intervals (95% CI) for one standard deviation (SD) change in baseline BMI, WC and WHR after adjustment for age, sex, ethnicity, current smoking and treatment allocation.
Results: Mean age was 66 years (SD = 6), 43% were female and 32% had macrovascular disease at baseline. Mean BMI was 28 kg/m² (SD = 5), WC was 98 (13) cm and WHR was 0.93 (0.08). During follow-up, 1147 major cardiovascular, 647 major coronary, 484 major cerebrovascular events and 542 cardiovascular deaths were recorded. A positive linear trend was observed for WC with cardiovascular, coronary events (both p-values ≤ 0.05) and cardiovascular death (p = 0.07). A similar pattern was observed for WHR with cardiovascular, coronary events and cardiovascular death (all p-values ≤ 0.001) and cerebrovascular events (p = 0.07). Multivariate HR (95% CI) associated with one higher SD for cardiovascular, coronary events and cardiovascular death were 1.10 (1.03-1.18), 1.13 (1.03-1.24) and 1.08 (0.98-1.19) for WC, respectively and 1.12 (1.05-1.19), 1.17 (1.08-1.28) and 1.19 (1.09-1.31) for WHR. BMI was not linearly related to any of the cardiovascular outcomes (all p-values > 0.6), but there was some suggestion of an inverse association with cerebrovascular events (p = 0.04), such that for every SD increment in BMI the risk of stroke was 0.92 (0.83-1.02). Sensitivity analyses excluding patients with macrovascular disease at baseline did not materially alter these results.
Conclusion: Data from this large, prospective, well characterised study indicate that markers of central obesity, but not BMI, are positively and continuously associated with cardiovascular risk in older individuals with T2D and to a lesser extent with cerebrovascular outcomes. This lack of association with BMI is not unexpected in a population limited to individuals who already have long-standing diabetes. There was some suggestion of an inverse association between BMI and the risk of stroke which warrants further investigation.

Differences in height and waist circumference explain gender differences in 2-hour plasma glucose levels - the Inter99 study

K. Færch[1], K. Borch-Johnsen[1,2], A. Vaag[1], T. Jørgensen[3], D.R. Witte[1];
[1]Steno Diabetes Center, Gentofte, [2]Faculty of Health Sciences, University of Aarhus, [3]Research Center for Prevention and Health, Glostrup, Denmark.

Background and aims: The prevalence of impaired glucose tolerance (IGT) is higher in women than in men. Currently, it is debated whether this higher prevalence in women is caused by hormonal factors or whether it is simply due to differences in body size between men and women and thereby differences in the ability to dispose of the fixed amount of 75 g glucose during an oral glucose tolerance test (OGTT). Therefore, the aim of this study was to test the hypothesis that men and women of same height and waist circumference have similar 2-hour post OGTT plasma glucose (2hPG) levels.
Materials and methods: We used baseline data from 3,007 non-diabetic men and 3,104 non-diabetic women of the Inter99 study with available information on height, waist circumference (WC), and 2hPG levels. Univariate analyses between 2hPG and height and between 2hPG and WC were performed stratified by gender. Furthermore, a linear regression model with 2hPG level as response variable and height, WC, and gender as explanatory variables was tested.
Results: The mean ± SD 2hPG levels were 5.99 ± 1.83 for men and 6.17 ± 1.69 for women (p<0.001 for diff.). In both men and women we found associations between 2hPG and WC (p<0.001) and inverse associations between 2hPG and height (p<0.001). When height, WC, and gender were included as explanatory variables, there was no difference in 2hPG levels between men and women (p=0.881), whereas both height and WC were still significantly associated with 2hPG levels (p<0.001). The figure illustrates 2hPG levels for men and women by height and WC strata.
Conclusion: Gender differences in the prevalence of IGT can be explained by differences in body size between men and women. This finding questions the validity of using the same standard 75 g-OGTT for classifying IGT in men and women of different body size.

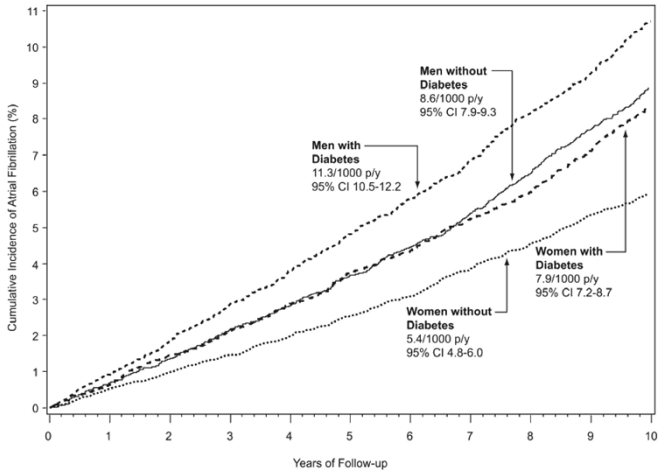
Prevalence and incidence of atrial fibrillation among patients with and without type 2 diabetes: a confluence of two epidemics?

G.A. Nichols[1], K. Reinier[2], P. Barnett[2], S.S. Chugh[2];
[1]Kaiser Permanente Center for Health Research, Portland, [2]Cedars-Sinai Medical Center, Los Angeles, United States.

Background and aims: Diabetes is a known risk factor for cardiovascular disease (CVD), but the relationship between diabetes and atrial fibrillation (AF) merits further evaluation. We sought to estimate and compare the prevalence and incidence of AF among patients with and without diabetes.
Materials and methods: From the electronic medical records of Kaiser Permanente Northwest, a group model HMO, we selected 10,213 patients who were members of the diabetes registry as of January 1, 1999, and 7,159 patients who entered the registry by December 31, 2004 (total=17,372). Index date was defined as January 1, 1999 or date of registry entry. We then matched these patients to KPNW members without diabetes on year of birth and sex. All patients were then followed until they died, left the health plan, or until December 31, 2008, whichever came first. We estimated the prevalence of AF at baseline, then followed patients without prevalent AF to estimate and compare the incidence of AF among those with and without diabetes, controlling for age, sex, race, body mass index, systolic blood pressure, cigarette smoking, and comorbidities including ischemic heart disease, stroke, valvular disease, hypertension, and heart failure.
Results: Mean age of the study sample was 58.4±11.5 years and 51.2% were men. The prevalence of AF was significantly greater among patients with diabetes (3.6% vs. 2.5%, p<0.0001). Prevalence increased with age in both groups, but did so more dramatically among diabetes patients. Over a mean follow-up of 7.2±2.8 years, the 16,741 diabetic patients without prevalent AF at baseline developed AF at an age/sex adjusted incidence rate of 9.6/1000 person-years (95% CI 9.0-10.2), compared to 6.9 (6.5-7.4) among the 16,930 non-diabetic patients. Thus, the relative risk of AF was 39% (29-50%) greater among persons with diabetes. Among men, the age-adjusted incidence of AF per 1,000 person-years was 11.3 (10.5-12.2) and 8.6 (7.9-9.3), respectively, for patients with and without diabetes, producing a 32% (19-46%) greater relative risk among men with diabetes. Among women, age-adjusted AF incidence was 7.9 (7.2-8.7) and 5.4 (4.8-6.0), respectively, with a higher relative risk attributable to diabetes of 48% (32-66%). After further controlling for other known risk factors, patients with diabetes were at 18% greater risk of developing AF (hazard ratio 1.18, 95% CI 1.07-1.30). AF risk associated with diabetes remained substantially higher among women (1.23, 1.07-1.43) than men (1.14, 1.01-1.29).

Conclusion: Atrial fibrillation is significantly more prevalent, and develops at a greater rate, among patients with diabetes. Although women are at a lesser absolute risk of AF than men, diabetes imparts a greater relative risk of AF among women than men. A potential mechanistic link between these two important disease conditions, and the differential effects of gender, warrants further investigation.



138

Hypoglycaemia and risk of myocardial infarction in U.S. veterans with diabetes

D.R. Miller[1], G. Fincke[1], J.-P. Lafrance[1], M. Palnati[1], Q. Shao[1], Q. Zhang[2], V. Fonseca[3], M. Riddle[4], S. Vijan[5], C.L. Christiansen[1];
[1]Department of Health Policy and Management, Boston University School of Public Health, Bedford, [2]Sanofi Aventis, Bridgewater, [3]Tulane University, New Orleans, [4]Oregon Health & Science University, Portland, [5]University of Michigan Health System, Ann Arbor, United States.

Background and aims: Hypoglycemia is a common and serious complication of diabetes treatment. There have been reports that hypoglycemia may increase risk of cardiovascular disease (CVD) and mortality, a concern heightened by recent trial reports of adverse outcomes in patients randomized to intensive glycemic control. These risks are not well understood, however, and further research is needed.
Materials and methods: We conducted case control studies of hypoglycemia among diabetes patients in the U.S. Veterans Health Administration (VA) to assess CVD risks, using the Diabetes Epidemiology Cohorts, a national linked database of all veteran VA diabetes patients in the U.S. Among diabetes patients in 2000-2004 with no history of myocardial infarction (MI), unstable angina, or cardiac surgery, we identified 63,519 cases with first MI and 1,009,746 controls with no MI. Controls were randomly matched to cases at a 12:1 ratio and assigned the index date of the case (hospital admission date for MI). Using diagnosis codes from inpatient and outpatient encounters, we identified hypoglycemic events prior to the index date (excluding the day of admission for MI and the day before to minimize potential ascertainment bias). MI risk was estimated using logistic regression with adjustment for CVD risk factors, other diabetes complications, other medical conditions, medications prescribed, laboratory test results, socio-demographic factors, and health care use. Analyses were stratified by insulin use. We also conducted a case-time-control analysis, comparing hypoglycemic event rates prior to the MI with rates occurring one year earlier, using a similar comparison in the controls to account for increasing age and severity of disease over the year.
Results: Hypoglycemic events in the year before the index date were more common in cases (9.6%) than controls (4.2%) with the greatest difference in the weeks before the index date. After adjusting for potential confounders, the odds ratios and 95% confidence intervals for MI associated with hypoglycemic events in the 2 weeks before the index date were 1.60 (1.41-1.81) for those not using insulin, 1.53 (1.33-1.75) for insulin users, and 1.94 (1.28-2.94) for new insulin users. MI risks were lower for hypoglycemia between 2 weeks and 6 months before the index date and there was no elevated risk for hypoglycemia occurring more than 6 months ago (0.96 (0.90-1.01) for the prior year in insulin users). MI risks were particularly high for hypoglycemia in a recent hospital stay prior to admission for the MI. We found similar elevated risks in the case-time-control analysis suggesting that the results are not explained by unmeasured confounding.
Conclusion: Hypoglycemia occurred more often than expected prior to MI in diabetes patients. It remains to be determined whether hypoglycemia is simply a marker for increased risk of imminent MI or has a direct effect in causing the infarction. Clinicians should be cognizant of these potential risks in managing diabetes patients.

OP 24 Effects of maternal diabetes and childhood obesity in diabetes

139

Reduced renal reserve in non-diabetic adults exposed in utero to maternal type 1 diabetes

C. Abi Khalil[1,2], F. Travert[1,2], S. Fetita[3], F. Rouzet[4], R. Roussel[1,2], S. Hadjadj[5], D. LeGuludec[4], J.-F. Gautier[3], M. Marre[1,2];
[1]Diabétologie-endocrinologie-nutrition, Hopital Bichat, Paris, [2]INSERM U695, Paris, [3]Diabétologie-endocrinologie-nutrition, Hopital Saint-Louis, Paris, [4]Service de médecine nucléaire, Hopital Bichat, Paris, [5]Diabétologie-endocrinologie-nutrition, CHU Poitiers, France.

Background and aims: Experimental animal studies support that fetuses exposed to hyperglycemia display impaired nephrogenesis and reduced global angiogenesis. We tested if such a phenomenon could be observed in humans.
Materials and methods: We studied renal microcirculation of non-diabetic Offspring from Type 1 Diabetic Mothers (OT1DM) compared to similar subjects born from Type 1 Diabetic Fathers (OT1DF). As Renal Functional Reserve (RFR) is a surrogate marker of nephron number and renal vasculature, we measured simultaneously Glomerular Filtration Rate (GFR, ^{51}Cr-EDTA clearance), Effective Renal Plasma Flow (ERPF, ^{123}I-Hippurate clearance), Mean Arterial Pressure (MAP, Dynamap®) and calculated Filtration Fraction (FF = GFR / ERPF), and Renal Vascular Resistances (RVR = MAP / ERPF), both at baseline, and during Amino Acid (AA) infusion
Results: The OT1DM (n = 19) and OT1DF (n =18) were similar for age (median 27 (range 18 - 41) vs 26 (18 - 37) years), sex ratio (14 F / 5 M vs 9 F / 9 M), BMI (23.1 ± 3.7 vs 22.6 ± 2.3 Kg/m^2), and birth weight (3288 ± 550 vs 3440 ± 489 g). During AA infusion, GFR rose from 103 (9) to 122 (14) ml/min in OT1DF, vs from 102 (12) to 110 (12) in OT1DM (inter-group comparison p<0.01), ERPF rose from 511 (72) to 591 (90) ml/min in OT1DF vs from 507 (57) to 530 (66) in OT1DM (p<0.01), and MAP varied from 85 (7) to 84 (5) mmHg in OT1DF versus from 89 (6) to 91(8) in OT1DM (p<0.01). RVR decreased less in OT1DM (from 0.18 (0.03) to 0.17 (0.03) mmHg/ml/min) than in OT1DF (from 0.17 (0.03) to 0.15 (0.02); p<0.001). In addition, GFR changes were related to birth weights in OT1DM (r=0.62,p<0.01), not in OT1DF(r=-0.08,NS), while the ranges of birth weights were similar in the 2 groups.
Conclusion: Fetal exposure to maternal diabetes is associated with reduced RFR (as assessed by comparative changes in GFR, ERPF and RVR), which may reflect a reduced number of nephrons and/or reduced renal microvascularisation. Thus, offspring of T1D mothers may be predisposed to glomerular and cardiovascular diseases later in life.

Perinatal outcome is worse in male newborns of women with pregestational diabetes mellitus

A. García-Patterson[1], J. Adelantado[2], G. Ginovart[3], A. de Leiva[1], R. Corcoy[1];
[1]Servei d'Endocrinologia, [2]Servei d'Obstetrícia, [3]Servei de Pediatria, Hospital de Sant Pau, Barcelona, Spain.

Background: Male sex is a well-known risk factor for unfavorable perinatal outcome that has only occasionally been assessed in diabetic pregnancy .
Aim: To assess perinatal outcome in infants of mothers with pregestational diabetes mellitus in relation to fetal sex.
Methods: Retrospective review using a prospectively collected database including all diabetic pregnancies attended in the Diabetes and Pregnancy Clinic of the Center from 1st January 1981 to 31st December 2006. The analysis was limited to single pregnancies of women with pregestational diabetes mellitus (381 with Type 1 DM and 69 with Type 2 DM). Evaluated maternal characteristics were: anthropometrics, diabetes duration and mean HbA1c in the three trimesters. Outcomes measured: stillbirth, neonatal mortality, perinatal mortality, major malformations, newborns small/large for gestational age, preterm birth, and a composite outcome including all of the former. Statistics: Chi-square test, Student T-test or Mann-Whitney U-test corresponding to qualitative variables, normally distributed quantitative variables and non-normally distributed quantitative variables. Significance was set at a bilateral p <0.05.
Results: Baseline and metabolic characteristics did not differ in mothers of male and female newborns. A consistent trend for worse outcome in male newborns was observed for most variables in both Type 1 and Type 2 DM without reaching statistical significance. Nevertheless the composite outcome was more frequent in male fetuses (56.2 vs 46.1%, p <0.05).
Conclusion: In women with pregestational diabetes mellitus, perinatal outcome is worse in male newborns despite similar maternal characteristics.

141

Anthropometric characteristics at 11 years in children exposed to maternal gestational diabetes mellitus or mild gestational hyperglycaemia in France: DIAGEST 2 study

A. Vambergue[1], S. Schaller[1], X. Lenne[2], O. Verier[3], M. Lepeut[4], S. Biausque[5], C. Dognin[6], P. Fontaine[1], Gestational Diabetes Study Group, Diagest Group;
[1]Diabetology, CHRU Lille, [2]CRESGE LEM, CNRS 8179, Lille, [3]Diabetology, CH, Valencienne, [4]Diabetology, CH, Roubaix, [5]Gynecology, CH, Seclin, [6]Gynecology, CH, Douai, France.

Background and aims: Intrauterine exposure to gestational diabetes (GDM) may promote offspring overweight or obesity and cardiometabolic risk. It has been shown that there was a relationship between maternal glucose tolerance during pregnancy and offspring obesity or systolic blood pressure at 3 years. The objective of this study was to determine the anthropometric measurements at 11 years in children exposed to gestational diabetes, mild gestational hyperglycaemia (MGH) compared to children whose mothers had a normal glucose tolerance (C) during pregnancy in a French population (466 GDM, 322 MHG and 221 C).
Materials and methods: Each child whom mother had participated in a previous study on the screening and diagnosis of GDM (DIAGEST study) underwent follow-up evaluations at a median age of 11 years. Measures included BMI, BMI z-score, waist circumference, skinfold thicknesses, documentation of medical history, dietary and physical activity habits. Childhood overweight and obesity were established using age-specific reference ranges.
Results: Five hundred fifteen children were assessed at 11 years of age, so the adherence to follow-up was 49.4%. We examined 257 offspring of GDM mothers, 150 offspring of MGH and 108 offspring of control mothers (49.9%, 29.1% and 21 % of the whole population respectively). According to the IOTF criteria, the rate of overweight and obesity were respectively 22.8% and 8.2% in the whole population. The percentages of fat mass were significantly higher among children born from GDM mothers or MGH mothers compared to children born from control mothers (25.7% vs 26.1% vs 23.7%; p< 0.05 respectively). In univariate analysis, there were a significant increase of the BMI z-score (1.80 vs 1.05, p<0.05), the waist circumference (71.64 cm vs 68.38 cm, p<0.05), the percentages of fat mass (27.15% vs 24.95%, p<0.05) among children born with a macrosomia compared to those without. In multivariate analysis, the only factor related to an increasing BMI z-score (p=0.0012), waist circumference (p=0.011) and percentage of fat mass (p=0.009), is macrosomia at birth in children born from mother with an abnormal glucose tolerance.
Conclusion: This study confirms that there is an association of maternal glucose tolerance during pregnancy with offspring adiposity at age 11 years. This association is dependent of the presence of macrosomia at birth. Exposure to a diabetic environment in utero predisposes to metabolic disturbances later in life. Maternal diabetes is associated with programming of overweight and obesity in offspring.

Prevalence and predictors of overweight in offspring of mothers with gestational diabetes

S. Hummel[1], H. Boerschmann[2], M. Pflüger[2], M. Hummel[2], A.G. Ziegler[2,1];
[1]Forschergruppe Diabetes der TU München, [2]Diabetes Research Institute, Munich, Germany.

Background and aims: Recently we have shown, that maternal type 1 diabetes (T1D) is not an independant risk factor for overweight in offspring of type 1 diabetic mothers, but that factors associated with maternal T1D, such as short breastfeeding duration and high birth size, predispose children to overweight during childhood. We now studied the prevalence and predictors of overweight in offspring of mothers with gestational diabetes (GDM) and evaluated the influence of Body mass index (BMI) on the development of insulin resistance.

Materials and methods: Data on child's weight and height were collected at age 2 and 8 years from 331 children born between 1989 and 2000 participating in the prospective German GDM offspring study. All children had a mother with GDM. Overweight was defined as BMI percentile ≥90, adjusted for sex and age. Prevalence of overweight was compared to a prospective cohort of offspring of mothers with T1D (n=912) born between 1989 and 2000 participating at a similar follow-up study (BABYDIAB). Data on birth weight/height, maternal BMI before pregnancy, insulin requirement and smoking during pregnancy were collected at birth, breastfeeding data at age 3 months, 9 months and 2 years. To identify predictors of overweight, a multiple logistic regression analysis was performed. As an indicator for insulin resistance, HOMA-IR was determined on fasting venous blood samples at age 8 years (n=18).
Results: Prevalence of overweight in offspring of mothers with GDM was 17.2% at age 2 years and 20.2% at age 8 years and was increased compared to offspring of mothers with T1D (14.6% at age 2 years and 11.5% at age 8 years; p=0.3 and p=0.04 respectively). Multivariate analysis including birth size, maternal BMI and maternal insulin requirement during pregnancy as covariates indicated that risk for overweight was increased throughout childhood in offspring of mothers with GDM who were born large for gestational age (HR 6.3, 95%CI:0.9-41.9, p=0.06 at 2 years of age and HR 5.2, 95%CI:1.2-23.0, p=0.03 at 8 years of age) and in offspring of mothers with a maternal BMI>30 kg/m² before pregnancy (HR 16.8, 95%CI:1.2-234.8, p=0.04 at age 2 years and HR 14.1 95%CI:1.4-147.3, p=0.03 at age 8 years). Smoking during pregnancy, duration of full breastfeeding and insulin requirement during pregnancy had no effect on weight development in offspring of mothers with GDM. At age 8 years, HOMA-IR was significantly increased in overweight offspring of mothers with GDM compared to normal weight offspring (p=0.003).
Conclusion: Prevalence of overweight during childhood, which is associated with higher risk of insulin resistance, is increased in offspring of mothers with GDM compared to offspring of mothers with T1D indicating that maternal diabetes type affects overweight risk. The finding that overweight risk is predicted by maternal obesity and high birth size suggests that both, genetic predisposition as well as exposure to maternal diabetic environment contribute to childhood growth in offspring of mothers with GDM.

Could insulin sensitivity predict growth restricted infants?
M. Dalfrà[1], E. Parretti[2], G. Pacini[3], G. Mello[4], A. Lapolla[1];
[1]Medical and Surgical Sciences, University of Padova, [2]Centro Donna, Azienda ULS 3, Pistoia, [3]Metabolic Modeling Unit, National Research Council, Padova, [4]Gynecology, Perinatology and Human Reproduction, University of Firenze, Italy.

Background and aims: The "Barker Hypothesis" suggests that low birth weight predicts future risk of developing obesity, cardiovascular disease and type 2 diabetes. Identification of the causes of fetal growth restriction (FGR) is critical for preventive and management strategies. It has been observed that post-glucose-load plasma insulin and glucose levels are lower in women with FGR fetuses than in women with a fetus with a normal growth. This seems to indicate that maternal carbohydrate metabolism might be involved in the pathogenesis of FGR. The aim of our study was to evaluate, in a large number of normotensive pregnant women with normal glucose tolerance, the effect of insulin sensitivity (evaluated with fating index QUICKI and dynamic index OGIS)and maternal anthropometric and demographic characteristics on fetal growth.
Materials and methods: 1814 Caucasian pregnant women with a pre-pregnancy BMI between 19 and 25, and singleton pregnancy were tested with a 75g 2-hour glucose load in the period between 24 and 28 weeks of gestation. FGR was defined by a birth weight below the 5th percentile for gestational age and developed in 99 (5.5%) pregnant women..
Results: Women with FGR showed lower weight gain (7.1±vs12.8±3.2 p<0.001), lower FPI (4.2±3.9vs 6.7±6.6;p0.007), AUC Glu (p<0.000) and AUC ins(p<0.000) higher QUICKI(0.46±0.14vs 0.39±0.06;p<0.000)and OGIS (469±71 vs444±65;p<0.0002) with respect to women with normal weight babies. Birth weight percentiles showed a positive correlation with weight gain (r=0.56, p<.01) and a negative correlation with IS_{QUICKI} (r=-65, p<.006). In multiple logistic regression analysis, IS_{QUICKI} and weight gain were shown to be statistically significant independent predictors of FGR. The adjusted odds ratios for FGR were 2.1 (95% CI 1.2-2.5) for each 0.05 IS_{QUICKI} increment in $IS_{QUICKI,}$ and 1.2 (95% CI 1.1-1.9) for each 500 g decrement in weight gain.
Conclusion: In this study we demonstrated that women with FGR pregnancies have higher insulin sensitivity than women with normal fetal growth. So we could suggest that increased insulin sensitivity leads to a reduction in metabolic substrates for fetal growth.

Factors determining childhood adiposity and cardiometabolic risk over a 5 year period - the Da Qing children study
Y.Y. Chen[1], Y.S. Lee[2], J.P. Wang[3], Y.Y. Jiang[3], H. Li[1], W.Y. Yang[1], Y.H. Hu[3], K.O. Lee[4], G.W. Li[1];
[1]Endocrinology, China-Japan Friendship Hospital, Beijing, China, [2]Pediatrics, National University of Singapore, [3]Cardiology, Da Qing First Hospital, China, [4]Medicine, National University of Singapore, Singapore.

Background and aims: Childhood adiposity is increasingly recognized as a significant predictor of cardiometabolic risks in later life. There are very few longitudinal studies of childhood adiposity, especially in Asian populations. We investigated various factors, including TV viewing time, birth weight, fasting insulin, glucose and triglycerides, and blood pressure, and their association with change in childhood adiposity over a 5 year period.
Materials and methods: 424 five-year-old Chinese children enrolling into four public elementary schools in Da Qing city, China, were recruited for this cohort study in 1998. Birth weight, TV viewing time, blood pressure, anthropometric measurements, fasting insulin, glucose and triglycerides levels were measured. Percentage ideal weight for height (WFH) was used as a measure of adiposity. All children were reassessed 5 years later. The children were ranked and classified into tertiles based on WFH at 5 years, or change in WFH from 5 to 10 years old. General linear model for analysis of variance was used to compare variables of interest in each tertile group. Multiple stepwise regression analysis was used to assess the association of TV time, birth weight, WFH at 5 years and WFH at 10 years. The study was approved by the Ethics Committee of the China-Japan Friendship Hospital and the Public Health Ministry of China.
Results: Significant associations were found in TV viewing time, birth weight and fasting insulin**.** (1) At 5 years of age, total TV viewing time was significantly longer in boys with higher WFH at 5 years (WFH5)(p<0.05), but not in girls(p=0.09). Change in WFH was significantly correlated with TV viewing time in both boys (top tertile 5.31±0.28 *vs.* lowest tertile 4.18±0.28 hrs/week, p<0.01) and girls (top tertile 5.31±0.29 *vs.* lowest tertile 4.41±0.29 hrs/week, p<0.05). An increase of 5 hours/week of TV viewing time led to 1.1 kg/m² increase in BMI over the 5 years follow-up. (2) Birth weight was significant greater in the top tertile of WFH5 in both boys (p<0.01) and girls (p<0.05), but not with change in WFH 5 years later. (3) Fasting insulin (FI) and HOMA-IR were significantly higher in the top tertile of WFH5 in boys (p<0.01) and girls (p<0.05). In addition, FI, HOMA-IR, systolic and diastolic blood pressures, and triglycerides remained significantly higher in the top tertile of change in WFH 5 years later.
Conclusion: Although both TV viewing time and birth weight affected adiposity during early childhood, TV viewing time may be the stronger determinant during later childhood and with change in WFH over 5 years. Greater change in WFH (from 5-10 years) may confer risk of development of cardiometabolic disease. Thus, reducing TV viewing time in young children may help to prevent the development of obesity and decrease risk of cardiometabolic disease.

OP 25 Cognitive function and type 2 diabetes mellitus

145

A longitudinal study on cognition in type 2 diabetes: no accelerated cognitive decline

E. van den Berg[1], Y.D. Reijmer[1], J.H.J. de Bresser[1,2], R.P.C. Kessels[3,4], L.J. Kappelle[1], G.J. Biessels[1], Utrecht Diabetic Encephalopathy Study Group;
[1]Department of Neurology, Rudolf Magnus Institute of Neuroscience, University Medical Center Utrecht, [2]Image Sciences Institute, University Medical Center Utrecht, [3]Donders Institute for Brain, Cognition, and Behaviour, Radboud University Nijmegen, [4]Departments of Medical Psychology and Geriatrics, Radboud University Nijmegen Medical Centre, Netherlands.

Background and aims: Type 2 diabetes mellitus (T2DM) is associated with an increased risk of cognitive dysfunction. In a previous cross-sectional study we showed that patients with T2DM (mean duration: 8 years) performed worse than controls on the domains memory, information processing speed and attention and executive functioning. Patients and controls were reexamined after a 4-year interval.
Materials and methods: Of the 178 participants at baseline (122 T2DM, 56 controls) 106 (60%; 68 T2DM, 38 controls) participated in the follow-up examination. Cognitive status of individuals that did not attend follow-up as ascertained with the Telephone Interview for Cognitive Status was slightly lower than in those that did attend (p=0.07). Performance on 11 neuropsychological tasks, covering 5 cognitive domains, was expressed in standardized z-scores. ANOVA for repeated measures was used to examine the effect of Group, Time and the Group×Time interaction.
Results: The T2DM and control groups were similar in age, estimated IQ and sex distribution. There was a significant effect of Time on the domains abstract reasoning (mean difference in z-scores between T1 and T2 -0.16, p=0.03) and attention and executive functions (-0.29, p<0.001). Significant between-group effects were found on information-processing speed (mean difference in z-scores for T2DM compared to controls: -0.37, p<0.05) and attention and executive functions (-0.25, p=0.04), and a trend in the same direction on memory (-0.16, p=0.07). There were no significant Group×Time interactions.
Conclusion: In this sample of non-demented patients with T2DM we found modest decrements in cognitive functioning compared to controls. Between-group differences at follow-up were similar to those found in the baseline examination. There was no accelerated decline in the T2DM group. Apparently, cognitive decrements in T2DM develop slowly, over a much longer time frame than the 4 years sampled in the current study.

Risks of cardiovascular disease and severe hypoglycaemia according to cognitive function in people with type 2 diabetes in ADVANCE

B.E. de Galan[1,2], S. Zoungas[2], A. Pillai[2], C. Anderson[2], C. Dufouil[3,4], F. Travert[4], A. Patel[2], S. Heller[5], M. Hackett[2], D. Grobbee[6], B. Neal[2], M. Woodward[2,7], S. MacMahon[2], J. Chalmers[2], ADVANCE Collaborative Group;
[1]General Internal Medicine 463, Radboud University Nijmegen Medical Centre, Netherlands, [2]The George Institute for International Health, Sydney, Australia, [3]INSERM, Paris, France, [4]UPMC University, Paris, France, [5]University of Sheffield, United Kingdom, [6]Julius Centre for Health Sciences and Primary Care, Utrecht, Netherlands, [7]Mount Sinai School of Medicine, New York, United States.

Background and aims: The relationship between cognitive dysfunction, cardiovascular (CV) disease and premature death is not well established in people with type 2 diabetes. We assessed the effects of cognitive dysfunction in 11,140 patients with type 2 diabetes who participated in the Action in Diabetes and Vascular disease: Preterax and Diamicron Modified Release Controlled Evaluation (ADVANCE) trial. We also tested whether cognitive function at baseline influenced the beneficial effects of blood pressure lowering and glycaemic control in the trial.
Materials and methods: Cognitive function was assessed using the Mini Mental State Examination at baseline, and defined by scores 28-30 ('normal', n=8689), 24-27 ('mild dysfunction', n=2231), and <24 ('severe dysfunction', n=212). Risks of CV events (non-fatal myocardial infarction, non-fatal stroke and CV death), all cause mortality, CV death, severe hypoglycaemia and interactions with treatment, were assessed using Cox proportional hazards analysis.
Results: Compared with normal cognitive function, both mild and severe cognitive dysfunction at baseline significantly increased the multiple-adjusted risks of major CV events (HR 1.27 [95% confidence interval, 1.11-1.46] and 1.42 [1.02-2.00]; both p<0.05), CV death (1.41 [1.16-1.71] and 1.57 [1.00-2.48]; both p≤0.05) and all-cause mortality (1.34 [1.16-1.55] and 1.52 [1.07-2.15]; both p<0.02). Severe, but not mild, cognitive dysfunction increased the risk of severe hypoglycaemia (HR 2.20 [1.19-4.06]; p=0.012). There was no evidence of heterogeneity of randomised treatment effects on these outcomes in subgroups defined according to baseline cognitive function.
Conclusion: Cognitive dysfunction is an independent predictor of clinical outcomes in people with type 2 diabetes but does not alter the effects of more intensive blood pressure or glucose lowering treatment on the risks of major CV events or death.

Correlates of cognitive function measured in frail elderly patients with diabetes mellitus

P. Mrak[1], I. Rakovac[2], A. Morak[1], K. Kienreich[1], C. Fritz[2], T.R. Pieber[2,3], B. Bauer[1];
[1]Province Hospital Hoergas, Gratwein, [2]Institute of medical technologies and health management, Joanneum Research, Graz, [3]Department of Endocrinology and Nuclear Medicine, Medical University of Graz, Austria.

Objective: Among elderly populations, impaired cognition imposes a heavy burden in terms of dementia-related quality of life, morbidity and mortality. Preventing or delaying cognitive decline would have considerable clinical and socioeconomic benefits. In this study, we investigated the relationship between cognitive function, glycaemic control and insulin treatment among frail elderly patients with diabetes mellitus.
Methods: Acute Geriatric Management and Remobilisation Units (AG/R) are specialized inpatient hospital wards introduced in Austria in recent years. AG/R provide interdisciplinary rehabilitation and mobilisation services for frail elderly patients. In AG/R Units Geriatric Comprehensive Assessment (GCA) is routinely used to assess the functional status of frail elderly patients and to guide the geriatric therapeutic process. In our analysis, we performed a record linkage between GCA data and a diabetes quality improvement dataset (FQSD). Multiple linear regression models were fitted in order to investigate correlations between cognitive function, measured by Mini Mental State Exam (MMS), and several potential correlates of cognitive function including age, sex, BMI and glycaemic control.
Results: Between November 2002 and November 2006, 316 consecutive patients with diabetes mellitus were admitted to AG/R unit at the Hoergas hospital. Mean age was 77 ± 9 years, with mean diabetes duration of 9 ± 10 years. 69% of patients were female, mean BMI was 26 ± 5 kg/m^2, mean HbA1c was 6.7 ± 1.2 %, and mean fasting plasma glucose (FPG) was 147 ± 54 mg/dl. Insulin was used by 26%. Median MMS score was 26 (IQR 23 - 28) points. In linear models, a relationship between MMS and age, BMI (non-linear) and stroke was established. Gender and insulin treatment did not show a significant correlation with MMS scores and were eliminated from the model. Impact of glyceamic control was explored by adding gylceamic control to the previous model: FPG and HbA1c were added in a stepwise fashion as predictors. An increase in 1 mg/dl of FPG resulted in a predicted decrease of 0.01 MMS score points (p=0.008). An increase of 1% HbA1c resulted in predicted MMS score decrease of 0.33 points (p=0.08). Further results are given in figure 1.
Discussion: In our sample, cognitive function was negatively associated with older age and stroke, and positively with moderate obesity. Inferior glyceamic control was associated with impaired cognitive function with FPG being a better predictor than HbA1c. Prospective controlled studies are needed in order to determine if the decline in cognitive function can be reversed, arrested or delayed with tight glyceamic control.

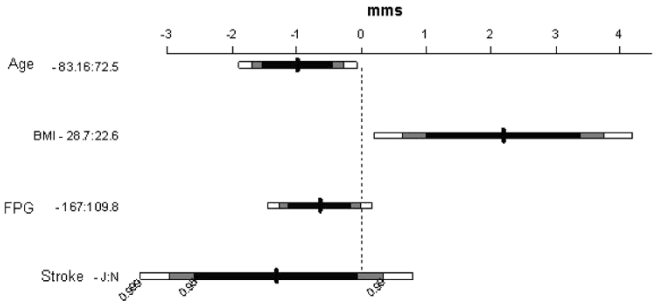

Figure 1: Impact of change of independent predictors from lower to upper quartile on predicted MMS scores. Black, grey and white bars represent 95%, 99% and 99.9% confidence intervals, respectively.

Rosiglitazone and cognitive stability in older persons with type 2 diabetes and mild cognitive impairment

A.M. Abbatecola, G. Paolisso;
Geriatric Medicine & Metabolic Disease, Second University of Naples, Italy

.

Background and aims: Type 2 diabetes mellitus (T2DM) has been consistently associated with a higher risk of cognitive decline, especially Mild Cognitive Impairment (MCI). Such findings suggest that T2DM can predict cognitive impairment through mechanisms affecting the amyloid accumulation or indirect mechanisms, namely cerebrovascular disease. Considering that insulin resistance (IR) is a critical component in the causal pathway to cognitive impairment, the objective of our study was to test whether an improvement in IR could explain cognitive performance variations in older person with MCI and T2DM that had recently began anti-diabetic oral or diet treatment over a 9 month observation period.
Materials and methods: Ninety-seven older persons (mean age: 76 ± 6 yrs) from a group of approximately two hundred individuals with MCI and T2DM in poor metabolic control that recently (less than 2 months) began anti-diabetic oral treatment with: metformin (1000mg/day) (n=30), or metformin (500mg/day) + rosiglitazone (4mg/day) (n=32) or in diet therapy (n=35) agreed to participate in study protocol. Exclusion criteria included: dementia, cardiovascular disease, severe hypertension, stroke, heart failure, MCI>6 months, or severe depression. All participants underwent a neuropsychological battery that consisted of the Mini Mental State Examination (MMSE), Rey Verbal Auditory Learning total recall (RAVLT), Trail Making Tests (TMTA, TMTB, DIFFBA) which was performed at baseline and every 12 weeks for 9 months along with biochemical and clinical testing (including electrocardiograms). Echocardiography and myocardial perfusion scintigraphy tests were performed in all participants at baseline and at the last follow-up.
Results: Baseline data: There were not any significant differences found between groups at baseline in any clinical or neuropsychological parameters. The mean values of the following parameters were found in the entire population at baseline: HbA_{1c}= 7.5 ± 0.5 %, FPG = 8.6 ± 1.3 mmol/l, FPI=148 ± 74 pmol/l, MMSE=24.9 ± 2.4, TMTA=61.6 ± 42.0, TMTB=162.8 ± 78.7, DIFFBA=101.2 ± 58.1, RAVLT=24.3 ± 2.1. Follow-up data. No participant had experienced any cardiovascular event during the study period. ANOVA models were created to test metabolic control parameters (fasting plasma insulin (FPI), fasting plasma glucose (FPG), HbA_{1c}) within and between groups over time. Metabolic control parameters (HbA_{1c}, FPG, FPI) significantly improved in the metformin and the metformin+rosiglitazone groups only (p for trend<0.05 in both groups). ANCOVA repeated models were performed to test cognitive performance variability independently of common confounders over time and showed that the metformin+rosiglitazone group maintained cognitive stability on all cognitive tests, the diet controlled group maintained stability on the MMSE test only and showed a decline in TMT-B (p for trend=0.024), executive efficiency (DIFFBA) (p for trend= 0.026) and RAVLT memory test (p for trend=0.011), while the metformin group maintained stability on MMSE, TMTs, but showed a decline in the RAVLT (p for trend=0.011). Using linear mixed effects models, the decline in FPI levels was independently associated with cognitive stability on the RAVLT memory test for the metformin + rosiglitazone group only (β=-3.333; p<0.001).
Conclusion: These findings suggest that rosiglitazone, may protect against cognitive decline in older persons with T2DM and MCI.

149

MRI correlates of cognitive decline in patients with type 2 diabetes

Y.D. Reijmer[1], J. de Bresser[2], E. van den Berg[1], C. Jongen[2], M.A. Viergever[2], R.P.C. Kessels[3], L.J. Kappelle[1], G.J. Biessels[1], Utrecht Diabetic Encephalopathy Study group;
[1]Neurology, University Medical Center Utrecht, [2]Image Sciences Institute, University Medical Center Utrecht, [3]Donders Institute for Brain, Cognition and Behaviour, Radboud University Nijmegen, Netherlands.

Background and aims: Type 2 diabetes (DM2) is associated with an increased risk of cognitive dysfunction and dementia. In a previous cross-sectional study we demonstrated cognitive decrements and brain abnormalities in DM2 patients compared to controls. Patients and controls were re-examined after 4 years to study changes over time. The present study focuses on brain MRI abnormalities underlying cognitive decline in patients with DM2.
Materials and methods: Cognitive functioning was assessed twice in 54 DM2 patients without dementia, with a 4-year interval. 1.5T MRI scans were obtained at both time-points. Automated volumetric measurements of sub-cortical structures, cortical gray-matter, lateral ventricles, white-matter lesions and cerebrospinal fluid volume were performed and expressed as a percentage of intracranial volume. Cognitive assessment consisted of 11 neuropsychological tasks, covering 5 cognitive domains. Only the 3 cognitive domains which showed a group difference at baseline were used for the present analyses (i.e. memory, information processing speed, attention and executive functioning). A regression based index, using the control group as a reference, was calculated to assess changes in cognitive test performance over time, adjusted for age, estimated IQ and sex. Changes in brain volume in DM2 patients with the 15% greatest decline in cognitive performance on any of the three domains (n=22) were compared to the other DM2 patients (n=32).
Results: There were no significant differences in any of the baseline parameters between patients that attended (n=54) and patients that did not attend follow up (n=44). DM2 patients within the 15% of greatest decline on any of the three domains showed a significant increase in white matter lesion volume (mean difference±S.E.: 0.12%±0.05; p<0.05) and ventricular volume (0.21%±0.06; p=0.001) over the 4-year period compared to DM2 patients without this reduction in cognitive performance. The groups did not differ on changes in sub-cortical structures (0.01%±0.20) or cortical gray-matter volumes (-0.34%±0.29).
Conclusion: These results indicate that white matter lesions and subcortical atrophy in DM2 may underlie the cognitive decline observed in a subgroup of DM2 patients.

The lifestyle intervention reversed cognitive function in aged people with diabetes mellitus, two year follow-up

N. Yamamoto[1], K. Otsuka[1], E. Takasugi[1], N. Hotta[1], T. Yamanaka[1], M. Ishikawa[1], G. Yamanaka[1], S. Murakami[2], K. Matsubayashi[3], T. Hanafusa[4];
[1]Internal Medicine, Tokyo Women's Medical University, Medical Center East, Arakawa, [2]Cardiology, Osaka Medical College, Takatsuki city, [3]Gentrogy, Center for Southeast Asian Studies, Kyoto University, [4]The First Department of Internal medicine, Osaka Medical College, Takatsuki city, Japan.

Background and aims: Type 2 diabetes is associated with poor performance on various cognitive tests, especially with aging. Cognitive impairment, with or without features of overt dementia, is a major cause of the disease burden in an aging population. However, regarding decreased cognitive function in elderly people with DM; it remains unclear whether the cognitive decline in elderly DM people is reversible. To clarify the reversibility of cognitive decline in elderly people with type 2 diabetes.
Materials and methods: In August 2006, we recruited 129 people aged older than 75 years who participated in free health screening offered by the Health Care Center of Tosa town in Japan. Written informed consent was obtained from participants. Before and after two years of lifestyle intervention, 55 people older than 75 years with DM or IGT defined as 75g OGTT and 74 control people were evaluated for cognitive function including MMSE, HDS-R and Koh's block design test.
Results: The DM group had significantly lower MMSE and HDSR scores in baseline than that of the NGT group (NGT vs. IGT vs. DM = 27.1±0.7 vs. 26.1±1.0 vs. 24.5±1.4 points, p<0.01, 26.7±0.8 vs. 26.4±1.1 vs. 23.8±1.6

points, $p<0.01$). The quantity of the MMSE and HDS-R score change between baseline and follow up was significantly larger in the DM group than in the control group (NGT vs. IGT vs. DM = -0.0±0.6 vs. -0.0±0.9 vs. 1.9±1.2 points, $p<0.01$, 0.0±0.9 vs. -0.1±0.9 vs. 1.7±1.6 points, $p<0.01$). The delayed recall function was lower in the IGT and DM group than in the NGT group at baseline, but no difference was found among the three groups after intervention (Baseline: NGT vs. IGT vs. DM = 2.6±0.3 vs. 2.1±0.3 vs. 1.6±0.3 points, $p<0.05$; After: NGT vs. IGT vs. DM = 2.6 ±0.2 vs. 2.3±0.2 vs. 2.2±0.5 points). Koh's block design test did not change before and after intervention. Stepwise regression analyses showed that the quantity of cognitive function changes independently in relation to DM group membership and HbA1c in baseline (standard $\beta = 0.3$, $p<0.05$, standard $\beta = 0.2$, $p<0.01$, respectively).
Conclusion: The lifestyle intervention involving glycemic control has a beneficial effect on selective aspects of cognitive decline in elderly people with type 2 diabetes mellitus.

High liver fat content is associated with impaired myocardial perfusion and metabolism in patients with uncomplicated type 2 diabetes
M. Diamant[1], L.J. Rijzewijk[1], J.T. Jonker[2], R.W. van der Meer[3], M. Lubberink[4], H.W.A. de Jong[4,5], J.A. Romijn[2], J.J. Bax[6], A. de Roos[3], R.J. Heine[1,7], A.A. Lammertsma[4], J.W.A. Smit[2], H.J. Lamb[3];

Background and aims: Cardiovascular disease (CVD) is the leading cause of mortality in type 2 diabetes (T2DM). Central obesity and hepatic steatosis, both hallmark abnormalities in T2DM, have been related to increased CVD. The aim of the present study was to investigate whether T2DM patients without clinical ischemic heart disease, as assessed by dobutamine-stress echocardiography, with high versus low liver fat content differ with respect to myocardial function and metabolism.
Materials and methods: In sixty-one T2DM patients (mean age±SE 56.8±0.7 yr, BMI 28.7±0.5 kg/m^{-2}, HbA_{1c} 7.1±0.1%) myocardial perfusion and substrate metabolism were assessed by positron-emission tomography using [^{15}O]water, [^{11}C]palmitate under fasting conditions and [^{18}F]-2-fluoro-2-deoxy-D-glucose under euglycaemic hyperinsulinaemic conditions. Additionally whole-body insulin sensitivity (M/I) was determined. Moreover, myocardial left ventricular (LV) systolic and diastolic function and dimensions were measured by magnetic resonance (MR) imaging and in a subgroup (n=25) the PCr/ATP ratio was assessed by [^{31}P]-MR spectroscopy. Patients were divided according to the liver median in a T2DM-low (n=30, liver fat ≤ 8.6%) versus T2DM-high (n=31, liver fat > 8.6%) liver fat group.
Results: Median (IQR) liver fat in T2DM-low was 3.1 (1.5-5.4) % and 20.3 (12.9-29.2) % in T2DM-high patients. Patients in both groups were well matched for age, HbA_{1c} and hemodynamics, but T2DM-high versus T2DM-low had a higher BMI (30.2±0.6 versus 27.1±0.6 kg/m^2, P<0.001). T2DM-high relative to T2DM-low showed decreased myocardial perfusion (P<0.016) and glucose uptake (P=0.002), PCr/ATP ratio (P=0.011) and M/I (P<0.001), whereas myocardial fatty-acid metabolism and LV diastolic and systolic function and dimensions were similar. Significant associations were found between hepatic fat and myocardial glucose uptake (Spearmans' rho r=-0.396, p=0.015), PCr/ATP ratio (r=-0.467, p=0.019) and M/I (r=-0.634, p<0.001). Myocardial glucose uptake was correlated with M/I (r=0.517, p<0.001) and PCr/ATP (Pearsons r=0.481, p=0.015). No correlations were found between myocardial metabolism and LV function.
Conclusion: High liver fat content in T2DM patients is associated with impaired whole-body insulin sensitivity which is paralleled by altered myocardial perfusion, substrate and high-energy phosphate metabolism.

Which cardiac fat depot is the best cardiometabolic risk marker?
A. Sironi, R. Petz, D. De Marchi, V. Positano, M. Lombardi, A. Gastaldelli; Clinical Physiology Institute, Pisa, Italy.

Background and aims: Fat around the heart (mediastinal fat) accumulates in both the epicardial (EPI) and extrapericardial (Ex-PER) or intrathoracic area. Most of published work focused on EPI, now recognized as a cardiometabolic risk factor, and only few studies measured Ex-PER, despite most of the fat is accumulated in this region. Thus, we investigated the associations between EPI, Ex-PER and mediastinal fat with metabolic dysfunction and coronary heart disease (CHD) risk in healthy subjects.
Materials and methods: We studied 113 subjects (94M/19F; age: 18-74 years, BMI: 15-40 kg/m^2) and measured total cardiac, Ex-PER, EPI, visceral (VF), subcutaneous (SC) fat depots, as well as cardiac function, by MRI. We also measured blood pressure, insulin sensitivity evaluated by QUICKI and OGIS, triglycerides (TG), cholesterol (total and HLD), glucose (FPG), insulin concentrations and 10-year CHD risk by Framingham score.

Results: Most of cardiac fat was constituted of Ex-PER (~77%). However, in this group we observed a wide range of variability for both cardiac fat depots (EPI ranged 172-2008 mm^2 and Ex-PER ranged 100-5056 mm^2). Both EPI and Ex-PER correlated significantly with BMI (r=0.34 and r=0.42), waist circumference (r=0.41 and r=0.53), visceral fat (r=0.40 and r=0.50), subcutaneous fat (r=0.40 and r=0.27). Only Ex-PER correlated significantly with mean blood pressure (r=0.29), insulin sensitivity (r=-0.22) and concentration of triglycerides (r=0.27). Only mediastinal fat and Ex-PER, but not EPI, could discriminate between subjects with more than 3 metabolic syndrome factors (ie, increased waist circumference, TG, FPG, blood pressure and/or low HDL) or medium to high CHD risk score (figure). However, no correlation was found with cardiac function parameters (ejection fraction or left ventricular volume and mass). After correcting for BMI and waist, CHD risk remained associated with Ex-PER (partial r=0.24, p=0.003) or mediastinal fat (partial r=0.24, p=0.004) but not EPI (partial r=0.08, p=ns).
Conclusion: Increased Ex-PER or mediastinal fat, but not EPI, at least when measured by MRI, are better markers of altered metabolic profile and CHD risk.

Effects of acute manipulation of serum NEFA concentrations on left ventricular (LV) energy metabolism in patients with heart failure
G. Perseghin[1], G. Fragasso[2], G. Lattuada[3], A. Salerno[2], A. Esposito[4], F. De Cobelli[4], T. Canu[4], A. Margonato[2], A. Del Maschio[4], L. Luzi[1];
[1]Internal Medicine, Instituto Scientifico H San Raffaele & Università degli Studi di Milano, [2]Clinical Cardiology – Heart Failure Clinic, Instituto Scientifico H San Raffaele, [3]Internal Medicine, Instituto Scientifico H San Raffaele, [4]Diagnostic Radiology, Instituto Scientifico H San Raffaele, Milano, Italy.

Background and aims: This study was designed to test the hypothesis whether acute changes in circulating energy substrates may be detrimental for the LV energy homeostasis in humans with heart failure.
Materials and methods: Cardiac function and the relative content of LV phosphocreatine (PCr) and ATP were assessed non-invasively using in vivo MR-imaging (MRI) and 31P MR-spectroscopy (MRS) in 10 individuals with chronic heart failure (age: 74±9 ys, BMI: 25.6±1.9 kg/m^2, NYHA class: 2 (1-3), ejection fraction (EF): 35±7%, fasting glucose: 96±11 mg/dl; fasting insulin: 6.3±3.0 μU/ml) in two experimental conditions 7 days apart. In Study 1 MRI and 31P-MRS data were acquired before and 3 to 4 hours after the administration of a i.v. bolus + continuous heparin infusion designed to achieve a serum NEFA concentration of 1.2-1.5 mM. In Study 2 the same procedure was performed before and 3 to 4 hours after the oral administration of Acipimox designed to achieve a serum NEFA concentration of 0.1-0.2 mM. Acquisitions were acquired in the fasting and resting state.
Results: During the studies serum glucose and insulin concentration did not significantly change; serum NEFA increased from 0.65±0.24 to 1.21±0.47 mM during Study 1 and dropped from 0.68±0.25 to 0.15±0.06 mM during Study 2. The PCr/ATP ratio did not change during Study 1 (from 1.70±0.22 to 1.75±0.34; P=0.49) meanwhile during Study 2 it dropped from 1.81±0.23 to 1.53±0.32 (P=0.016) and the percent change was also different (102±12% vs. 85±15%; P=0.009). In parallel the LVEF did not change during Study 1 (from 35±13% to 34±13%; P=0.21) meanwhile it dropped from 36±12% to 33±11% (P=0.03) during Study 2
Conclusion: In individuals with chronic heart failure acute reduction of serum NEFA concentration impaired LV energy metabolism meanwhile a two-fold increment did not induce any detectable change. These data demonstrate that deprivation of energy substrates in the acute setting may be detrimental for cardiac metabolism

Role of HDL glycation in counteracting the inhibitory effect of oxidized LDL on endothelium-dependent vasorelaxation
M.-C. Brindisi[1,2], L. Perségol[1], L. Duvillard[1], B. Vergès[1,2];
[1]INSERM Research Center 866, [2]Teaching Hospital, Dijon, France.

Aims/hypothesis: In healthy normolipidaemic and normoglycaemic control subjects, HDL are able to reverse the oxidized LDL-induced inhibition of vasodilation. We have previously shown that in type 1 diabetic patients, HDL do not protect against inhibition of endothelium dependant vasorelaxation induced by oxidized LDL. This defect was not explained by abnormalities in HDL composition, size or paraoxonase activity. The aim of this study was to analyse the role of glycation of HDL on this vasodilation effect.
Methods: Blood samples were collected from healthy patients. Extracted HDL particles, separated by ultracentrifugation, were glycated in vitro using a procedure with a highly concentrated glucose solution, mimicking the "in vivo" conditions of glycation in type 1 diabetes. Vasoreactivity was evaluated by the relaxation response to acetylcholine of rabbits aorta rings pre-contracted with noradrenaline, before and after two hours incubation with or without different lipoprotein fractions (Krebs'buffer; ox-LDL; normal HDL; normal HDL + ox-LDL; glycated HDL; glycated HDL + ox-LDL).
Results: Lipid composition of normal and glycated HDL was similar. The difference between the two kinds of HDL was glycation. Indeed the mean of the ratio Fructosamine/ApoA1 was 17.58 μmole /g of protein for normal HDL and 48.67 μmole /g of protein for glycated HDL. Oxidized LDL inhibited endothelium vasodilation (maximal relaxation (Emax) = 53.34 ± 27.06 vs 98.67 ± 10.16 % for incubation in Krebs'buffer, p<0.005). Normal HDL were able to counteract the oxidized LDL-induced inhibition of vasorelaxation (Emax = 78.75 ± 19.72 vs 53.34 ± 27.06 %, p=0.003), whereas glycated HDL had no effect (Emax = 46.64 ± 21.72 vs 53.34 ± 27.06 %, p=0.35).
Conclusion: Our data indicate that glycation of HDL is responsible for the inability of HDL particles to counteract the oxidized LDL-induced inhibition of endothelium-dependant vasorelaxation. Glycation of HDL is likely to be one important factor explaining the absence of vasodilation effect of HDL particles in patients with diabetes.

Higher plasma sRAGE levels are associated with incident cardiovascular morbidity and mortality as well as all-cause mortality in type 1 diabetes: a 12-yr follow-up study
J.W.M. Nin[1], A. Jorsal[2], I. Ferreira[1], C.G. Schalkwijk[1], M.H. Prins[3], H.-H. Parving[4], L. Tarnow[2], P. Rossing[2], C.D.A. Stehouwer[1];
[1]Internal Medicine, Maastricht University Medical Centre, Netherlands, [2]Steno Diabetes Center, Gentofte, Denmark, [3]Clinical Epidemiology and Medical Technology Assessment, Maastricht University Medical Centre, Netherlands, [4]Medical Endocrinology, University Hospital of Copenhagen, Denmark.

Background and aims: Plasma soluble receptor for advanced glycation end-products (sRAGE) is a putative indicator of RAGE expression, which is associated with vascular complications. Studies so far have shown contradictory results and whether sRAGE is associated with incident cardiovascular disease (CVD) and mortality is unknown. We have therefore addressed this question in a prospective cohort study of individuals with type 1 diabetes (T1D) and the extent to which any such association could be explained by renal dysfunction (estimated GFR, eGFR).

Materials and methods: We studied 358 individuals (187 with diabetic nephropathy and 171 with persistent normoalbuminuria, 216 men, mean age at baseline of 41±10 yrs) who were followed for a median period of 12.3 (7.1-12.5) years. Plasma sRAGE was measured at baseline by means of ELISA; eGFR was estimated by the MDRD equation; data on non-fatal CVD events were obtained from patient and hospital files, and data on mortality were retrieved from the Danish National Register. We used multiple Cox regression analyses, first adjusted for age, sex, duration of diabetes and HbA1c, and further for other CVD risk factors (i.e. total cholesterol, systolic BP and smoking, and also eGFR) to investigate the association between sRAGE and the incidence of fatal and non-fatal CVD and all-cause mortality. Results are expressed by HR and respective 95% CI.
Results: During the follow-up 100 (27.9%) patients suffered a fatal or non-fatal CVD event and, considering all causes, 91 (25.4%) died. The incidence of fatal and non-fatal CVD and of all-cause mortality increased with increasing levels of sRAGE (Figs. 1A and 1B): HR=1.50 (95%CI: 1.27 to 1.77, p<0.001) and HR=1.46 (1.25 to 1.70, p<0.001) per 1 SD increase in plasma sRAGE, respectively. These associations were attenuated after adjustments for CVD risk factors [HR=1.30 (1.09 to 1.54), p=0.003 for fatal and non-fatal CVD events, and HR=1.30 (1.10 to 1.52), p=0.002 for all-cause mortality], but were further attenuated after adjustment for eGFR [HR=1.16 (0.96 to 1.40), p=0.125 for fatal and non-fatal CVD events and HR=1.18 (0.99 to 1.41), p=0.073 for all-cause mortality].
Conclusion: Higher levels of sRAGE are associated with incident fatal and non-fatal CVD and all-cause mortality in T1D. Although we cannot exclude the possibility that eGFR is a confounder in the examined association, our findings suggest that renal dysfunction could mediate, at least in part, the association between plasma sRAGE and the high risk of CVD in T1D.

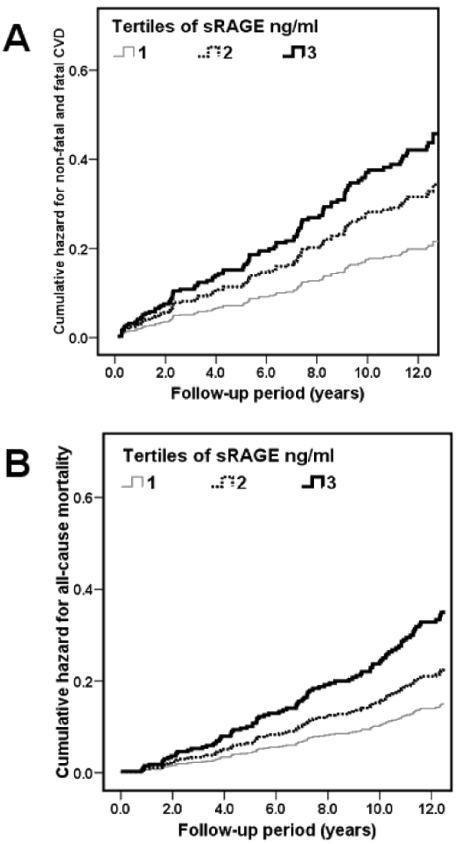

Figure 1: Cummulative hazard for non-fatal and fatal cardiovascular events (A) and all-causemortality (B) across tertiles of sRAGE. Data are adjusted for age, sex, duration of diabetes and HbA1c.

Type 2 diabetes significantly modulates the impact of TCF7L2 rs7903146 variant on the risk of coronary atherosclerosis

A. Muendlein[1], C.H. Saely[1,2], S. Rhomberg[1,3], G. Sonderegger[1], P. Rein[1,2], T. Winder[1], S. Beer[1], A. Vonbank[1,2], H. Drexel[1,2];
[1]VIVIT Institute, Feldkirch, Austria, [2]Department of Internal Medicine, Academic Teaching Hospital Feldkirch, Austria, [3]Private University in the Principality of Liechtenstein, Triesen, Liechtenstein.

Background and aims: Variations in the transcription factor 7-like 2 (TCF7L2) gene, particularly rs7903146, increase the risk of type 2 diabetes (T2DM). Coronary artery disease (CAD) is the most frequent cause of death in T2DM patients, and CAD shares common risk factors with T2DM. Potential associations between TCF7L2 variant rs7903146 and coronary atherosclerosis are unknown.
Material and methods: We addressed the association between rs7903146 and CAD in a large cohort of 1595 consecutive Caucasian patients undergoing coronary angiography for the evaluation of stable CAD. An additive model of inheritance was used; significant CAD was diagnosed in the presence of coronary stenoses ≥50%.
Results: The prevalence of T2DM significantly increased from homozygous carriers of the frequent allele over heterozygous subjects to those who were homozygous for the rare allele (20.3%, 24.9%, and 31.3%; p_{trend}=0.001). In the total study cohort, variant rs7903146 was significantly associated with the presence of significant CAD (adjusted odds ratio (OR) 1.27 [1.06-1.51]; p=0.008). Importantly, subgroup analyses with respect to the presence of T2DM showed a strong and significant association between variant rs7903146 and significant CAD in T2DM patients (n=373; OR=1.84 [1.27-2.68]; p=0.001), whereas in non-diabetic subjects (n = 1222), variant rs7903146 was not associated with significant CAD (OR=1.08 [0.88-1.32]; p=0.446). An interaction term T2DM x rs7903146 was significant (p=0.004), indicating that this variant had a significantly stronger impact on CAD in patients with T2DM than in non-diabetic individuals.
Conclusion: We conclude that T2DM significantly modulates the impact of TCF7L2 rs7903146 variant on angiographically characterized coronary atherosclerosis.

Defective insulin crystallisation in beta cells in the absence of ZnT8

K. Lemaire[1], M.A. Ravier[2], A. Schraenen[1], J.W.M. Creemers[3], R. Van de Plas[4], M. Granvik[1], D. Daro[2], E. Waelkens[1], F. Chimienti[5], G. Rutter[6], P. Gilon[2], P. in 't Veld[7], F. Schuit[1];
[1]Molecular Cell Biology, KULeuven, Leuven, Belgium, [2]Unit of Endocrinology and Metabolism, University of Louvain, Brussels, Belgium, [3]Department of Human Genetics, KULeuven, Belgium, [4]Department of Electrical Engineering (ESAT), KULeuven, Belgium, [5]Sas, inac/scib, Mellitech, Grenoble, France, [6]Section of Cell Biology, Imperial College, London, United Kingdom, [7]Department of Pathology, Vrije Universiteit Brussel, Belgium.

Background and aims: In beta cells, zinc co-crystallises with insulin in dense-core secretory granules, but the exact role of zinc in insulin biosynthesis, storage and secretion is unknown. Polymorphism in the ZnT8 gene confers susceptibility to T2D, and autoantibodies to ZnT8 protein are observed in T1D. The aim of this study was to assess the role of ZnT8 in beta cells using mice that are deficient in ZnT8 expression (*ZnT8*$^{-/-}$ mice).
Materials and methods: *ZnT8*$^{-/-}$ mice have a deletion of the promotor region and first exon. ZnT8 expression was assessed by RT-PCR, Western blots, and immunohistochemistry. Beta cell ultra-structure was investigated by transmission electron microscopy. Glucose tolerance was measured at age 6, 12, 25 and 52 weeks and after 10 weeks on high fat diet. Insulin processing was analysed via ^{35}S pulse chase experiments and *in situ* mass spectral tissue profiling of pancreatic islets. Insulin release from isolated islets was measured in perifusion experiments, and zinc exocytosis from islet cell clusters was monitored by total internal fluorescence microscopy.
Results: *ZnT8*$^{-/-}$ mice were completely negative for the expression of islet ZnT8 mRNA and protein. Absence of ZnT8 expression caused loss of zinc release upon stimulation of exocytosis, indicating that ZnT8 is the only zinc transporter responsible for efflux of zinc to the secretory granules. Also dense-core insulin granules were absent in *ZnT8*$^{-/-}$ beta cells (92.2 ± 6.6 vs 7.0 ± 2.7 %, p<0.0001); instead, immature, pale insulin "progranules" were detected, which were larger (433±83 vs 375±84 nm, p<0.001) than insulin granules in control cells. This phenotypic change was associated with loss of *in situ* and *in vitro* staining of islets with dithizone and disappearance of the bright light reflection of isolated islets. In contrast, rates of insulin biosynthesis, insulin content and insulin release after glucose stimulation were well preserved in *ZnT8*$^{-/-}$ mice. Moreover, when *ZnT8*$^{-/-}$ mice were fed a normal diet, glucose tolerance was preserved. However, when fed a high fat diet, the *ZnT8*$^{-/-}$ mice had the tendency to gain more weight and became glucose intolerant.
Conclusion: This study shows the importance of beta cell secretory granule ZnT8 transporter in the formation of insulin crystals which -in turn- explains islet dithizone staining and the bright light reflection of isolated islets. Our *in vivo* data also suggest that zinc-insulin crystals allow a better insulin packaging efficiency in beta cell granule stores, which is relevant for resisting abnormal glucose homeostasis under the metabolic stress of a high fat diet.

Metabolic amplification of insulin secretion in mouse islets: role of beta cell microtubules and microfilaments

N.I. Mourad, M. Nenquin, J.-C. Henquin;
Unit of Endocrinology and Metabolism, University of Louvain, Brussels, Belgium.

Background and aims: Two pathways control glucose-induced insulin secretion. The triggering pathway involves closure of KATP channels in the beta cell membrane, depolarization, influx of Ca^{2+} and a rise in the cytosolic concentration of ionized Ca^{2+} ($[Ca^{2+}]c$), which then triggers exocytosis of insulin granules. The amplifying pathway augments insulin secretion without further increasing $[Ca^{2+}]c$. It is not known how this metabolic amplification augments the efficacy of Ca^{2+} on exocytosis. In the present study, we tested a previously proposed hypothesis suggesting that amplification results from the acceleration of insulin granule translocation from a reserve pool to the exocytotic sites at the plasma membrane. Such translocation is thought to involve granule movement along microtubules, followed by their transfer across a sub-membrane web of microfilaments.
Materials and methods: After 18h culture, normal mouse islets were treated for 90 min with agents known to interfere with microfilament function (cytochalasin B, latrunculin B or jasplakinolide), with microtubule function (taxol or vinblastine) or both (taxol and cytochalasin B). The amplifying effect of glucose was tested by comparing insulin secretion and $[Ca^{2+}]c$ in low (1-3mmol/l) or high (15mmol/l) glucose after $[Ca^{2+}]c$ was raised by a high concentration (500µmol/l) of tolbutamide (KATP channels closed) or by 30mmol/l KCl in the presence of 100µmol/l diazoxide (KATP channels open).
Results: In control islets, glucose amplified insulin secretion in the presence of tolbutamide (~ 4x) and of KCl (~ 2x). Depolymerization of microfilaments by cytochalasin B or latrunculin B augmented (2-3x) tolbutamide- or KCl-induced insulin secretion in low glucose without affecting $[Ca^{2+}]c$, and did not impair the amplifying action of high glucose. Amplification in the presence of KCl was even larger (~ 4x). Surprisingly, stabilization of microfilaments by jasplakinolide also augmented tolbutamide- and KCl-induced insulin secretion in low glucose (~1.5x) independently of $[Ca^{2+}]c$ changes, and did not affect the amplification of secretion by high glucose. Both stabilization (taxol) and depolymerization (vinblastine) of microtubules inhibited (~1.4x) insulin secretion in low glucose + KCl or tolbutamide, and unexpectedly attenuated the $[Ca^{2+}]c$ rise induced by both stimuli. Nevertheless, this did not impair the amplifying effect of high glucose. Amplification of insulin secretion was also unaltered in islets treated by a combination of cytochalasin B and taxol.
Conclusion: Pharmacological disruption of beta cell microfilaments markedly augments insulin secretion independently of $[Ca^{2+}]c$ changes, which supports the concept of the inhibitory role of microfilaments in exocytosis. In contrast, the inhibition of insulin secretion by agents affecting microtubules may partly be attributed to a previously unreported lowering of $[Ca^{2+}]c$. Finally, metabolic amplification does not appear to require functional microfilaments or microtubules. The results, therefore, do not support the hypothesis suggesting that the process corresponds to mobilization of insulin granules from a reserve pool, but point to a more distal step of stimulus-secretion coupling.

Glucose- and hormone-induced cAMP oscillations in intact prancreatic islets

G. Tian, E. Gylfe, A. Tengholm;
Medical Cell Biology, Uppsala University, Sweden.

Background and aims: Cyclic AMP is an important messenger in insulin and glucagon secretion from pancreatic β- and α-cells. However, little is known about the kinetics of cAMP signals in islet cells. In the present study we investigated the effects of adenylyl cyclase-activating hormones and glucose on the cAMP concentration beneath the plasma membrane ($[cAMP]_{pm}$) of cells within intact isolated mouse islets.
Materials and methods: Islets were isolated from the pancreata of C57/Bl mice and infected with adenovirus expressing a fluorescent translocation biosensor for $[cAMP]_{pm}$. After attachment of the islets to coverslips, biosensor fluorescence changes were recorded from the superficial islet cells adhering to the glass using ratiometric evanescent wave microscopy. β-cells were identified based on their large size and $[cAMP]_{pm}$-lowering in response to adrenaline, while α-cells were smaller and reacted to adrenaline with an increase of $[cAMP]_{pm}$.
Results: In islets exposed to 3 mM glucose, $[cAMP]_{pm}$ was low and stable. Addition of 1-100 nM GLP-1 or glucagon induced prompt elevation of $[cAMP]_{pm}$ with oscillations synchronized among β-cells identified by $[cAMP]_{pm}$ lowering after exposure to 5 µM adrenaline. The GLP-1 and glucagon response patterns were dose-dependent with increasing duration of each $[cAMP]_{pm}$ oscillation with concentration of the stimulus. The hormone-induced $[cAMP]_{pm}$ elevations were markedly enhanced by a rise of the glucose concentration to 11 mM. Elevation of the glucose concentration to 11 or 20 mM in the absence of hormone stimuli induced a marked increase of $[cAMP]_{pm}$ and slow oscillations (frequencies range 0.13-0.59/min) both in α-cells reacting to subsequent addition of adrenaline with elevation of $[cAMP]_{pm}$ and in cells where adrenaline suppressed $[cAMP]_{pm}$. The glucose-induced $[cAMP]_{pm}$ oscillations persisted but with diminished amplitudes after removal of extracellular Ca^{2+}.
Conclusion: Glucagon, GLP-1 and glucose stimulation is associated with pronounced changes of cAMP concentration beneath the plasma membrane of individual cells within intact pancreatic islets. Such oscillations should contribute to the pulsatile release of islet hormones. The glucose-induced elevation of $[cAMP]_{pm}$ in α-cells may underlie a recently identified Ca^{2+}-independent stimulatory action of the sugar on glucagon secretion.

160

Subplasmalemmal Ca^{2+}measurements in pancreatic beta cells support the existence of an amplifying effect of glucose on insulin secretion

M.A. Ravier[1], R. Cheng-Xue[1], A.E. Palmer[2], J.-C. Henquin[1], P. Gilon[1];
[1]Endocrinology and Metabolism, University of Louvain, Brussels, Belgium, [2]Chemistry and Biochemistry, University of Colorado, Boulder, United States.

Background and aims: Triggering and amplifying pathways are thought to underlie glucose (G) stimulation of insulin secretion by β-cells. In the triggering pathway, G metabolism leads to a K_{ATP} channel-dependent depolarization that promotes Ca^{2+} influx via L-type Ca^{2+} channels, with subsequent increase in the cytosolic Ca^{2+} concentration ($[Ca^{2+}]_c$) and triggering of exocytosis. The cellular mechanisms of the K_{ATP} channel-independent amplifying pathway are still elusive. One proposal is that G metabolism augments the efficacy of cytosolic Ca^{2+} on exocytosis without a further increase in $[Ca^{2+}]_c$. However, G has been reported to modulate the properties of Ca^{2+} channels. It is thus possible that $[Ca^{2+}]$ changes confined to the exocytotic domain beneath the plasma membrane escaped detection during measurements of global $[Ca^{2+}]_c$. Therefore, we investigated whether an increase in subplasmalemmal $[Ca^{2+}]$ ($[Ca^{2+}]_{SM}$) might explain the apparent amplifying effect of G.
Materials and methods: We generated an adenovirus encoding the Ca^{2+} indicator D3-cpv (not targeted) and expressed it in clusters of β-cells from NMRI mice. LynD3-cpv (targeted to plasma membrane) was selectively expressed in β-cells within intact islets by the combination of LoxStopLox-LynD3-cpv and RIP-Cre adenoviruses. $[Ca^{2+}]_{SM}$ changes were monitored using total internal reflection fluorescence microscopy. In some experiments insulin secretion was measured in parallel.
Results: When β-cell clusters expressing D3-cpv were stimulated by increasing [G] from 3 to 15mmol/l, $[Ca^{2+}]_{SM}$ was found to change similarly to global $[Ca^{2+}]_c$ measured by conventional techniques: an initial transient drop was followed by a large biphasic increase, with well synchronized oscillations during the second phase. Simultaneously, insulin secretion was stimulated. This shows that β-cell function was not altered by expression of the fluorescent Ca^{2+}-probe. The amplifying pathway was studied in the presence of diazoxide, to hold K_{ATP} channels open, and of 30mmol/l KCl to depolarize β-cells, induce Ca^{2+} influx and stimulate insulin secretion. Under these conditions, increasing [G] from 3 to 15mmol/l caused a transient decrease in $[Ca^{2+}]_{SM}$ in most cells (22/24), followed by a return to pre-stimulatory values. Importantly, no cell showed an increase in $[Ca^{2+}]_{SM}$ while insulin secretion augmented about 2-fold. Pretreatment of the clusters with thapsigargin, a blocker of Ca^{2+} uptake by the endoplasmic reticulum, attenuated the initial decrease in $[Ca^{2+}]_{SM}$ produced by high glucose, but did not unmask any $[Ca^{2+}]_{SM}$ increase (n=25 cells), while insulin secretion remained stimulated. In control experiments, small $[Ca^{2+}]_{SM}$ fluctuations could be detected during repetitive variations of KCl between 30 and 32mmol/l (9/10 cells), which attests that our system has the required sensitivity to observe potential G effects. Finally, selective expression of LynD3-cpv in β-cells within intact islets did not reveal any $[Ca^{2+}]_{SM}$ increase upon glucose stimulation in the presence of 30mmol/l KCl and diazoxide, whereas the small changes imposed by variations of [KCl] between 30 and 32 mmol/l could be detected.
Conclusion: Amplification of insulin secretion by glucose does not involve an increase in β-cell subplasmalemmal $[Ca^{2+}]$ and can thus be ascribed to an increase in the efficacy of the triggering Ca^{2+} signal.

161

Hormonal inhibition of endocytosis: novel roles for norepinephrine, prostaglandin E_1 and Gz

S.G. Straub[1], Y. Zhao[1], Q. Fang[2], M. Lindau[2], G.W.G. Sharp[1];
[1]Molecular Medicine, [2]Applied Engineering and Physics, Cornell University, Ithaca, United States.

Background and aims: Increased $[Ca^{2+}]i$ stimulates both exocytosis and endocytosis. As norepinephrine and other physiological inhibitors of insulin release block exocytosis even in the face of increased $[Ca^{2+}]i$, an increase in endocytosis under such circumstances would be undesirable. Therefore, we tested the hypothesis that inhibitors of exocytosis would inhibit endocytosis when $[Ca^{2+}]i$ is increased.
Materials and methods: Whole cell and cell attached patch clamp capacitance measurements were applied using INS 832/13 cells to investigate the action of inhibitors of insulin exocytosis on endocytosis. Blocking peptides and pharmacological agents were employed in the study.
Results: When the cells were stimulated by depolarizing pulses of -70 mV to +10 mV under conditions of very high Ca^{2+} influx, e.g. 100 msec with 10 mM $[Ca^{2+}]o$ or 500 msec with 2.6 mM $[Ca^{2+}]o$, exocytosis was strongly increased and was followed immediately by endocytosis. Importantly, with these high levels of Ca^{2+} influx the effects of norepinephrine and prostaglandin E_1 (PGE_1) to block the stimulated exocytosis were abolished. This allowed us to study the effects of the inhibitors on endocytosis. Norepinephrine and PGE_1 inhibited endocytosis to the same extent as deltamethrin and cyclosporine, two well-known inhibitors of calcineurin and endocytosis. Inhibition of endocytosis by norepinephrine was blocked by yohimbine indicating that the effect was due to the α_2-adrenergic receptor but, surprisingly, it was not blocked by pre-treating the cells for 48 hours with pertussis toxin indicating the involvement of a pertussis toxin-insensitive G protein. Synthetic peptides mimicking the C-termini of G protein α subunits block the interaction of the G proteins with their receptors and can be used to determine which G proteins are involved in a specific effect. Dialyzing a synthetic peptide mimicking the C-terminus of the α-subunit of Gz into the cells blocked the inhibition of endocytosis by NE whereas a peptide consisting of the same amino acids but in random order was without effect. Inhibition of endocytosis by PGE_1 was also blocked by the Gz peptide. Cell attached capacitance measurements of single vesicles indicated that inhibition by norepinephrine was due to a decrease in the number of endocytotic events without a change in vesicle size. Analysis of fission pore kinetics revealed two distinct fission modes with norepinephrine selectively inhibiting the rapid fission events. As expected, deltamethrin, which is a calcineurin inhibitor and acts to inhibit the earliest stage in the sequence of events leading to endocytosis, i.e. to prevent the activation of calcineurin by increased $[Ca^{2+}]i$, decreased the number of endocytic events without affecting the fission pore kinetics.
Conclusion: These findings determine a novel action of norepinephrine and PGE_1 on endocytosis in insulin secreting cells and a novel action for Gz in the control of endocytosis. Similar mechanisms are likely operating in other cell types also, e.g. where inhibition of synaptic transmission occurs in the CNS.

A novel "distal" inhibitory effect of norepinephrine on the beta cell - retardation of the refilling of the readily releasable granule pool

G.W.G. Sharp[1], Y. Zhao[1], Q. Fang[2], S.G. Straub[1], M. Lindau[2];
[1]Molecular Medicine, [2]School of Applied Engineering Physics, Cornell University, Ithaca, United States.

Background and aims: The aim of this study was to understand the mechanisms responsible for the "distal" effect by which physiological inhibitors of insulin secretion block exocytosis downstream of increased$[Ca^{2+}]i$
Materials and methods: Whole cell and cell-attached patch clamp capacitance measurements were applied using INS 832/13 cells to investigate the mechanisms governing the distal effects of norepinephrine, and to identify the heterotrimeric G proteins involved. Antibodies against the α and β subunits of the heterotrimeric G proteins, blocking peptides and pharmacological agents were used in the study.
Results: The exocytosis elicited by a depolarizing pulse of 100ms from -70mV to +10mV with 2.6mM $[Ca^{2+}]o$ was inhibited by norepinephrine. This inhibition was blocked by the addition of antibodies against G protein β subunits while antibodies against Gαcommon alone were without effect. In accord with these data, the action of norpinephrine was mimicked by the βγ-activating peptide mSIRK. Moreover, inhibition of exocytosis by norepinephrine was significantly attenuated by botulinum toxin A (BoNT/A), which cleaves off the C-terminal 9 amino acids of SNAP-25, and also by a synthesized 14 amino acid peptide containing the BoNT/A cleavage site on SNAP-25. Thus the interaction between βγ and the C-terminus of SNAP-25 is responsible for the action of norepinephrine to inhibit exocytosis. However, with a train of 15 stimulating pulses each of 100 ms duration, the antibody against Gβ only blocked the inhibitory effect of norepinephrine on the exocytosis triggered by the 1st pulse and an "apparent" inhibitory effect of norepinephrine persisted for the remaining duration of the pulse chain. This persistent effect was abolished by the simultaneous addition of antibodies against Gβ and Gαcommon. These data combined suggested that the antibody against Gβ was blocking all of the inhibitory effect of norepinephrine on exocytosis but that an effect of norepinephrine via Gα to retard the filling of the RRP reduced the availability of granules for release - hence the apparent inhibition of exocytosis by norepinephrine in the presence of antibody against Gβ. A double pulse study to directly determine the time-course of refilling of the RRP was carried out under conditions of high Ca^{2+} influx (500ms stimulations from -70mV to

+10mV with 2.6mM [Ca^{2+}]o. This high level of Ca^{2+} influx blocks the effect of norepinephrine on exocytosis and empties the RRP. The rate of refilling was determined by applying 2nd pulses at intervals of from 1 to 40 seconds. Norepinephrine markedly retarded the refilling rate. To determine which G protein(s) were responsible, peptides mimicking the C-terminal amino acids of G protein α subunits, that block G protein interaction with their receptors, were added intracellularly. The Gαi-1/2 peptide blocked the effect of norepinephrine on refilling. A peptide with the amino acids in random order, and peptides for, Gαi-3, Gαo-1, Gαo-2, and Gαz were without effect.
Conclusion: The distal inhibition of insulin secretion by norepinephrine is due to two effects, 1. Inhibition of exocytosis by a Gβγ interaction with SNAP-25 on the SNARE complex and 2. Retardation of the refilling of the readily releasable pool by Giα-1/2.

Complement factor H is expressed in adipose tissue in association with insulin resistance
J. Moreno-Navarrete[1], R. Martínez-Barricarte[2], V. Catalán[3], M. Sabater[1], J. Gómez-Ambrosi[3], F. Ortega[1], M.R. Chacón[4], W. Ricart[1], J. Vendrell[4], G. Frühbeck[3], S. Rodríguez de Cordoba[2], J. Fernández-Real[1];
[1]Hospital of Girona, [2]Centro de Investigaciones Biológicas, Madrid, [3]Clínica Universitaria de Navarra, Pamplona, [4]University Hospital of Tarragona, Spain.

Background and aims: Activation of the alternative pathway of the complement system, in which factor H (fH; *CFH*) is a key regulatory component, has been suggested as a link between obesity and metabolic disorders. We aimed to study the associations between circulating and adipose tissue gene expressions of *CFH* and complement factor B (fB; *CFB*) with obesity and insulin resistance.
Materials and methods: Circulating fH and fB were determined by ELISA in 398 subjects (140 with normal glucose tolerance and 258 with altered glucose tolerance). Insulin sensitivity was measured using the frequently sampled intravenous glucose tolerance test (FSIVGTT). *CFH* and *CFB* gene expressions were evaluated in 76 adipose tissue samples, in isolated adipocytes and stromo-vascular cells (SVC) (n=13) by real time PCR using TaqMan® technology. The effects of weight loss were investigated in an independent cohort of 42 subjects.
Results: Circulating fH and fB were significantly increased in subjects with AGT (195.4 ± 63.5 *vs.* 175.2 ± 53.4 μg/ml, p=0.01 and 285.9 ± 90.5 *vs.* 231.95 ± 58.8 μg/ml, p<0.0001, respectively). Both circulating fH and fB were positively associated with BMI, waist-to-hip ratio, systolic and diastolic blood pressure, fasting glucose, glycated hemoglobin, log fasting triglycerides, LBP and sTNFR2; and negatively with insulin sensitivity and HDL-cholesterol. Age (p=0.03) and insulin sensitivity (p=0.01) contributed independently to circulating fB variance after controlling for the effects of waist-to-hip ratio, log fasting triglycerides and LBP in multiple lineal regression models. Only insulin sensitivity (p=0.02) contributed independently to circulating fH variance in the same model.
For the first time, *CFH* gene expression was detected in the adipose tissue (significantly increased in subcutaneous compared with visceral fat). *CFH* gene expression in visceral fat was significantly associated with insulin resistance. In contrast, *CFB* gene expression was significantly increased in omental fat but also in association with fasting glucose and triglycerides. The SVC fraction was the responsible of these differences, although isolated adipocytes also expressed fB and fH at low levels. Weight loss led to significantly decreased circulating fB (p=0.025) and fH (p=0.009) levels.
Conclusion: Increased circulating fH and fB concentrations in subjects with altered glucose tolerance could reflect increased SVC-induced activation of the alternative pathway of complement in omental adipose tissue linked to insulin resistance and metabolic disturbances.

TIMP-3 expression is regulated by SirT1
M. Cardellini, R. Menghini, V. Casagrande, A. Marino, M. Fabrizi, R. Lauro, M. Federici;
Department of Internal Medicine, University of Rome, Italy.

Background and aims: We recently identified Tissue Inhibitor of Metalloproteinase 3 (TIMP3), the endogenous inhibitor of A Disintegrin and Metalloprotease Domain 17 (ADAM17) and other Metalloproteinases (MMPs), as a gene modifier for insulin resistance and vascular inflammation in mice. We also described that in human carotid atherosclerotic plaques TIMP3 was significantly reduced in subjects with Type 2 diabetes leading to ADAM17 and MMP9 overactivity.
The aim of this study was to identify metabolic factors reducing TIMP3 expression and activity in Coronary Artery Smooth Muscle Cells (CASMC).
Materials and methods: CASMC (Lonza) were cultured and treated for 24 hours respectively with glucose (20 mM, HG), mannitol (20 mM, Man), insulin (10-7M, INS), 100μg/ml native LDL, 100μg/ml oxidized LDL (oxLDL),

100µg/ml Glycated-LDL (glyLDL). Since previous data suggested that LXR regulates TIMP3 expression, we used LXR agonists such as T0901317, 22-s and 22-r hydroxycholesterol and GW3965. Since LXR is regulated by SirT1 deacetylase, we also used SirT1 inhibitor Sirtinol. CASMC were therefore treated with 10µM 22-R-hydroxycholesterol (RH, Sigma-Aldrich), 10µM 22-Shydroxycholesterol (SH, Sigma-Aldrich), 5µM T0901317 (T09, Sigma-Aldrich), 3µM GW3965 (GW, Sigma-Aldrich), and 50µM Sirtinol (Calbiochem). Proteins and total RNA were extracted and TIMP3 levels and ADAM17 activity were assayed respectively by RT-PCR and fluorimetric assay. Knockdown of SirT1 in CASMC was performed trasfecting 1 µg of SIRT1 siRNA (sc-40986, Santa Cruz Biotechnology) and 0.8 µg of control siRNA-A (sc-40986, Santa Cruz Biotechnology) by Dharmafect1 (Dharmacon). For Timp3 promoter regulation assay we transfected cells with 2 µg of Human SirT1 cDNA clone (RG218134, Origene), 10 ng of renilla and Timp3 Gene Promoter Reporter Vector (LR1034,Panomics) or 2 µg of TransLucent Control Vector using Nucleofector II (program A-033,AMAXA). The Luciferase assay was performed with Dual-Luciferase Reporter Assay System (Promega) according to manufacturer's instructions.

Results: We found that among the various treatments only high glucose and Sirtinol significantly reduced TIMP3 expression in CASMC ($p<0.01$). Treatment of CASMC with Sirtinol determined an increased metalloprotease activity as measured by ADAM17 activity ($p<0.01$). To confirm a direct role of SirT1 in regulation of TIMP3 expression, we used a small interference RNA (siRNA) approach. Knockdown of SirT1 in CASMC resulted in marked reduction of TIMP3 expression but not Timp1/2/4 and ADAM10/17/MMP9. To substantiate SirT1 effects on TIMP3, CASMC were cotransfected with human SirT1 cDNA and Timp3 promoter luciferase reporter vector, confirming that SirT1 positively modulates TIMP3 expression. Human Endothelial Vein Umbilical Cells and Monocyte-like THP-1 cells were treated with Sirtinol resulting in a significant decrease in TIMP3 expression in both cell types ($p<0.01$). Finally, we analyzed TIMP3 and SirT1 expression in human atherosclerotic plaques (n=60) from diabetic and non diabetic subjects with symptomatic cerebrovascular disease. We observed that TIMP3 expression is positively correlated to SirT1 expression in human disease ($R=0.4$, $p<0,03$).

Conclusion: Our data suggest that TIMP3 expression is regulated by SirT1 deacetylase activity in human vascular cells and in human atherosclerotic plaques. A defective control of SirT1 on TIMP3 expression may lead to increased metalloprotease activation and favour the progression of atherosclerosis.

Experimental weight gain in humans induces insulin resistance in absence of systemic or adipose tissue inflammation

A. Viardot[1], D. Samocha-Bonet[1], J.R. Greenfield[1,2], L.V. Campbell[1,2], L.K. Heilbronn[1];
[1]Diabetes & Obesity Research Program, Garvan Institute of Medical Research, [2]Department of Endocrinology, St Vincent's Hospital, Sydney-Darlinghurst, NSW, Australia.

Background and aims: Low grade inflammation is often reported in obesity and is postulated to be causal in the development of insulin resistance and progression to type 2 diabetes. However, supportive evidence in humans is less conclusive, and there is increasing data suggesting that insulin resistance may precede accumulation of macrophages in adipose tissue and the local and systemic inflammation process. Our objective was to assess whether high-fat overfeeding in humans induces insulin resistance, and whether this is associated with an increase in markers of inflammation.

Materials and methods: We performed a prospective experimental 28 day high-fat overfeeding study in 28 healthy individuals. This was achieved by increasing food intake by +1000kcal/day from baseline, and increasing their fat intake from 34.3% to 45.8%. Changes in body weight, body composition (dual X-ray absorptiometry), insulin sensitivity (hyperinsulinaemic-euglycaemic clamp), serum inflammation markers, immune cell activation and macrophage numbers in abdominal subcutaneous adipose tissue (flow cytometry of stroma-vascular fraction) were recorded.

Results: Subjects with a starting BMI of 25.4±0.7 kg/m2 gained in average 2.8±0.2 kg ($p<0.001$) in bodyweight and increased fat mass by 1.8±0.2kg ($p<0.0001$). Insulin sensitivity (glucose infusion rate/fat free mass) decreased by 9.5% from 51.6±3.2 to 46.6±2.9 µmol/kg/min ($p=0.01$). There was a significant increase in circulating C-reactive protein (1.1±0.2 to 1.5±0.3 ng/ml, $p<0.01$) and monocyte chemoattractant protein-1 (MCP-1)(166±14 to 208±22 pg/ml, $p<0.01$), but no change in IL-6 (1.4±0.1 to 1.3±0.1 pg/ml, $p=0.44$) and soluble intercellular adhesion molecule-1 (207±10 to 203±9 ng/ml, $p=0.49$). We observed no change in macrophage numbers in adipose tissue, circulating immune cell numbers or expression of their surface activation markers. Importantly, there was no association between changes in insulin sensitivity and changes in inflammation markers.

Conclusion: Weight gain induced insulin resistance was observed in the absence of development of a significant inflammatory state, suggesting that inflammation is unlikely to be a substantial contributing factor to insulin resistance at this early stage of fat accumulation. The early increase in circulating MCP-1 may play a role in future recruitment of macrophages into adipose tissue.

The role of IL-1R1 mediated macrophage accumulation in adipose tissue - insights into the development of obesity-induced insulin resistance

K.A. Harford[1], M. Claessens[1], E. Oliver[1], C. Reynolds[1], O. Finucane[1], K.H.G. Mills[2], H.M. Roche[1];
[1]Nutrigenomics Research Group, UCD, [2]School of Biochemistry and Immunology, Trinity College, Dublin, Ireland.

Background and aims: Macrophages are a heterogeneous population of cells that play a role in the innate immune response to infection. Recent studies have shown that macrophages are key cells in the development of obesity, wherein there is progressive infiltration of macrophages into the adipose tissue. These adipose tissue macrophages are referred to as classically-activated, or M1, macrophages. They release pro-inflammatory cytokines such as IL-1, IL-6 and TNFα, creating an inflammatory response that can contribute to insulin resistance and type 2 diabetes mellitus (T2DM). In lean individuals macrophages are in an M2-polarization or alternatively-activated state and are thought to protect against inflammation. The IL-1 receptor type 1 (IL-1R1) is responsible for transmitting the pro-inflammatory effects of IL-1. The aim of the present study was to determine the number of adipose tissue macrophages and their activation state using flow cytometry in wildtype (WT) mice and in IL-1R1$^{-/-}$ mice at certain time points over a period of 16 weeks.

Materials and methods: C57BL/6 WT and IL-1R1$^{-/-}$ mice with a C57BL/6 background were fed a high-fat diet (45 % energy from fat) for 16 weeks. At weeks 0, 6 and 16 epididymal adipose tissue (EAT) and visceral adipose tissue (VAT) samples were taken from the C57BL/6 wildtype (WT) and IL-1R1$^{-/-}$ mice. Adipocytes and stromal vascular cells (SVC) were isolated from the adipose tissue by collagenase treatment. SVC were labelled with antibodies for macrophage markers F4/80, CD11B and CD11C and analysed by flow cytometry to determine the number of macrophages and activation status of the macrophages present. Triple-positive cells (F4/80$^+$CD11B$^+$CD11C$^+$) are associated with the M1-polarization state, while double-positive cells (F4/80$^+$CD11B$^+$CD11C$^-$) indicate M2 macrophages.

Results: At week 0 there is a significantly larger population of F4/80$^+$CD11B$^+$CD11C$^-$ (M2) cells in the EAT and VAT of the IL-1R1$^{-/-}$ group compared to the WT group ($p<0.05$) but no difference between groups in the number of F4/80$^+$CD11B$^+$CD11C$^+$ (M1) cells. However after 6 weeks on a high-fat diet there is a larger population of the more active F4/80$^+$CD11B$^+$CD11C$^+$ (M1) cells in the EAT of the WT group compared with the IL-1R1$^{-/-}$ group ($p<0.05$) while there is a reduced number of F4/80$^+$CD11B$^+$CD11C$^-$ (M2) cells in the IL-1R1$^{-/-}$ group compared to week 0 . After 16 weeks on a high-fat diet there is no significant difference in the number of F4/80$^+$CD11B$^+$CD11C$^+$ (M1) cells between the two groups of mice. Interestingly by week 16 there is a higher population of F4/80$^+$CD11B$^+$CD11C$^-$ (M2) cells in the EAT and VAT of the WT group compared to the IL-1R1$^{-/-}$ group ($p<0.05$).

Conclusion: These results imply that impairing IL-1 signalling decreases the macrophages ability to switch from an M2-polarization state to the pro-inflammatory M1-polarization state. This outcome delays the infiltration of M1 macrophages into the adipose tissue, thereby lowering the pro-inflammatory response and attenuating the progression of insulin resistance. Further studies are continuing in order to determine the molecular mechanisms by which this process occurs.

Exercise and weight loss both improve factors in the metabolic syndrome but only weight loss improves adiponectin and inflammatory markers

B. Richelsen, T. Christiansen, S.K. Paulsen, J.M. Bruun, S.B. Pedersen;
Medical Department C, Aarhus University Hospital, Denmark.

Background: Both exercise and weight loss are associated with improvements in the metabolic syndrome but the mechanisms involved may be different for the two interventions. It is suggested that changes in the fat mass may affect other tissues through release of so-called adipokines, and in analogy to that muscle activity may induce more systemic effects through release of myokines. Here we investigated the individual and the combined effect of exercise and diet-induced weight loss on visceral fat (VAT) accumulation, adiponectin (total and HMW), inflammatory markers, and insulin sensitivity.
Material and methods: 80 obese women and men were divided in three group and treated for 12 weeks with 1) exercise only (EXO), 2) Diet-induced weight loss (DIO) - 8 weeks treatment with VLED followed by 4 weeks weight loss maintenance diet, and 3) the combined group with both exercise and diet-induced weight loss (DEX). VAT and fat mass were determined by MRI. Fat and muscle biopsies were taken (PCR determinations). Circulating levels of insulin, glucose (HOMA), lipids, adiponectin and inflammatory markers (Luminex) were determined before and at the end of the intervention.
Results: Weight loss was after the 12 weeks 3.5 kg (EXO) and 12 kg in both DIO and DEX. Vo2 max was increased with 18-22% (P<0.01) in the two exercise groups with no change in DIO. The reduction in VAT was related to the total weight loss and not to the intervention (exercise vs. diet). HOMA decreased in all three groups(p<0.05 in the DIO and DEX groups), however, only to a non-significant level in the EXO group (P=0.09). Circulating total adiponectin and HMW-adiponectin were significantly increased and MIP1α, MCP1, IL-6, IL-15, and IL-18 were significantly reduced (P < 0.05) in the diet-induced weight loss groups (DIO and DEX) without any changes in the EXO group. No changes in muscle mRNA (TNFα, IL-6, IL-15) were observed in any of the groups (neither in the EXO group). Adiponectin mRNA was upregulated in AT in all three groups. There was no gender differences in the response to exercise and diet-induced weight loss.
Conclusion: Both regular exercise and diet-induced weight loss were able to improve some aspects of the metabolic syndrome such as improving insulin sensitivity. In this group of obese subjects we found that larger weight losses improve levels of adiponectin and low grade inflammation whereas exercise had no independent effects on these risk factors. We suggest that the metabolic effects of exercise is mediated primarily in the muscle tissue and the metabolic changes seen in other tissues are mediated by the well-known changes in insulin, adrenalin, GH, FFA etc. associated with muscle work and not by specific myokines. In contrast larger reduction in the fat mass may have systemic effects through changes in the release of adipokines from AT in combination with changes in insulin and FFA.

The effect of weight loss on intra-abdominal fatty acid metabolism in metabolic syndrome

A.C. Karmi[1], A. Viljanen[1], R. Borra[1], B. Fielding[2], T. Viljanen[1], K. Frayn[2], P. Iozzo[1], P. Nuutila[1];
[1]Turku PET Centre, Finland, [2]Oxford Centre for Diabetes, Endocrinology, and Metabolism University of Oxford, Churchill Hospital, United Kingdom.

Background and aims: Abdominal visceral adipose tissue (VAT) is considered to be more metabolically active than abdominal subcutaneous adipose tissue (SAT) and is thought to be more detrimental than SAT. The aim of the study was to compare fatty acid uptake (FU) in VAT and SAT and the effect of weight loss on regional FA metabolism in patients with metabolic syndrome.
Materials and methods: Regional FU was studied in 18 obese non-diabetic subjects (age 43±6 year, BMI 34.0± 3.9 kg/m^2) were studied in fast using PET and a trapping palmitate analogue with [18F]-fluoro-6-thia-heptadecanoic acid (FTHA). Indirect calorimetry and stable FA isotope [U-^{13}C]-palmitate were used to determine FA oxidation. Subjects were studied before and 6 weeks after very-low-calorie-diet (VLCD) for 6 weeks and one recovery week. MRI and MRS were used for anatomical reference and fat content measurements.
Results: The subjects lost 11.2±2.5 kg and body fat 18.5±5.2% (p<0.007). The mass of VAT decreased by -22.7±16.4% and of SAT by 19.5±10.1% (p< 0.001 for both). FU in VAT was 4-fold higher per volume than in abdominal SAT both before and after VLCD (p<0.001). FU into VAT depots (14.2× vs. 12.5×) and SAT depots (7.0× vs.6.5×umol/min) remained unchanged. In contrast FU decreased in femoral SAT (p<0.006), liver and muscle (p<0.01). A decrease in liver adiposity (p<0.001) and muscle fat content was found. EE decreased by 11.5±4.7% (p<0.0001). In whole-body level total fat oxidation was increased (from 4.07±1.29 to 5.82±1.11 umol/(FFMkg×min), (p=0.002) while total CHO oxidation was decreased 14.4±3.4 to 5.3±3.6 umol /(FFMkg×min), (p<0.0001). The non-plasma oxidation (plasma TGs and intraorgan TGs in muscle and adipose tissue) increased from -1.03±1.78 to 1.73±1.69 umol/(FFM×min) (p=0.0002) and the whole-body re-esterification decreased from 15.05±5.18 to 11.56±3.72 umol/(FFM×min) (p=0.04). Neither plasma FFA, palmitate, glycerol nor 3-OHB were changed after VLCD, but cholesterol, LDL-cholesterol and TGs decreased (p<0.002).
Conclusion: We conclude that fatty acids are taken up several folds more in VAT than in SAT in obese subjects. Rapid weight loss does not change the FA retention into VAT, although it reduces FA uptake into liver and muscles and shifts and enhances fat oxidation from non-plasma storages enhanced. The missing adaptation of VAT fatty acid metabolism during dieting might partly explain the problems to maintain the lower body weight.

OP 29 Novel therapies for type 2 diabetes mellitus

Dapagliflozin as an add-on to metformin lowers hyperglycaemia in type 2 diabetes patients inadequately controlled with metformin alone

C.J. Bailey[1], J.L. Gross[2], L. Bastone[3], A. Bastien[4], J.F. List[4];
[1]Diabetes Research, Aston University, Birmingham, United Kingdom, [2]Endocrine Division, Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil, [3]Global Biometric Sciences, Bristol-Myers Squibb, Hopewell, United States, [4]Global Clinical Research, Bristol-Myers Squibb, Princeton, United States.

Background and aims: Dapagliflozin (DAPA), a novel oral antidiabetic agent with an insulin-independent mechanism, is currently being developed for treating type 2 diabetes mellitus (T2DM). DAPA decreases hyperglycaemia by selectively inhibiting glucose reabsorption by renal sodium-glucose co-transporter 2. This trial (Study 014ST) was conducted to evaluate the efficacy and safety of DAPA as an add-on to metformin (Met) over 24 weeks in T2DM patients inadequately controlled with Met alone.
Materials and methods: This randomized, double-blind, placebo-controlled, multicenter trial in North and South America enrolled patients with T2DM, ages 18-77 years old. Eligible patients had inadequate glycaemic control (HbA1c 7.0-10.0%) on stable dosing with Met ≥1500 mg/d. After a 2-wk lead-in phase, 546 patients were equally randomized to once daily DAPA 2.5 mg, 5 mg, 10 mg, or placebo (PBO), plus open-label Met. The primary endpoint was change in HbA1c at wk 24. Other endpoints included changes in fasting plasma glucose (FPG) and % change in total body weight at wk 24.
Results: Compared to add-on PBO at wk 24, all add-on DAPA groups showed significant mean reductions from baseline in HbA1c (**Table**). Endpoint reductions in FPG were also significant for all DAPA groups vs PBO. Greater proportions of patients in all DAPA groups achieved HbA1c <7.0% at wk 24 than patients on PBO. Weight loss with DAPA was continuous and progressive. More patients treated with DAPA achieved weight decreases ≥5% compared to PBO. Generally, adverse events were balanced across all groups. Compared with PBO, rates of urinary tract infections were similar or lower for DAPA (PBO, 8.0%; DAPA 2.5 mg, 4.4%; DAPA 5 mg, 7.3%; DAPA 10 mg, 8.1%), while rates of genital infections were higher (PBO, 5.1%; DAPA 2.5 mg, 8.0%; DAPA 5 mg, 13.1%; DAPA 10 mg, 8.9%). Laboratory monitoring revealed no clinically meaningful changes in markers for renal impairment or increases in mean serum creatinine. Changes in supine BP at wk 24 ranged from -3.1 to -5.9 systolic/-2.1 to -2.7 diastolic mmHg with DAPA, compared to -0.3 systolic/-0.4 diastolic mmHg with PBO. A similar proportion of patients across all 4 treatment groups, including PBO, had BP measurements suggestive of orthostatic hypotension but without reported symptoms. Reports of hypoglycaemia were similar (PBO, 2.9%; DAPA 2.5 mg, 2.2%; DAPA 5 mg, 3.6%; DAPA 10 mg, 3.7%), and none led to discontinuation of study medication.
Conclusion: In T2DM patients who were inadequately controlled with Met alone, the addition of once daily DAPA appeared safe and was associated with significantly improved glycaemic control and clinically meaningful weight loss over 24 weeks compared to PBO.
Supported by: Bristol-Myers Squibb and AstraZeneca

Dapagliflozin improves glycaemic control in insulin-resistant patients with type 2 diabetes

J.P.H. Wilding[1], P. Norwood[2], C. T'joen[3], A. Bastien[4], J.F. List[4], F.T. Fiedorek[4];
[1]Diabetes and Endocrinology Clinical Research Unit, University Hospital Aintree, Liverpool, United Kingdom, [2]Valley Research, Fresno, United States, [3]Global Biometric Sciences, Bristol-Myers Squibb, Braine-l'Alleud, Belgium, [4]Global Clinical Research, Bristol-Myers Squibb, Princeton, United States.

Background and aims: For many T2DM patients who require insulin plus oral antidiabetics (OADs), the effectiveness of treatment is often limited by weight gain and insulin-resistance. Dapagliflozin (DAPA) is an insulin-independent oral agent that blocks renal glucose reabsorption by selectively inhibiting sodium-glucose co-transporter 2. This 12-week pilot study (Study 009) was designed to determine the efficacy and safety of DAPA in T2DM patients who were poorly controlled with insulin (at least 50 units/day) plus OADs (metformin and/or thiazolidinediones).
Materials and methods: The trial involved 26 study centers in the United States and Canada. In order to initially monitor glycaemic parameters with reduced insulin dosing, a small preliminary cohort (n = 4) received 20 mg single-blind DAPA, baseline OADs and 50% of baseline insulin dose. Afterward, the larger primary cohort (n = 71) was randomized to double-blind placebo (PBO), 10 mg DAPA or 20 mg DAPA once daily, plus baseline OADs and 50% of baseline insulin.
Results: At week 12, DAPA lowered HbA1c, postprandial glucose (PPG), and weight more than PBO (**Table**). In both DAPA groups, 65.2% of patients showed decreases in HbA1c ≥0.5% versus 15.8% of patients in the PBO group. Dapagliflozin produced dose-dependent responses in both fasting plasma glucose (FPG) and PPG. There were mean decreases in standing systolic/diastolic blood pressure in both DAPA groups (-7.2/-1.2 mmHg change from baseline of 130.7/78.9 mmHg [10 mg DAPA], -6.1/-3.9 mmHg change from baseline of 126.9/76.5 mmHg [20 mg DAPA]), compared to an increase in the PBO group (+2.8/+0.3 mmHg change from baseline of 128.9/76.9 mmHg). Adverse events (AEs) were balanced across all groups. Most frequently reported AEs (>5% in any group) included pollakiuria (urinary frequency), back pain, nasopharyngitis, nausea, headache, and upper respiratory tract infection. Three patients in the PBO group, 7 patients in the 10 mg DAPA group, and 6 patients in the 20 mg DAPA group reported episodes of hypoglycaemia. Of these, 1 patient in the PBO group reported major hypoglycaemia.
Conclusion: In insulin-resistant patients who had insulin reduced by 50%, DAPA was well tolerated, and improved glycaemic control and lowered weight more than PBO.

Mean Change from Baseline (95%CI) at Week 12 (LOCF)

	PBO [n=23]	10 mg DAPA [n=24]	20 mg DAPA [n=24]

Colesevelam HCl improves glucose metabolism and increases plasma glucagon-like peptide 1 and glucose-dependent insulinotropic polypeptide concentrations in subjects with type 2 diabetes

C. Beysen[1], K.C. Deines[1], E.L. Tsang[1], E.J. Murphy[2], M. Chan[1], J.M. Edmonds[1], R.A. Neese[3], M.K. Hellerstein[3];
[1]KineMed, Inc, Emeryville, [2]University of California at San Francisco, San Francisco, [3]Department of Nutritional Sciences, University of California at Berkeley, United States.

Background and aims: Colesevelam HCl is a bile-acid sequestrant indicated to improve glycemic control in subjects with type 2 diabetes (T2DM). The aim of this multi-center, randomized, double-blind study was to investigate potential glucose-lowering mechanism(s) of colesevelam.
Materials and methods: Subjects with T2DM (HbA_{1C}, 6.7-10.0%) were randomized to either 3.75g/d colesevelam HCl (n=27) or placebo (n=28) for 12 weeks. Fasting endogenous glucose production (EGP), gluconeogenesis, glycogenolysis and plasma glucose clearance were measured in each subject at baseline and post-treatment using stable isotope infusion studies of [U-$^{13}C_6$]glucose and [2-$^{13}C_1$]glycerol. Plasma glucose, insulin, total glucagon-like peptide 1 (GLP-1), total glucose-dependent insulinotropic polypeptide (GIP) and glucagon concentrations were also measured during fasting state and following a meal tolerance test.
Results: Significant treatment differences in least square (LS) mean (±SE) HbA_{1C} (-0.62 ± 0.23 %, P<0.01) and fasting plasma glucose (-23 ± 11 mg/dl, P<0.05) were observed at 12 weeks with colesevelam vs. placebo. Colesevelam increased fasting total GLP-1 (+10 ± 4 pmol/l, P=0.01), postprandial total GLP-1 AUC (+2,267 ± 750 pmol/l/300 min, P<0.01) and postprandial GIP AUC (+3.859 ± 857 pmol/l/300 min, P<0.0001) compared to placebo. Plasma glucose clearance increased significantly with colesevelam but was unchanged with placebo (+0.26 ± 0.42 and -0.06 ± 0.39 ml/kg FFM/min, respectively, P<0.01 between groups). EGP and glycogenolysis were unchanged with colesevelam and increased significantly with placebo (P<0.05), although the changes from baseline were not different between groups. Fasting and postprandial insulin and glucagon, fasting GIP and absolute gluconeogenesis were not different between the colesevelam and the placebo groups.
Conclusion: Colesevelam reduced HbA_{1C}, fasting plasma glucose and increased glucose clearance in the fasting state, compared to placebo, without the increase in EGP that occurred in placebo. The improvement in glucose homeostasis in the colesevelam group corresponded with an increase in fasting GLP-1 and postprandial GLP-1 and GIP concentrations.

Efficacy and safety of the 11-beta-HSD1 inhibitor, INCB13739, added to metformin therapy in patients with type 2 diabetes

R. Huber[1], S. Banarer[2], V. Fonseca[3], S. Inzucchi[4], G.F. Hollis[1], R. Flores[1], R. Levy[1], B. Williams[1], J. Rosenstock[2];
[1]Incyte Corporation, Wilmington, [2]Dallas Diabetes and Endocrine Center, Dallas, [3]Tulane University Health Sciences Center, New Orleans, [4]Yale University School of Medicine, New Haven, United States.

Background and aims: INCB13739 (13739) is a selective inhibitor of 11-beta-hydroxysteroid dehydrogenase type 1 (11-β-HSD1) being developed for the treatment of type 2 diabetes (T2DM).
Materials and methods: This randomized, double-blind, placebo (PBO)-controlled trial assessed the efficacy and safety of 13739 in combination with metformin (MET) in patients with T2DM inadequately controlled by MET monotherapy. The primary endpoint was the change from baseline in HbA1c at week 12. After a 2 week PBO run-in period, patients (n=159; mean BMI=32.7. kg/m^2; mean HbA1c=8.3%; mean duration of T2DM=6.8 yr) were assigned to receive 13739 at doses of 5 mg (n=27), 15 mg (26), 50 mg (24), 100 mg (27), 200 mg (27) or PBO (28) once-daily in addition to a stable MET regimen for 12 weeks.
Results: Mean changes from baseline in HbA1c were significantly (p<0.01) greater for 13739 100 mg (-0.6%) and 200 mg (-0.5%) vs. PBO (0.0%) at week 12. Although plasma lipids were well controlled at baseline, both the 100 mg and 200 mg doses trended downward with a significant (p=0.03) treatment effect observed for the 100 mg dose in LDL-cholesterol (LDL-C) (-16 and +3 mg/dL for 100 mg vs. PBO, respectively). The frequency and severity of adverse events following 13739 treatment were similar to those observed in subjects randomized to PBO. 13739 did not affect sex hormone levels or the aldosterone-renin axis. A dose dependent increase in morning plasma ACTH was reached by week 4 and then plateaued (mean = 48 pg/mL in the 200 mg group at week 12; normal range <63.3 pg/mL). Plasma DHEA-s increased in a dose-dependent manner in concert with ACTH, reaching a maximum at week 4 in the 200 mg group (mean = 198 ug/dL) which was within age and gender-based normal ranges. Plasma morning cortisol, late-night salivary cortisol, and response to Cortrosyn challenge were unchanged from baseline, indicating that the changes in ACTH likely reflect compensatory HPA axis activity to maintain normal circulating cortisol homeostasis.
Conclusion: 13739 was very well tolerated and is the first 11-β-HSD1 inhibitor to demonstrate improvements in HbA1c and LDL-C in patients with T2DM.

173

Treatment with VI-0521 (phentermine and topiramate) leads to one year durable glycaemic benefit and weight loss in subjects with type 2 diabetes

W.T. Garvey[1], B. Troupin[2], C. Peterson[2], T. Najarian[2], P. Tam[2], W. Day[2];
[1]Dept of Nutrition Sciences, University of Alabama - Birmingham, [2]VIVUS, Inc, Mountain View, United States.

Background and aims: VI-0521, a low-dose, once daily combination of phentermine (PHEN) and topiramate (TPM) has been shown to produce significant weight loss, improvements in blood pressure and lipids, and in diabetic subjects, statistically and clinically significant reductions in HbA1c and blood glucose. This study demonstrates that in subjects with type 2 diabetes, previously reported metabolic and cardiovascular benefits persist through one year of treatment, with a favorable tolerability and safety profile.
Materials and methods: This was a 56-week double blind, placebo-controlled, multi-center study. Subjects were type 2 diabetics who had completed a previous (28-week) study evaluating VI-0521, and elected to continue with their randomized treatment [PHEN/TPM 15/92 (n=75) or Placebo (n=55)] for an additional 28 weeks. The primary endpoint for the study was the change in HbA1c from baseline (week 0) to Week 56. Subjects underwent dietary and lifestyle counseling throughout the 1-year period. All subjects were actively managed, in that investigators were required to adjust concomitant anti-diabetic and anti-hypertensive medications in response to blood glucose or blood pressure values that were outside of protocol-specified thresholds.
Results: The 1-year treatment cohort consisted of 130 type 2 diabetic subjects (69% female, mean age 49 years, 86% Caucasian, 59% Hispanic/Latino, 11% Black; mean baseline weight 96kg, BMI 35 kg/m^2, HbA1c 8.7%, mean fasting glucose 9.6 mmol/L). At baseline, 11 % of subjects were drug naïve, 28% were on monotherapy, and the remainder (>60%) were treated with 2 or more oral medications for their diabetes. At week 56, the VI-0521 group showed a reduction from baseline in HbA1c of 1.6% compared to 1.1% in the placebo group (p=0.038). 53% of VI-0521 treated subjects achieved the HbA1c benchmark of less than 7%, with 32% achieving a HbA1c of <6.5%, compared to 40% and 16%, respectively, in subjects managed without VI-0521. In the VI-0521 group, fasting glucose dropped 2.42 mmol/L at 56 weeks, compared to 1.42 mmol/L in placebo (p=0.02), and statistically significant improvements were also seen in postprandial glucose control as measured by 1,5-anhydroglucitol (GlycoMark, p=0.01). These glycemic targets were met in VI-0521 treated subjects despite a net reduction in their anti-diabetic medication, in contrast to the placebo treated subjects who required increased anti-diabetic medications. VI-0521 treated subjects lost 9.4% of their baseline body weight by 56 weeks, compared to 2.7% in the placebo group (p<0.001). VI-0521 was well tolerated, with no treatment related SAEs, and one discontinuation due to an AE in VI-0521, versus none in placebo. Adverse events were generally mild to moderate, and occurred at lower rates in the second six months of the study. Severe events occurred in 6 subjects on VI-0521, and 4 in placebo treated subjects. Greater than 90% of participants in both groups completed 56 weeks of treatment.
Conclusion: At one year, treatment of type 2 diabetic patients with VI-0521 produced sustained and clinically meaningful reductions in HbA1c, fasting and postprandial glucose, and body weight compared to placebo, in a well-tolerated once daily formulation. This was achieved on a background of mandated treatment to standard of care glycemic targets in both placebo and VI-0521 treatment groups.

Farnesoid-X receptor agonists - a new therapeutic class for diabetes and NAFLD - first clinical data

S. Mudaliar[1], L. Morrow[2], R. Henry[1], M. Kipnes[3], A. Sanyal[4], C. Sciacca[5], M. Hompesch[2], P. Clopton[1], A. Mavian[1], D. Shapiro[5];
[1]VA San Diego Healthcare System and, San Diego, [2]Profil Institute for Clinical Research, Inc., Chula Vista, [3]DGD Clinic, San Antonio, [4]Virginia Commonwealth University, Richmond, [5]Intercept Pharmaceuticals, Inc., San Diego, United States.

Background and aims: 6-ethyl chenodeoxycholic acid (CDCA), INT-747, is a novel derivative of the primary human bile acid CDCA, (the natural ligand for the farnesoid-X receptor (FXR), a nuclear hormone receptor). INT-747 is ~100x more potent an FXR agonist than CDCA and *in vitro* increases insulin secretion by human pancreatic islets, enhances adipocyte lipid storage and secretion of adiponectin and leptin.
Materials and methods: This double blind, placebo (Pbo) controlled, study evaluated the effects of INT-747 on insulin sensitivity by means of a two stage euglycemic insulin clamp. Patients with Type 2 diabetes and non-alcoholic fatty liver disease (NAFLD), diagnosed by elevated aminotransferases (20%), imaging (84%) and/or histology (3%), were randomized to receive placebo, INT-747 25mg or 50mg once daily for 6 weeks. 64 patients enrolled (Pbo: n=23; INT-747 25mg: n=20, INT-747 50mg: n=21). Glucose disposal rate (GDR) (mg . kg^{-1} . min^{-1}) was determined (pre and post treatment) after steady state was achieved with low and high dose insulin (Ins) infusions (60 and 120mU x m^2 body surface area/min).
Results: Fasting plasma insulin concentrations tended to be higher after treatment with 25mg vs. Pbo. The greatest responses appeared to occur in patients with BMI <40kg/m^2 and HbA_{1c} >7%. Adverse experiences (AEs) were generally mild/moderate and not clearly different across groups (placebo 61%, 25mg 45%, 50mg 76%). Constipation (19% in 50mg group) was the most common. Minor increases in LDL (25 and 50mg) and decreases in HDL and triglycerides (50mg) were seen. ALT (25mg) and GGT (both doses) decreased by ~25% and 50% (p<0.001), respectively.
Conclusion: In this study INT-747 was well tolerated and improved GDR and weight loss in Type 2 diabetics with NAFLD.

The association between cardiac autonomic neuropathy with metabolic and other factors in subjects with type 1 and type 2 diabetes mellitus

C. Voulgari, M. Psallas, N. Katsilambros, N. Tentolouris;
1st Department of Propaedeutic Medicine, Athens University Medical School, Laiko General Hospital, Greece.

Background and aims: Cardiac autonomic neuropathy (CAN) is a common complication of diabetes and is associated with poor prognosis. However, little is known about the risk factors for the development of CAN, especially in subjects with type 2 diabetes (T2DM). The aim of this cross-sectional study was to examine the relationship between CAN and clinical and metabolic parameters as well as microvascular and other complications in patients with either type 1 (T1DM) or T2DM.
Materials and methods: A total of 600 patients (T1DM: *n*=200; T2DM: *n*=400) were recruited. Participants with overt nephropathy or macrovascular complications were excluded. CAN was diagnosed when two out of the four classical autonomic function tests were abnormal.
Results: In T1DM, multivariate logistic regression analysis, after adjustment for gender, age, central fat distribution, duration of diabetes and lipids demonstrated that the odds (OR, 95% confidence intervals) of CAN increased with factors such as onset of diabetes in the puberty [2.64 (1.02-6.30), *P*=0.02], microalbuminuria [2.48 (1.32-4.64), *P*=0.005], retinopathy [1.13 (1.04-1.41), *P*<0.001], smoking [1.14 (1.05-1.40), *P*=0.002] and measures such as higher HbA_{1c} values [1.54 (1.05-2.25), *P*=0.02], LDL-cholesterol [1.01 (1.00-1.24), *P*=0.02], triglycerides [1.01 (1.00-1.02), *P*=0.003] and systolic blood pressure [1.03 (1.00-1.05), *P*=0.01]. The same analysis in patients with T2DM, after adjustment for gender, age, blood pressure, lipids, and antidiabetic treatment demonstrated that central fat distribution [1.03 (1.00-1.03), *P*=0.05], longer duration of diabetes [1.04 (1.01-1.08), *P*=0.006], higher HbA_{1c} values [1.19 (1.02-1.38), *P*=0.02], LDL-cholesterol [1.01 (1.00-1.01), *P*=0.004], triglycerides [1.00 (1.00-1.00), *P*=0.05], retinopathy [1.34 (1.17-1.66), *P*=0.001], microalbuminuria [1.21 (1.12-1.35), *P*<0.001], smoking [1.25 (1.11-1.59), *P*=0.002] and severity of smoking (>20 cigarettes/day) [1.34, (1.15-1.71), *P*=0.004] were independently associated with higher odds of CAN.
Conclusion: In patients with T1DM, the risk of CAN is associated with onset of diabetes in the puberty, glycemic control, blood pressure, dyslipidemia, microalbuminuria, retinopathy and smoking, while in patients with T2DM with duration of diabetes, glycemic control, dyslipidemia, microvascular complications, central fat distribution and smoking.

176

Indices of cardiac autonomic function correlate with arterial stiffness in young normotensive and normoalbuminuric patients with type 1 diabetes

E. Diakoumopoulou[1], S. Liatis[1], A. Tsiakou[1], K. Alexiadou[1], N. Tentolouris[1], N. Katsilambros[2];
[1]1st Internal Medicine Department, Athens University Medical School Laiko Hospital, Athens, Greece, [2]Athens University Medical School, Greece.

Background and aims: Arterial stiffness is increased in type 1 diabetes (T1D), even before any clinical complications from the disease are evident. The diminished vascular compliance found in diabetes is believed to be multifactorial, with hyperglycemia playing a mandatory pathogenetic role. Conflicting data exist, however, regarding the relationship between cardiac autonomic function and arterial stiffness in T1D. The aim of this study was to investigate the association between cardiac autonomic function and large artery elasticity in young normotensive and normoalbuminuric T1D patients.
Materials and methods: Normotensive T1D patients, aged <40 years, without clinical evidence of nephropathy were consecutively selected from the outpatient diabetes clinic of our institution. Large artery stiffness was assessed by measurement of carotid-femoral pulse wave velocity (PWV). Cardiac autonomic function was assessed by the battery of the cardiovascular tests proposed by Ewing and Clarke. The heart rate response to slow, deep breathing, to Valsalva manoeuvre and to standing up were assessed from ECG recordings of RR intervals.
Results: Data from 66 individuals were analyzed (age 27.1±6.0 years, 31 [47%] men, diabetes duration 12.3±7.7 years, HbA_{1C} 7.4±1.5%). Mean PWV value was 5.6±0.9 m/sec, whereas mean expiration/inspiration (E/I) index

(an index of heart rate variability during deep breathing) was 1.33±0.16, mean 30:15 ratio (an index of heart rate change after taking the upright position) was 1.33±0.18 and mean Valsalva ratio (the ratio of the longest RR interval after the manoeuvre to the shortest interval during it) was 1.94±0.40. There was a strong negative correlation of PWV with E/I index, (r=-0.533 p<0.001) and a weaker one with 30:15 ratio (r=-0.275, p=0.025). In multivariate linear regression analysis, after taking account for confounding factors (i.e. age, sex, diabetes duration, arterial blood pressure, smoking, body mass index and waist to hip ratio), E/I index was the strongest predictor of PWV (standardized β-regression coefficient=-0.348, p=0.002). E/I index, age and waist circumference accounted for the 43.7% of PWV variability.
Conclusion: Cardiac autonomic function expressed as E/I index is a strong predictor of large arterial stiffness, in young normotensive and normoalbuminuric T1D patients.

177

Association between the abnormal test of sudomotor function (Neuropad®) and markers of increased cardiovascular risk and the chronic complications of diabetes

D.S. Tesic[1], P. Pantelinac[1], V. Popovic[2], M. Mitrovic[1], J. Novakovic-Paro[1], B. Vukovic[1];
[1]Clinic of Endocrinology, Diabetes and Metabolic Diseases, [2]Clinic of Vascular Surgery, Clinical Centre of Vojvodina, Novi Sad, Serbia.

Background and aims: We have explored the possible role of using a commercially available test of distal autonomic function (Neuropad®) in routine clinical practice by examining clinical and metabolic factors associated with an abnormal response to a test in a population of 499 patients with diabetes.
Materials and methods: 499 patients were recruited from those attending a routine specialist diabetes clinic. All were assessed for the quality of glycaemic control, cardiovascular risk factors and the presence of complications. Somatic sensory neuropathy was documented using the Neuropathy Disability Score, and autonomic neuropathy (sudomotor neuropathy) was determined on the sole of the foot using the Neuropad® response including time to colour change. Patients were divided into two groups: those with normal (pad pink at ten minutes) and abnormal (pad wholly or patchily blue).
Results: There were 151 patients with type 1 (72 male, mean age 41.2±13.7y; mean disease duration 15.4±10.3y) and 348 with type 2 (159 male, mean age 62.0±8.8y; mean disease duration 14.8±8.6y). NDS was >5 (abnormal) in 130 (26.1%) and no change in Neuropad colour by 10 minutes was observed in 121 (24.2%). An abnormal Neuropad test was observed in 70 (19.0% of 369) patients with a normal NDS. Mean time to complete Neuropad colour change was 10.8±7.3 mins in patients with an abnormal NDS, and 7.0±5.5 mins in those without neuropathy (p<0.001). Significant direct correlations were observed between an abnormal Neuropad test and age (r_s=0.31, p<0.001), waist circumference (r_s=0.17, p=0.003), BMI (r_s=0.25, p<0.001); significant negative correlations were observed with height (r_s=-0.17, p<0.001) and serum HDL cholesterol (r_s=-0.13, p=0.003). Patients with abnormal sudomotor function were older (60.8±10.5y) than those who were normal (54.0±14.9y, p<0.001), as well as having a longer disease duration (16.8±9.4 vs. 14.8±9.7, p=0.045), high BMI (29.4±5.8 vs. 27.4±2.5) and a higher prevalence of hypertension (54.6% vs. 42.1%, p=0.018). Patients with an abnormal sudomotor response also had a higher prevalence of maculopathy (29.8% vs 16.7%, p=0.008), symptomatic neuropathy (62.8% vs 48.5%, p=0.04), history of myocardial infarction and/or stent and/or bypass surgery (20.7% vs. 13.2%, p=0.05), peripheral arterial disease (9.1% vs 4.5%, p=0.04), history of foot ulcers (5.8% vs 0.8%, p=0.003) and major amputations (2.5% vs 0.0%, p<0.001).
Conclusion: These findings illustrate the close association between the finding of an abnormal test of sudomotor function, markers of increased cardiovascular risk and the presence of chronic complications of diabetes. There may be a place for inclusion of routine testing of sudomotor function in the routine assessment of people with diabetes. These preliminary data suggest that it may be more sensitive than the NDS in detecting distal neuropathy.

178

Role of oxidative stress in predicting the progression of somatosensory and cardiac autonomic nerve dysfunction in diabetic patients. A 6-year prospective study

D. Ziegler[1,2], S. Kuehne[1], C. Sohr[1], M. Roden[1,2], J. Nourooz-Zadeh[3];
[1]Institute for Clinical Diabetology, German Diabetes Center at the Heinrich Heine University, Düsseldorf, Germany, [2]Department of Internal Medicine / Metabolic Diseases, University Hospital, Düsseldorf, Germany, [3]Department of Medicine, Royal Free and University College London School of Medicine, United Kingdom.

Background and aims: Oxidative stress is implicated in the pathogenesis of experimental diabetic neuropathy, but prospective studies in diabetic patients are lacking. We aimed to evaluate whether the plasma levels of various biomarkers of oxidative stress predict the progression of diabetic neuropathy and mortality over 6 years.
Materials and methods: We followed 89 diabetic patients (mean±SD; age: 54±14 years, diabetes duration: 12±10 years, HbA1c: 9.4±1.7%, 54% male, 69% type 2, 59% with polyneuropathy), 72 of whom underwent nerve function reassessment after 6.2±0.8 years, whereas 17 died after 4.2±1.0 years. Markers of oxidative stress in plasma at baseline included superoxide, hypochlorous acid, peroxynitrite (all ABEL assay), 8-iso-prostaglandin F2α, vitamin E/lipid ratio, and vitamin C. Neuropathy was assessed by symptoms and deficits, motor and sensory nerve conduction velocity (MNCV, SNCV), vibration perception thresholds (VPT), thermal detection thresholds (TDT), and heart rate variability (HRV).
Results: Despite a reduction in HbA1c by -1.4±1.6% (p<0.001), median SNCV, sural SNCV, peroneal MNCV, malleolar VPT, and warm TDT deteriorated from baseline to follow-up (all p<0.05). Multivariate regression analyses demonstrated that increased superoxide generation was associated with a decline in median SNCV (β=-0.997; p=0.036) and deterioration in HRV at rest (OR: 1.63 [95% CI: 1.09-2.44]; p=0.017) from baseline to follow-up. Low vitamin E/lipid ratio predicted a decrease in peroneal MNCV (β=0.760; p=0.036) and tended to relate to the change in malleolar VPT (β=-0.725; p=0.077), while vitamin C was associated with the change in cold TDT (β=-0.094; p=0.032), but after full adjustment, these effects did not persist. Superoxide (highest quartile) was associated with an increased risk of mortality (HR: 5.75 [95% CI: 1.59-20.88]; p=0.047).
Conclusion: Increased plasma superoxide generation predicted the decline in sensory and cardiac autonomic nerve function and mortality over 6 years in diabetic patients, whereas the predictive value of other oxidative stress markers was either less consistent or lacking.

The effect of glucose variability on the risk of peripheral and autonomic neuropathy in type 1 diabetes

T.M. Vriesendorp[1], S.E. Siegelaar[1], E.S. Kilpatrick[2], A.S. Rigby[3], S.L. Atkin[4], J.B.L. Hoekstra[1], J.H. DeVries[1];
[1]Internal Medicine, Academic Medical Center, Amsterdam, Netherlands, [2]Clinical Biochemistry, Hull Royal Infirmary, United Kingdom, [3]Cardiology, University of Hull, United Kingdom, [4]Diabetes, Hull York Medical School, United Kingdom.

Background and aims: While the presence of an effect of glycemic variability on microvascular complications as retinopathy and nephropathy has been negated, it is unknown whether glycemic variability may influence neuropathy. In literature, it is suggested that the nervous system may be particularly susceptible to glucose variability. We analyzed data from the Diabetes Control and Complications Trial (DCCT) to assess whether glycemic variability is a risk factor for the development of peripheral or autonomic diabetic neuropathy.
Materials and methods: Seven-point glucose profiles were collected quarterly during the DCCT in 1441 individuals with type 1 diabetes. Peripheral neuropathy was assessed at baseline and at 5 years follow-up, autonomic neuropathy at baseline and 4 years follow-up. The effect of the glycemic variability, expressed as standard deviation (SD) and mean amplitude of glycemic excursions (MAGE) on the development of peripheral and autonomic neuropathy was assessed using a logistic regression model, with adjustment for age, sex, disease duration, treatment group and prevention cohort. Finally, the additional effect of glucose variability over the effect of HbA1c and mean glucose on neuropathy was computed using the same technique.
Results: Glucose variability, quantified by mean SD and mean MAGE, had no effect on the incidence of clinical neuropathy confirmed by autonomic

or electromyography (EMG) abnormalities (SD Odds Ratio [OR] 1.07, 95% Confidence Interval [CI] I 0.83-1.35, p=0.67; MAGE OR 1.06, CI 0.96-1.20, p=0.23) or clinical neuropathy alone (SD OR 0.95, CI 0.77-1.18, p=0.66; MAGE OR 1.01, CI 0.91-1.11, p=0.90). Glucose variability appeared to have a possible effect on overall autonomic dysfunction but not when adjusting for HbA1c or mean glucose (SD OR 1.08 and 1.09, CI 0.82-1.44 and 0.80-1.48, p=0.58 and 0.57 respectively; MAGE OR 1.09 and 1.10, CI 0.96-1.23 and 0.97-1.25, p=0.18 and 0.13 respectively). Only for one specific autonomic function parameter, beat-to-beat heart rate variation < 20 plus a Valsalva ratio > 1.5, the effect remained significant when adjusting for mean glucose (SD OR 2.64, CI 1.17-5.94, p=0.02; MAGE OR 1.42, CI 1.07-1.90, p=0.02), but not when adjusting for HbA1c (SD OR 1.84, CI 0.90-3.76, p=0.09; MAGE OR 1.30, CI 0.98-1.72, p=0.072).
Conclusion: Glucose variability does not appear to be an additional risk factor in the development of diabetic peripheral or autonomic neuropathy over and above HbA1c or mean glucose.

IGT-associated neuropathy and its possible involvement with metabolic syndrome
Y. Sako[1], N. Sekiguchi[1], J. Iwasaki[2], K. Okadome[3];
[1]Department of Metabolism Endocrinology and Diabetology, [2]Department of Health Check, [3]Department of Surgery, Saiseikai Fukuoka General Hospital, Fukuoka, Japan.

Background and aims: Increasing epidemiological evidence implicates the prediabetic state of impaired glucose tolerance (IGT) as a risk factor for macrovascular complications. Recent studies also suggest a causal relationship between IGT and peripheral neuropathy. The clinical characteristics of IGT-associated neuropathy are not well understood. The aim of this study is to determine the prevalence of IGT-associated neuropathy, and to assess associations between peripheral sensory neuropathy (PSN) and each component of metabolic syndrome.
Materials and methods: We examined 150 patients with IGT (age: 54.7±10.0 years, BMI: 23.7±2.8, FBS: 102.4±10.3 mg/dl, HbA1c:5.3±0.3%, CVr-r at rest: 3.61±1.66%; M±SD) and 176 NGT (normal glucose tolerance) control subjects (age: 50.4±11.7, BMI: 22.5±2.8, FBS: 92.5±7.4, HbA1c: 5.1±0.3, CVr-r: 3.88±1.89). We determined the prevalence of PSN in each group. PSN was defined as the existence of neuropathic symptoms and tendon reflex abnormality and impaired vibratory sensation. Two abnormalities out of three were considered pathological. We also investigated associations between PSN and each component of metabolic syndrome (hyperglycemia: IGT & IFG, hypertension, dyslipidemia, waist circumference) in total subjects (N=326) using multivariate statistical analysis for significance testing.
Results: Significant differences were not found between IGT and NGT control subjects regarding the following parameters: age, BMI, FBS, HbA1c, CVr-r. Prevalence of PSN in IGT subjects assessed by our criteria was 18.0%, while that of PSN in NGT control subjects was 3.9%. The prevalence of PSN in IGT was significantly higher than that in control NGT subjects (p<0.001). In univariate analysis, PSN was significantly associated with age (p=0.0008), IGT (p=0.0002) and IFG (p=0.001) and tended to be significantly associated with hypertension (p=0.052) but not with sex, waist circumference and dyslipidemia. In multivariate analysis, PSN was independently associated with IGT (odds ratio 4.34) and IFG (4.47) and tended to be independently associated with hypertension (2.01), age (2.29), waist circumference (1.74) and sex (1.75).
Conclusion: The result that neuropathy is more common in patients with IGT than in normoglycemic controls strongly supports an association between prediabetes and neuropathy. Our data indicates that metabolic syndrome may be involved in the pathogenesis of IGT-associated neuropathy. Longitudinal studies are needed to establish the temporal relationship between IGT-associated neuropathy and diabetic neuropathy.

Independent effects of weight gain and fetal programming on metabolic complications in SGA adults
T. Meas, E. Carreira, S. Deghmoun, C. Lévy-Marchal;
Internal Medicine, Université Paris 7, France.

Introduction: The relationship between a low birth weight and the development of insulin resistance (IR) and the Metabolic Syndrome (MS) has been well documented at different periods of life. But little is known about the progression of MS in young adults born small for gestational age (SGA), in particular on the respective roles of SGA and weight gain.
Aim: We have previously reported an increased gain of fat mass with ageing in young adults born SGA beyond the simple effect of time. We hypothesized that being born SGA would promote a marked progression of IR and MS not only reflecting this gain of fat mass but reflecting also fetal programming.
Subjects and methods: Subjects were selected from a community-based cohort where subjects were all born full-term either SGA (Birth Weight< 10th percentile) or appropriate for gestational age (AGA) (25th <BW<75th percentile). 1273 subjects were prospectively followed over 7.5 yr, representing 78 % of the initial cohort. Metabolic syndrome was assessed using the WHO definition.
Results:

	AGA (n=697)	SGA (n=576)	P value
Baseline observation			
Age (years)	22.1 ± 3.8	22.0 ± 3.8	0.78
Sex ratio % (M/F)	47/53	45/55	0.68
BMI (kg/m^2)	22.6 ± 3.7	22.4 ± 4.2	0.39
MS n (%)	1 (0.14)	15 (2.60)	*0.008*
HOMA-IR	1.02 ± 0.5	1.18 ± 0.9	*0.001*
Observation at follow-up			
Follow-up duration	7.5 ± 2.6	7.4 ± 2.5	0.49
BMI (kg/m^2)	24.1 ± 4.3	24.2 ± 5.3	0.65
Delta BMI (kg/m^2)	+ 1.5 ± 2.4	+ 1.8 ± 2.7	0.02
Fat mass (%)	22.1 ± 8.2	23.1 ± 8.9	0.04
HOMA-IR	1.27 ± 0.6	1.41 ± 0.8	*0.004*
Delta HOMA-IR	0.25 ± 0.6	0.24 ± 0.9	0.61/0.28*
MS n (%)	34 (4.9)	51 (8.9)	*0.05/0.08**

All comparisons are adjusted on gender, age, BMI, socio-economical status and family history of metabolic disorders. * Same model with delta BMI instead of BMI
Conclusion: At both visits, subjects born SGA are more insulin resistant and have a significantly higher prevalence of MS in comparison to those born AGA, despite a very steep progression of MS in the AGA group. SGA subjects remain more affected at 30 years of age following a higher gain in body size, which tends to overcast the effect of being born SGA. Our data suggest that being born SGA induces early metabolic disorders, further amplified by the weight gain with time when adults, both probably resulting from fetal programming. Moreover, the modest increase in IR contrasts with the constant and much higher prevalence of MS, suggesting that the metabolic complications are not related only to the degree of fat mass but that fetal programming strongly affects the physiology of the adipose tissue.

Fatty Liver Index (FLI) as a new cardiometabolic risk marker: validation in the RISC study

A. Gastaldelli[1], M. Kozakova[2], A. Sironi[1], R. Petz[1], A. Mari[3], E. Ferrannini[2], RISC Investigators;
[1]Metabolism Unit, Fondazione Toscana G. Monasterio and CNR Institute of Clinical Physiology, Pisa, [2]Department of Internal Medicine, University of Pisa, [3]Institute of Biomedical Engineering, National Research Council, Padova, Italy.

Background and aims: FLI is a new index recently proposed as a predictor of the presence of fatty liver (FL) which includes in its formula waist, BMI, triglyceride and γGT levels (FLI>60 =likelihood >78% presence FL; FLI<20=likelihood >91% absence of FL). However, these parameters are also implicated in the development of diabetes, CHD and atherosclerosis. Aim of this study was to validate FLI *vs* MR spectroscopy and to evaluate in the RISC population if a high FLI score could predict metabolic alterations and presence of atherosclerosis.
Materials and methods: The RISC study recruited 1308 European subjects (age 30-60 years, BMI 20-45 kg/m^2) free of diabetes, hypertension and clinically manifest cardiovascular diseases (CVD). We evaluated FLI, metabolic profile, glucose tolerance (OGTT), peripheral insulin sensitivity (M/I, by euglycaemic-hyperinsulinaemic clamp), hepatic insulin resistance (HIR=Insulin*EGP measured with glucose tracer, n=400), beta cell function (by mathematical modelling of the C-peptide response to oral glucose), physical activity (PA, by accelerometry), coronary heart disease risk (CHD, by Framingham score), early carotid atherosclerosis (as intima-media thickness, IMT, by ultrasound). In a separate group of subjects (n=37), hepatic fat content (HF) was evaluated by MR spectroscopy and compared with FLI.
Results: Subjects with FLI<20 had no HF (range 0.4-4.2%, n=6), while those with FLI>60 had steatosis (*ie*, HF>5%, range 8.6-24.0%, n=10). FLI was well correlated with HF (r=0.61, p=0.0001). RISC subjects with FLI>60 - *vs* those with FLI<20 - were more insulin resistant at the whole-body level (M/I=88±3 *vs* 167±3 μmol·min^{-1}·kg$_{ffm}^{-1}$·pM^{-1}) and in the liver (HIR=737±51 *vs* 361±16 μmol·min^{-1}·kg$_{ffm}^{-1}$·pM) and beta cell glucose sensitivity was impaired (114±5 *vs* 142±4 pmol·min^{-1}m^{-2}·mM^{-1} , all p<0.0001). The RISC population was at low risk for CHD (only 9% of the subjects had medium-to-high risk, while 83% were below average). By multivariate analysis, 10-year CHD score was positively associated with BMI and waist, and negatively with PA and M/I (AdjR^2=0.24, all p<0.01). FLI was strongly related to CHD in univariate analysis (R^2=0.23) and remained so independently of PA (AdjR^2=0.26, p<0.0001). IMT was low on average (0.602±0.002 mm, range 0.38-1.02) and positively associated with age and established atherosclerotic risk factors (BMI, waist, systolic blood pressure (SBP), LDL, fasting plasma glucose) and negatively with HDL, physical activity, FLI and M/I (all p<0.0001). In a multivariate model, independent determinants of IMT were M/I (p=0.01), age, SBP, LDL and gender (all p<0.0001, AdjR^2=0.27). When FLI was added, it replaced M/I as an independent predictor of IMT (AdjR^2=0.27, p=0.0001).
Conclusion: In middle-aged non-diabetic subjects, high values of FLI were associated with increased insulin resistance, IMT and CHD risk; calculation of FLI from simple metabolic and anthropometric data can be a useful cardiometabolic risk marker.

Relationships between hepatic stearoyl-CoA desaturase 1 activity and mRNA expression with liver fat content in humans

A. Peter[1], A. Cegan[2], S. Wagner[3], A. Königsrainer[3], I. Königsrainer[3], H.-U. Häring[1], E. Schleicher[1], N. Stefan[1];
[1]Department of Internal Medicine, Devision of Endocrinology, Diabetes, Vascular Medicine, Nephrology, University of Tübingen, Germany, [2]Faculty of Chemical Technology, Department of Biological and Biochemical Sciences, University of Pardubice, Czech Republic, [3]Department of General, Visceral and Transplant Surgery, University of Tübingen, Germany.

Background and aims: The enzyme stearoyl-CoA desaturase (SCD) 1 has gained much interest as a future drug target to treat fatty liver and its metabolic consequences. However, there is little and inconsistent human data about expression and activity of this important enzyme. We, therefore, investigated the hepatic activity and expression of SCD1 and their relationships with liver fat content in human liver samples.
Methods: Fifteen subjects undergoing liver surgery were studied. SCD1 activity was estimated from the ratio of oleate (C18:1) to stearate (C18:0) and palmitoleate (C16:1) to palmitate (C16:0) within five lipid subfractions that were separated by thin layer chromatography. Furthermore, SCD1 mRNA expression and liver fat content were measured.
Results: Similar to previous studies, we observed a strong positive correlation between liver fat content and the C18:1/C18:0-ratio in the combined fatty acid (FA) fractions (r=0.98, p<0.0001), which could be interpreted as higher SCD1 activity with increasing liver fat content. However, the hepatic SCD1 mRNA expression did not correlate with liver fat content (r=0.4, p=0.13). To solve this conflicting data, we further analyzed the FA composition of five hepatic lipid subfractions and their contribution to total hepatic FA. With increasing liver fat content the amount of FA from the TG fraction increased (r=0.96, p<0.0001), whereas the FA from the phospholipid (PL) fraction remained unchanged (r=-0.13, p=0.28). These two lipid fractions contain 87±6% of the total hepatic FA and show a distinct FA composition. This results in a 18-fold higher C18:1/C18:0-ratio in TG than in the PL fraction. Supporting the SCD1 mRNA expression data, when the C18:1/C18:0-ratio of the TG fraction was analyzed, the strong correlation with liver fat content, observed in total hepatic FA, was absent (r=0.43, p=0.06; r=0.17, p=0.5 for C16:1/C16:0). This paradox may be due to the fact that with increasing liver fat content the proportion of FA from the TG fraction that has a high C18:1/C18:0-ratio increased. The analysis of total hepatic FA could therefore mislead to the interpretation that SCD1 activity is strongly associated with liver fat content.
Conclusion: We provide important novel information that SCD1 activity and mRNA expression are not elevated in subjects with high liver fat content and that the FA composition of lipid subclasses, rather than of mixed lipids should be interpreted to estimate SCD1 activity.

Hepatic steatosis does not result in insulin resistance in subjects with familial hypobetalipoproteinaemia

N.M. Lammers[1], M.E. Visser[2], A.J. Nederveen[3], M. van der Graaf[4], A. Heerschap[4], M.T. Ackermans[5], H.P. Sauerwein[1], E.S.G. Stroes[2], M.J.M. Serlie[1];
[1]Endocrinology & Metabolism, AMC, Amsterdam, [2]Vascular Medicine, AMC, Amsterdam, [3]Radiology, AMC, Amsterdam, [4]Radiology, UMC St Radboud, Nijmegen, [5]Clinical Chemistry, Laboratory of Endocrinology, AMC, Amsterdam, Netherlands.

Background and aims: Hepatic steatosis is strongly associated with hepatic and whole body insulin resistance. Yet the causal relationship between hepatic steatosis and insulin resistance remains uncertain. Subjects with familial hypobetalipoproteinemia (FHBL) are characterized by low levels of apolipoprotein B and an increased risk of hepatic steatosis. However FHBL-patients are not characterized by disturbances in glucose metabolism. To investigate the role of liver fat in the development of insulin resistance we studied glucose metabolism in subjects with FHBL and matched controls.
Materials and methods: We measured endogenous glucose production (EGP) and hepatic and peripheral insulin sensitivity (Rd) in the basal state and during a two-step hyperinsulinemic euglycemic clamp using stable isotopes. We included 8 male subjects with established FHBL and 8 healthy controls, matched for sex, age, BMI, waist to hip ratio and physical activity. Hepatic triglyceride content (IHTG) was measured using magnetic resonance spectroscopy (STEAM, TE/TR=20/3000 ms, 6 acquisitions, voxel size 27 cm3). Intramyocellular lipid content (IMCL) was measured by magnetic resonance spectroscopic imaging (TE/TR=30/1100 ms, matrix size 32x32). Voxels inside the soleus muscle were selected for analysis.
Data are presented as median [minimum-maximum].
Results: IHTG was significantly higher in patients compared to controls (27 % [16-38] vs. 5 % [0-31] respectively, p= 0.045), while IMCL was similar in subjects with FHBL and controls (9.6 % [5.7-12.8] vs. 8.8 % [6.7-22.8] respectively).
Basal EGP and basal insulin levels did not differ. Insulin-mediated suppression of EGP as well as Rd were not different between patients and controls (61.2% [17.7-86.9] vs. 75.6% [43.6-82.8] respectively (p=0.48) and 40.6 μmol/kg.min [35.0-42.6] vs. 48.7 μmol/kg.min [24.9-71.8] respectively (p= 0.18)). Glucoregulatory hormones during the clamp were similar.
Conclusion: Subjects with FHBL and severe hepatic steatosis show no hepatic or peripheral insulin resistance. Our results indicate that hepatic steatosis *per se* is not sufficient to cause insulin resistance.

185

Rates of lipid fluxes in the adipose tissue *in vivo* after a mixed meal in morbid obesity

P. Mitrou[1], G. Dimitriadis[2], E. Boutati[2], V. Lambadiari[2], E. Maratou[1], V. Komesidou[3], A. Papakonstantinou[4], N. Katsilambros[5], T. Economopoulos[2], S.A. Raptis[1,2];
[1]Hellenic National Center for Research, Prevention and Treatment of Diabetes Mellitus and its Complications (H.N.D.C), [2]2nd Department of Internal Medicine and Research Institute, Athens University Medical School, "Attikon" University Hospital, [3]Department of Nutrition "Evangelismos" Hospital, [4]1st Department of Surgery, "Evangelismos" Hospital, [5]"Evgenidion" Hospital, Athens University Medical School, Athens, Greece.

Background and aims: Although insulin resistance in obesity is established, information on insulin action on lipid fluxes, in morbid obesity, is limited. This study was undertaken in morbidly obese subjects to investigate insulin action on triacylglycerol fluxes and lipolysis across adipose tissue (AD).
Materials and methods: A meal was given to 30 obese [age 34±1yrs, BMI 47±1kg/m^2] and 10 non-obese subjects (age 39±4yrs, BMI 23±1kg/m^2). Plasma samples for glucose, insulin, triglycerides and non-esterified-fatty-acids (NEFA) were taken for 360min from a vein draining the abdominal subcutaneous AD and from the radial artery. AD blood flow (BF) was measured with ^{133}Xe.
Results: In obese vs non-obese: (1) Arterial glucose was similar ($AUC_{0\text{-}360min}$ 2173±73 vs 2040±40mMmin), but insulin was increased (23578±2372 vs 10331±608mU/Lmin, p=0.0004) (2) AD BF was decreased (657±48 vs 1345±102ml/100mltissue, p=0001) (3) Arterial triglycerides (501±37 vs 260±32nmol/Lmin, p=0.0007) and NEFA (166±17 vs 97±11nmol/Lmin, p=0.017) were increased (4) Lipoprotein lipase (LPL) was decreased (5±2 vs 80±3pmol/100mlAD, p=0.009) (5) Arteriovenous triglyceride differences were similar (10±4 vs 19±6mmol/Lmin) (6) AD lipolysis (24±10 vs 10±4pmol$_{glycerol}$/Lmin), NEFA fluxes (34±11 vs 74±32μmol/100mltissue), veno-arterial NEFA differences (20.7±5 vs 21.3±10mmol/100mltissue) and total AD NEFA release (27±9 vs 11±6mmol) were similar.
Conclusion: in morbid obesity: (a) hypertriglycerinemia could be attributed to a defect in the postprandial dynamic adjustment of LPL, partly caused by blunted BF and (b) postprandialy there is a relative impairment of AD to buffer NEFA excess, despite normal NEFA output.

186

Evidence against the involvement of the mTOR/S6-kinase signalling pathway in obesity-associated insulin resistance of skeletal muscle

B. Brunmair[1], K. Stadlbauer[1], M. Promintzer[1], C. Fuernsinn[1], Z. Szoecs[1], B. Ludvik[1], G. Prager[2], M. Krebs[1];
[1]Department Medicine III, [2]Department of Surgery, Medical University of Vienna, Vienna, Austria.

Background and aims: The nutrient-sensitive kinase mammalian target of rapamycin (mTOR) and its downstream targets S6-kinase (S6K) and 4E-Binding Protein1 (4E-BP1) are known to mediate amino acid induced insulin desensitisation. Activation of this signalling cascade enhances serine phosphorylation of insulin receptor substrate-1, resulting in impairments of insulin signalling and glucose utilisation. As it is still unknown, whether the mTOR/S6K pathway is involved in obesity induced insulin resistance of human skeletal muscle, this study aimed to provide evidence for or against a link between obesity, the mTOR/S6K pathway and modulation of insulin signalling in man.
Materials and Methods: Morbidly obese insulin resistant patients (n=10) and healthy volunteers (n=7) were studied (age: 37.4±3.6 vs 35.7±5.2 years; BMI: 49.4±1.9 vs 23.8±0.7 kg/m^2; glucose infusion rate during euglycemic-hyperinsulinemic clamp: 1.7±0.3 vs 8.8±1.2 mg*kg^{-1}*h^{-1}; p<0.002). Blood was sampled and needle biopsies were collected from skeletal muscle in the basal state. Muscle samples were blotted, prepared free of blood, fat and connective tissue and snap frozen within 30 seconds in liquid nitrogen. The activity of S6K (relative amount of protein in phosphorylated state), the expression and serine phosphorylation of IRS-1 (Ser307; Ser636/639), the expression of 4E-BP1, p85-PI3-kinase (PI3K) and protein-kinase-B (PKB) as well as the expression and phosphorylation of AMP-kinase (AMPK), which also modulates mTOR/S6K activity, were determined by Western blot analysis. Results are given as means±SEM.
Results: Muscle biopsies from morbidly obese patients exhibited significantly increased serine-phosphorylation of IRS-1 on Ser307 (% increase vs controls: +602±223%, p<0.03), while phosphorylation on Ser636/639 showed a parallel, but not significant trend (+384±263%, ns). Total IRS-1 expression was not different between controls and obese patients (% of controls: 72.7±33.7%, ns) and the expression of downstream insulin signalling proteins PI3K and PKB did not vary between the two groups (% of controls: PI3K, 101.9±16.8%, ns; PKB, 85.6±14.5%, ns). Furthermore, S6K activity was similar in muscle from obese patients and healthy controls (S6K in phosphorylated state: 33±6% vs 31±8%; ns), suggesting that enhanced mTOR signalling is not the cause of obesity-induced IRS-1 serine phosphorylation. In line with this conclusion, a trend towards reduction rather than an increase of 4E-BP1 expression was observed in muscle from obese patients (% decrease vs controls: -35±17%, p=0.061, ns) and the amount of activated (phosphorylated) AMPK was unchanged (phosphorylated AMPK, % of controls, 73.8±29.6, ns).
Conclusions: The results show that obesity induced insulin resistance is associated with an increase of IRS-1 serine phosphorylation in skeletal muscle. Expression of total IRS-1 and downstream insulin signalling proteins PI3K and PKB is not altered in obesity, indicating that reduced insulin signalling is more likely due to phosphorylation/activation deficiencies than due to decreased total protein expression. No evidence was obtained for an involvement of the nutrient-sensitive mTOR/S6K signalling cascade in obesity associated muscle insulin resistance.

Yokono[10], H. Onuma[2], H. Osawa[2]; [1]Takanoko Hospital, Diabetes Research Center, Matsuyama, Japan, [2]Dept. of Molecular and Genetic Medicine, Ehime University, Toon, Japan, [3]Sumitomo Hospital, Osaka, Japan, [4]Baylor Institute for Immunology Research, Dallas, United States, [5]Dept. of Metabolic Medicine, Osaka University, Japan, [6]First Dept. of Internal Medicine, Osaka Medical College, Takatsuki, Japan, [7]Kurashiki Central Hospital, Okayama, Japan, [8]Kochi Medical School, Nankoku, Japan, [9]Dept. of Surgery, Ehime University, Toon, Japan, [10]Dept. of Internal and Geriatric Medicine, Kobe University, Japan.

Background and aims: Insulin administration causes various types of immune response to insulin, but there had been no reports that insulin administration triggers pancreatic β cell destruction, namely type 1 diabetes (T1DM) in patients with type 2 diabetes (T2DM). Recently, we first reported on 3 cases of T1DM developed after insulin administration. The objective of this study was to further collect such cases, and characterize these clinical, immunological and genetic background.

Material and methods: A total of 6 patients (4 men and 2 women) with T1DM developed after insulin administration were included in this study from diabetic clinics in Japan. Serum or urinary C-peptide, autoantibodies to glutamic acid decarboxylase (GAD65) and IA-2, insulin antibody, and HLA class II haplotypes were analyzed. Using ELISPOT according to the protocol by Moriyama et al., the secretion of Th1-associated interferon-γ and Th2-associated interleukin-4 from peripheral mononuclear cells upon stimulation with diabetes-related antigens, GAD65 protein and several important peptide fragments of insulin, were investigated in 4 cases. Pancreatic biopsy with laparoscope was performed by the specialist of pancreatic surgery in one case. The study was approved by the ethics committee of the Ehime University Hospital.

Results: T2DM was diagnosed at the average age of 42.6 (34-52) years in these cases. Mean maximum BMI was 30.2 (24.2-40.9) kg/m2. They all developed insulin deficiency 8.2 (2-17) months after insulin administration at the age of 59 (50-70) years, but they had neither received insulin therapy nor had autoantibody to GAD65 before insulin administration. Fasting serum C-peptide levels were 1.56 ± 0.68 ng/ml, and urinary C-peptide levels were 83 ± 13 μg/day before insulin administration. After the initiation of insulin administration, serum and urinary C-peptide levels were rapidly decreased to 0.09 ± 0.01ng/ml, and 5.3 ± 6.8 μg/day, respectively. Insulin allergy was developed in 3 cases, and high titer of insulin antibody was observed in 3 cases after insulin administration. Autoantibodies to GAD65 and IA-2 were not detected in 3 cases through their entire clinical course, but were transiently and weakly positive in 2 cases. In one case, high titer of GAD antibody was observed immediately after the development of T1DM. They all had T1DM high-risk HLA class II haplotypes in Japanese. GAD-reactive and insulin-peptides-reactive Th1 cells were identified in 2 of 4 cases. In a histological examination of pancreatic tissues obtained by a pancreatic biopsy in one case, typical insulitis was observed.

Conclusion: The present study suggests that insulin administration may trigger TIDM in patients with T2DM having T1DM high-risk HLA class II haplotypes, and that autoreactive T cells may contribute to the development of T1DM.

Interim results of a phase I/II clinical trial of a DNA plasmid vaccine (BHT-3021) for type 1 diabetes

P. Gottlieb[1], G. Eisenbarth[1], L. Harrison[2], P. Colman[3], B. Roep[4], J. Quan[5], N. Solvason[5], L. Steinman[6], H. Garren[5], BHT-3021 Study Group; [1]Barbara Davis Center, Aurora, United States, [2]The Walter & Eliza Hall Institute of Medical Research, Parkville, Australia, [3]Royal Melbourne Hospital, Parkville, Australia, [4]Leiden University Medical Center, Netherlands, [5]Bayhill Therapeutics, Inc., San Mateo, United States, [6]Stanford University, United States.

Background and aims: DNA plasmid vaccines are a highly effective antigen-specific treatment of autoimmune disease in various animal models and in a multiple sclerosis clinical trial.

Materials and methods: BHT-3021 is a DNA plasmid that encodes full-length human proinsulin, currently in a phase I/II, randomized, blinded, placebo-controlled, dose escalation trial in T1D patients (0.3 mg, 1 mg, 3 mg or 6 mg), in which BHT-3021 or saline placebo is injected intramuscularly on a weekly basis for 12 weeks.

Results: Complete safety and pancreatic function data to 6 months after randomization are available for the first two dose cohorts (1 mg and 3 mg). Nine C-peptide positive patients were enrolled in the first cohort and eleven in the second cohort, randomized 2:1 active to placebo. Adverse event (AE) and laboratory data on these patients suggest that BHT-3021 is safe and well-tolerated. No serious adverse events have been reported in patients receiving BHT-3021. Most AEs were mild or moderate in severity.

Treatment with BHT-3021 may preserve ß-cell function as measured by C-peptide levels. C-peptide levels were maintained at six months after randomization in patients treated with 1 mg (mean increase of 2 pmol/L from baseline) and with 3 mg of BHT-3021 (mean increase of 34 pmol/L from baseline). In contrast, C-peptide levels declined in placebo treated patients (mean decrease of -127 pmol/L from baseline). At fifteen weeks after randomization, there was a corresponding decline in mean HbA1c levels of 0.13% Hb with 1 mg and of 0.44% Hb with 3 mg of BHT-3021. Patients treated with placebo had no substantial change in HbA1c levels at this time point.

Conclusion: These preliminary data indicate that 1mg and 3mg of BHT-3021 is safe and may preserve ß-cell function as well as improve glycemic control. Complete 6 month data on 0.3mg and 6mg of BHT-3021 are expected by June 2009.

Autoimmunity and obesity in children and young adolescents

C. Guglielmi[1], S.R. Eldrich[2], C. Tiberti[3], R. Buzzetti[3], S. Caprio[4], P. Pozzilli[1];
[1]University Campus Bio Medico, Roma, Italy, [2]Michigan University, Ann Arbor, United States, [3]Sapienza University, Roma, Italy, [4]Yale University, New Heaven, United States.

Background and aims: A few obese youths with diagnosis of type 2 diabetes have evidence of islet-cell autoimmunity. The increasingly 'obesogenic' environment which favours insulin resistance could account for the development of islet cell autoimmunity through different mechanisms. Blood glucose concentrations are controlled by a loop incorporating two components, the beta cells which secrete insulin and the insulin sensitive tissues (liver, muscle, adipose) which respond to it. The accelerator hypothesis identifies three processes which variably accelerate beta cell loss: constitution, insulin resistance and the immune response to it. None of the accelerators leads to diabetes in the absence of weight gain, a condition which may explain the rising incidence of all diabetes in the developed and developing world. Raised blood glucose accelerates beta cell apoptosis (glucotoxicity) and, by increasing beta cell immunogenicity, further accelerates apoptosis in subjects genetically predisposed to intense immune response. Accordingly, body mass is central to the development and rising incidence of all types of diabetes including type 1 diabetes (T1D).
Materials and methods: In order to throw new light on this hypothesis, we have investigated pancreas, thyroid and gastric autoimmunity in a population of obese children/young adolescents with normal glucose tolerance (n=251; 109 males and 142 females), impaired glucose tolerance (IGT) (n=113; 53 males and 60 females) and type 2 diabetes (T2D) (n=15; 4 males and 11females). These subjects had a BMI ≥ 30 and their mean age was 13.6, 13.4 and 13.7 years, respectively.
Results: Mean basal/2 hours post glucose insulin levels were 32/168, 41/320 and 58/454 uU/ml, in normal, IGT and T2D subjects, respectively. GAD autoantibodies were detected in 6/251 (2.4%) obese subjects but in none of IGT or T2D subjects. Insulin autoantibodies were detected in 1 obese subject whereas IA-2 autoantibodies were negative in all subjects tested. Furthermore, we detected anti-TPO (thyroperoxidase) autoantibodies in 3/6 GAD positive subjects. Finally anti gastric parietal cells and anti 21-hydroxylase autoantibodies were negative in all subjects tested.
Conclusion: Considering that GAD autoantibodies are detectable in 0.5% of control school children with normal body weight, we conclude that obesity may lead to a significant increase of islet cell autoimmunity in normal youths, a finding in line with the accelerator hypothesis.

Zinc transporter 8 autoantibody profiles in patients with recently diagnosed type 1 diabetes

S. Krause[1], U. Mollenhauer[2], A. Jäger[2], V. Lampasona[3], E. Bonifacio[4], A.-G. Ziegler[1,2], P. Achenbach[1,2];
[1]Diabetes Research Group, Munich University of Technology, Germany, [2]Diabetes Research Institute, Forschergruppe Diabetes e.V. at Helmholtz Center Munich, Neuherberg, Germany, [3]San Raffaele Scientific Institute, Milan, Italy, [4]Center for Regenerative Therapies, Dresden University of Technology, Germany.

Background and aims: Zinc transporter 8 (ZnT8) has been identified as a new target-antigen for autoantibodies in type 1 diabetes. The specificity of ZnT8 autoantibodies (ZnT8A) can vary with respect to binding of two ZnT8 allelic variants carrying at amino acid 325 either arginine (R325) or tryptophan (W325). This study was to determine ZnT8A profiles in patients with recent-onset type 1 diabetes.
Materials and methods: ZnT8A were measured in sera of 202 young patients from Germany with recently diagnosed diabetes (median time from diagnosis 1 day, IQR 0-7; median age 8.8 years, IQR 5.2-12.8, range 1.2-18.9) using Protein A-based radiobinding assays and COOH-terminal constructs of the R325 or W325 variants of human ZnT8. Autoantibodies to glutamate decarboxylase (GADA) and insulinoma-associated protein 2 (IA-2A) were also measured in all samples, as were insulin autoantibodies (IAA) in samples from patients obtained within the first two weeks of diagnosis.
Results: ZnT8A were detected in 122 (60%) patients, among them 121 of 176 (69%) with positive other islet autoantibodies (GADA, IA-2A, IAA) and 1 of 26 patients who were negative for other autoantibodies (P<0.0001). Age at diagnosis did not differ between autoantibody-positive and negative patients (P=0.9). Among the 122 ZnT8A positive patients, 41 (34%) had antibodies that only bound the ZnT8 R325 variant, 11 (9%) had antibodies that only bound with the ZnT8 W325 variant, and 70 (57%) had antibodies that bound with both ZnT8 R325W variants. Prevalence of ZnT8A restricted to one of the ZnT8 variants was not associated with age at diagnosis (P=0.9). ZnT8A were more often found in patients who already had autoantibodies against two or more islet autoantigens other than ZnT8: 25 of 45 (56%) patients previously classified as single autoantibody-positive were ZnT8A-positive, as compared to 96 of 131 (73%) with multiple autoantibodies (P=0.03).
Conclusion: Autoimmunity against the COOH-terminal region of ZnT8 is a common feature in young patients with recent-onset type 1 diabetes. ZnT8A are more often found in patients with a more widespread antibody-response to multiple islet autoantigens. Testing for ZnT8 antibodies should be performed against the two major polymorphic variants.

Human mesenchymal stem cells modulate cellular immune response to islet antigen GAD in type 1 diabetes

E. Favaro[1], I. Miceli[1], I. Ossola[1], C. Caorsi[2], M. Giovarelli[2], P. Cavallo Perin[1], G. Camussi[1], M.M. Zanone[1];
[1]Department of Internal Medicine, [2]Department of Medicine and Experimental Oncology, University of Turin, Italy.

Background and aims: MSCs can exert an immunoregulatory activity, modulating several T cell functions, and exerting a profound immunosuppressive effect on virtually any component of the immune system, in a MHC-independent way. Studies on the immunomodulatory potential of MSC in type 1 diabetes, a Th1-mediated autoimmune disease, are lacking. We aimed to evaluate whether human bone marrow-derived MSCs may inhibit islet antigen specific T cell activation in type-1 diabetes. To elucidate the MSC immunoregulatory activity, *in vitro* co-culture experiments with GAD-challenged PBMCs obtained from type-1 diabetic patients were performed and the number of IFN-gamma producing T cells and the release of IFN-gamma were evaluated. To investigate the underlining mechanisms, changes in T cell cytokine profile, to dissect a pro-inflammatory or anti-inflammatory phenotype, and the role of PGE2 were explored.
Materials and methods: IFN-gamma, IL-4 and IL-10 ELISPOT responses to GAD in 9 new-onset type 1 diabetic patients were evaluated in PBMC cocultures and parallel PBMC-hMCSs cocultures. A SI (ratio of mean spot number in the presence of GAD to number in the presence of diluent) ≥ 3 was chosen as positive in ELISPOT assay. Levels of prostaglandin E2 (PGE2), IFN-gamma, IL-4 and IL-10 in supernatants were measured by ELISA. PGE2 inhibition experiments with NS-398 and indomethacin were also performed.
Results: By IFN-gamma ELISPOT, 5 diabetic patients showed a positive response to GAD. The presence of MSCs (1:1 ratio) resulted in a decrease in the number of spots in the IFN-gamma ELISPOT in the presence of GAD (mean spots without MSCs 53.8 ± 32, with MSCs 11.8 ± 8, $p < 0.05$). Coculture transwell experiments, in which MSCs were separated from PBMCs, failed to inhibit the response, indicating that the MSC effect required a physical interaction. Further, supernatants from MSCs did not inhibit the response to GAD. MSCs incubation with the PGE2 synthesis inhibitors abrogated the immune suppressive effect on GAD induced IFN-gamma T cell response. In cocultures, IL-10 secreting cells were not detectable by ELISPOT in response to GAD whereas IL-4 secreting cells were detected. This was confirmed by ELISA that showed that hMCSs significantly inhibited the IFN-gamma production, and increased the IL4 and PGE2 production. Inhibitors of PGE2 abrogated MSCs-mediated immune modulation.
Conclusion: In the present study we found that allogenic human MSCs can abrogate *in vitro* a pro-inflammatory Th1 response to an islet antigenic stimulus, in new onset diabetic patients. The contact between T cells and MSCs in all patients responding to GAD consistently abrogated the T cell production of IFN-gamma, assessed *in vitro* at the single cell level by ELISPOT and inhibited IFN-gamma secretion. MSCs induced in PBMC of responder patients IL-4 producing cells and IL-4 secretion, suggesting a possible switch to an anti-inflammatory Th2 signalling of T cells. Moreover, we found that the contact between MSCs and PBMC is required and enhanced PGE2 production.

Adipose tissue development in non-obese diabetic mice is controlled by the Toll-like receptor 4

E. Gülden, K. Sakai, J. Weiß, C. Habich, V. Burkart;
German Diabetes Centre, Düsseldorf, Germany.

Background and aims: Recent studies point to an effect of body weight development on the progression of type 1 diabetes (T1D). The body weight is largely determined by the adipose tissue mass, which mainly consists of adipocytes, a cell type sharing basic features with innate immune cells. Activation and differentiation of innate immune cells are under strict control of Toll-like receptors (TLR) which mediate the recognition of antigenic microbial structures but may also be involved in the induction of autoimmunity. In a recent study we observed that TLR4, a prominent member of the TLR family, has a significant impact on the pathogenesis of autoimmune diabetes in non-obese diabetic (NOD) mice. Based on these considerations the current study was designed to investigate whether TLR4 is able to modulate the progression of insulin deficiency diabetes by controlling adipose tissue development in the NOD mouse.
Materials and methods: Our studies were performed in NOD mice carrying the spontaneous TLR4 defect of the C57BL/10ScCr ($TLR4^{-/-}$) mouse and in the non diabetes-prone mouse strain C57BL/10ScSn ($TLR4^{+/+}$) and its related, TLR4-deficient strain C57BL/10ScCr. The development of diabetes and body weight was monitored and thin sections of visceral adipose tissue were evaluated morphometrically. Isolated adipocytes were differentiated in vitro in the presence of the TLR4 ligand lipopolysaccharide (LPS). LPS-responsiveness of the cells was assessed by the release of interleukin-6 (IL-6) and monocyte chemoattractant protein-1 (MCP-1) as determined by ELISA.
Results: Female NOD $TLR4^{-/-}$ mice showed a significant acceleration of diabetes development ($p<0.01$). Until the age of 21 weeks 8.3 % of NOD $TLR4^{+/+}$ mice but 71.4 % of NOD $TLR4^{-/-}$ mice developed diabetes. Accelerated diabetes development was associated with significantly increased body weight ($p<0.0001$). At the age of 21 weeks the body weight of NOD $TLR4^{+/+}$ mice was 25.4 ± 1.4 g and of NOD $TLR4^{-/-}$ 27.5 ± 2.3 g. In female mice of the C57BL/10Sc strain TLR4 had no significant effect on body weight development. At the age of 21 weeks C57BL/10ScSn ($TLR4^{+/+}$) mice weighed 27.5 ± 2.4 g and C57/BL10ScCr ($TLR4^{-/-}$) mice weighed 27.4 ± 1.8 g. Histological analyses of adipose tissue revealed smaller adipocyte sizes (668 ± 413 μm^2) in NOD $TLR4^{-/-}$ mice when compared to the tissue of NOD $TLR4^{+/+}$ mice (963 ± 776 μm^2) ($p<0.01$). Compared to NOD $TLR4^{+/+}$ mice the adipose tissue of NOD $TLR4^{-/-}$ mice contained a 2.9 - 4.1 fold higher proportion of cells with the morphology of immature preadipocytes including multiple lipid droplets. Preadipocytes isolated from NOD $TLR4^{+/+}$ mice express TLR4 and showed a dose- and time-dependent release of the inflammatory mediators IL-6 and MCP-1 in response to LPS. NOD $TLR4^{-/-}$ adipocytes were largely unresponsive to LPS. The potential effect of TLR4 on the development of the inflammatory activity of mature NOD mouse-derived adipocytes was investigated by continuous LPS-exposure of cells during in vitro differentiation. Chronic TLR4 activation during adipocyte differentiation significantly reduced LPS-induced IL-6 release from 1.9 ± 0.1 to 1.1 ± 0.1 ng/ml and MCP-1 release from 57.3 ± 14.0 to 45.4 ± 9.1 ng/ml.
Conclusion: Our results identify TLR4 as a regulator of the differentiation and the inflammatory activities of adipocytes in NOD mice. The findings further implicate that TLR4 affects the progression of autoimmune diabetes in NOD mice by controlling the development of adipose tissue.

Activation of the CaMKK/CaMKIV cascade by exendin-4 stimulates ABCA1 expression in pancreatic beta cells

H. Imachi, K. Murao, J. Li, T. Muraoka, F. Kikuchi, T. Yoshimoto, T. Ishida;
Faculty of Medicine, Kagawa University, Japan.

Background and aims: The insulin secretagogue hormone GLP-1 (glucagon-like peptide-1) and its long-acting agonist exendin-4 are new treatment agents for diabetes. GLP-1 stimulates glucose-dependent insulin secretion and lowers blood glucose levels. ATP-binding cassette transporter A1 (ABCA1) is a pivotal regulator of lipid efflux from cells to apolipoproteins and plays an important role in reverse cholesterol transfer. Recent reports indicate that ABCA1 in pancreatic βcells influences insulin secretion and glucose homeostasis. This study investigates whether exendin-4 which medicates stimulatory effects on ABCA1 gene expression, could interfere with the Ca2+/calmodulin (CaM)-dependent protein kinase (CaMK) cascade.
Materials and methods: ABCA1 expression was examined by real-time polymerase chain reaction (PCR), Western blot analysis, and reporter gene assay in rat insulin-secreting INS-1 cells incubated with exending-4. CaMKIV activity was assayed by detection of activation-loop phosphorylation (Thr196) of CaMKIV. We investigated the influence of the constitutively active form (CaMKIVc) or dominant-negative mutant (CaMKIVdn) of CaMKIV on ABCA1 promoter activity.
Results: Increased abundance of ABCA1 protein was noted in response to rising concentrations of exendin-4 with maximum induction at 10 nM. Real-time PCR analysis showed at significant increase in the abundance of ABCA1 mRNA in response to rising concentration of exendin-4. Exendin-4 also stimulated ABCA1 promoter activity, but failed to do so in the presence of STO-609, a CaMKK inhibitor. Next we examined CaMKIV, one of the downstream effecter kinases of CaMKK to determine which downstream effecter kinases of CaMKK is imvolved this mechanism. Upregulation of CaMKIVc phosphorylation (at Thr196) peaked after 10 min of exposure to exendin-4. CaMKIVc enhanced or upregulated ABCA1 promoter activity in INS-1 cells. Furthermore, cotransfection of the CaMKIVdn significantly suppressed the exendin-4-upregulated activity of the ABCA1 promoter.
Conclusion: Activation of the CaMKK/CaMKIV cascade by exendin-4 stimulated ABCA1 gene transcription, indicating that exendin-4 plays an important role in insulin secretion in pancreatic β cells.

194

Effect of GLP-1 and Exendin-4 on GLUT-2 and GLUT-4 expression in insulin-resistant state

P. Moreno, B. Nuche-Berenguer, I. Gutierrez-Rojas, N. González,
I. Valverde, M.L. Villanueva-Peñacarrillo;
Metabolism, Nutrition and Hormones, Fundacion Jimenez Diaz, Madrid, Spain.

Background and aims: GLP-1 is an incretin with andiabetic properties, that acting through specific receptors directly stimulates glucose transport and metabolism in extrapancreatic tissues -liver, muscle and fat-, where also controls the expression of the main glucotransporter, in normal and diabetic states. Exendin-4 (Ex-4), structurally homologous to GLP-1 but more stable when in plasma circulation, shares with GLP-1 many of its glucoregulatory and other actions. Here we studied the effect of GLP-1 and Ex-4, in prolonged treatment, on GLUT-2 and GLUT-4 expression in liver and muscle, respectively, of insulin-resistant (IR) rats, compared to normal (N).
Materials and methods: IR model was induced in male Wistar rats by chronic feeding -8 weeks- with standard chow combined with D-fructose (20% in the drinking water). IR (n=5-10 rats/group) and N (n=5-10 rats/group) rats were 3-days treated with saline (control), GLP-1 (0.86 nmol/kg/h) or Ex-4 (0.1nmol/kg/h); blood samples were taken before and by the end of the treatment for plasma glucose and insulin (RIA) measurements; GLUT-2 and GLUT-4 expression -protein, by Western blot and mRNA, by RT-PCR- was respectively studied in liver and muscle; liver glycogen content was enzymaticaly measured.
Results: In the muscle, GLUT-4-protein in IR was higher than normal (243±39% N-control, $p<0.05$), and so it was the mRNA (3.8±1.0 times N-control, $p<0.05$); in N, GLP-1 treatment slightly reduced GLUT-4-protein (77±8% N-control, $p<0.05$) and increased the mRNA (12.5±2.9 times N-control, $p<0.01$), while in IR, GLP-1 stimulated both GLUT-4-protein

(383±59% IR-control, $p<0.02$) and mRNA (15.7± 3.5 times IR-control, $p<0.01$); Ex-4 treatment in N stimulated both GLUT-4 protein (122±2% N-control, $p<0.001$) and mRNA (1.6±0.2 times N-control, $p<0.02$), and further increased the protein value in IR (176±27% IR-control, $p<0.05$) as well as the mRNA (30±10 times IR-control, $p<0.01$). In the liver, GLUT-2 protein in IR was lower ($p<0.01$) than normal (66±8% N-control) while the mRNA was higher (8.1±1.4 times N-control, $p<0.001$); in N, GLP-1 treatment decreased the GLUT-2-protein value (81±3% N-control, $p<0.05$) and also the mRNA (0.43±0.13 times N-control, $p<0.05$), confirming previous observations, while Ex-4 induced a stimulation in the protein (174±18% N-control, $p<0.02$) without altering the mRNA; in IR, GLP-1 and Ex-4 both increased GLUT-2 protein (GLP-1: 223±28% IR-control; Ex-4: 187±17%, both $p<0.01$), and in a very high extent, the mRNA (overall mean: 567±42 times IR-control). Liver glycogen content in IR (52±4 µg/mg protein) was much lower ($p<0.001$) than that in N (395±34 µg/mg protein); neither GLP-1 nor Ex-4 treatment modified the value in N, but both similarly increased that in IR (GLP-1: 73±6 µg/mg protein, $p<0.01$ *vs* IR-control; Ex-4: 88±13 µg/mg protein, $p<0.05$ *vs* IR-control).

Conclusion: The increase in the reduced liver glycogen content of IR rats, after GLP-1 or Ex-4 treatment, could be accounted by their stimulating effect upon GLUT-2 gene expression, at the transcriptional and translational level. The previously reported normalizing action of GLP-1 and Ex-4 upon muscle glucose transport could also be due to their increasing effect on GLUT-4 expression.

Oleic acid ingestion increases its concentration in the terminal ileum and directly stimulates glucagon-like peptide-1 secretion in protein kinase Cζ-dependent manner

R. Iakoubov[1], A. Ahmed[1], L.M. Lauffer[1], R.P. Bazinet[2], P.L. Brubaker[1,3];
[1]Physiology, [2]Nutritional Sciences, [3]Medicine, University of Toronto, Canada.

Background and aims: Luminal nutrients, especially long-chain fatty acids (e.g. oleic acid; OA) increase secretion of the insulinotrophic hormone, glucagon-like peptide-1 (GLP-1) from the intestinal L cells in the terminal ileum and colon. However, it is currently not known whether OA ingestion causes a sufficient increase in distal luminal OA as required for GLP-1 secretion. Furthermore, our lab recently proposed a protein kinase Cζ (PKCζ)-dependent mechanism for OA-induced GLP-1 secretion in vitro; however, its in vivo relevance remained unknown. Therefore, we determined both luminal and tissue OA concentrations in fasted and OA-fed rats, and examined the effects of direct OA-stimulation on GLP-1 secretion using a novel model of intestinal PKCζ knockdown.

Materials and methods: To assess the effects of OA ingestion, fasted Wistar rats (150-250g) received an oral gavage (OG) with 2.5 ml OA solution (90% pure). The rats were sacrificed at 0-120min, followed by collection of plasma samples, and chyme and tissue samples from the terminal ileum. The lipid fraction was analyzed by flame-ionisation chromatography. For PKCζ knockdown, we developed a PKCζ siRNA- and GFP-expressing adenovirus; the knockdown efficiency was verified in vitro by western blot of GLUTag cells, an L cell line. The feasibility and safety of intracolonic infusion (ICI) were assessed by barium ICI and X-ray. Therefore, ICI of OA was performed in fasted rats to directly stimulate the intestinal L cells, followed by blood collection at 0-60min. Some rats received prior ICI of 10^9 pfu/ml PKCζ siRNA-adenovirus to induce intestinal knockdown, followed by 3 days recovery and then ICI of OA. Plasma glucose, insulin and bioactive GLP-1 levels were detected by glucose analyzer, ELISA and ECL-based bioassay, respectively.

Results: Chyme from the fasted rats contained 0.75±0.39µmol/g OA; this was slightly increased at 20 (0.90±0.15µmol/g) and 40 min (1.03±0.16µmol/g) after OG, and was markedly elevated after 60 (105.4±50.0µmol/g, $p<0.01$) and 120 min (52.6±48.8µmol/g, $p<0.05$). While the tissue OA content did not change during the 2hr, OA plasma levels increased after OG, from 37.0±8.3µM in fasted rats to 80.2±20.5µM after 60 and 81.5±16.7µM after 120 min ($p<0.05$). To evaluate the direct effects of OA on GLP-1 secretion, 125 mM (124 µmol/g) of OA was infused into the colon and terminal ileum of anaesthetized, sitagliptin-treated rats. OA infusion did not affect glucose or insulin levels; however, GLP-1 plasma levels increased from 19.7±6.2pg/ml in fasting rats to 68.6±15.9pg/ml after 30 ($p<0.05$ vs. basal and control) and 102.2±21.3pg/ml after 60 min ($p<0.01$ vs. basal and control). Furthermore, pretreatment of rats with the PKCζ siRNA-adenovirus, induced intestinal GFP expression, and caused up to a 75% reduction in the GLP-1 secretory response to ICI of OA.

Conclusion: Following oral ingestion, OA levels in the terminal rat gut are sufficient to induce GLP-1 secretion. Furthermore, PKCζ is necessary for OA-induced GLP-1 secretion in vivo, thereby supporting the role of PKCζ as a novel therapeutic target to enhance GLP-1 levels in patients with type 2 diabetes. Finally, adenovirus-mediated intestinal knockdown is a promising technique to investigate intestinal physiology when knockout models are not viable or available.

Sugar detection by GLUT2 is involved in GLP-1 secretion and incretin effect

A. Ait Omar, A. Grosfeld, M. Le Gall, A. Benkouhi, E. Brot-Laroche, A. Leturque, P. Serradas;
UMRS 872, Centre de Recherche des Cordeliers, Paris, France.

Background and aims: GLUT2 is a sugar transporter but also a membrane receptor sensitive to variation of extracellular sugar concentrations. It triggers a signalling cascade indicating to the cells how to adapt functions to sugar environment. We created a transgenic mouse with impaired signalling downstream GLUT2 (GLUT2-SDD sugar detection deficient mice) and demonstrated *in vivo* the importance of this signalling pathway in the regulation of glucose homeostasis, renal glucose re-absorption and insulin secretion in response to glucose (Stolarczyk *et al.*, PLOSone 2007). GLP-1 is secreted by intestinal L-cells after nutrient ingestion and increased insulin secretion from pancreatic beta-cells during hyperglycemia contributing to the incretin effect. The aim of the present study was to investigate the impact of sugar sensing triggered by GLUT2 on GLP-1 production by enteroendocrine cells in GLUT2-SDD mice.

Materials and methods: Isoglycaemic oral (3.6 g/Kg) and intraperitoneal (ip) glucose administration were performed on 10-week-old GLUT2-SDD and control mice fasted for 24h. The same mice were used for both types of glucose tolerance test (oral and ip) with an interval of one week. GLP-1 and insulin secretion responses were measured during oral and ip tests using multiplex technology. Intestinal GLP-1 content was determined by conventional ELISA. L-cell morphology was evaluated in intestine of the two groups of mice by GLP-1 immunofluorescence.

Results: Glucose intolerance was observed in GLUT2-SDD mice only in response to oral glucose load. Indeed, ip glucose injection induced a similar response in GLUT2-SDD and control mice. The glycaemia areas under curve were respectively in control and transgenic mice 670±50 and 930±50 $mg.dl^{-1}.min^{-1}$ ($p<0.05$) during the oral load, whereas they were 1410±90 and 1610±100 $mg.dl^{-1}.min^{-1}$ during ip administration. As expected the comparison between oral *versus* ip glucose administration in control mice showed that insulin secretion was higher during the oral test than during the ip test (area under curve respectively 220±20 and 101±16 pM. min^{-1} $p<0.01$). In contrast, no difference in insulin secretion was observed in transgenic mice in response to oral compared to ip glucose administration (area under curve respectively 140±20 and 120±20 pM. min^{-1}), suggesting a loss of incretin effect in GLUT2-SDD mice. In accordance with these results, GLP-1 secretion in control mice was increased 5 minutes after oral glucose load but not after ip administration ($p<0.05$) whereas the oral glucose-induced GLP-1 secretion was absent in transgenic mice. L-cell morphology and intestinal GLP-1 content appeared preserved in GLUT2-SDD mice compared to controls, suggesting that glucose detection by GLUT2 is involved in GLP-1 secretion but not in GLP-1 production since intestinal hormonal content is not impaired.

Conclusion: These findings show that insulin response to oral glucose partly relies on efficient secretion of GLP-1, which depends on adequate sugar detection by GLUT2 in the intestine.

GIP and GLP-1 normalize glucose tolerance by normalizing islet adaptation to insulin resistance without increasing glucose effectiveness in high-fat fed mice

G. Pacini[1], B. Ahren[2];
[1]Metabolic Unit, ISIB-CNR, Padova, Italy, [2]Clinical Sciences, Lund University, Lund, Sweden.

Background and aims: Insulin resistance is adaptively compensated by an increase of insulin secretion and glucose effectiveness. However, these ad-

aptations are inadequate in mice after high-fat feeding that yields markedly reduced glucose elimination after intravenous glucose, because of insufficient hyperinsulinemia and glucose effectiveness. We investigated whether these defective adaptations can be normalized by the incretin hormones glucose-dependent insulinotropic polypeptide (GIP) and glucagon-like peptide-1 (GLP-1).

Materials and methods: C57BL/6J mice were fed a normal chow (ND, 11%) or a diet with 60% fat for 8 weeks (HD). After a baseline blood samples was taken, a bolus injection of glucose at 35 g/kg with or without addition of synthetic GIP or GLP-1 (at 0.03, 0.3 or 3 nmol/kg) was given intravenously followed by six blood samples taken within 50 (normal diet) or 75 min (high-fat diet) for analysis of glucose and insulin. Data were analyzed with minimal model that provides insulin sensitivity index (S_I) and glucose effectiveness (S_G). Insulin secretion was assessed as the increase in insulin levels during the first 5 min after injection (dAIR), and glucose elimination was estimated as the percent reduction of glucose (after logarithmic transformation) during the first 20 min after administration (K_G). Beta-cell adaptation was calculated as S_I×dAIR (disposition index, DI) and beta-cell function as delta peak insulin/delta peak glucose.

Results: K_G was lower in HD fed mice (P<0.001). At 0.03 nmol/kg, neither GIP nor GLP-1 significantly affected K_G in HD; at 0.3 nmol/kg, the incretins significantly increased K_G, but not to normal values. However, at 3 nmol/kg, K_G was completely normalized by both GIP (2.28±0.22, n=11) and GLP-1 (1.96±0.24, n=17). This was associated with markedly increased dAIR and beta-cell function (p<0.001); S_I was not affected, but the resulting DI was completely normalized. In contrast, S_G, which was increased by HD, was slightly reduced, but not normalized, by the incretins.

Conclusion: GIP and GLP-1 completely normalize the glucose elimination in severe insulin resistance in mice after high-fat feeding by normalizing the disposition index; this derives from marked upregulation of the islet adaptation to insulin resistance without any effect on insulin sensitivity and with no improvement of insulin-independent mechanisms of glucose elimination.

Metabolic parameters

Metformin activates the AMPK pathway and improves survival of murine and human L-cells but does not directly increase GLP-1 secretion

L.M. Lauffer[1], A. Grieco[1], R. Iakoubov[1], P.L. Brubaker[1,2];
[1]Physiology, [2]Medicine, University of Toronto, Canada.

Background and aims: Intestinal L-cells secrete the hormone glucagon-like peptide-1 (GLP-1) in response to nutrients and other secretagogues; GLP-1 then increases both insulin secretion and satiety. GLP-1 analogs and degradation inhibitors are therefore now in use as therapy for type 2 diabetes. Metformin, a well-established anti-diabetic drug, is known to increase circulating GLP-1 levels in humans through a mechanism that does not involve decreased GLP-1 degradation but may, possibly, include increased release of GLP-1, enhanced L cell proliferation and decreased L cell apoptosis.

Materials and methods: Human (NCI-H716) and mouse (GLUTag) L-cell lines were incubated for 2 hr with medium alone, oleoylethanolamide (OEA: 5-20μM; a novel GPR119-dependent GLP-1 secretagogue, positive control), metformin (5-150μM) or the AMPK-activator AICAR (0.1-1mM; positive 'AMPK' control) prior to RIA for GLP-1 secretion. Activation of the AMPK pathway was verified in both cell lines by presence of phospho-AMPK (normalized to total AMPK), as detected by western blot. To assess L cell survival, GLUTag cells were treated for 24 hr with metformin (150μM), AICAR (1mM) or OEA (10μM), followed by induction of apoptosis with cytokines or staurosporine, and immunoblot for cleaved Caspase-3, an early marker of apoptosis. L cell proliferation following the same treatment (metformin, AICAR or OEA) was assessed by 3H-thymidine incorporation.

Results: Treatment of NCI-H716 or GLUTag cells with different concentrations of metformin or AICAR did not increase GLP-1 secretion (n=6-9); in contrast, treatment with OEA increased GLP-1 release by 2.6±0.2-fold (p<0.001) and 2.1±0.2-fold of basal (p<0.001), in NCI-H716 and GLUTag cells (n=6-9), respectively. Treatment with metformin (150μM) or AICAR (0.1mM) did not affect normalized phospho-AMPK levels after 1 hr of treatment in either cell line; however, metformin increased phospho-AMPK levels in NCI-H716 cells by 1.8- and 1.7-fold, after 6 and 24 hr, respectively (n=3), while AICAR induced a nearly 2-fold increase in phospho-AMPK levels after 24, but not after 6 hr. In contrast, both metformin and AICAR increased the normalized phospho-AMPK in GLUTag cells by 1.5- and 1.8-fold, respectively, after 6, but not after 24 hr of treatment (n=3). Finally, incubation of GLUTag cells with metformin (150μM), AICAR (1mM) and OEA (10μM) decreased L-cell apoptosis by 33±4% (p<0.01), 8±1% (p<0.01) and 33±6% (p<0.01), respectively. While the same concentrations of metformin and OEA did not affect proliferation of the GLUTag cells, AICAR increased proliferation by 74±7% compared to control (p<0.001).

Conclusion: Although metformin is known to increase GLP-1 levels in patients, our study demonstrates that doses of metformin comparable to plasma levels achieved in such patients do not directly stimulate GLP-1 release from intestinal L cell lines; however, metformin improves survival of the L cells by decreasing apoptosis, potentially by modulating the AMPK signaling pathway. Nonetheless, the mechanism of action of metformin to increase GLP-1 levels in humans in vivo needs further exploration. Taken together, these findings suggest that use of metformin, possibly in combination with a direct GLP-1 secretagogue, such as OEA, and a GLP-1 degradation inhibitor, may lead to a favorable GLP-1 profile in patients with type 2 diabetes.

The Fas apoptotic inhibitory protein TOSO induces proliferation in human beta cells

G. Dharmadhikari[1], M.K. Muehle[2], F.T. Schulthess[1], J. Kerr-Conte[3], F. Paroni[1], K. Maedler[1];
[1]Centre for Biomolecular Interactions, University of Bremen, Germany, [2]University of California, United States, [3]Thérapie Cellulaire du Diabète, Lille, France.

Background and aims: Decreased β-cell mass reflects a shift from quiescence/proliferation into apoptosis, it plays a crucial role in the pathophysiology of type 1 and type 2 diabetes and limits the outcome of islet transplantation. A major apoptotic pathway which triggers glucose- and autoimmunity- mediated β-cell apoptosis is the activation of the Fas/FasL system. Here we show that switching the Fas pathway using Fas apoptotic inhibitory protein (Faim/TOSO), which regulates apoptosis upstream of caspase 8, is a promising target to block β-cell apoptosis and to increase proliferation.
Materials and methods: TOSO expression in pancreatic sections was analyzed by immunofluorescence in 8 patients with T2DM and 8 healthy controls. Human isolated islets were exposed to increasing glucose (5.5-33.3 mM) and IL-1β (0.1-5 ng/ml) with and without TOSO down-regulation by siRNA (siTOSO) or β-cell specific TOSO over-expression by RIP-TOSO plasmid transfection. Apoptosis, proliferation and TOSO expression were analyzed. To answer the question if there is a sub-population of β-cells in human islets in culture, which is especially replication-active, we incorporated the thymidine analogs 5-chloro-2-deoxyuridine (CldU) and 5-iodo-2-deoxyuridine (IdU) into cultured β-cells after TOSO transfection and measured cycles of proliferation.
Results: Triple immunostaining for TOSO, insulin and glucagon in pancreatic sections of healthy controls and patients with T2DM revealed that TOSO is clearly expressed in the β-cells and down-regulated in diabetes. We observed a 5.5-fold increase in TOSO by short-term incubation of islets with glucose (12 h), a condition when glucose induced proliferation (1.8-fold increase in Ki67 positive β-cells). In contrast, TOSO was down-regulated to almost undetectable levels after long-term incubation for 72 h, a condition where glucose induced β-cell apoptosis (2.5-fold increased β-cell apoptosis at 33.3 mM compared to 5.5 mM glucose). Previously, we have found that the cytokine IL-1β has a dual role on β-cell turnover; it induces proliferation at low dose and apoptosis at high dose. In line with this finding, low dose IL-1β induced and high dose almost depleted TOSO mRNA expression. These studies lead to the hypothesis that TOSO may regulate a switch between proliferation and apoptosis in the β-cell.
To investigate the physiological role of TOSO, we over-expressed and depleted TOSO in the β-cell. Incubation of human islets with siTOSO for 4 days depleted TOSO expression together with 3.5-fold induction of apoptosis. β-cell apoptosis was 4-fold increased by the cytokine mix IL-1β and IFNγ and 3.5-fold by 33.3 mM glucose, which was prevented by RIP-TOSO over-expression. On day 2 and 4 after RIP-TOSO transfection, we incorporated the thymidine analogs 5-chloro-2-deoxyuridine (CldU) and 5-iodo-2-deoxyuridine (IdU), respectively, into cultured islets. RIP-TOSO resulted in a 3.5-fold induction of proliferation. Only a small percentage (~2%) of the proliferating β-cells were co-labeled for CldU and IdU suggesting a very limited capacity of β-cells to undergo multiple rounds of proliferation.
Conclusion: Our data suggest that TOSO is an important regulator of β-cell turnover and could be an important tool to switch β-cell apoptosis into proliferation and to maintain and generate a sufficient β-cell mass.

Protective roles of S-nitrosoglutathione reductase (GSNOR), a negative regulator of protein S-nitrosylation, in obesity- and streptozotocin-induced diabetes

M. Kaneki[1], Y. Chiba[1], M. Fukaya[1], M. Sakai[1], S. Shinozaki[1], T. Kitamura[2], H. Ito[3], J. Stamler[4];
[1]Dept. of Anesthesia and Critical Care, Massachusetts General Hospital, Harvard Medical School, Charlestown, United States, [2]Metabolic Signal Research Center, Gunma University, Japan, [3]Dept. of Internal Medicine, Tokyo Metropolitan Geriatric Institute, Japan, [4]Dept. of Internal Medicine, Duke University, Durham, United States.

Background: Nitric oxide (NO) and inducible NO synthase (iNOS) play important roles in dysfunction and destruction of pancreatic β-cells as well as obesity-induced insulin resistance. However, it remains largely unknown how NO and iNOS modulate function and survival of β-cells. We have previously shown that Akt/PKB is reversibly inactivated by protein S-nitrosylation, the covalent attachment of NO moiety to cysteine thiols and the major mediator of diverse actions of NO. S-nitrosoglutathione (GSNO) reductase (GSNOR), which is expressed in various cell types, including β-cells, decomposes GSNO and thereby reduces S-nitrosylated proteins in cells.
Methods and results: GSNOR knockout (-/-) mice exhibited glucose intolerance, insulin resistance, attenuated insulin secretion, increased blood glucose levels and lower plasma insulin concentrations under fasted and fed conditions, as compared with wild-type mice (Fasted BS: KO: 158 ± 4 mg/dl; WT: 137 ± 3, $p<0.0001$, Fasted Insulin: KO: 0.74 ± 0.04 ng/ml; WT: 0.96 ± 0.05, $p<0.01$). Moreover, GSNOR deficiency aggravated high-fat diet-induced diabetes. Multiple low-dose streptozotocin treatment (MLD-STZ, 37.5 mg/kg/day, IP, for 5 consecutive days) induced diabetes (BS ≥ 300 mg/dl) in 14 out of 21 male GSNOR-/- mice and enhanced β-cell apoptosis, although none of wild-type mice (n=22) became diabetic by MLD-STZ (χ^2: $P<0.001$). siRNA-mediated knockdown of GSNOR accelerated both NO donor- and cytokine (IL-1β + IFN-γ)-induced apoptosis in cultured INS-1 cells. Notably, iNOS deficiency almost completely blocked MLD-STZ-induced diabetes in GSNOR-/- mice and reversed the increases in β-cell apoptosis, but did not affect resting hyperglycemia or low insulin levels.
Conclusion: These results indicate that GSNOR plays a protective role against iNOS-mediated apoptosis of β-cells, while under normal condition GSNOR exerts beneficial effects on β-cell function via iNOS-independent mechanisms. Our findings highlight GSNOR as a potential anti-diabetogenic molecular target.

miRNAs posttranscriptionally regulate cytokine-induced Bcl-2 family members

L.G. Grunnet[1,2], C. Bang-Berthelsen[2], B. Kutlu[3], F. Ortis[3], N. Billestrup[2], D. Eizirik[3], F. Pociot[2], T. Mandrup-Poulsen[1,2];
[1]Department of Biomedical Sciences, University of Copenhagen, Denmark, [2]Steno Diabetes Center and Hagedorn Research Institute, Gentofte, Denmark, [3]Université Libre de Bruxelles, Belgium.

Background and aims: In β-cells, cytokine-induced pro-apoptotic signaling is dependent on Bcl-2 family proteins. However, the regulation of Bcl-2 proteins at mRNA and protein levels following cytokine exposure is incompletely understood. In other cell systems, the expression of Bcl-2 family members is regulated by miRNAs. The aims of this study were to characterize the effects of cytokines on target Bcl-2 family member mRNA and protein expressions and to investigate a putative regulatory role of miRNA.
Materials and methods: INS-1 cells were exposed to IL-1β (160pg/ml) and IFNγ (5ng/ml) for 1 to 24h, and expressions of Bcl-2, Bak1, Bax, $BclX_L$, Bid were assessed with qRT-PCR and immunoblotting. Bioinformatic tools were used to identify miRNAs with putative target sites in the 3`UTR of the Bcl-2 member RNAs. miR-150, -15b, -27b, -125a, -326, -133a and Let-7c were chosen for further examination. The expressions of miR-150, -326, -133a and Let-7c were characterized by qRT-PCR in the absence or presence of cytokines (12 and 24h). A reporter construct containing the Luciferase gene cloned with the 3'UTR of Bid was used to investigate a regulatory role of miRNA on Luciferase activity and Bid protein expression. A construct containing the Luciferase gene with its native 3'UTR was used as a negative control. Luciferase activity was measured in the presence or absence of 4 miRNAs with putative binding sites in the Bid 3'UTR (miR-326, miR-15b, miR27b and miR125b) and 4 negative control miRNAs.

Results: Cytokines induced expression of Bak, Bax, $BclX_L$ and Bid (fold induction 3.5, 2.7, 2.6 and 8.1, respectively, all $p<0.05$, Student's paired t-test), but not Bcl-2 mRNAs; however this was not correlated with increased protein expressions. Cytokines were further found to increase the expression of miR-150, miR-326 and miR-133a (fold induction 1.5, 4.0 and 1.9, respectively, all $p<0.05$), but not Let-7c. All of the investigated candidate miRNAs, but none of the negative controls inhibited Luciferase activity from the Luciferase-Bid 3'UTR reporter system (49-53%, $p<0.05$). Further, when the Bid 3'UTR containing construct was used to sequester endogenously expressed miRNAs, cytokines induced Bid protein expression 3.4 fold relative to the effect of over-expressing a construct containing the native 3'UTR of Luciferase (n=2-3).
Conclusion: This study has demonstrated mRNA but not protein levels of Bcl-2 family members to be up-regulated following cytokine exposure. We suggest that the posttranscriptional repression of at least Bid is mediated by miRNAs. miRNAs are thereby suggested at novel regulators of cytokine-induced signalling, and modulation of miRNAs may represent a new strategy to prevent cytokine-induced β-cell apoptosis.

Beta cell maturation enhances cytokine sensitivity via iron metabolism
M.F. Tonnesen[1], J. Friberg[2], L.G. Grunnet[3], P. Hagedorn[4], M. Aalund[4], A.E. Karlsen[5], F. Pociot[2], T. Mandrup-Poulsen[1,3];
[1]Dept. of Translational Diabetology, Hagedorn Research Institution, Gentofte, [2]Dept. of Diabetes Genome Biology, Hagedorn Research Institution, Gentofte, [3]Core Unit for Medical Research Methodology, Institute of Biomedical Sciences, University of Copenhagen, [4]NeuroTech, Copenhagen, Denmark, [5]Diabetes Biology, Novo Nordisk, Måløv, Denmark.

Background and aims: Pro-inflammatory cytokines and reactive oxygen species (ROS) generation play major roles in the pathogenesis of type 1 diabetes (T1D) and in islet transplantation by causing impairment of β-cell function and apoptosis. β-cell acquisition of sensitivity to IL-1β is associated with β-cell maturation and pancreatic duodenal homeobox factor-1 (Pdx-1) expression, but the molecular mechanisms are unknown. The aim of this study was to compare IL-1β-induced signaling and apoptosis in immature- and mature β-cells and reveal molecular mechanisms based on gene expression profiling.
Materials and methods: INS-1rαβ cells with doxycycline-inducible Pdx-1 or dominant negative (DN)-Pdx-1 expression were a gift from Claes B. Wollheim. IL-1β-induced cell death was determined by TUNEL, cleavage of caspase-3 and ELISA death detection assay. NFκB activation was determined by electric mobility shift assay (EMSA) and Luciferase reporter assay. Affymetrix microarray analysis was used for gene expression profiling and candidate genes verified in newborn rat islets by Western blotting and realtime PCR. Iron uptake was measured by the calcein assay and ^{55}Fe uptake. ROS formation was measured by using the H_2DCF dye. Iron chelator desferrioxamine (DFO) and siRNA-mediated divalent metal transporter 1 (DMT1) knockdown was used to block IL-1β-induced iron uptake.
Results: Pdx-1 over-expressing INS-1rαβ cells were more sensitive to the toxic effect of IL-1β compared to wildtype and DN-Pdx-1 expressing cells (310%, $p<0,05$). IL-1β-induced NFκB transcriptional activity was increased (>200%, $p<0,05$) in Pdx-1 overexpressing cells and bioinformatic analysis of microarray data suggested altered iron homeostasis as an important factor in IL-1β sensitivity of Pdx-1 expressing cells. Observations were verified in IL-1β-exposed rat and human islets, where increased expression (400%, $p<0,01$) of the NFκB-regulated iron transporter DMT1 and several other iron regulated genes were shown. This correlated with increased IL-1β-induced iron uptake and iron-catalysed ROS formation in cell lines and rat islets. Immunostaining of rat pancreatic sections indicate high basal DMT1 expression in β-cells cells compared α-cells. Pharmacological inhibition of iron uptake by treatment with DFO reduced IL-1β-induced ROS formation and cell death dose-dependently. DMT1 knockdown with three different siRNA protected INS-1 cells against IL-1β-induced apoptotic cleavage of caspase3.
Conclusion: Pdx-1-driven β-cell maturation causes IL-1β-sensitivity in insulin secreting cells. Our data suggest that this process depends upon enhanced NFκB activity and increased expression of the NFκB-regulated iron transporter DMT1, leading to increased iron uptake, ROS production and apoptotic β-cell death.

Morphologic changes of the endocrine pancreas in Japanese non-obese type 2 diabetes
M. Miuchi, J.-I. Miyagawa, K. Konishi, E. Nagai, T. Katsuno, S. Kataoka, H. Konya, T. Hamaguchi, M. Namba;
Division of Diabetes & Metabolism, Internal Medicine, Hyogo College of Medicine, Nishinomiya, Japan.

Background and aims: It has been demonstrated that the "beta cell mass" in the pancreas of the patients with type 2 diabetes mellitus (T2DM) is decreased even in the early stage of the disease in the Caucasian population. In Japanese population, the capacity of insulin secretion has been shown to be less robust compared to that of the Caucasian population, and this is thought to be more important than the existence of insulin resistance in view of the pathoetiology in the development of Japanese T2DM. However, little is known on the morphologic change in the endocrine pancreas of the patients with T2DM. Therefore, we tried to clarify the morphologic change of the beta cells of pancreas in patients with Japanese non-obese T2DM.
Materials and methods: Pancreas tissues of patients with non-obese T2DM aged 65.1±10.5 years (DM, n=17) and age-matched non-obese non-diabetic subjects aged 67.3±10.5 years (non-DM, n=15) were obtained by surgical operations and autopsies. BMI of both groups of diabetic patients and non-diabetic subjects were 20.3±3.1 and 20.0±2.4 kg/m^2, respectively. Three sets (more than 500 μm distant from each other) of formalin-fixed, paraffin-embedded sections were made from head, -body and -tail portions of each pancreas. At least 3 pancreatic sections from each set were immunostained with islet hormones (insulin, glucagon and somatostain) by immuno-fluorescent and/or immuno-histochemical method. From these sections, we calculated relative beta cell area (%), relative islet number (/cm^2), relative beta cell number (/cm^2) and beta cell size (μm^2) using digital image analyzer (BZ-H1A) equipped on a fluorescence microscope BZ-8000 (KEYENCE).
Results: Relative beta cell area was significantly decreased in DM group compared to that of non-DM group (0.80 ± 0.78 vs 1.05 ± 0.80%, $p<0.05$), especially in pancreas head (0.48±0.24 vs 0.76±0.44%, $p<0.001$). There was a trend to increase in the relative islet number in DM group. Relative beta cell number was significantly increased only in a pancreas tail of the DM group (28,399.4±16,445.6 vs. 20,166.5±11,771.9/cm^2, $p<0.05$). Beta cell size was significantly decreased in all portion of the pancreas in DM group (45.7±27.1 vs 80.6±33.3 /μm^2, $p<0.001$).
Conclusion: In the pancreas of Japanese patients with non-obese T2DM, the relative beta cell area was decreased, especially in the head portion, but the relative number of beta cells does not appear to be decreased at least in the present study. Our results indicate that the decrease in the relative beta cell area, so-called "beta cell mass", in non-obese type 2 diabetes mellitus was mainly caused by the reduction of the beta cell size.

PDX-1 translocates to the cytosol in type 2 diabetes
A. Ardestani[1], N.S. Sauter[2], J. Kerr-Conte[3], J.-H. Cho[4], F. Paroni[1], K. Maedler[1];
[1]Centre for Biomolecular Interactions, University of Bremen, Germany, [2]Endocrinology & Diabetes, University Hospital Zurich, Switzerland, [3]Thérapie Cellulaire du Diabète, Lille, France, [4]College of Medicine, Kangnam St. Mary's Hospital, Seoul, Republic of Korea.

Background and aims: The transcription factor PDX-1 plays a critical role during β-cell development and in glucose induced insulin gene transcription in adult β-cells. Glucose exposure up to 24 h leads to translocation of PDX-1 from the nuclear periphery to the nucleoplasm, whereas under conditions of oxidative stress, PDX-1 shuttles from the nucleus to the cytosol. The possible pathophysiological role of such PDX-1 translocation is unknown and disturbances in PDX-1 shuttling may be an important mechanism of β-cell failure in T2DM. In the present study we asked the following questions: where is PDX-1 located in diabetic islets and does normalizing glycemia change PDX-1 localization?
Materials and methods: PDX-1 expression in pancreatic sections was analyzed by immunofluorescence staining in 8 patients with T2DM and 8 healthy controls, and in 2 animal models of T2DM, the *db/db* mouse and the high fat/high sucrose diet fed mouse (HFD). Islets from the mice were isolated and analyzed for PDX-1 localization and apoptosis by Western blotting. Human islets were cultured for 96 h with increasing glucose concentrations, or with 2 ng/ml IL-1β with or without addition of recombinant human IL-1Ra and PDX-1 localization was analyzed in Bouin fixed islet sections.

Results: In all islets from patients with T2DM, PDX-1 protein was localized in the cytosol, whereas in the non-diabetic controls, PDX-1 was in the nucleus. Also, in the hyperglycemic 8 week old db/db mice and in mice fed the HFD for 16 weeks, PDX-1 protein was localized in the cytosol and β-cell apoptosis was increased. In contrast, IL-1Ra overexpression in both mouse models maintained normoglycemia, β-cell survival and PDX-1 nuclear localization.
Importantly, in human islets exposed for 96 h to 22.2 mM glucose or to 2 ng/ml IL-1β, PDX-1 was found in the cytosol, whereas IL-1Ra induced a similar restoration of PDX-1 nuclear translocation in isolated islets. We found the JNK-pathway as a possible link in the downstream signaling from IL-1Ra to PDX-1. In isolated human islets, phosphorylated JNK-levels were increased by 11.1 and 33.3 mM glucose or in the presence of IL-1β, this was inhibited by IL-1Ra treatment.
Previous studies suggested that JNK-activation leads to PDX-1 export. Human islets were treated with 22.2 mM glucose or IL-1β, with or without the addition of a small peptide that inhibits JNK-activity. In the glucose and IL-1β treated cells, we found cells that co-express insulin and PDX-1 in the cytoplasm, as well as cells that showed cytoplasmic PDX-1 with almost no detectable insulin. JNK-inhibition prevented glucose- and IL-1β-induced PDX-1 translocation and kept the transcription factor in the nucleus in most cells, indicating that the JNK-pathway is involved in regulating PDX-1 localization.
Conclusion: Our results suggest that β-cell failure correlates with the cytosolic localization of PDX-1. IL-1Ra improves β-cell survival and function through maintaining PDX-1 expression in the nucleus and suggest a potential role for IL-1Ra in the treatment of diabetes.

A dominant mutation in the obesity susceptibility gene *FTO* results in reduced fat mass with enhanced lipid and carbohydrate metabolism
C.D. Church[1], E.A.L. Bagg[2], S. Lee[3], J.S. McTaggart[3], L. Moir[1], R. Deacon[4], T. Gerken[2], C.J. Schofield[2], F.M. Ashcroft[3], R.D. Cox[1];
[1]Diabetes and Metabolism, Mammalian Genetics Unit, Didcot, [2]Chemistry Research Laboratory and Oxford Centre for Integrative Systems Biology, University of Oxford, [3]Department of Physiology, Anatomy and Genetics, Henry Wellcome Centre for Gene Function, Oxford, [4]Department of Experimental Psychology, University of Oxford, United Kingdom.

Background and aims: Human single-nucleotide polymorphisms within intron 1 of the *FTO* gene are associated with increased body mass index and type 2 diabetes. The risk allele is not associated with fetal growth but confers an increased risk of obesity with homozygous risk allele carriers weighing ~3kg more than controls. As the obesity-associated SNPs are intronic it is unclear whether changes in FTO expression or splicing are the cause of obesity or if regulatory elements within intron 1 influence upstream or downstream genes. We tested the idea that a single base pair change in the *Fto* gene may reveal a body weight and metabolic phenotype.
Materials and methods: A novel *N*-ethyl-*N*-nitrosourea (ENU) point mutation in exon 6 of the *Fto* gene was identified (Fto^{I367F}). Phenotyping of heterozygous and homozygous mice fed standard (SD) or high fat diets (HFD) was performed by 10 and 20 week food intake measurement and 18 week metabolic rate assessment. Body composition was determined by dual energy X-ray absorptiometry at 24 weeks. Gene expression analysis by microarray in white adipose tissue (WAT), skeletal muscle and liver was performed at 16 weeks and blood plasma and tissues were collected and analysed at 24 weeks.
Results: We show that homozygous and heterozygous mice carrying the dominant Fto^{I367F} mutation exhibited a maturity-onset reduction in body weight diverging from wildtype at 12 weeks of age ($P < 0.01$) and becoming ~10% less than wildtype by 24 weeks old ($P < 0.01$). Analysis of 24 week old Fto^{I367F} mice and controls revealed a 16-18% reduction in total fat mass per mouse compared to wildtype ($P<0.01$). Fto^{I367F} mice on HFD also exhibit reduced adiposity (37.5% ± 1.0 compared to 42.2% ± 0.9, $P< 0.01$) and increased lean mass (24.5g ± 0.52 compared to 26.4g ± 0.34, $P< 0.01$). Fto^{I367F} mice have increased energy expenditure ($P < 0.01$), and unchanged food intake and locomotor activity. Biochemical *in vitro* studies by non-denaturing mass spectrometry suggest the mutation modifies FTO function likely by altering its dimerisation state. Gene expression profiling in homozygote Fto^{I367F} mice revealed substantial (≥ ± 1.5 fold) mRNA expression changes in WAT (n = 359), skeletal muscle (n= 210) and liver (n = 339) including some fat and carbohydrate metabolism genes and an improved inflammatory profile in the WAT of Fto^{I367F} mice.
Conclusion: The Fto^{I367F} *mouse* provides direct functional evidence that *Fto* is a causal gene underlying obesity. In contrast to the recently published mouse knockout mutation in *Fto* our model is fully viable and is not growth retarded. The Fto^{I367F} mouse provides a physiologically relevant model for studying FTO due to similarities with the effect size of the human association as demonstrated by the dominant maturity-onset reduction in weight and fat mass. This study suggests that a search for human coding mutations may be informative and that inhibition of FTO activity is a possible development for the treatment of morbid obesity.

[1]CBATEG, University Autonomous of Barcelona, [2]CIBER de Diabetes y Enfermedades Metabolicas Asociadas (CIBERDEM), Barcelona, Spain.

Background and aims: Obesity is a metabolic disease whose frequency has increased dramatically during the last few years. During development of obesity there is an expansion of fat mass which may lead to hypoxia in certain

parts of adipose tissue because angiogenesis becomes insufficient to maintain normoxia in the entire adipose depot. This reduction in adipose tissue blood flow may trigger insulin resistance via effects on adipokine expression and/or adipocyte differentiation. One of the main factors involved in adipose tissue angiogenesis is the vascular endothelial growth factor (VEGF), which can be secreted by adipose tissue. To examine whether an increase in adipose tissue angiogenesis could protect against obesity-induced hypoxia and, in consequence, decrease inflammation and insulin resistance in this tissue, transgenic mice overexpressing VEGF in adipose tissue were generated.
Materials and methods: Transgenic animals were generated by microinjection into oocytes of a chimeric gene in which the murine VEGF cDNA was under control of the aP2 promoter and were then characterized.
Results: In aP2VEGF transgenic mice, adipose tissue VEGF expression and VEGF serum levels were increased compared with control animals. Moreover, adipose tissue vessel density was higher in transgenic mice than in controls. However, no differences in body weight, food intake or serum glucose levels were observed between groups. Similarly, serum levels of free-fatty acid, triglyceride, glycerol and hormones like adiponectin, leptin and insulin were unchanged. When fed a high fat diet, body weight gain was lower in transgenic mice than in controls. This was parallel to lower WAT weight and to different adipocyte size distribution with decreased adipocyte mean area. Energy expenditure was increased in transgenic mice related to controls. However, no differences in food intake were observed between control and transgenic mice. Moreover, trangenic mice under a HFD also showed a decrease in insulin serum levels in parallel with an increase in whole body insulin sensitivity. In these transgenic mice, fed either a high-fat diet or a chow diet, the overexpression of VEGF in adipose tissue led to an increase in macrophage infiltration. However, flow cytometry analysis of white adipose tissue of these animals showed that the infiltrate population of transgenic mice was different from the population of control mice. White adipose tissue infiltrate of transgenic mice had increased MGL-1 and GR-1 levels and decreased MHC class II and neuropilin, all these indicating that whereas adipose tissue from control mice on a HFD have M1 proinflammatory macrophages, adipose tissue from aP2VEGF transgenic animals both in chow and in HFD had increased M2 "alternatively activated" macrophages, which may protect adipocytes from inflammation.
Conclusion: Thus, these results suggest that the increase in energy expenditure and the M2 inflitrate in white adipose tissue of aP2VEGF transgenic mice protects them against high fat diet-induced insulin resistance and obesity.

Background and aims: In recent years it has become evident that obesity is associated with chronic low grade inflammation that contributes to the development of insulin resistance. It is believed that obesity-induced inflammation mainly originates from expanding adipose tissue. Recently, important metabolic effects have been attributed to Interleukin (IL)-1β. Processing of IL-1β requires cleavage by caspase-1, a cysteine protease regulated by a complex of proteins including NALP3 and ASC that are clustered into the inflammasome. The aim of our study was to test whether caspase-1 and the inflammasome are involved in the development of obesity and insulin resistance.
Materials and methods: White adipose tissue (WAT) from humans, diet- or genetically (db/db and ob/ob) induced obese animals and caspase-1- or NALP3-deficient animals were studied using qPCR and western blot analysis. In addition, WAT and insulin sensitivity of ob/ob animals that were treated for two weeks with an inhibitor of caspase-1 were examined.
Results: qPCR and Western blot analysis revealed that caspase-1 is well expressed in both human and mouse WAT. Interestingly, caspase-1 activity in WAT was increased during both diet- and genetically-induced obesity, resulting in elevated levels of mature IL-1β in WAT of obese animals. Differentiation of pre-adipocytes isolated from caspase-1- and NALP3- deficient mice resulted in more metabolically active fat cells that were more insulin sensitive and produced more adiponectin compared to cells originating from wild-type animals. WAT of caspase-1-deficient animals displayed a change in adipose tissue morphology towards smaller adipocytes. Caspase-1- and NALP3-deficient animals had a significant improvement of insulin sensitivity compared to wild-type mice. Finally, treatment of Ob/Ob animals with a chemical inhibitor of caspase-1 for two weeks led to a robust improvement of insulin sensitivity and reduction in weight gain.
Conclusion: Caspase-1 is present in human and mouse adipocytes and affects adipose tissue functioning and insulin sensitivity during the development of obesity. Our data reveal a physiological role of caspase-1 and suggests that caspase-1 inhibition represents a novel therapeutic target in clinical conditions associated with obesity and insulin resistance.

Gender differences in 11β-hydroxysteroid dehydrogenase activity in relation to markers of obesity and insulin resistance
J. deSchoolmeester[1], J. Palming[2], T. Persson[3], D. Gill[1], F. Renström[4], M. Lundgren[4], M.K. Svensson[2], A. Rees[1], J.W. Eriksson[2,5];
[1]AstraZeneca R&D, Macclesfield, United Kingdom, [2]Dept of Molecular & Clinical Medicine, Sahlgrenska University Hospital, Gothenburg, Sweden, [3]AstraZeneca R&D, Lund, Sweden, [4]Dept of Medicine, Umeå University Hosptial, Sweden, [5]AstraZeneca R&D, Mölndal, Sweden.

Background and aims: Inhibition of 11β-hydroxysteroid dehydrogenase 1 (11βHSD1), an enzyme that regulates local tissue cortisol levels, is a potential treatment of obesity and type 2 diabetes. Increased 11βHSD1 activity and expression in adipose tissue has previously been shown to be linked to obesity. The main purpose of this study was to assess the relationship between 11βHSD1 activity in human subcutaneous (sc) adipocytes and different indices of adiposity (including body fat, adipocyte size, BMI and waist circumference) as well as plasma markers of insulin resistance and, in addition, to address the impact of gender.
Materials and methods: Non-diabetic male (M, n=23) and female (F, n=31) volunteers were recruited; age 47.8±1.9 (mean±SEM), BMI 26.8±0.5 (range 21-38 kg/m^2). Blood sampling, sc abdominal adipose tissue biopsies and anthropometric measurements were performed following overnight fast and body fat was measured by bioimpedance. Sc and omental (om) adipose biopsies (n=4) were obtained during elective abdominal surgery. Mature adipocytes were isolated by collagenase digestion and cell number and size determined. 11βHSD1 activity was measured in the presence or absence of a novel specific and potent 11βHSD1 inhibitor during 5-6 h incubation with 100 nmol/l cortisone including ^{3}H-cortisone tracer. ^{3}H-cortisone and ^{3}H-cortisol in the incubation media were measured using radiometric HPLC and activity was expressed as % conversion of cortisone to cortisol per h per 10^6 cells.
Results: There was no significant difference in sc 11βHSD1 activity between M (3.8±0.6%/h/10^6 cells) and F (3.4±0.7%/h/10^6 cells). In the subjects where both sc and om cells were assessed, 11βHSD1 activity did not differ between the depots; sc 2.4±1.2%/h/10^6 cells; om 2.4±1.2%/h/10^6 cells. A near complete inhibition of 11βHSD1 activity was achieved with the novel inhibitor in both sc and om adipose tissue, and potency was similar (IC50 1-2 nM) for both fat depots. 11βHSD1 activity in sc adipocytes positively correlated with body fat (M, r=0.57, p=0.009; F, r=0.43, p=0.04) and cell size (F, r=0.59, p=0.001; M, r=0.40, p=0.06). A positive correlation between 11βHSD1 activity and BMI (M, r=0.47, p=0.025; F, r=0.31, p=0.08) was statistically significant only in men, and this was also true for waist circumference (M, r=0.63, p=0.001; F r=0.26, p=0.18). A positive correlation was also observed with fasting glucose in both groups (M, r=0.41, p=0.049; F, r=0.46, p=0.016), although only men displayed a positive correlation to fasting insulin (r=0.58, p=0.005). Multiple regression analyses, including the above variables, showed that only adipocyte size predicted 11βHSD1 activity (M, r^2=0.27, p=0.028, F, r^2=0.47, p=0.001).
Conclusion: The data demonstrates increased 11βHSD1 activity in human subcutaneous adipocytes with obesity, and adipocyte size is an important

and independent marker in this relationship. In men, but not women, there was also an association between markers of insulin resistance, i.e. waist and serum insulin, and 11βHSD1 activity. The data suggest that there are differences between men and women in the link between 11βHSD1 activity and metabolic phenotypes.

Adipose tissue is directly targeted and initiated by bacterial LPS at the early onset of HFD-induced metabolic diseases

E. Luche[1], B. Cousin[2], A. Waget[1], M. André[2], P. Valet[3], L. Casteilla[2], R. Burcelin[1];
[1]Institut de Médecine Moléculaire de Rangueil, Eq 2, INSERM U858, [2]Université Paul Sabatier, IFR 31, UMR 5241 Métabolisme, [3]Institut de Médecine Moléculaire de Rangueil, Eq 4, INSERM U858, Toulouse, France.

Background and aims: We recently showed, in the mouse and in human that a fat-enriched diet (HFD) increased plasma Lipopolysaccharide (LPS) concentration in the blood and was responsible for the low tone inflammation observed during metabolic diseases. This mechanism depended on the LPS receptor CD14 and targeted the adipose tissue since CD14 knockout mice did not developed obesity in response to HFD. Conversely, in response to a one month LPS infusion the adipose cell number was increased and the cells were smaller suggesting and increased precursor proliferation.
Materials and methods: We here aimed to determine whether LPS could trigger directly the adipose depot and initiate the proliferation of adipose tissue precursors without recruiting bone marrow cells. To this aim we grafted adipose depots from wild type and CD14 KO mice on the back of CD14 KO mice. The CD14 KO recipient mice are unable to generate inflammation in response to a LPS infusion. The grafted mice underwent a continuous one month infusion of LPS by the mean of osmotic minipumps.
Results: At completion of the infusion we showed that HKII, GLUT4, FAS, and ACC mRNA concentrations and the insulin-stimulated glucose utilization rates (clamp experiments) were reduced in the grafted wild type fat pad when compared to the CD14 KO fat pad. This suggested a state of insulin resistance induced by the LPS infusion, and hence inflammation, which was directly affecting the wild type fat pad. This was confirmed by the increased quantification of the mRNA coding for the cytokines IL1, PAI-1, TNFa and the chemokines MCP-1, MIF, osteopontin and by the high amount of F4/80 positive cells as determined by FACS analysis and adipose tissue histology. Importantly, this set of data was similar to that obtained in mice treated with HFD for one month. In a second set of experiments we determined that the number of cells from the vascular fraction was dramatically increased only in the grafted wild type fat pad. We determined by FACS analysis that all precursor populations were similarly increased including preadipocytes, macrophages, and preendothelial cells. In vitro LPS stimulation increased the proliferation of cell types isolated from the stroma vascular fraction of wild type but not CD14 adipose depot. Conversely, in vitro the LPS treatment reduced the adipose cell differentiation process as assessed by lipid accumulation and the expression of adipogenic markers from wild type but not from CD14KO precursors.
Conclusion: We showed that LPS, which originates from intestinal microflora, can trigger directly the adipose depot by a CD14 dependent mechanism to initiate the proliferation of adipose tissue precursors. Hence intestinal microflora could be a regulatory factor controlling adipose tissue plasticity and insulin resistance.

The life-span determinant p66shcA mediates fat-induced insulin resistance

S. Chiatamone Ranieri, S. Fusco, G. Pani;
General Pathology, Catholic University Medical School, Rome, Italy.

Background and aims: Emerging evidence indicates in fatty acid and cytokine- induced oxidative stress a major cause of peripheral insulin resistance. The life-span determinant p66shcA promotes organismal ageing in part by eliciting the generation of Reactive Oxygen Species in mitochondria; additionally, structural features of p66shc clearly indicate that this adapter molecule may directly participate in signal transduction downstream of the Insulin RTK receptor. Thus far, however, a potential role role for p66shcA in the establishment of adipose-induced insulin resistance has not been investigated.
Materials and methods: Sex and age-matched lean Wild Type (WT) and p66-deficient (p66KO) C57Bl6 mice were subdued to glucose (1g/Kg) and Insulin (1 U/Kg) tolerance tests, and early signaling events elicited by Insulin in the white fat analysed biochemically. Obese mice were obtained by genetic crossbreeding with C57Bl6 Lep^{Ob}, leptin-deficient mice. $WT^{Ob/Ob}$ and $p66KO^{Ob/Ob}$ hybrid mice were monitored for 80 weeks for food consumption and weight gain, and glucose homeostasis and Insulin responses assessed as described for lean mice. Committed adipocytic precursor cells were prepared from WT and p66KO adipose tissue, serum starved for 16 hours and stimulated *in vitro* with insulin (100 ng/ml for 10'). Phosphorylation of Insulin Receptor Substrate-1 AKT/PKB kinase, and activation of the mTOR/S6K pathway were assessed by phospho-specific immunoblotting of total protein extracts. Molecular interactions between p66shc and component of the insulin signaling cascade were further investigated in 3T3-L1 preadipocytes and in HEK 293-T cell upon overexpression or siRNA-mediated knock-down of proteins of interest.
Results: Glucose and Insulin tolerance tests revealed no significant differences in lean p66KO mice compared to WT controls except for a slight reduction in blood glucose response to acute insulin. However, lack of p66 reduced fat accumulation and ameliorated fasting hyperglycaemia and glucose intolerance of Ob/Ob animals. In keeping with this finding, biochemical analysis of white fat from p66KO animals revealed higher expression of the master Insulin receptor transducer IRS-1 and of enhanced interaction of IRS-1 with PI3Kinase. Importantly,also isolated adipocyte precursors from p66KO obese mice appeared to be resistant to insulin desentization induced by in vitro exposure to TNF alpha or excess free fatty acid, when compared to p66-WT control cells. Mechanistic studies performed in 3T3L1 and 293-T cells revealed that p66shc form a complex with IRS-1 in insulin stimulated cells, and facilitates IRS recruitment of the S6K kinase, a putative mediator of insulin receptor desensitization by nutrient overload. Additionally, changes in p66shc levels, achieved by genetic manipulation, positively correlated with phosphorylation of both S6 Kinase and IRS-1. Finally, in 3T3L1 cells, FFA-induced insulin resistance was accompanied by Ser 36 phosphorylation of p66shc, and both responses were prevented by the ROS scavenger Catalase.
Conclusion: Taken together the above observations
a) Demonstrate the involvement of p66shc in the establishment of adipose-associated insulin resistance in vivo and in vitro, providing a link between oxidative stress, ageing and Type II Diabetes.
b) Outline a potential molecular mechanism in the p66-mediated association between IRS-1 and S6K, as components of a signal-inhibitory loop responsible for insulin resistance.

OP 36 Insulin therapy in type 2 diabetes mellitus

211

Metformin, sulphonylurea and insulin therapies maintain glycaemic control over five years in 4900 people with type 2 diabetes

J.D. Best[1], P. Drury[2], T. Davis[3], M.-R. Taskinen[4], A. Kesäniemi[5], A. Keech[6]; [1]University of Melbourne, Australia, [2]Auckland Diabetes Centre, New Zealand, [3]University of Western Australia, Perth, Australia, [4]University of Helsinki, Finland, [5]University of Oulu, Finland, [6]University of Sydney, Australia.

Background and aims: Type 2 diabetes is characterised by insulin resistance and impaired beta cell function that deteriorates over time. It is generally accepted that glycaemic control worsens over time, even with the intensification of standard diabetes care (metformin, sulphonylureas and insulin). In the Fenofibrate Intervention and Event Lowering in Diabetes (FIELD) study we investigated the hypothesis that a PPARα agonist, fenofibrate, could reduce the risk of cardiovascular disease in patients with type 2 diabetes. Because the FIELD study was not directed at improving glycaemic control or modifying other aspects of diabetes care, it also provided the opportunity to observe standard diabetes care, predominantly in the primary care setting, in 63 different regions within Australia, New Zealand and Finland.
Materials and methods: Glycaemic control and diabetes management in the placebo-treated cohort of 4900 patients (age 62 ± 7 years, 37% women, median duration of diabetes 5 years) were monitored for a median follow-up period of 5 years.
Results: Median HbA1c was 6.9% at baseline (2 measurements) and 7.0% at study end (p<0.0001); median fasting glucose was 8.5 mmol/L and fell to 7.9 mmol/L respectively (p<0.0001). Median weight was 86.3 kg at baseline and fell to 85.0 kg at study end (p<0.0001). Baseline therapy for diabetes was lifestyle measures only in 27%, oral agents in 67% and insulin in 14% (8% also taking oral agents). During the study insulin use increased to 28% (19% also taking oral agents) and use of oral agents to 77%. Only 2% of patients at baseline and 4% at study end were taking any oral agents other than metformin or sulphonylureas. Insulin therapy was initiated in 855 of the 4900 patients (20% of those not already taking insulin) at a median HbA1c of 8.2% and resulted in a sustained reduction to 7.6%. Median weight at insulin initiation was 86.5 kg and increased by 4.6 kg over the subsequent 5 years. Progression to insulin treatment in those on oral hypoglycaemic medication at baseline was associated with worse insulin secretory function. Both HOMA2-%S and HOMA2-%B predicted treatment progression in logistic models.
Conclusion: The FIELD study showed that glycaemic control in type 2 diabetes can be maintained in a large cohort with standard diabetes therapy (metformin, sulphonylureas and insulin) over a period of 5 years. The glycaemic benefits of newer therapies for type 2 diabetes should be judged against what is achievable with standard diabetes care. These findings are relevant to the delivery of diabetes care in many other countries, including those with more limited healthcare resources.
FIELD study supported by Laboratoires Fournier, France (now Solvay Pharmaceuticals) and Medical Research Council, Australia

212

Is there an association between frequency of self adjustment of insulin dose and metabolic control in patients with diabetes mellitus type 2?

E. Beluchin, L. Bäz, N. Müller, C. Kloos, G. Wolf, U.A. Müller;
Dept. Internal Medicine III, University Hospital Jena, Germany.

Background and aims: Intensified insulin therapy is widely used in patients with diabetes type 2 (DM2). In patients with type 1 diabetes frequent self monitoring and adaptation of insulin dose improved metabolic control, quality of life and reduced hypoglycaemia. Recent randomised controlled studies did not reveal an advantage of intensified insulin therapy in DM2. However, no study mentioned the frequency of insulin dose adjustment by the patients themselves. We studied the association of insulin dose adjustment in a large group of well educated patients with DM2 in Germany.
Materials and methods: We assessed the number of self adjustment of the insulin dose in 300 insulin treated patients with DM2 (age 66.8y; time since diagnosis 15.8y; BMI 32.9; HbA1c 7.4%) in an university outpatient department. The number of self adjustments of insulin dose was obtained from the last 14 days of the patient diary. All patients had a structured education on conventional or flexible insulin therapy. Self adjustment of insulin dose was defined as each change of the insulin dose compared to the same time of the previous day. Skipped and additional injections were also counted as dose adjustment. The patients were grouped to: now adjustments, 1-13 adjustments and >=14 adjustments per 14 days.
Results: 193 patients (64%) adapted their insulin dose at least once in 14 days. 107 patients used a fixed schedule without self adjustment. Patients with frequent adjustments (>=14) compared to the group with no self adjustment were younger (64.5 vs. 68.9y; p=0.001), had a higher insulin dose (77.3U vs. 53.6U/d; p=0,001), more injections (3.7 vs. 2.4/d; p=0,001), more blood glucose self controls (26.3 vs. 18.6/wk; p<0,001), a higher social status (11.5 vs. 9.8; p=0,001; max. score 21) and a longer follow up (8.2 vs 4.8y; p<0,001). No significant differences were observed regarding last BMI (32.8 vs. 33.4 kg/m²), last HbA1c (7.29 vs. 7.46%) and mean HbA1c (7.73 vs. 7.82%). In the regression analysis with mean individual HbA1c as dependent variable, time since diagnosis, number of self adjustments of insulin doses, number of insulin injections, number of blood glucose self monitoring, BMI and social status score as independent variables, only the number of blood glucose self monitoring (R^2 0,41; p<0.001) and BMI (R^2 0.65; p<0.001) had a significant association with HbA1c.
Conclusion: In an university outpatient department two thirds of well educated patients with diabetes type 2 on insulin therapy practice insulin dose self adjustments at least once per 14 days. The hypothesis that frequent self adjustments of the insulin dose is associated with better metabolic control was not confirmed in this retrospective cohort analysis. A randomised controlled trial is needed for the definitive proof of evidence regarding the value of self adjustment of insulin dose in DM2.

Once daily initiation with biphasic insulin aspart 30 (BIAsp 30) versus insulin glargine in patients with type 2 diabetes inadequately controlled with oral drugs - a randomized controlled trial

E. Franek[1], S. Kalra[2], M. Pesic[3], A. Smahelova[4], H. Thomsen[5], K. Strojek[6]; [1]Centralny Szpital Kliniczny MSWIA w Warszawie, Poland, [2]Bharti Hospital, Kunjpura Road, Karnal, India, [3]Clinical Centre Nis, Serbia, [4]Fakultni Hospital, Hradec Kralove, Czech Republic, [5]NovoNordisk A/S, Aalborg, Denmark, [6]Department of Internal Diseases, Diabetology and Nephrology, Zabrze, Poland.

Background and aims: The aim of the trial was to compare the efficacy and safety of biphasic insulin aspart 30 (BIAsp 30) with insulin glargine, both administered once daily to insulin-naive subjects with type 2 diabetes inadequately controlled with two oral anti-diabetic drugs
Materials and methods: In this 26-week, open-label, randomized, parallel-group, multinational, treat-to-target trial, 480 insulin-naïve subjects (mean age 56 years, mean HbA1c 8.5% and duration of diabetes 9.3 years) from 15 countries were randomized to receive either BIAsp 30 before dinner or insulin glargine at bedtime, both in combination with metformin and glimepiride. In all, 433 subjects completed the trial.
Results: After 26 weeks of treatment, the estimated mean reduction in HbA_{1c} (from baseline) was −1.41% with BIAsp 30 and −1.25% with insulin glargine, with a statistcally significant difference of −0.16%, 95%CI [−0.30;−0.02], p=0.029. The plasma glucose levels at end of treatment were significantly lower with BIAsp 30 both after dinner (BIAsp 30-glargine = -0.52, 95%CI [−1.02; −0.03], p=0.04) and at bedtime (BIAsp 30-glargine = −0.78, 95%CI [−1.25;−0.31], p<0.01) than with insulin glargine. The rate of hypoglycaemia was low in both treatment arms, and major hypoglycaemic episodes were few (three episodes with BIAsp 30 and two with insulin glargine). The relative risk of experiencing a nocturnal (0:00-6:00 a.m.) hypoglycaemic episode, however, was significantly higher with BIAsp 30 than with insulin glargine (1.1 vs 0.5 episodes/year, RR = 2.41, 95%CI [1.34;4.34], p=0.003). At initiation, the mean insulin daily dose was 0.18 U/kg in both treatment groups but after 26 weeks of treatment the dose had increased to 0.32 U/kg with BIAsp 30 vs 0.29 U/Kg with insulin glargine. Increase in body weight was similar in both arms: 1.74 kg with BIAsp 30 and 1.67kg with insulin glargine. The safety profile, as judged from reports of adverse events and clinical laboratory data, was comparable for the two treatments, and treatment satisfaction was not significantly different.
Conclusion: Findings from once daily BIAsp 30 versus once daily insulin glargine both in combination with metformin and glimipiride:
1: HbA_{1c} and postprandial hyperglycaemia was reduced significantly more with BIAsp 30
2: Low rate of hypoglycaemia was observed with both regimens, but significantly higher rate of nocturnal hypoglycaemia with BIAsp 30
3: Weight gain and treatment satisfaction were similar with the two regimens

214

Examining patient outcomes following different regimens of biphasic insulin aspart 30/70 (BIAsp 30, NovoMix® 30) in the large, multinational, IMPROVE™ observational study

R.J. Ligthelm[1], P. Valensi[2], W. van der Lubbe[3];
[1]Preventive medicine, EHM Clinic Hoofddorp, Rotterdam, Netherlands, [2]Department of Endocrinology, Diabetology, Nutrition, Jean Verdier Hospital, Paris Nord University, Bondy, France, [3]Global Marketing, Novo Nordisk A/S, Bagsværd, Denmark.

Background and aims: The IMPROVE observational study has shown that biphasic insulin aspart 30/70 (BIAsp 30) improves glycaemic control in patients with type 2 diabetes, regardless of pre-study therapy. Here we present a sub-analysis of effectiveness and safety of BIAsp 30 in patients grouped according to their starting and final injection frequency to determine which regimens resulted in the best patient outcomes.
Materials and methods: From the total of 52,419 patients from China, India, Japan, Canada, Russia, Italy, Poland and Greece enrolled in the IMPROVE study, n= 41,436 were included in this analysis as they had injection frequency data at baseline and final visit. Patients were divided into five treatment regimens based on their starting and final injection frequency of BIAsp 30: once-daily (OD) to OD (n=2943), OD to twice-daily (BID) (n=2613), BID to BID (n=33,880), OD to thrice-daily (TID) (n=141), and BID to TID (n=1859). Effectiveness and safety parameters and dose were analysed in these groups.
Results: Baseline patient demographics are given in the Table. Patients who started on BIAsp 30 BID had shorter duration of diabetes than those who started on BIAsp 30 OD (Table). Patients in all five dosing regimens showed significant reductions from baseline in HbA_{1c}, fasting blood glucose (FBG) and postprandial blood glucose (PPBG) at the end of the study (all $p<0.0001$; the Table below shows PPBG for breakfast across dosing regimens, and a similar pattern was seen for PPBG after lunch and dinner, also all $p<0.0001$ for change from baseline). Those patients who started BIAsp 30 therapy with BID injections consistently achieved greater reductions in glycaemic parameters than did those who started with an OD injection (Table). Consequently, over 50% of patients who started on BIAsp 30 BID achieved HbA_{1c} <7.0%, compared with approximately 40% for those who started on BIAsp 30 OD (Table). The final injection frequency did not appear to influence glycaemic outcome. All groups showed a significant reduction in major hypoglycaemia. Minor hypoglycaemia decreased in those who finished on OD or BID BIAsp 30 but increased in those who finished on TID BIAsp 30 (Table). BIAsp 30 daily doses from baseline to final visit increased with the number of daily insulin injections (Table).
Conclusion: BIAsp 30 is an effective therapy for patients with type 2 diabetes, regardless of initial or final injection regimen. Starting BIAsp 30 therapy with BID injections was more effective at improving glycaemic control than starting with an OD injection. Higher final injection frequency (TID) and hence dose was associated with increased minor hypoglycaemia compared with pre-study therapy, highlighting the importance of careful titration when BIAsp 30 is used in a TID regimen.

Long-term sustained safety and efficacy of continued use of Technosphere insulin in subjects with type 2 diabetes

N. Amin, A. Boss, P. Richardson;
MannKind Corporation, Valencia, United States.

Background and aims: Technosphere Insulin (TI) is a rapid-acting inhaled insulin with an action profile that mimics early meal-related insulin release. Safety and efficacy of TI has been previously demonstrated in controlled clinical trials of up to 2 years duration. The goal of this study was to examine the changes in lung function and glycemic control in subjects with type 2 diabetes over 4 years of continued treatment with TI.
Materials and methods: Subjects with diabetes who had completed any of the two 3-month, controlled, randomized phase II clinical trials were offered continued open-label TI as their exclusive prandial insulin regimen. Spirometry and lung carbon monoxide diffusing capacity (DL_{CO}) were measured every 6 and 12 months, respectively. HbA_{1c} was measured every 3 months. Hypoglycemia for this study was defined as blood glucose levels less than 3.5 mmol/l or symptoms of hypoglycemia that resolved after appropriate caloric intake.
Results: A total of 229 subjects (59% male, 41% female) were enrolled in the trial. In all, 199 subjects were exposed to treatment for >1 year, 175 for >2 years, 60 for >3 years, and 31 for >42 months. Annualized change in forced expiratory volume in 1 second was -0.048±0.0006 l/year and in DL_{CO} was -0.332±0.085 ml/min/mm Hg after 4 years of continued treatment with TI. Mean HbA_{1c} was 7.97% at baseline, 7.88% at month 3, 7.79% at month 6, 7.97% at month 12, 7.87% at month 18, 8.04% at month 24, 8.06% at month 30, 7.81% at month 36, 7.40% at month 42, and 6.45% at month 48. Overall, hypoglycemia rates remained stable at 0.31 events/subject-month during the first 6 months and 0.42 events/subject-month after 3 years, as measured over the final 12 months of TI therapy.
Conclusion: Changes in the lung functions after 4 years of TI therapy were small and similar to the changes expected in adults with type 2 diabetes. TI therapy maintained sustainable glycemic control for at least 4 years.

Healthcare costs of long-acting insulin analogues compared with NPH insulin in patients using a basal regimen: a Danish perspective

J. Gundgaard[1], M. Aagren[2], T.L. Thomsen[3];
[1]COWI A/S, Lyngby, Denmark, [2]Novo Nordisk Inc, Princeton, United States, [3]Novo Nordisk A/S, Virum, Denmark.

Background and aims: Insulin analogues may be able to offer health benefits to patients with diabetes, but also carry a higher price compared with conventional human insulins. The objective of this study was to compare the healthcare cost outcome of a basal insulin regimen of long-acting insulin analogues (LAIA) with neutral protamine Hagedorn (NPH) insulin, in patients with type 2 diabetes (T2D). Analysis was based on Danish healthcare costs.
Materials and methods: Data were extracted from national registers to involve the entire Danish population. Included in the analysis were prescription, hospital in- and out-patient care costs and socioeconomic variables. Suitable patients were identified during a 1 year index period (2005) and allocated to treatment with either LAIA or NPH insulin. Inclusion criteria were at least two prescriptions in the index period of LAIA (insulin detemir or insulin glargine) or NPH respectively and no switch to the other product in the follow-up period. Patients with at least one oral antidiabetic drug prescription between 1995 and 2007 and fewer than two prescriptions of fast-

acting insulin were identified. The patients from the LAIA group (n=303) were matched with patients from the NPH group (n=8523) with respect to observable variables using propensity scores. Healthcare costs were analysed for a follow-up period of 2 years, maximum. Figure 1 illustrates the distribution of costs for each of the treatment populations.
Results: The highest proportion of healthcare costs in both treatment groups could be attributed to inpatient care, accounting for 46% and 38% in the NPH and LAIA groups, respectively. Analysed in isolation the cost of basal insulin based on prescription data was significantly lower for the NPH treatment group compared to the LAIA group (p<0.0001). Overall annual healthcare costs however, which included all prescription medicine, amounted to €6230 in the NPH group and €5524 in the LAIA group. This difference in total costs between treatments groups was not statistically significant (p=0.302).
Conclusion: Costs for patients with T2D on a basal insulin regimen using LAIA do not seem to be higher in terms of healthcare resource than costs for patients using NPH insulin. This national study is ongoing and is expected to be revised with longer follow up and increasingly robust hospital data.

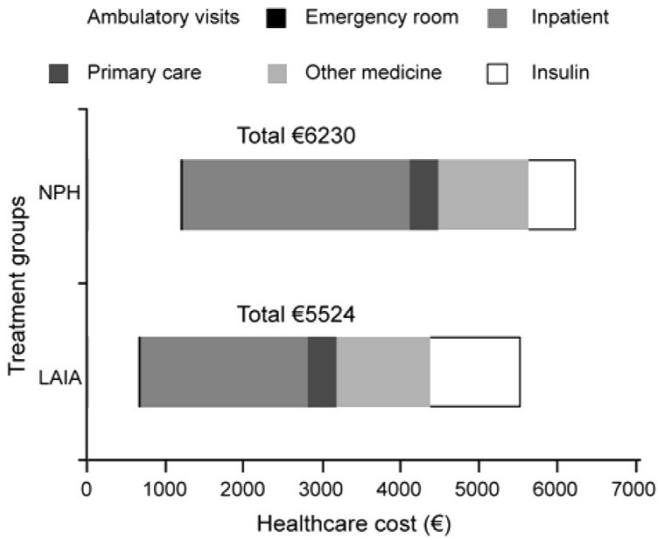

Figure. Follow-up annual healthcare costs 2005/6. NPH, neutral protamine Hagedorn insulin; LAIA, long-acting insulin analogues. Exchange rate: 2nd January 2009

To amputate or not to amputate? Healing rates following minor amputation vs conservative treatment of diabetic foot ulcers
M.S.P. Huijberts, P. van Battum, L. Prompers, I. Ferreira, N.C. Schaper, Eurodiale Study Group;
Dept. of Internal Medicine, Maastricht University Medical Centre, Netherlands.

Background and aims: Minor amputation is performed frequently as part of the management of diabetic foot ulcers. The decision to amputate is made by the professional in charge and is guided by factors such as the extent of tissue loss and bone involvement. The extent to which healing rates following minor amputation or conservative treatment differ is unclear. Therefore we have examined this in a large European cohort of diabetic foot ulcer patients.
Materials and methods: We examined 1088 patients from the Eurodiale study, a prospective cohort study of patients with new diabetic foot ulcers who were followed, on a monthly basis, until healing, death, major amputation or up to a maximum of 1 year. Ulcers were treated according to international guidelines. Patient, foot and ulcer characteristics were obtained at baseline, and data on minor amputations were collected on a monthly basis. Multiple logistic regression models were used to compare the probabilities of healing between those subjects who underwent vs. those who did not underwent a minor amputation. These analyses were first adjusted for the differences between patients in time at which minor amputations took place (model 1) and then for characteristics previously identify to be independently associated with minor amputation (i.e. male sex, depth of the ulcer, peripheral artery disease and infection, model 2) and further for additional characteristics also previously identified as independent predictors of healing in this cohort (model 3).
Results: Within the follow-up period 194 patients (22%) underwent at least one minor amputation; overall healing rate was 77%. Patients who underwent a minor amputation were more likely to heal than those who did not: OR=1.69 (95%CI: 0.98-2.92, model 1). After taking into account the baseline differences, between these 2 groups, in independent correlates of minor amputation, the odds of healing were 2.63 times greater (95%CI: 1.47-4.70) among subjects who underwent minor amputation than those who did not (model 2). Further adjustments for other characteristics known to independently determine healing only slightly attenuated these odds: OR=2.53 (95%CI: 1.39-4.59).
Conclusion: Performing a minor amputation is associated with a higher probability of healing as compared to conservative treatment of diabetic foot ulcers. Nevertheless, for every individual diabetic patient with a foot ulcer the choice for conservative treatment or minor amputation should be made taking into account the potential short- and long term burden, risks and benefits.
The Eurodiale study was supported by the EC (5 FP Grant QLG4-CT-2002-01524)

Diabetic foot disease and reduction of major amputations in Italy: results of an Italian 5-year study (2001-2005)
R. Anichini[1], F. Lombardo[2], C. Caravaggi[3], A. DeBellis[1], M. Maggini[2];
[1]Internal Medicine, Diabetes Unit, Pistoia, [2]Epidemiology, Istituto Superiore di Sanità, Rome, [3]Diabetic Foot Unit, Abbiategrasso Milano, Italy.

Background and aims: Until now in Italy clear data on the incidence of amputation rate in diabetic subjects compared to non diabetic subjects , as well as on the hospitalization rate for diabetic foot problems are not available. Moreover the amount of peripheral arterial disease and relative vascular procedures has not been well evaluated yet. In the present study we present accurate and complete data on hospitalization for diabetic foot (ulcers, gangrene, diabetes-related lower extremity amputations (DRLEAs) and non diabetes-related lower extremity amputations (non-DRLEAs) in Italy over a 5 -year period (2001-2005).the data base for this study was taken from Italian Register of DRG (ICD9-CM ed 2002), containing information regarding all hospital admissions for diabetic patients, including diabetic foot problems occurred during years 2001-2005.

Results: From 2001 to 2005 in Italy the hospitalization rate (HR) (for all causes) for diabetes patients significantly increased from 9.2 (in 2001) (x 1000 inhabitants) to 10.24 (in 2005): in these years the prevalence of diabetes increased from 3.9 (x 100 inhabitants) in 2001 to 4.2 (x 100 inhabitants)(Italian National Health data base). In table 1 is shown the hospitalization rate (per 100,000 inhabitants) of diabetic population; in years 2001 - 2005 hospitalization for ulcers increased by 42%; gangrene by 28% and hospitalization for peripheral arterial occlusive disease by 27%. In the same period of time it was observed that, while minor amputations were increased, major amputations seemed to show a linear trend to reduction. The ratio between DRLEAs and non-DRLEAs was in these years about 75%. Moreover, in 2001 the total number of vascular procedures was 4549 (2285 endovascular peripheral revascularization angioplasty and 2264 surgical procedures peripheral bypass); in 2005 the total number of vascular procedures rose to 10325 with a significant increase of peripheral angioplasty (7735) in comparison with surgical procedures.
Hospitalization rate= patients recovered at least once a year for a specific pathology/ inhabitants
Conclusion: In the study period (2001-2005) in Italy the incidence rate of major DRLEAs was decreased.These results could be possibly explained with the implementation of Diabetic Foot Care occurred in Italy since1999, following the publication of International Consensus on Diabetic Foot. It is notable the increasing amount of peripheral angioplasty as a diagnostic-therapeutic approach in the peripheral arterial occlusive disease. This finding provides support for the critical role of revascularization in diabetic foot disease and we expect this technique has become even more feasible in the last years.

Table1	2001	2002	2003	2004	2005
Peripheral arterial occlusive disease :	42.0	47.8	50.3	52.4	53.5
Diabetic foot Ulcers	22.2	26.3	29.1	30.2	31.6
Gangrena	13.0	15.4	16.0	16.5	16.7
Peripheral amputations*:					
minor	4.8	5.6	6.0	6.7	6.7
major	3.3	3.7	3.8	3.6	3.5
total	8.4	9.8	10.2	10.6	10.6

*Traumatic and neoplastic amputations are not included , minor: ICD9 8411-8412, major: ICD9 8413-8419

A multiprofessional project to reduce the incidence of lower-limb amputation in the diabetic population

C. Lemaire[1], J. Caron[2], J. Coquart[3], A. Boulogne[1], H. Topolinski[1], F. Wibaux[1], C. Gillot[1], L. Clement[4];
[1]Diabetology, Germon et Gauthier Hospital, Bethune, [2]Endocrinology, General Hospital, Calais, [3]Quality Department, Germon et Gauthier Hospital, Bethune, [4]Réseau Prevart, Bethune, France.

Background and aims: Many diabetic patients develop peripheral vascular disease that, when severe, may require lower-limb amputation (LLA). To avoid LLA, educational and therapeutic handling must be proposed. Since 2003, action plan to reduce the incidence of LLA was performed in the country of Bethune (North of France, 250 000 h). This action plan includes: vocational training of podiatrists, nurses, and medical doctors, distribution of nylon filaments for medical doctor, campaigns of detection, educational intervention program...
The purpose of this study was to examine the effects of interprofessional educational and therapeutic handling on the incidence of LLA in the diabetic population.
Materials and methods: This study was conducted in the Central Hospital of Bethune. The inclusion criteria were LLA performed because of peripheral vascular and/or neuropathy disease(s) since 1/01/2000 through 31/12/07. All patients undergoing LLA in the operating room were recorded consecutively. The anthropometric and clinical data were collected, then analyzed from Khi² or paired Student's t-test.
Results: During the 7-year period, LLA was performed on 285 patients. 213 were diabetic (65% men; age: 66.0 yrs; HbA1c: 8.3%). Since 2003, although the number of hospitalized patients in hospital increased, the number of LLA decreased year by year : 29 in 2000 vs 19 in 2007. Since 2005, the incidence of LLA was significantly reduced (1,97 0/00 000 vs 1.34 in 2007). The number of amputated patients because of peripheral vascular disease was similar; whereas the number of amputated patients with neuropathy decreased. LLA especially concerned: men > 60 years, with type 2 diabetes since more than 10 years, not controlled, with diabetic complications (e.g., retinopathy, nephropathy, ischemic cardiomyopathy...). Moreover, the patients have foot wound since more than 8 weeks. The population with peripheral artery disease was older ($p < 0.001$), their incidence of reamputation was higher ($p < 0.05$). Their LLA was often proximal ($p < 0.001$) with a higher complication rate ($p < 0.001$), and a lower prognostic ($p < 0.001$).
Conclusion: These results suggest that the multiprofessional educational and therapeutic handling have beneficial effects on the incidence of LLA in the diabetic patients with neuropathy. Further studies are necessary to verify these results.

220

Can we limit frequency of amputations in diabetic foot ulcer (DFU) patients?

G. Rosinski, A. Krakowiecki, E. Sobol, M. Kasprowicz;
Gastroenterology and Metabolic Diseases, Medical University of Warsaw, Poland.

Background: DFU clinic in Warsaw was established in 2000 and provides specialized DFU care for the whole Mazovian region (over 5 mln inhabitants).
Among 1200 patients of our DFU Outpatient Clinic (DOC) 107 were qualified for high amputations before admission but the limbs were saved. In the region covered by DOC incidence of high amputations decreased from 8.3 per 100,000 in 2006 to 7.1 in 2007.
The aim of the study was to describe the group who underwent plantar or high amputations in order to investigate possibilities of reducing frequency of amputations.
Methods: Analysis comprised 866 patients of DFU clinic in Warsaw with complete data available, including 420 patients with amputations.
Classification of DFU was based on:
• Assessment for diabetes peripheral neuropathy: neurotensimeter, monofilament, camerton
• Assessment for peripheral artery disease: ABI < 0.7 - ischemic type
• Charcot artropathy was distinguished based on clinical presentation and presence of foot bone lesions.
Amputations were classified as plantar of high (above the ankle).
Results:

Characteristics of the patients of the clinic (whole group) and of the patients with amputation

Whole group (N=866)	*Amputation group (N=420)*
Sex: 65.3% males, 34.7.% females	Sex: 74.6% males, 25.4% females
Residence: 70.0% urban, 30% rural	Residence: 80.8% urban, 19.2%rural
-Education: 37.5% primary, 50.0% secondary, 12.5% higher,	-Education: 42.9 primary, 53.0% secondary, 8.1% higher
DFU type: 60.7% neuropathic, 10.3% ischemic, 29% mixed	DFU type: 23.7% neuropathic, 39.3% ischemic, 37.1% mixed

There were 442 amputations, including 86 (19,5%) high amputations.
Frequency of amputation significantly higher:
• in patients from rural areas
• in ischemic DFU (Table 1)
Plantar amputations were significantly more frequent in case of ulcers localized in the foot areas 1 and 2 independently of the type of DFU.
Plantar amputations were more frequent on the left foot.
Localization of lesions preceding plantar amputations
The percentage of high amputations among all amputations decreased significantly from 31,9% in 2000-2001 to 14,1% in 2006-2007.
The percentage of high amputations was higher among persons with elementary education (36.2%) then among persons who completed secondary schools or university degrees (19.9%).
Conclusion: 1. Lesions localized in fields 1 and 2 often lead to plantar amputations and should be closely followed.
2. Less educated people may require reinforced educational messages in order to prevent amputations, especially high amputations.
3. Population of rural areas may have poor access to specialized care and may profit from telemedicine.

221

The mortality of patients with acute Charcot foot compared to patients with neuropathic ulcers and the normal population

F. Game, J. Van Baal, W. Jeffcoate;
Foot Ulcer Trials Unit, Nottingham, United Kingdom.

Background and aims: The mortality associated with the acute Charcot foot is not clear, and its assessment is made difficult by the rarity of the condition and the influence of population selection on those managed in specialist centres. Two studies have previously reported that mortality is very low: Armstrong et al reported no deaths in a population of 55 patients, with a mean follow-up of 92.6 weeks while Fabrin et al noted just two deaths in a retrospective study with a total of 115 patients followed for a mean of 48 months. On the other hand, we have previously reported much higher mortality in a series of 47 patients who presented between 1980 and 2000. These patients were compared with an equivalent population, referred with neuropathic ulceration. 44.7% of patients with Charcot died after 3.7 years mean follow-up, compared with 34.0% died of those with neuropathic ulcers, after a similar follow-up period, but these were not significantly different. The purpose of this study was to attempt to confirm our previous findings in a more recent population attending in the same specialist centre. We have therefore reviewed a population presenting with an acute Charcot foot, and compared the outcome in a matched population with neuropathic foot ulcers.
Materials and methods: Details of all patients with an acute Charcot foot and newly referred to our multidisciplinary service between 2000 and 1st October 2007 were extracted from the specialised foot clinic database, and survival checked against the hospital master patient index. The results were compared with those from a population referred with a neuropathic foot ulcer first referred over the same time, and matched for age, gender and diabetes duration and also a matched normal population derived from normative UK data .
Results: A total of 70 (70% Type 2 diabetes, mean age 57.4 (SD ±12) years; 68.8% male) patients presented with an acute Charcot foot to our multidisciplinary service. There were 66 matched patients with neuropathic foot ulcers. By 1 October 2008, 13 (18.6%) patients with a Charcot foot had died (8 men) at a mean age of 61.7±11.5 years and after a median of 2.1 (95% CI 0.5-5.6) years. 22 (33.3%) patients in the control group had also died (20 men) at mean age of 65.1±11.0 years, and after a median of 1.3 (0.2-5.6 years (p=0.13). Kaplan-Meier survival analysis was performed. Log rank tests for the equality of the survivor function for the Charcot and control patients showed no significant difference between groups (p=0.17). When the two cohorts (1980 to 2000 and 2000 to 2007; 117 patients with acute Charcot and 113 controls)were combined, the median time to death in the Charcot patients was 3.7 (95% CI 0.09-14.9) years and there was no different from the control ulcer patients: 2.7 (0.2-15.5) years (p=0.57). Kaplan-Meier survival analysis similarly showed no difference between the 2 groups (p=0.81). The median survival of a matched normal population derived from normative UK data was 22.3 (CI 19.4-25.3) years, compared with 7.9 (5.1-11.8) and 8.4 (6.0-9.8) years in Charcot and neuropathic ulcer groups, respectively (p<0.001).
Conclusion: These data confirm the high mortality in patients with an acute Charcot foot, and also show that mortality is equally high in those with neuropathic foot ulcers. The high mortality in both groups may relate to an increased prevalence of arterial calcification associated with neuropathy, and the effect of arterial calcification on pulse pressure and cardiovascular mortality.

222

Serum levels of osteoprotegerin are raised in diabetic peripheral neuropathy and are significantly correlated with peripheral arterial calcification

M.E. Edmonds[1], A. Korzon-Burakowska[1], R. Saldana Chaparro[2], T. Dew[2], S. Stock[2], C. Moniz[2], N.L. Petrova[1];
[1]Diabetic Foot Clinic, [2]Department of Clinical Biochemistry, King's College Hospital, London, United Kingdom.

Background and aims: The osteoprotegerin (OPG) signalling pathway has been linked with diabetic neuropathy. The aim was to measure serum OPG in diabetic patients with and without neuropathy and to investigate its possible association with vibration perception threshold as a marker of large fibre neuropathy and with the presence of peripheral arterial calcification on foot and ankle radiographs.
Materials and methods: We studied 45 patients with diabetic neuropathy, 88 patients without neuropathy and 22 healthy controls. Serum levels of osteoprotegerin were measured using ELISA (Biomedica, Austria). All patients had palpable foot pulses. Large fibre neuropathy was assessed by measuring vibration perception threshold (VPT) at the apex of the hallux and the mean of both feet was calculated. A subset of 38 patients was also assessed for the presence of peripheral arterial calcification on foot and ankle x-rays.
Results: Serum OPG was significantly raised in patients with diabetic neuropathy compared with patients without neuropathy (5.1 pmol/l [3.8-6.1] versus 3.9 pmol/l [3.0-4.9], p=0.005; median [25th-75th percentile]) and also compared with healthy controls (5.1 pmol/l [3.8-6.1] versus 2.9 pmol/l [2.6-3.8], p<0.001). Overall, serum OPG levels were positively correlated with the mean VPT (r= 0.262, p=0.009). In the subset of 38 patients, serum OPG was significantly correlated with the presence of peripheral arterial calcification (r= 0.445, p=0.005) as well as the mean VPT (r=0.253, p=0.012). Serum OPG was raised in both type 1 and type 2 diabetic neuropathic patients. In type 1 diabetes, serum OPG was significantly raised in patients with neuropathy compared with patients without neuropathy (5.0 pmol/l [3.9-5.7] versus 3.8 pmol/l [2.9-4.6], p=0.042) and also compared with healthy controls (5.0 pmol/l [3.9-5.7] versus 2.9 pmol/l [2.6-3.8], p<0.001). Furthermore, in type 2 diabetes serum OPG was raised in patients with neuropathy compared with patients without neuropathy (5.5 pmol/l [3.4-6.6] versus 4.0 pmol/l [3.2-4.9], p=0.05) and also compared with healthy controls (5.5 pmol/l [3.4-6.6] versus 2.9 pmol/l [2.6-3.8], p<0.001).
Conclusion: Serum OPG is raised in both type 1 and type 2 diabetic patients with neuropathy. Furthermore, serum OPG is significantly correlated with peripheral neuropathy and peripheral arterial calcification.

Serum Fibroblast Growth Factor 21 in human obesity: regulation by hyperinsulinaemia and relationship with energy expenditure and glucose and lipid oxidation

M. Straczkowski, I. Kowalska, A. Nikolajuk, A. Adamska, M. Karczewska-Kupczewska, A. Lebkowska, E. Otziomek, M. Gorska;
Department of Endocrinology, Diabetology and Internal Medicine, Medical University of Białystok, Poland.

Background and aims: Recent studies suggested that Fibroblast Growth Factor 21 (FGF21) might increase glucose uptake in adipocytes and reduce plasma glucose and triglycerides in animal models of diabetes. The aim of the present study was to assess serum FGF21 concentration in lean and obese subjects, its regulation by hyperinsulinemia and relationship with insulin sensitivity, resting energy expenditure (REE) and glucose and lipid oxidation.
Materials and methods: We examined 85 subjects with normal glucose tolerance, 42 lean (BMI <25 kg/m^2, 19 males and 23 females) and 43 overweight or obese (BMI between 25 and 40 kg/m^2, 20 males and 23 females). Euglycemic hyperinsulinemic clamp was performed in all subjects. In 28 participants, 14 lean and 14 obese, serum FGF21 was also measured after clamp. In 48 subjects, 25 lean and 23 obese, indirect calorimetry was performed in the baseline state and during last 30 minutes of the clamp. An increase in respiratory quotient (ΔRQ) in response to insulin was used as a measure of metabolic flexibility.
Results: Fasting serum FGF21 did not differ between the lean and obese groups. Hyperinsulinemia resulted in an increase in serum FGF21 (p=0.024), due to an increase in the obese (p=0.022), but not in the lean group (p=0.43). In consequence, post-clamp serum FGF21 was markedly higher in the obese subjects (p=0.029). Fasting FGF21 was related to waist-to-hip ratio (r=0.35, p=0.001), triglycerides (r=0.44, p<0.0001), and REE in the baseline and hyperinsulinemic state (r=0.40, p=0.004 and r=0.34, p=0.018, respectively). Post-clamp FGF21 was associated with BMI (r=0.51, p=0.004), waist circumference (r=0.58, p=0.0007), fasting and post-load insulin (r=0.52, p=0.004 and r=0.41, p=0.029, respectively), baseline and clamp REE (r=0.46, p=0.02 and r=0.40, p=0.049, respectively) and ΔRQ (r=-0.47, p=0.01). In the obese group, additional correlations between fasting FGF21 and an increase in glucose oxidation (r=-0.53, p=0.009) and a decrease in lipid oxidation (r=0.45, p=0.025) in response to insulin was observed.
Conclusion: Our data show that serum FGF21 is associated with insulin resistance-related abnormalities of human obesity.

Angiotensin II increases insulin-stimulated whole body glucose disposal but impairs insulin-induced capillary recruitment in healthy volunteers

A.M. Jonk[1], A.J. Houben[1], N.C. Schaper[1], P.W. de Leeuw[1], E.H. Serné[2], Y.M. Smulders[2], C.D. Stehouwer[1];
[1]Dept of Medicine, Maastricht University Medical Centre and Cardiovascular Research Institute Maastricht, [2]Dept of Medicine, VUMC, Amsterdam, Netherlands.

Background and aims: Insulin induces precapillary vasodilatation and capillary recruitment, contributing to glucose uptake (↓) and blood pressure(↓) regulation. Blocking the renin-angiotensin system (RAS) in hypertensive subjects improves insulin sensitivity. In contrast, studies in healthy subjects have demonstrated enhanced insulin-stimulated glucose uptake with Angiotensin II (AII) infusion. Possibly, this effect is mediated via the microcirculation. In the present study we determined the effects of AII on insulin-induced microvascular function in relation to insulin sensitivity and blood pressure regulation in healthy subjects.
Materials and methods: In 18 lean healthy subjects microvascular function was examined at baseline, during insulin infusion (hyperinsulinaemic euglycaemic clamp 50mU·kg^{-1}·hr^{-1}), and during co-infusion of AII (2ng·kg^{-1}·min^{-1}) or phenylephrine (0.5μg·kg^{-1}·min^{-1}) (PE; pharmacological control). Using capillaroscopy we determined skin capillary density (n/mm^2), capillary recruitment (peak n/mm^2 during post-occlusive reactive hyperemia, PRH), and capillary density during venous congestion (n/mm^2). We determined whole body glucose uptake (WBGU, (mg·kg^{-1}·min^{-1}·pmol·L^{-1})*100) and blood pressure. All subjects were tested on a high sodium diet (220 mmol/day). In addition, we studied the pressor responses to AII and PE in seven subjects during normoinsulinaemia.
Results: Compared to the basal state, hyperinsulinaemia increased baseline capillary density (56.4±13.3 vs. 52.8±11.2 n/mm^2, P<0.01), capillary recruitment (71.7±10.3 vs. 68.7±8.7 n/mm^2, P=0.03), and density during venous congestion (82.0±13.1 vs. 80.0±12.7 n/mm^2, P<0.01). Infusion of AII, but not PE, reduced insulin-induced capillary recruitment (65.2±8.0 vs. 71.7±10.3 n/mm^2, P=0.02) and venous congestion (73.9±12.1 vs. 82.0±13.1 n/mm^2, P=0.03). AII and PE had an equal pressor response during normoinsulinemia (ΔMAP AII 14.2; PE 12.9mmHg). During hyperinsulinemia the pressor response to PE, but not to AII, was reduced (p=0.03) (ΔMAP AII 12.7; PE 5.3 mmHg). AII, but not PE infusion, augmented insulin-stimulated WBGU (2.4±0.71 vs. 2.68±0.64; P<0.01).
Conclusion: Our data indicate that insulin increases skin capillary density, skin capillary recruitment (PRH), and density during venous congestion. We found a reduction in insulin-stimulated capillary recruitment and density at venous congestion with AII, and not PE infusion. In addition, our blood pressure data indicate that AII, and not PE, affects insulin-mediated blood pressure reduction. Therefore, our data suggest possible interactions of AII with insulin signaling pathways at different levels in the (micro)circulation (i.e., at capillary level and the level of the resistance arteri(ol)es). However, despite these attenuating effects of AII on insulin-mediated capillary recruitment, AII infusion stimulated whole body glucose uptake. Because skin microcirculation is thought to be representative of that of skeletal muscle, these data suggest that AII influences glucose disposal in tissues other than skeletal muscle, and (or) that AII influences muscle glucose uptake through non-vascular effects.

225

Effect of hyperglycaemia on whole-body glucose metabolism and muscle glycogen synthase activity during physiological hyperinsulinaemia in type 2 diabetes

B.F. Vind[1], J.B. Birk[2], H. Beck-Nielsen[1], K. Højlund[1], J.F.P. Wojtaszewski[2];
[1]Department of Endocrinology and Metabolism, Odense University Hospital, [2]Copenhagen Muscle Research Centre, University of Copenhagen, Denmark.

Background and aims: In type 2 diabetes, insulin-stimulated glucose disposal (Rd) is reduced, mainly due to decreased glycogen synthesis in skeletal muscle. This has been associated with decreased insulin activation of glycogen synthase (GS). Previous investigations have suggested that hyperglycemia may compensate for these defects, although sufficient control studies were lacking. In this study, we examined the effect of hyperglycemia on insulin action on glucose metabolism and GS activity in patients with type 2 diabetes.
Materials and methods: Whole-body glucose metabolism was studied in 12 patients with type 2 diabetes and 10 lean, healthy and 10 obese non-diabetic control subjects by means of indirect calorimetry and tracers during a euglycemic-hyperinsulinemic clamp. In addition, the diabetic subjects underwent a hyperglycemic-hyperinsulinemic clamp. Muscle biopsies from m. vastus lateralis were obtained for examination of GS fractional velocity and I-form activity, which are believed to reflect the degree of dephosphorylation of GS.
Results: During euglycemia (~5.5 mmol/l), insulin-stimulated Rd, glucose oxidation, and non-oxidative glucose metabolism were reduced in the diabetic group compared to both control groups (all p<0,01). Insulin-stimulated GS activity were also lower in the diabetic group compared with the obese and lean groups (I-form activity: type 2 diabetes 28.5 ± 2.7, obese 36.2 ± 2.4, lean 38.7 ± 2.4 %; p<0.01). When the diabetic subjects were studied under hyperglycemia (9.3 mmol/l), the insulin-stimulated values of glucose metabolism were all normalized compared with the control groups, whereas the insulin activation of GS (I-form activity: type 2 diabetes 28.6 ± 2.0) remained impaired compared to the control groups (p<0.01).
Conclusion: These data confirm that hyperglycemia compensates for decreased whole-body glucose disposal in type 2 diabetes. However, in contrast to previous less well-controlled studies, normalization of insulin action on GS activity does not seem to be the cellular mechanism in skeletal muscle that contributes to the compensatory effect of hyperglycemia in type 2 diabetes.

226

Intramyocellular ATP flux is not dependent on insulin action in type 2 diabetes

E.L. Lim, M.I. Trenell, K.G. Hollingsworth, F.E. Smith, P.E. Thelwall, R. Taylor;
Newcastle Magnetic Resonance Centre, Newcastle upon Tyne, United Kingdom.

Background and aims: Mitochondrial dysfunction has been implicated in the pathogenesis of type 2 diabetes (T2D). The reduced capacity of mitochondria to produce ATP in muscle of type 2 diabetes could be a consequence of reduced insulin action and hence reduced need for ATP rather than a primary mitochondrial defect. We hypothesised that normalising the rate of glycogen synthesis by the mass action effect of hyperglycaemia would normalise ATP flux in T2D.
Materials and methods: ^{31}P magnetic resonance spectroscopy (MRS) was used for the direct in vivo measurement of the rates of intramyocellular ATP flux and inorganic phosphate (Pi) concentration whilst ^{13}C MRS was used to measure glucose storage as muscle glycogen. ^{13}C-enriched glucose (20%) was infused to clamp blood glucose. Measurements were made before and during standard isoglycaemic hyperinsulinaemic (40mU/m^2/min) clamps and hyperglycaemic hyperinsulinaemic clamps on separate days. Eleven sedentary T2D subjects (age 56 ± 2 years; BMI 29.1 ± 1.2 kg/m^2; HbA_{1c} 6.6 ± 0.2%) and five age-, BMI-, and physical activity-matched normal glucose tolerance subjects were studied.
Results: Insulin stimulated muscle glycogen synthesis was 43% lower in T2D than controls during isoglycaemic hyperinsulinaemia (glycogen increment from basal: 20.6 ± 11.2 vs. 58.8 ± 10.6 units; *p<0.05*). Under conditions of hyperglycaemic hyperinsulinaemia, both T2D and controls had increased muscle glycogen synthesis by ~2.6 fold compared to that observed under isoglycaemic hyperinsulinaemia (glycogen increment from basal: 55.2 ± 18.1 vs. 199.6 ± 43.4 units; *p<0.05*). These observations were consistent with overall glucose disposal rates (T2D: 4.79 ± 0.57 vs. 7.69 ± 0.80 and Controls: 6.73 ± 0.57 vs. 11.81 ± 1.10 mg/kg/min for iso- and hyper-glycaemia respectively; *p<0.05*). In contrast, ATP flux did not change in T2D or controls after 90 min of isoglycaemic hyperinsulinaemia (-4.2 vs. 4.2% from basal respectively). ATP flux during hyperglycaemic hyperinsulinaemia did not change in T2D (2.1% from basal) but increased by 28.5% (*p<0.05* vs. basal) in controls. The calculation of ATP flux depends upon measurement of intramyocellular Pi, and this increased to a similar extent in T2D and controls (to 4.32 ± 0.23 vs. 4.31 ± 0.27 and 4.59 ± 0.55 vs. 4.91 ± 0.47 mmol/l for iso- and hyper-glycaemia respectively).
Conclusion: These data demonstrate that the defect in insulin-stimulated intramyocellular ATP flux in T2D is not directly related to insulin-stimulated muscle glycogen synthesis.

Proteome analysis in muscle biopsies of lean, obese and obese type 2 diabetic patients

H.H. Klein[1], J. Giebelstein[1], J.W. Dietrich[1], W. Schechinger[1], G. Poschmann[2], K. Podwojski[2], K. Stühler[2], H.E. Meyer[2], K. Levin[3], H. Beck-Nielsen[3], K. Højlund[3];
[1]BG University Hospital Bergmannsheil, Bochum, Germany, [2]MPC, Ruhr University Bochum, Germany, [3]Odense University Hospital, Denmark.

Background and aims: The mechanisms of insulin resistance in obesity and diabetes are largely unknown. Here we analysed human skeletal muscle tissue using a proteomic approach with the goal to identify proteins with different expression between lean, obese and/or obese diabetic subjects. Since biopsies were obtained before and at the end of hyperinsulinemic clamps, the effect of insulin on protein expression could also be analysed.
Materials and methods: Proteome analysis was perfomed using M. quadriceps biopsies obtained before (basal, B) and at the end of 180 min glucose clamps (400mU/m^2/min, CL) from 10 lean (L; BMI 24.2±0.5), 11 obese (O; BMI 33.7±1.4) and 10 obese type 2-diabetic (OD; BMI 33.5±1.1; HbA_{1c} 7.3±0.4) patients. 50 µg protein muscle tissue lysates were labeled with CyDye fluor and expression profiles analysed by 2D-differential gel electrophoresis (2D-DIGE). For this, 31 gels were run resulting in 93 spot maps (62 individual samples and 31 internal standards). Analysis of relevant spots was performed by nano liquid chromatography electrospray ionization-MS/MS analysis (nano-HPLC/ESI-MS/MS).
Results: About 2400 individual spots were detected in all gels. Of these, 548 spots were considered relevant based on the criteria that there was at least one significant difference (t-test) and a mean difference of at least two-fold between the 6 groups of samples (basal and clamp biopsies of L, O, OD), and 95 of these proteins were identified by nano-HPLC/ESI-MS/MS (37% structural, 26% metabolic, 37% unassigned proteins). Using these criteria, between O and L 145 and 74 spots were different in the basal and clamp biopsies, respectively, and 26 in both. Of these, 10 spots have been identified (70% structural, 30% metabolic). Between OD and O 55 and 55 spots were different in the basal and clamp biopsies, respectively, with 9 being different in both. If all 31 basal and 31 clamp biopsies were compared, differences were found in 71 spots of which 8 have been identified (62.5% structural, 25% metabolic, 12.5% unassigned). Since several clinical parameters showed a considerable overlap between groups, it was also analysed in all 31 basal and clamp biopsies, respectively, whether spot volumes were correlated to these parameters. Significant correlations (spearman correlation on ranks) with clamp GDR were found in 209 and 97 spots of basal or clamp biopsies, respectively, and in 58 spots both B and CL biopsies were positively (31) or inversely (27) correlated. 15 spots have been identified (47% structural, 53% metabolic). Other significant correlations were observed with BMI (B 132, CL 43, both B and CL 16 spots), serum adiponectin (B 92, CL 116, both B and CL 31 spots), FFA concentration (B 30, CL 31, both B and CL 2 spots), basal glucose (B 73, CL 52, both B and CL 9 spots) or basal lipid oxidation (B 101, CL 55, both B and CL 19 spots).
Conclusion: Using this approach it was possible to identify proteins whose expression is associated with obesity or type 2-diabetes, respectively and proteins whose expression is influenced by a 180 min in vivo insulin stimulation. Moreover, in this relatively large data set, correlations between the abundance of proteins and clinical parameters could be analysed.

Adding exercise to a 16-week very low calorie diet increases skeletal muscle mitochondrial copy number and peak oxygen consumption in obese, insulin-treated type 2 diabetic patients

I.M. Jazet[1], M. Snel[1], A. Gastaldelli[2], M. Frolich[3], E. Ferrannini[2], J.A. Romijn[1], H. Pijl[1], D.M. Ouwens[4], A.E. Meinders[1];
[1]Endocrinology/General Internal Medicine, Leiden University Medical Center, Leiden, Netherlands, [2]University of Pisa School of Medicine, National Research Center, Italy, [3]Clinical Chemistry, Leiden University Medical Center, Netherlands, [4]Molecular Cell Biology, Leiden University Medical Center, Netherlands.

Background and aims: Loss of 50% overweight using a very low calorie diet (VLCD, Modifast®, 450 kcal/day) improves whole-body insulin sensitivity and PKB-regulated skeletal muscle insulin signalling in obese insulin-dependent type 2 diabetic (DM2) patients. This study investigates whether adding exercise to calorie restriction has additional beneficial effects, especially on skeletal muscle.
Materials and methods: Twenty-seven obese (BMI 37.2 ± 0.89 kg/m^2 (mean ± SEM)) insulin-treated DM2 patients underwent a 16-week VLCD. Thirteen of them simultaneously followed an exercise programme consisting of one-hour in-hospital training and four 30-minute training sessions on a home-bicycle weekly. Oral glucose-lowering agents and insulin were discontinued 3 weeks prior to and at the start of the VLCD, respectively. A euglycemic-hyperinsulinemic clamp with stable isotopes (6,6-2H2-glucose) combined with skeletal muscle biopsies, indirect calorimetry and peak oxygen consumption testing (VO2max) were performed before and after the intervention.
Results: Baseline characteristics between study groups were identical. Both groups lost considerable weight (-23.7 ± 1.7 kg VLCD-only vs. -27.2 ± 1.9 kg VLCD+exercise, p=NS) with the exercise-group losing more fat mass. Glycemic control improved considerably and similarly in both groups (HbA1c: VLCD-only 7.9 ± 0.2 % to 6.7 ± 0.3 %, p=0.008; VLCD+exercise 7.5 ± 0.4 % to 5.7 ± 0.2 %, p<0.0001) despite the fact that all glucose-lowering agents including insulin were withdrawn. Insulin-stimulated glucose-disposal increased equally in both study groups (15.0 ± 0.9 to 39.2 ± 4.7 µmol.min^{-1}.kglbm^{-1} VLCD-only vs. 17.0 ± 1,0 to 37.5 ± 3.5 µmol.min^{-1}.kglbm^{-1} in VLCD+exercise), as did PKB-regulated insulin signaling (PRAS40 and AS160). In contrast, skeletal muscle mitochondrial DNA (mtDNA) content increased only in the VLCD+exercise group (1211 ± 185 to 2288 ± 358, p=0.016), not in the VLCD-only group (1397 ± 240 to 1196 ± 179, p=NS). The increase in mtDNA was accompanied by an increased VO_{2max} (+6.6 ± 1.7 ml.min^{-1}.kglbm^{-1} vs. +0.7 ± 1.5 ml.min^{-1}.kglbm^{-1} VLCD-only, p=0.017)

and lower basal glucose oxidation (and hence higher basal lipid oxidation) rates and a greater increase in insulin-stimulated glucose oxidation in the VLCD+exercise group as compared to the VLCD-only group, suggesting enhanced metabolic flexibility.
Conclusion: Adding exercise to a 16-week VLCD does not have additional effects on whole-body insulin sensitivity or PKB-regulated signalling pathways. It does however preserve lean body mass, and increases skeletal muscle mtDNA content. The latter was associated with an increase in VO2max and a greater flexibility to switch between glucose and lipid oxidation.

The cost of diabetes complications: registry-based analysis of days absent from work
U. Ploug[1], J. Sørensen[2], K. Jansen[3];
[1]Novo Nordisk Scandinavia AB, Copenhagen, [2]University of Southern Denmark, Odense, [3]IMS Health, Copenhagen, Denmark.

Background and aims: As a chronic disease, many of the costs of diabetes stem from the associated complications rather then the disease itself. These add a considerable burden on health care systems across Europe. But patients, employers and society incur an additional, indirect cost trough the absence from work caused by sickness days and early retirement, yet little is known about the size of such costs. The unique Danish person identification number enables researchers to combine data from different administrative registries, including the municipal sickness benefit register that contains data on absence from work and subsidies paid. The aim of this study was to analyse the annual number of days absent from work associated with a range of complications in individuals with diabetes.
Materials and methods: 34882 adults aged 18-70 years with a history of hospital diagnosed diabetes (ICD-10 code: E10-E14) were identified from a large national sample of the Danish population (n=2.2 mio. persons (40% of the Danish population) with 6 years' hospital utilisation data). The occurrence of a complication was defined as a hospital admission with a specified diagnosis or procedure code. Data on sickness episodes with municipal subsidy (i.e. sickness periods longer than 14 calendar days) were retrieved for each individual. Those individuals in early retirement (n=9720), voluntary retirement (n=3320) and receiving social benefits (n=1335) were assumed to be absent from work the whole year. Days absent from work attributable to complications were defined as the difference in mean absence days between individuals with and without the specified complication and were calculated for the first and subsequent years after the initial episode of the recorded complication.
Results: The table shows the 10 most frequent complications in the adult diabetic population and the average attributable days of absence from work. Angina pectoris, ischemic stroke and heart failure were the three most frequent complications. Heart failure, amputation, renal disease and peripheral vascular disease were on average associated with more than three months additional absence from work during the first year and subsequent years. Ulcers and neuropathy were complications that were associated with more days absent from work during the first year than in subsequent years.
Conclusion: Diabetes complications are associated with a substantial number of additional days absent from work. The avoidance of these complications could benefit both patients and society.

Additional days absent from work assoc. with diff. compl. in diabetes patients (n=34882)

Complication	First year of complication		Subsequent years of complication	
	n with compli-cation	Additional days absent from work (95% CI)	n with #compli-cation	Additional days absent from work (95% CI)
Myocardial infarction	839	62.4 (51-71)	1419	64.9 (56-74)
Angina pectoris	1432	56.0 (47-65)	3500	71.6 (66-78)
Peripheral vascular disease	723	86.1 (73-99)	1692	91.6 (83-100)
Ischemic stroke	919	81.6 (70-93)	1905	94.7 (87-103)
Heart failure	896	95.0 (84-106)	1557	102.5 (94-111)
Renal disease	341	93.7 (75-112)	575	93.1 (79-107)
Uninfected ulcer	360	82.6 (65-100)	578	74.7 (61-89)
Infected ulcer	289	39.2 (19-59)	676	16.0 (2-29)
Neuropathy	317	38.7 (20-58)	1083	19.1 (9-30)
Amputation	325	99.2 (80-118)	422	90.2 (74-107)

The English national diabetes audit 2003-2008

B. Young[1], J. Henderson[2], B. Turner[3], R. Hillson[4];
[1]Salford Royal Hospital, [2]NHS Information Centre, Leeds, [3]Diabetes UK, London, [4]Department of Health, London, United Kingdom.

Background and aims: In England standards were established in 2003 by the Diabetes National Service Framework and subsequently by NICE guidelines for the key annual processes and treatment targets of diabetes care. To facilitate improvement towards these standards a national clinical annual audit was established concurrently.
Materials and methods: A dataset was approved by the NHS Information Standards Board and implemented in clinical information systems. Automated and manual annual data extraction systems were established by the NHS Information Centre (IC) to which data is uploaded securely and confidentially. This data is linked via a unique NHS number to hospital discharge data which is also compiled by the IC. Summary reports are produced annually and participants can also use a secure online data analysis tool.
Results: Participating clinical services collaboratively audited 253,000 patient records in 2003-4 rising to 1,420,000 in 2007-8. The audit now includes 67% of the diagnosed population or 57% of the estimated (YHPHO PBS3 model) population of people with diabetes in England. The diagnosed versus estimated ratio has improved (77% 2003-4 increased to 86% 2007-8). Care processes completion rates have improved year on year e.g. HbA1c measurement (76% 2003-4 to 91% 2007-8), retinal screening (47% 2003-4 to 69% 2007-8), while completion of all nine key processes has improved from 7% in 2003-4 to 40% in 2007-8. Treatment target achievement rates have also improved e.g. HbA1c<7.5% 53% in 2003-4 increasing to 63% in 2007-8, Cholesterol<5mmol/l 65% to 78%. However these encouraging average national figures conceal wide variations; thus in 2007-8 some health economies achieved all nine key care processes in only 16% while in others it was 63% while for glucose control in some areas only 40% of people with diabetes achieved HbA1c <7.5% in while others 72% achieved this level; and nationally the HbA1c <7.5% target was achieved in only 18% of children and young people. The pattern in respect of acute and late complications also shows national trends and local variation: thus overall the rates of DKA, MI, CVA & Major amputation have remained stable while renal failure treatment is increasing; but, for example, DKA, MI & CVA rates vary three to four fold, renal failure treatment rates vary six to eight fold and major amputation rates vary more than tenfold between localities.
Conclusion: This national quality monitoring programme is: helping local care providers accurately to benchmark against peer services; facilitating improvements in care and outcomes; and providing commissioners and policymakers with robust information about performance against the national standards. It has documented significant improvement over 5yr and the continuing extent of local variation suggests much more improvement is possible.

Appraisal and comparison of guidelines for the management of people with type 2 diabetes in eight European countries

M.A. Stone[1], J.C. Wilkinson[1], G. Charpentier[2], N. Clochard[3], U. Lindblad[4], U.A. Müller[5], J. Nolan[6], G. Rutten[7], M. Trento[8], K. Khunti[1];
[1]University of Leicester, United Kingdom, [2]Center Hospitalier Sud Francilien, Corbeil, France, [3]Scientific Institute of Public Health, Brussels, Belgium, [4]Göteborg University, Sweden, [5]Universitätsklinikum Jena, Germany, [6]St James Hospital, Dublin, Ireland, [7]University Medical Centre Utrecht, Netherlands, [8]Universita' degli Studi di Torino, Italy.

Background and aims: A wealth of evidence exists for process and outcome measures for the management of people with type 2 diabetes (T2DM); numerous guidelines have been developed internationally with the aim of transferring this evidence to clinical practice. There have been previous reports of variations between evidence based recommendations in guidelines produced in different countries. The current study is part of a research programme investigating standards of care for people with type 2 diabetes across eight countries in Europe. We aimed to compare the guidelines from these countries, including rigour of development and recommendations for clinical practice.
Materials and methods: The most recent guidelines for T2DM were identified from Belgium, England & Wales, France, Germany, Ireland, Italy, the Netherlands and Sweden. The Appraisal of Guidelines for Research and Evaluation (AGREE) instrument was used to assess the quality of each guideline in six domains: scope and purpose; stakeholder involvement; rigour of development; clarity and presentation; applicability; and editorial independence. In addition, a study-specific data collection form was developed to extract details of each guideline's recommendations for key process and outcome indicators selected for clinical relevance. Appraisal and data extraction were conducted independently by two researchers in the UK or the country of origin of the guideline.
Results: The date of publication of the guidelines ranged from 2000 to 2008. There was considerable variation in AGREE domain scores for different guidelines, including a range of 31% to 95% for rigour of development. The highest mean domain scores (from pooled results for all countries) related to reporting of the scope and purpose of the guidelines and clarity and presentation (mean score 81% for both domains). Only three guidelines (England & Wales, the Netherlands, Sweden) were given the overall assessment 'strongly recommended' by their appraisers, but the others were all rated as 'recommend with provisos or alterations'. Specific recommendations given in the eight guidelines were broadly similar but, at detailed level, there were variations, particularly in relation to the level of information provided. Specified targets ranged from <6.5% to <7% for HbA1c and from <130mmHg to <140mmHg and 80mmHg to <85mmHg for systolic and diastolic blood pressure respectively. Only half of the guidelines provided a target for BMI and only two (Belgium, Germany) included waist measurement targets. Information included in recommendations for self-management education ranged from a complete lack of detail to a comprehensive list of topics to be covered.
Conclusion: Appraisal of the current guidelines for the management of T2DM in eight European countries indicated considerable variation in respect of AGREE quality measures, including rigour of development. Although there was a substantial degree of consensus for specified targets, there were some differences at detailed level and wide variation in the amount of information provided.

Differences in the quality of diabetes care caused by social inequalities disappear after treatment in a tertiary care centre in Germany

L. Bäz, N. Müller, E. Beluchin, C. Kloos, G. Wolf, U.A. Müller;
Dept. Internal Medicine III, University Hospital Jena, Germany.

Background and aims: Low social status is associated with an increased number of diabetic late complication and higher mortality. We studied the association of social status and quality of diabetes care at entry and at last observation in a tertiary care centre in Germany.
Materials and methods: Social status and quality of care (HbA1c, blood pressure, BMI) were assessed in 582 patients (128 DM1: age 48.7y; duration of diabetes 19.7y; 51% female, HbA1c 7.4%; BMI 26.8; follow up 8,8J; 454 DM2: age 65.2y; time since diagnosis 13.7y; 45.5% female; HbA1c 7.3%; BMI 32.2, follow up 5.5y; insulin therapy 71.5%) at entry and at last observation in a large university outpatient department for endocrinology and metabolic diseases. Social status (score 3-21) was determined by three components (score 1-7 each): education, highest professional position achieved and household net income.
Results: The mean social score (SS) was 11.65 (min. 3; max. 20) in DM1 and 10.86 (3-21) in DM2. At entry patients with DM1 and the lowest SS-tertile were older (59.5 vs 47.5y; p=0.001), had a higher BMI (25.8 vs 23.0; p=0.001), diabetes duration (18.9 vs. 16.4 n.s.), a higher HbA1c (9.4 vs 8.8; n.s.), higher syst. BP (141.5 vs. 130.3; p=0.002) and higher diast. BP (86.2 vs. 78.2; p=0.001) compared to the highest SS-tertile. After a mean follow up of 8.8y differences in syst. BP (134.8 vs. 140.0; n.s.), diast. BP (85.1 vs. 84.3; n.s.) and HbA1c (7.4 vs. 7.5; n.s.) between the lowest and highest SS tertile were equalized HbA1c decreased by 0.056% per each point of social score after adjustment for diabetes duration and self monitoring (p=0.006). At entry patients with DM2 and the lowest SS tertile had a longer duration of diabetes (15.1 vs 13.1y; p=0.034), higher BMI (31.8 vs 28.7; p=0.001) and higher HbA1c (8.9 vs 8.4; p=0.022). No differences were seen regarding age (65.4 vs 66.3y; n.s.), syst. (144.9 vs. 143.2; n.s) and diast. BP (80.8 vs 82.5; n.s.). After a mean follow up of 5.5y differences in HbA1c (7.2 vs. 7.2%; n.s.) were neutralized or did not change BMI (33.3 vs 29.9; p=0.001), syst. (143.8 vs 141.7; n.s.) and diast. BP (86.2 vs 86.0; n.s.). HbA1c increased by 0.031% per each kg/m² after adjustment for SS, diabetes duration, self monitoring and dose adjustments (p=0.006).

Conclusion: Low social status is associated with worse quality of care at entry in a tertiary care centre. These differences partly disappeared after 5-9 years treatment and education in a tertiary care centre.

Relationship between HbA_{1c} and risk of micro/macrovascular complications and healthcare costs among type 2 diabetes in a US managed care cohort

M. Bron[1], K. Clements[2], N. Emptage[2], D. Taylor[2], B.J. Pandya[1];
[1]Takeda Pharmaceuticals North America, Inc., Deerfield, United States, [2]i3 Innovus, Medford, United States.

Background and aims: Poor glycemic control (>7.0%) in patients with type 2 diabetes (T2D) may increase risk of complications, leading to higher healthcare costs. This study examined the relationship between HbA1c level and diabetes-related complications and costs among T2D patients.
Methods: Using a large database of privately-insured individuals in the United States, a retrospective claims analysis was conducted on T2D patients in 2002-2003 with no history of diabetes-related complications or recent T2D medication changes. Total healthcare costs included facility, provider, and pharmacy costs. Costs of diabetes-related complications were derived from claims with an ICD code for a macrovascular (myocardial infarction, CVD, stroke, CAD, peripheral vascular disease) or microvascular (neuropathy, nephropathy, amputation, retinopathy) diabetes-related complications. Cox models assessed the association between HbA1c and risk of macro/microvascular diabetes-related complications, adjusting for patient characteristics. Patients were followed up to 3 years. General linear models (GLM) and 2-part models assessed the association between HbA1c and costs for those with 2+ years follow-up.
Results: Of the 41,182 patients with no history of diabetes-related complications, 26.8% and 44.7% developed macro- and microvascular complications, respectively. Risk of macrovascular diabetes-related complications increased 2% and risk of microvascular diabetes-related complications increased 3% for each one unit increase in HbA1c (HR=1.02, 95% CI 1.01-1.03 and HR=1.03, 95% CI 1.02-1.04, respectively). Among the 11,053 patients with 2+ years follow-up, total mean adjusted costs were 26,167 US dollars (95% CI 25,929-26,406 US dollars) and did not differ by HbA1c strata. Costs related to diabetes-related complications increased with increasing HbA1c (Figure). In the short term there was a decrease in provider costs as HbA1c increased, from 8,384 US dollars in those with HbA1c < 6.5 to 7,648 US dollars in those with HbA1c > 9.0 that was not reflected in facility and pharmacy costs.
Conclusion: Total costs did not significantly differ by HbA1c strata. With increasing HbA1c, diabetic-related complications increased coinciding with related costs, particularly for HbA1c >8.0%. While provider costs are higher for patients with better glycemic control, in the long run they may be offset by lower costs related to diabetes-related complications.

Guarding medical prescriptions in patients with renal failure: a new warning system on renal dysfunction

H. Joosten[1], C.J. Boogerd[2], R.J. Slingerland[3], T.J. Jansen[4], O. Schwantje[4], E.V. v.d.Pijl[2], H.J.G. Bilo[1];
[1]Internal Medicine, Isala Clinics, [2]Farmacology, Dispensary Boogerd-Kluin, [3]Clinical Chemistry and Laboratory Medicine, Isala Clinics, [4]Family Medicine, Isala Clinics, Zwolle, Netherlands.

Background and aims: Many guidelines stress the importance of monitoring medical prescriptions to prevent adverse drug reactions (ADR), especially in patients with polypharmacy or comorbidity, like in diabetes mellitus (DM). From data of the Dutch HARM (Hospital-Admissions-Related-to-Medication) study in 2006 an incidence of 41.000 medication-related admissions in the Netherlands was calculated (of which 19.000 possibly preventable). Renal failure appeared one of the main independent risk factors. Considering the increasing incidence of renal impairment in DM, these patients are more at risk for medication-related complications.
The aim is to optimize monitoring the adequacy of medical prescriptions in DM patients with decreased renal function in primary care, by means of automatic data processing of laboratory estimated glomerular filtration rate (eGFR) values below 40 ml/min/1.73 m^2 towards both pharmacists as well as general practitioners (GPs).
Materials and methods: From June until November 2008 a pilot study was performed in which the regional laboratory selected all patients with an eGFR ≤ 40 ml/min/1.73 m^2 (MDRD4) and biweekly informed the two participating dispensaries and six GPs. Within the study population a subgroup of patients with DM was identified. Pharmacists checked the identified patients' actual drug regimen on current contra-indications. In all these patients an alarm signal warned for low eGFR with every relevant new prescription. All signals and interventions triggered by this warning were registered.
Results: During the study period a total of 121 patients with an eGFR ≤ 40 ml/min/1.73 m^2 were registered, of whom 43 patients were treated by the participating GPs. Current medication lists were evaluated and revealed a contra-indication for 147 maintenance medications, and 204 warnings were registered on new and repeat prescriptions. Six percent (n=22) of the warnings resulted in consultation with the prescribing physician, mainly because of a suspected overdose or an absolute contra-indication in relation to eGFR. Overall, 24% of the study population had DM, with a median eGFR of 28 ml/min/1.73 m^2. In half of this subgroup the prescribed medication was not started and an alternative treatment proposed instead, due to the risks of (nephro)toxicity. This concerned antibiotics, analgetics and statins. Pharmacists advised a dose-reduction of anti-gout medication in 3 patients. One patient (eGFR 23 ml/min/1.73 m^2) on metformin changed to insulin therapy. In the overall study population mainly antibiotics, diuretics and anti-gout therapy were discontinued. Several times GPs were reminded to check on serum digoxin levels or on renal function shortly after start of new medication.
Conclusion: This pilot study shows that the introduction of a relatively simple warning system improves patient care and safety. A considerable amount of patients with a low eGFR had DM, a population vulnerable for adverse drugs reactions. This collaboration of pharmacists, clinical chemists, GPs and nephrologists resulted in a stricter medication monitoring for patients with an impaired renal function and DM.

Maturity-onset diabetes of the young in Danish and Czech families due to mutation in the insulin gene

T.W. Boesgaard[1], S. Pruhova[2], E. Andersson[1], O. Cinek[2], B. Obermannova[2], J. Lauenborg[3], P. Damm[3,4], R. Bergholdt[1], F. Pociot[1], T. Jørgensen[4,5], J. Lebl[2], O. Pedersen[1,4], T. Hansen[1,6];
[1]Steno Diabetes Center and Hagedorn Research Institute, Gentofte, Denmark, [2]Department of Pediatrics, Second Faculty of Medicine, Charles University, Prague, Czech Republic, [3]Center for Pregnant Women with Diabetes, Department of Obstetrics, Copenhagen University Hospital, Rigshospitalet, Denmark, [4]Faculty of Health Science, University of Copenhagen, Denmark, [5]Research Center for Prevention and Health, Glostrup University Hospital, Denmark, [6]Faculty of Health Science, University of Southern Denmark, Odense, Denmark.

Background and aims: Insulin gene (*INS*) mutations have recently been described as a common cause of permanent neonatal diabetes (PNDM) and a rare cause of diabetes diagnosed in childhood or adulthood. We aimed to determine the prevalence, phenotype and treatment of *INS* mutation in MODYX patients, gestational diabetes patients (GDM) and GAD65 negative type 1 diabetic patients.
Materials and methods: *INS* was sequenced in 117 MODYX patients (n = 48 Danish and n = 69 Czech), 85 patients with GDM, 37 GAD negative type 1 diabetic patients and 96 glucose tolerant individuals. All MODYX probands were from families fulfilling the conventional criteria of MODY and they were all screened negative for mutations in the MODY genes *HNF4A*, *GCK* and *HNF1A*. All women with GDM and all GAD negative type 1 diabetic patients had a positive family history of diabetes. The control group were randomly selected from the population based sampled Inter99 study.
Results: One novel heterozygous mutation c.17G>A, R6H, was identified in the pre-proinsulin gene (*INS*) in a Danish MODYX family (se figure 1). The proband was diagnosed at 20 years of age with mild diabetes and treated with diet and oral hypoglycaemic agent (OHA). His son (20 years) carried the mutation but had a normal glucose tolerance. The brother to the proband carried the mutation and was diagnosed with diabetes at 51 years of age; a daughter of the brother carried the mutation and was diagnosed with impaired glucose tolerance at the age of 26. In a Czech MODY proband a previous described R46Q mutation was found (se figure 1). The mutation co-segregates with diabetes in two affected relatives and is not present in any of three non-diabetic family members or 96 control individuals. The proband, a 17 years old girl, was diagnosed with mild diabetes at 13 years of age. The proband was treated with insulin since onset of diabetes. Her mother was diagnosed at 14 years of age with symptoms of polyuria and polydipsia and treated with insulin from the onset of diabetes. The grandmother was diagnosed with diabetes at 35 years of age and treated with OHA and insulin. No diabetogenic mutations were found in GDM women or GAD negative type 1 diabetic patients.
Conclusion: Mutations in *INS* can be a rare cause of MODY and we conclude that screening for mutations in *INS* is recommended in MODYX patients.

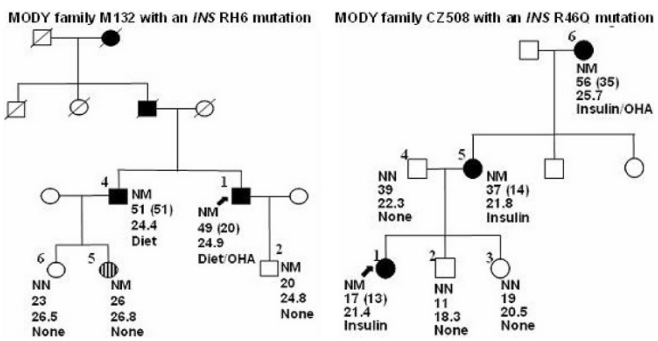

Figure 1: Pedrigrees of the MODY families with the *INS*RH6 and R46Q mutations. The symbols denote the following square: male, circle: female, empty symbol: normal grucose tolerant subject, filled symbol: diabetic subject, striated filled: impaired glucose tolerance status, symbol with arrowhead: proband. The text to each individual represents the following: Genotype, age of examination (age of diagnosis), BMI (kg/m^2) and treatment.

Mutations in the insulin gene resulting in a MODY phenotype: marked differences in clinical presentation, metabolic status and pathogenic effect through ER retention

G. Meur[1], G.A. Rutter[1], A. Simon[2], N. Harun[1], A. Dechaume[3], A. Bonnefond[3], M. Virally[4], A. Tarasov[1], T.W. Boesgaard[5], T. Hansen[5], O. Pedersen[5], J.-F. Gautier[6], P. Froguel[7,3], M. Polak[2], M. Vaxillaire[3];
[1]Division of Medicine, Imperial College, London, United Kingdom, [2]Necker Enfants Malades Hospital, Inserm, U845, Paris, France, [3]Centre National de la Recherche Scientifique-UMR8090, Institute of Biology, Lille 2 University, Pasteur Institute, France, [4]Department of Endocrinology and Diabetes, Lariboisière Hospital, Paris 7 University, France, [5]Steno Diabetes Center, Gentofte and Faculty of Health Sciences, University of Southern Denmark, Odense, Denmark, [6]Department of Endocrinology and Diabetes, Saint-Louis Hospital, Paris 7 University, France, [7]Genomic Medicine, Hammersmith Hospital, Imperial College, London, United Kingdom.

Background and aims: Heterozygous mutations in the human insulin (*INS*) gene have recently been identified as a (common) cause of non-syndromic neonatal or early-infancy diabetes. Here, we sought to identify *INS* mutations that are associated with maturity-onset diabetes of the young (MODY) or non autoimmune diabetes in mid-adult life, and to explore the molecular mechanisms involved.
Materials and methods: The *INS* gene was sequenced in 16 French Caucasian probands with MODY, but without known MODY associated mutations, 95 patients with non autoimmune early-onset diabetes (diagnosed <35 years) presented with at least one affected first degree relative, and 292 normoglycemic controls. Three identified insulin mutants were generated by site-directed mutagenesis of cDNA encoding human preproinsulin-GFP (C-peptide) chimera. GFP localisation was assessed by Nipkov spinning disc confocal microscopy and secreted proinsulin was measured by radioimmunoassay. ER stress marker mRNAs (XBP-1, BiP, CHOP) were quantitated by real-time RT-PCR.
Results: A novel mutation in the *INS* gene, L30M affecting the hydrophobic core, was identified in five individuals with early onset of diabetes (onset 17-36 years, range of BMI: 19-25.5 kg/m^2 at last examination) in a single family. In contrast to wild type preproinsulin, L30M preproinsulin-GFP fluorescence was largely colocalised with ER markers in MIN6 β-cells. Correspondingly, secretion of mutant proinsulin from HEK293 cells was significantly (p=0.0043) compromised with only 40.7% for L30M compared to 83.1% for wild type proinsulin being secreted. By contrast, a novel mutation in the signal peptide (R6H) identified in a Danish patient displayed normal targeting to secretory granules and proinsulin secretion. A previously-described mutation at the B/C junction (R55C) was also identified in a MODY proband. Whilst the patient developed diabetes at nine years and required exogenous insulin therapy, this mutation also co-segregated with diabetes in two other diabetic relatives (mother at 37 and sister at 33 years). The underlying molecular pathology of the latter is currently under study.
Conclusion: We describe three novel *INS* mutations co-segregating with early-onset diabetes in mid adult life with a clinical presentation compatible to a MODY pattern. These lead to the production of insulin molecules with markedly different trafficking properties and effects on ER stress, possibly implying distinct molecular pathological mechanisms for each.

Functional characterisation of the glucokinase regulatory protein gene variant P446L shows diminished regulation by fructose-6 phosphate resulting in increased glucokinase activity

N.L. Beer[1], N.D. Tribble[1], C. Roos[2], M. Orho-Melander[2], A.L. Gloyn[1];
[1]Oxford Centre for Diabetes Endocrinology & Metabolism, University of Oxford, United Kingdom, [2]Department of Clinical Sciences, Diabetes and Cardiovascular Disease Genetic Epidemiology, Lund University, Lund, Sweden.

Background and aims: Genome wide association scans and subsequent fine mapping have identified a common SNP rs1260326 (c.1403 c>t, p.P446L) associated with raised triglycerides and lower fasting plasma glucose levels in the general population. Individuals homozygous for the risk allele (L) have on average a 0.15 mmol/L increase in triglyceride levels and a 0.06 mmol/L reduction in fasting glucose levels compared to individuals with 2 copies of the wild-type allele (P). Glucokinase regulatory protein (GKRP) inhibits glu-

cokinase (GCK) activity in liver by binding competitively with respect to its substrate glucose. GKRP is regulated by the phosphate esters fructose 6- and fructose 1-phosphate (F6P and F1P), which enhance or diminish its inhibition of GCK activity, respectively. We hypothesised that variant P446L-GKRP could have a reduced ability to inhibit GCK, thus resulting in increased glycolytic flux and glucose uptake in liver.

Materials and methods: Recombinant human GCK, and both wild-type (WT) and P446L GKRP preparations were made (n = 3 independent protein preparations for both regulatory proteins). GCK kinetic activity was determined spectrophotometrically using an $NADP^+$-coupled assay. P446L-GKRP and WT-GKRP inhibition of GCK activity and regulation by F1P and F6P were determined. Activity/mg was calculated for each GKRP preparation and experiments carried out using either the same activities or equimolar concentrations of protein of WT and P446L-GKRP. One GKRP unit was defined as that causing 50% inhibition of 10 m-units/ml GCK under standard assay conditions in 5mM glucose at 37°C.

Results: Assays matched for protein activity/mg showed no difference in dose-dependent inhibition of GCK activity with WT and P446L-GKRP over a glucose concentration range of 0-100mM. There was also no difference in F1P-mediated regulation at concentrations up to and including 500μM (92.8 ± 1.2% GCK activity for WT vs. 93.6 ± 1.4% for P446L-GKRP; means ± SEM; n = 18; P = 0.24). However, regulation by 25-500μM F6P was significantly attenuated with P446L-GKRP (31.9 ± 2.6 to 23.3 ± 1.0% vs 28.5 ± 2.8 to 21.2 ± 0.8% for WT; n = 18; P = 0.03). Experiments using equimolar concentrations of both WT and P446L-GKRP confirmed that, there was no difference in F1P-mediated inhibition of the 2 regulatory proteins at concentrations up to 500μM (92.5 ± 2.6% GCK activity for WT vs. 90.1 ± 1.8% GCK activity for P446L; n = 9; P = 0.20), and that the response of P446L-GKRP to 0-500μM F6P was significantly diminished compared to WT (71.9 ± 1.4 to 33.8 ± 3.1% vs. 63.7 ± 2.6 to 14.1 ± 1.2% respectively; n = 9; $P = 4x10^{-11}$).

Conclusion: P446L-GKRP has diminished F6P regulation at physiological concentrations of this phosphate ester resulting in increased GCK activity. This is predicted to increase glycolytic flux in the liver, promoting both increased glucose metabolism and elevating concentrations of malonyl-CoA. Since malonyl-CoA is both a substrate for *de novo* lipogenesis and an inhibitor of carnitine-palmitoyl transferase-1, increased concentrations would be predicted to inhibit fatty acid oxidation and therefore channel fatty acyl-CoA into triglyceride synthesis.

Investigating novel mutational mechanisms for glucokinase mutations with near normal or paradoxical kinetics

N.D. Tribble[1], N. Beer[1], J. Grimsby[2], S. Baltrusch[3], A.L. Gloyn[1]; [1]OCDEM, Oxford University, Headington, United Kingdom, [2]Hoffmann-La Roche Inc., Department of Metabolic Diseases, Nutley, United States, [3]Institute of Medical Biochemisty and Molecular Biology, Rostock University, Germany.

Background and aims: Heterozygous inactivating mutations of glucokinase (*GCK*) increase the threshold for glucose stimulated insulin secretion to around 7mmol/L and result in elevated fasting plasma glucose levels (>5.5mmol/L) causing maturity-onset diabetes of the young (MODY) subtype glucokinase (GCK). Functional studies have identified a number of *GCK* mutations (A53S, G72R, H137R, G264S G299R and V367M) where routine kinetics has failed to explain the GCK-MODY phenotype. It is therefore possible that there are alternative mechanisms involved that explain the pathogenic effects of these mutations. We hypothesised that defects in regulation by GCK activators and inhibitors could be a novel mutational mechanism. The aim of our study was to kinetically examine these 6 mutations in the presence of 3 different GCK regulators: a synthetic small molecular activator, human glucokinase regulatory protein (GKRP) and the bi-functional enzyme PFK-2/FBPase-2.

Materials and methods: Recombinant human islet wild-type GCK and the selected mutations were expressed in the form of glutathione S-transferase (GST) fusion proteins. Kinetics in the presence of the 3 different regulators was determined spectrophotometrically using an NADP+ coupled assay with glucose-6-phosphate dehydrogenase.

Results: As expected, all of the mutant GCK enzymes showed near normal kinetics, with relative activity indices ranging from 0.76 to 1.58 relative to wild type. The G72R mutant was the only enzyme that failed to respond to either the GCK activator (fold increased activity of 0.96 vs 16.95 ± 1.1 [WT] at 60μM) or GKRP (decreased activity of 1.03 ± 0.04 vs 3.55 ± 0.43 fold [WT] at 200nM). This is consistent with previous reports on G72R. When using PFK-2/FBPase-2, G72R showed the lowest response of all 4 mutants (G72R activity increased by only 1.6 ± 0.02 fold [n=4] with 200μM, significantly less [p>0.005] than WT 2.0 ± 0.03 [n=16]). This lack of response to the activator may reflect a defect in binding which could have additional consequences for GCK catalytic stability.

Conclusion: This is the first study examining the response of mutant A53S, H137R, G264S G299R, V367M proteins to regulators of GCK. Only the G72R enzyme showed a marked lack of response to all GCK regulators compared to wild type GCK. This study gives further insight into the importance of GCK residue G72 in the activation of GCK by the bi-functional enzyme and suggests that the binding site could lie within this region. Our data supports the existence of alternative mutational mechanisms (e.g. post-translational or transcriptional mechanisms yet to be determined) which are responsible for the hyperglycaemia in patients with these *GCK* mutations.

Loss-of-function mutations in SIM1 cause a specific form of Prader-Willi-like syndrome

F. Stutzmann[1], M. Ghoussaini[1], C. Couturier[1], M. Marchand[1], V. Vatin[1], L. Corset[1], C. Lecoeur[1], B. Balkau[2], F. Horber[3], D.J. Driscoll[4], A.P. Goldstone[5], J. Weill[6], J.L. Michaud[7], D. Meyre[1], P. Froguel[1,8]; [1]CNRS-UMR8090, Lille, France, [2]INSERM U780, Orsay, France, [3]University of Berne, Klinik Lindberg, Switzerland, [4]Department of Pediatrics, College of Medicine, Gainesville, United States, [5]Metabolic and Molecular Imaging Group, Imperial College London, United Kingdom, [6]Pediatric Department, University Hospital, Lille, France, [7]Research Center, Hôpital Sainte Justine, Montreal, Canada, [8]Genomic Medicine, Hammersmith Hospital, Imperial College, London, United Kingdom.

Background and aims: In mice, haploinsufficiency of SIM1 induces hyperphagic obesity, the chromosomal abnormalities in the SIM1 region have been rarely described in children with syndromic obesity. However, the involvement of this transcription factor in syndromic and monogenic obesity has never been conclusively demonstrated in humans.

Materials and methods: We sequenced the SIM1 coding region in 44 children affected by the Prader-Willi syndrome-like (PWSL) and 246 patients with severe familial obesity (BMI ≥ 40 kg/m² for adults and BMI ≥ 97th percentile for age and gender for children). Familial cosegregation studies and functional analysis evaluated whether mutations had a loss-of-function effect causing obesity.

Results: Four non-synonymous mutations (Q152E, E458K, R581G and T714A) were identified in four Prader-Willi syndrome-like cases and the H323Y mutation was found in two obese sisters. The five mutations led to a significant decrease in SIM1 transcriptional activity (range of residual activity: 20.4-53.5%) in reporter assay analysis. None of these mutations were identified in a further 3,896 non-obese individuals and 3,543 obese patients. We then carefully assessed the syndromic phenotypes of the PWSL patients (4 probands and 5 relatives with available data) and observed features that are characteristic of SIM1-deficiency: a round face, a small nose, depressed nasal bridge, prominent philtrum and narrow palpebral fissure. None of the patients was hypotonic at birth but 6/9 were hyperphagic, all displayed mental retardation. Six of them also had behavioural troubles and five had development retardation. In contrast to 15q PWS and to 6q chromosomal abnormalities-related syndrome short hands were not observed in SIM1-deficient subjects and hypogonadism was anecdotal (2/7).

Conclusion: Mutations responsible for SIM1 haplo-insufficiency have been found in 9% of our PWSL children. They are characterized by a specific spectrum of syndromic phenotype that may help for diagnosis. Screening of SIM1 mutations may take part in further diagnosis procedures, complementing cytogenetics.

The use of 1,5 anhydroglucitol level as a clinical test to differentiate subtypes of diabetes

K.R. Owen[1,2], A. Pal[1,2], C. Dudley[1,2], M.P. Selwood[3], R. Klyne[4,2], B. Barrow[1,2], J.P. Grew[1,2], A.J. Farmer[3,2], M.I. McCarthy[1,2], A.L. Gloyn[1,2];
[1]Diabetes Research Laboratories, University of Oxford, [2]Oxford NIHR Biomedical Research Centre, [3]Department of Primary Health Care, University of Oxford, [4]Diabetes Trials Unit, University of Oxford, United Kingdom.

Background and aims: Assigning the correct molecular diagnosis in Maturity-onset diabetes of the young (MODY) informs prognosis and treatment, but currently requires genetic resequencing. It would be advantageous to identify biochemical tests which aid prioritisation of samples for genetic testing. 1,5 Anhydroglucitol (1,5AG) is a monosaccharide which undergoes renal tubular re-absorption. Glucose competes for re-absorption at the same carrier, so with glycosuria, 1,5AG serum levels decrease. Recently, it was shown that patients with HNF1A-MODY (who have low renal glucose threshold) have lower 1,5AG levels than patients with Type 2 DM (T2DM) matched for glycaemic control. We aimed to investigate 1,5AG levels in a wider range of diabetes subtypes and evaluate its role in clinical diabetes diagnostics.
Materials and methods: Serum 1,5AG was analysed in subjects with: HNF1A-MODY (n=23); GCK-MODY (n=24); Type 1 diabetes (T1DM, n=29); latent autoimmune diabetes of adulthood (LADA, n=42); and T2DM (n=206). Data were log-transformed and ANOVA and pairwise comparisons calculated. ROC curve analysis was performed to assess the discriminative accuracy of 1,5AG with regard to diabetes aetiology.
Results: No difference in 1,5AG levels were seen between patients with HNF1A-MODY and T2DM (p=0.15), T1DM (p=0.97) or LADA (p=0.5), although after correcting for HbA1c 1,5AG levels were lower in patients with HNF1A-MODY compared to T2DM (p=0.001).
1,5AG levels in patients with GCK-MODY were higher than all other groups. Means [SD range] in μg/ml were: GCK-MODY 13.06 [5.74-29.74]; HNF1A-MODY 4.23 [2.12-8.44]; T1DM 3.09 [1.45- 6.57]; LADA 3.46 [1.42- 8.45] and T2DM 5.43 [2.12-13.23], $p<10^{-4}$ for GCK-MODY v.s. each group.
The discriminative accuracy of 1,5AG levels (as per ROC curve analysis) was 0.80 for GCK-MODY v.s. T2DM, 0.86 for GCK-MODY v.s. HNF1A-MODY, but only 0.60 for HNF1A-MODY v.s. T2DM.
Conclusion: Our data suggests that 1,5AG levels are unlikely to be useful in differentiating HNF1A-MODY from T2DM in a clinical setting. In this dataset 1,5AG levels performed well in discriminating GCK-MODY from all other subtypes. The higher 1,5AG levels in GCK-MODY are likely explained by the known modest post-challenge glucose increment. This requires replication in undifferentiated sample sets, but suggests measurement of 1,5AG could help inform decisions regarding diagnostic testing for GCK-MODY.

Plasma insulin and glucagon responses to a maximal hyperglycaemic stimulus and arginine infusion in subjects with impaired glucose tolerance and type 2 diabetes mellitus

V. Chavez, R. Guardardo-Mendoza, C.V. Iannucci, F. Folli, S. Kamath, R.M. Jhingan, R.A. DeFronzo, D. Tripathy;
Medicine/Diabetes, UTHSCSA, San Antonio, United States.

Objective: Progression from impaired glucose tolerance (IGT) to type 2 diabetes mellitus (T2DM) is determined by beta cell failure to compensate for increased insulin resistance. However, the natural history of these islet abnormalities remain poorly defined. Though, impaired glucagon suppression following a test meal has been reported in T2DM, glucagon response to a maximal hyperglycemic stimulus and non-glucose stimulus Arginine in IGT is not clear.
Methods: We assessed glucagon suppression and release under maximal glycemic and non-glycemic (arginine)-stimulated conditions in subjects with NGT (n=13, age=42±4 y, BMI=28±2, HbA_{1c}=5.1±0.1%), IGT (n=12, age=52±2 y, BMI=33±1, HbA_{1c}=5.8±0.1%) and T2DM (n=15, age=53±3 y, BMI=34±1, HbA_{1c}=8.1±0.2%) individuals. Each subject received OGTT and two (+125 and 400 mg/dl) hyperglycemic clamp followed by IV Arginine (5 grams) bolus. Insulin, C peptide and glucagon were measured q 15 min during OGTT and q 2-10 min during hyperglycemic clamp.
Results: Acute insulin response (AIR_{0-10}) was decreased in IGT vs. NGT (252 ±47 vs. 323±59 μU/ml) and further reduced in T2DM (14±8 vs. 323±59 μU/ml, p<0.001). Second phase insulin response (AUC_{10-80}) was similar in NGT and IGT (2717 ±605 vs. 2921 ± 608 μU/ml) and markedly decreased in T2DM (633±180 μU/ml, p<0.001). During the hyperglycemic second step AUC_{80-160} was similar in IGT and NGT (5261±1300 vs. 6282 ±2300 μU/ml), but reduced in T2DM (1105 ±250 μU/ml, p<0.001). After adjusting for insulin resistance (Matsuda index), the insulin secretion/insulin sensitivity index ($AIR_{0-10,}$ $AUC_{10-80,}$ AUC_{80-160}) was significantly diminished in both IGT and T2DM vs. NGT (all p<0.001). Glucagon suppression during fist step (AUC_{10-80}) was impaired by 69% (-114 pg/ml) in IGT and 71% (-108 pg/ml) in T2DM vs. NGT (-363 pg/ml). Similar defects in glucagon suppression were observed during the second clamp step in IGT and T2DM (both p<0.01). In contrast, arginine elicited a 2.0-and a 2.6-fold greater increase in glucagon secretion in IGT and T2DM (both p<0.001) vs. NGT.
Conclusion: Regulation of glucagon suppression and release is impaired in IGT, as well as T2DM, indicating early dysregulation of alpha cell physiology, in addition to impaired beta cell function in the natural history of T2DM.

242

Effects of variations in duodenal glucose load on glycaemia, insulin and GLP-1 in type 2 diabetes

C.K. Rayner[1,2], J. Ma[1,2], A. Pilichiewicz[1,2], C. Feinle-Bisset[1,2], H.L. Checklin[1,2], J.M. Wishart[1,2], K.L. Jones[1,2], M. Horowitz[1,2];
[1]Discipline of Medicine, Royal Adelaide Hospital, [2]Centre of Clinical Research Excellence in Nutritional Physiology, Interventions and Outcomes, The University of Adelaide, Australia.

Background and aims: The postprandial incretin response has been reported to be deficient in type 2 diabetes (T2D), but most studies have not controlled for variations in the rate of gastric emptying. We evaluated the glycaemic, insulin and glucagon-like peptide-1 (GLP-1) responses to intraduodenal (ID) glucose in patients with T2D, and compared these to our previous data from 10 healthy controls (HC).
Materials and methods: 8 males with well-controlled T2D (age 57 ± 4 yrs; BMI 26.5 ± 1.4 kg/m^2; glycated haemoglobin 6.2 ± 0.3 %), managed by diet alone, were studied on four separate occasions in single-blind, randomized order. Data were compared to HC (age 32 ± 4 yrs; BMI 25.1 ± 0.4 kg/m^2). Blood glucose and plasma hormones were measured during 120 min ID glucose infusions at (i) 1 ("G1"), (ii) 2 ("G2"), and (iii) 4 ("G4") kcal/min, or (iv) saline control ("S"). Data are presented as mean ± SEM.
Results: Results are summarized in the figure. T2D patients had higher basal (P < 0.0001) and incremental (P < 0.0001) blood glucose responses to each glucose load, compared to HC. In HC, there was no significant difference between the glycaemic response to G2 and G4, whereas in T2D, blood glucose was greater after G4, compared to G2 (P < 0.005). In both groups, the

increases in insulin and GLP-1 to increasing glucose loads were not linear; responses to G1 and G2 were minimal, whereas the responses to G4 were much greater than to G1 and G2 (P = 0.0001 for each). In T2D, the insulin responses to both G2 and G4 were greater than HC (P < 0.05 for each).
Conclusion: In patients with well-controlled T2D, blood glucose, insulin, and GLP-1 responses are critically dependent on the duodenal glucose load, and GLP-1 responses are not deficient, when compared to HC.

The role of GLP-1 in the enteroinsulinar axis in type 2 diabetes mellitus
A. Bedorf, G. Kutscherauer, M. Nicolaus, B. Göke, J. Schirra;
Department of Internal Medicine II, Campus Großhadern, University of Munich, Germany.

Background and aims: The incretin effect as part of the enteroinsulinar axis constitutes the difference between the total postprandial (PP) and the isoglycemic fasting insulin response. The insulinotropic gut born hormones GLP-1 and GIP account for the incretin effect in healthy humans. The incretin effect is reduced in type 2 diabetes mellitus (T2DM). Because several studies have indicated a failure of synthetic GIP to stimulate insulin secretion in T2DM in contrast to GLP-1, a defect of the GIP action has been suggested.
To quantify the contribution of endogenous GLP-1, we examined the insulinotropic action and the incretin effect of an oral glucose tolerance test (OGTT) in patients with T2DM during GLP-1 receptor blockade using exendin(9-39) (Ex-9).
Materials and methods: Double-blind, placebo-controlled, randomized, cross-over study in 24 patients with T2DM (61±7 y, HbA1c 6.2±0.2, BMI 27.7±0.9). On two separate days blood glucose and plasma insulin concentrations were measured during the four hours after ingestion of an OGTT (75g) with and without an intravenous background infusion of Ex-9 (900 pmol/kg/min) or saline. This dose of Ex-9 blocks the insulinotropic effect of GLP-1 in human by at least 95%. On two further days the blood glucose excursions obtained during the OGTTs were mimicked by intravenous glucose (isoglycemic clamp). The incretin effect was calculated as the difference between the postprandial and the isoglycemic fasting plasma insulin concentrations.
Results: During fasting, Ex-9 increased blood glucose concentrations (120±4.3 vs 132±5.4 mg/dl, saline vs Ex-9, P<0.001) without change in plasma insulin. In addition, after ingestion of the OGTT Ex-9 increased the mean PP blood glucose excursion (77±5 vs 84±5 mg/dl, P=0.038) and the PP incremental glucose peak (156±5 vs 167±6 mg/dl, P=0.008). In spite of increasing PP glucose, Ex-9 decreased the mean PP plasma insulin excursion significantly (MPI, 32±6 vs 26±4 µU/ml, P=0.007). The isoglycemic clamps mimicked postprandial glucose excursions of the OGTTs with R^2=0.932±0.009 under saline and R^2=0.943±0.008 under Ex-9, respectively. The calculated PP incretin effect amounted to 18.6±3.4 µU/ml under saline control (59±5% of MPI) which was significantly reduced but not eliminated under Ex-9 (10.5±1.7 µU/ml, 44±4% of MPI, P=0.005 vs saline).
Conclusion: In patients with T2DM, endogenous GLP-1 significantly reduces fasting and postprandial glycemia. Because of its insulinotropic properties GLP-1 contributes to the postprandial incretin effect in T2DM patients. However, similar to healthy subjects, GLP-1 accounts for only about 50% of the PP incretin effect in T2DM. We suggest, that GIP accounts for the remaining incretin effect in T2DM. Since the relative contribution of GLP-1 and non-GLP-1 incretins is preserved in T2DM we suggest that the reduced incretin effect in T2DM may represent a general failure of the B-cell rather than a specific defect of the enteroinsulinar axis.

Glucagon responses to increasing oral loads of glucose and corresponding isoglycaemic i.v. glucose infusions in patients with type 2 diabetes and healthy subjects
F.K. Knop[1], J.O. Bagger[2], A. Lund[2], H. Vestergaard[2], J.J. Holst[3], T. Vilsbøll[1];
[1]Department of Internal Medicine F, Gentofte Hospital, [2]Department of Endocrinology, Herlev Hospital, [3]Department of Biomedical Sciences, The Panum Institute, Copenhagen, Denmark.

Background and aims: Type 2 diabetes mellitus (T2DM) is associated with inappropriate glucagon response (hypersecretion and delayed and reduced suppression) to 50-g OGTT whereas isoglycaemic i.v. glucose infusion (IIGI) results in a completely normal glucagon response in these patients. This suggests that glucagonotropic signaling originates from glucose stimulation of the gastrointestinal tract. Therefore, we aimed to evaluate glucagon responses to increasing amounts of glucose given orally and IIGIs in patients with T2DM and in control subjects.
Materials and methods: Glucagon responses were measured on six separate days during three 4-hour OGTTs with increasing loads of glucose (25 g, 75 g

and 125 g) and three corresponding IIGIs in 8 patients with T2DM (age: 57±4 years; BMI: 29.5±1.0 kg/m^2; HbA_1c: 7.0±0.3% (mean±SEM)) and 8 healthy subjects (age: 57±4 years; BMI: 28.9±0.7 kg/m^2; HbA_1c: 5.4±0.1%).
Results: Isoglycaemia corresponding to the OGTTs was obtained during i.v. challenges. In the control subjects no difference in glucagon suppression during the first 60 minutes of the 25-g OGTT and the corresponding IIGI (-249±49 *vs.* -208±35 pM·1h; *p*=NS) was observed. Contrary, patients with T2DM exhibited significant glucagon suppression only following the IIGI (-2±36 *vs.* -228±29 pM·1h; *p*=0.006). At higher oral glucose loads this difference increased and became evident in healthy control subjects also (Table 1)
Conclusion: In patients with T2DM increasing amounts of orally ingested glucose (25, 75 and 125 g) elicit progressively inappropriate glucagon responses as compared to IIGIs, which result in normal glucagon suppression. This is also observed in control subjects when ≥75 g glucose is ingested orally, suggesting it to be a physiological phenomenon which has deteriorated pathologically in T2DM.

Table 1. Values are mean iAUC (0-60 min) for plasma glucagon responses (pM•1h) ± SEM

Development of an *in silico* model to extrapolate whole body glucose - insulin homeostasis by altering tissue specific effects, simulation of SGLT-2 inhibition in type 2 diabetes
N.R. Hill, J.C. Levy, D.M. Matthews;
Oxford University, United Kingdom.

Background and aims: The inhibition of gut and renal sodium-glucose co-transporters (SGLTs) has been proposed as a novel therapeutic approach for the treatment of diabetes. SGLT-2 inhibitors acutely induce renal glucose excretion by a change in the renal threshold. HOmeostatic Model Assessment (HOMA) is a model based on the interaction of organs or tissues (liver, muscle, pancreatic beta-cells, brain, gut) represented by equations derived from empirical data. It has become an international standard for measuring beta-cell function and insulin resistance in large studies where detailed physiology is not possible. We have developed an interactive Homeostatic Model of Assessment (iHOMA) in which the parameters of the individual models are modifiable through an onscreen interface using visual analogue controls. The iHOMA model can be used for *in silico* calculations of the specific effects drugs may have on glucose metabolism. The aim was to mathematically model the effect of an SGLT-2 inhibitor in patients with Type 2 diabetes (T2DM) using the iHOMA program.
Material and methods: A total of 428 patients (239 Male) with T2DM were retrospectively analysed from the Diabetes in Families (DIF) study. The DIF study was a population-based collection of patients with T2DM and their siblings sampled from GP practices in Oxfordshire and Northamptonshire. Although patients were on a variety of drugs none of these were likely to interfere with their renal glucose excretion. They had a mean BMI 30.4 (±5.6) kg/m2 , mean age 62(±11) years, mean HbA1c 7.9 (±1.6), mean Fasting Plasma Glucose(FPG) of 9.6 (±3.1) mmol/l and geometric mean Fasting Plasma Insulin (FPI) of 112.0 (range 65.8 - 190.5) pmol/l. Beta-cell function and insulin resistance were calculated for each subject using HOMA and used as inputs into the interactive model. The iHOMA program was developed by the authors at the University of Oxford and has been validated against the original HOMA algorithms. The iHOMA program was used to mathematically simulate the effect of an SGLT-2 inhibitor enhancing glucose excretion by the kidneys. FPG and FPI were then calculated for each subject using iHOMA adjusted for the effects of the SGLT-2 inhibitor.
Results: Using the iHOMA program, which can account for tissue-specific glucose metabolism effect, the simulated whole body effect by altering renal excretion of glucose was moderate. A paired-sample t-test revealed a significant difference in the mean FPG (9.6 vs. 8.9, p<0.01) mmol/l a decrease of 0.7 mmol/l. The FPG change in concentration was accompanied by a change in the geometric mean FPI (112.0 vs. 99.3, p<0.01) pmol/l, a decrease of 12.7 pmol/l.
Conclusion: The development of the iHOMA program enables the investigation of pharmacological effects of a novel therapy on glucose metabolism *in silico*. The model suggests that SGLT-2 inhibitors have the potential to effect a moderate change in glucose in people with T2DM. However, it is important that these data are replicated and validated in a prospective randomised control trial.

Reduced amylin (IAPP) secretion in response to hyperglycaemia and arginine are characteristic of impaired glucose tolerance and type 2 diabetes
D. Tripathy, R. Guardardo-Mendoza, A.O. Chavez, F. Folli, C.V. Iannucci, R.M. Jhingan, R.A. DeFronzo;
Diabetes, Medicine, University of Texas Health Science Center, San Antonio, United States.

Objective: Islet amyloid deposition is a characteristic feature of T2DM. Islet amyloid polypeptide (IAPP) is co-secreted with insulin, but its secretion profile and relationship to other islet hormones (insulin, C-peptide) in response to glucose and non-glucose stimulus has not been clearly defined.
Methods: Forty subjects, 13 NGT (age=42, BMI=28±2, HbA1c=5.1±0.1%), 12 IGT (age=52, BMI=33±1, HbA1c=5.8±0.1) and 15 T2DM (age=53, BMI=34±1, HbA1c=8.1±0.2) received OGTT and 2 steps hyperglycemic (+125 and +400mg/dl) clamp followed by IV arginine (5g) bolus. The acute insulin (AIR), C-peptide (ACPR) and IAPP (AIAR) responses during each hyperglycemic step and following arginine (AIR_{Arg}) were assessed and Matsuda index of insulin sensitivity was calculated from OGTT.
Results: As expected, AIR and ACPR during both hyperglycemic steps (0-10 and 80-90 min) and after arginine (160-170 min) progressively decreased from NGT to IGT to T2DM. Fasting IAPP concentrations were 13±3, 9±1 and 16±3 pM in NGT, IGT and T2DM. Incremental IAPP AUC from 0-10 min of the clamp was 46±6, 37±17 and -5±8pM (p<0.05) in NGT, IGT and T2DM, and IAPP response to hyperglycemia + arginine was 271±72, 507±69 and 186.2±11 pM (p<0.05), respectively. The ratio of IAPP/C peptide during the first 10 min of hyperglycemia was higher in T2DM (3.9±0.5) and IGT (3.0±0.4) than NGT (2.0±0.2) (p<0.05) subjects, but after prolonged (80 min) and severe hyperglycemia (160 min) as well as after arginine stimulus (160-166 min) it was lower in T2DM versus NGT and IGT. The acute amylin response ($AIAR_{0-10}$) correlated with $ACPR_{0-10}$ (r=0.665, p<0.001), AIR_{0-10} (r=0.543, p<0.001), FPG (r= -0.508, p<0.005) and 2-h glucose (r= -0.571, p<0.005).
Conclusion: In conclusion, early IAPP secretion (0-10min) is higher in T2DM and IGT vs NGT but is reduced in response to prolonged hyperglycemia and arginine. IAPP/C-peptide ratio is higher during early hyperglycemia but with more prolonged and severe hyperglycemia it is decreased in T2DM. Defects in IAPP processing and secretion may lead to amyloid deposits and beta cell dysfunction in T2DM.

247

Central GLP-1 receptor antagonism partially reduces the action of peripheral GLP-1 to improve insulin sensitivity in high-fat-fed mice

E.T. Parlevliet, J.E. de Leeuw van Weenen, J.A. Romijn, H. Pijl;
Endocrinology, LUMC, Leiden, Netherlands.

Background and aims: Continuous infusion of glucagon-like peptide-1 (GLP-1) improves insulin sensitivity in both humans and rodents. The improvement of insulin sensitivity may result solely from GLP-1's actions in the periphery by a direct impact on tissues like muscle and fat. On the other hand, compelling evidence supports a role for the GLP-1 receptor (GLP-1R) in the brain in modulating glycemic control. Here, we evaluated the role of the central GLP-1R in improving insulin sensitivity in diet-induced insulin resistant mice.
Materials and methods: High-fat-fed insulin resistant C57Bl/6 mice were implanted a cannula in the lateral cerebral ventricle, which was connected to an osmotic minipump for the continuous delivery of the GLP-1R antagonist exendin-9 (EX-9) or cerebral spine fluid (CSF). After 5 days recovery a second minipump was implanted for the continuous s.c. delivery of GLP-1 or PBS. After 2 weeks of intervention a hyperinsulinemic euglycemic clamp was performed to monitor insulin sensitivity.
Results: The rate of glucose infusion necessary to maintain euglycemia was significantly increased by GLP-1 when compared to control animals (CSF/PBS: 17 ± 10; CSF/GLP-1: 43 ± 9 µmol/min/kg; P<0.01). Blocking the central GLP-1 receptor in combination with continuous GLP-1 infusion diminished the effect on GIR by 38% (EX-9/GLP-1: 27 ± 11 µmol/min/kg; P<0.01 vs. CSF/GLP-1). Central GLP-1R antagonism alone did not affect GIR compared to controls (EX-9/PBS: 20 ± 13 µmol/min/kg). GLP-1 treatment significantly increased insulin's action to stimulate glucose disposal compared to both CSF/PBS and EX-9/PBS mice (CSF/PBS: 30 ± 17; CSF/GLP-1: 54 ± 21; EX-9/PBS: 31 ± 16 % from basal; P<0.05). Central Ex-9 infusion tended to diminish the capacity of GLP-1 to stimulate insulin mediated glucose disposal (EX-9/GLP-1: 40 ± 18 % from basal, p=0.22 vs. CSF/GLP-1). GLP-1 reinforced the capacity of insulin to suppress endogenous glucose production (CSF/PBS: 24 ± 22; CSF/GLP-1: 65 ± 24; EX-9/PBS: 34 ± 25 % from basal), and central GLP-1 receptor antagonism tended to diminish this effect of GLP-1 (EX-9/GLP-1: 43 ± 26 % from basal; P=0.061 vs. CSF/GLP-1).
Conclusion: Activation of central GLP-1 receptors partially mediates the effect of peripheral GLP-1 administration to beneficially impact on insulin action in insulin resistant mice.

Effect of replacing pre-meal insulin for exenatide on body weight, insulin secretion and hepatic/muscle fat in well-controlled insulin-treated patients with type 2 diabetes

K. Cusi[1,2], C. Mendoza[1], M. Mathew[1], J. Chen[1], A. Gastaldelli[1], J. Lynch[1], C. Darland[2];
[1]The University of Texas H.S.C. at San Antonio, San Antonio, United States, [2]The Veterans Affairs Medical Center, San Antonio, United States.

Background and aims: Intensive insulin therapy with long-acting basal plus rapid-acting pre-meal insulin may lead to optimal glycemic control in patients with type 2 diabetes mellitus (T2DM) at the expense of weight gain and an increased risk of hypoglycemia. Exenatide, a GLP-1 receptor agonist known to lower postprandial and day-long plasma glucose in T2DM, may help avoid these side effects while maintaining good metabolic control. However, this has not been carefully studied and little is known about the mechanisms that are involved when combining insulin plus exenatide. Therefore, we investigated in well-controlled T2DM patients on basal long-acting insulin the impact of replacing rapid-acting pre-meal insulin with exenatide twice daily.
Materials and methods: We recruited 24 patients with T2DM (age=58±3, gender=21/3 (M/F), BMI=32.8±4.4 kg/m^2, FPG=121±35 mg/dl, A1c=7.1±0.9%) well-controlled after 6 months of insulin detemir plus pre-meal insulin aspart (INS). While all patients continued insulin detemir, the pre-meal insulin was discontinued and replaced with exenatide twice daily for 6 months (INS+EXE). Before and after treatment all patients were admitted to the research unit for the following metabolic measurements: 1) plasma glucose/insulin secretion during a 4-hour mixed meal and during a day-long metabolic profile (day 1); 2) insulin secretion during a hyperglycemic clamp (day 2; exenatide given only on day 1 and not the morning of the test); 3) plasma hsCRP levels; 4) liver (LFAT) and intramyocellular (IMCL) fat content by magnetic resonance spectroscopy (MRS).
Results: Adding exenatide to insulin detemir insulin (INS+EXE; results available in 17) allowed to maintain similar glycemic control after 6 months (A1c: 7.1±0.9%vs. 6.8±0.7%; NS), even as pre-meal rapid-acting insulin was discontinued (42±5 units). The mean insulin detemir dose at bedtime was no different at the end of the study. Use of INS+EXE was associated with a substantial reduction in body weight (-4.6 kg±1.1, p<0.001). During the 4-hour mixed meal, mean plasma glucose (190±9 vs. 138±7 mg/dl) and the glucose increase above baseline (83± 8 vs. 32±8 mg/dl, p<0.001) were both significantly lower after INS+EXE compared to INS (both p<0.001). During the hyperglycemic clamp, second phase insulin secretion increased significantly with INS+EXE (+19%; p<0.05) compared to insulin treatment. INS+EXE significantly reduced systemic inflammation as plasma hsCRP concentration decreased by 50% from 3.8±0.9 to 1.9±0.5 mg/L (p<0.04 vs. INS). Liver fat by MRS (data available in 12 patients) was reduced by 17% (from 12.1±1.3 to 10.0±1.1%; p=0.09) but intramyocellular lipids were unchanged (from 0.79±0.1 to 0.74±0.1%; NS). INS+EXE was well tolerated. Adverse events: INS+EXE was not associated with clinically significant hypoglycemia; 3 patients reported mild nausea that resolved within 4 weeks.
Conclusion: In well-controlled insulin-treated T2DM patients, replacement of pre-meal rapid acting insulin for exenatide twice daily is well accepted and allows equivalent glycemic control to intensified basal/pre-meal insulin therapy. Beneficial features of INS+EXE include significant weight loss, enhancement of insulin secretion, amelioration of systemic inflammation and reduction hepatic steatosis.

Glucose-dependent insulinotropic polypeptide leads to upregulation of inflammatory cytokines and calcitonin peptides in human adipocytes involving the PKA pathway

K. Timper, J. Grisouard, H. Zulewski, K. Dembinski, T. Radimerski, M. Fischer, U. Keller, B. Müller, M. Christ-Crain;
Department of Biomedicine, Division of Endocrinology, Diabetology and Clinical Nutrition, Basel, Switzerland.

Background and aims: Glucose-dependent insulinotropic polypeptide (GIP), a 42-amino acid peptide, is released from entero-endocrine K-cells upon nutrient ingestion. Plasma GIP levels are increased by high-fat diet and GIP has recently been shown to directly promote fat accumulation in adipocytes via a specific GIP receptor. Inhibition of GIP signalling in mice was able to prevent the development of obesity-induced diabetes. Adipose tissue produces proinflammatory cytokines such as interleukin (IL)-1β and IL-6 which are involved in obesity related insulin resistance. We have shown recently that upon inflammatory stimulation adipose tissue expresses CALC-I gene products including procalcitonin (Pro-CT) and calcitonin gene-related peptide (CGRP). Now we hypothesized that GIP is a mediator of low grade inflammation by increasing production of inflammatory cytokines and subsequently calcitonin peptides. In addition we assessed the question whether the GIP effects were mediated via the protein kinase A (PKA) pathway.
Materials and methods: Human preadipocytes obtained from surgical biopsies and preadipocyte-derived adipocytes were exposed to human GIP recombinant peptide GIP(1-42) (1h, 1nM), the GIP receptor antagonist GIP(6-30) (pre-incubation 15min, 10µM) as well as H-89, a PKA inhibitor (pre-incubation 1h, 20µM) and their combinations. mRNA-expression of IL-1beta, IL-6, Pro-CT and CGRP were analyzed by real-time PCR. CGRP protein concentrations were determined in supernatants by human-specific radioimmunoassay kits.
Results: In GIP-treated preadipocytes, mRNA-expression of IL-6, IL-1β, Pro-CT and CGRP was not altered. In differentiated adipocytes, 1h GIP-treatment increased mRNA-expression of IL-6 to 255%±41% of control (p<0.001). IL-6 expression was reduced by GIP(6-30) to 29%±3% (p<0.001) and by H-89 to 47.93%±8% (n.s.) of GIP alone. GIP (1nM) increased mRNA-expression of IL-1β to 145%±37% of control (n.s.) and was not significantly reduced by GIP(6-30). Induction of CT mRNA-expression to 1433%±17% of control (p<0.001) due to GIP (1nM) treatment was down-regulated to 10%±4% (p<0.001) by pre-incubation with GIP(6-30) and to 70.26%±11% (n.s.) by H-89, respectively. CGRP expression was increased to 187%±57% (P<0.01)

by GIP-stimulation and reduced to 53.77%±12% (p<0.01) by GIP(6-30) and to 3.44%±2% (p<0.001) by H-89. Measurement of CGRP-protein release revealed an induction to 170%±50% (p<0.01) due to GIP treatment.
Conclusion: These data demonstrate the potential of GIP to induce mRNA expression of pro-inflammatory cytokines and CALC-I gene products in human adipocytes involving the PKA-pathway. This indicates a potential role of GIP in the initiation of low grade inflammation in obesity and related insulin resistance and might represent an "entero-adipose-axis".

Effects and mechanism of glucagon-like peptide-1 on injury of mice cardiomyocytes induced by hypoxia-reoxygenation
Y. Xie, W.-W. Sha, X. Zhou, W.-L. Wang, L.-P. Han, D.-Q. Li, D.-M. Yu; Metabolic Disease Hospital, Tianjin Medical University, China.

Background and aims: Although the insulinotropic role of glucagon-like peptide-1 (GLP-1) in type 2 diabetes mellitus has been substantiated, its role in cardioprotection remains largely unknown. This study aimed to determine effects of GLP-1 on injury of mice cardiac myocytes induced by hypoxia-reoxygenation (H/R) and possible mechanisms.
Methods: The cultured neonatal mice cardiac myocytes were randomly divided into seven groups: normal control group, H/R group, GLP-1+H/R group, GLP-1+H/R+UO126 group, GLP-1+H/R+LY294002 group, H/R+UO126 group, H/R+LY294002 group. Lactate dehydrogenase (LDH) activity, apoptosis rate of cardiac myocytes, caspase-3 activity were detected after the injury of H/R.
Results: Compared with normal control group, the activity of LDH , cardiac myocyte apoptosis rate ,caspase-3 activity all increased significantly in H/R group (p<0.01). Compared with H/R group, these three indexes all decreased in H/R+GLP-1 group (p<0.01). However those changes of LDH activity, apoptosis rate, caspase-3 activity were inhibited by LY294002 (phosphatidylinositol 3-kinase inhibitor, PI3K inhibitor) and UO126 (mitogen-activated protein kinase inhibitor, MAPK inhibitor) respectively.
Conclusion: GLP-1 can directly act on cardiac myocytes and protect them from H/R injury mainly by inhibiting their apoptosis,the mechanism of which may be concerned with GLP-1's effects on apoptosis or anti-apoptosis may be through phosphatidylinositol 3-kinase (PI3K)-Akt pathway and mitogen-activated protein kinase (MAPK) signaling pathway.

Exendin-4 stimulates proliferation of human coronary artery endothelial cells through eNOS- and PI3K/Akt-dependent pathways but independently of GLP-1 receptor
Ö. Erdogdu[1], D. Nathanson[2], Å. Sjöholm[2], T. Nyström[2], Q. Zhang[1]; [1]Department of Clinical Science and Education, [2]Department of Clinical Science and Education, Division of Internal Medicine, Södersjukhuset, Karolinska Institutet, Stockholm, Sweden.

Background and aims: We previously showed that human coronary artery endothelial cells (HCAECs) express the glucagon-like peptide 1 (GLP-1) receptor and that GLP-1 ameliorates endothelial dysfunction in type 2 diabetic patients with coronary heart disease. Exendin-4 is a stable GLP-1 receptor agonist and has been approved for clinical use against type 2 diabetes. In contrast to its effect on metabolism and endothelial function, the role of GLP-1 and its analogue on endothelial cell growth is not known. In the present study, we have investigated the effect of Exendin-4 on cell proliferation and its underlying mechanisms in HCAECs *in vitro*.
Materials and methods: HCAECs were incubated with Exendin-4 (10 nM), GLP-1 (7-36) (100 nM) or the major GLP-1 metabolite GLP-1 (9-36) (100 nM), respectively, in serum-deficient medium in the presence of 5 mM glucose for 48 h. Phosphorylation and expression of endothelial nitric oxide synthase (eNOS) and Akt were examined after 48 h incubation by Western blotting using anti-phospho-eNOS (Ser1177), anti-eNOS, phospho-Akt (Ser 473) and anti-Akt antibodies, respectively. ^{3}H-thymidine incorporation was assayed in 96-well plates as a measure of DNA synthesis after 48 h incubation. Cell viability was assessed using Trypan blue exclusion.
Results: Incubation of HCAECs with Exendin-4 for 48 h resulted in a dose-dependent increase in DNA synthesis; subsequent neogenesis was confirmed by an increased cell number. To investigate the roles of eNOS and PI3K in the Exendin-4 induced proliferation, the specific eNOS inhibitor L-NAME and the PI3K inhibitor LY294002 were used. The Exendin-4 induced proliferation was completely abolished by L-NAME and significantly suppressed by LY294002. Western blot showed that Exendin-4 dose-dependently stimulated phosphorylation of eNOS. The Exendin-4-stimulated activation of eNOS was associated with an increased NO production and was blocked by L-NAME or LY294002. Application of GLP-1 (7-36) or its major metabolite GLP-1 (9-36) also resulted in eNOS activation, to same extent as Exendin-4 alone. The effect of Exendin-4 on eNOS activation was further examined in the presence of GLP-1 (7-36). Results from Western blotting revealed that Exendin-4 induced eNOS phoshorylation was unaffected by co-incubation with GLP-1 (7-36). The GLP-1 receptor antagonist Exendin (9-39) alone suppressed the basal phosphorylation of eNOS. However, co-incubation of Exendin (9-39) with Exendin-4 did not interfere with the Exendin-4 induced eNOS phosphorylation. In addition, incubation of HCAECs with Exendin-4 caused an increased Akt phosphorylation, an effect which was inhibited by LY294002.
Conclusion: Our results suggest that Exendin-4 stimulates proliferation of human coronary endothelial cells. The effect of Exendin-4 seems to be GLP-1 receptor-independent and is mediated through the PI3K/Akt and eNOS activation pathways. The beneficial effects of Exendin-4 on human coronary artery endothelial cells add yet another salutary property to incretin-based antidiabetic therapy, increasing its clinical utility in type 2 diabetic patients in whom endothelial dysfunction is a salient feature that adversely affect their survival.

Impairment of synaptic plasticity and learning in GLP-1 receptor knockout mice: interaction between type 2 diabetes and Alzheimer's disease
P.L. Mc Clean[1], T. Abbas[1], E. Faivre[1], D.J. Drucker[2], C. Hölscher[1]; [1]School of Biomedical Sciences, University of Ulster, Coleraine, United Kingdom, [2]Banting and Best Diabetes Centre, University of Toronto, Canada.

Background and aims: Type 2 diabetes is a known risk factor for Alzheimer's disease (AD), with impairments in insulin signalling contributing to neurodegeneration. The incretin hormone Glucagon-like peptide-1 (GLP-1) has been shown to normalise insulin signalling in type 2 diabetes. Importantly, GLP-1 also plays a role in neuronal activity and brain functions. The aim of this study was to elucidate the specific role of GLP-1 receptors in synaptic plasticity and cognitive processes in the GLP-1 receptor knockout (GLP-1R KO) mouse model.
Materials and methods: Male GLP-1R KO mice and age-matched, control, wild-type (WT) animals with the same C57/Bl6 genetic background were used to assess exploratory behavior and learning and memory in open field, object recognition and spatial water maze tasks. Long term potentiation (LTP), was measured in GLP-1R KO and WT mice, in area CA1 of the hippocampus using a high frequency stimulation protocol.
Results: In open field assessment a small increase in speed of movement in GLP-1R KO mice (p<0.05) was observed. GLP-1R KO animals also exhibited slightly reduced anxiety levels (p<0.05), compared with WT controls. In an object recognition task GLP-1R KO animals displayed similar exploratory behavior to WT mice, but failed to differentiate between novel and familiar objects (p<0.05). No impairment was detected in an object relocation task. In a water maze task, GLP-1R KO mice were impaired in the acquisition phase (p<0.001) and in the probe trial (p<0.05). LTP in area CA1 of the hippocampus was severely impaired in GLP-1 KO mice (p<0.0001). Paired-pulse facilitation was also impaired at 25ms interstimulus interval (p<0.05), but not at intervals of increasing duration.
Conclusion: These results demonstrate that lack of GLP-1 receptor function impairs synaptic plasticity and some forms of learning and memory formation. They show that GLP-1 receptor signalling plays a specific role in neurotransmission and cognition. GLP-1 receptors appear to play a role in synaptic activity and neurotransmitter release, similar to the effects on insulin release in beta-cells. The results also help to explain previous results that show neuroprotective effects of GLP-1 analogues in models of Alzheimer's disease.

PS 1 Genetics of type 1 diabetes

253

Bayesian network to investigate the dependency and interaction between HLA, INS, PTPN22 and CTLA4 genes in type 1 diabetes

R.A. Portuesi[1], L. Lausser[2], M.L. Spoletini[3], S. Zampetti[3], A. Petrone[3], B. Boehm[2], H.A. Kestler[4], P. Pozzilli[1], R. Buzzetti[3];
[1]University Campus Bio-Medico, Rome, Italy, [2]Internal Medicine I, University Hospital of Ulm, Germany, [3]University "La Sapienza", Rome, Italy, [4]Institute for Neural Information Processing, University of Ulm, Germany.

Background and aims: Type 1 diabetes (T1D) is a multifactorial and polygenic disease with four major susceptibility genes (HLA (DR/DQ), CTLA4, INS, PTPN22) that by interacting with each other and with environmental factors, determine disease onset. These genes are known to be involved in immune regulation whereas INS modulates insulin expression in human thymus. The incidence rate of T1D is increasing uniformly in Italy with an annual average increase of 3.6%. The genetic profile of individuals who develop diabetes appear to change in countries with a high T1D incidence shifting from predominantly high-risk HLA genotypes towards higher percentage of median and low-risk HLA genotypes. The aim of this study was to investigate in T1D.
Materials and methods: Genetic data (HLA, PTPN22, INS, CTLA4) were analysed from a group of 391 T1D patients and 100 controls (M/F 1.06, age 1-41) diagnosed by participating centres of the IMDIAB group in continental Italy. Diagnosis of T1D was based on the ADA classification criteria. The control group was recruited from the Blood Transfusion Service in Rome. We divided HLA alleles in high, moderate and low risk for T1D, CTLA4 and PTPN22 alleles in susceptibility/non susceptibility alleles, and INS gene alleles in susceptibility/protection. We estimated a Bayesian network to study dependencies and interactions between the different alleles in relationship to group status. Bayesian networks, also called belief networks, are probabilistic graphical models that represent a set of variables and their probabilistic dependencies. In the present study the model was trained on genetic variables and group status (T1D / control). A hill climbing algorithm was used for fitting the model.
Results: The frequency of the HLA genotypes with high, moderate and low risk was 18.9%, 55.2% and 25.8% in T1D patients (2%, 5%, 93% in controls). The model shows that group status is directly influenced by HLA ($p = 1.4*10^{-30}$) and INS ($p=3.0*10^{-8}$), and that there is a dependency of INS on HLA ($p = 3.0*10^{-5}$). For high, moderate and low risk HLA corresponding conditional frequencies of 0.74, 0.76 and 0.55 for INS susceptibility alleles were found. Separating the data group wise, leads to corresponding conditional probabilities of 1, 0.4, 0.34 for the control group and 0.73, 0.76, 0.75 for the patient group for high, moderate and low risk respectively. No significant connection between HLA and PTPN22 ($p = 0.07$) and CTLA4 and INS ($p = 0.1$) could be found.
Conclusion: This study confirms that HLA (DR/DQ) and INS susceptibility alleles are the major determinants of the disease. By analysing all 491 subjects a higher probability for INS susceptibility alleles was found in the presence of high and moderate risk HLA alleles. However, if we consider INS susceptibility alleles only in the T1D group, these are less frequent in high risk HLA alleles. Further substantiation is needed for the identification of the statistically significant conditional dependency of INS on HLA.

Both isolated type 1 diabetes and polyautoimmune beta cell failure of APS2 share the same susceptibility profile at gene loci: HLA DR, CTLA4, and INS in the T1DGC dataset

K. Badenhoop[1], H. Kahles[1], E. Ramos-Lopez[1], B. Boehm[2], T1DGC;
[1]Endocrinology, Diabetes & Metabolism, University of Frankfurt am Main, [2]Endocrinology, Diabetes & Metabolism, University of Ulm, Germany.

Background and aims: Type 1 diabetes (T1D) may occur as isolated immune mediated ß-cell disease or as part of polyglandular syndrome, mostly type 2 (APS2) where other endocrine and non-endocrine autoimmune disorders develop in the later course or are already present at T1D manifestation. These APS2 associated T1D patients often suffer from complicated metabolic control due to the comorbidities or medication. We reasoned whether the established genetic susceptibility markers differ in isolated T1D from APS2 associated T1D.
Materials and methods: Data from the RR 2008.07 dataset of the T1DGC were used to study transmission rates of the susceptible HLA DR, CTLA4 and INS alleles either to T1D only or T1D with APS2 manifestations (autoimmune thyroid disease, Addison´s disease, multiple sclerosis, vitiligo, alopecia, rheumatoid arthritis).
Results: Altoghether 5125 individuals had sufficient phenotypic and genotypic information. We identified 2820 T1D and 341 T1D/APS2 patients. In both groups a strong susceptibility was conferred by HLA DR3, DR4 (transmission rate 75.2 % and 75.7% , p=2,e-110 and 1,e-15, but no difference between the grouops) whereas DR1 and DRX were associated with significant protection. Whereas a non-significant trend was observed for the CTLA4+49 SNP in isolated T1D (p=0.0624), no difference in transmission was found in T1D/APS2 patients. The association at the INS locus however is significant only in T1D (p=1,e-15) but not in T1D/APS2 (p=0.0516) transmissions.
Conclusion: In conclusion the isolated form of T1D and the one with APS2 comorbidities do not appear to differ at major susceptibility loci. Interaction of genetic and environmental factors is therefore assumed to determine multiorgan autoimmunity in T1D patients.

HLA Class I allele B39 defines the rate of progression of autoimmunity in children with HLA-DRB1*0404-DQB1*0302 haplotype

K. Lipponen[1], Z. Gombos[1], R. Hermann[1], R. Veijola[2], O. Simell[3], M. Knip[4], J. Ilonen[1];
[1]Immunogenetics Laboratory, University of Turku, [2]Department of Paediatrics, University of Oulu, [3]Department of Paediatrics, University of Turku, [4]Hospital for Children and Adolescents, University of Helsinki, Finland.

Background and aims: HLA associated susceptibility to type 1 diabetes is mainly defined by alleles of class II DR and DQ genes but contribution of some class I alleles in A and B loci has been also demonstrated. It has been proposed, that class II genes determine the initiation of autoimmunity whereas class I genes might determine the progression of beta-cell damage. This would fit to the antigen recognition in context of class II alleles by CD4 cells initiating the immune response whereas cytotoxic CD8 cells respond to antigenic peptide presented by class I molecule. We have previously found that the risk for type 1 diabetes conferred by HLA-DRB1*0404-DQB1*0302 haplotype is dependent on the presence of HLA-B39 allele in the genotype.
Materials and methods: Children participating the Finnish Diabetes Prediction and Prevention (DIPP) study who developed at least 2 different diabetes associated autoantibodies (ICA, IAA, GADA or IA-2A) and were positive for DRB1*0404-DQB1*0302 haplotype were selected for the analysis. Children were followed at regular visits including blood samples at 3-12 month intervals since birth and at as a rule 3 month intervals since converting positive for an autoantibody. HLA-DRB1 and DQB1 alleles were defined using lanthanide labelled sequence specific oligonucleotides in microtitre plate based assay and B39 was typed using sequence specific primers for specific amplification and visualisation of the product on agarose gel. Autoantibodies were analysed using standard methods.
Results: The progression of autoimmunity after the time-point of appearance of the first autoantibody positive sample (IAA, GADA or IA-2A) was compared between children positive and negative for B39 allele. Kaplan-Meier analysis demonstrated more rapid development of clinical type 1 diabetes among children positive for B39 compared to those negative for this allele (P=0.00042). 9 of 40 (22.5%) children with B39 developed the disease compared to 5 of 114 (4.4%) children without B39. Mean survival time for B39 positive children with type 1 diabetes was 1.7 years and for B39 negative 2.4 years.
Conclusion: The result confirms the significance of this particular class I association in the progression of established autoimmunity into clinical diabetes.

256

Capture of type 1 diabetes-susceptible HLA-DR-DQ haplotypes in Japanese by tag single nucleotide polymorphisms

K. Nakanishi[1,2], C. Watanabe[1], Y. Shima[3];
[1]Dept. of General Internal Medicine and Metabolism, Toranomon Hospital, Kawasaki, [2]Okinaka Memorial Institute for Medical Research, Tokyo, [3]Laboratory of Biochemistry, Kyorin University Faculty of Health Science, Tokyo, Japan.

Background and aims: HLA-DR and -DQ loci in MHC class II region most strongly confer the susceptibility to type 1 diabetes. However, DNA typing of HLA-DR and -DQ alleles are complicated. We tried to develop the methods to identify type1 diabetes-susceptible HLA-DR-DQ haplotypes rapidly using tag single nucleotide polymorphisms (SNPs) for HLA class II alleles, and estimated the disease risk using these SNPs.
Materials and methods: A total of 211 subjects including 201 patients with type 1 diabetes (men/women: 115/86, age at onset: 34 ± 14 years, mean ± SD) and 10 patients with other diseases were typed for tag SNPs and HLA-DRB1, -DQA1, and -DQB1 alleles. In addition, 300 control subjects were typed for tag SNPs. All subjects were Japanese. Based on the report of de Bakker et al. (Nat Genet 38:1166, 2006), we chose rs2395185 (T) and rs411326 (C) as tag SNPs for DRB1*0405, rs3129888 (G) as tag SNP for DRB1*0802, rs6457617 (T) as tag SNP for DQA1*03, and rs3998159 (A) as tag SNP for DQB1*0303. These SNPs were typed by TaqMan assay. HLA-DRB1, -DQA1 and -DQB1 alleles were typed by PCR-RFLP methods.
Results: One hundred and twenty-six of 128 DRB1*0405 haplotypes had T allele in rs2395185 (sensitivity: 98.4 %), whereas only 150 of 294 non-DRB1*0405 haplotypes had G allele (specificity 51.0 %). One hundred and sixteen of 128 DRB1*0405 haplotypes had C allele in rs411326 (sensitivity: 90.6 %), whereas only 87 of 135 non-DRB1*0405 haplotypes had T allele (specificity 64.4 %). However, T allele of rs2395185 captured all DR4 haplotypes involving not only DRB1*0405 but also other DR4 specificities including DRB1*0405-DQA1*03-DQB1*0401, 0303, 0302, or 0402, DRB1*0406 -DQA1*03-DQB1*0302, and DRB1*0403-DQA1*03-DQB1*0302 etc. and all DR9 haplotypes including DRB1*0901-DQA1*03-DQB1*0303 or 0302 at sensitivity of 98.5 % (262 /266) and specificity of 94.9 % (148/156). In addition, G allele of rs3129888 captured DRB1*0802 haplotypes including DRB1*0802-DQA1*03-DQB1*0302 and DRB1*0802-DQA1*0401-DQB1*0302 or 0402 at sensitivity of 92.3 % (24/26) and specificity of 99.0 % (390/394). As for haplotypes involving DQA1*03, sensitivity of T allele of rs6457617 was 98.9% (282/285), but specificity was only 64.4 % (87/135). Sensitivity of A allele of rs3998159 for capturing DRB1*0303 haplotypes was 99.1 % (108/109), but specificity was only 17.4 % (51/311). Frequency of T allele of rs2395185 was increased in patients with type 1 diabetes (64.4 %, 259/402) compared with normal controls (38.7 %, 232/600, p<0.0001) [Odds ratio (95% confidence interval) (OR: 95% CI): 2.87 (2.21-3.74)]. When GG genotype of rs2395185 was regarded as reference group, OR (95% CI) for developing type 1 diabetes in TT or GT genotype of rs2395185 was 9.49 (5.37-17.3) (p<0.0001) or 2.72 (1.65-4.62) (p<0.0001), respectively. On the other hand, frequency of G allele of rs3129888 did not differ between patients with type 1 diabetes and normal controls [7.0 % (28/402) vs. 6.5 % (39/597), p=0.80].
Conclusion: Tag SNPs of rs2395185 and rs3129888 could capture type 1 diabetes-susceptible HLA-DR-DQ haplotypes involving all DR4 and DR9 specificities and DRB1*0802, respectively. Especially, rs2395185 showed high odds ratio enough to estimate the risk for type 1 diabetes. This is the valuable resource for screening subjects at risk in prevention trial for type 1 diabetes.

257

KIR genes confer susceptibility to type 1 diabetes in Swedish patients positive for Coxsackie virus B antibodies

S.K. Sedimbi[1], S.K. Vasan[1,2], D. Zhi[3], C.B. Sanjeevi[1];
[1]Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden, [2]Department of Endocrinology, Diabetes & Metabolism, Christian Medical College and Hospital, Vellore, India, [3]Endocrinology, Children's Hospital of Fudan University, Shanghai, China.

Background: Natural Killer (NK) cells are potent modulators of innate (and adaptive) immune responses. Killer Ig-like receptors (KIR) are a group of activatory and inhibitory receptors expressed on NK cells, which bind to specific motifs of Human Leukocyte Antigen (HLA) Class I molecules. The activation or inhibition of NK cell activity depends on the overall signal generated as a result of the dynamic balance between activatory and inhibitory KIRs. The varying KIR/HLA genotypes in each individual in a population and among different populations are a mechanism by which immune system fights pathogens. However, this might also modify susceptibility related to autoimmune diseases. KIR genes have been associated with Type 1 Diabetes (T1D) in certain populations. Several enteroviruses such as Coxsackie virus B (CVB), Ljungan virus, rota virus, mumps virus, cytomegalovirus, and rubella virus have been associated with T1D.
Aims: In the present study we had tested the hypothesis that: i) presence (or absence) of certain KIR genes along with their HLA-C ligands confers susceptibility to T1DM, and ii) KIR genes confer higher risk to T1DM in subjects positive CVB antibodies.
Subjects and methods: The study included a total 315 consecutively diagnosed new onset T1DM patients and 249 age, gender and region matched healthy controls belonged to the age group 0-14 years, collected as a part of two major studies previously done in Sweden. DNA extracted previously was whole genome amplified using REPLI-g mini kit (Qiagen, Hilden, Germany) as per the manufacturer's instructions. A quality control was performed to access the quality of the amplified DNA. The amplified DNA was tested for the presence of framework genes, KIR2DL4, KIR3DL2 and KIR3DL3. Only those samples which were positive for all the three framework genes were included in the study. KIR and HLA-C ligand genotyping was performed using PCR-sequence specific primer (SSP) methodology. The subject material has been previously tested for high risk HLA, autoantibodies to GAD65, IA-2 and IAA, CVB antibodies and alleles of MICA and SUMO4.
Results: i) KIR genes frequencies were investigated in patient and healthy control populations belonging to the age groups 0-14 years. No significant difference was observed. ii) KIR and CVB: Of the 315 T1DM patients in 0-14 year age group, 223 were previously tested for CVB antibody and 55 out of 223 were positive for CVB. KIR and HLA-C ligand frequencies were compared among CVB antibody + and CVB antibody - patients. KIR2DL5 (OR (95%CI) =1.95 (1.06-3.61) P=0.03) and KIR2DS5 (OR (95%CI) =1.94(1.03-3.66) P=0.04) were positively associated with T1DM in patients positive for CVB antibody. The combined presence of KIR2DL5 and KIR2DS5 was significantly increased in CVB antibody positive patients when compared to CVB antibody negative patients, in the 0-14 year age group (OR (95%CI) =2.11 (1.11-4.03), P= 0.02). Combined absence of KIR2DL5 and KIR2DS5 was however significantly high in CVB antibody negative patients compared to CVB antibody positive patients.
Conclusion: KIR2DL5 and KIR2DS5 are important predisposing genes in CVB antibody positive Swedish patients.

Novel polymorphism in the PTPN2 gene is associated with type 1 diabetes mellitus in Russian patients

Y.A. Seregin[1], E.Y. Lavrikova[1], A.G. Nikitin[1], L.I. Zilberman[2], T.L. Kuraeva[2], V.V. Nosikov[1];
[1]National Research Centre "GosNII genetika", [2]Endocrinology Research Centre, Moscow, Russian Federation.

Background and aims: Last generation genomic scans for type 1 diabetes mellitus (T1DM) susceptibility revealed a group of genes coding protein tyrosine phosphatases of non-receptor type (PTPNs). At least 3 members of this family (*PTPN2*, *11* and *22*) were found to be located in the regions of maximum linkage to T1D on chromosomes 18, 1 and 12, respectively. In the current study we aimed to perform a mapping of one of these genes, *PTPN2*, using tag-SNP approach, in a group of T1DM patients from Russia. The use of taq-SNPs helps to evaluate association not only for single SNPs but for linkage blocks inside the gene region.
Materials and methods: A group of 176 T1DM patients and 206 unrelated controls of Russian origin were recruited in Endocrinology Research centre, Moscow. Genotyping was performed using Taqman assays on ABI 7500 thermocycler. Allele and genotype distributions in T1DM and control subjects, significance of association and the odds ratios were calculated using SPSS 11.0 software.
Results: A set of 4 tag SNPs (rs2542151, rs2847281, rs3737361, rs547268) was designed within *PTPN2* gene and 5' and 3' flanked regions using Hapmap web site. Minimum allele frequencies for affected SNPs were assumed to be 0.2. One of these polymorphisms, rs2542151, was previously found to be highly associated with T1DM. T1DM patients and controls were genotyped for all 4 polymorphisms and for HLA DR3/DR4 susceptible haplotypes.

Analysis of genotyping data demonstrated that none of these *PTPN2* polymorphisms were in significant linkage disequilibrium and all of them were in Hardy-Weinberg equilibrium in a control group. Analysis of association revealed significant difference in allele and genotype frequencies for one of *PTPN2* polymorphisms, rs2847281, which represents *C*/*T*. Particularly, we found that allele *T* and genotype *TT* appeared more frequently in T1DM patients (73% vs. 63%, OR=1.58, Pc=0.004; 59% vs. 42%, OR=1.93, Pc=0.006, respectively). In contrast, "traditional" rs2542151 polymorphism was not associated with T1DM in Russian patients living in Moscow. In order to reduce an effect of HLA genes we calculated the difference between T1DM and control group after removal of all carriers of DR3/DR4 heterozygous genotype. We observed stronger association in this case (76% vs. 63%, OR=1.81, Pc=0.0004 for allele *T*; 63% vs. 42%, OR=2.28, Pc=0.0007 for genotype *TT*). Polymorphism rs2847281 is located in intron 5 of *PTPN2* gene and unlikely represents a functional variant. In order to assess functional significance of association we searched for known polymorphisms being in strong linkage with rs2847281, and we have not found any coding or regulatory SNP. Thus, further sequencing of linkage blocks is required to find new SNPs involved in disease progression pathway.
Conclusion: We found a novel polymorphism in *PTPN2* gene which is associated with type 1 diabetes mellitus. Our data suggest that rs2847281 SNP is one of the strongest genetic markers of T1D in Russian patients living in Moscow.

CNDP1 gene polymorphism predicts progression from nephropathy to end-stage renal disease in type 1 diabetes mellitus
A. Alkhalaf[1,2], S.J.L. Bakker[1], N. Vionnet[3], P. Rossing[4], H.J.G. Bilo[2,5], G.J. Navis[1], L. Tarnow[4];
[1]Internal Medicine - Nephrology, University Medical Center Groningen, Netherlands, [2]Diabetes Center, Zwolle, Netherlands, [3]Centre National de Génotypage, Evry Cedex, France, [4]Steno Diabetes Center, Gentofte, Denmark, [5]University Medical Center Groningen, Netherlands.

Background and aims: Homozygousity of a 5-leucine repeat (5L-5L) in the carnosinase gene CNDP1 has been found to be associated with diabetic nephropathy in cross-sectional studies, mainly in type 2 diabetes. However, longitudinal data on renal function are limited. We prospectively investigated whether allelic variation in CNDP1 gene is associated with risk for progression from nephropathy to end-stage renal disease (ESRD) in patients with type1 diabetes.
Materials and methods: Prospective observational study in patients with type1 diabetes and nephropathy defined by persistent albuminuria 300 mg/24h. GFR was measured after a single injection of ^{51}Cr-EDTA. Leucine repeat in the CNDP1 gene was assessed by fluorescent DNA analysis system. ESRD was defined as need for start of chronic dialysis or kidney transplantation.
Results: 410 patients (59.3% male, age 41.9 10.3 years) were included. At baseline, duration of diabetes was 28 8.7 years, HbA1c 9.4 1.5%, serum creatinine 101 (interquartile range (IQ) 81-134) mol/L, GFR 77 33 ml/min and urinary albumin excretion 593 (IQ 267-1518) mg/24h. 5L-5L was found in 156 (38%) patients. After 9.5 (IQ 7.1-12.6) years of follow-up, 28 patients (17.9%) with 5L-5L developed ESRD vs. 42 (16.5%) with any other allelic variant [Cox-regression hazard ratio (HR)=1.1 (95% CI 0.7-1.8), P=0.69]. After adjustment for potential confounders, including baseline GFR, albuminuria, HbA1c, and blood pressure in a multivariate Cox-regression model, 5L-5L was associated with increased risk for progression to ESRD [HR= 1.8 (1.0-3.0), P=0.02].
Conclusion: In this prospective study on allelic variation in CNDP1 gene, homozygousity of a five-leucine repeat was associated with an increased risk for progression from nephropathy to ESRD in patients with type 1 diabetes. Interference in carnosine metabolism could be renoprotective in diabetic nephropathy.In this prospective study on allelic variation in CNDP1 gene, homozygousity of a five-leucine repeat was associated with an increased risk for progression from nephropathy to ESRD in patients with type 1 diabetes. Genetic effects of MCF2L2 Leu359Ile polymorphism on diabetic nephropathy
H.F. Gu, S. Efendic, K. Brismar;
Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden.

Background and aims: MCF2L2 (MCF.2 cell-line derived transforming sequence-like 2) is a Rho family guanine-nucleotide exchange factor (GEF), and Rho protein plays an important role in the pathogenesis of cardiovascular disorders. The aim of this study was to investigate the genetic effect of Leu359Ile variant of MCF2L2 on diabetic nephropathy (DN).
Materials and methods: Americans subjects of European descent, including 574 (female 264/male 310) type 1 diabetes (T1D) patients with DN and 594 (353/241) T1D patients without DN were selected from Genetics of Kidney Diseases in Diabetes (GoKinD) study. Leu359Ile (T1165G) is a detectable non-synonymous single nucleotide polymorphism (nsSNP) in the MCF2L2 gene. Genotyping experiments were performed with TaqMan allelic discrimination.
Results: The G allele frequency in female T1D patients with DN was lower compared to female T1D without DN (0.165 vs. 0.220, P=0.017, OR=0.701). The association between Leu359Ile polymorphism and DN among female T1D patients was significant (P=0.005, OR=0.615 by the dominant model and P=0.018, OR=0.757 with Armitage's trend tests). Further analysis indicated that female T1D-DN patients carrying with GG genotype had lower creatinine (1.44±0.24 mg/mL vs. 1.95±0.13 and 1.96±0.19) and cystatin (1.73±0.33 mg/L vs. 2.21±0.12 and 2.20±0.21) levels compared to the carriers with TT and TG genotypes. The association of this polymorphism with DN among male T1D patients was not statistically significant.
Conclusion: The present study provides the evidence that MCF2L2 Leu359Ile variant is associated with decreased risk of DN in female T1D patients. Questions of gender difference and GEF biology have been taken into our consideration with replication and functional studies.

Polymorphism of glutamate-cysteine ligase catalitic subunit (*GCLC*) and glutathione peroxidase 3 (*GPX3*) genes as risk factors for overt nephropathy in type 1 diabetes mellitus
S.M.S. Vieira[1,2], A. Cavaleiro Luna[1], M. Zanella Fortes[1], M. Nery[3], M. Queiroz[3], S.A. Dib[4], M.F. Vendramini[2], M.J. Azevedo[5], D. Giannella-Neto[1], L.H. Canani[5], M. Corrêa-Giannella[1];
[1]Endocrinology, Laboratory for Cellular and Molecular Endocrinology (LIM-25), São Paulo, [2]Endocrinology, Instituto de Assistência Médica ao Servidor, São Paulo, [3]Endocrinology, Endocrine Division, Hospital das Clinicas, São Paulo, [4]Endocrinology, Centro de Diabetes, Federal University of São Paulo, [5]Endocrinology, Endocrine Division, Hospital de Clınicas de Porto Alegre, Brazil.

Background and aims: Diabetic nephropathy (DN) represents one of the leading causes of end-stage renal disease and affects approximately one third of type 1 diabetic patients during their lifetime, at times irrespective of the glycemic control. These findings, taken together with results of family and epidemiological studies point to the existence of genetic susceptibility to the renal lesions induced by the metabolic disturbances triggered by chronic hyperglycemia. The aim of this study was to test whether genes involved in glutathione (GSH) metabolism are candidates for nephropathy susceptibility in patients with type 1 diabetes mellitus. To this end, two functional polymorphisms were genotyped in Brazilian type 1 patients: -129C→T in *GCLC*, the gene coding for the catalytic subunit of glutamate-cysteine ligase, the rate-limiting enzyme in GSH synthesis, and -65T→C in *GPX3*, the gene coding for plasma glutathione peroxidase, an important antioxidant enzyme
Materials and methods: 263 patients were divided into two groups according to the presence (n = 87) or absence (n = 176) of overt diabetic nephropathy (DN), defined by persistent macroalbuminuria or proteinuria, or renal replacement therapy
Results: The allelic distribution of both polymorphisms was consistent with the Hardy-Weinberg equilibrium. The presence of at least one T allele of *GCLC* –129C→T (OR = 2.84; CI 95% = 1.33 -6.06; p = 0.007) and of at least one C allele of *GPX3* -65T→C (OR = 2.61; CI 95% = 1.31 - 5.20; p = 0.006) were independent risk factors for overt DN after adjustment for other risk factors. The combination of the wild type genotypes of *GCLC* and *GPX3* poly-

morphisms (CC/TT) was protective for overt DN (OR = 0.37, CI 95% = 0.20 - 0.68; p = 0.001)
Conclusion: this study provides evidence that the evaluated polymorphisms, associated to a lower transcriptional activity of *GCLC* and *GPX3* genes, and probably to a smaller GSH antioxidant pool, constitute risk factors for overt DN in type 1 diabetic patients.

Frequencies of GCLC and GPX3 genotypes and genotype combinations according to nephropathy status

	Without overt diabetic nephropathyn=176	With overt diabetic nephropathyn=87	*P* value
Genotypes			
GCLC (CT + TT)	22 (12.5)	20 (23.0)	0.029
GPX3 (TC + CC)	33 (18.8)	32 (36.8)	0.001
Genotype combinations (*GCLC*/*GPX3*)			
CC/TT	122 (69.3)	40 (46.0)	<0.001

Prognostic relevance of autoantibodies against IA-2beta in IA-2A-positive school children from the general population
J. Heide[1], S. Krause[2], U. Walschus[1], A.-M. Hoss[1], R. Wassmuth[3], P. Achenbach[2], M. Schlosser[1];
[1]Department of Medical Biochemistry and Molecular Biology, Ernst-Moritz-Arndt University Greifswald, Karlsburg, [2]Diabetes Research Group, TU Munich, [3]TU Dresden, Germany.

Background and aims: Autoantibodies (AAb) against islet autoantigens like Glutamate decarboxylase (GADA), Protein tyrosine phosphatase (IA-2A) and Insulin (IAA) are established serological markers of beta-cell specific autoimmunity in the prediabetic phase and are therefore used for prediction of Type I diabetes mellitus (T1DM). In the mid-1990s, AAbs against another Protein tyrosine phosphatase (IA-2beta) which is structurally similar to IA-2 (74% amino acid sequence homology for the intracellular domains) were also found to be associated with T1DM. The aim of the present study was to assess the prevalence of AAbs against IA-2beta (IA-2betaA) in IA-2A-positive children from the general population with no first-degree T1DM heredity, and to examine whether the detection of IA-2betaA could be used to further stratify the risk for progression to T1DM in IA-2A-positive subjects.
Materials and methods: Serum samples from 71 IA-2A-positive schoolchildren from the Karlsburg Type-1-Diabetes Risk Study, a general population-based combined AAb screening for GADA, IAA and IA-2A, were examined for the presence of IA-2betaA by radio-ligand binding assay using [^{35}S] methionine-labelled human recombinant intracellular portion of IA-2beta. Additionally, PCR and DNA hybridization with specific non-radioactive probes were used for determination of the HLA-DQB1 genotype.
Results: IA-2betaA were detected in 32.4% (23/71) of the IA-2A-positive children. 95.7% of them (22/23) had multiple diabetes-associated AAbs (GADA, IA-2A and/or IAA), only 1/23 (4.3%) has singular IA-2A ($p<0.0001$). 21/23 (91.3%) of the IA-2betaA-positive children also had a T1DM-associated HLA-DQB1 haplotype (HLA-DQB1 *0302 and/or *02) while only 2/23 (8,7%) had neutral HLA-DQB1 alleles ($p<0.0001$). The HLA-DQB1*0302 haplotype was more common (12/21 subjects, 57.1%) than the HLA-DQB1*02 haplotype (9/21 subjects, 42.9%). No IA-2betaA-positive child had the dominant-protective HLA-DQB1 allele *0602. 18 children progressed to T1DM, of those 11 (61.1%) were IA-2betaA-positive and had also multiple AAbs. The risk for IA-2A-positive children to develop T1DM was therefore significantly higher with detection of IA-2betaA than without IA-2betaA reactivity ($p<0.01$). All IA-2betaA-positive subjects with at least one diabetes-associated HLA-DQB1 allele developed T1DM. Testing for IA-2betaA in IA-2A-positive subjects had a specificity of 61%, a sensitivity of 77%, a positive predictive value of 48% and a negative predictive value of 85%.
Conclusion: The occurrence of IA-2betaA is associated with known T1DM risk factors like positivity for multiple AAbs and presence of T1DM-associated HLA-DQB1 alleles as well as with progression to T1DM. In IA-2A-positive subjects from the general population, the detection of IA-2betaA can help to further stratify the risk for progression to T1DM by identifying probands with a higher risk. Therefore, based on specificity and sensitivity as well as positive and negative predictive value, testing for IA-2betaA in IA-2A-positive subjects should be included in AAb-based risk assessment for prediction of T1DM.

Decrease in GAD-65, IA-2 and insulin autoantibodies during non-diabetic pregnancy
S.R. Lindehammer[1], I. Hansson[1], B. Midberg[2], S.A. Ivarsson[3], K. Lynch[1], J. Dillner[4], Å. Lernmark[1];
[1]Diabetes and Celiac Disease, Clinical Sciences, Malmoe, [2]Department of Medical Microbiology, Center for Oncology / Tumor registry, Malmoe, [3]Unit Pediatrics, Clinical Sciences, Malmoe, [4]Department of Laboratory Medicine, Medical Microbiology, Malmoe, Sweden.

Background and aims: To investigate seroconversion occurrence of type 1 diabetes associated autoantibodies in non-diabetic pregnancies concurrently explore if pregnancy alters the circulating levels of these autoantibodies.

Materials and methods: Obtained blood samples from all mothers in the Skåne region during the first trimester of pregnancy and at the time of delivery between September 2000 and August 2004 have been analyzed for type 1 diabetes associated autoantibodies GADA, IA-2A and IAA. Altogether we compared 244 non-diabetic mothers positive for at least one of the three autoantibodies with 1419 control mothers matched by age and first trimester sampling date ± seven days.
Results: The level differences in GADA was significantly lower (p<0.0001) from the first trimester to delivery. Although the number of mothers was fewer the IA-2A levels showed a similar development in level differences as GADA. The level difference in IA-2A was significantly lower (p<0.0001) from the first trimester to delivery. The level difference IAA was significantly lower (p<0.005) from the first trimester to delivery. The decreasing levels of IAA were not as pronounced as the decrease in GADA and IA-2A levels. Furthermore the increasing levels off IAA were more numerous and greater in difference between the first trimester and delivery compared to the other two autoantibodies.
Conclusion: This present study supports the notion of decreasing levels of all three detected autoantibodies in samples taken at the time of the delivery compared to the samples taken at the end of the first trimester.

Insulin antibodies and selected markers of insulin resistance during the initial 2 years of type 1 diabetes in children
B. Mianowska, A. Szadkowska, I. Pietrzak, E. Czerniawska, A. Zmysłowska, O. Wegner, K. Wyka, A. Heinrich, W. Fendler, J. Bodalski, W. Młynarski;
Department of Pediatrics, Oncology, Hematology and Diabetology, Medical University, Lodz, Poland.

Background and aims: The aim of the study was to estimate the relation between insulin antibodies (IA) and selected markers of insulin resistance in children with type 1 diabetes mellitus (T1DM).
Materials and methods: IA were measured as total anti-insulin antibodies (expressed in %) by a radioimmunometric assay in 71 patients (age at T1DM onset 6.8-17.6 years; 44 males) at 3 time-points: T1DM onset (baseline), after 6 months (6.mth) and after 24 months (24.mth). Following parameters were included into statistical analysis as markers of insulin resistance: M-index (i.e. glucose disposal rate determined by euglycemic hyperinsulinaemic clamp technique by de Fronzo; mg/kg/min; the lower M-index - the higher insulin resistance), daily insulin dose (U/kg/day), Z-score of BMI (body mass index). Other parameters included into multivariate analysis were: age at T1DM onset, glucagon-stimulated C peptide after 6 minutes and HbA1c. Associations with a final value of p<0.05 were considered statistically significant.
Results: Baseline: Initial values of IA correlated only with age at T1DM onset (R=-0.23; p=0.049). 6.mth: The following parameters correlated with IA level: M index (R=0.29; p=0.02), insulin dose (R=0.24; p=0.02), Z-score of BMI (R=-0.23; p=0.06) and age at T1DM onset (R=-0.26; p=0.03). In multivariate analysis only M-index and insulin dose remained significant. R^2 for whole model equaled 0.19 (p <0.001). 24.mths: Age at T1DM onset (R=-0.29; p=0.01) was correlated with IA titer. Z-score of BMI (R=-0.19; p=0.14) showed borderline significance. In multivariate analysis age at T1DM onset was confirmed to influence IA titer, Z-score of BMI showed borderline significance (p=0.09). R^2 for whole model equaled 0.07 (p<0.001).
Conclusion: 1) IA do not increase insulin resistance assessed as M-index, 2) Positive correlation between IA and M-index after the 6.mth may indicate that IA can promote glucose disposal rate at same time-points of T1DM course 3) Negative correlations between IA and Z-score of BMI after the 6.mth and after the 24.mth of T1DM require further clarification.

Autoantibodies to REG family proteins in Japanese diabetes patients
N.J. Shervani[1], N. Noguchi[1], T. Ikeda[1], I. Takahashi[1], T. Yoshikawa[1], A. Yamauchi[2], A. Uruno[1], K. Nata[3], S. Takasawa[2], H. Okamoto[1], A. Sugawara[1];
[1]Department of Advanced Biological Sciences for Regeneration, Tohoku University Graduate School of Medicine, Sendai, [2]Department of Biochemistry, Nara Medical University, Kashihara, [3]Department of Medical Biochemistry, Iwate Medical University School of Pharmacy, Yahaba, Japan.

Background and aims: Reg, an autocrine/paracrine growth factor for β-cell regeneration was first isolated from regenerating islet cDNA. Recombinant REG ameliorated diabetes in 90% depancreatised rats and non-obese diabetes mice. The human *REG* family consists of five genes (viz; *REG Iα*, *REG Iβ*, *REG III*, *HIP/PAP* and *REG IV*), which share a common gene structure with 6 exons and 5 introns encoding homologous 158-175 amino acids secretory proteins. REG proteins are expressed at the event of tissue injury and regeneration. We have previously identified autoimmunity against REG Iα in Japanese Type 1 and Type 2 diabetes patients. Autoantibodies to REG Iα showed a correlation with the duration of diabetes and ages of patients at the onset of the disease. Owing to sequence homology and similarity in protein expression between various REG family members, it is of great interest to study the occurance of autoimmunity against other REG family members and understand its association with autoimmune diseases, if any. In the present study we have analysed the presence of autoimmunity to REG Iβ, REG III, HIP/PAP and REG IV in diabetes patients.
Materials and methods: Over 300 subjects with diabetes and 75 healthy controls were selected from Tohoku University Hospital (Sendai, Japan). All controls and patients were informed of the purpose of the study and their consent was obtained. The cDNA of each *REG* gene was cloned into pTriEX-4 multiple expression system vector (Novagen®) and proteins were expressed in *E. coli*, with conjugated S-tag sequence at N-Terminal to fascilitate one-step affinity purification on S-Protein agarose (Novagen®). Autoantibodies against REG proteins were detected by Western Analysis. Each purified REG protein was electrophoresed on SDS-polyacrylamide gel, and electrotransfered on PVDF membrane. After blocking with milk solution the membranes were incubated with patient sera as primary antibody, at appropriate fold dilutions. HRP conjugated goat Anti-human monoclonal IgG (American Qualex) were used as secondary antibody, and signal was detected by ECL Plus Western Blotting System (GE Healthcare). Signal intensity from each patient serum was measured by densitometric analyses, using ImageJ software. Statistical significance of the occurance of anti-REG autoimmunity in patients' sera and its correlation with the general characteristics of diabetes patients was analysed by Chi-squared test, Student's t-test, simple regression analyses and ANOVA analyses.
Results: Significant autoimmunity was found against REG Iβ in 10% of Type1, 32% of Type 2, and 2.7 % non-diabetes controls (P = 0.001), and against REG III in 15% of Type1, 20% of Type 2, and 1.4 % non-diabetes controls (P = 0.0001). There was significant difference between anti-REG Iβ positive (39.8 ± 1.6) and negative (33.5 ± 1.0) groups in age at onset of diabetes (P = 0.0024). Autoantibodies against HIP/PAP and REG IV antigens were not detected in diabetes patient sera.
Conclusion: These results suggest that diabetes patients may carry autoantibodies against REG Iβ and REG III. Thus, autoimmunity against REG family proteins may be associated with diabetes, and different REG family members may serve as separate biomarkers.

Composite multi-antigen probes enhance detection of type 1 diabetes autoantibodies
J.M. Wenzlau, T.J. Gardner, L. Yu, G.S. Eisenbarth, H.W. Davidson, J.C. Hutton;
Barbara Davis Center for Childhood Diabetes, Aurora, United States.

Background and aims: A major goal in Type 1 Diabetes (T1D) is to conduct population based screening of genetically-at-risk individuals prior to clinical disease onset. Autoantibody assays provide highly sensitive and specific measures of auto-immunity and assays of insulin, GAD65, IA-2, and ZnT8 autoantibodies detect greater than 90% of newly diabetic subjects. However, the current methodology requires multiple single target assays. We reasoned that combining multiple epitopes into a single "poly-antigen" probe would improve efficiency and may simultaneously enhance specificity and/or sensitivity, especially for low affinity antibodies.
Materials and methods: We constructed probes of T1D autoantigen homo- and hetero- multimers. Compound ZnT8 and IA-2/phogrinÂ¸ fusion proteins were combined into a single chain analyte using polypeptide linkers of different lengths and amino acid composition. We further optimized probe parameters by "trimming" epitope components, re-ordering individual domains, and comparing synthetic dimers with monomers joined by coiled/coils. Constructs were tested in radioimmunoprecipitation assays against a panel of sera derived from new onset T1D patients and HLA and age matched controls.
Results: Analysis with monomer compared to homo-dimer probes showed enhanced reactivity to the dimeric fusion proteins, most significantly in sera

having marginal reactivity. Hetero-dimeric probes containing both polymorphic variants (325R and W) of ZnT8 C-terminal domain showed enhanced sensitivity as compared to monomers (78% vs 53% (325R) / 48% (325W)) to a panel of new onset sera without compromising specificity (>99%). Probes containing homo-dimers of the N-terminal domain also displayed increased sensitivity relative to monomer N-terminal constructs. Binding to N-terminal dimers increased autoimmunity detection from 5.0% with a monomer probe to 16.8% with dimeric constructs, however specificity declined to 95%. Expanding the linker between monomers improved assay sensitivity, but their order appeared benign. Homo-dimeric constructs of IA-2 and phogrin also had improved sensitivity. Heterodimeric IA-2/phogrin fusion proteins detected both antigenic specificities from a single probe without loss of specificity, and provided higher sensitivity. In contrast, heterodimers comprising IA-2 and ZnT8 were able to detect mono-specific sera to each antigen, but did not show enhanced sensitivity over the individual monomers. Comparison of inter- and intra-assay variation indicated that both the homo- and heterodimeric probes showed greater consistency (CV <20%) providing a "tighter" cut-off than their monomer counterparts. Consequently, sera on the cusp of scoring positive readily exceeded the cut-off with the dimeric probes.
Conclusion: Our data show a significant advantage of employing epitope multimers. Combining two ZnT8 C-term variants, two N-term domains, or the two IA-2 family orthologues improves assay sensitivity. The lower CV achieved with dimeric probes could not entirely account for the improved sensitivity of these assays suggesting that additional factors such as increased avidity due to duplication of monomer epitopes, or detection of dimer-specific epitopes play a role. We conclude that our strategies improve the sensitivity of current RIAs without conceding specificity.

Involvement of the Ig heavy chain locus in autoantibody reactivity in Portuguese type 1 diabetes patients
M.I.H. Rolim[1], J.M. Boavida[2], R. Duarte[2], R. Pina[2], C. Valadas[2], S. Pratas[2], R. Carvalho[2], J. Costa[1], D. Ligeiro[3], M.R. Sancho[3], M.M. Catarino[4], C. Penha-Gonçalves[1];
[1]Disease Genetics, Instituto Gulbenkian de Ciência, Oeiras, [2]Associação Protectora dos Diabéticos de Portugal, Lisboa, [3]Centro de Histocompatibilidade do Sul, Lisboa, [4]Faculdade de Farmácia da Universidade de Lisboa, Portugal.

Background and aims: Autoantibodies are linked to Type 1 Diabetes (T1D), but their role in disease pathogenesis has long been disputed. Autoantibodies are mostly seen as a by-product of the autoimmune attack that targets the pancreatic Beta cell. Nevertheless, autoantibodies are frequently detected before disease onset and non-pancreatic Beta cells are frequently observed in the in Type 1 Diabetes patients. These observations suggest that autoantibodies may be related take part in early phases of the disease process. The aim of this study was to analyze the contribution of specific single nucleotide polymorphisms (SNPs) in Immunoglobulin Heavy Chain loci (IgHG, IgHD, IgHM and IgHV) to autoantibody reactivity and to disease susceptibility.
Materials and methods: A group of 102 diabetics and their relatives, collected at the Associação Protectora dos Diabéticos de Portugal, were genotyped for 15 genetic markers in IgH loci, specifically 4 SNPs in IgHG locus, 4 SNPs in IgHD locus, 5 in IgHM locus and 2 in IgHV locus. Genetic association with T1D and with the pattern of autoantibodies was evaluated through Transmission Disequilibrium Tests (TDT) and case-control analysis.
Results: TDT analysis suggested that SPNs in the heavy chain locus, mapping on the IgHG and IgHM regions were associated to T1D in a cohort of portuguese patients (P-value=0,0455 and P-value=0,006, respectively). The T1D patients were studied for the presence of autoantibodies (including anti-ICA; IA2; GADA and gliadin) and by comparing patients showing one autoantibody versus patients showing multiple-autoantibodies we also found out that SNPs on the IgH locus, over the region of IgD, IgM and IgHV were controlling antibody multireactivity in T1D patients (P-value=0,0021, P-value=0,0020, P-value=0,0032, respectively). Furthermore, TDT analysis revealed that the IgH locus was associated to disease in T1D patients showing autoantibody mono-reactivity but not multi-reactivity (P-value(IgHM)=0,0047 and P-value(IgHV)=0,014).
Conclusion: These results suggest that the IgH locus may influence disease genetic susceptibility through influencing autoantibody reactivity, raising the possibility that inherited ability to generate auto-antibodies is a component of T1D pathogenesis.

Phenotype versus immunotype and endogenous insulin production in diabetes in adults - does the clinical assessment still have a meaning in classifying patients?
S.M. Zawada-Targoni, J. Taton, A. Czech;
Chair and Department of Internal Medicine and Diabetology, Medical University of Warsaw, Poland.

Background and aims: The category of diabetes in adults, clinically diagnosed as type 2, includes a number of subtypes and groups of patients. The various presence, configuration and concentration of autoimmune diabetogenic process markers, insulin secretion, insulin resistance and Body Mass Index makes this group of patients very heterogeneous. Despite our present knowledge about the etiology of diabetes, clinical phenotypic assessment is frequently the first and sometimes the only one criterion of classification and treatment choice. The aim of this study was to analyze whether there is a correlation between clinical phenotype, endogenous insulin production and immunotype in the polish population of adults with newly diagnosed diabetes and to establish simple algorithm of additional studies supplementing clinical evaluation when needed.
Materials and methods: The study included 142 patients, aged 20-79 yrs, with diabetes diagnosed on the basis of current WHO criteria as diabetes type 2. Patients underwent detailed physical examination, and biochemical studies: fasting glucose, insulin and glucagon test with peptide C assessment. The concentration of autoantibodies against pancreatic beta-cells (glutamic acid decarboxylase antibodies - GADA and protein tyrosine phosphatase-like protein antibodies -IA-2) was measured. Insulin resistance was established on the basis of HOMA.
Results: The studied group of patients classified as diabetes type 2 (according to WHO criteria) was very heterogeneous in age, BMI (normal in 52,8%; overweight - 26,5%; obesity 20,7%), insulin resistance (confirmed in 42,9%) and endogenous insulin production (fasting insulin 1,1 to 21 mU/l), established on the basis of glucagon test (fasting peptide C:0,1-4,39 ng/ml, after glucagon stimulation:0,1-10,3 ng/ml). GADA were found in 38,7% and IA-2 in 24,7% of patients. GADA were twice as common as IA-2 in patients <40yo and at the age of 47 yrs the frequency of IA-2 was higher than GADA (p=0,003). IA-2 were more common in overweight patients (67vs33%, p=0,004). There was no correlation between the presence of antibodies and insulin resistance, in 33% of patients both abnormalities were present.
Conclusion: Diabetes in adults is very heterogeneous disease, in which the clinical assessment is not enough for appropriate classification. Presence of phenotypic symptoms of diabetes type 2 and insulin resistance does not exclude autoimmunity. Also reversely lean body mass does not exclude the presence of insulin resistance. Therefore we suggest the algorithm for appropriate classification and choice of treatment besides clinical examination should include assessment of: 1) beta cell function (glucagon test);2) insulin resistance (HOMA);3)autoimmunity a)GADA <40 yrs ;b)IA-2 >50 yrs; c) IA-2 in BMI>25 kg/m^2. This would permit the optimal choice of proper treatment plans.

Analysis of CD25+ and CD45RA+ regulatory subsets of CD4+ T lymphocytes: comparison between nondiabetic first degree relatives and recent onset type 1 diabetes
T. Milicic[1], N. Lalic[2], A. Jotic[2], I. Markovic[3], M. Zamaklar[2], K. Lalic[2], L. Lukic[2], N. Rajkovic[2], M. Macesic[2], J. Seferovic[2];
[1]Clinical Center of Serbia, Institute for Endocrinology, [2]Institute for Endocrinology, [3]Institute for Biochemistry, Belgrade, Serbia.

Background and aims: Previous studies have reported an important role of the changes in CD4+ T cell subsets in the initial phase of Type 1 diabetes (T1D). However, the changes in CD4+CD25+ and CD4+CD45RA+ T suppressor subsets of the regulatory T cells in nondiabetic first degree relatives (FDR) of patients with T1D, have not yet been clarified. Therefore, the aim of this study was to analyze the percentage of the regulatory CD4+CD25+ and CD4+CD45RA+ T cell subsets in 50 nondiabetic FDR (group A), 30 recent-onset T1D patients in insulin-requiring state (IRS) at the onset (group B) and 19 T1D patients in the state of clinical remission (CR) (group C), as well as in 25 healthy, age-matched control subjects (group D).
Materials and methods: T1D was diagnosed in accordance to WHO criteria. The CR was defined as optimal metabolic control without insulin lasting >30

days. The percentage of CD4+CD25+ and CD4+ CD45RA+ T cell subsets was analysed by using two-color immunofluorescence staining and flowcytometry.
Results: When the percentage of CD4+CD25+ T lymphocytes was analyzed, we found that in group A it was higher vs group B (A: 5.30±0.10 vs B: 2.24±0.25, p<0.05). Moreover, the percentage of CD4+CD25+ T cells in group A reached the values similar to those in group C, being slightly lower than in group D (A: 5.30±0.10 vs C: 5.17±0.14; D:6.20±0.84%, p=NS). Simultaneously, the percentage of CD4+CD45RA+T cells was found to be higher in group A vs group B (A: 25.56±2.08 vs 20.3±1.6, p<0.05). In addition, the percentage of CD4+CD45RA+T cells in group A became similar to those in C and not significantly lower compared to group D (A: 25.56±2.08 vs C:24.8±1.2; D:27.0±2.0, p=NS).
Conclusion: Our results have demonstrated that nondiabetic FDR of patients with T1D, showed higher levels of the suppressor CD4+CD25+ and CD4+ CD45RA+ subsets of T regulatory lymphocytes compared to the patients at onset of T1D, but similar to those in CR. The results imply that the onset and clinical course of T1D might be modulated on the level of those T regulatory cell subsets.

High risk vs low risk nondiabetic first degree relatives of type 1 diabetics: differences in CD4+CD25+ and CD4+CD161+ T regulatory subsets but not in insulin sensitivity levels

A. Jotic[1], N.M. Lalic[1], T. Milicic[1], I. Markovic[2], M. Zamaklar[1], K. Lalic[1], L. Lukic[1], N. Rajkovic[1], M. Macesic[1], J. Seferovic[1];
[1]Institute for Endocrinology Clinical Centre of Serbia, [2]Institute for Biochemistry, Belgrade, Serbia.

Background and aims: It has been previously suggested that changes in $CD4^+$ T lymphocyte subsets might be associated with the onset of Type 1 diabetes (T1D). However, the relevance of immunological changes in CD25+ and CD161+ suppressor subsets of the CD4+ T regulatory cells, and metabolic changes in insulin sensitivity levels, for the development of T1D have not yet been elucidated in nondiabetic first degree relatives (FDRs) of patients with T1D. Therefore, the aim of this study was to compare the changes in (a) CD25+ and CD161+ subsets of $CD4^+$ T lymphocytes in peripheral blood and (b) insulin sensitivity levels among two groups of nondiabetic FDRs exhibiting difference in risk for developing T1D in accordance to presence or absence of glutamic acid decarboxylase antibody (GADA) positivity and the preservation of the capacity of first-phase insulin response (FPIR, insulin levels 1+3 min after IVGTT) and the group of healthy controls. Thus, in the study we included 15 high-risk nondiabetic FDRs (GADA+, FPIR < 45mU/l) (group A) and 35 low-risk nondiabetic FDRs (GADA-, FPIR > 45mU/l) (group B) and 17 healthy unrelated control subjects (GADA-, FPIR > 45mU/l) (group C).
Materials and methods: T1D and glucose intolerance were excluded in the study by using WHO criteria. GADA levels were determined by ELISA. The percentages of CD4+CD25+ and CD4+CD161+ T cell subsets were analyzed in peripheral blood by using two-color immunofluorescence staining and flowcytometry. Insulin sensitivity was tested by using euglycemic hyperinsulinemic clamp method. This test was implemented by infusing insulin at the rate of 1 mU/kgbw/min during 120 min and glucose infusion was adjusted manually, at 5 minute intervals, to maintain target glycemia at 90 mg/dl. Total glucose uptake was calculated on the basis of the amount of glucose infused during steady state period (80-120 minutes).
Results: When the percentage of CD4+CD25+ T lymphocytes was analyzed it was found to be lower in group A vs groups B and C (A: 3.58 ±0.82 vs B: 5.80±0.55; C:6.10±0.75%, p<0.05). Simultaneously, the percentage of CD4+CD161+ T cells was found to be lower in group A vs groups B and C (A: 4.68±0.43 vs B 6.18±1.01; C: 6.30±0.91%, p<0.05). However, when insulin sensitivity was tested, total glucose uptake did not differ significantly in group A compared to groups B and and C (A: 5.87±0.11 vs B: 6.58±0.27; C: 6.78±0.28 mg/min/kg, p=NS).
Conclusion: Our results have demonstrated that high risk vs low risk FDRs showed lower leves of both CD25+ and CD161+ subsets of CD4+ T regulatory lymphocytes, and did not differ in insulin sensitivity levels. The results also imply that the risk for developing T1D might be strongly influenced on the level of the activity of these subsets of T regulatory cells but not by the changes in insulin sensitivity.

271

Vitamin D supplementation increases the frequency of regulatory T cells in apparently healthy humans

B. Prietl[1], S. Pilz[1], A. Tomaschitz[1], B.M. Obermayer-Pietsch[1], W.B. Graninger[2], T.R. Pieber[1,3];
[1]Department of Internal Medicine, Medical University of Graz, [2]Department of Clinical Immunology, Medical University of Graz, [3]Joanneum Research Forschungsgesellschaft mbH, Graz, Austria.

Background and aims: Several epidemiological studies support potential beneficial effects of vitamin D supplementation during infancy and childhood on the incidence of type 1 diabetes later in life. Vitamin D is thought to have an important regulatory role in modulating the immune response by increasing the frequency or function of regulatory T cells (Tregs). Tregs are critical for maintaining immunologic homeostasis and downregulation of undesired immune responses to self-antigens. Thus, Tregs might have the potential to prevent autoimmune-mediated destruction of insulin-producing beta-cells in the pancreas. In the present study, we aimed to elucidate, whether Treg frequency could be enhanced by vitamin D supplementation in apparently healthy individuals.
Materials and methods: We determined the percentage of Tregs (%Tregs) within 20000 $CD4^+$ T cells isolated from peripheral blood of 20 healthy donors before and 4 weeks after vitamin D supplementation (140000 IU as a single dosis). Fluorescence-activated cell sorting (FACS) was used to measure cell surface expression of CD4, CD25 and CD127 as well as intracellular expression of the transcription factor FoxP3. Serum 25-hydroxyvitamin D levels were measured by means of radioimmunoassay.
Results: Our study cohort consisted of 20 study participants [13 females, 7 males; median age (with interquartile range): 31.4 (28.1-34.5) years]. 25(OH)D levels increased from a median level of 23.7 (17.9-25.1) ng/ml serum at baseline to 46.5 (39.9-51.2) ng/ml serum four weeks after vitamin D supplementation. Accordingly, the median percentage of Tregs increased significantly from a median baseline level of 5.1 (3.6-6.1) % to a level of 6.4 (5.0-7.6) % ($p \leq 0.001$ for Wilcoxon rank sum test). Levels of C-reactive protein were within the normal range before and after vitamin D supplementation and did not significantly vary between the two study visits.
Conclusion: We showed that vitamin D supplementation significantly increased the frequency of Tregs in peripheral blood of apparently healthy humans over a short time period. This immune-modulatory effect of vitamin D might support the previously observed associations of vitamin D deficiency and autoimmune diseases such as type 1 diabetes mellitus. Hence, our finding provides a rationale for further studies to investigate the effects of vitamin D on beta cell survival in type 1 diabetes.

272

Smoking predicts short partial remission of type 1 diabetes

S. Pilacinski, D. Zozulinska-Ziolkiewicz, A. Gawrecki, B. Wierusz-Wysocka;
Department of Internal Medicine and Diabetology, Poznan University of Medical Sciences, Poland.

Background and aims: Factors predicting the duration of partial remission of type 1 diabetes are known to be associated with the degree of initial metabolic disturbances and also with features of insulin resistance. Cigarette smoking is associated with decreased insulin sensitivity but its influence on the length of remission is unknown. Therefore, the aim of this study was to assess the relationship between cigarette smoking and duration of partial remission of type 1 diabetes.
Materials and methods: We followed prospectively 149 patients (48 women and 101 men, aged 16-35, mean age 25 ± 5), admitted to the Department with newly diagnosed type 1 diabetes and then attending the outpatient clinic. Thirty patients presented with diabetic ketoacidosis (DKA), mean glycaemia at diagnosis was 23.2 ± 8.4 mmol/l, HbA_{1c} 10.9 ± 2.5 % and BMI 21.9 ± 3.0 kg/m^2. In all patients intensive functional insulin therapy in multiple injections was introduced. Partial remission was defined as an insulin dose ≥0.3 U/kg/24h and an HbA_{1c} value <7% with baseline serum C-peptide concentration over 0.5 µg/l. Duration of remission was calculated from the onset of the disease. Statistical analysis was performed using Statistica 7.0 software. Mann-Whitney U test, Fisher's exact test and Cox proportional-hazards method were used.
Results: Sixty-eight patients remained in partial remission after one year of observation, in 39 patients partial remission ended before 12 months of dis-

ease and 42 patients did not enter remission. Group with remission exceeding one year did not differ from the remaining patients (with no or short remission) in age, initial: BMI, glycaemia, serum TC, LDL-C and HDL-C, serum C-reactive protein (hsCRP) concentration and presence of diabetes-related autoantibodies (ICA, GADA, anti-IA2). In the group with remission exceeding one year significantly lower prevalence of cigarette smoking (28% vs. 51%, p=0.007), higher male predominance (79% vs. 58%, p=0.008), lower incidence of DKA at onset (11% vs. 29%, p=0.005), lower initial HbA_{1c} (10.3 ± 2.1% vs. 11.3 ± 2.4%, p=0.022) and lower serum triglyceride concentration (1.68 ± 2.20 vs. 1.70 ± 1.30 mmol/l, p=0.028) were noted. In the Cox proportional-hazards model, cigarette smoking was associated with shorter duration of remission, independently from gender and presence of DKA at diagnosis.
Conclusion: Cigarette smoking may be associated with shorter duration of partial remission of type 1 diabetes.

Age-period-cohort analysis of temporal trend of diabetes incidence in age group 0-14 years in Italy: the RIDI study group

G. Novelli[1], M. Maule[2], F. Carle[3], V. Cherubini[3], S. Piffer[4], R. Lorini[5], M.T. Tenconi[6], L. Iughetti[7], S. Toni[8], A. Iannelli[3], A. Falorni[9], P. Pozzilli[10], F. Prisco[11], M. Songini[12], G. Bruno[1];
[1]Internal Medicine, University of Turin, [2]Cancer Epidemiology Unit, CeRMS and CPO Piemonte, University of Turin, [3]Polytechnic University of Marche, [4]Dep of Epidemiology, Trento, [5]Dep of Pediatrics, Firenze, [6]University of Pavia, [7]University of Modena, [8]University of Firenze, [9]Internal Medicine, University of Perugia, [10]Dep of Endocrinology, University of Roma, [11]University of Napoli, [12]Osp. S. Michele, Cagliari, Italy.

Background and aims: Epidemiological studies on type 1 diabetes have shown geographical and temporal variations in incidence of the disease, suggesting the effect of environmental determinants on the pathogenesis of the disease, which are still unknown. Few data are available in tha Mediterranean area. RIDI was set up in 1997 aiming to co-ordinate pre-existing registries for the incidence of T1DM in Italy and to promote the establishment of new registries in uncovered areas.
Materials and methods: Our data are regularly updated from 12 local registries: 7 regional registries and 5 province registries, covering a population at risk of 15 million of inhabitants (35% of the whole Italian population). All registries report newly diagnosed insulin-treated children, defined as the date when the first insulin injection was give and each registry employed at least 2 independent data sources for case ascertainment. This report is based on 5289 incident cases registered in period 1990-2003. Poisson regression models have been used to estimate the effects of sex, age (five three-years age groups: 0-2, 3-5, 6-8, 9-11, 12-14), calendar time (four three-year periods: 1990-92, 1993-95, 1996-98, 1999-2001, and one two-year period: 2002-03) and birth cohorts (nine six-year birth cohorts: 1978, 1981,…1999, 2001 mid-years).
Results: In the period 1990-2003, 5289 incident cases of type 1 diabetes have been identified among children aged 0-14 years. The incidence rate was 12.52 per 100,000 person-year, significantly higher in boys (13.34; 95% CI: 12.86-13.83) than in girls (11.66; 95% CI: 11.20-12.14). Large geographical variations in risk within Italy were evident, with the highest risk in Sardinia, an intermediate risk in Central-Southern Italy, and the highest risk in Northern Italy, particularly in the Trento Province, where an incidence rate of 30.48/100,000 was registered. A steep increasing risk from age 0-2 years was evident, with a doubling incidence rates in the age group 3-5 years, a quite similar risk in age 6-8, a slight further increase in age group 9-11 years. An increasing temporal trend was evident both examining all Italian data and separately the three Italian macroareas. Controlling for age and sex, the annual increase was 3.50% (2.80-4.19). With respect to the calendar period 1990-1992, the incidence rates were higher in the following four time periods. With respect to the birth cohort 1987-1993, the incidence rates increased approximately linearly from the cohort 1975-81 to for the cohort 1999-2003, RR=1.52 (1.18-1.96). The best model was the one with sex, age and a linear time trend (drift).
Conclusion: Increasing temporal trend is evident in Italy. Age period-cohort analysis, however, shows that the variation over time has a linear component that cannot be ascribed to either the calendar period or the cohort.

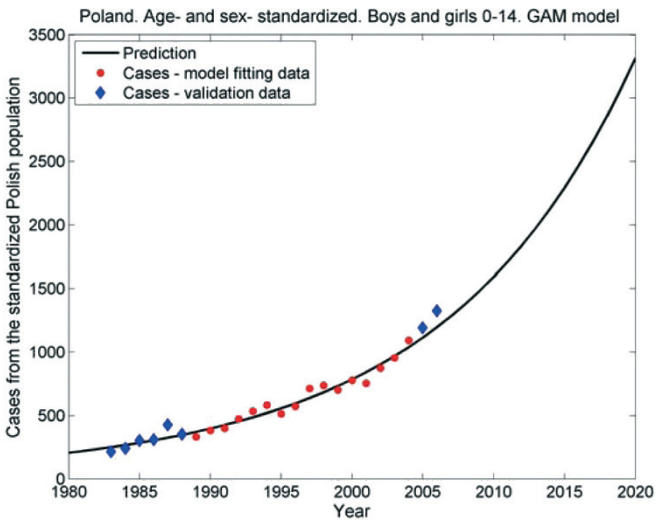
The dynamics of incidence of type 1 diabetes in Polish children, 1983-2020: where are we?

P. Jarosz-Chobot[1], J. Polanska[2], A. Szadkowska[3], A. Kretowski[4], E. Bandurska-Stankiewicz[5], M. Ciechanowska[6], G. Deja[1], M. Mysliwiec[7], J. Peczynska[4], J. Rutkowska[5], A. Sobel-Maruniak[8], P. Fichna[9], A. Chobot[10], M. Rewers[11];
[1]Silesian University of Medicine, Katowice, Poland, [2]System Engineering Group, The Silesian University of Technology, Gliwice, Poland, [3]Medical University of Lodz, Poland, [4]Medical University of Bialystok, Poland, [5]University of Warmia and Mazury, Olsztyn, Poland, [6]Collegium Medicum, Jagiellonian University, Cracow, Poland, [7]Medical University of Gdansk, Poland, [8]Provincial Hospital No 2, Rzeszow, Poland, [9]Poznan University of Medical Sciences, Poland, [10]Association for Children with Diabetes, Katowice, Poland, [11]Barbara Davis Center, University of Colorado, Denver, United States.

Background and aims: The incidence of childhood type 1diabetes (T1DM) has been increasing world-wide. The aim of this study was to evaluate the time trends in the incidence of childhood T1DM in Poland and to develop a predictive model for the near future.
Materials and methods: Regional registers that covered 35% of the Polish population ascertained prospectively using the EURODIAB criteria incident cases of T1DM under the age 15 years, between 1989-2004. Generalized additive modeling (GAM) was used to predict the annual number of new cases in the overall Polish population between 1989 and 2020.
Results: The primary study population included 4268 incident T1DM cases (2230 boys and 2038 girls). In 1989-2004, the average age-sex-standardized incidence was 9.9 per 100 000 per year (95% CI 8.5-11.6). The incidence has increased more than 3-fold, from 5.2 to 17.2 per 100 000 per year, between 1989 and 2004. The incidence has increased the most among children aged 5-9 years, on average by nearly 1.0/100 000 per year (95% CI 0.8-1.1). There was a significant non-linear component to the time trend ($p<0.000001$). Figure shows the standardized number of T1DM cases in the overall Polish population 0-14 years of age, during the observation period, as well as the best-fitting time trend. Based on this model, assuming constant population size, 32375 Polish children are expected to develop T1DM between 2005 and 2020. Datasets comparable to the primary register, preceding or following the study period, were analyzed to estimate the validity of this model. The observed number of new cases in the Silesia and Lodz register during 2005-2006 was similar to that predicted from the generalized time trend model: 371 vs. 390, error 5.1%. The prediction error of 1.2% for the Lodz register incidence in 1983-1988 further validated the model.
Conclusion: During the recent 15-years, the incidence of childhood T1DM in Poland has increased 3-fold, with predicted additional at least 3-fold increase between 2005-2020. While 12465 cases were diagnosed in 1989-2004, more than 32000 cases are expected in the following 15 years.



The work was partially financed by KBN grant no 402279134 and EUBIROD grant no 2007115

275

Age-specific trends of type 1 diabetes incidence in childhood differ between sexes in Germany

A. Stahl[1], C. Bächle[1], M. Grabert[2], R.W. Holl[2], G. Giani[1], J. Rosenbauer[1], in cooperation with the German Pediatric Surveillance Unit (ESPED) and the DPV-initiative, and the Competence Network Diabetes mellitus;
[1]Institute for Biometrics and Epidemiology, German Diabetes Centre, Düsseldorf, [2]Institute of Epidemiology, University of Ulm, Germany.

Background and aims: A large risk population and a sufficiently long observation period are important preconditions for valid estimation of type 1 diabetes incidence in childhood and its temporal trend. Aim of the present study was to estimate incidence and time trend of type 1 diabetes in children 0-14 years of age in the large risk population of the German federal state North Rhine-Westphalia (NRW) during 1996-2007.
Materials and methods: During the study period the average risk population was 2.84 million children. The North Rhine-Westphalian diabetes incidence register ascertains newly diagnosed cases of type 1 diabetes by means of three data sources: the prospective hospital-based active surveillance system ESPED, annual inquiries among paediatric, internal, and general medical practices, and the computer-based documentation system DPV founded for quality control and scientific research in paediatric diabetes care. Completeness of ascertainment was estimated by the capture-recapture-method using log-linear modelling. Point and interval estimates (95%-CI) of incidence rates (per 100,000 person-years) were based on Poisson distribution. Age-and sex-standardized rates were estimated by the direct method using equal weights. Poisson regression analysis was applied to assess time trends.
Results: During 1996-2007 a total of 7,049 newly diagnosed diabetic children aged 0-14 years (3,678 boys, 3,371 girls) were registered. Ascertainment was estimated to be 98.2% (95%-CI: 98.0%-98.4%) complete. The overall age- and sex-standardized incidence rate was 20.4 (20.0-20.9). The age-standardized incidence among boys (20.8, 20.1-21.5) was slightly higher than among girls (20.1, 19.4-20.8, $p=0.124$), among 10-14 years old children the difference was significant (25.2, 23.9-26.5 vs. 22.1, 20.9-23.4, $p<0.001$). Incidence depended significantly on age ($p<0.001$). Age-specific estimates for age groups 0-4, 5-9, and 10-14 years were 14.8 (14.1-15.6), 22.9 (22.0-23.8), and 23.6 (22.8-24.5), respectively. Annual incidence rates ranged between 16.0 in 1997 and 24.4 in 2007. The average annual incidence increase was estimated as 4.1% (3.4%-4.8%). Overall, there were no significant differences in incidence trends among boys and girls (annual increase: 4.2% vs. 3.9%, $p=0.715$) or among age groups (0-4, 5-9 and 10-14 years: 4.7%, 4.3% and 3.5%, $p=0.402$). However, the annual incidence increase in 10-14 years old girls (1.9%) was significantly lower than among younger girls and boys of the same age ($p<=0.01$).
Conclusion: This study based on a large risk population and high case ascertainment confirms that incidence of type 1 diabetes in childhood is steadily increasing in Germany. Interestingly, differential trends between sexes were observed among children 10-14 years old. Based on the actual incidence rate, there are annually about 2,800 children newly diagnosed with type 1 diabetes in Germany underlining the public health importance of childhood diabetes care. Further research is needed to identify causes of the continuous rise of diabetes incidence and differential trends between sexes.

No association between vitamin D levels and the risk for islet autoimmunity and type 1 diabetes: the Diabetes Autoimmunity Study in the Young (DAISY)

M. Simpson[1], H. Brady[1], G. Eisenbarth[2], M. Rewers[2], H. Erlich[3], J.M. Norris[4];
[1]Colorado School of Public Health, Aurora, [2]Barbara Davis Center for Chilhood Diabetes, Aurora, [3]Human genetics, Roche Molecular Systems, Pleasanton, [4]Epidemiology, Colorado School of Public Health, Aurora, United States.

Background and aims: Vitamin D has been implicated as having a protective effect on the risk for islet autoimmunity (IA) and type 1 diabetes (T1D) because of its functions as a modulator of the immune system. The aims of this study were to investigate the associations between plasma 25-hydoxyvitamin D (25[OH]D) levels and potential gene by 25[OH]D interactions respectively, and the risk for developing IA and subsequent T1D in children at increased risk for T1D.

Materials and methods: Since 1993 the Diabetes Autoimmunity Study in Young (DAISY) in Denver, Colorado has been following children at increased risk of T1D for the development of IA and T1D. Plasma 25[OH]D was measured in DAISY children using a case-cohort study design. In addition, 25[OH]D was measured every 3-6 months once children became IA positive. The *BsmI* variant of the vitamin D receptor (*VDR*), the *-23 HphIA* variant in the insulin gene (*INS*), *R620W* variant in the *PTPN22* gene, and the *JO27_1* variant in *CTLA4* were genotyped in all children. Cox proportional hazards analyses with 25[OH]D as a time-varying covariate were conducted to examine predictors of the following outcomes of interest: 1) IA, as defined by positivity for insulin, glutamic acid decarboxylase, or insulinoma-associated antigen-2 autoantibodies on 2 consecutive visits (n= 70 IA cases) and 2) T1D (n= 42 T1D cases in children with IA after a mean age of follow-up of 6.8 years). Mixed modeling was performed to examine the predictors of 25[OH]D over time.
Results: An avergage of 5 visits were analyzed per child. Plasma 25[OH]D levels showed an expected seasonal pattern with a peak in summer. In addition, dietary intake of vitamin D, age of study participant, and body mass index were associated with 25[OH]D levels. (figure 1). Adjusting for HLA genotype, family history of T1D, and ethnicity, plasma vitamin D was not associated with the risk for IA (HR: 1.02, 95 CI: 0.98-1.05, p-value: 0.34), nor was it associated with progression to T1D in IA positive children (HR: 0.90, 95 CI: 0.64-1.26, p-value: 0.54). There were no significant interactions between 25[OH]D and the polymorphisms listed above on the risk for IA or T1D.
Conclusion: 25[OH]D levels are not associated with IA or T1D in our population of children at increased risk for T1D.

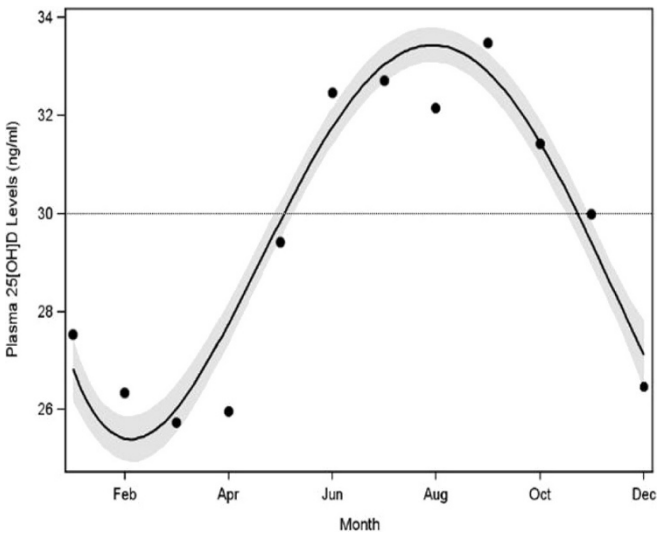

Figure 1: Plasma vitamin D levels vs onth of the year • represents mean 25[OH]D levels for each month. The curve is the yearly predicted curve for vitamin D, adjusting for age at the time of the blood draw (p<0.001), standardized body mass index (p=0.04), dietary intake of vitamin D (p=0.06), and ethnicity (p=0.011). The horizontal line represents the cutoff for insufficiency (30 mg/ml).

Seroconversion in the DPT-1 Study: evidence of triggering of autoimmune process at different ages

K. Vehik[1], M.J. Haller[2], P. Xu[1], D.A. Schatz[2], J. Krischer[1], DPT-1 Study Group;
[1]Pediatrics Epidemiology Center, University of South Florida, Tampa, [2]College of Medicine, University of Florida, Gainesville, United States.

Background and aims: The purpose of this study was to determine the timing of islet cell antibodies (ICA) autoimmune seroconversion in first- and second- degree relatives of patients with type 1 diabetes (T1D).
Materials and methods: Study subjects were identified through the Diabetes Prevention Trial - Type 1 (DPT-1) which screened 55,476 subjects 3-18 years of age for ICA for potential accrual to a study to delay or prevent T1D. 1964 were ICA positive (≥ 10 JDF units) at the time of initial screening. 16,218 subjects who were initially ICA negative were recalled for annual rescreening; and 412 seroconverted to ICA positive subsequently.
Results: The median ICA seroconversion age was 9.5 years. The age distribution of seroconversion closely mirrored that of those ICA positive at initial screening. There was no significant difference in risk of ICA seroconversion by age (p=0.75), although there appears to be two peaks at 10-11 years and 17-18 years. Human leukocyte antigen (HLA) haplotypes were not significantly different between those children ICA positive at time of initial screening and those that seroconverted at a rescreening (p=0.15). Siblings of patients with T1D had a 24% greater risk of ICA seroconversion compared to other relatives (HR: 1.24, 95%CI 1.0-1.5).
Conclusion: While the risk of ICA seroconversion varies little across the age spectrum studied, it does appear that young (< age 8) children have a lower risk of seroconversion as compared to those initially screened, but as age increases the risk increases and eventually surpasses that of those initially screened. Public health implications of this finding suggest more than one autoantibody screening should be conducted to capture those that seroconvert and that by age 8 years the yield reaches or exceeds the magnitude of the prevalence.

Association of type 1 diabetes at onset with enterovirus infections in probands, siblings and parents

A. Salvatoni[1], G. Bianchi[1], A. Baj[2], G. Maccari[2], A. Toniolo[2];
[1]University of Insubria, Department of Pediatrics, [2]University of Insubria, Laboratory of Medical Microbiology, Varese, Italy.

Background and aims: Type 1 diabetes (T1D) is primarily a cell-mediated autoimmune disease with autoantibodies to several islet antigens. What triggers the destruction of islet beta-cells is uncertain, but viruses are prominent among candidates. A number of studies have shown epidemiological links between the onset of childhood diabetes and enterovirus (EV) infections. At the time of T1D diagnosis, the occurrence of EV infections has been investigated in six families having one diabetic child. The aim was to evaluate whether, at presentation, EVs were present in diabetic probands and whether these agents could spread among family members.
Materials and methods: Twenty-three subjects (12 children and 11 parents) belonging to six families have been investigated. The age of diabetic children was 3 to 14 years (n=8). EV genomes and infectivity were searched for in serum samples and peripheral blood leukocytes (PBL). To this end, RT-PCR with a panel of primers directed to the conserved 5`UTR and 3D regions of different EVs was used together with cell culture methods aiming at detect-

ing virus infectivity and the expression of viral proteins. Partial molecular identification of EV types was obtained by direct sequencing. Using the above methods, EV genomes and infectivity were not detected in the blood of 20 healthy controls.
Results: HLA typing showed that all members of the six investigated families carried the high-risk alleles DR3 and/or DR4. At diagnosis, EV genomes and infectivity were detected in 16/23 investigated subjects (12/12 children and 4/11 parents). Two siblings who were infected but not diabetic at the time of diagnosis, developed diabetes during follow-up (latency of 3 and 9 months from the index case). Six out of 8 diabetic children carried the DR3/DR4 phenotype (75%). Different EVs belonging to the A and B species were detected. However, each family was infected by only one EV type. According to the traditional nomenclature, only members of the coxsackie A group and echoviruses were represented. At diagnosis, the median HbA1c level was 10.9%. Glucagon-stimulated C-peptide was undetectable in 4/8 children. One year after diagnosis, all patients were under insulin treatment. The insulin requirement was <0.4 IU/kg/day in 2/8 patients. In the remaining 6 children, the median insulin requirement was 1.0 IU/kg/day.
Conclusion: At the time of diagnosis, a high prevalence of EV sequences and viral infectivity has been detected not only in diabetic children, but also in family members. Different EV types appeared to be involved. Development of multiple cases within the same family is an uncommon event. However, among the six families that have been investigated, two additional diabetes cases developed in previously normoglycemic EV-infected siblings. Thus, in genetically susceptible individuals, EV infections may represent a triggering factor of T1D.

Similar frequencies of HLA risk genotypes in type 1 diabetes over the past six decades in a southern European Caucasian population
P. Pozzilli[1], M. Spoletini[2], S. Zampetti[2], M. Capizzi[2], S. Kyanvash[1], C. Venditti[2], R. Buzzetti[3], IMDIAB Group[1];
[1]Endocrinology, Campus Bio-Medico, [2]Clinical Sciences Department, Sapienza, University of Rome, [3]Clinical Scineces, "Sapienza" Univerisity, Rome, Italy.

Background and aims: The major genes responsible for at least 50% of the type 1 diabetes (T1D) genetic component are human leukocyte antigens (HLA) linked. The incidence of childhood onset T1D increased progressively over the past half century. Recent data showed that high risk HLA genotypes are becoming less frequent over time in youths with T1D of non Hispanic white and Hispanic origin. In the present study we evaluated the frequency of high, moderate and low risk HLA genotypes in a southern European Caucasian population of T1D that showed an increase in incidence in the past decades.
Materials and methods: We analysed 723 randomly T1D patients born from 1950 to 2008 and diagnosed at the mean age of 14.9 ±7.8 years (age range 5-36). Typing for HLA-DRB1 and DQB1 loci was performed by a reverse line blot assay. HLA genotypes were classified in three risk categories, based on the absolute risk values previously estimated in our population: high risk for DRB1*03-DQB1*0201/DRB1*04-DQB1*0302 genotype (DRB1*04 not 0403,06,11);moderate risk for DRB1*04-DQB1*0302/DRB1*04-DQB1*0302,DRB1*03-DQB1*0201/DRB1*03-DQB1*0201, DRB1*04-DQB1*0302/X (X not DRB1*02, 03, DRB1*04-DQB1*0302 (DRB1*04 not 0403, 06, 11) or DQB1*0602) genotypes and DRB1*03/X (X not DRB1*02, 03, DRB1*04-DQB1*0302 (DRB1*04 not 0403, 06, 11) or DQB1*0602); low risk for the remaining genotypes. Subjects were subdivided by years of birth in two cohorts: 1950-1989 and 1990-2008. The HLA genotypes frequencies between cohorts were analyzed using the chi2 test.
Results: We observed that the proportion of the three HLA risk categories (22.3% high, 61% moderate and 18.4% low, vs. 20.4% high, 59.3% moderate and 18.6% low, respectively) was similar between the two cohorts.
Conclusion: We demonstrated that the distribution of T1D HLA risk categories did not change over the past six decades in this Caucasian population in contrast with what reported elsewhere in Caucasians from Australia and in non Hispanic white and Hispanic patients. This indicates that in our population, despite the increase in incidence of the disease, the distribution of HLA genotype categories among T1D patients remains the same.

The Novosibirsk city type 1 diabetes registry among children: trends for 1980-2008 study periods
O.V. Sazonova[1,2], E.V. Shubnikov[3], G.I. Simonova[3], V.A. Galenok†[1], E.A. Vaskina[1], O.A. Nikiforov[1,2], A.G. Akopova[2], I.A. Kalinina[2], Y.P. Nikitin[3];
[1]Novosibirsk State Medical Academy, [2]Municipal Diabetes Center, Clinical Hospital 1, [3]Institute of Internal Medicine, Novosibirsk, Russian Federation.

Background and aims: Novosibirsk is a big industrial City in Western Siberia, Russia. The population of City takes third place among Russian Cities. The aim of the study was to describe trends of Type 1 Diabetes Mellitus (T1DM) incidence among children from 0 to 14 years old in Novosibirsk City during 1980-2008 study periods.
Materials and methods: Data for 1980-1989 and 1990-1999 study periods was collected according the standards of WHO program "DiaMond" and data for 2000-2008 years according the National Russian Registry of DM. Two sources of information have been used during the both studies: data from all Novosibirsk hospitals and data from all Novosibirsk children' endocrinologists. The criteria of diagnosis were based on the Diagnosis of Diabetes, age of onset from 0 to 14 years, citizenship of Novosibirsk City for at least 1 year before manifestation.
Results: During 1980-2008 study period 651 children of 0-14 years old were diagnosed and registered (324 boys, 327 girls) with total incidence of 9,7 cases per 100000 children (95% CI:7,9-11,6). The mean T1DM incidence among boys in 1980-1989, 1990-1999 and 2000-2008 study periods was 5,7 per 100000 boys (4,2-7,1), 8,5 (6,1-10,9) and 15,0 (11,8-18,1) accordingly. The incidence among girls for the same study periods was 5,1 (3,7-6,5), 8,5 (7,4-9,6) and 17,2 (14,1-20,2). For both sexes the incidence was 5,4 (4,1-6,6), 8,5 (7,1-9,9) and 16,0 (14,0-18,0) accordingly. We have revealed the peculiarities of T1DM incidence growth among 0-4, 5-9 and 10-14 age groups of boys and girls during study periods. We have found significant growth of incidence among girls 0-4 years old during 1980-1989, 1990-1999 and 2000-2008 study periods: 2,3 (0,6-4,0), 5,9 (3,2-8,6) and 10,8 (6,6-15,0). We have found significant growth of incidence among boys 0-4 years old only for 1990-1999 study period: 8,3 (5,5-11,2), compare with 2,7 (1,2-4,2) for 1980-1989 and 8,4 (3,7-13,1) for 2000-2008 study periods. For the 5-9 years old children the incidence growth was significant as for boys: 4,9 (2,2-7,5), 8,9 (5,1-12,7) and 19,5 (15,4-23,6) for 1980-1989, 1990-1999 and 2000-2008 study periods, so as for girls: 6,0 (3,6-8,4), 10,3 (6,9-13,8) and 22,5 (16,8-28,7). We have found significant growth of incidence among 10-14 years old children only for 2000-2008 study period: 18,1 (6,8-29,3) for boys, so as for girls: 18,3 (14,7-22,0), compare with 10,0 (6,3-13,7), 8,2 (4,7-11,6) for boys and 7,3 (4,7-9,9), 8,7 (6,9-10,5) for girls in 1980-1989 and 1990-1999 study periods. There were no significant differences in incidence among boys and girls (9,5(7,6-11,4) and 10,0(7,9-12,2) during 1980-2008 study periods. We also have found picks of manifestation of T1DM in March, June and September during 1980-2008 study periods with lowest incidence in July.
Conclusion: T1DM incidence among 0-14 years old children of Novosibirsk City is high and constantly growing as for boys, so as for girls. The highest T1DM incidence rates were revealed in 5-9 and 10-14 years old groups. But the highest incidence growth was revealed for 0-4 and 5-9 years old groups for both sexes. We think that environmental factors responsible for seasonal manifestations played a major role in such unfavourable trends of T1DM incidence in Novosibirsk City.

281

Low-grade inflammation and endothelial dysfunction precede the increase in pulse pressure in type 1 diabetes: a 20-yr longitudinal study
I. Ferreira[1], P. Hovind[2], C.G. Schalkwijk[3], H.-H. Parving[4], C.D. Stehouwer[3], P. Rossing[2];
[1]Depts Internal Medicine & Clinical Epidemiology, Maastricht University Medical Centre, Netherlands, [2]Steno Diabetes Center, Gentofte, Denmark, [3]Dept Internal Medicine, Maastricht University Medical Centre, Netherlands, [4]Dept Medical Endocrinology, Rigshospitalet, University Hospital of Copenhagen, Denmark.

Background and aims: Arterial ageing is accelerated in diabetes. This is illustrated by steeper increases in pulse pressure (PP), a marker of arterial stiffening, with ageing, in diabetic than in non-diabetic individuals, which may partially explain their increased cardiovascular risk. The mechanisms involved in accelerated arterial ageing remain unknown, however, but low-grade inflammation and/or endothelial dysfunction have been suggested to

play an important role. We have therefore investigated whether the longitudinal increases in markers of inflammation (CRP and sICAM-1) and endothelial dysfunction (sICAM-1 and sVCAM-1) were associated with and *preceded* the increases in PP in an inception cohort of individuals with type 1 diabetes (T1D).
Materials and methods: The study population consisted of 277 T1D patients (114 women) from an outpatient diabetic clinic (Gentofte, Denmark), who were consecutively admitted, upon diagnosis, between Sep'79-Aug'84 (mean age at diagnosis 27.5 ± 13.8 yrs; 216 adults). These patients attended the outpatient clinic every 3-4 months throughout a total follow-up period of >20 yrs, as part of their routine evaluation, which included measurement of blood pressure (BP) and other risk factors. PP (the pulsatile component of BP) was calculated as systolic - diastolic pressure. CRP, sICAM-1 and sVCAM-1 were measured in serum samples collected throughout the whole longitudinal period. We used generalized estimating equations (GEE) to investigate, longitudinally, the associations hypothesized; in order to ascertain 'possible causality', we also investigated the associations between levels of CRP, sICAM-1 and sVCAM-1 at any time point and changes in PP 2 years thereafter (autoregressive GEE model). All analyses were adjusted for sex, age at diagnosis, smoking, anti-hypertensive treatment and mean arterial pressure (the steady component of BP). Results hereby obtained are expressed as longitudinal regression coefficients (per SD increase in serum marker) and respective 95%CI.
Results: PP increased by 0.53 mmHg/yr (95%CI: 0.47; 0.60), CRP by 0.033 mg/l/yr (0.028; 0.039), sICAM-1 by 1.8 ng/ml/yr (1.0; 2.6) and sVCAM-1 by 1.8 ng/ml/yr (0.3; 3.2) over the 20-yr longitudinal period. Higher levels of lnCRP, sICAM-1 and sVCAM-1 were all positively associated with higher levels of PP: 0.53 mmHg (0.05; 1.00), 1.09 mmHg (0.53; 1.66) and 0.94 mmHg (0.40; 1.48) per SD, respectively. In auto-regressive GEE models, sICAM-1 and sVCAM-1, but not lnCRP, were also associated with PP: 0.56 mmHg (0.18; 0.94), 0.53 mmHg (0.17; 0.90) and -0.01 mmHg (-0.38; 0.35) per SD, respectively. Adjustments for other risk factors, i.e. HbA1c, cholesterol, BMI, creatinine and urinary albumin excretion, did not change these associations.
Conclusion: Life-course increases in low-grade inflammation and endothelial dysfunction are associated with and *precede* increases in pulse pressure. Our findings thus support, for the first time with a truly longitudinal design, the view of early involvement of these mechanisms in the premature development of arterial stiffness in diabetes.

PS 4 Prediabetes and screening for type 2 diabetes

282

New approach to diabetes screening
A.V. Dreval, I.V. Misnikova, I.A. Barsukov;
Endocrinology, Moscow Region Research Clinical Institute, Moscow, Russian Federation.

Background and aims: Leading international organizations (WHO, ADA, IDF) offer different models of screening of glucose metabolism abnormalities (GMA). Aims: 1) the comparison of different GMA screening models via determination of their sensitivity and specificity for diagnosing T2DM, IGT and IFG; 2) to develop new screening model, which simplify screening procedure and to reduce expenses on its conduction while keeping high sensitivity and specificity.
Materials and methods: Population-based screening for GMA among 2508 individuals of Moscow County. Standard 2-h 75 g OGTT was performed using HemoCue analyzers in subjects previously undiagnosed with diabetes. 626 subjects (24,9%) with GMA were found followed the 1999 WHO criteria. Depending on diagnostic criteria (ADA-2003 or WHO-1999) and research method (only FBG, OGTT) 5 screening models were considered: Model 1. Screening according to WHO, 1999 criteria (with using OGTT in all persons);Model 2. Screening according to ADA, 2003 criteria (OGTT not used); Model 3. Use of OGTT only for subjects with IFG to be measured by ADA criteria; Model 4. Use of OGTT only for subjects with IFG according to WHO criteria; Model 5. Use OGTT only for subjects with FPG > 5.0 mmol/l; Sensitivity (Se) and specificity (Sp) of screening models is compared based on definition of T2DM, IGT, IFG on formula: Se=TP/(TP+FN), Sp=TN/(TN+FP),TP-True Positive, TN-True Negative, FN-False Negative, FP-False Positive.
Results: Screening conducted according to model 1 makes it possible to discover the highest percentage of patients with T2DM and IGT. Removal of OGTT or limited use of OGTT as suggested in other screening models leads to a decrease in the diagnosing of T2DM and IGT in the population. Therefore, using screening model 2 we cannot find persons with IGT and 4% of T2DM patients (among some patients T2DM is diagnosed at the 2nd point of OGTT). A decrease in the diagnosing of IGT could worsen the prognosis of T2DM development among this category of people. When there is no information about the presence of IGT, corresponding preventative measures to decrease the risk of T2DM will not be taken. We suggest that the risk of glycemia increasing following a 75 g load of glucose is minimal given a certain level of FPG. Therefore, no people with hyperglycemia were found after loading given FPG of up to 4.0 mmol/l it was minimal given glycemia from 4.1 to 5.0 mmol/l. Given glycemia from 5.1 to 5.5 mmol/l, the risk of IGT appearing grew by 2.26 times. Given glycemia from 5.6 to 6.0 mmol/l, the risk grew by nearly 4 times. Correspondingly, the risk of discovering T2DM and IGT at the second point after loading could be considered minimal among people with glycemia of up to 5.0 mmol/l and OGTT could be excluded from the screening model. According to our data, 23.3% of those examined had FPG of less than 5.0 mmol/l. Excluding OGTT among this category could make it possible to save funds spent on the conduction of screening. We suggest a new model: use OGTT only for subjects with FPG > 5.0 mmol/l.
Conclusion: Screening model 5 (use OGTT only for subjects with FPG >5.0 mmol/l) displays high sensitivity for diagnosing T2DM (0.99) and for IGT (0.93). New screening model allows to reduce expenses by excluding OGTT among subjects with FPG < 5.1 mmol/l, share of which makes 23.3% among participants.

283

A comparison of screening strategies for impaired glucose tolerance and type 2 diabetes mellitus in a UK community setting: a cost per case analysis
K. Khunti[1], N.A. Taub[1], C.L. Gillies[1], K.R. Abrams[1], L.J. Gray[1], S.L. Hiles[2], D. Webb[2], B.T. Srinivasan[2], M.J. Davies[2];
[1]Department of Health Sciences, [2]Department of Cardiovascular Sciences, University of Leicester, United Kingdom.

Background and aims: Universal screening for vascular risk is to be introduced in the UK starting in April 2009, for those aged over 40 years. This will have a substantial impact on health care resources, therefore it is essential to

investigate different methods for pre-screening people at high risk. Currently, there is no systematic or structured screening policy for Type 2 Diabetes (T2DM) in most countries. The aim of this study was to assess effectiveness and cost efficiency of a combination of different screening methods for undiagnosed T2DM and impaired glucose regulation (IGR included IGT and/or IFG) in a multi-ethnic community setting.

Materials and methods: A random sample of people aged 40-75 years from 24 general practices in Leicestershire were invited for a 75g Oral Glucose Tolerance Test (OGTT), as the ADDITION (Leicester) screening study. Participants provided a detailed medical history, anthropometric measurements and completed the FINDRISC questionnaire. Clinical effectiveness was compared using sensitivity, specificity, and the area under the ROC curve. We compared 17 approaches to screening involving FINDRISC and our own Leicester self-assessment (LSA) and Leicester primary-care-data (LPD) risk scores, in addition to fasting glucose and HbA1c. The cost-effectiveness of tests was assessed by 'cost per case', i.e. the total estimated cost of screening a specified population, modeling cost components such as nursing cost rates, nursing time, administration costs, lab test costs. This is then divided by the number of cases identified, as estimated using test sensitivity values from the study sample data. As an improvement on previous screening cost-effectiveness models, these models were run within a Bayesian framework, using a simulation-based approach that incorporates uncertainty around both the estimated costs and sensitivity values.

Results: 6749 individuals participated: the age range was 25-75 years (SA) and 40-75 (WE); mean age was 56.1 (SD 10.8), 47.7% were male and 27.5% were of south Asian ethnicity. 6372 individuals (94.4%) had all relevant data recorded and were included in the analysis; of these 202 (3.2%) were diagnosed at OGTT with screen-detected T2DM, and an additional 902 (14.2%) were diagnosed with IGR. Estimated cost implications varied substantially for the 212 screens we considered; results for three screens are shown in the Table for illustration.

Conclusion: The suggested strategies provide a number of tools for screening people for T2DM and IGR. A stepwise screening strategy using self-assessment or practice routine data to calculate a risk score, followed by a FPG or HBA1c is an efficient screening strategy for detecting T2DM and T2DM/IGR in a community setting.

Table. Sample, 3 of the 212 screening methods modelled.

Stage 1	Stage2	Stage 3	Proportion to OGTT (%) (SE)		Est. cost per T2DM case detected (€) (SE)	
HbA1c ≥6.0	OGTT		22.3	(0.5)	1713	(55)
LSA≥14	HbA1c≥5.8	OGTT	29.8	(0.6)	1245	(51)
LPD≥5.00	HbA1c≥6.0	OGTT	18.8	(0.5)	931	(42)

Diagnostic value of glycated haemoglobin as a screening test for diabetes mellitus

Y. Hu, W. Liu, Y. Chen, M. Zhang, S. Li, X. Liu, T. Han, L. Ji;
Division of Endocrinology, Renji Hospital, Shanghai Jiaotong University, Shanghai, China.

Background and aims: To assess the validity of fasting plasma glucose (FPG) and/or glycated haemoglobin (HbA1c) as screening tests for diabetes mellitus.

Materials and methods: A total of 2298 subjects (956 male and 1342 female) in Shanghai area were included. All subjects underwent a 75g oral glucose tolerance test (OGTT) and HbA1c measurement. Receiver operating characteristic curve (ROC curve) analysis was used to examine the sensitivity and specificity of FPG and HbA1c for detecting diabetes, which was defined as a FPG≥7.0 mmol/L or a post-challenge 2-h plasma glucose≥11.1 mmol/L.

Results: 1. Based on 1999 WHO criteria,830 had normal glucose tolerance(NGT),110 had impaired fasting glucose(IFG),380 had impaired glucose tolerance(IGT),183 had IGT and IFG,795 had diabetes. The prevalence of newly diagnosed diabetes was 34.6% (*n*=795). 2. Based on the ROC curve,the optimal cut-point of FPG related to diabetes diagnosed by OGTT was 6.1mmol/L that was associated with a sensitivity and specificity of 81.5% and 81.0% respectively; The optimal cut-point of HbA1c related to diabetes diagnosed by OGTT was 6.1%,which was associated with a sensitivity and specificity of 81.0% and 81.0% respectively; The screening model using FPG≥6.1mmol/L or HbA1c≥6.1% had sensitivities of 96.5% for detecting undiagnosed diabetes;The screening model using FPG≥6.1mmol/L and HbA1c≥6.1% had specificity of 96.3% for detecting undiagnosed diabetes.

Conclusion: The simultaneous measurement of FPG and HbA1c might be a more sensitive and specific screening tool for identifying high-risk individuals with diabetes at an early stage.

sensitivitis and specificities of different screening models for detecting diabetes

screening model	sensitivity (%)	specificity (%)	positive likelihood ratio	negativelikelihood ratio
FPG≥5.6mmol/L	92.5	54.3	2.02	0.46
FPG≥7.0mmol/L	54.5	100	∞	0.46
FPG≥6.1mmol/L	81.5	80.5	4.18	0.23
HbA1c≥6.1%	81.0	81.0	4.26	0.23
FPG≥6.1mmol/L and HbA1c≥6.1%	66.0	96.3	17.84	0.35
FPG≥6.1mmol/L or HbA1c≥6.1%	96.5	65.2	2.77	0.05

Differences between the 10-year incidence of retinopathy and chronic kidney disease in screening-detected and in usual care-detected type 2 diabetes patients. The Hoorn Study

H. Zavrelova[1], M. Alssema[2], G. Nijpels[3], B.C.P. Polak[1], A.C. Moll[1], P.J. Kostense[2], C.D.A. Stehouwer[4], J.M. Dekker[2];
[1]Ophthalmology, EMGO Institute for Health and Care Research, VU University Medical Center, Amsterdam, [2]Epidemiology & Biostatistics, EMGO Institute for Health and Care Research, VU University Medical Center, Amsterdam, [3]General Practice, EMGO Institute for Health and Care Research, VU University Medical Center, Amsterdam, [4]Internal Medicine, Maastricht University Medical Centre, Netherlands.

Background and aims: The onset of type 2 diabetes (T2DM) complications is known to occur in many patients several years before T2DM is diagnosed. Early detection of T2DM patients by screening would be meaningful if a reduction of complications like retinopathy and chronic kidney disease could be achieved. We investigated whether screening-detected T2DM patients carry a lower risk of retinopathy and chronic kidney disease than T2DM patients diagnosed in usual care.

Materials and methods: In the Hoorn Study, a population-based cohort study (n=2484, age 50-75) of diabetes and diabetes complications, 115 patients were classified as having newly diagnosed T2DM after screening at baseline, 44 of whom participated in the 10-year follow-up examination. The 10-year incidence of complications of these screening-detected patients was compared to the 10-year incidence of complications as estimated from cross-sectional annual medical examinations in usual care-detected T2DM patients (n=1336). The regression coefficient of the relation between the proportion of complications and the T2DM duration was used to compute an estimated 10-year incidence of T2DM complications in the usual care-detected T2DM patients.

Results: The 10-year incidence of retinopathy and chronic kidney disease in the screening detected patients were 12.2% (5/41) (95% confidence interval (CI): 4.1% to 26.2%) and 37.8% (14/37) (95% CI: 22.5% to 55.2%), respectively. In the usual care-detected patients the estimated 10-year incidence of retinopathy was 8% (95% CI: 3% to 13 %) and for chronic kidney disease 20% (95% CI: 13% to 26 %). The difference in 10-year incidence between screening and usual care-detected patients shows a 4.2% (95% CI: -5.9% to 14.3 %) higher incidence for retinopathy and 17.8% (95% CI: 2.1 to 33.6%) higher incidence for chronic kidney disease in screening-detected compared to usual care-detected patients. The screened subjects were characterized by a markedly higher blood pressure as compared to the usual care detected patients, at time of diagnosis and 10 years later.

Conclusion: Surprisingly, this study showed that the incidence rate of retinopathy and chronic kidney disease is higher in screening-detected patients compared to patients detected in usual care. This suggest that non-symptomatic hyperglycemia confers a high-risk for diabetic complications. Thus, screening for T2DM might help detect patients in an earlier stage of the disease with need to initiate strict treatment on multiple risk factors for retin-

opathy and chronic kidney disease in order to prevent the development of these complications.

Pre-diabetes is associated with abnormal ventricular diastolic function in Korean population

N. Kim[1], J. Seo[1], H. Kim[1], H. Cho[1], S.J. Yang[2], J. Park[2], D.L. Kim[3], S. Kim[1], K. Choi[1], S. Baik[1], D. Choi[1], C. Shin[1], H. Lim[1], S. Lim[1], S. Kim[1];
[1]Korea University Hospital, Ansan, [2]Endocrinology and Metabolism, Korea University, Seoul, [3]Internal Medicine, Konkuk University, Seoul, Republic of Korea.

Background and aims: Patients with diabetes have an increased incidence of congestive heart failure. The recent use of sensitive and less load-dependent techniques such as myocardial velocity by tissue Doppler imaging has demonstrated subclinical left ventricular (LV) dysfunction is common in diabetic patients without known cardiac disease. However, the impact of prediabetes on LV dysfunction has not been studied in a population-based study. In the present study, we aimed to evaluate the extent to which prediabetes is associated with LV structure and function.
Materials and methods: The subjects consisted of 1221 Koreans aged 40-69 years from the Korean Genome Epidemiology Study, which is an ongoing prospective population-based study. Data were collected from a comprehensive health examination and subjects with LV systolic dysfunction or known CVD were excluded.
Results: Glucose tolerance status was assessed by fasting (FPG) and 2 hour glucose after 75g glucose loading (2hPG). Categories of glucose regulation was defined by the 2003 ADA criteria; normal glucose tolerance (NGT, FPG <5.6 and 2hPG <7.8 mmol/l, n=581), prediabetes (FPG=5.6-6.9 and/or 2hPG=7.8-11.0 mmol/l, n=434) and diabetes (FPG≥7.0 or 2hPG ≥11.1 mmol/l or previous clinical diagnosis, n=200). Echocardiography was used to assess LV structure (LV mass) and systolic (LV ejection fraction) and diastolic function, by pulse-wave Doppler (E/A ratio; ratio of early to late diastolic mitral flow velocity) and tissue Doppler imaging (Ea; early diastolic velocity). From NGT to prediabetes to diabetes, LV mass increased, and E/A ratio and Ea decreased progressively [LV mass index (mean±SD), 86.5±17.5, 88.7±16.8, 91.2±19.4 g/m^2, p=0.001; E/A ratio, 1.23±0.40, 1.10±0.32. 1.02±0.32, p<.0001; Ea, 7.57±1.91, 7.02±1.63, 6.47±1.65 cm/s in NGT, prediabetes, and diabetes, respectively, p<.0001]. However, ejection fraction and other parameters of conventional Doppler indexes were comparable in the three groups. After adjusting for age, sex, body mass index, and blood pressure, Ea was lowest in subjects with diabetes, and significantly lower in those with prediabetes than with NGT (mean±SE, 7.26±0.07, 7.00±0.08, 6.66±0.11 cm/s in NGT, prediabetes, and diabetes, p<.0001). E/A ratio was also lower in those with prediabetes than NGT, but comparable in subjects with prediabetes and diabetes in the multivariate model (mean±SE, 1.17±0.02, 1.10±0.02, 1.05±0.02 cm/s in NGT, prediabetes, and diabetes, p<.0001).
Conclusion: Diastolic dysfunction was evident in subjects with prediabetes independently of body mass index and hypertension. Screening those with prediabetes for diastolic dysfunction may identify subjects with risk for cardiovascular morbidity and mortality.

One third of the Portuguese population has diabetes or "pre-diabetes" - Diabetes Prevalence Study in Portugal

L. Gardete-Correia[1], S. Massano-Cardoso[2], J.M. Boavida[3,4], J.-F. Raposo[1], C. Mesquita[1], C. Fona[1], R. Carvalho[1];
[1]Portuguese Diabetes Association (APDP), Lisbon, [2]Hygiene and Social Medicine Institute, Coimbra, [3]Portuguese Diabetes Programe, Directorate General of Health, Lisbon, [4]Portuguese Society of Diabetology, Lisbon, Portugal.

Background and aims: The number of people with diabetes has been increasing all over the world to an extent that can be called as an epidemic. Until this moment the Portuguese data came from either Catalonian data (IDF), either from the Portuguese Statistics Institute (2006) by patients' self-reference.
The objectives of this study were to determine in the Portuguese population aged between 20 and 79 years the prevalence of type 2 diabetes and pre-diabetes defined as Impaired fasting glucose (IFG) levels and Impaired glucose tolerance (IGT)
Materials and methods: Taking into account the number of inhabitants (7.657.529 people between 20 and 79 years old), 122 sub-statistical units were selected with regional and national representativeness. Within each sub-statistical unit, the resident population was randomly chosen by age and gender. The total sample was constituted by 5.167 subjects, which corresponds to an acceptance rate of 63,2% of the invitations sent to participate in the Study. The national prevalence and comparative prevalence have been calculated. Fasting glycaemia and 2 hour OGTT were made to all non-diabetic subjects. The diagnostic criteria used were the referenced by WHO. The Study took place between January 2008 and January 2009.
Results: The national diabetes prevalence is 11,7%, (95% CI: 10,8% - 12,6%) with a significant difference between men: 14,2% (95% CI: 12,5% - 15,5%); and women: 9,5% (95% CI: 8,5% - 10,6%). 6,6% of the subjects had a previous diabetes diagnosis and 5,1% were undiagnosed. The comparative prevalence found was 9.8% (5.3% with previous diagnosis of diabetes and 4.4% undiagnosed). 905.035 people aged between 20 and 79 years have diabetes, from which 395.134 subjects (43,6% of the total) didn't know they had diabetes. By age groups, the results show that: 2,4% of the population aged between 20 and 39 years; 12,6% of the people from 40 to 59 years old and 26,3% of the people aged between 60 and 79 years have diabetes. 23,2% (1.782.663 people) have IGF and/or IGT. The population from Azores (an autonomous region) has the highest regional results, with a diabetes prevalence of 14,3% (9,2% with diagnosed diabetes and 5,1% with undiagnosed diabetes).
Conclusion: Diabetes is a chronic disease with a high prevalence in Portugal, which along with "pre-diabetes" reaches one third of the population over 20 years old, being among the highest numbers in Europe. 34.9% of the population aged between 20 and 79 years have diabetes or "pre-diabetes", corresponding to 2.687.698 Portuguese resident people. Concerning people with diabetes we observe an high number of males and as described in another countries a high number- 43,6% - of undiagnosed people with diabetes.

Adiponectin trajectories in the 13 years prior to the onset of type 2 diabetes mellitus - The Whitehall II study

A.G. Tabak[1,2], M. Carstensen[3], M. Kivimaki[1], M. Jokela[1], M. Roden[3], M.J. Shipley[1], D.R. Witte[1,4], E.J. Brunner[1], C. Herder[3];
[1]Department of Epidemiology and Public Health, University College London, United Kingdom, [2]1st Department of Medicine, Semmelweis University Faculty of Medicine, Budapest, Hungary, [3]Institute for Clinical Diabetology, German Diabetes Center, Duesseldorf, Germany, [4]Steno Diabetes Center, Gentofte, Denmark.

Background and aims: Low levels of serum adiponectin have repeatedly been associated with the development of type 2 diabetes (T2D). To clarify the issues of timing and causality, we examined trajectories of adiponectin prior to T2D diagnosis compared to trajectories in non-cases, who did not develop diabetes during follow-up.
Materials and methods: Case-cohort study within the Whitehall II cohort with a total of 2809 participants (27.2% women, age at baseline [mean±SD] 49.3±5.9 years, BMI 25.3±3.5 kg/m^2). Serum levels of adiponectin were measured at up to three time points for the 335 cases with incident T2D during the follow-up period and 2474 controls remaining T2D-free (phase 3, the baseline: 1991-94, phase 5: 1997-99, and phase 7: 2003-04). In the analysis, year 0 was set at diabetes diagnosis for cases and at a randomly selected time point during follow-up for non-cases. Adiponectin levels were traced backwards to participants' first clinical screening to assess trajectories during 13 years prior to T2D diagnosis. Multilevel models adjusted for age, sex and ethnicity were based on 755 measurement points in cases and 5095 measurement points in the remaining cohort.
Results: Adiponectin levels were lower among diabetes cases 13 years before year 0 (mean difference 0.28 [95% CI 0.21-0.34] $\log_2$ mg/L). Adiponectin levels decreased log-linearly throughout the observation period in non-cases by 0.011 [95% CI 0.006-0.0.017] $\log_2$ mg/L/year from 9.3 [95% CI 9.1-9.5] to 8.8 [95% CI 8.6-9.0] mg/L. The decline in adiponectin from 7.9 [95% CI 7.5-8.3] to 7.1 [95% CI 6.8-7.4] mg/L among cases was significantly steeper than that among controls (mean difference in slopes 0.005 [95% CI 0.001-0.0.010] $\log_2$ mg/L/year). After adjustment for contemporaneous body mass index, the difference in adiponectin levels between cases and non-cases was halved but remained significant (mean difference 0.15 [95% CI 0.09-0.22] $\log_2$ mg/L) while the slopes were no longer different from each other (p>0.05).
Conclusion: Adiponectin levels differ markedly between those who develop T2D and those who do not, more than a decade before diagnosis, but do

not appear to be involved in the immediate changes that precede the disease onset. The more rapid decline in adiponectin levels among cases compared to non cases is explained largely by differences in BMI and BMI changes of the two groups.
Adiponectin measurements were funded by a Medical Research Council (UK) New Investigator Award

Work stress increases risk of type 2 diabetes in middle-aged Swedish women
C.-G. Östenson[1], M. van den Donk[2], A. Hilding[1];
[1]Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden, [2]Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Netherlands.

Background and aims: In cross-sectional analyses in the Stockholm Diabetes Prevention Program, a population-based cohort, stress factors at work and low sense of coherence (SOC), a factor for successful coping with stressors, were associated with type 2 diabetes in middle-aged Swedish women. We investigated these associations prospectively in both men and women in the Stockholm Diabetes Prevention Program.
Materials and methods: The study included 3205 Swedish women and 2227 Swedish men, aged 35-56 years, with normal glucose tolerance at baseline. At follow-up, type 2 diabetes was detected in 60 women after 8 years and in 111 men after 10 years. We analysed the associations of work stress by high demands, low decision latitude, job strain (a combination of high demands and low decision latitude), shift work, and overtime work with type 2 diabetes. Furthermore, we studied low SOC in association with type 2 diabetes. Baseline work factors and SOC were measured by questionnaire. We calculated odds ratios (OR) and 95% confidence intervals using multiple logistic regression analysis. ORs were adjusted for age and education, while analysis revealed that data were not confounded by factors like waist, BMI, physical inactivity, smoking and family history of diabetes.
Results: In women, we found no association between high work demands (age-adjusted OR 1.0 (0.5-2.0); fully adjusted OR 1.2 (0.6-2.4)), overtime work (age-adjusted OR 0.9 (0.5-1.6); fully adjusted OR 1.1 (0.6-1.9)), or low SOC (age-adjusted OR 0.9 (0.4-2.1); fully adjusted OR 0.8 (0.3-1.8)) and type 2 diabetes. Low decision latitude was associated with type 2 diabetes on its own (age-adjusted OR 2.7 (1.4-5.5); fully adjusted OR 2.3 (1.1-4.9)), and combined with high demands (job strain; age-adjusted OR 3.9 (2.1-7.4), fully adjusted OR 3.4 (1.7-6.5)). Shift work seemed associated with type 2 diabetes (age-adjusted OR 2.6 (1.2-5.3); age and education adjusted OR 2.4 (1.2-5.1)), but this increased risk was partly explained by BMI (age, education and BMI adjusted OR 2.2 (1.0-4.9). In men, high work demands seemed to protect against type 2 diabetes (age-adjusted OR 0.5 (0.3-0.9); fully adjusted OR 0.6 (0.3-1.0)), whereas low SOC seemed to increase diabetes risk (age-adjusted OR 1.9 (1.2-3.1); fully adjusted OR 1.7 (1.1-2.9)). There were no associations between decision latitude (age-adjusted OR 0.9 (0.7-1.3); fully adjusted OR 0.9 (0.6-1.2)), shift work (age-adjusted OR 1.2 (0.7-2.1)); fully adjusted OR 1.1 (0.6-2.0)), or overtime work (age-adjusted OR 0.8 (0.5-1.3)); fully adjusted OR 0.9 (0.6-1.4)) and type 2 diabetes.
Conclusion: This prospective study indicates that risk of type 2 diabetes is influenced by stress factors at work in middle-aged women and men. In women, type 2 diabetes risk is increased by low decision latitude, especially in combination with high work demands, and shift work, but not by overtime work or low SOC. In men, type 2 diabetes risk is decreased by high work demands, and increased by low SOC.

Trends in the epidemiological situation on diabetes among adult population in Russia
O. Maslova, Y. Suntsov, I. Cazakov, L. Bolotskaja;
National Research Centre for Endocrinology, Moscow, Russian Federation.

Background and aims: All over the world is marked growth of number patients with diabetes (DM), finding epidemic scales. Monitoring of situation on DM in Russia carries out the State Register of DM (SRDM) which represents information-analytical system of the regional centers. The aim of this study was to estimate trends in the prevalence, incidence and mortality of adult diabetic patients in Russia.
Materials and methods: Using the regional centers SRDM database, we estimated trends in the prevalence, incidence and mortality of adult diabetic patients from 2002 to 2007. All patients with type 1 (T1DM) or type 2 (T2DM) DM were aged > 18 yrs.
Results: Number of diabetic patients (millions) in Russia increased considerably from 1.078 in 2002 to 2.807 in 2007. Prevalence of T1DM increased by 2.1% (from 217.9 (2002) to 222.5 (2007) per 100.000 adult person-years). Prevalence of T2DM increased by 30.5% (from 1696.1 (2002) to 2214.0 (2007) per 100.000 adult person-years). Incidence of DM increased 1.4-fold among adult population, basically at the expense of patients with T2DM. So incidence of T2DM increased by 45% (from 166.2 (2002) to 241.0 (2007) per 100.000 adult person-years), whereas incidence of T1DM decreased by 1.4% (with 14.3 (2002) to 14.1 (2007) per 100.000 adult person-years). Incidence of T1DM was higher (~1.5-fold) in males, than in females. Incidence of T2DM was higher (~2.3-fold) in females, than in males. Mortality of diabetic patients decreased from 31.3 (2002) to 28.9 (2007) per 100.000 adult person-years (for T1DM) and from 341.9 (2002) to 339.5 (2007) per 100.000 adult person-years (for T2DM). Average lifetime of diabetic patients increased from 54.9±0.75 yrs to 57.2±0.28 yrs (for T1DM) and from 69.2±0.11 yrs to 71.6±0.10 yrs (for T2DM).
Conclusion: Thus, prevalence of DM in Russia increased by 16.3%. Incidence of T2DM increased by 45%, whereas incidence of T1DM decreased by 1.4% and mortality decreased by 1.3%, lifetime of diabetic patients increased by 1%.

PS 5 Prevalence of type 2 diabetes

291

Prevalence of diabetes among adults aged from 18 to 74 years living in mainland France - the French Nutrition and Health Survey (ENNS 2006-2007)

C. Bonaldi[1], M. Vernay[2], C. Roudier[2], B. Salanave[2], K. Castetbon[2], A. Fagot-Campagna[1];
[1]Maladies Chroniques et Traumatismes, Institut de Veille Sanitaire, Saint Maurice, [2]Unité de Surveillance et d'Epidémiologie Nutritionnelle, Institut de Veille Sanitaire, Bobigny, France.

Background and aims: The purpose of this study was to investigate the prevalences of diagnosed and undiagnosed diabetes, and impaired fasting glucose in adults from 18 to 74 years living in mainland France.
Materials and methods: Data come from the French Nutrition and Health Survey conducted in 2006-2007 which describes the nutritional situation of children aged from 3 to 17 years and adults aged from 18 to 74 years living in mainland France. A three stages stratified probability sampling design was used to assure a nationwide basis analysis (*n*=2,413 adults included in our analysis). Diagnosed diabetes was identified by self-questionnaire (self-reported diabetes or oral hypoglycemic medication or insulin). Fasting plasma glucose was used to categorize people with undiagnosed diabetes (FPG≥7.0 mmol/l) and impaired fasting glucose (World Health Organisation criteria : 6.1≤FPG <7.0 mmol/l; American Diabetes Association criteria : 5.6≤FPG <7.0 mmol/l).
Results: The prevalence of total diabetes was 4.9% (3.9-6.2) for the total 18-74 years population. The prevalence of diagnosed diabetes (with medication or not) was estimated to 3.9% (3.0-5.1), so the prevalence of undiagnosed diabetes reached 1.0% (0.6-1.7). The prevalence of the treated diabetes by oral or insulin medication was 3.4% (2.5-4.4). The proportion of 18-74 years old adults with impaired fasting glucose was 5.6% (4.3-7.4) according to WHO criteria and 15.5% (13.2-18.1) according to ADA criteria. Prevalences of diagnosed diabetes and impaired fasting glucose were about twofold for men than women (5.4% versus 2.5% and 7.9% versus 3.4% (WHO) or 19.9% versus 11.2% (ADA) respectively), and no difference by sex was observed for the prevalence of undiagnosed diabetes.
Conclusion: On a nationwide basis sample, this study brings a first estimation of the prevalence of the total diabetes (diagnosed, with medication or not, and undiagnosed) and impaired fasting glucose in adults aged from 18 to 74 years living in mainland France. We found only one diabetic person on five was not diagnosed.

Metabolic syndrome in patients with bipolar disorders and the general population of Spain: findings from a population-based case-control study: the BIMET-VIVA study

R. Gabriel[1], L. Lorenzo[2], M. Alonso[2], A.M. González[3], E. Vieta[4], J.M. Montes[5], J. Rejas-Gutiérrez[6], F.J. Mesa[6];
[1]Clinical Epidemiology, Hospital Universitario La Paz and RECAVA Network, Madrid, [2]Clinical Epidemiology, Hospital Universitario La Paz, Madrid, [3]Department of Psychiatry, Hospital Santiago Apóstol and Stanley Research Center, Psychiatry, CIBERSAM, Vitoria, [4]Institute of Neuroscience, Hospital Clínic, University of Barcelona, IDIBAPS, Barcelona, [5]Department of Psychiatry, Hospital del Sureste, Arganda del Rey, Madrid, [6]Medical Unit, Pfizer-Spain, Madrid, Spain.

Background and aims: To compare the frequency of Metabolic Syndrome (MS) and its components between patients with Bipolar Disorder (BD) under psychiatric pharmacological treatment with the general population in Spain.
Materials and methods: The BIMET study enrolled during a 12-month period 532 (321 females-60.3%), consecutive unselected patients (mean age 46.3±13 years), according to DSM-IV TR criteria, from several mental health centres across Spain. The VIVA Study is a multicentre (9 sites), population-based, epidemiological study investigating the Variability of Insulin with Visceral Adiposity (VIVA). Both studies were concurrent in time and performed between 2007-2008. A random sample of 1560 individuals (three controls per case), matched by age (mean age 47.6±9.4 years) and sex, were selected from the VIVA data set (n=2.828). Fasting blood glucose (FBG), HDL-cholesterol, triglycerides, BMI, waist circumference and blood pressure were measured in both study groups. The National Cholesterol Educational Program NCEP/ATP III and the International Diabetes Federation (IDF) definitions were used for MS. Bivariate and multivariate comparisons (conditional logistic regression for matched case-control studies) were performed.
Results: Overall, the prevalence of MS-NCEP was 25.1% (95%CI 21.1-29.5) in BD patients and 19.3% (95%CI 17.4-21.4) in controls (p<0.05). Corresponding figures for IDF were 34.8% (95%CI 30.1-39.6) vs. 29.8% (95%CI 27.5-32.1) (p<0.05). Gender-related differences between BD patients and controls were only observed in males (28.5% vs 16.8% for NCEP and 40.2% vs. 26.4% for IDF) (all p values <0.001). Among BD patients, males showed a higher frequency of MS than females (28.5% vs. 23.0% by the NCEP criterium and 40.2% vs. 30.9% by the IDF). There was a higher prevalence of IDF-abdominal obesity in the Spanish female population 78.7% in BD and 66.2% in controls) compared with male population (64.7% in BD and 49.8% in controls). BD patients, males or females, had also higher values than controls in BMI 28,2±5,4 vs. 27,6±4,5 (p=0.02); waist circumference: 96±17,1cm vs.88,4±11,5cm (p<0.001); triglycerides: 145,4±102,2 mg/dl vs.116,8±81,4 mg/dl (p<0.001); and systolic blood pressure in males:129±14,6 mmHg vs.125,9±19,2 mmHg (p=0.02). Logistic regression identified the waist circumference and triglycerides as the two main independent variables explaining the higher frequency of MS observed in BD patients than in controls.
Conclusion: One out of three BD patients under psychiatric pharmacologic treatment in Spain, have MS according to the IDF criteria. This is significantly higher than in the general population, where the prevalence of abdominal obesity is already very high, particularly in women. The components of the MS which better explain the observed higher prevalence of MS in BD patients than in the general population, are waist circumference and triglycerides.

294

Changes in life expectancy of people with type 2 diabetes relative to non-diabetics over the last 40 years, from Reykjavik-AGES Study

B. Thorsson[1], E. Olafsdottir[1,2], T. Aspelund[1,2], G. Sigurdsson[1,3], R. Benediktsson[1,3], T.B. Harris[4], L.J. Launer[4], G. Eiriksdottir[1], V. Gudnason[1,2];
[1]Icelandic Heart Association, Kopavogur, Iceland, [2]University of Iceland, Reykjavik, Iceland, [3]Landspitali University Hospital, Reykjavik, Iceland, [4]NIA/NIH, Bethesda, United States.

Background and aims: People with type 2 diabetes (T2D) have shorter life expectancy than non-diabetics. Recent studies have suggested that life expectancy of people with T2D has improved relative to non-diabetics. We examine changes in relative mortality of people with T2D in two age categories over a time span of 40 years.
Materials and methods: Participants from the Reykjavík Study in 1967-1996 and the AGES-Reykjavik Study in 2002-2005 were divided into four cohorts. Two middle aged cohorts, one from 1972 (n=9972), mean age 53 years, and the other from 1983 (n=4760), mean age 56 years, were followed for 20 years. Similarly two cohorts of elderly people were followed, one for 5.5 years from 1993 (n=1599), mean age 78 years, and the other for 3.5 years from 2003 (n=4952), mean age 76 years. Age and gender adjusted hazard ratio (HR) of dying from all causes and from cardiovascular disease (CVD) was estimated for people with T2D and compared to non-diabetics using Cox survival analysis
Results: For middle aged diabetics the HR of dying from any cause compared to non-diabetics was 1.64 (95%CI= 1.45-1.86) in 1972, and 1.58 (95%CI= 1.31-1.89) in 1983. For the elderly diabetics the calculated HR of dying from any cause compared to non-diabetics was 1.71 (95%CI= 1.31-2.22) in 1993, and 1.60 (95%CI= 1.30-1.98) in 2003. From 1972 to 1983 the decline in HR of middle aged diabetics of dying from all causes was 3.7%. From 1993 to 2003 decline in HR in elderly diabetics of dying from all causes was 3.5%. The data show a gradual decrease in relative mortality for diabetics compared to non-diabetics over a long time period, although not statistically significant. Similar trends are seen in HR of diabetics dying from CVD.
Conclusion: Since 1967 the general increase in life expectancy of the Icelandic population has also benefitted people with type 2 diabetes. However, the observed small decline in relative mortality and CVD rate for diabetics over the study period still shows a persistent difference in life expectancy between people with T2D and non-diabetics.

Socioeconomic position and incidence of LADA and type 2 diabetes - 11-year follow-up of the Nord-Trøndelag Health Study

L. Olsson[1], A. Ahlbom[1], V. Grill[2,3], K. Midthjell[4,2], S. Carlsson[1];
[1]Karolinska Institutet, Stockholm, Sweden, [2]Norwegian University of Science and Technology, Trondheim, Norway, [3]Trondheim University Hospital, Trondheim, Norway, [4]HUNT Research Center, Verdal, Norway.

Background and aims: It has been shown that type 2 diabetes is more prevalent in lower socioeconomic groups. Conversely, an increased risk of type 1 diabetes has been seen in children from families with a high socioeconomic position. The aim of this study was to investigate whether the risk of latent autoimmune diabetes in adults (LADA) also is associated with socioeconomic position, and if so, whether the association can be explained by traditional risk factors, such as overweight, smoking and physical inactivity.
Materials and methods: We used information from an 11 year follow-up of the population-based Nord-Trøndelag Health Study. In this cohort (n=38,725), 86 incident cases of LADA (anti-GAD positive and insulin independent at diagnosis), and 879 incident cases of type 2 diabetes were identified. Socioeconomic position was measured by self-reported information on education and occupation.
Results: High education (university level) was associated with an approximately two times increased risk of LADA (RR 1.9, 95% CI 1.1-3.6), in comparison with low education (primary school). Adjustment for lifestyle and psychosocial factors strengthened this association (RR 2.7, 95% CI 1.4-5.2). Conversely, the risk of type 2 diabetes was decreased in subjects with a high educational level (RR 0.6, 95% CI 0.5-0.9). This risk reduction was explained by differences in lifestyle and psychosocial situation, and primarily overweight (adjusted RR 1.0, 95% CI 0.7-1.3). Similar results were seen when socioeconomic position was measured by occupation, i.e. a high occupational position was associated with an increased risk of LADA and a reduced risk of type 2 diabetes.
Conclusion: This is the first study to indicate that the risk of LADA is increased in subjects with a high socioeconomic position. On the other hand, these subjects had a reduced risk of type 2 diabetes, which was explained by a healthier lifestyle in general, with lower prevalence of overweight, smoking and physical inactivity. The association between LADA and a high socioeconomic position was not explained by traditional risk factors, indicating that some other environmental or lifestyle factors must be involved. The similarity of the results to previous findings for type 1 diabetes suggests that the explanation includes factors related to the autoimmune process.

The metabolic changes and diabetic complications in the Chinese patients with newly diagnosed type 2 diabetes

Z. Xu, L. Shi, Y. Wang;
Diabetes Center, 306th Hospital of PLA, Beijing, China.

Background and aims: To evaluate biochemical characteristics and the change trend of diabetic complications in the Chinese patients with newly diagnosed type 2 diabetes from 1994 to 2008
Materials and methods: We utilized the database of the diabetes complications assessment and analysed the metabolic disorder and the diabetic complications change in the patients with newly diagnosed diabetes.
Results: 2085 cases were collected, including male 1189 and female 896. The average age was significantly younger, 51.6 $\pm$ 13.1 vs. 54.6 + 7.9 yrs (2008 vs. 1994). No case with the age 20-29 yrs and 5% of the patients with age 30-39 in 1994, but 2% with the age 20-29 and 16% cases with the age 30-39 yrs in 2008. BMI was increased from the 24.48 $\pm$ 4.15 in 1994 to 26.03 $\pm$ 3.63 in 2008. Abnormal percentage of the patients with BMI ≥25kg/m^2, WHR ≥ 0.90 (male) or ≥ 0.85 (female) increased significant from 63.6 %, 75.0% and 71.4% in 1994 to 79.6 %, 95.2 % and 93.8 % in 2008. Both SBP and DBP were not significantly changed. The fasting blood and postprandial blood glucose,HbA1c decreased from 10.3 mmol/L, 15.2 mmol/L, 11.1% in 1994 to 9.0 mmol/L and 14.3 mmol/L, 8.6% in 2008, respectively. The average TG level increased from 1.7 mmol/L in 1994 to 2.1 mmol/L in 2008, however, TC and HDL level were no significant changed. The prevalence of patients with diabetic retinopathy decreased from 28.2%, 25.0%, 39.2%, 28.9%, 14.9%, 8.4%, 11.1%, 6.1%, 11.2%, 8.4%, 4.5%, 4.0%, 4.1%, 3.5%, 3.9% from 1994 to 2008. The prevalence of diabetic nephropathy increased from 17.7% in 1994 to 24.6% in 2008. The prevalence of diabetic cardiovascular disease increased from 14.3% in 1994 to 24.1% in 2008. Compared with the patients without microvascular complications, the patients with microvascular complications had higher SBP, DBP and HbA1c (136/78 vs. 130/77 mmHg, 9.41% vs. 9.11%). The patients with macrovascular complications had higher age, SBP, TC and TG than those without macrovascular complications (53.4 vs. 50.0 yrs; 132 vs. 129 mmHg; 5.3 vs. 5.1 mmol/L and 2.6 vs. 2.1 mmol/L).
Conclusion: The younger percentage of the newly diagnosed diabetic patients in china is bigger. The macrovascular factors impacts these patients, such as obese and hyper TC and TC levels, higher systolic blood pressure, even if the prevalence of diabetic retinopathy decreased significantly.
We thank the Beijing capital medical development grant for supporting this study

Sex and all-cause mortality in hospitalized patients with type 2 diabetes mellitus

P.S. Koureta[1], E. Gouveri[2], A.E.G. Alaveras[2];
[1]1st Medical Department, Tripolis, [2]1st Medical Department, Athens, Greece.

Background and aims: Many clinicians believe that diabetes mellitus exerts an excess risk of death among those patients in need of hospitalization for any reason. Women with diabetes in particular seem to suffer an excess risk of death due to cardiovascular risk factors, a risk that has not been adequately studied for patients hospitalized for other complications such as an infection.
Materials and methods: A retrospective cohort study was conducted, comparing all patients with any common infection hospitalized in our clinic during a decade, (1990-2000), to matched (for age and sex) patients hospitalized for any reason other than infection. The risk ratios of death according to sex, as well as that attributable to diabetes mellitus and to infectious disease, between those with and without diabetes were calculated, using multiple logistic regression analysis models.
Results: The cohort consisted of 4959 patients, 2583 hospitalized for any common infection (491(19.01%) with diabetes and 2092 without) and 2376 patients, matched for age and sex, hospitalized for any reason other than infection (337(14.18%) with diabetes and 2039 without). There were 96(11.59%) deaths among the 828 diabetic patients and 406(9.83%) deaths among the 4131 non-diabetic patients. The overall risk of death, for patients hospitalized for any reason, did not differ between patients with and without diabetes (OR=0.91 95% CI 0.53-1.56). There were 36(11.80%) deaths among 305 diabetic men and 60(11.47%) deaths among 523 diabetic women. The risk of death did not differ between diabetic and non-diabetic patients according to sex (interaction OR=1.58 95% CI 0.94-2.66). There were 174(14.77%) deaths among 1178 men and 149(10.60%) deaths among 1405 women hospitalized with any common infection. The risk of death did not differ between diabetic and non-diabetic patients with concomitant infection (interaction OR=0.95 95% CI 0.61-1.48), after sex was taken into account.
Conclusion: Diabetes mellitus did not seem to exert an excess risk of dying for those patients in need of hospitalization for any reason, a result that did not differ even for diabetic patients with concomitant complications, such as any common infection. Women with diabetes do not seem to suffer an excess risk of dying when in need of hospitalization for any reason compared to their men counterparts.

Is diabetes mellitus linked to an increased risk of cancer?

M. Alves[1], C. Neves[1], M. Pereira[1], F. Lopes[2], J.L. Medina[1];
[1]Endocrinology Service, [2]Hospital de São João, Porto, Portugal.

Background and aims: Some studies have shown an association between obesity, hiperinsulinemia, insulin resistance and type 2 diabetes and an increased risk of developing certain kinds of cancer. It is our aim to evaluate the prevalence of cancer in diabetic and nondiabetic patients admitted to a central hospital in the north of Portugal between 1999 and 2008.
Materials and methods: We retrospectively analysed data from all inpatients that satisfied the International Classification of Diseases (9th version) criteria for cancer disease and diabetes between 1999 and 2008. Statistical analysis was performed with Student's t-test. A two-tailed p value < 0.05 was considered significant.
Results: During the period of the study there were a total of 980128 admissions, 4743 of which with the diagnosis of diabetes mellitus and cancer, and

23032 with cancer without diabetes. They were 20092 men and 14867 women with a mean age of 61,9 years old in the group of diabetic patients with cancer, and 20092 men and 14867 women with a mean age of 54,1 years old in the nondiabetic group with cancer. We found no positive correlations between diabetes and cancer. Instead, there were positive correlations between nondiabetic status and cancer. Prevalence of ear, nose, mouth and throat cancers (2.43% vs 2.47%; r=0.848, p=0.002), respiratory system cancers (2.34% vs 2.56%; r=0.708, p=0.033), digestive malignancy (1.78% vs 2.43%; r=0.763, p=0.017), bone and joint malignancies (2.39% vs 2,51%; r=0.805, p=0.009), breast cancer (2.44% vs 2.47%; r=0.942, p=0.000), kidney and urinary tract cancers (1.8% vs 2.5%; r=0.736, p=0.024), male reproductive system cancers (1.5% vs 2.4%; r=0.881, p=0.001) and female reproductive system cancers (2.59% vs 7.02%, r=0,888, p=0.001) was significantly higher in nondiabetic than in diabetic patients. There were no significant differences in the prevalence of nervous system, hepatobiliar and pancreatic malignancies in diabetic and nondiabetic patients.
Conclusion: Unlike other studies, we did not find any positive correlation between diabetes mellitus and cancer. Although many issues may be responsible for these results, we also think that it is possible that the more recent advised use of insulinsensitizers, such as metformin or glytazones, could be responsible for the mitigation of our results.

New onset diabetes mellitus after kidney transplantation in Denmark
M. Hornum[1], K.A. Jørgensen[2], J.M. Hansen[3], F. Thomsen-Nielsen[4], E.R. Mathiesen[5], B. Feldt-Rasmussen[1], NODM Study Group;
[1]Nephrology, Rigshospitalet, Copenhagen, [2]Nephrology, Skejby University Hospital, Aarhus, [3]Nephrology, Herlev University Hospital, Copenhagen, [4]Nephrology, Odense University Hospital, [5]Endocrinology, Rigshospitalet, Copenhagen, Denmark.

Background and aims: To investigate the development of new onset diabetes mellitus (NODM) in a prospective study of 89 non-diabetic patients on the Danish waiting list for kidney transplantation.
Materials and methods: Included were 48 kidney recipients (Tx-group, age 39±13 years, males/females 33/15). 41 uremic patients on the waiting list for kidney transplantation served as controls (controls, age 47±11 years, males/females 29/12). All were examined at baseline before transplantation and after 12 months. The prevalence of diabetes, pre-diabetes, insulin sensitivity index (ISI) and insulin secretion index (ISecr) were estimated, using an oral glucose tolerance test with measurements of plasma-glucose and -insulin.
Results: NODM was present in 13% (6/48, p=0.03) at one year after transplantation when 44 % received tacrolismus, 56 % ciclosporin, 94 % prednisolon (average 6 mg) and 96 % mycophenolate mofetil. Only one patient in the control group developed NODM. At baseline 27% had prediabetes in the Tx-group. ISI in the Tx-group deteriorated from 7.4±4 to 5.3±3 at 0 and 12 months after transplantation (p=0.005). In the controls, ISI was 8.2±5 and 8.5±5 (NS). The ISecr improved in the Tx-group compared with controls, (p=0.01 between groups). Within groups, ISecr in the Tx-group changed from 35 ±19 to 42±25 between 0 to 12 months (p=0.06) compared with 30 ±17 to 27±15 in controls (NS).
Conclusion: One year after kidney transplantation NODM was present in 13%. This was mainly due to a further increase in insulin resistance and was observed despite of an improved insulin secretion.

Cardiovascular risk factors in the Netherlands over 17 years: results from the Hoorn Study and the New Hoorn Study
E. van 't Riet[1,2], M. Alssema[1,2], G. Nijpels[1,3], J.M. Dekker[1,2];
[1]EMGO Institute for Health and Care Research, [2]Department of Epidemiology and Biostatistics, [3]Department of General Practice, VU University Medical Center, Amsterdam, Netherlands.

Background and aims: Since repeated data on the level of cardiovascular risk factors from epidemiological studies are lacking, little is known on the changes in cardiovascular risk factors in the general population of the Netherlands. Therefore, our aim was to describe the changes in blood glucose, lipid profile, blood pressure and adiposity over 17 years in the Netherlands.
Materials and methods: Data from two random samples of the Dutch population (50-65 years old) were used: 1592 participants from the Hoorn Study (1989) and 1718 participants from the New Hoorn Study (2006). Fasting plasma glucose (FPG), plasma glucose 2 hours after an oral glucose tolerance test (OGTT) with a 75 g glucose load (2hrPG), HbA1c, cholesterol (total, HDL and LDL) and triglycerides were determined. In addition, weight, height, systolic blood pressure, diastolic blood pressure and waist circumference were measured.
Results: Between 1989 and 2006, mean HbA1c increased significantly in both sexes, while mean 2hrPG increased in men only and no change was observed in the prevalence of diabetes (Table 1). Significantly better mean levels of cholesterol (lower total and LDL cholesterol, higher HDL cholesterol) and triglycerides were present in 2006. Mean systolic blood pressure increased significantly, especially in men. Mean body mass index (BMI) and waist circumference showed a significant increase in men only.
Conclusion: A significant increase in mean HbA1c, 2hrPG, systolic blood pressure, BMI and waist circumference was observed between 1989 and 2006 in the general 50-65-year old population of the Netherlands, especially in males. In contrast, lipid profile became more favourable in both sexes and no change was observed in the prevalence of diabetes.

Central obesity and cardiovascular risk factors in south Asians and white Europeans with type 2 diabetes. A report from the United Kingdom Asian Diabetes Study (UKADS)

A. Tahrani[1,2], S. Bellary[3], P. O'Hare[4,5], S. Mughal[3,2], N. Raymond[4], K. Johal[5], S. Kumar[4,5], A.H. Barnett[1,2], A. Rahim[3];
[1]University of Birmingham, [2]The Biomedical Unit, Birmingham, [3]Heart of England NHS Foundation Trust, Birmingham, [4]University of Warwick, Coventry, [5]Warwickshire Institute of Diabetes Endocrinology and Metabolism (WISDEM), Coventry, United Kingdom.

Background: The relation between waist circumference (WC) and cardiovascular risk factors (CVD-RF) has not been well-studied in South Asians (SA) with type 2 diabetes (T2D).
Aims: To assess and compare CVD-RF between SA and White Europeans (WE) with T2D at different degrees of central obesity.
Methods: A cross-sectional study. SA and WE, above 35 years of age, with T2D from the UKADS were included. CVD-RF defined as hypertension (HTN) (BP>140/80mmHg or the use of anti-hypertensives), hypercholesterolemia (total cholesterol>4mmol/l or on lipid lowering treatment) and/or nephropathy (ACR>2.5 and 3.5 for men and women respectively). WC was divided into 5 groups in women (≤80cm, 80.01-90, 90.01-100, 100.01-110, >110, categories 1-5 respectively) and men (≤90cm, 90.01-100, 100.01-110, 110.01-120, >120, categories 1-5 respectively). Data presented as medians or frequencies
Results: 1486 SA and 492 WE (52% and 58% males respectively). Participants' characteristics: SA vs. WE: age (56 vs 66 years. P<0.001), BP-systolic (139vs 142mmHg, p<0.001), BP-diastolic (83 vs 83 mmHg, p=0.2), LDL (2.3 vs 1.9mmol/l, p<0.001), HDL (1.2 vs 1.4 mmol/l, p<0.001), Trigs (2.49 vs 2.03 mmol/l, p<0.001), HbA1c (7.9 vs 6.9%, p<0.001), diabetes duration 6 vs 4 years, p<0.001), HTN (83 vs 93%, p<0.001), hypercholesterolemia (90 vs 91%, p=0.4), nephropathy 27 vs. 26%, p=0.4). CVD-RF in SA and WE in relation to WC categories is summarised in Table 1 (data presented as medians). The prevalence of HTN, hypercholesterolemia or nephropathy was not different between SA and WE across WC categories. The differences in HDL, trigs and HbA1c could not be accounted by differences in medications between groups. WE were on more statins than SA. However, linear regression showed that ethnicity is independently related to LDL levels (B: 0.13, p=0.003) in a model that includes all anti-lipid and anti-diabetic therapy.
Conclusions: In T2D, SA had higher LDL, HbA1c, Trigs and lower HDL levels compared to WE with a similar WC despite being younger. Aggressive CVD-RF management in this group is needed. Despite having higher LDL levels, fewer SA were prescribed statins.

AT is a research fellow supported by the NIHR

CV risk factors in South Asians (SA) and White Europeans (WE) in regard to waist circumference (WC).

Changes in all-cause and CVD mortality in three Finnish middle-aged population cohorts with and without diabetes during a 10-year follow-up

N.C. Barengo, J.O. Tuomilehto;
Public Health, University of Helsinki, Finland.

Background and aims: When diabetes is increasing in many populations, it may result in a leveling off of the decrease in all-cause and cardiovascular disease (CVD) mortality. This may be called 'diabetes-cardiovascular risk paradox'. The objective of this study was to assess changes in all-cause mortality rates among people with and without diabetes between three large study cohorts with baseline assessments 10 years apart and followed up for 10 years.
Material and methods: Six population surveys were carried out in 1972, 1977, 1982, 1987, 1992 and 1997 in randomly selected independent cohorts in North Karelia and Kuopio, Eastern Finland. For the analyses the 1972 and 1977 cohorts (cohort 1), the 1982 and 1987 cohorts (cohort 2) and the 1992 and 1997 cohorts (cohort 3) were combined and followed-up for 10 years regarding all-cause and CVD mortality. The patients developing incident dia-

[1]adjusted for age, education, smoking, systolic blood pressure, serum cholesterol and BMI
[2]baseline diabetes or diabetes during 10-year follow-up

betes during the follow-up or having diabetes at baseline were derived from the national drug reimbursement records of the Social Insurance Institution and the hospital admission records of the National Hospital Discharge Register by computer-based record linkage.
Results: A total of 17 361 men and 18 707 women were followed up for 10 years. The risk of all-cause mortality decreased in cohort 3 compared to the first two cohorts in both men and women who did not develop type 2 diabetes during the follow-up. CVD mortality decreased in cohort 2 and 3 compared to cohort 1 in both gender. In men with diabetes, all-cause mortality did not significantly change during the follow-up. The Hazard Ratio (HR) for all-cause mortality after adjustment for age, education, smoking, systolic blood pressure, BMI and serum cholesterol was 0.84 in cohort 2 (95% CI 0.51-1.38) and 0.57 in cohort 3 (95% CI 0.28-1.18). No statistically significant changes regarding all-cause mortality were observed in women in cohort 2 (HR 1.54; 95% CI 0.96-2.49) or cohort 3 (HR 0.59; 95% CI 0.23-1.49), either. The respective HRs for CVD mortality was 0.61 (cohort 2; 95% CI 0.3-1.23) and 0.25 (cohort 3; 95% CI 0.07-0.87) in men and 1.50 (cohort 2; 95% CI 0.84-2.68) and 0.14 (cohort 3; 95% CI 0.02-1.04) in women.
Conclusions: While all-cause and CVD mortality seems to decrease in the non-diabetic segment of the population, no changes have been observed in women with diabetes. Only men of the latest cohort had a reduced CVD mortality rate. Special attention should be given to prevent the onset of diabetes in the population and to intensify the management of patients with diabetes.

303

Impact of quality of HbA_{1c} control and changes in HbA_{1c} level on cardiovascular events in a population based study with type 2 diabetes: The Diabetes In Germany (DIG) Study
M. Hanefeld, C. Koehler, I. Benke, J. Stelzer, P. Ott;
Center for Clinical Studies, GWT-TUD GmbH, Dresden, Germany.

Background and aims: Significance of HbA1c control in patients with long-term diabetes is still a matter of debate. So far little is known on significance of HbA1c and its change in late phases of the disease as independent risk factor in populations with HbA1c in the range of 7%.
We therefore analyzed incidence of major cardiovascular events (MACE) (1) in relation to established targets of HbA1c and (2) in relation to change over follow-up.
Material and methods: 4020 unselected patients with type 2 diabetes aged 35-80 years from 238 sites, follow-up 3.7 years, 2959 completed the study or died (n=175, 5.98%), 2213 (89.8%) had no MACE at baseline. MACE was history of myocardial infarction and/or coronary revascularisation and/or stroke. Change of HbA1c was greater or equal +0.3% or lower or equal -0.3% from HbA1c at baseline versus stability: no change in the interval ±0.3%.
Results: Average HbA1c at baseline was 7±1.2%, after 3.7 years 7.03±1.08%, diabetes duration 8.4 years. 251 (10.2%) patients reported a first event during follow-up. 845 patients had HbA1c lower than 6.5% with an event rate of 6.9%. The corresponding figures for HbA1c between 6.5% and 7% were 463 (7.2%), for HbA1c between greater or equal than 7 and 8% 550 (7.3%) and for HbA1c greater or equal than 8% 354 (9%). Change was associated with a significantly higher event rate: greater than +0.3% 8.1% events, lower than -0.3% 7.9% vs. stability (4.9%, p=0.03). In stepwise regression analysis with major risk factors age, smoking, male sex and HbA1c change in both directions were independent predictors of newly reported cardiovascular events.
Conclusions: In a German population based cohort of patients with average HbA1c of 7% level of diabetes control had no effect on cardiovascular event rate. However, change of HbA1c in both directions was associated with a significantly increased cardiovascular risk. Event rate was in the same range whether IDF or ADA target level was applied.

Prediciton of recurrent cardiovascular events in a general, pre-diabetic and diabetic population. The Hoorn Study
G. Nijpels[1], A.A.W. van der Heijden[1], M. Alssema[1], S.D.M. Bot[1], C.D.A. Stehouwer[2], J.M. Dekker[1];
[1]The EMGO Institute for Health and Care Research, VU University Medical Center, Amsterdam, [2]Maastricht University Medical Centre, Netherlands.

Background: Several prediction formulas exist to estimate the risk of a first cardiovascular event in a general population as well as in a population with type 2 diabetes. Characteristics such as blood pressure, cholesterol, smoking status and diabetes are known predictors for a first cardiovascular event, with addition of glycemic level (HbA_{1c}) in the diabetes population. Because of the increase in obesity and diabetes prevalence worldwide, and improved care after a first cardiovascular event, the number of people at risk for a recurrent cardiovascular event is growing. Less is known about predictors of a recurrent cardiovascular event in the general population, in a population with intermediate hyperglycemia or persons with type 2 diabetes. The aim of this study is to investigate 1) differences in absolute risk of a recurrent event between persons with normal glucose tolerance, intermediate hyperglycemia, and type 2 diabetes, and 2) which characteristics are predictors of a recurrent cardiovascular event in the general population, and in persons with intermediate hyperglycemia or type 2 diabetes.
Methods: The Hoorn study is a population-based cohort study among 2484 men and women, aged 50-75 at the baseline examination in 1989. Of these, 515 participants had a history of cardiovascular disease at baseline or developed a first event during 10-years of follow-up (ICD-codes: 390-459), and were at risk for a recurrent event. We identified significant predictors of a recurrent cardiovascular event during follow-up (ICD-codes: 390-459, 789) by Cox proportional hazards models using stepwise backward strategy.
Results: During a mean of 5.3 years of follow-up, 176 (34%) second cardiovascular events had occurred. In the total population, male sex, increasing age, higher level of triglycerides and higher glycemic level predicted a recurrent cardiovascular event. When stratified by glucose status, a recurrent event occurred in 31% of persons with normal glucose tolerance and in 34% of persons with intermediate hyperglycemia. The highest percentage of recurrent

Table. Predictors of a recurrent cardiovascular event stratified by glucose status group

General population		HR	p-value
Male sex		1.59 (1.16 - 2.16)	0.004
Age (years)		1.06 (1.03 - 1.09)	<0.001
Triglycerides (mmol/L)		1.26 (1.09 - 1.45)	0.002
HbA_{1c} (%) (continuous)		1.16 (1.01 - 1.32)	0.030
Normal glucose tolerance			
Male sex		1.54 (1.02 - 2.30)	0.038
Age (years)		1.07 (1.04 - 1.10)	< 0.001
Triglycerides (mmol/L)		1.31 (1.02 - 1.67)	0.032
Intermediate hyperglycemia			
HbA_{1c} (%)	≤ 5.5	1 (referent)	0.030
	> 5.5	2.24 (1.08 - 4.65)	
Male sex		2.76 (1.34 - 5.69)	0.006
Triglycerides (mmol/L)		1.50 (1.17 - 1.93)	0.001
Type 2 diabetes			
HbA_{1c} (%)	≤ 6.0	1 (referent)	0.026
	6.0 - 7.0	3.01 (1.14 - 7.91)	0.008
	>7.0	3.11 (1.35 - 7.19)	
Total/HDL cholesterol ratio		1.17 (1.00 - 1.38)	0.054
Intermediate hyperglycemia or type 2 diabetes			
HbA_{1c} (%)	≤ 6.0	1 (referent)	0.031
	6.0 - 7.0	1.87 (1.06 - 3.31)	0.001
	>7.0	2.62 (1.48 - 4.63)	
Total/HDL cholesterol ratio		1.16 (1.04 - 1.28)	0.006

cardiovascular events was observed in the population with type 2 diabetes (46%). In participants with intermediate hyperglycemia or type 2 diabetes, glycated hemoglobin was a main predictor.
Conclusions: The results of this study suggest that risk factors for a recurrent cardiovascular event differ from the known risk factors for a first event. Furthermore, the predictors for the population with intermediate hyperglycemia or type 2 diabetes were different compared to subjects without glucose abnormalities. Glycemic level was an important predictor in the general population as well as in persons with intermediate hyperglycemia or type 2 diabetes.

Association between the metabolic syndrome and coronary artery disease or ankle-arm index: mediation by low-grade inflammation and/or endothelial dysfunction (the CODAM study)
M. Jacobs[1,2], M.M.J. van Greevenbroek[1,2], C.J.H. van der Kallen[1,2], I. Ferreira[3,1], E.E. Blaak[4], E.J.M. Feskens[5], C.G. Schalkwijk[1,2], C.D.A. Stehouwer[1,2];
[1]Department of Internal Medicine, Maastricht University Medical Centre, [2]Cardiovascular Research Institute Maastricht (CARIM), Maastricht University Medical Centre, [3]Department of Clinical Epidemiology and Medical Technology Assessment, Maastricht University Medical Centre, [4]Department of Human Biology, Maastricht University Medical Centre, [5]Division of Human Nutrition, Wageningen University, Maastricht, Netherlands.

Background: The Metabolic Syndrome (MetS) is associated with both coronary artery disease (CAD) and peripheral arterial disease and these associations may be related to low-grade inflammation and/or endothelial dysfunction.
Aim: To address the role of low-grade inflammation and endothelial dysfunction in the associations between the metabolic syndrome and CAD or ankle-arm index (AAIx; an available and reproducible method for the detection of peripheral arterial disease).
Methods: The study population consisted of 574 subjects (age: 59.6 ± 7.0 years, 61.3% men, 54.7% MetS; NCEP-ATP 2005 criteria) from the Cohort Study Diabetes and Atherosclerosis (CODAM) cohort. Presence of CAD was assessed by extensive questionnaires and ECG. The AAIx was calculated by dividing the highest of the ankle pressures (dorsalis pedis or tibial arteries) in either leg by the highest pressure at the brachial artery. The following biomarkers markers were measured in fasting plasma: (1) markers of inflammation (C-reactive protein, IL6, serum amyloid A, ceruloplasmin, haptoglobin, soluble intercellular adhesion molecule) and (2) markers of endothelial dysfunction (soluble vascular cell adhesion molecule, e-selectin, von Willebrand factor). Each biomarker was transformed into a Z-score and an inflammation score and an endothelial score were then calculated as the average of the Z-scores of the six inflammation markers and as the average of the three markers of endothelial dysfunction, respectively. Multiple logistic and linear regression analyses were used to determine the associations of the metabolic syndrome, low-grade inflammation and endothelial dysfunction with CAD or AAIx (outcomes), adjusted for age, sex and smoking.
Results: The MetS was associated with CAD (OR (95% CI) = 1.75 (1.14-2.69), p=0.011). Adjusting this association for the inflammation score, the strength of this association was reduced by 26%, but adjustment for endothelial dysfunction did not affect the strength of the association (attenuation <6%).
The MetS was also associated with AAIx (β (95% CI) = -0.036 (-0.056; -0.016), p<0.001). Adjusting for the inflammation score reduced the strength of this association by 28% and for endothelial dysfunction the strength of this association was reduced by 19%. When low-grade inflammation and the endothelial score were included simultaneously into the model, the strength of the association was reduced by 36% (β (95% CI) = -0.023 (-0.004; -0.002), p=0.035).
Conclusion: Low-grade inflammation, but not endothelial dysfunction can partly explain the association between the metabolic syndrome and CAD. On the other hand, both low-grade inflammation and endothelial dysfunction can each independently explain part of the association between the metabolic syndrome and AAIx.

Metabolic syndrome vs Framingham risk score for association of coronary heart disease: the Korean Health and Nutrition Examination Survey, 2005
D.-J. Kim, J.-H. Noh, J.-H. Park, K.-S. Ko, B.-D. Rhee, K.-H. Lim;
Department of Internal Medicine, Inje University College of Medicine, Koyang, Republic of Korea.

Background and Aim: Although many studies have been shown that metabolic syndrome (MS) is associated with significantly increased risk of developing coronary heart disease (CHD), recent several studies in Western population, indicate that MS is inferior to the Framingham Risk Score (FRS), one of traditional risk scoring system, in predicting CHD. However there has been no study about predictability of MS vs. FRS for CHD in Far-East Asian population. We have assessed the relative associations of MS using National Cholesterol Education Program (NCEP) criteria vs. FRS with CHD in national representative cohort of South Korea.
Population and Methods: This study was based on the data obtained from the third Korea National Health and Nutrition examination Survey (KNHANES III) among non-institutionalized civilians in the Republic of Korea, which was conducted by the Korean Ministry of Health and Welfare in 2005. This survey is a nationwide representative study using a stratified, multistage probability sampling design for the selection of household units. A total of 34,145 individuals from these sampling frames were included in the health interview survey; among them, 5,497 persons aged 18 to 99 years were identified as participants in our study, with laboratory test and nutritional survey data. Trained interviewers visited participant's homes and administered a standardized questionnaire on daily life style. The participants were, also, asked to recall a physician's diagnosis of CHD (angina or myocardial infraction). MS was defined by NCEP criteria. The FRS for CHD was calculated for each participants.
Results: Median age in this study population were 46 (18-92) in men (n=2355) and 45 (18-99) years in women (n=3142). Body mass index were 24.0 3.1 in men and 23.5
3.4 kg/m^2 in women. Prevalence of self-reported CHD was 1.7% in men and 2.1% in women. Participants were categorized according to quintiles of FRS in each sex. Receiver-operating characteristics (ROC) curves and their respective areas under the curve (AUCs) were used to compare the ability of the FRS and the number of components of metabolic syndrome to predict CHD in each sex. In men, AUC of FRS was significantly larger than that of MS [0.763 (0.707-0.819) vs. 0.628 (0.542-0.714), p<0.01]. In women, AUC of FRS was comparable to that of MS [0.776(0.728-0.824) vs. 0.734 (0.674-0.795), not significant].
Conclusion: The study showed that FRS was more closely associated with CHD compared to MS in Korean men.

Prevalence of cardiovascular disease in people with diabetes with and without schizophrenia: a population-based cohort study
L.C. Bresee[1], S.R. Majumdar[2], S.B. Patten[3], J.A. Johnson[1];
[1]School of Public Health, University of Alberta, Edmonton, [2]Department of Medicine, University of Alberta, Edmonton, [3]Departments of Community Health Sciences and Psychiatry, University of Calgary, Canada.

Background and aims: Individuals with diabetes have a high prevalence of cardiovascular (CV) risk factors and cardiovascular disease (CVD), as do individuals with schizophrenia. It is unclear, however, whether the prevalence of CVD is further increased in people with diabetes and schizophrenia. The objective of this study was to evaluate prevalence of CV risk, CVD, and revascularization procedures in people with diabetes and schizophrenia compared to people with diabetes only.
Materials and methods: A population-based cohort study was used to evaluate the study objective. Information from the databases of Alberta Health and Wellness was used to create the cohort, and included all individuals aged 20 years and older with diabetes in the Canadian province of Alberta from 1995 to 2006. Individuals with diabetes were identified using criteria from the Canadian National Diabetes Surveillance System. Schizophrenia, CV risk (hypertension, dyslipidemia), CVD (congestive heart failure [CHF], stroke, acute coronary syndrome, ischemic heart disease, arrhythmia, old myocardial infarction), and revascularization procedures (coronary artery bypass grafting, percutaneous transluminal coronary angioplasty) were identified using physician claims data, ambulatory care data, and hospitalization data. Prevalence of CV risk, CVD, and revascularization was compared using mul-

tivariable logistic regression analysis while adjusting for age, sex, healthcare subsidy, and number of physician visits (to control for surveillance bias).
Results: We identified 129,438 people with diabetes, and 2,621 (2.0%) of these individuals had schizophrenia. Individuals with diabetes only were older (mean age 60.3 years vs. 57.6 years), more likely to be male (51% vs. 42.9%), and less likely to have subsidized health care (39.6% vs. 73.3%) compared to individuals with schizophrenia and diabetes. After multivariable adjustment, prevalence of dyslipidemia was not significantly different between groups (OR: 0.97; 95% CI: 0.89 - 1.05), and hypertension was less prevalent in people with diabetes and schizophrenia (OR: 0.60; 95% CI: 0.55 - 0.65). Individuals with schizophrenia and diabetes were more likely to have CHF (OR: 1.31; 95% CI: 1.18 - 1.46), stroke (OR: 1.27; 95% CI: 1.14 - 1.42), and CVD (OR: 1.19; 95% CI: 1.10 - 1.30), but were less likely to undergo revascularization (OR: 0.51; 95% CI: 0.41 - 0.63).
Conclusion: Despite having a higher prevalence of CVD, individuals with schizophrenia and diabetes were significantly less likely to undergo revascularization compared to people with diabetes only. Also, prevalence of CV risk factors was lower (hypertension) or no different (dyslipidemia) between groups. This may be due to a lack of screening, or other lifestyle risk factors increasing the risk of CVD in those with schizophrenia and diabetes.

High prevalence of residual dyslipidemia in statin-treated patients with diabetes mellitus in Europe and Canada: results of the Dyslipidemia International Study

H. Drexel[1], J. Feely[2], J. Ferrieres[3], A. Gitt[4], J.-R. Gonzalez-Juanatey[5], K. Korsgaard Thomsen[6], P. Lundman[7], P. Marques da Silva[8], T. Pedersen[9], D. Wood[10], F. Chazelle[11], M. Hackett[11], J. Kastelein[12], L. Leiter[13]; [1]Landeskrankenhaus Feldkirch, Austria, [2]Trinity Centre, St. Jame's Hospital, Dublin, Ireland, [3]Toulouse University, School of Medicine, France, [4]Kardiologie, Herzzentrum Ludwigshafen, Germany, [5]Servicio de Cardiologia, Hospital Clinico Universitario, Santiago de Compostela (A Coruna), Spain, [6]Dept. of Cardiology, Sydvetjyusk Sygehus Esberg, Esbjerg, Denmark, [7]Dept. of Clinical Sciences, Karolinska Institutet, Stockholm, Sweden, [8]Nucleo de Investigacao Arterial, Servico de Medicina, Lisbon, Portugal, [9]Ulleval University Hospital, Oslo, Norway, [10]National Heart and Lung Institute, London, United Kingdom, [11]Merck & Co., Whitehouse Station, United States, [12]Dept. of Vascular Medicine, Academic Medical Center, Amsterdam, Netherlands, [13]Division of Endocrinology & Metabolism, University of Toronto, Canada.

Background and aims: Though statins are considered the essential and most widespread therapy for prevention of cardiovascular disease, statin-treated patients remain at increased cardiovascular risk. This study was designed to better explain the residual risk by assessing the prevalence of persistent lipid abnormalities.
Materials and methods: DYSIS was a cross-sectional study conducted by 2987 general practitioners, endocrinologists/diabetologists, cardiologists and internists in 12 countries. Patients were recruited consecutively who were ≥ 45 years of age, on statin therapy ≥ 3 months, agreed to a clinical exam and had a least one lipid value.
Results: 22, 063 were enrolled between April 2008 and February 2009. Of these, 8613 (39%) had diabetes, with an average age of 66.3 years (± 9.4), 41.2 % female. According to ATP III guidelines 76.5% had metabolic syndrome while the IDF criteria defined 86.8% as having metabolic syndrome. Of the total enrollment, 19,132 had sufficient lipid data to assess dyslipidemia.
Conclusion: Though the patients with DM were more likely to have LDL-C at target, they were less likely to have normal HDL-C and TGs

ESC Guidelines	Patients with DM N = 7558 (39.%%)	Patients without DM N = 11,574 (60.5%)
LDL-C at goal (1)	58.5%	47.5%*
LDL not at goal and:		
HDL-C normal & TG normal	16.2%	29.2%*
Low HDL-C & TG normal (2)	3.2%	3.7%
High TG & HDL-C normal (3)	13.9%	14.1%
Low HDL-C & high TG	8.3%	5.6%*
Low HDL-C &/or high TG	25.4%	23.4%*

LDL-C=low-density lipoprotein cholesterol; HDL-C=high-density lipoprotein cholesterol; TG=triglycerides. (1) ≥ 2.5/2.0 mmol/L (high risk); ≥ 3.0 mmol/L (low risk); (2) < 1.0 mmol/L (male); <1.2 mmol/L (female); (3) > 1.7 mmol/L *statistically significant

Vitamin D deficiency is associated with type 2 diabetes mellitus and insulin resistance in 3290 patients referred to coronary angiography

S. Pilz[1], A. Tomaschitz[1], B.O. Boehm[2], B.R. Wimkelmann[3], W. März[4]; [1]Department of Internal Medicine, Division of Endocrinology and Nuclear Medicine, Medical University of Graz, Austria, [2]Department of Internal Medicine I, Division of Endocrinology and Diabetes, Ulm University, Germany, [3]Cardiology Group, Frankfurt-Sachsenhausen, Germany, [4]Synlab, Centre of Laboratory Diagnostics, Heidelberg, Germany.

Background and aims: There is accumulating molecular and epidemiological evidence that vitamin D is important for beta-cell function and glucose metabolism. We aimed to evaluate whether 25-hydroxyvitamin D (25[OH]D) is associated with type 2 diabetes mellitus and insulin resistance in patients with an indication for coronary angiography.
Materials and Methods: 25(OH)D was determined in 3290 patients from the LUdwigshafen RIsk and Cardiovascular Health (LURIC) study, a prospective cohort study among patients referred to coronary angiography. We measured fasting glucose and fasting insulin to calculate the homeostasis model assessment of insulin resistance (HOMA-IR). In addition, we performed a standardized 75-gram oral glucose tolerance test in the vast majority of study participants without known diabetes mellitus.
Results: Median 25(OH)D levels in ng/ml (with interquartile range) were 16.8 (11.0-24.1) in patients with normal glucose metabolism (n=1415), 16.4 (10.6-24.1) in patients with impaired glucose metabolism (impaired fasting glucose and/or impaired glucose tolerance) (n=827), 14.9 (10.0-21.2) in patients with newly diagnosed diabetes mellitus (n=476) and 12.7 (8.1-19.3) in patients with previously known type 2 diabetes mellitus (n=572) (P for trend <0.001 for ANCOVA adjusted for age, sex, BMI and season of blood draw). In a linear regression analysis including HOMA-IR as the dependent variable and age, sex, body mass index, season of blood draw and 25(OH)D as explanatory variables we observed a significant inverse association of 25(OH)D and HOMA-IR (β-coefficient = -0.070; p<0.001).
Conclusions: We have shown that a poor vitamin D status is associated with type 2 diabetes mellitus and insulin resistance. These results suggest that vitamin D supplementation might be useful for the prevention and/or treatment of type 2 diabetes mellitus.

How much do we know about obesity and diabetes? A survey of British male drivers

J. Deville-Almond[1], A.A. Tahrani[2,1], J. Grant[1], M. Gray[1], N. Thomas[2,1], S. Taheri[2,1];
[1]The Biomedical Unit, [2]University of Birmingham, United Kingdom.

Background: Obesity and type 2 diabetes (T2DM) are major public health challenges. Behaviour modification necessary to tackle these conditions requires individual awareness of the existing problem.
Objectives: We assessed adiposity perception, awareness of the relation between adiposity and T2DM, and the relation between adiposity and weight loss attempts.
Methods: A cross-sectional study. British male drivers were randomly recruited at Motorway service stations across the UK between May-July 2007. Participants completed a questionnaire and had body mass index (BMI), waist circumference (WC), body composition and random blood cholesterol and glucose measurements. BMI was classified into normal, overweight and obese based on the WHO criteria. WC >94cm was considered as a marker of central obesity as per the international diabetes federation criteria.
Results: 266 men, median age 52 years and BMI 28.25kg/m^2 participated. Obesity prevalence was 35% and 73% based on BMI and WC, respectively. 46% were overweight based on BMI. Based on the questionnaire 29% of the participants thought they were "thin" or "just right", 64% and 7% thought they were overweight and obese, respectively. There was no difference in age between the self-perception categories (53 vs. 50 vs. 51 years, p=0.35). Participants underestimated their WC (94.3±10.22 vs. 102.86±11.41cm, estimated vs. actual, p<0.001). Of participants with normal BMI, 18% thought they were overweight, while 26% of overweight thought they were "just right" and 19% of obese recognised their obesity. Based on WC, 30% of participants with normal WC thought they were obese and 9% of obese realised they were obese. Only 25% and 42% of participants recognised that T2DM is associated with obesity and large waist, respectively. 81% and 62% of overweight and obese participants (based on BMI) and 71% with central obesity believed that they were **not** at increased risk of T2DM. Adiposity self perception weakly predicted weight loss attempts (Lambda 0.28, p=0.008). Participants' BMI and WC did not predict attempts to lose weight (p=0.12, p=0.2 respectively). 43% and 18% who were either overweight or obese (based on BMI) and 33% with central obesity had not attempted to lose weight. On the other hand, 51% of normal subjects (based on WC) have attempted to lose weight. The majority of patients who thinks their weight is normal but who are overweight/obese based on BMI and/or WC did not attempt to lose weight. In contrast, individuals who perceived themselves to be overweight/obese, have attempted to lose weight even though they fall into the normal range based on BMI/WC. 92% of participants with central obesity and 97% and 87% of overweight and obese participants (based on BMI) had never sought medical advice regarding weight management.
Conclusion: Individuals significantly underestimate their degree of adiposity. A significant proportion of overweight/obese subjects had never attempted to lose weight. Participants underestimate their risk of T2DM. A significant proportion is not aware of the association between adiposity and T2DM. Participants self perception (rather actual) of adiposity predicted attempts of weight loss. The majority of participants never considered seeking medical advice regarding weight. Further public education regarding obesity, its associated health risks and what healthcare professionals can provide is needed.

Differential effects of ethnicities on the relationship between body mass index and insulin resistance in Singapore

D.S. Gardner[1], S. Taslim[2], J. Lee[2], M. Tan[2], D. Heng[3], E. Tai[1];
[1]Department of Endocrinology, Singapore General Hospital, [2]Department of Community, Occupational and Family Medicine, National University of Singapore, [3]Epidemiology & Disease Control Division, Ministry of Health, Singapore.

Background and aims: Singapore has a high prevalence of diabetes mellitus, which is at least partially attributable to an increase in obesity, acting through its effects on insulin resistance (IR). The three ethnic groups in Singapore exhibit differences in the levels of obesity and IR. However, Malays, which have the highest body mass index (BMI), do not have the highest levels of IR, raising the possibility that the relationship between BMI and IR may differ between ethnic groups. Accordingly, the aim of this study was to examine the relationship between BMI and IR in a sample of Asian Indian, Malay and Chinese populations living in Singapore.
Materials and methods: 5472 individuals from 4 previous cross-sectional studies carried out in Singapore were followed up between 2004-2007. Anthropometric measures were taken and fasting blood samples were drawn for glucose, insulin. Insulin resistance was derived using the homeostasis model assessment method.
Results: As a group, BMI correlated well with IR (r = +0.55, p<0.001). Asian Indian m (M) and women (W) had equivalent BMI (kg/m^2) (M: 25.1 $\pm$ 4.2; W: 26.8 $\pm$ 5.0) to the Malays (M: 25.4 $\pm$ 4.0, W: 26.9 $\pm$ 5.4) but higher compared with the Chinese (M: 23.5 $\pm$ 3.6, W: 22.4 $\pm$ 3.8). Notwithstanding, Asian Indian men and women were more insulin resistant (M: 3.0 $\pm$ 3.2, W: 3.0 $\pm$ 3.1) compared to both Malay (M: 2.2 $\pm$ 2.5, W: 2.2 $\pm$ 1.8) and Chinese (M: 1.8 $\pm$ 1.8, W: 1.7 $\pm$ 1.7), all p<0.001. Each unit gain in BMI was associated with the largest delta rise in IR in the Chinese population followed by Indians and Malays (p for interaction<0.001). This relationship was more marked in women.
Conclusion: Much of the literature on IR in Asian ethnic groups has focused on the increased IR in Asian Indians which occurs at relatively low BMI. Our study confirms these findings. Unexpectedly, our data suggests that the Chinese population may be at even greater risk of increased insulin resistance with weight gain but are currently protected by the relatively low BMI. If this is true, it makes the prevention of obesity in this ethnic group, as China undergoes rapid socio-economic development even more important than it already is.

Obesity is associated with poorer clinical outcomes following insulin initiation for patients with type 2 diabetes

S. Kumar[1], B. Wilson[2], L. Watson[3], J. Alsop[3];
[1]WISDEM, University Hospital, Coventry, [2]Eli Lilly & Co Ltd, Basingstoke, [3]Louise Watson Consulting Ltd, Buxton, United Kingdom.

Background and aims: Little information is available on the association between BMI at time of insulin initiation with attainment of targets for glycaemic control in type 2 diabetic (T2DM) patients. This study was designed to describe HbA1c and weight post the first prescription for insulin.
Materials and methods: A cohort of patients with diagnostic codes for T2DM were selected from the General Practice Research Database (GPRD) for the period January 1st 2002- March 31st 2008. No patient had been prescribed insulin in the 6 months prior to the first insulin prescription (index date). Additionally, patients had to have ≥ 2 further prescriptions for insulin in the 12 months post the index date as well as ≥ 2 BMI and ≥2 HbA1c recordings (one index, one post index). Patients also had to have a minimum of 12 months data post the index date. The cohort was stratified into BMI categories at the time of insulin initiation: normal (18.5-24.9 Kg/m^2); overweight (25.0-29.9 Kg/m^2); obese (30.0-34.9 Kg/m^2); clinically obese (35.0-39.0 Kg/m^2); morbidly obese (≥40 Kg/m^2). At 6-monthly intervals (up to 24 months) information on HbA1c, BMI and weight was extracted for those patients with data at that point. A sensitivity analysis was conducted using the subset of patients who had data at every time point. A multivariate repeated-measures linear model was fitted assessing weight change from point of insulin initiation to 12 months. Adjustment was made for age, gender, region, baseline HbA1c, oral therapy and insulin type.
Results: 3783 patients fulfilled the inclusion criteria (normal weight, n=672; overweight, n=1259; obese, n=1070; clinically obese, n=480; morbidly obese, n=302). The median HbA1c value at the time of insulin initiation was 9.6% (interquartile range IQR 8.6-11.0). The greatest reductions in HbA1c were seen in the first 6 months of insulin use in all BMI categories. The improvement in HbA1c appeared to be greatest in those with lower BMI: median observed HbA1c at initiation and 6 months was 9.7% and 7.9% in normal weight patients and 9.6% and 8.2% in the clinically obese , respectively. A minority of patients achieved target HbA1c (≤7.5%) at any of the 6-monthly timepoints up to 24 months (for patients with a HbA1c at 24 months, the proportion achieving target was: normal 41%; overweight 34%; obese 30%; clinically obese 26%; morbidly obese). Sensitivity analysis supported these findings. The greatest weight gain was observed in the first six months and

appeared highest in normal weight patients (median 3.59 kg [IQR] 0.5-7.0) reducing to 2.00 kg (IQR-1.3-4.1) in clinically obese and 0.8 kg (IQR -2.4-4.5) in morbidly obese . Multivariate models showed that after adjustment for confounders, normal weight patients made the greatest gains; 5.07kg (95% CI 3.35, 6.79) as did those with HbA1c ≥ 12.1%; 5.55kg (95% CI 3.81, 7.28).
Conclusion: Obesity appears to be associated with a poorer response to insulin illustrated by higher HbA1c values and lower achievement of target. Patients with lower BMI have higher weight gains post insulin exposure than the obese, which may have clinical and public health implications, which require further investigation.

High prevalence of obesity in the Spanish working population. Results from ICARIA study
A. Goday[1], E. Calvo[2], M.A. Sánchez[2], M. Cabrera[2], S. Santamaría[2], R.M. Pozas[2], N. Duque[3], J. Reviriego[3], A. Grande[4], D. Socarrás[4];
[1]Servicio de Endocrinología y Nutrición, Hospital del Mar, Barcelona, [2]Ibermutuamur, Mutua de Accidentes de Trabajo y Enfermedades Profesionales, Madrid, [3]Dpto. Investigación Clínica, Laboratorios Lilly., Madrid, [4]Sociedad de Prevención, Ibermutuamur, Madrid, Spain.

Background and aims: Obesity is one of the prevailing processes of major socio-health impact based on its high prevalence, its progressive growth and its relation to multiple associated diseases. The epidemiological data available in Spain are based on local or autonomic studies, as well as on health surveys with antropometric data stated by the pollsters. The aim of this study is to describe the prevalence of obesity in the Spanish working population, as well as its evolution in the recent years.
Materials and methods: Information obtained from medical screenings on companies carried out by IBERMUTUAMUR from May 3, 2004 through November 30, 2007 in all of the autonomous communities, which included 1,441,267 subjects. 356,030 subjects were excluded due to lack of complete medical records to calculate the BMI, with a final sample of 1,085,237 subjects, 74% men and 26% women, between 18-29 years: 30%; 30-39 years: 33,1%; 40-49 years: 22,5%; 50-59 years: 11,8%; >60 years: 2,6%. The weight and the size were obtained by direct measurement. Overweight was defined by BMI of 25-29,9, obesity by BMI>30, and morbid obesity by BMI>40kg/m^2
Results: The prevalence of obesity was 15.9% (18.5% in men and 8.7% in women). The prevalence of overweight was 38.5% (44.6% in men and 22% in women). A progressive increase was observed in the prevalence of obesity with the age: 18-29 years: 9.5%, 30-39 years: 14.6%, 40-49 years: 19.9%, 50-59 years: 25.4%, >60 years: 26.6%. For overweight, the prevalence was, according with the age groups: 28.5%, 39%, 44.3%, 48.9% and 51.4%, respectively. Progressive increase in obesity was observed during the 4-year study period (2004-2007), in men (17.7%, 18.1%, 18.7%, 19.1%), in women (7.7%, 8.4%, 9%, and 9.3%) and in the total (15%, 15.4%, 16.1%, 16.4%). The maximum prevalence in autonomous communities was observed in Cantabria (21.1%), in the Canary Islands (18.6%) and in Andalucía (18.1%), and the minimum in La Rioja (11.1%), in Navarra (11.7%) and in Cataluña (12.1%). Morbid obesity was observed in 0.5% of the subjects.
Conclusion: The prevalence of obesity and overweight in the Spanish working population are very high and constantly increasing. There are significant differences in the geographical distribution of obesity in Spain. These findings emphasize once more the need to boost specific obesity prevention and treatment (programs). The medical screening on companies is an excellent and efficient way to obtain information about the epidemiology of obesity and other prevailing processes, particularly if the studies are based on the active working population.

Predictors of drug choice in newly diagnosed type 2 diabetes
A. Hutchison[1], D. Russell-Jones[2], C.S. de Vries[1];
[1]Pharmacy & Pharmacology, University of Bath, [2]CEDAR Centre for Endocrinology Diabetes and Research, University of Surrey, Guildford, United Kingdom.

Background and aims: Whilst, according to prescribing guidelines, type II diabetes is managed first by diet if appropriate, then by oral antidiabetic agents and with insulin only if insufficient diabetes control is achieved, in practice prescribing varies with some patients receiving insulin relatively early and others not receiving insulin despite poor control. This will impact on studies of differences in long-term diabetes-related morbidity associated with different treatments. We set out to establish what patient characteristics predict drug choice in type II diabetes.
Materials and methods: Using the UK General Practice Research Database (GPRD), all those newly diagnosed with type II diabetes between 1 January 1998 and 31 March 2007 were identified. The GPRD has been used extensively for epidemiological research in diabetes as well as other disease areas. Patient characteristics (sex, age at diagnosis, smoking, alcohol use, BMI, HbA1c at diagnosis, and comorbidity) were established as was prescribing of antidiabetic agents. Multivariate survival analysis of drug choice associated with any of these patient characteristics was carried out using Cox regression in Stata and hazard ratios (HR) with 95% confidence intervals (CI_{95}) were calculated.
Results: Out of 80,308 newly diagnosed study participants, 38,946 (48.5%) went on to receive drug treatment for their type II diabetes. Those with HbA1c values >10.0 were 25 times more likely to receive medication than those with normal control (HR 25.3; CI_{95} 19.3-33.1); women were less likely to receive drug treatment than men (HR 0.82; CI_{95} 0.78-0.85). The proportion initiated on insulin as their first antidiabetic drug halved from 6.1% in 1998 to 2.9% in 2007 (p<0.05). Other than being female (HR 0.84; CI_{95} 0.76-0.92), having poor glycaemic control (HR 1.53; CI_{95} 1.06-2.21) and being underweight (HR 1.94; CI_{95} 1.53-2.45), there were no obvious predictors of insulin being preferred over oral products.
Conclusions: In the UK, women were less likely than men to receive medicines when diagnosed with type II diabetes. Amongst those receiving antidiabetic medicines, men were more likely than women to receive insulin as their first antidiabetic drug. Other predictors were unsurprising; they included high BMI and poor glycaemic control.

Hospital insulin therapy is associated with a reduced rate of mortality
R. Juneja[1], M. Waddell[1], A. Golas[1], Q. Zhang[2], J. Carroll[3], D. Nelson[3], S. Flanders[4], C. Roudebush[3];
[1]Indiana University, Indianapolis, [2]sanofi-aventis US, Bridgewater, [3]Clarian Health, Indianapolis, [4]Beaumont Hospitals, Royal Oak, United States.

Background and aims: Uncontrolled hospital hyperglycemia and hypoglycemia are both associated with increased morbidity and mortality. While insulin therapy is used to control blood glucose, it is associated with higher rates of hypoglycemia. We sought to determine the relationship between insulin treatment for hyperglycemia and mortality.
Materials and methods: We examined relationships between insulin therapy and mortality in adult hospitalized patients without end stage disease who spent at least one day in ICU, with >1 BG test. Data is from 20,273 hospital admissions at two US academic centers between June 2003 and September 2007; analyzed for a potential mediation effect of glucose (BG) control and hypoglycemia and adjusted for diabetes status and primary inpatient diagnosis.
Results: Mean age was 60 vs 55 yrs for insulin therapy (IT+) vs no-insulin therapy (IT-) group, with 42% female in each group and 48 vs 7% with diabetes, respectively. Mean (±SD) for first BG was 9.0 (±4.5) vs 7.0 (±2.4) mmol/L; for last BG was 7.7 (±3.0) vs 6.3 (±1.8) mmol/L; 41 vs 5% had hypoglycemia (<3.9 mmol/L) and 9 vs <1% severe hypoglycemia (<2.2 mmol/L) in IT+ vs IT-. Unadjusted mortality was 9.2 vs 5.6% for IT+ vs IT- (p<0.0001). After accounting for age, diabetes status, first BG and primary diagnosis, adjusted mortality rate (π) was estimated as 5.5 vs 4.0% for IT+ vs IT- (p<0.0001). Further adjustment for hypoglycemia, % low BG (<7.2 mmol/L), % high BG (>10.0 mmol/L), and mean BG, yielded 6.0 vs 5.1% (p=0.0099) mortality. A final model reversed the relationship between IT and mortality by adding 2-way interactions between IT, DM, hypoglycemia, first BG, and mean BG and demonstrated a protective benefit of IT (π = 6.4 vs 8.6% for IT+ vs IT- with difference (δ= -2.2%, p<0.01). Patients with diagnosed diabetes had 6.0% mortality relative to 9.1% (δ= -3.1%, p<0.01) in those without diabetes. Mortality was estimated to be 10.8% for patients experiencing hypoglycemia (<3.9 mmol/L) vs 5.0% (δ= 5.7%, p<0.01) for patients without hypoglycemia, regardless of insulin therapy. Estimated mortality in patients with hypoglycemia was 6.9% for IT+ and 16.4% for IT- in contrast to 5.9% for IT+ and 4.3% for IT- in patients without hypoglycemia, p<0.01.
Conclusion: This retrospective study found that although unadjusted mortality appears higher in IT+ patients, careful adjustments for relevant parameters demonstrate a protective effect of insulin therapy on hospital mortality. Hospital insulin therapy is associated with a reduced rate of mortality.

Hypoglycemia was found to be a potential contributing factor for hospital mortality with or without insulin intervention.

	Mortality Rate[a], %	Difference (Δ), %	*P*-value

25-hydroxyvitamin D levels and association with all-cause mortality in patients with type 2 diabetes mellitus

H. Dobnig[1], S. Pilz[1], H. Scharnagl[2], W. Renner[2], U. Seelhorst[3], B. Wellnitz[3], A. Fahrleitner-Pammer[1], B.O. Böhm[4], W. März[2];
[1]Department of Internal Medicine, Medical University of Graz, Austria, [2]Clinical Institute of Medical and Chemical Laboratory Diagnostics, Medical University of Graz, Austria, [3]LURIC Study non-profit LLC, Freiburg, Germany, [4]Department of Internal Medicine, University of Ulm, Germany.

Background and aims: We recently demonstrated that low baseline 25-hydroxyvitamin D (25OHD) levels in a large mixed patient population followed for a median of 7.7 years were predictive of all-cause and cardiovascular mortality (Arch Intern Med 2008; 168: 1340-1349). The aim of the present secondary analysis was to analyze whether patients with and without type 2 diabetes mellitus (DM) show a difference in that association. Such an analytical approach seems justified since patients with DM typically present with various distinct clinical comorbidities.
Materials and methods: All in all 1036 patients with DM and 2221 non-diabetic patients (non-DM) were included in this analysis. In order to adjust for seasonal variation in 25OHD levels we formed month-specific percentiles for the overall cohort. Patients with 25OHD levels above the 90th percentile [mean 25OHD level 35 (DM) and 33 ng/mL (non-diabetics)] were taken as referent population and compared to the respective diabetic and non-diabetic patient cohorts. Cox proportional hazards regression models were used including age, sex, physical activity, smoking status, cystatin C, NT-proBNP, systolic and diastolic blood pressure, use of statins, ACE inhibitors and beta blockers as confounders.
Results: Important differences in baseline characteristics were found for age (61 vs 66 years; non-DM vs DM), BMI (27.2 vs 28.7) and HbA1c levels (5.8 vs 7.3) (all P<0.001). Mean 25OHD levels were 15.3 (DM) and 18.2 ng/mL (non-DM; P<0.001). In general, the increase in all-cause mortality with declining 25OHD levels was more prominent for the non-DM patient group. Whereas a statistical significant increase in all-cause mortality already became evident with 25OHD levels below the 70th percentile in non-DM patients, 25OHD levels in DM patients had to be below the 20th percentile to be significantly associated with mortality. The interquartile range for 25OHD levels varying with season of the year below which mortality significantly increased was 15 to 23 ng/mL for the non-DM and 7 to 10 ng/mL for the DM cohort. Patients with 25OHD levels ≤10th percentile had a multivariate-adjusted hazard ratio for all-cause mortality of 5.1 (CI; 2.8 to 9.1) for non-DM as opposed to 2.9 (1.5 to 5.6) for patients with DM, respectively.
Conclusion: In conclusion, for the same month adjusted decrease in 25OHD levels the relative increase in mortality was greater for patients without DM than for those with DM. Nevertheless, 20% of patients with DM had 25OHD levels that were accompanied by a two- to threefold increase in mortality. Our data suggest that one in five patients with DM has 25OHD levels that are associated with a marked rise in mortality.

PS 8 Replicated genes for diabetes and obesity

A low "genetic load" of risk variants for type 2 diabetes is associated to better beta cell function in patients with newly diagnosed type 2 diabetes

S. Bonetti[1], M. Trombetta[1], L. Boselli[1], G. Malerba[2], E. Trabetti[2], P.F. Pignatti[2], M. Muggeo[1], E. Bonora[1], R.C. Bonadonna[1];
[1]Department of Biomedical and Surgical Sciences-Section of Endocrinology and Metabolism Disease, University of Verona, [2]Department of Mother and Child, Biology and Genetics-Section of Biology and Genetics, University of Verona, Italy.

Background and aims: Genetic variability at a number of single nucleotide polymorphisms (SNPs) has been convincingly associated to the risk of type 2 diabetes (DM2). Each SNP, however, per se contributes quantitatively little to overall risk and is often of questionable biological significance in affecting the determinants of glucose (G) regulation. Thus, we aimed at assessing the joint effect of DM2 associated SNPs on key metabolic phenotypes, i.e. beta-cell function and insulin sensitivity, of patients with newly diagnosed DM2.
Materials and methods: 388 (263 M/125 F) drug-naive and GADA-negative patients (age: median=59.0 yrs; I.Q. range: 52-65; BMI:29.4 kg/m^2; 26.5-33.0) with newly diagnosed DM2 were studied. Beta-cell function and insulin sensitivity were assessed by mathematical modeling of G/C-peptide curves during a 240' frequently sampled OGTT and by euglycemic insulin clamp, respectively. The beta-cell responses to the rate of increase of G (derivative or dynamic control: DC; units: [pmol.m^{-2}]/[mM.min^{-1}]) and to G concentration (proportional or static control, PC, presented as the insulin secretion rate at G concentrations of 5.5, 8.0, 11.0, 15.0 and 20.0 mM, respectively; units: pmol.min^{-1}.m^{-2}) are herein reported. Insulin sensitivity is presented as the M value in the last 60' of the clamp (units: μmol.min^{-1}.m^{-2}). The following SNPs (related gene) were assessed: rs7903146 (TCF7L2), rs1111875 (HHEX), rs7756992 (CDKAL1), rs679931 (CACNA1E), rs5219 (KCNJ11), rs13266634 (SLC30A8), rs4402960 (IGF2BP2), rs10010131 (WFS1) and rs4430796 (TCF2). A "genetic load" score was computed by summing the number of at risk alleles. Patients were divided in 3 groups: low (LGL: ≤7, n=92), intermediate (IGL: 8-10, n=222) and high (HGL: ≥11, n=74) "genetic load" score. Parametric and nonparametric statistical methods were used as appropriate.
Results: No significant differences in age, gender, BMI, and HbA1c were detected across LGL, IGL and HGL groups. However, fasting plasma G was lower (p<0.03) in the LGL (6.8±1.4 mM) than in the IGL (7.3±1.9 mM) and HGL (7.4±1.5 mM) groups. Insulin sensitivity (607±356; 611±355; 640±356, p=0.89) and the DC of beta-cell function (643±742, 592±643, 558±546, p=0.98) were both similar across the 3 groups. However, both IGL and HGL displayed significantly worse (p=0.01) PC of beta-cell function (157±60, 212±101, 332±177, 528±320, 778±523 and 152±56, 200±85, 326±167, 532±305, 797±498 in the IGL and HGL, respectively, at 5 G levels) than LGL (172±71, 247±117, 410±231, 648±411, 948±646).
Conclusion: A lower number of the DM2 risk alleles assessed in this study hallmarks newly diagnosed DM2 patients with better beta-cell function. Genotyping DM2 risk alleles in newly diagnosed patients may be of help in optimizing metabolic therapy and in refining metabolic prognosis.

Study of the relationship between the accumulation of genes responsible for type 2 diabetes mellitus and clinical presentation

Y. Kamura[1], M. Iwata[1], Y. Hukushima[1], C. Kobashi[1], S. Murakami[2], M. Ishiki[1], A. Takano[3], I. Usui[1], R. Temaru[4], K. Yamazaki[1], M. Urakaze[1], K. Higuchi[5], N. Akagawa[6], H. Katou[2], K. Tobe[1];
[1]First Department of Internal Medicine, Toyama University, [2]Shakaihoken Takaoka Hospital, [3]Saiseikai Takaoka Hospital, [4]Nanto City Hospital, [5]Itoigawa General Hospital, [6]Asahi General Hospital, Asahi-machi, Japan.

Background and aims: Several studies in Japan have reported that 9 to 10 sigle-nucleotide polymoriphhisms (SNPs) were involved in the onset of type 2 diabetes mellitus(T2DM) among Japanese. However, T2DM is a multifactorial disease whose onset depends not only on genetic predisposition but also environmental factors, and it remains unclear to what extent genetic predisposition affects clinical presentation. It has been reported in large scale studies in Europa that the odds ratio of each polymorphism on diabetes onset is

low, ranging from 1.1 to 1.5. Consequently, it may be that the accumulation of several polymorphisms induces the onset of diabetes. In this study, the effect of several polymorphisms and their combination on the clinical presentation of T2DM was investigated.
Materials and methods: The subjects were 620 T2DM outpatients of our hospital and associated hospitals and 501 controls.10 SNPs in 10 candidate T2DM-susceptibility genes, HHEX (rs1111875), CDKAL1 (rs7756992), CDKN2A/B (rs10811661), SLC30A8 (rs13266634), KCNJ11 (rs5219), IGF2BP2 (rs4402960), PPARG (rs4402960), TCF7L2 (rs7903146), FTO (rs8050136) and KCNQ1 (rs2237892), were genotyped by TaqMan PCR assay. Clinical information, including present BMI, age at the diagnosis of diabetes, history of body weight, age at the maximum body weight, family history, disease period, FPG, HbA1c, CPI (=F-CPR*100/FPG) and treatment, was collected and compiled in the database of Japanese Diabetes Conplication and its Prospective study(JDCP).
Results: The associations between the number of risk alleles for each polymorphism with the clinical data were investigated. There were no significant differences between total number of risk alleles (0-2) for each gene and the age at diagnosis of diabetes. Of these 10 genes, only 4 genes, CDKAL1, CDKN2A/B, SLC30A8 and KCNQ1 exhibited a significant difference between the T2DM group and the control group, and the odds ratio for the 4 genes were 1.62, 2.18, 1.71 and 2.39, respectively. The mean total number of risk alleles for the 4 genes with a significant difference from the control group was 4.9 in the T2DM group and 3.5 in the control group ($p<0.01$). The association of the number of risk alleles in 4 genes with clinical data was investigated. In comparison of the clinical presentation between the groups with a total of three or fewer risk alleles in 4 genes and six or more, although the maximum BMI of the former group was 28.5, which was greater than that of the latter group (27.1), the age at diagnosis of diabetes was 51.5 years in the former group and 48.1 years in the latter group ($p<0.05$). Regarding the indices of insulin secretory capacity, serum CPR was 2.09 in the former group and 1.67 in the latter group, and CPI was 1.55 and 1.16 respectively, showing a significant difference ($p<0.01$).
Conclusion: It was suggested that the risk alleles for each individual polymorphism have little effect on the onset of diabetes, however, the accumulation of risk alleles is associated with decreased insulin secretion and the earlier onset of diabetes.

Can knowledge about the multiple common type 2 diabetes susceptibility gene variants be applied to discriminate between glucose tolerance and diabetes?

T. Sparsø[1], N. Grarup[1], C. Andreasen[1], A. Albrechtsen[2], J. Holmkvist[1], G. Andersen[1], T. Jørgensen[3,4], K. Borch-Johnsen[5,6], A. Sandbæk[7], T. Lauritzen[7], S. Madsbad[4,8], T. Hansen[1,6], O. Pedersen[1,4];
[1]Hagedorn Research Institute, Gentofte, [2]Department of Biostatistics, University of Copenhagen, Gentofte, [3]Research Centre for Prevention and Health, Glostrup University Hospital, [4]Faculty of Health Science, University of Copenhagen, [5]Steno Diabetes Center, Gentofte, [6]Faculty of Health Science, University of Aarhus, [7]Department of General Practice, Institute of Public Health, Aarhus, [8]Hvidovre University Hospital, Denmark.

Background and aims: The list of validated type 2 diabetes susceptibility variants has recently been expanded from three to 19. The identified variants are common and have low penetrance in the general population. The aim of this study was to investigate the combined effect of the 19 variants by applying receiver operating characteristics (ROC) to demonstrate the discriminatory value between glucose-tolerant individuals and type 2 diabetes patients in a cross-sectional population of Danes.
Materials and methods: The 19 variants were genotyped in 4,093 type 2 diabetic patients and 5,302 glucose-tolerant individuals.
Results: Single variant analyses demonstrated allelic odds ratios (OR) ranging from 1.04 (95%CI: 0.98,1.11) to 1.33 (95%CI: 1.22,1.45). When combining the 19 variants subgroups with extreme risk profiles we showed a 3-fold difference in risk of type 2 diabetes (lower 10% carriers with ≤15 risk alleles vs. upper 10% carriers with ≥22 risk alleles, OR 2.93 (95%CI: 2.38,3.62,p=1.6×10-25). We calculated the area under a ROC curve to estimate the discrimination rate between glucose-tolerant individuals and type 2 diabetes patients based on the 19 variants. We found an area under the ROC curve of 0.60. No evidence of epistasis could be demonstrated. Simulation studies of 50 variants with minor allele frequency (MAF)=0.25, OR=1.10, 50 variants with MAF=0.25, OR=1.15, 25 variants with MAF=0.02, OR=0.02, 25 variants with MAF=0.01, OR=2.0, and 25 variants with MAF=0.005, OR=3 in 10,000 controls and 10,000 cases showed an area under the curve of 0.83.
Conclusion: The 19 validated common diabetes gene variants enable detection of subgroups at a substantial increased risk of type 2 diabetes; however the discrimination between glucose tolerance and type 2 diabetes is still too inaccurate to have clinical relevance. In contrast, by applying simulation studies we show that rare variants with considerable higher OR are expected to push the area under the ROC curve towards a threshold acceptable for clinical utility.

The titre of antiGAD influences diabetes-associated genes in LADA patients: results from the HUNT study

E. Pettersen[1], F. Skorpen[2], K. Kvaløy[3], K. Midthjell[4], V. Grill[5];
[1]Norwegian University of Science and Technology, Dept. of Cancer Research and Molecular Medicine, Levanger, [2]Norwegian University of Science and Technology, Dept. of Laboratory Medicine, Children's and Women's Health, Trondheim, [3]Norwegian University of Science and Technology, Dept. of Public Health and General Practice, Levanger, [4]Norwegian University of Science and Technology, Dept. of Public Health and General Practice, Verdal, [5]Norwegian University of Science and Technology, Dept. of Cancer Research and Molecular Medicine, Trondheim, Norway.

Background and aims: Need for insulin treatment in Latent Autoimmune Diabetes in the Adult (LADA) patients associates with autoimmune activity as assessed from titres of antiGAD. Here we tested whether high titres of antiGAD increase the association of LADA with genes conferring risk of type 1 and low titres with genes conferring risk of type 2 diabetes.
Materials and methods: DNA samples collected from the HUNT study (1995-96) were used for analysis. We analysed 120 type 1 diabetic, 126 LADA, 1090 type 2 diabetic and 1503 age and gender matched non diabetic subjects for 60 SNPs located in loci known to be associated with type 1 or type 2 diabetes, including 14 tag-SNPs used for HLA haplotyping. For HLA-typing we genotyped recommended tag SNPs for different HLA-alleles, which combined in HLA haplotypes were known to be associated with type 1 diabetes. LADA patients were then dichotomised on the basis of antiGAD-levels below (low antiGAD) or above (high antiGAD) the median of antiGAD. Genotype distributions were tested by logistic regression analysis under additive, dominant and recessive models. Odds ratio (OR) and 95% confidence intervals (CI) were calculated. Phasing HLA haplotypes and testing for association within cases and controls were performed by PLINK software and SPSS (version 14.0). Adjustment for sex, age and BMI was applied when appropriate. Correction for multiple testing was done by max(T) permutation.
Results: The type 2 diabetes associated *FTO* and *TSPAN8* genes and the majority of the most strongly associated HLA haplotypes for type 1 diabetes, were found to be significantly associated with LADA in general. One distinct haplotype GCA for DRB1*0401-DQA1*0301-DQB1*0301 was found to be associated with higher risk only for LADA ($p=0.013$). After dichotomising for antiGAD the AA/AC genotypes of rs8050136, GG/GC of rs1861866 and TT/TC of rs9931491 in the *FTO*-gene and the CC/CT genotypes of rs7961581 in *TSPAN8* were associated only with low-antiGAD LADA ($p=0.004$, $p=0.006$, $p=0.002$ and $p=0.0004$, respectively). The same *FTO* and *TSPAN8* genotypes were also associated with type 2 diabetes ($p=0.005$, $p=0.047$, $p=0.004$ and $p=0.009$, respectively). No associations were found between *FTO* and *TSPAN8* and type 1 diabetes. The strongly associated type 2 diabetes gene *TCF7L2* (rs7903146) was not associated with LADA in general, nor in subgroups of antiGAD. The HLA haplotypes were, after dichotomising for antiGAD, found to be mainly associated with high antiGAD LADA patients, except the GCA-haplotype for DRB1*0401-DQA1*0301-DQB1*0301 which was associated with higher risk in low antiGAD LADA patients ($p=0.0003$). Interestingly, yet another distinct haplotype was found, the GCTA-haplotype for DRB1*0401-DQA1*0301-DQB1*0302, which was only associated with higher risk in low antiGAD LADA ($p=0.006$) and not with type 1 and type 2 diabetes.
Conclusion: These findings indicate that genetic heterogeneity in LADA is linked to a varying degree of autoimmune activity.

321

Explorative analyses of the population impact of type 2 diabetes associated SNPs on diabetes related traits - the HUNT study

C.G.P. Platou[1,2], K. Midthjell[3], K. Hveem[1];
[1]Department of Public Health and General Practice, Norwegian University of Science and Technology, Levanger, [2]Department of Internal Medicine, Levanger Hospital, Nord-Trøndelag Health Trust, [3]Department of Public Health and General Practice, Norwegian University of Science and Technology, Verdal, Norway.

Background and aims: Several genome wide association studies have identified single nucleotide polymorphisms (SNPs) associated with type 2 diabetes (T2D). These SNPs could act through T2D related traits and conditions and have an impact in such in people without T2D. This study explores the potential impact of some of these SNPs on T2D related traits (BMI, lipids, non-fasting glucose, blood pressure and self reported cerebro- and cardiovascular ischemic disease) in a general, normoglycaemic population.
Materials and methods: T2D related traits were identified in the second Nord-Trøndelag Health Study (HUNT2 1995-97). Thirteen T2D susceptible SNPs were replicated in samples from HUNT2 using TaqMan allelic discrimination assay. Preliminary study population n=1402 (later to be increased to n>4000), persons without diabetes and with a non-fasting glucose below 7.8 mmol/l. Associations between T2D related SNPs and relevant traits were analysed with logistic and linear regression adjusted for sex, age and BMI in an additive model of inheritance. Correction for multiple testing was not performed in this explorative setting.
Results: A negative association was identified for diastolic hypertension (>90 mm Hg) with the gene regions THADA (rs7578597; OR=0.19, 95% CI: 0.04 - 0.82, p=2.7x10^{-2}), TSPAN8 (rs796181; OR=0.51, 95% CI: 0.30 - 0.97, p=1.3x10^{-2}) and TCF7L2 (rs7903146; OR=0.46, 95% CI: 0.25 - 0.84, p=1.1x10^{-2}). Likewise for myocardial infarction with BCL11A (rs10490072; OR=0.45, 95% CI: 0.21 - 0.96, p=3.8x10^{-2}), for BMI with CAMK1D (rs12779790; regression coefficient=-0.43, 95% CI: -0.82 - -0.04, p=2.9x10^{-2}), for total cholesterol with BCL11A (rs10490072; regression coefficient=-0.11, 95% CI: -0.16 - -0.01, p=3.4x10^{-3}) and for HDL-cholesterol with BCL11A (rs10490072; regression coefficient=-0.04, 95% CI: -0.07 - -0.01, p=2.3x10^{-2}) and FTO (rs8050136; regression coefficient= -0.04, 95% CI: -0.07 - -0.01, p=1.2x10^{-2}). A positive association was observed for microalbuminuria with FTO (rs8050136; OR=3.90, 95% CI: 1.43 - 10.59, p=7.7x10^{-3}), for cerebral stroke with FTO (rs8050136; OR=2.17, 95% CI: 1.06 - 4.44, p=3.4x10^{-2}) and for increased levels of non-fasting blood glucose (for glucose values < 7.8 mmol/l) with the gene regions NOTCH2 (rs10923931; regression coefficient=0.12, 95% CI: 0.03-0.21, p=1.0x10^{-2}), ADAM30 (rs2641348; regression coefficient=0.14, 95% CI: 0.04-0.23, p=3.9x10^{-3}) and JAZF1 (rs864745; regression coefficient=0.06, 95% CI: 0.00 - 0.12, p=4.4x10^{-2}).
Conclusion: In a normoglycaemic population, T2D related SNPs were negatively associated with diastolic hypertension, myocardial infarction, BMI and increasing levels of both total cholesterol and HDL-cholesterol. A positive association was observed for microalbuminuria, cerebral stroke and increased levels of non-fasting blood glucose (for glucose values < 7.8 mmol/l). More samples will be added to further explore the possible clinical relevance of these associations when studying the population effect of T2D associated SNPs.

322

Analyses of the combined discriminative value of 20 validated obesity susceptibility variants, separately and in combination with environmental factors

C.H. Andreasen[1], T. Sparsø[1], N. Grarup[1], A. Albrechtsen[2], K. Borch-Johnsen[3,4], A. Sandbæk[5], T. Lauritzen[5], T. Jørgensen[6,7], O. Pedersen[1,7], T. Hansen[1,8];
[1]Hagedorn Research Institute, Gentofte, [2]Department of Biostatistics, University of Copenhagen, [3]Steno Diabetes Center, Gentofte, [4]Faculty of Health Science, University of Aarhus, [5]Department of General Practice, University of Aarhus, [6]Research Centre for Prevention and Health, Glostrup University Hospital, [7]Faculty of Health Science, University of Copenhagen, [8]Faculty of Health Sciences, University of Southern Denmark, Odense, Denmark.

Background: Within the last few years, genome-wide association studies have led to the identification of 20 genetic variants associating with obesity or related phenotypes. The variants are common and exhibit moderate effect sizes in the general population. The aim of this study is to investigate the combined effect of these variants and their ability to discriminate between normal weight and overweight/obese individuals in a cross-sectional population of Danes, by applying receiver operating characteristics (ROC).
Methods: The 20 variants were genotyped in 4 study groups: the population-based Inter99 study, the ADDITION Denmark screening study cohort, a population-based study group and a type 2 diabetic patient group both sampled at Steno Diabetes Center. The combined study population included 5,512 normal weight, 7,458 overweight and 5,044 obese individuals.
Results: Individual variant analyses demonstrated per allele odds ratios (OR) for the 20 variants ranging from 1.07 (95% CI 1.00-1.13) to 1.27 (95% CI 1.20-1.35). When combining the variants, individuals with extreme risk profile carrying more than 22 risk alleles (highest percentile) showed a significant increase in risk of both overweight 1.69 (1.41-2.03), $p = 8.2 \times 10^{-9}$ and obesity 2.14 (1.75-2.62), $p = 2.4 \times 10^{-14}$, compared to individuals with minimal risk profile carrying less than 14 risk alleles (lowest percentile). The area under ROC curve predicting overweight and obesity using data on the 20 SNPs was determined to 0.53 and 0.58, respectively. When combining SNP data with information regarding age, sex, diet, physical activity, smoking, education, employment and use of anti-obesity drugs, the discriminative ability measured by area under the ROC curve increased to 0.64 for overweight and 0.70 for obesity, which for obesity is higher than for environmental factors alone (AUC = 0.67).
Conclusion: The 20 newly identified obesity variants confer a significantly increased combined risk of both overweight and obesity in carriers of many risk alleles. The discriminative value of the 20 variants is still sparse and too inaccurate for clinical preventive purposes.

Variants in *RAPGEF1*, *ENPP1*, *TP53*, *NRF1*, *SLC2A2*, *SLC2A4* and *FOXC2* do not associate with type 2 diabetes or related phenotypes in studies of 9,750 Danes

N. Grarup[1], K. Burgdorf[1], A. Sandbæk[2], T. Lauritzen[2], T. Jørgensen[3,4], T. Hansen[1,5], O. Pedersen[1,3];
[1]Hagedorn Research Institute, Gentofte, [2]Department of General Practice, Institute of Public Health, Aarhus University, [3]Faculty of Health Sciences, University of Copenhagen, [4]Research Centre for Prevention and Health, Glostrup University Hospital, [5]Faculty of Health Sciences, University of Southern Denmark, Odense, Denmark.

Background and aims: In 2008 a comprehensive step-wise study of 222 candidate genes in type 2 diabetes reported association of variants in *RAPGEF1*, *ENPP1*, *TP53*, *NRF1*, *SLC2A2*, *SLC2A4* and *FOXC2* with type 2 diabetes in a study of 4,805 Finnish individuals. We aimed at validating these associations in a Danish case-control study and furthermore sought to evaluate the impact on diabetes-related intermediary traits of these variants in a population-based sample.
Materials and methods: We genotyped nine genetic variants in seven genes (*RAPGEF1* rs4740283, *ENPP1* rs2021966 and rs858341, *TP53* rs1042522, *NRF1* rs1882095, *SLC2A2* rs10513684 and rs5400, *SLC2A4* rs222852 and *FOXC2* rs4843165) in 5,976 middle-aged subjects from the population-based Inter99 cohort who all had undergone an OGTT. Furthermore these variants were genotyped in additional samples adding up to a case-control study comprising 4,974 glucose-tolerant participants and 3,586 type 2 diabetic cases.
Results: Based on the effect sizes and genetic models previously reported we had >95% statistical power for all variants to detect association with type 2 diabetes at a 5% significance level. In analyses adjusted for the effect of age, sex and BMI none of the nine variants associated with type 2 diabetes when applying the same genetic model as previously reported (OR for individual variants 1.01 - 1.26, *P*-values for individual variants: 0.07 - 0.8). However for all nine variants the estimate of association was in the same direction as previously described. In studies of diabetes-related quantitative traits in 5,883 participants without treated type 2 diabetes of the Inter99 cohort we observed nominal associations of *ENPP1* rs858341 with 2.8%, 3.1% and 2.1% increases in incremental area under the serum insulin, plasma glucose and serum C-peptide curves during an OGTT (95% CI 0.6-4.9%, *P*=0.01; 0.4-5.7%, *P*=0.02; and 0.7-3.4%, *P*=0.003, respectively). Furthermore, *TP53* rs1042522 associated nominally with a 0.034 mmol/l increase in fasting plasma glucose per allele (95% CI 0.0045-0.064 mmol/l, *P*=0.02).
Conclusion: Recently reported associations of variants in *RAPGEF1*, *ENPP1*, *TP53*, *NRF1*, *SLC2A2*, *SLC2A4* and *FOXC2* do not associate with type 2 dia-

betes in the Danish population, however we are not able to exclude modest effects of these loci. This study underlines difficulties in replicating genetic association studies and further large-scale collaborative analyses are needed to clarify the impact of these variants.

A variant in the *KCNQ1* gene predicts future type 2 diabetes and mediates impaired insulin secretion
A. Jonsson[1], B. Isomaa[2,3], T. Tuomi[2,4], J. Taneera[1], A. Salehi[5], P. Nilsson[6], L. Groop[1,4], V. Lyssenko[1];
[1]Clinical Sciences, Diabetes & Endocrinology, Lund University, Malmö, Sweden, [2]Folkhälsan Research Centre, Helsinki, Finland, [3]Malmska Municipal Health Care Center and Hospital, Jakobstad, Finland, [4]Medicine, Helsinki University Central Hospital and University of Helsinki, Finland, [5]Clinical Sciences, Endocrine Pharmacology, Lund University, Malmö, Sweden, [6]Clinical Sciences, Medicine, Lund University, Malmö, Sweden.

Background and aims: Two independent genome wide association studies for type 2 diabetes (T2D) in Japanese have recently identified common variants in the *KCNQ1* gene being strongly associated with T2D. Here we studied whether variants in *KCNQ1* would influence BMI, insulin secretion and action and predict future T2D in subjects from Scandinavia.
Materials and methods: Risk of T2D conferred by *KCNQ1* rs2237895 was studied in 2,830 T2D cases and 3,550 controls from Sweden and prospectively in 16,061 individuals from the Malmö Preventive Project. Effect of genotype on insulin secretion/action was assessed cross-sectionally in 3,298 non-diabetic subjects from the PPP-Botnia Study and longitudinally in 2,328 non-diabetic subjects from the Botnia Prospective Study (BPS). KCNQ1 expression and glucose-stimulated insulin secretion was measured in human islets from 18 and 10, respectively, non-diabetic donors.
Results: The C-allele of *KCNQ1* rs2237895 was associated with increased risk of T2D in both the case-control (OR 1.23 [1.12-1.34], $p=5.6\times10^{-6}$) and the prospective (OR 1.14 [1.06-1.22], $p=4.8\times10^{-4}$) study. Furthermore, the C-allele was associated with decreased insulin secretion (CIR p=0.013; DI p=0.013) in the PPP-Botnia study and in the BPS at baseline (CIR $p=2.1\times10^{-4}$; DI p=0.0015) and during follow-up (CIR $p=3.8\times10^{-4}$; DI $p=8.3\times10^{-4}$). The CC-carriers showed a reduced glucose-stimulated insulin secretion from human islets (p=0.0058).
Conclusion: A common variant in the *KCNQ1* gene is associated with increased risk of future T2D in Scandinavians which can be explained by its influence on insulin secretion.

Genetic variation in KCNQ1 associates with beta cell function and fasting glucose levels: a study of 3734 subjects comprising three Asian ethnicities
D.P.K. Ng[1], J. Tan[2], S. Nurbaya[1], D. Gardner[2], S. Ye[1], E.S. Tai[2];
[1]Community, Occupational and Family Medicine, National University of Singapore, [2]Endocrinology, Singapore General Hospital, Singapore.

Background and aims: The potassium voltage-gated channel, KQT-like subfamily, member 1 (*KCNQ1*) has been found through a genome-wide association study to be a strong candidate for conferring susceptibility to type 2 diabetes in East Asian and European populations. We sought to describe the potential association between polymorphisms at the *KCNQ1* locus with insulin resistance, β-cell function and other type 2 diabetes-related traits in a sample of Chinese, Malays and Asian-Indians living in Singapore.
Materials and methods: We examined the associations between 4 previously reported *KCNQ1* SNPs with type 2 diabetes-related traits in 3734 participants from the population-based NHS98 cohort (2520 Chinese, 693 Malay, 521 Asian-Indians). Insulin resistance was calculated from fasting insulin and glucose using the Homeostasis model assessment method, while pancreatic β-cell function was assessed using the corrected insulin response at 120 minutes (CIR_{120}).
Results: SNPs rs2237897, rs2237892, rs2283228 were significantly associated with type 2 diabetes (OR= 1.48, $p=3\times10^{-4}$; OR=1.38, p=0.002; OR=1.31, p=0.012 respectively). Within the Chinese population, the risk alleles for rs2237897, rs2237892, rs2283228 were significantly associated with higher fasting glucose levels (p=0.014, 0.011 and 0.034 respectively) and reduced CIR_{120} (p=0.007, 0.013, 0.014 respectively). A similar trend was observed among the Malay and Asian-Indian minority groups although this did not reach statistical significance due to limited sample sizes.
Conclusion: The increased risk for type 2 diabetes associated with *KCNQ1* is likely to be caused by a reduction in insulin secretion. Further studies will be useful to replicate these findings and to fully delineate the role of *KCNQ1* and its related pathways in disease pathogenesis.

The type 2 diabetes-associated C-allele of rs2237895 *KCNQ1* associates with reduced insulin release following an oral glucose load
K. Banasik[1], J. Holmkvist[1], G. Andersen[1], H. Unoki[2], T.S. Jensen[3], C. Pisinger[4], K. Borch-Johnsen[5,6], S. Brunak[3], S. Maeda[2], T. Hansen[1,7], O. Pedersen[1,8];
[1]Hagedorn Research Institute, Gentofte, Denmark, [2]Laboratory for Endocrinology and Metabolism, Yokohama, Kanagawa, Japan, [3]Center for Biological Sequence Analysis, Lyngby, Denmark, [4]Research Centre for Prevention and Health, Glostrup, Denmark, [5]Steno Diabetes Center, Gentofte, Denmark, [6]Faculty of Health Science, Aarhus, Denmark, [7]Faculty of Health Science, Odense, Denmark, [8]Faculty of Health Science, Copenhagen, Denmark.

Background and aims: Polymorphisms in the potassium channel, voltage-gated, KQT-like subfamily, member 1 (*KCNQ1*) gene have recently been reported to associate with type 2 diabetes. The primary aim of the present study was to investigate the putative impact of these *KCNQ1* polymorphisms (rs2283228, rs2237892, rs2237895, and rs2237897) on estimates of glucose-stimulated insulin release.
Materials and methods: Genotypes were examined for association with serum insulin levels following an oral glucose tolerance test (OGTT) in a population-based sample of 6,039 middle-aged and treatment-naïve individuals of whom 4,568 were glucose-tolerant. Insulin release indices estimated from the OGTT and the interplay between insulin sensitivity and insulin release were investigated using linear regression and Hotelling T2 analyses.
Results: Applying an additive genetic model the minor C-allele of rs2237895 was associated with reduced insulin levels 30 min (mean±SD: (CC) 277±160 vs. (AC) 280±164 vs. (AA) 299±200 pmol/l, p=0.008) after an oral glucose load, insulinogenic index (29.6±17.4 vs. 30.2±18.7vs. 32.2±22.1, p=0.007), incremental area under the insulin curve (20,477±12,491 vs. 20,503±12,386 vs. 21,810±14,685, p=0.02) among 4,568 glucose-tolerant individuals. Adjustment for the degree of insulin sensitivity had no effect on the measures of reduced insulin release. The rs2237895 risk genotype had a similar impact in the total sample of treatment-naïve individuals. No association with measures of insulin release were identified for rs2237892, rs2237897 or rs2283228.
Conclusion: In a population-based sample of 4,568 glucose-tolerant and middle-aged people, the type 2 diabetes-associated rs2237895 C-allele of *KCNQ1* was associated with reduced insulin release following an oral glucose load, suggesting that the increased risk of type 2 diabetes previously reported for this variant is likely to be mediated through an impaired beta cell function.

***IRS-1* G972R and type 2 diabetes: a paradigm for the difficult ascertainment of the contribution to disease susceptibility of "low frequency-low risk" variants**
E. Morini[1], S. Prudente[1], E. Succurro[2], M. Chandalia[3], Y.-Y. Zhang[4], S. Mammarella[5], F. Pellegrini[6], C. Powers[4], V. Proto[1], B. Dallapiccola[1], A. Cama[5], G. Sesti[2], N. Abate[3], A. Doria[4], V. Trischitta[1];
[1]IRCCS Casa Sollievo della Sofferenza – Mendel Institute, Rome, Italy, [2]Dept of Exp and Clin Med, Un Magna Græcia, CZ, Italy, [3]Div of Endocr and Metab UTMB, Galveston, United States, [4]Res Div, Joslin Diabetes Center, Boston, United States, [5]Dept of Oncol and Neurosc, Un G. D'Annunzio, Chieti, Italy, [6]Dept of Clinl Pharm and Epidem, Consorzio Mario Negri Sud, S. Maria Imbaro, Italy.

Background and aims: Insulin receptor substrate-1 (IRS-1) plays a central role in insulin signalling and glucose homeostasis. A deleterious role on both

in vivo and *in vitro* insulin sensitivity and secretion has been repeatedly and unanimously reported for the relatively infrequent "loss of function" *IRS-1* G972R SNP (rs1801278, minor allele frequency=0.05). Despite this strong candidacy, results on its association with type 2 diabetes (T2D) have been conflicting, making the role of this SNP uncertain. To obtain further insights onto this topic, we performed a meta-analysis of all available case-control studies.

Materials and methods: We analyzed all case-control studies published as of January 2009 and we included also five unpublished case-control studies in which all study subjects were self-reported Whites: four sets from the Genetics of T2D in Italy and the United States (GENIUS T2D) Consortium and one set recruited in Chieti, Italy. Of the 35 available studies, only those in which both cases and controls were in HWE were meta-analyzed (n=30), comprising 11,857 cases and 10,758 controls.

Results: According to a dominant model (GR+RR compared to GG individuals) R972 variant tended to be associated with T2D, though failing to reach statistical significance (OR=1.09, 95%CI 0.96-1.24 p=0.195). Some evidence of heterogeneity was observed across studies (p=0.064). In a meta-regression analysis, neither the mean BMI of cases nor that of controls (available in 21 studies corresponding to 19,368 individuals) explained a significant proportion of such heterogeneity (2.1%, p=0.47 and 1%, p=0.77, respectively). By contrast, the mean age at T2D diagnosis explained 49% of this heterogeneity (p=0.03) in the 12 studies (8,967 individuals) in which this variable was available. When these studies were subdivided in tertiles of mean age at T2D diagnosis, summary ORs of T2D were 1.51 (95%CI 1.17-1.95), 1.24 (95%CI 0.96-1.59) and 0.88 (95%CI 0.68-1.14) in the youngest (39-44.9 yrs at diagnosis), intermediate (45-50.9 yrs) and oldest (51-58 yrs) tertile (p for trend of ORs=0.0017).

Conclusion: Our findings illustrate the difficulties of ascertaining the contribution of "low frequency-low risk" variants to T2D susceptibility. In the specific context of the R972 variant, 200,000 study subjects would be needed to have 80% power to identify a 10% increase in T2D risk at genome-wide significance levels. Under these circumstances, a strategy aimed at improving outcome definition and decreasing its heterogeneity may critically enhance our ability to detect genetic effects, thereby decreasing the required sample size. Our data suggest that focusing on early-onset diabetes, which is characterized by a stronger genetic background, may be part of such strategy.

Association study between LXRβ polymorphisms and type 2 diabetes mellitus

K. Solaas[1], V. Legry[2], K.B. Holven[3], K. Retterstol[4], P.M. Thorsby[5], J. Ferrières[6], S. Tonstad[7], H. Rootwelt[8], S. Lien[9], B. Halvorsen[10], M.S. Nenseter[10], P. Amouyel[2], K. Birkeland[1], A. Meirhaeghe[2], H.I. Nebb[3]; [1]Department of Endocrinology, Oslo University Hospital, Aker, Norway, [2]INSERM, U744, Institut Pasteur de Lille, Université de Lille 2, France, [3]Department of Nutrition, Univ of Oslo, Norway, [4]Oslo University Hospital, Rikshospitalet, Norway, [5]The Hormone Laboratory, Oslo University Hospital, Aker, Norway, [6]Department of Cardiology, Toulouse University School of Medicine, Rangueil Hospital, France, [7]Department of Preventive Medicine, Oslo University Hospital, Ulleval, Norway, [8]Department of Medical Biochemistry, Oslo University Hospital, Rikshospitalet, Norway, [9]Centre for Integrative Genetics, Norwegian University of Life Sciences, Oslo, Norway, [10]Research Institute for Internal Medicine, Oslo University Hospital, Rikshospitalet, Norway.

Background and aims: Liver X receptors (LXRs) are nuclear receptors involved in the control of lipid and carbohydrate metabolism as well as inflammation. LXRs exist in two isoforms, LXRα and LXRβ, with similar protein structure and ligand binding, but somewhat different physiological functions. LXRβ shows a ubiquitously tissue expression. The role of LXRβ is still under investigation. However, the study of mice deficient for LXRβ has revealed important specific functions of LXRβ. LXRβ polymorphisms have so far been associated with Alzheimer's disease and obesity. We hypothesized that single nucleotide polymorphisms (SNPs) in the LXRβ gene are associated with some of the metabolic changes seen in patients with type 2 diabetes mellitus (T2DM).

Materials and methods: We used the following cohorts: *French individuals from the Lille and Toulouse MONICA studies (http://www.ktl.fi/monica), n=2315. *The Norwegian HUNT study (http://www.ntnu.no/dmf/hunt/english), n=2930. Genomic DNA was isolated from whole blood. SNPs were genotyped by the restriction fragment length polymorphism method or the iPLEX system from SEQUENOM for use with the MassARRAY platform. Statistical differences between groups were analyzed by χ^2 or ANOVA tests. *In silico* functional analysis: MatInspector by Genomatix.

Results: We sequenced the LXRβ gene in 86 individuals with metabolic syndrome and 10 control individuals, and identified 9 SNPs with a minor allele frequency above 5%. Then we genotyped 5 tag-SNPs in the two cohorts. We identified an association between a tag-SNP (rs17373080) representing a big haplotype block and the risk of T2DM (OR=1.77, p=0.01) and obesity (OR=1.26, p=0.05) in both men and women. *In silico* analyses showed that another SNP located in intron 4 -in linkage with rs17373080- would create a binding site for the hepatic nuclear factor 4 (HNF4) and nuclear factor 1 (NF1A, B, C and X) transcription factors. *In vitro* EMSA and cell transient transfections will be performed to examine the impact of this polymorphism on LXRβ expression.

Conclusion: Our results indicate that a putative functional polymorphism in the LXRβ gene is associated with T2DM and obesity.

329

Association between variants in the INSIG1 gene and the risk of type 2 diabetes and related traits

M. Szopa[1,2], A. Meirhaege[3], J. Luan[1], T. Vidal-Puig[4], P. Amouyel[3], N.J. Wareham[1], R.J.F. Loos[1]; [1]MRC Epidemiology Unit, Institute of Metabolic Science, Addenbrooke's Hospital, Cambridge, United Kingdom, [2]Department of Metabolic Diseases, Jagiellonian University, Medical College, Krakow, Poland, [3]INSERM, U744, Institut Pasteur de Lille, France, [4]MRC Centre for Obesity and Associated Diseases, Biochemistry, University of Cambridge, Institute of Metabolic Science, Addenbrooke's Hospital, United Kingdom.

Background and aims: Insulin-induced gene 1 (INSIG1) is a protein that blocks proteolytic activation of sterol regulatory element-binding proteins (SREBPs), transcription factors that activate genes regulating cholesterol and fatty acid metabolism and possibly genes involved in glucose homeostasis. In

the present study, we tested for association between six tagSNPs, capturing all common variation in the *INSIG1* gene and risk of type 2 diabetes, obesity and related traits in 11,168 individuals from six population-based and case-control studies.
Materials and methods: Six *INSIG1* tagSNPs were genotyped in participants from the Hertfordshire study, the MRC Fenland study, the MRC Ely study, the MONICA-Lille study, the Addition (Cambridge) study, and the Cambridgeshire case-control study. For each study, we tested for association between SNPs and [1] risk of diabetes and obesity using logistic regression, and [2] continuous traits (BMI, waist circumference, fasting glucose, glucose 120' OGTT, plasma cholesterol, HDL, LDL and triglyceride levels, systolic and diastolic blood pressure levels) using linear regression, assuming an additive model. Summary statistics of each study were meta-analyzed using inverse variance methods.
Results: The meta-analysis of the three case-control studies, including 1,711 cases and 2,992 controls, showed no compelling evidence of association between any of the six *INSIG1* SNPs and the risk of type 2 diabetes. Although minor alleles of rs10258075 and rs10271719 tended to be associated with a higher risk of type 2 diabetes (OR 1.40 [95%CI 1.07-1.83], p = 0.015 and OR 1.31 [95%CI 1.00 - 1.70], p = 0.046, respectively), these observations were not significant when accounting for multiple testing. We tested for the association between the six SNPs and the risk of obesity in the 3 population-based studies, yet none of *INSIG1* SNPs showed significant association. In agreement with the case-control analyses, none of the association between the *INSIG1* SNPs and any of the six metabolic traits showed convincing association. While a few nominally significant associations emerged, they did not survive correction for multiple testing.
Conclusion: Although our study was sufficiently powered to identify associations of small effect size, our results suggest that common genetic variation in *INSIG1* is unlikely to have a major impact on type 2 diabetes and obesity risk and related traits.

***FOXO1* variation and relationships with type 2 diabetes and intermediary quantitative traits**
G. Andersen[1,2], K. Yanagisawa[1], E.-M.D. Nielsen[1], T. Sparsø[1,2], T.I.A. Sørensen[3], C.S. Rose[1], T. Jørgensen[4,5], K. Borch-Johnsen[1,4], J. Holmkvist[1,2], O. Pedersen[1,2], T. Hansen[1,2];
[1]Steno Diabetes Center, Gentofte, [2]Hagedorn Research Institute, Gentofte, [3]Institute of Preventive Medicine, Copenhagen University Hospital, Centre for Health and Society, [4]Research Centre for Prevention and Health, Glostrup University Hospital, [5]Faculty of Health Sciences, University of Copenhagen, Denmark.

Background and aims: The transcription factor Foxo1 is involved in liver glucose metabolism, pancreatic beta-cell proliferation, and differentiation of adipocytes and skeletal muscle cells making human *FOXO1* a candidate gene for abnormal glucose regulation. We investigated whether variants in *FOXO1* are associated with type 2 diabetes, obesity, or with alterations in insulin sensitivity or insulin release.
Materials and methods: We performed a screening for rare mutations with subsequent genotyping in family studies and large-scale tagging of frequent single-nucleotide polymorphisms. A mutation analysis was carried out in 61 Danish type 2 diabetic patients. We tagged *FOXO1* using HapMap data and genotyped five variants (rs7337995, rs1334241, rs7981045, rs2701880, and rs2755213) in 7960 individuals of which 6898 were characterised by an oral glucose tolerance test.
Results: The mutation analysis resulted in the identification of four variants; Ala511Val, -30C>T, 2074T>C, and 2600delA. In family studies the two rare Ala511Val and -30C>T variants did not co-segregate with type 2 diabetes. In case-control studies of type 2 diabetes and obesity only the rs7337995 variant A-allele showed association with obesity (p = 0.02), and in studies of fasting and post-oral glucose load measurements of plasma glucose and serum insulin and C-peptide only the rs1334241 polymorphism was related to modest alterations in serum C-peptide release. No relationships with estimates of insulin resistance were observed, and no haplotype association or SNP-SNP interaction was found for any trait.
Conclusion: We conclude that common variation of FOXO1 is not a major contributor to the pathogenesis of type 2 diabetes.

Association of *TCF7L2* gene haplotypes with diabetes type 2, gestational diabetes but not with polycystic ovary syndrome in Czech cohorts
B. Bendlová, J. Včelák, M. Vaňková, P. Lukášová, S. Pražáková, O. Bradnová, H. Kvasničková, K. Vondra, J. Vrbíková;
Institute of Endocrinology, Prague, Czech Republic.

Background and aims: Polymorphisms in the human transcription factor 7-like 2 (*TCF7L2*), which plays a key role in the Wnt signaling pathway, are strongly associated with type 2 diabetes (T2D) in multiple populations. Risk genotypes in *TCF7L2* gene are associated with impaired insulin secretion and incretin effect and with hepatic insulin resistance. The aim of our study was to examine the role of *TCF7L2* gene variants in the pathogenesis of T2D, gestational diabetes (G) and polycystic ovary syndrome (PCOS) in Czech population.
Materials and methods: The study involved 1460 Czech Caucasian individuals: 347 patients with T2D (D: M/F 115/232); 261 gestational diabetics (G); 147 offspring of T2D (O: M/F 48/99); 329 women with PCOS defined according to ESHRE consensus (PCOS) and 376 controls (C: M/F 123/253). Oral glucose tolerance test (oGTT) with sampling for blood glucose, insulin, C-peptide, proinsulin and glucagon and insulin tolerance test (ITT) were performed (except of T2D patients). Moreover, anthropometric parameters, 29 biochemical parameters and hormones and oGTT- and ITT- derived indices were evaluated. The SNPs: rs7901695 (T>C); rs7903146 (C>T); rs12255372 (G>T) in the *TCF7L2* gene were assessed by ABI TaqMan SNP Genotyping Assays. Particular haplotypes were generated by PHASE software. Statistics (Chi-Square test, Mann-Whitney test and GLM Anova) was done using NCSS 2004.
Results: PHASE generated 6 haplotypes whereas four most frequent haplotype combinations TCG/TCG, CTT/TCG, CTT/CTT and CTG/TCG were studied. The frequency of the risk homozygous CTT/CTT haplotype combination was decreasing in the studied groups as follows: D 10.6, O 9.5, G 6.1, C 5.32 and PCOS 4.9 [%] and the distribution of CTT carriers did not differ in particular groups with respect to BMI. The CTT haplotype showed a signif. association with T2D with OR [95%CI] 1.57 [1.23;2.01], p=0.0003, for CTT homozygotes the OR was 2.25 [1.28;3.98], p=0.006. Interestingly, the frequency of the fourth most often haplotype combination CTG/TCG was almost twice higher in gestational diabetics compared with all other studied groups (7.7% vs 2.9-4.26%) and it was associated with gestational diabetes risk, OR 2.59 [1.12;6.01], p=0.036. In cohorts we did not observe the influence of risk *TCF7L2* haplotype on fasting and stimulated insulin, proinsulin, C-peptide and glucagon secretion and on any other screened parameter except of polyunsaturated fatty acids where the % of fasting PUFA was significantly decreased in CTT carriers vs. non-carriers in control women (p=0.0009), esp. due to lower proportion of (n-6) PUFA. The same trend was apparent in gestational diabetics (p=0.06). After pooling of all women (except of T2D patients), the signif. decreased levels of oGTT-stimulated insulin were apparent but the insulinogenic index as well as disposition indices did not differ between CTT carriers and non-carriers. The most significant association remained % of fasting PUFA, even after adjustments for age and BMI (p=0.00008, power 0.98) or HOMAR (p=0.0001, power 0.97).
Conclusion: The strong association of *TCF7L2* haplotypes with T2D and gestational diabetes was confirmed. The most risk haplotype combination for T2D is CTT/CTT but surprisingly, CTG/TCG for gestational diabetes. In women, the CTT carriership was associated with lower % of fasting PUFA. The association with polycystic ovary syndome was not found.

Evaluation of chloride channel-3 as a potential target for TCF7L2-dependent impairment of insulin secretion
X. Jing, Y. Zhou, P. Osmark, S. Lang, L. Groop, O. Hansson, E. Renström;
Lund University Diabetes Centre, Malmö, Sweden.

Background and aims: The transcription factor TCF7L2 is the most important type 2-diabetes gene discovered to date. The splicing pattern of the transcription factor is complex and varies among tissues. We have recently demonstrated that human (and rat) islets primarily express a TCF7L2 mRNA species that contains exon 4. Here we have investigated the correlation between expression of the exon 4-containing TCF7L2 splice variant and expression of ion channel target genes in human islets of Langerhans.
Materials and methods: The percentage of the exon4-containing-TCF7L2 transcripts was measured with QPCR using absolute quantification. Statis-

tic analyses were performed using non-parametric Spearsman correlation (SPSS 16.0). Candidate genes were analysed using Gene Set Analysis Tool kit (http://bioinfo.vanderbilt.edu/). Using rat clonal INS-1 cells, ClC-3 was silenced using the EGFP-containing $P^{RNA\text{-}H1.1}$ vector (GenScript Corp, Piscataway, NJ, U.S.A) with 76 basepair shRNA insert with the CTCCGGAATTCCAGAGATTAA target sequence in rat ClC-3. Expression and knockdown was verified by immunoblotting using an anti-ClC-3 antibody (kindly provided by Prof. T. Jentsch). Insulin granules were purified using a Phogrin-EGFP adenovirus (BD Adeno-X expression system 1, Clontech, CA, U.S.A). INS-1 cells were homogenized and EGFP-positive particles were collected using a Becton Dickinson Cell Sorter. Secretion in ClC3-silenced cells was quantified as the ratio of secreted hGH over total hGH content/well, in cells coexpressing hGH and the shRNA.

Results: The binding motif (A-C/G-A/T-T-C-A-A-A-G) of TCF7L2 was investigated in the promoter region of all annotated genes and regions in the human genome using a bio-informatics approach (Pearl). All together 2759 annotated genes were found to contain the TCF7L2 binding motif. Out of these 2759 genes, the expression of 205 genes correlated significantly (P=0.05) with exon4-containing-TCF7L2 expression. Using pathway analysis, the Chloride Channel 3 (CLCN3) was identified as a potential target and further evaluated. ClC3 protein expression was first verified by immunoblotting, and then silenced by RNA interference. A 65% down-regulation in ClC3 protein expression coincided with a 27% decrease (P<0.05) in regulated secretion. Cell fractionation experiments demonstrated that ClC-3 was primarily associated with intracellular membranes. A purified insulin granules preparation was enriched in insulin by a factor of ~20 over the homogenate when normalized to protein content. Interestingly, the granule fraction also expressed significantly higher amounts of ClC-3 than the total cell homogenate, whilst not expressing markers of plasma membrane, lysosomes, SLMV, early or recycling endosomes, or mitochondria.

Conclusion: The splicing pattern of TCF7L2 affects expression of the chloride channel ClC-3, which in turn has the capacity to regulate insulin secretion. This action is likely to involve a direct action on the ion composition of the insulin granule interior.

Studies of circulating plasma levels of glucose, insulin, glucagon and incretins following a meal challenge in carriers of high and low risk *TCF7L2* genotypes

A.P. Gjesing[1], L. Kjems[2], M.A. Vestmar[1], A. Linneberg[3], C.F. Deacon[4], T. Jørgensen[3,4], J.J. Holst[4], O. Pedersen[1,5], T. Hansen[1,6];
[1]Hagedorn Research Institute and Steno Diabetes Center, Gentofte, Denmark, [2]Novaris Pharmaceuticals, Cambridge, United States, [3]Research Centre for Prevention and Health, Glostrup, Denmark, [4]Faculty of Health Science, Copenhagen, Denmark, [5]Faculty of Health Science, Aarhus, Denmark, [6]Faculty of Health Science, Odense, Denmark.

Background and aims: The rs7903146 T-allele of transcription factor 7-like 2 (*TCF7L2*) has in several populations shown association with type 2 diabetes. The biological mechanism behind this association is, however, only partly elucidated. Some studies have indicated that the effect of the *TCF7L2* T-allele might be mediated via decreased incretin secretion and/or action. We aimed to study circulating levels of glucose, proinsulin, insulin, glucagon, glucagon-like peptide-1 (GLP-1), glucagon-like peptide-2 (GLP-2) and gastric inhibitory polypeptide (GIP) among individuals carrying the high-risk rs7903146 TT-genotype and low-risk GG-genotype, respectively, following a standardised meal challenge.

Materials and methods: A meal challenge was performed in 31 glucose-tolerant men (age: 54 ± 7 years and BMI: 26 ± 3 kg/m^2) with rs7903146 TT-genotype and in 31 glucose-tolerant age- and BMI-matched men with GG-genotype (age: 53 ± 6 years and BMI: 26 ± 3 kg/m^2). Plasma levels of proinsulin, insulin, C-peptide, glucose, glucagon, GLP-1, GLP-2 and GIP were obtained 0, 15, 30, 45, 60, 75, 90, 105, 120, 135, 150, 180, 210, 240 min after ingestion of a standardised breakfast meal.

Results: Carriers of the high risk TT-genotype had a significantly lower level of fasting plasma glucose (5.44 ± 0.36 mmol/l vs 5.76 ± 0.41 mmol/l, p=0.002). In contrast, levels of plasma GIP were significantly higher among TT-genotype carriers 135 min to 180 min during the meal challenge (67.41 ± 31.20 pmol/l vs. 50.57 ± 21.04 pmol/l, p=0.03). We did not observe any differences in fasting or stimulated levels of proinsulin, insulin, GLP-1, GLP-2 or glucagon. Analyses estimating prehepatic insulin secretion rates, beta-cell responsiveness to glucose and incretin secretion are presently being performed.

Conclusion: No significant difference in post-prandial levels of glucose, insulin, proinsulin, GLP-1, GLP-2 and glucagon was observed. Surprisingly, we found a significantly lower level of fasting plasma glucose among TT-genotype carriers and higher levels of post-prandial plasma GIP.

Direct molecular phenotyping in crosses and congenic strains of the diabetic Goto-Kakizaki rat identifies novel diabetes candidate genes

M. Ria[1], M.-T. Bihoreau[1], S.P. Wilder[1], S.C. Collins[2], K. Argoud[1], P.J. Kaisaki[1], P. Rorsman[2], D. Gauguier[1];
[1]The Wellcome Trust Centre for Human Genetics, University of Oxford, [2]Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, United Kingdom.

Background and aims: Insulin resistance and altered insulin secretion are cardinal features of type 2 diabetes (T2D). The Goto-Kakizaki (GK) rat is an inbred model of spontaneous T2D extensively used to identify genetic loci causing pathophysiological components of the disease. The aim of the study is to characterise functional candidate genes for obesity and diabetes through molecular phenotype analysis derived by genome wide gene transcription profiling in panels of F2 hybrids and congenic strains of the GK and non-diabetic Brown Norway (BN) rats.

Materials and methods: Illumina BeadChips were used to determine the abundance of over 20,000 transcripts in fat biopsies of GKxBN F2 hybrids (n=138) and in liver, skeletal muscle and fat biopsies of rats of 11 BN.GK congenic strains containing GK alleles across various segments of chromosome 1 on a BN genetic background. R/qtl was used for expression quantitative trait locus (eQTL) mapping. Transcript and protein levels were further tested by qRT-PCR and Western Blotting. The biological role of variants identified in functional and positional candidate genes was tested by chemiluminescent assays in transfected cell lines. Insulin secretion tests were performed in incubated islets.

Results: Data from genome-wide gene expression of fat biopsies in the F2 cross identified 585 statistically significant eQTLs (LOD>9), mostly regulated in *cis*, that co-localise to a large extent with QTLs for diabetes/obesity related variables and ^{1}H-NMR metabonomic traits. Analysis of tissue-specific expression profiles in chromosome 1 congenic strains indicated that the vast majority of differentially expressed transcripts were found in fat and liver, with a large proportion of the latter (74%) being liver-specific. Replicated eQTLs in F2 hybrids and congenics which co-segregate with the insulin secretion QTL, include genes localised in a 2Mb congenic locus in chromosome 1 associated with altered insulin secretion in vivo and vitro. Potentially functional variants were found in differentially expressed genes at the locus, including in a glutamate transporter (*Slc1a1)* that may account for the insulin secretion QTL.

Conclusion: Combining eQTL mapping in F2 crosses and congenics provides a novel strategy to identify positional and functional candidate genes for diabetes and obesity QTLs.

Circulating HMW adiponectin isoform is heritable and shares a common genetic background with insulin resistance in non diabetic white Caucasians from Italy: evidences from a family-based study

C. Menzaghi[1], L. Salvemini[1], G. Paroni[1], C. De Bonis[1], D. Mangiacotti[1], G. Fini[1], A. Doria[2,3], R. Di Paola[1], V. Trischitta[1,4];
[1]Research Unit of Diabetes and Endocrine Diseases, IRCCS, San Giovanni Rotondo, Italy, [2]Joslin Diabetes Center, Boston, MA, United States, [3]Harvard Medical School, Boston, United States, [4]Università "Sapienza", Rome, Italy.

Background and aims: Reduced circulating adiponectin levels contribute to the etiology of insulin-resistance. Adiponectin circulates in three different isoforms: high (HMW), medium (MMW), and low (LMW) molecular weight. The genetics of adiponectin isoforms is mostly unknown.
Our aim was to investigate whether and to which extent circulating adiponectin isoforms are heritable and whether they share common genetic backgrounds with insulin resistance-related traits.
Materials and methods: In a family based sample of 640 non diabetic White Caucasians from Italy, serum adiponectin isoforms concentrations were measured by ELISA. Three SNPs in the *ADIPOQ* gene previously reported to affect total adiponectin levels (rs17300539, rs1501299 and rs677395) were genotyped. The heritability of adiponectin isoform levels was assessed by variance component analysis. A linear mixed effects model was used to test association between SNPs and adiponectin isoforms. Bivariate analyses were conducted to study genetic correlations between adiponectin isoforms levels and other insulin resistance-related traits.
Results: All isoforms were highly heritable (h^2=0.60-0.80, p=$1x10^{-13}$-$1x10^{-23}$). SNPs rs17300539, rs1501299 and rs6773957 explained a significant proportion of HMW variance (2-9%, p=$1x10^{-3}$-$1x10^{-5}$). In a multiple-SNP model, only rs17300539 and rs1501299 remained associated with HMW adiponectin (p=$3x10^{-4}$ and $2.0x10^{-2}$). Significant genetic correlations (p=$1x10^{-2}$-$1x10^{-5}$) were observed between HMW adiponectin and fasting insulin, $HOMA_{IR}$, HDL-cholesterol and the metabolic syndrome score. Only rs1501299 partly accounted for these genetic correlations.
Conclusion: Circulating levels of adiponectin isoforms are highly heritable. The genetic control of HMW adiponectin is shared in part with insulin resistance-related traits and involves, but is not limited to the *ADIPOQ* locus.

Angiopoietin-like protein 3 polymorphism is associated with dyslipidaemia in Korean type 2 diabetic patients

K. Lee, J. Chung, D. Cho, D. Chung, M. Chung;
Chonnam National University Medical School, Gwangju, Republic of Korea.

Background and aims: Patients with type 2 diabetes mellitus frequently have central obesity and several forms of dyslipidemia. Angiopoietin-like protien 3 (ANGPTL3) has metabolic effects within adipose tissue, such as inhibition of lipoprotein lipase activity and stimulation of lipolysis. These effects were convincingly demonstrated in mice. These observations may indicate that Angptl3 might regulate lipid metabolism and distribution of body fat. We hypothesized that genetic variation within the ANGPTL3 gene contributes to metabolic traits, such dyslipidemia and obesity in patients with type 2 diabetes mellitus. We therefore genotyped for the 2 single nucleotide polymorphisms (SNPs) rs17123725 (C/T) and rs12023629 (A/G) of ANGPTL3, and investigated that the polymorphism is associated with metabolic traits in type 2 diabetic patients.
Materials and methods: One hundred and thirty-six type 2 diabetic patients (M: 65, F: 71; mean age: 59.80 ± 12.23 years) and forty-one control subjects (M: 18, F: 23; mean age: 58.49 ± 12.29 years) were recruited. All subjects underwent assessment for diabetes duration, the degree of obesity, and measured fasting plasma glucose, fasting immunoreactive insulin, HbA_{1C}, fasting plasma C-peptide, fasting free fatty acid, high sensitivity C-reactive protein and lipid profiles. The polymorphisms of ANGPTL3 were genotyped by direct sequencing of the corresponding polymerase chain reaction product.
Results: The genetic frequency of rs17123725 (CT) hetero type was not significantly different between type 2 diabetic patients and control subjects (11.8% vs. 9.8%, P= 0.722). Type 2 diabetic patients with rs17123725 (C/T) polymorphism had significantly the use of HMG-CoA inhibitors and fibric acids than those with rs17123725 (TT) wild type (62.5% vs. 32.8%, P <0.05). Age, body mass index, waist circumference, HbA1C, total cholesterol level, HDL-cholesterol level, LDL-cholesterol and Triglyceride level were not different in two groups. After adjusted for the use of HMG-CoA inhibitors and fibric acids, this polymorphism was independently associated with triglyceride. We analyzed type 2 diabetic patients according to rs17123725 (CT) hetero type polymorphism, excluding the patients with the use of HMG-CoA inhibitors and fibric acids. Type 2 diabetic patients with rs17123725 (CT) hetero type polymorphism had significantly higher level of triglyceride than patients with rs17123725 (TT) wild type (208.3 ± 114.6 vs. 136.1 ± 81.3 mg/dL, P < 0.05). All the genotyping of rs12023629 of ANGPTL3 revealed rs12023629 (A/G).
Conclusion: This study suggested that the rs17123725 (C/T) polymorphism might be associated with dyslipidemia in Korean type 2 diabetic patients.

Screening of 336 single nucleotide polymorphisms (SNPs) in 85 obesity-related genes revealed that *MKKS* and *MYO9A* variants are associated with metabolic syndrome

K. Hotta[1], T. Nakamura[2], J. Wada[3], H. Masuzaki[4], T. Funahashi[5], K. Hamaguchi[6], K. Tanaka[7], K. Yamada[8], T. Hanafusa[9], S. Oikawa[10], H. Yoshimatsu[11], K. Nakao[4], N. Kamatani[2];
[1]Laboratory for Endocrinology and Metabolism, RIKEN, Kanagawa, [2]Laboratory for Statistical Analysis, RIKEN, Kanagawa, [3]Department of Medicine and Clinical Science, Okayama University Graduate School of Medicine and Dentistry, [4]Department of Medicine and Clinical Science, Kyoto University Graduate School of Medicine, [5]Department of Metabolic Medicine, Osaka University, [6]Department of Community Health and Gerontological Nursing, Oita University, [7]Institute of Health and Sport Sciences, University of Tsukuba, Ibaraki, [8]Division of Endocrinology and Metabolism, Kurume University, Fukuoka, [9]First Department of Internal Medicine, Osaka Medical College, [10]Division of Endocrinology and Metabolism, Nippon Medical School, Tokyo, [11]Department of Anatomy, Biology and Medicine, Oita University, Japan.

Background and aims: Genetic factors are important in the development of metabolic syndrome. However, the genetic background of metabolic syndrome remains unclear. We screened single nucleotide polymorphisms (SNPs) in 85 obesity-related genes to determine which may be associated with metabolic syndrome.
Materials and methods: Patients with metabolic syndrome (n=1080) and control individuals without metabolic syndrome (control-1; n=1524) were recruited for this study. Control-2 (n=528) was selected from control-1 who had no risk of the metabolic syndrome. A total of 336 SNPs in 85 genes selected from the JSNP database were genotyped. Discriminant scores were estimated by linear discriminant analysis using age, gender, BMI, fasting plasma glucose, triglycerides, HDL cholesterol, systolic and diastolic blood pressure, and treatments of diabetes, dyslipidemia, and hypertension as variables. The differences in discriminant scores between two genotype groups (either dominant or recessive model) were analyzed by the Mann-Whitney U test using case and control-1. We conducted case-control association analyses using case and control-2.
Results: Three SNPs in the *MKKS* gene were significantly related to metabolic syndrome by case-control association study using case and control-2; rs1545 (odds ratio [OR] adjusted for age and gender, 1.45; 95% confidence interval [CI], 1.21-1.74; *P*=0.000043 [additive model]); rs1547 (OR, 1.45; 95% CI, 1.21-1.74; *P*=0.000041); and rs2294901 (OR, 1.46; 95% CI, 1.22-1.75; *P*=0.000033). We selected five tag SNPs (rs2294901, rs221667, rs6133922, rs6077785 and rs6108572). They were in one linkage disequilibrium (LD) block and rs6133922 (*P*=0.00042), rs6108572 (*P*=0.000013), and rs6077785 (*P*=0.000019) were significantly associated with metabolic syndrome. The discriminant score for the AA homozygotes at SNP (rs2306576) in *MYO9A* gene was significantly higher than those for the AG heterozygotes and the GG homozygotes (*P*=0.000077).
Conclusion: Genetic variations in the *MKKS* and *MYO9A* genes may influence the risk of metabolic syndrome.

Genetic variants across regulatory pathways of lipid and glucose metabolism: interaction effects with BMI on glucose levels

C.M. Povel[1,2], E.J.M. Feskens[1], S. Imholz[2], C. Wijmenga[3], M.E.T. Dolle[2], J.M.A. Boer[2];
[1]Division of Human Nutrition, Wageningen University, [2]National Institute for Public Health and the Environment (RIVM), Bilthoven, [3]Deparment of Biomedical Genetics, University Medical Centre Utrecht, Netherlands.

Background and aims: Much of the genetic variation in glucose levels remains to be discovered. Especially, research on gene-environment interactions is scarce. Overweight is the main environmental risk factor for hyperglycemia. Transcriptional regulation is important for both weight maintenance and glucose control. We therefore analyzed 349 single nucleotide polymorphisms (SNP's), occurring in transcriptional pathways of glucose and lipid metabolism, and their interaction effects with body mass index (BMI) on glucose levels.
Materials and methods: 349 SNP's were measured in 3244 participants of the Doetichem cohort. Non-fasting glucose levels and BMI were measured at baseline and after 6 years. SNP x BMI interactions were analyzed by mixed models and adjusted for age, sex and time since last meal. False Discovery Ratio (FDR) < 0.2, was used to adjust for multiple testing.
Results: Two SNP's, rs8192678 (P-value = 0.0002; FDR=0.07) and rs3755863 (P=0.0012; FDR=0.17), showed a significant interaction with BMI. These SNP's are both located in the PPARGC1A gene. In subjects with a BMI <=25 kg/m^2, rs8192678 (P=0.02) and rs3755863 (P=0.03) were significantly associated with glucose levels. No effect was observed in subjects with BMI >25 kg/m^2.
Conclusion: Using a pathway based approach, we found a significant association between the PPARGC1A (rs8192678; rs3755863) x BMI interaction and glucose levels. The association between glucose and PPARGC1A was only present in lean subjects.This suggests that the effect of the PPARGC1A gene, which is involved both in fatty acid oxidation and glucose metabolism, is modified by BMI.

339

The association of FTO gene haplotypes with OGTT stimulated metabolic parameters in lean women

P. Lukasova, J. Vcelak, M. Vankova, H. Kvasnickova, J. Vrbikova, B. Bendlova;
Laboratory of Molecular Endocrinology, Institute of Endocrinology, Prague, Czech Republic.

Background and aims: Several single nucleotide polymorphisms (SNPs) in the fat mass and obesity associated gene (*FTO*) are related to the susceptibility to diabetes mellitus type 2 (DM2) through an influence on obesity that plays an important role also in the pathogenesis of polycystic ovary syndrome (PCOS). Nevertheless, the mechanism by which the FTO influences obesity related traits is still unknown. The aim of our study is to compare the *FTO* gene haplotypes frequencies in the groups of patients with PCOS and healthy controls without family history of DM2 and PCOS; and to evaluate the associations of the haplotypes with detailed anthropometric data, parametres of glucose and lipid metabolism, selected hormones and adipokines.
Materials and methods: The SNPs: rs1421085 (T/C); rs1121980 (G/A); rs17817449 (T/G) and rs9939609 (T/A) in the *FTO* gene were assesed by ABI TaqMan SNP Genotyping Assays; haplotypes were generated using programme PHASE. Study cohorts: 294 patients with PCOS defined according to ESHRE consensus (age 27.7±6.36 years; BMI 26.8±6.55 kg/m^2) and 234 healthy women (age 29.8±10.67 years; BMI 23.4±4.41 kg/m^2) were biochemically (29 parameters) and anthropometrically (measurements were evaluated using programme Antropo) carrefully characterized including 3h OGTT and derived indices. For statistical evaluation (Chi-square test, Mann-Whitney test, ANOVA), NCSS 2004 software was used.
Results: Two major haplotypes TGTT; CAGA (covering more than 92 % of all possible combinations) did not differ in frequency distributions between groups. The association of the carriership of the risk haplotype CAGA with BMI was stronger in PCOS patients (p=0.003) than in controls (p=0.018). In the PCOS group the frequency of the minor haplotype CAGA significantly increased from the normal weight via the overweight to obese patients (p=0.008). To evaluate the influence of CAGA risk haplotype on metabolic parameters, we focused on lean subjects (BMI < 25 kg/m^2). After pooling of lean PCOS and control women, significantly increased late phase OGTT stimulated levels of glucose (120min p=0.014; 150min p=0.021), C-peptide (120min p=0.031; 150min p=0.005; 180min p=0.022) and insulin (150min p=0.027; 180min p=0.007) were detected in CAGA carriers vs. non-carriers. The lean CAGA carriers had decreased several disposition indices (beta-cell function x insulin sensitivity) (p=0.011 - p=0.043) and also significantly higher levels of fasting and OGTT stimulated growth hormone (0min p=0.020; 60min p=0.001).
Conclusion: Our study suggests that FTO influences not only BMI and obesity related traits but in lean persons it could also affect metabolic parameters such as OGTT stimulated glucose, insulin, C-peptide and surprisingly growth hormone levels.

Impact of variation near MC4R on whole body fat distribution, liver fat and weight loss

A. Haupt[1], C. Thamer[1], M. Heni[1], F. Machicao[1], H. Staiger[1], F. Schick[2], J. Machann[2], N. Stefan[1], H.-U. Häring[1], A. Fritsche[1];
[1]Department of Internal Medicine, Division of Endocrinology, Diabetology, Angiology, Nephrology, [2]Section on Experimental Radiology, Department of Diagnostic Radiology, Eberhard-Karls-University, Tübingen, Germany.

Background and aims: Polymorphisms near the melanocortin-4 receptor (MC4R) gene locus are associated with body weight. Recent studies have shown that they influence insulin sensitivity and incidence of the metabolic syndrome. Thus, we hypothesized that the candidate SNP rs17782313 near MC4R additionally influences body fat distribution and its change during lifestyle intervention.
Materials and methods: To test this, 343 subjects were genotyped for SNP rs17782313, T/C. Body composition was assessed using magnetic resonance technique. Subjects were characterized by an oral glucose tolerance test. 242 subjects participated in a 9 month lifestyle intervention.
Results: The C allele was associated with a higher BMI (p=0.0013), but had no impact on glucose tolerance or insulin sensitivity (all p>0.10). There was an effect of the SNP on total fat (p=0.022) and non-visceral fat (p=0.017), but not on liver fat and visceral fat (all p>0.33). During lifestyle intervention, SNP rs17782313 has no impact on changes in body weight or fat distribution.
Conclusion: Despite an association with BMI and non visceral adipose tissue, the SNP rs17782313 did not influence visceral adipose tissue. Thus, this candidate SNP for human obesity may preferentially affect the accumulation of subcutaneous adipose tissue. Furthermore, the variation near MC4R has no effect on success of weight loss during lifestyle intervention.

Insulin-stimulated glucose uptake in subcutaneous fat and liver in patients with the mitochondrial m.3243A>G mutation

M.M. Lindroos[1], R. Borra[1], K.A. Virtanen[1], V. Lepomäki[1], P. Iozzo[1,2], K. Majamaa[3], P. Nuutila[1];
[1]Turku PET Centre, University of Turku and Turku University Hospital, Finland, [2]PET Centre, National Research Council, Pisa, Italy, [3]Department of Neurology, University of Oulu, Finland.

Background and aims: Insulin resistance in adipose tissue and excess liver fat have been associated with mitochondrial dysfunction in metabolic syndrome and lipodystrophy. The aim of this study was to assess the effect of mitochondrial DNA point mutation m.3243A>G, the most common cause of mitochondrial diabetes, on adipose tissue and liver metabolism.
Materials and methods: Fifteen patients with m.3243A>G, eight with no glucose lowering medication (group 1) and seven patients with diabetes (group 2) were studied. In addition, 12 patients with metabolic syndrome and no glucose lowering medication and 20 healthy controls were examined. Regional glucose uptake was measured using positron emission tomography and 2- [^{18}F] fluoro-2-deoxyglucose during euglycemic hyperinsulinemia. Liver fat was assessed with proton magnetic resonance spectroscopy.
Results: Glucose uptake in subcutaneous fat was lower and free fatty acid levels were higher during hyperinsulinemia in groups 1 and 2 and in patients with metabolic syndrome as compared to the controls. (5 ± 1 and 6 ± 1 and 6 ± 1 vs 12 ± 1; μmol•min^{-1}•kg^{-1} and 0.09 ± 0.02, 0.16 ± 0.03, 0.12 ± 0.02 vs 0.05 ± 0.01; mmol•l^{-1}, Mean ± SE). Insulin-stimulated glucose uptake in the liver in groups 1 and 2 and in patients with metabolic syndrome did not signifi-

cantly differ from that in the controls (22 ± 3 and 17 ± 2 and 14 ± 1 vs 18 ± 1; μmol•min^{-1}•kg^{-1}). Liver fat content was not significantly elevated in groups 1 and 2 but was significantly higher in patients with the metabolic syndrome as compared to controls (4.7 ± 3 and 2.5 ± 1 and 8.5 ± 2 vs 1.2 ± 1; %).
Conclusion: Our results suggest that the patients with the m.3243A>G mutation are insulin resistant in adipose tissue with no concurrent metabolic changes in liver.

DPP-IV inhibitors are efficient adjunct therapy in HNF-1α MODY patients
B. Katra[1], T. Klupa[1], J. Skupien[1], S. Gorczynska-Kosiorz[2], K. Wanic[1], M. Szopa[1], M. Borowiec[3], E. Kozek[1], M.T. Malecki[1];
[1]Department of Metabolic Diseases, Jagiellonian University, Krakow, [2]Department of Internal Medicine, Diabetology and Nephrology, Medical University of Silesia, Zabrze, [3]Department of Pediatrics, Medical University of Lodz, Poland.

Background and aims: The pharmacogenetic effect of marked sulphonylurea (SU) sensitivity in HNF-1α MODY has been well documented and, as such, SU remains the first line therapy in the treatment of MODY3 patients. Over time, however, this treatment becomes insufficient in a substantial number of these subjects. Dipeptidyl-peptidase (DPP)-IV inhibitors are a new class of therapeutic agents that enhance insulin secretion, a major pathophysiological defect in HNF-1α MODY. For the first time, we report two patients with HNF-1α gene mutations who failed to respond to SU monotherapy but showed marked response to DPP-IV inhibitors.
Aim of the study: To assess the efficacy of DPP-IV inhibitors in HNF-1α MODY patients who failed to respond to SU monotherapy and safety.
Materials and results: Case 1- a 39 years old female patient with a ArgR171X HNF-1α mutation and a 7 year history of diabetes treated with 80 mg of gliclazide and 1000 mg of metformin. At entry into the study, her initial HbA1c and mean glucose levels on Continuous Glucose Monitoring System (CGMS) were 7.2% and 162 mg/dL, respectively. Sitagliptine, a DPP-IV inhibitor, at a dose of 100 mg/day was added to the patient's previous treatment regimen. Case 2- a 62 years old female patient with a IVS7nt-6G>A mutation and a 41 year history of diabetes treated with 240 mg/day of gliclazide and 6 IU of insulin/day. Her initial HbA1c was 8.8%, and her average glycemia on CGMS record reached 172 mg/dL. In addition to her previous regimen, we began combined therapy that included 50 mg of the DPP-IV inhibitor vildagliptine twice daily. At the re-examination 3 months after the initiation of DPP-IV therapy, HbA1c levels of both patients had fallen to 6.3%. Similarly, significant improvement in glycemic control on CGMS was observed as the average glycemia decreased to 114 mg/dL and 134 mg/dL in Case 1 and Case 2, respectively. No episodes of hypoglycemia below 60 mg/dL were recorded and no other side effects were reported during the 3-month treatment period. Importantly, we saw a substantial rise in insulin level increments during Intravenous Glucose Tolerance Tests performed at the beginning and at the end of the observation in both patients (by 9.8 and by 13.4 μIU/ml in Case 1 and Case 2, respectively).
Conclusion: In summary, DPP-IV inhibitors seem to be an effective and safe component of combined therapy in HNF-1α MODY patients. We postulate that a future randomized controlled trial should determine their efficacy as an alternative to SU monotherapy in this monogenic diabetes.

Serum cystatin C level in diabetic HNF-1α gene mutation carriers
N. Nowak[1], J. Skupien[1], S. Gorczynska-Kosiorz[2], K. Wanic[1], T. Klupa[1], M. Szopa[1], M. Borowiec[3], E. Kozek[1], M.T. Malecki[1];
[1]Department of Metabolic Diseases, Jagiellonian University, Medical College, Krakow, [2]Department of Interal Medicine, Silesian School of Medicine, Zabrze, [3]Department of Paediatrics, Lodz Medical University, Poland.

Background and aims: Cystatin C is a low molecular weight protein produced at a constant rate in all nucleated cells. It is freely filtered in the renal glomeruli, reabsorbed and catabolised in the proximal tubules. Cystatin C was shown to be an excellent marker of glomelular filtration rate (GFR) in various group of patients, including diabetic subjects. The hepatocyte nuclear factor (HNF-1α) gene mutations cause one of subtypes of MODY. The phenotype is not only an early-onset diabetes, but also renal tubulopathy and impaired synthesis of certain proteins. Our aim was to measure cystatin C serum level in diabetic HNF-1α gene mutation carriers and investigate whether it is altered in this monogenic form of diabetes, in order to evaluate its clinical applicability as a GFR marker.

Materials and methods: We examined 25 HNF-1α MODY patients (mean age at examination 33.6 yrs, mean diabetes duration 8.7 years) and 98 individuals with type 1 diabetes (T1DM) (33.9 yrs and 14.2 yrs, respectively). In all study individuals serum cystatin C level was measured by immunonephelometric method.
Results: The mean cystatin C level was 0.77±0.22 mg/L in HNF-1α MODY and 0.87±0.22 in T1DM, while mean serum creatinine level was 73.0±21.1 umol/L and 68.2±20.1 umol/L, respectively. After adjusting for sex, age, diabetes duration, BMI and HbA1c in linear regression model, there was no significant difference in creatinine levels between the groups, while cystatin C serum concentration was 0.11 mg/L higher in T1DM cohort (p=0.013). We estimated patients' GFR with creatinine-based methods (Cockroft Gault, MDRD and Jelliffe formulas) and cystatin C-based methods (Tan, MacIsaac and Stevens equations). Across all used approaches, there was a consistent, about 15-20 ml/min/1.73m^2 greater difference between creatinine based and cystatin C based GFR estimates in MODY cohort compared to T1DM.
Conclusion: In summary, we present some evidence that cystatin C serum level in HNF-1α MODY might be altered by factors associated with the mutations in this transcription factor. This fact may limit its clinical applicability as a GFR marker in the examined monogenic form of diabetes.

A novel compound heterozygote mutation of transferrin receptor 2 gene exhibits severe diabetes in a Japanese patient with haemochromatosis
K.-I. Tsuchida[1], K. Misawa[1], S. Taneda[1], M. Kawanaka[2], G. Yamada[2], H. Kawabata[3], N. Tomosugi[4], Y. Tatsumi[5], A. Hattori[5], H. Hayashi[5], H. Nakayama[1], N. Manda[1];
[1]Internal Medicine, Manda Memorial Hospital, Sapporo, [2]Kawasaki Hospital, Kawasaki Medical School, Okayama, [3]Graduate School of Medicine, Kyoto University, [4]Medical Research Institute, Kanazawa Medical Institute, Uchinada, [5]Department of Medicine, Aichi Gakuin University School of Pharmacy, Nagoya, Japan.

Hereditary hemochromatosis (HH) is a group of disorders characterized by progressive iron overload, which may lead to severe clinical pathological conditions including diabetes and liver cirrhosis. Here we report a novel compound heterozygote mutation in transferrin receptor 2 (TFR2) gene in a Japanese patient with HH who exhibits severe diabetes, liver fibrosis and pituitary hypogonadism. DNA was extracted from whole blood sample with informed consent. The coding regions and splicing sites of the HFE, TFR2, HJV and HAMP genes were analyzed by direct sequencing of PCR-amplified genomic DNA. In the TFR2 gene, a novel compound heterozygote mutation, 1100T>G (L367R) and 2008-9ACdel, were found in this patient with hemochromatosis at the age of 40 years. Abdominal computed tomography showed very high liver density and severely atrophic pancreas. Serum ferritin was 10191 ng/ml, and transferrin saturation rate was 94.2 % and serum hepcidin was 0.6 ng/ml which was extremely suppressed despite of remarkable iron overloading. Liver biopsy showed mild hepatic fibrosis with sever and diffuse iron deposition in both Kupfer cells and hepatocytes. His insulin secretion was severely impaired, requiring treatement with daily fifth insulin injections (44U/day). We previously reported 6 TfR-2 related Japanese HH cases from 4 families for (a homozygous AVAQ 594-597 deletion, L490R and A364T missense mutations, and V561X nonsense mutation in the TFR2 gene). Among 7 TfR2-related cases including the current case, all had liver diseases and 4 had diabetes. Clinical manifestations of these TfR2-HH cases varied widely from almost no symptoms to very severe pathological conditions. HH is thought to be rare in Orientals including Japanese because of the low prevalence of the C282Y mutation of the HFE gene in Asians. However, the current case and our previous results suggest that the TFR2 mutations may not be very rare in hemochromatosis in Japan. Further study is required to elucidate the frequency of TFR2-related HH in patients with diabetes and liver dysfunction in Japan.

Increased transferrin saturation and C282Y/C282Y genotype predict diabetes mellitus in two general population cohorts and a case-control study
C. Ellervik[1], T. Mandrup-Poulsen[2,3], H.U. Andersen[2], A. Tybjærg-Hansen[4], M. Frandsen[2], H. Birgens[5], B.G. Nordestgaard[6];
[1]Department of Clinical Biochemistry, Copenhagen University Hospital, Næstved, [2]Steno Diabetes Center and Hagedorn Research Institute, Gentofte, [3]Center for Medical Research Methodology, Copenhagen, [4]Department of Clinical Biochemistry, Copenhagen University Hospital, [5]Department of Hematology, Herlev University Hospital, [6]Department of Clinical Biochemistry, Herlev University Hospital, Denmark.

Background: Diabetes mellitus is a common late complication to hereditary hemochromatosis. Previous studies of the predictive value of transferrin saturation or hemochromatosis genotypes for diabetes mellitus are hampered by the weaknesses of cross-sectional or case-control study designs in limited study populations. In this study, we investigated for the first time the predictive value of increased transferrin saturation or C282Y/C282Y genotype in a large study of populations of inhabitants from larger Copenhagen by comparing hazard ratios for developing diabetes in the general population with odds ratios for diagnosed diabetes obtained from both a cross-sectional population and a case-control design.
Methods: We examined 9726 individuals from the Copenhagen City Heart Study, 30,000 individuals from the Copenhagen General Population Study, and 6120 patients with either type 1 or type 2 diabetes mellitus representing three study designs: a prospective study with 15 years of follow-up, a case-control study, and a cross-sectional study.
Results: Increasing levels of transferrin saturation above 50% were associated with increased risk of diabetes (p-trend=0.002). In the prospective study, transferrin saturation above 60% was associated with diabetes with a hazard ratio of 2.1(1.1-3.9). In the cross-sectional and case-control studies, odds ratios were 2.0(1.0-3.8) and 2.9(2.0-4.2), respectively. For women, the corresponding risks were 3.7(1.2-11), 4.0(1.1-14), and 4.1(1.8-8.9). The hazard ratio for developing need of any anti-diabetic medication in C282Y/C282Y individuals was overall 2.2(1.0-4.6) and in women 2.9(1.1-2.7); stratification by insulin and oral anti-diabetic medication revealed similar results in women. Kaplan-Meier curves for women indicated that the risks of diabetes mellitus in individuals with transferrin saturation above 60% or need of anti-diabetic medication in the C282Y/C282Y genotype were greater in postmenopausal women. Apart from the case-control study, risks conferred by iron overload or genotype in men were not significantly increased.
Conclusion: Transferrin saturation above 60% and C282Y/C282Y genotype predict diabetes mellitus overall and in women; the greater risk in postmenopausal women is explained in part by cessation of menstrual blood loss and estrogen deficiency promoting reactive oxygen species formation to which pancreatic beta-cells are particularly susceptible.

The G-75A polymorphism of the Apolipoprotein A1 gene influences the effect of statin therapy on HDL-cholesterol levels in South Asian patients with type 2 diabetes
A.N. Dixon[1], S.D. Rees[1], A.C. Britten[1], S. Kumar[2], J.P. O'Hare[2], A.H. Barnett[1], M.A. Kelly[1];
[1]Division of Medical Sciences, University of Birmingham, [2]Warwick Medical School, United Kingdom.

Background and aims: Background: Apolipoprotein A1 (*ApoA1*) is the main structural lipoprotein of the HDL-cholesterol (HDL-C) particle and as such plays an important role in the regulation of reverse cholesterol transport. Several polymorphisms of the *ApoA1* gene have been identified and the G-75A polymorphism has been associated with higher HDL-C levels and in some studies with a greater increase in HDL-C with statin treatment. The effect of the G-75A polymorphism on HDL-C and the influence of statin therapy on HDL-C levels in South Asian individuals with type 2 diabetes, however, have not previously been investigated. The aims of this study were firstly to determine the effect of the G-75A polymorphism on HDL-C levels prior to statin treatment and secondly to examine the effect of statin treatment on HDL-C according to *ApoA1* genotype.
Materials and methods: This was a retrospective study of ethnically distinct Punjabi patients with type 2 diabetes who had been recruited to the UK Asian Diabetes Study. Data from 180 patients (81 men, 99 women) was investigated.

All patients were statin-niave and were commenced on either atorvastatin or pravastatin. Follow-up data was collected after 2-years. Genotyping was performed by restriction fragment length polymorphism.
Results: Three was no significant difference in baseline HDL-C levels between individuals with the -75A allele compared to those homozygous for the -75G allele (1.24+/-0.29 vs. 1.18+/-0.26mmol/l, p=NS). For those patients with the -75A allele there was no significant change in HDL-C with statin therapy (1.24+/-0.29 vs. 1.22+/-0.32mmol/l, p=NS), whereas there was a significant increase in HDL-C in individuals homozygous for the -75G allele (1.18+/-0.26 vs. 1.30+/-0.29mmol/l, p<0.0005).
Conclusion: This study has demonstrated that the G-75A polymorphism of the ApoA1 gene influences the effect of statins on HDL-C levels in South Asian patients with type 2 diabetes. Whether the greater increase in HDL-C levels with statin treatment for individuals homozygous for the -75G allele results in a greater reduced risk of cardiovascular disease requires further investigation.

Efficacy and safety of sulphonylurea use in permanent neonatal diabetes due to KCNJ11 gene mutations - minimum 2-year follow-up

M.T. Malecki[1], T. Klupa[1], J. Skupien[1], B. Mirkiewicz-Sieradzka[1], A. Gach[2], A. Noczynska[3], M. Szalecki[4], E. Kozek[1], J. Nazim[5], W. Mlynarski[2], J. Sieradzki[1];
[1]Department of Metabolic Diseases, Jagiellonian University, Medical College, Krakow, [2]Department of Paediatrics, Lodz Medical University, [3]Department of Endocrinology and Diabetology for Children and Adolescents, Wroclaw Medical University, [4]Regional Diabetes Outpatient Clinic, Kielce, [5]Department of Paediatric Endocrinology, Jagiellonian University, Medical College, Krakow, Poland.

Background and aims: The most frequent causes of permanent neonatal diabetes mellitus (PNDM) are mutations in the KCNJ11 gene encoding the Kir6.2 subunits of the beta-cell K-ATP channel. Recently, many patients with Kir6.2-related PNDM have been successfully transferred from insulin therapy to sulphonylurea (SU) treatment, resulting in an immediate improvement in glycemic control. The long-term impact of SU treatment in PNDM patients, however, has not been determined. We aimed to investigate efficacy and safety of SU treatment in patients with PNDM due to KCNJ11 gene mutations that were on SU over a period of minimum 2 years.
Materials and methods: We monitored glycemic control and the occurrence of potential side effects in 14 Kir6.2-related PNDM patients from Poland (mean age 14.0 years, range 5-50) that carried various KCNJ11 mutations and that were on SU over the period of at least 2 years.
Results: The average HbA1c level prior to the switch from insulin to SU was 7.69% (range 6.3-10.2). A rapid improvement in glycemic control was achieved, as the mean reduction of HbA1c levels during the first visit following the transfer to SU (approximately 3-6 months post-transfer) was 1.68%. This level of glycemic control was maintained over the entire period of observation (median 34 months, range 27-51) with an average HbA1c level of 6.0% (range 5.3-6.7%) at the last visit. Three of the 14 patients were lost to follow-up: one was not available for examination, while SU treatment was discontinued in two others as a result of a diagnosis of hepatitis C and for socioeconomic reasons, respectively. Of the 11 patients observed over the entire follow-up period, a rapid progression of retinal changes was observed in one patient, a 34 years old woman, with pre-existing proliferative diabetic retinopathy. No causal relationship between these changes and SU treatment could be proven. In all the others patients, no side effects were observed.
Conclusion: In summary, the switch from insulin therapy to SU treatment in PNDM related to KCNJ11 mutations was found to be an efficient therapeutic method over a period of at least 2 years. Although no side effects were associated with SU treatment, its role in the development of chronic disease complications requires further attention.

The comparative metabolomics of the experimental rat and diabetic patient urinary composition

M. Dambrova[1], I. Konrade[2], A. Jankevics[1], E. Skapare[2], O. Pugovics[1], E. Liepinsh[1];
[1]Latvian Institute of Organic Synthesis, [2]Riga Stradins University, Riga, Latvia.

Background and aims: Metabolomics has developed to an accepted and valuable diagnostic tool to distinguish healthy and diseased state individuals. The comparative metabolomics of the diabetic experimental animal and patient samples is important for translational research and early diagnosis of Type 2 diabetes mellitus (DM). Among commonly used experimental models of diabetes, Zucker (fa/fa) rats represent obesity related disease state, whereas Goto-Kakizaki (G-K) rats are characterized by impaired glucose tolerance. The aim of the study was to develop appropriate methodology for metabolomic studies of urine samples taken from healthy and diabetic individuals.
Materials and methods: In present study, we used metabolomic analysis strategy based on nuclearmagnetic resonance (NMR) method to compare metabolite profiles of urine samples excreted by male G-K and Zucker (fa/fa) rats with those of age matched Wistar rats, as well as Type 2 DM patients and healthy individuals. Animals (male rats, 12 weeks at the beginning of experiment): 30 G-K and 10 Wistar rats; 40 Zucker (fa/fa) and 10 Wistar rats. Samples: Averaged daily urine samples were collected at the age of 12,14,16 and 20 weeks. Patients: 43 randomly selected human urine samples of Type 2 DM patients, and 20 samples of healthy volunteers. Chenomx NMR software was used for data processing and metabolite identification. Principal Components Analysis (PCA) and Partial Least Squares Discriminant Analysis (PLS-DA) analyses were carried out by pls and caret packages within statistical language R using in-house routines. PLS-DA models were evaluated using bootstrap resampling and cross model validation methods.
Results: PLS-DA models showed good classification accuracy between Wistar - G-K and Wistar -Zucker (fa\fa) animal strains (accuracy > 0.90). Eligible classification accuracy was obtained also by evaluation PLS-DA models of human urine samples (accuracy > 0.75). The metabolomic signatures of analyzed urine samples from Type 2 DM showed metabolite patterns different from those of healthy individuals both in experimental animal and patient samples. The metabolite profile included changed levels of creatine, citrate, hippurate, phenylalanine and some unidentified metabolites in the urine samples of G-K rats compared to Wistar rats, as well as Zucker (fa/fa) compared to Wistar rats and in the urine samples of Type 2 DM patients compared to healthy volunteers. Increased concentrations of glucose, niacinamide and trigonelline were observed in Zucker (fa/fa) and clinical samples, but not in G-K rat samples. Changes in formate and lactate concentrations were observed in G-K animal samples, but not in Zucker (fa/fa) and Type 2 DM patient samples.
Conclusion: The metabolomic studies of urine samples from diabetic individuals provide further insights concerning experimental methodologies for data generation and processing, as well as possible markers for diabetes research. Even though several components of metabolic profiles in Zucker (fa/fa), G-K rats and Type 2 DM patient samples are similar, our results give evidence that both models of experimental diabetes and clinical samples are clearly different in respect to metabolomic studies, which might be useful for evaluation of drug effects and understanding of metabolic syndrome and diabetes related metabolic pattern fingerprints.

Detection of plasma amino acids and metabolites by mass spectrometry and magnetic resonance spectroscopy: effects of insulin deprivation in type 1 diabetes

I.R. Lanza[1], L.E. Ward[1], S. Zhang[2], H. Karakelides[1], D. Raftery[2], K. Nair[1];
[1]Division of Endocrinology, Mayo Clinic, Rochester, [2]Department of Chemistry, Purdue University, West Lafayette, United States.

Background and aims: Nuclear magnetic resonance spectroscopy (NMR) and mass spectrometry (MS) provide a wealth of distinct and complementary information from biological specimens that can help understand how biochemical pathways that are altered in by insulin deficiency. We used both of these analytical tools to determine the impact of insulin deficiency on plasma metabolic profiles during insulin deprivation and insulin treatment in type 1 diabetic participants.

Materials and methods: Type 1 diabetic individuals (N=7) were studied during insulin treatment (glucose=5.3±0.1 mM) and following 8 hours insulin deprivation (16.7±0.7mM) and compared with non-diabetic controls. Plasma samples were analyzed by ^{1}H NMR and by liquid chromatography tandem mass spectrometry following derivatization with Waters Masstrak AAA solution.
Results: Plasma glucose, acetone, acetoacetate and beta-hydroxybutyrate (by NMR) and branched chain amino acids (by MS) were elevated (P<0.05) during insulin deprivation as expected. In contrast, the plasma concentrations of gluconeogenic amino acids (by MS) were lower or unchanged during insulin deprivation. Many amino acid metabolites such as alpha-amino-N-butyric acid, alpha-aminoadipoic acid, beta-amino butyric acid and cystathionine were elevated (P<0.05) during insulin deprivation. Plasma lactate, acetate and citrate (citric acid cycle) and allantoin (index of oxidative stress) (by NMR) were all elevated (<0.05) during insulin deprivation. Five amino acids (valine, isoleucine, alanine, tyrosine, and histidine) were measured by both methods and demonstrated similar absolute micromolar concentrations and effects of insulin deprivation. All changes in metabolic pathways were normalized by insulin treatment in comparison with non-diabetic participants.
Conclusion: The concentrations of five amino acids were similar when measured by both MS and NMR, underscoring the sensitivity and accuracy of both analytical techniques for these compounds. The MS-based approach for measuring plasma amino acids and its metabolites revealed not only an expected increase in branched chain amino acids during insulin deprivation but also an increase in concentrations of many individual amino acid metabolites, indicating insulin's specific effects on amiDetectionno acid metabolism. The observed decrease in many gluconeogenic amino acids is consistent with enhanced gluconeogenesis during insulin deprivation. Furthermore, NMR analyses revealed a unique metabolic fingerprint of insulin deprivation in diabetes, evidenced by significantly (P<0.05) elevated tricarboxylic acid cycle intermediates. It is likely that plasma citrate levels are elevated as a result of a downstream limitation in the tricarboxylic acid cycle or mitochondrial electron transport. These results support that insulin deficiency causes muscle mitochondrial dysfunction, and accumulation of citrate may have increased the acetyl CoA/CoA ratio, resulting in less acetylation of acetate and increased conversion of pyruvate to lactate. Very high allantoin in plasma is indicative of high oxidative stress during insulin deficiency. These results demonstrate the potential of MS and NMR analyses of plasma as a powerful tool to map altered metabolic pathways in diabetes and related metabolic disorders.

The genetic association between *HK1* and increased HbA_{1c} but not other glycaemic control related traits reveals the link between anaemia and HbA_{1c}

A. Bonnefond[1], M. Vaxillaire[1], N. Bouatia-Naji[1], B. Balkau[2], M. Marre[3], J. Tichet[4], M.-R. Jarvelin[5], C. Lévy-Marchal[6], F. Horber[7,8], S. Hadjadj[9], J.-P. Riveline[10], G. Charpentier[10], R. Sladek[11], D. Meyre[1], P. Froguel[1,5]; [1]Genomics and Molecular Physiology of Metabolic Diseases, CNRS UMR8090, Lille Cedex, France, [2]Inserm-U780, Villejuif, France, [3]Inserm-U695, Paris, France, [4]IRSA, La Riche, France, [5]Imperial College London, United Kingdom, [6]Inserm-U690, Paris, France, [7]Klinik Lindberg, Berne, Switzerland, [8]Winterthur and University Berne, Switzerland, [9]Inserm-U927, Poitiers, France, [10]Corbeil-Essonnes Hospital, France, [11]McGill University Montreal, Canada.

Background and aims: Recently, a genome-wide association study reported an association between glycated hemoglobin (HbA1c) and rs7072268 within *Hexokinase1* (*HK1*). HK1 is ubiquitously expressed and contributes to catalyse the first step in the glycolytic pathway. Deficiency of HK1 in red blood cells (RBC) causes severe nonspherocytic hemolytic anemia in both humans and mice. Here we studied the contribution of rs7072268 to HbA1c, glucose homeostasis and type 2 diabetes (T2D) in several prospective European cohorts (overall ~14,000 individuals). In addition, we assessed the impact of rs7072268 on two RBC-related (hemoglobin and hematocrit).
Materials and methods: The impact of rs7072268 on HbA1c and the hematologic traits was first assessed in 4,663 non diabetic middle-aged French adults from the DESIR cohort and in 2,474 non diabetic obese Swiss adults. Other glucose homeostasis related phenotypes were studied in DESIR as well as in 5,346 individuals from the Northern Finland Birth cohort at 16 years of age; in 1,473 young French adults from the Haguenau study; and in 2,475 additional non diabetic French subjects. A T2D case-control study included 7,572 T2D French individuals and 5,562 controls. All genotyping was performed using a TaqMan assay.
Results: The rs7072268-T allele strongly associates with increased HbA1c (under an additive model, ß = $0.031\%_{HbA1c}$, overall p = $3.06x10^{-6}$). Paradoxically, we found no significant association with any other marker of glucose control (fasting glucose, 2h-post OGTT glucose levels, fructosamine levels). In contrast, the rs7072268-T allele decreases both hematocrit and hemoglobin levels (ß = $-0.166\%_{Hematocrit}$, p = $8.57x10^{-4}$ and ß = -0.056g/dl, p = $8.81x10^{-4}$, respectively). The T2D case-control analysis displayed no evidence for association after correction for multiple testing. However, a modest association was found with early-onset T2D only (under the best model [recessive], OR = $1.21\ [1.15\text{-}1.27]_{95\%CI}$, p = $1.70x10^{-3}$), and the rs7072268 genotype distribution was statistically different between early and late-onset diabetics (p = $5.20x10^{-3}$). In contrast, the rs7072268-T allele improves insulin sensitivity (Homa-IR) with no significant effect on insulin secretion Homa-B index after correction for multiple testing.
Conclusion: The *HK1* rs7072268-T allele strongly associates with increased HbA1c in European populations. Surprisingly, despite adequate study power, rs7072268 is not associated with other markers of glucose control. An explanation of this paradox may be its deleterious effect on RBC-related hemoglobin and hematocrit. HK1 may impair the relationship between serum glucose levels and HbA1c through its anaemic effect, which may have clinical implications for T2D diagnosis and management. The putative association with early-onset T2D is under investigation in large sample sets.

PS 12 Cytokines and ER stress in beta cells

Analysis of compartiment-specific caspase activation and oxidative damage through proinflammatory cytokines in insulin-producing cells

I. Mehmeti, S. Lortz, S. Lenzen;
Institute of Clinical Biochemistry, Hannover Medical School, Germany.

Background and aims: Type 1 diabetes is an autoimmune disease characterised by selective destruction of pancreatic ß-cells. Proinflammatory cytokines, such as IL-1ß, IFN-γ and TNF-α, are key mediators of ß-cell death in autoimmune diabetes mainly by the induction of signalling pathways ultimately leading to apoptosis. In this process, reactive oxygen species (ROS) and reactive nitrogen species (RNS) generated during cytokine-induced ß-cell destruction are involved as mediators of ß-cell death. In previous studies we have shown that overexpression of a mitochondrially located catalase (MitoCat) prevented the increase of caspase-9 activity after cytokine treatment. Therefore, the aim of this study was to characterise the influence of antioxidative enzymes and proinflammatory cytokines on the activation of ER-specific caspase-12 and additionally to investigate the interaction of cytokine-mediated ER-stress, mitochondrial apoptosis induction and oxidative DNA damage.
Materials and methods: Quantification of caspase-9 and caspase-12 activity in insulin-producing RINm5F control cells and in cells overexpressing cytosolic catalase (CytoCat) or mitochondrially located catalase (MitoCat) was performed after a 24 h exposure to IL-1ß or to a cytokine mixture (IL-1ß, TNF-α und IFN-γ) by flow cytometry. In order to examine the contribution of caspase-12 in cytokine-mediated ß-cell death, we additionally treated cells with a caspase-12 specific inhibitor. The cell viability was measured by the MTT assay and the oxidative DNA damage caused by hydroxyl radicals was quantified with 8-oxoguanine as a specific biomarker in a flow cytometry based assay after 72 h cytokine exposure.
Results: Exposure of insulin-producing RINm5F control cells to cytokines resulted in a significant activation of caspase-9 and ER-specific caspase-12. A comparable cytokine-mediated activation of caspase-12 was also observed in Cyto- and MitoCatalase overexpressing cells. However, the overexpression of MitoCatalase prevented the increase of caspase-9 activity after cytokine stimulation. Treatment of cells with a caspase-12 inhibitor led to a significant decrease of cytokine-mediated caspase-12 activation. Nevertheless, the inhibition of caspase-12 had no effect on caspase-9 activation and the cell viability was in the presence or absence of the caspase-12 inhibitor significantly decreased after cytokine incubation. Furthermore, the exposure of control and CytoCat cells to cytokines resulted in a significant induction of cytokine-reinforced iron catalysed hydroxyl radical mediated DNA damage, while the overexpression of MitoCat efficiently diminished the formation of 8-oxoguanine.
Conclusion: These results suggest that the mitochondrial apoptosis pathway is crucial for cytokine-mediated ß-cell death, whereas the inhibition of the ER-specific caspase-12 had no influence on cytokine-induced decrease of cell viability. Overexpression of mitochondrially located MitoCatalase could successfully suppress activation of caspase-9 and cytokine-induced hydroxyl radical mediated DNA damage, resulting in a greater resistance against proinflammatory cytokines. These data indicate that caspase-9 and not caspase-12 activation is crucial for apoptosis induction in insulin-producing cells and there is no crosstalk between the activation of these two compartment-specific caspases.

Inhibition of palmitate- and thapsigargin-induced GADD34 expression is associated with increased beta cell apoptosis

L. Fransson, Å. Sjöholm, H. Ortsäter;
Department of Clinical Science and Education, Södersjukhuset, Karolinska Institutet, Stockholm, Sweden.

Background and aims: Phosphorylation of eukaryotic translation initiation factor 2α (eIF2α) on its serine 51 residue reduces the rate of protein synthesis. The gene product of EIF2AK3, PERK, is a protein kinase residing in the endoplasmic reticulum (ER) membrane and is responsible for eIF2α phosphorylation under conditions of compromised ER function. Pancreatic β-cells are vulnerable to disturbances in PERK signalling. This is indicated by the diabetic phenotype associated with mutations in the genes PERK or eIF2α that abolish the ability to phosphorylate eIF2α. The phosphorylation status of eIF2α (p-eIF2α) is also controlled by dephosphorylation events catalyzed by protein phosphatase 1 and its regulatory subunit 15A, also known as GADD34. Expression of GADD34 is enhanced when p-eIF2α is increased and provides negative feedback loop. Pharmacological inhibition of eIF2α dephosphorylation by salubrinal has previously been shown to induce apoptosis by itself and to potentiate palmitate-induced apoptosis. However, since salubrinal increases expression of GADD34 the effects of this compound might depend on elevated levels of GADD34. The aim of the present study was to further investigate the relationship between GADD34 expression and pancreatic β-cell death induced by palmitate and thapsigargin.
Materials and methods: MIN6 cells were treated with a siRNA directed against GADD34. After siRNA treatment cells were exposed to 0.5 mM palmitate or 300 nM thapsigargin. After culture we assessed apoptosis induction by measuring DNA degradation. We also analyzed the phosphorylation status of PERK, eIF2α and protein levels of CHOP by Western blotting. Protein synthesis was assessed by measuring incorporation of ^{35}S-labeled serine and methionine. Cellular levels of mRNA were measured by quantitative PCR. Data is presented as means±sem and differences were evaluated by Students t-test.
Results: Treating MIN6 cells with thapsigargin activated PERK, as assessed by its phosphorylation. After 2 h of treatment, PERK phosphorylation had increased to 169±24 % ($p<0.05$) compared to untreated cells. Its activation increased steadily throughout the 22 h exposure period ending at 524±12 % of baseline level. In contrast, p-eIF2α peaked already after 4 h of treatment at 455±48 % ($p<0.05$) compared to untreated cells and retuned to basal levels after 18 h. This indicates a strong negative feedback. Indeed, in control cells thapsigargin caused 25±4 fold increase in GADD34 mRNA levels while the induction was only 3±0.6 fold in siRNA-treated cells. In concordance, the rate of protein synthesis paralleled p-eIF2α. Exposing cells to palmitate gave a similar, but somewhat delayed, response pattern. In cells with reduced levels of GADD34, p-eIF2α expression was enhanced by palmitate (60±15 %) and thapsigargin (45±10 %) treatment compared with negative siRNA-treated cells. Also, CHOP protein levels were increased by palmitate (50 %) and thapsigargin (35 %) treatment. Apoptosis, measured as DNA degradation, was enhanced in cells with reduced levels of GADD34 by palmitate (25±3 %) and thapsigargin (20±4 %) treatment compared with negative siRNA-treated cells.
Conclusion: In the present study, we show that inhibition of palmitate- and thapsigargin-induced expression of GADD34 is associated with increased pancreatic β-cell apoptosis. Hence, treating β-cells with a siRNA against GADD34 gives a phenotype similar to that obtained by salubrinal treatment.

Inflammatory cytokines and ER stress converge on DP5/Hrk activation: a novel mechanism for pancreatic beta cell apoptosis

E.N. Gurzov, F. Ortis, D.A. Cunha, G. Gosset, A.K. Cardozo, D.L. Eizirik;
Laboratory of Experimental Medicine, Universite Libre de Bruxelles (ULB), Belgium.

Background and aims: Cytokines contribute for pancreatic beta cell apoptosis in type 1 diabetes (T1D) but the mechanisms leading to cell death remain to be clarified. Based on microarray analysis of insulin-producing INS-1E and primary beta cells we have identified upregulation of death protein 5 (DP5)/harakiri (Hrk) after cytokine treatment. DP5 belongs to the pro-apoptotic BH3-only protein family. We presently evaluated the role of DP5 for ER stress- and cytokine-induced beta cell dysfunction and death.
Materials and methods: INS-1E and primary FACS-purified beta cells were transfected with control or siRNAs targeting DP5 and treated with cytokines (IL-1β 10-50 U/ml+ IFN-γ 100 U/ml) or the ER stressor CPA (20 μM). The NO blocker L-NMA was used at 2.5 mM and the JNK inhibitor SP600125 at 10 μM. Real time RT-PCR, reporter analysis, immunofluorescence, Western blot, and viability assays (Hoechst/PI and caspase-3 activation) were performed to identify proteins involved in the mechanisms of DP5-mediated apoptosis.
Results: Cytokines induced DP5 expression in primary beta cells and INS-1E cells (3-25 fold increase in mRNA expression, n = 3-4, $P<0.05$). DP5 knockdown (KD) by RNA interference (>80% inhibition) prevented cytokine-induced cell death in INS-1E cells (14% apoptosis in cytokine-treated DP5 KD

cells vs. 29% apoptosis in cells treated with cytokines and control siRNA, n = 5, P<0.001). Similar findings were observed in primary beta cells. ER stress induced by CPA also increased DP5 expression and its inactivation by KD decreased apoptosis in primary beta cells (19% apoptosis in DP5 KD and CPA-treated vs. 30% apoptosis in CPA-treated control cells; n = 3; P<0,05). CPA-induced DP5 upregulation was prevented by chemical JNK/c-Jun inactivation. DP5 activation by cytokines also involves JNK/c-Jun phosphorylation and was antagonized by the anti-apoptotic protein JunB. Importantly, mitochondrial release of cytochrome *c* and ER stress are actually a consequence of potentiated DP5 activation via cytokine-mediated nitric oxide (NO) formation. Combined inhibition of JNK/c-Jun and NO formation abolished cytokine-induced DP5 mRNA upregulation and fully protected INS-1E cells from apoptosis (20% apoptosis in cytokine-treated cells vs. 6% apoptosis in JNK/NO inactivated cells treated with cytokines, n = 5, P<0.001).
Conclusion: Our findings demonstrate that DP5 is central for beta cell apoptosis following different stimuli, and that it can act up- and downstream of ER stress. These observations contribute to solve two important questions, namely the mechanism by which cytokines induce beta cell death and the nature of the downstream signals by which ER stress "convinces" differentiated secretory cells, such as beta cells, to trigger apoptosis. DP5 may be thus an interesting target for the prevention of beta cell demise in T1D.

The role of endoplasmic reticulum stress induced by glucosamine in pancreatic beta cells dysfunction
A. Lombardi[1], R. Aversa[2,3], C. Garbi[2], G.A. Raciti[2,3], S. De Vitis[1], S. Turco[1], R. Coda[2,3], C. Miele[2,3], L. Ulianich[2,3], B. Di Jeso[1];
[1]DiSTeBA, Università del Salento, Lecce, [2]DBPCM, Università degli Studi di Napoli, Italy, [3]IEOS-CNR, Naples, Italy.

Background and aims: The endoplasmic reticulum (ER) represents the cellular compartment where newly synthesized proteins acquire their correct folding. Many factors can interfere during this process, leading to the accumulation of misfolded proteins into the ER. Such ER dysfunction is collectively termed "ER stress". To survive under ER stress conditions, cells activate a self-protective mechanism, termed the unfolded protein response (UPR). The ER dysfunction plays an important role in various diseases including Type 2 diabetes (T2D). It has been reported that hyperglycaemia (HG) causes the progressive deterioration of beta cells through a mechanism called glucose toxicity and that ER stress may be involved in the consequent pancreatic beta cell dysfunction. Glucosamine (GlcN), generated by the hexosamine pathway (HP) during HG, induces ER stress and causes disturbances similar to glucose toxicity. In this study, we sought to evaluate the role of ER stress induced by GlcN in cultured beta cells (INS-1E) and in isolated pancreatic mouse islets.
Materials and methods: Islets were isolated from male C57 mice by pancreatic digestion with collagenase. Total RNA was extracted from INS-1E cells or islets by the acid phenol method, and real-time PCR was performed to analyze the expression pattern of both beta-cell and UPR specific genes. Protein levels were measured by Western blotting; protein subcellular distribution and expression by immunofluorescence. Cell viability was assessed by MTT assays.
Results: MTT assays showed that 24 hours incubation with 10 mM GlcN did not affect INS-1E cells viability. In these conditions, both mRNA and protein levels of the ER stress marker BiP increased by 3.5- and 2.5-fold, in mouse islets and in INS-1E cells, respectively. Furthermore, GlcN determined also a 2-fold increase of Chop mRNA levels, another important marker of the UPR. In isolated islets, GlcN decreased by 70% the mRNA levels of both GLUT2 and glucokinase (GK) and by 80% the Insulin1 (Ins1) mRNA levels. Interestingly, similar results were obtained when INS-1E cells and islets were treated with Tunicamycin (Tun), a classical ER stress inducer that inhibits glycosilation. These effects were very likely exerted at the transcriptional level, as demonstrated by a parallel downregulation of the mRNA of the beta-cell specific transcription factors Pdx1 and NeuroD1. Furthermore, in INS-1E cells, confocal immunofluorescence studies showed a loss of the specific insulin signal constituted by secretory vescicles clustered in a sub-plasmamembrane location. Treatment of INS-1E cells with the chemical chaperon 4-Phenyl Butyric Acid (PBA 2.5 mM) was capable of partially prevent ER stress induced by GlcN and Tun, as demonstrated by a reduced induction of BiP mRNA levels. Furthermore, GLUT2 and Ins1 mRNA levels reduction was almost completely abolished. Oxidative stress appeared not to be involved in ER stress induction by GlcN, as treatment of INS-1E cells with the antioxidant N-acetyl-L-cysteine (NAC 1mM) did not modify the GlcN-induced increase of BiP mRNA levels.
Conclusion: The activation of the hexosamine pathway leads to alterations in the expression pattern of beta cell specific genes through the induction of ER stress implying that this mechanism could be responsible at least in part, for glucotoxicity-induced beta cell dysfunction.

Protection against stress-induced apoptosis by high density lipoproteins in pancreatic beta cells
J. Petremand[1], G. Waeber[2], C. Widmann[1];
[1]University of Lausanne, [2]CHUV, Lausanne, Switzerland.

Background and aims: High Density Lipoproteins (HDL) have been reported to protect pancreatic beta against cytokine-, serum deprivation-, and oxidized LDL-induced apoptosis. We have recently determined that HDLs could also protect beta cells against ER (endoplasmic reticulum) stress-induced apoptosis in a very effective manner. As ER stress is one of the mechanism that induces beta-cells failure and death in the development of T2D and because the mechanisms of protection of HDLs are not well known in pancreatic beta-cells, we have started to assess by which mechanisms HDLs were protecting beta cells from ER stress.
Materials and methods: MIN6 cells were treated with 2 micro g/ml tunicamycin or 0.5 µM thapsigargin for 6 or 24 hours in the presence or in the absence of 1 mM HDL-cholesterol. ER stress markers (BiP protein expression levels, XBP1 splicing, ATF4 mRNA levels) and apoptosis were then assessed. The activation of PI3K-Akt pathway was also determined by Western blot analyses.
Results: By scoring pycnotic nucleus we confirmed that HDLs were protective against thapsigargin (TG) and tunicamycin (TM)-induced apoptosis. We then assessed the activation of the three ER stress pathways in presence of TG or TM with or without HDLs. ER markers induced by TG such as XBP-1 splicing or BIP expression were blocked by HDLs. ATF4 mRNA was partially reduced, suggesting that HDL could be able to act upstream of the ER, where TG is acting. However these markers, that are also induced by TM, were not blocked by HDLs even if the cells were partially protected, suggesting that in this case HDL could act more downstream of the ER response. Secondly, we looked at the involvement of the PI3K/Akt pathway by using the PI3K inhibitor LY294002 and a dominant negative form of Akt. PI3K inhibition was found to be deleterious for beta cells but HDL could partially reverse this toxic effect. In addition, when PI3K was inhibited, HDLs could still activate Akt. However, in the presence of a dominant-negative form of Akt, HDLs were still able to protect against TG- and TM-induced apoptosis in MIN6 cells, suggesting that the PI3K/Akt pathway might not be required for HDLs to protect beta cells.
Conclusion: These data demonstrate the potent protective effect of HDLs on beta cells experiencing ER stress. These results suggest that protocols aimed at increasing HDL blood levels could exert protective functions against development of diabetes. Further characterization of the intracellular signals modulated by HDLs and that favour beta cell survival is now crucially warranted.

3 b hydroxysteroid-delta 24 redactase (DHCR24) protects pancreatic beta cells against endoplasmic reticulum (ER) stress induced apoptosis
X. Lu[1], B. Gao[2], J. Liu[1], X. Cao[1], F. Hou[1], Z. Liu[1], S. Hisao[3];
[1]School of Life Science, Liaoning University, Shenyang, [2]Institute of Basic Medical Sciences, Shenyang Medical College, [3]College of Life and Health Science, Chubu University, Shenyang, China.

Background and aims: 3 beta-Hydroxysteroid-delta 24 reductase (DHCR24) is an endoplasmic reticulum-resident, multifunctional enzyme that possesses anti-apoptotic and cholesterol-synthesizing activities. We demonstrated that DHCR24 protects embryonic fibroblasts from apoptotic cell death induced by ER stress. We also proved that the protection was achieved by eliminating intracellular ROS produced by ER stress. Accumulating evidence suggests that endoplasmic reticulum (ER) stress involved in the pathogenesis of diabetes, contributing to pancreatic beta-cell loss and insulin resistance. The aim of the study was to investigate whether DHCR24 protect the apoptosis of pancreatic beta-cells induced by ER stress.

Materials and methods: MIN6 cells were cultured in the growth medium and infected by adenovirus expressing DHCR24 tagged with myc (Ad-DHCR24-myc) or transfected with siRNA targeting DHCR24 (siDHCR24). The Adenovirus expressing lacZ (Ad-lacZ) or non-targeting siRNA (siControl) were used as the controls. Tunicamycin (TM) was used as the ER-stress inducer. Western blotting was used to analyze the signaling cascade caused by ER stress. The survival of beta-cells were observed by the phase-contrast microscopy and calculated by dye-exclusion method using Trypan Blue. Apoptosis was determined by measuring the cleaved-caspase 3 by immuno-cytochemistry.
Results: Ad-DHCR24-myc infected MIN6 cells were resistant to TM-induced apoptosis, as compared to the Ad-LacZ infected cells. Western blot analysis revealed that expression of Bip/Grp78, a major ER chaperone, was increased stronger in Ad-DHCR24-myc cells. The sustained activation of ATF6 (Activating transcription factor-6) was also observed in Ad-DHCR24-myc infected MIN6, suggesting the upregulation of Bip induced sustained activation of ATF6, which might contribute to the anti-apoptotic function of DHCR24 upon the ER stress. When the mRNA of DHCR24 has been knocked down by the siDHCR24 in MIN6, the cells became much more susceptibile to ER stress, producing much more apoptotic cells, compared to the siControl-transfected cells.
Conclusion: This is the first demonstration that DHCR24 can protect pancreatic beta-cell from apoptotic cell death induced by ER-stress.

Exendin-4 and cAMP protect pancreatic beta cells from lipotoxic ER stress via induction of antiapoptotic defense mechanisms
D.A. Cunha[1], L. Ladrière[1], F. Ortis[1], M. Igoillo-Esteve[1], E.N. Gurzov[1], D.L. Eizirik[1], M. Cnop[1,2];
[1]Laboratory of Experimental Medicine, Université Libre de Bruxelles, [2]Division of Endocrinology, Erasmus Hospital, Brussels, Belgium.

Background and aims: Chronic exposure of pancreatic beta cells to saturated free fatty acids (FFA) causes endoplasmic reticulum (ER) stress and apoptosis, and may contribute to beta cell loss in type 2 diabetes. GLP-1 receptor activation has previously been shown to increase beta cell survival following exposure to synthetic ER stressors through ATF4-CHOP signaling and eIF2α dephosphorylation. We presently evaluated the molecular mechanisms involved in the protection by the GLP-1R agonist exendin-4 against the more physiologic ER stress and apoptosis induced by FFA in beta cells.
Materials and methods: INS-1E or FACS-purified primary rat beta cells were exposed to the FFA oleate or palmitate (0.5 mM, 1% BSA) with or without exendin-4 (10-50 nM) or the cAMP generator forskolin (20 μM). To selectively activate signaling in the ATF4-CHOP branch of the ER stress response, we used salubrinal (75 μM), an inhibitor of eIF2α dephosphorylation. Apoptosis was detected by Hoechst/propidium iodide staining, mRNA expression by real time RT-PCR and protein expression and eIF2α phosphorylation by Western blot. Protein knockdown was achieved by siRNA transfection.
Results: Palmitate-induced primary beta cell apoptosis was reduced from 23 ± 2 % to 14 ± 2 % and 10 ± 1 % by exendin-4 and forskolin respectively ($n = 4$; $p < 0.05$ vs palmitate) after 24 h. Exendin-4 and forskolin also prevented beta cell apoptosis induced by oleate (14 ± 2 % to 9 ± 2 % and 7 ± 1 %; $n = 4$; $p < 0.05$) or salubrinal (18 ± 1 % to 11 ± 1 % and 9 ± 1 %; $n = 4$; $p < 0.05$) after 24 h. Similar findings were observed in INS-1E cells (14 h). Using CHOP knockdown (93 % inhibition of CHOP protein compared to control siRNA treated with palmitate; $n = 3$; $p < 0.05$) we examined the involvement of ATF4-CHOP-GADD34 feedback signaling on forskolin-mediated INS-1E cell survival. The CHOP siRNA did not abrogate the protective effects of forskolin against palmitate (18 ± 3 % for control siRNA to 17 ± 3 % for CHOP siRNA; $n = 4$), excluding this pathway as the antiapoptotic mediator. We therefore examined the other branches of the ER stress response. Exendin-4 and forskolin induced XBP1s but its knockdown (74 % decrease in XBP1s protein; $n = 3$; $p < 0.05$) did not modify the antiapoptotic effect. Exendin-4 and forskolin potentiated the induction of the ER chaperone BiP by oleate (1.8- and 1.6- fold; $n = 4$; $p < 0.05$) or palmitate (1.7- and 2.1-fold; $n = 4$; $p < 0.05$). A 50 % decrease in BiP expression by siRNA resulted in a partial loss of the cAMP-mediated protection against palmitate (13 ± 1 % for control siRNA to 29 ± 3 % for BiP siRNA; $n = 4$; $p < 0.05$). The AP-1 subunit JunB, known to protect beta cells against synthetic ER stress, was also induced by forskolin (5-fold; $p < 0.05$). JunB knockdown abolished the cAMP protection against oleate, and it partially decreased the protection against palmitate (17 ± 2 % for control siRNA to 28 ± 2 % for JunB siRNA; $n = 4$; $p < 0.05$).
Conclusion: Exendin-4 and forskolin protect beta cells against lipotoxic ER stress and apoptosis by enhanced BiP and JunB expression. These findings identify two possible therapeutic targets to alleviate beta cell ER stress in type 2 diabetes.

Protein levels of GRP78 and protein disulfide isomerases A3 and A6 are decreased during thapsigargin treatment of INS-1E cells
V. Rosengren[1], H. Johansson[2], L. Fransson[1], J. Lehtiö[2], Å. Sjöholm[1], H. Ortsäter[1];
[1]Clinical Science and Education, [2]Oncology and Pathology, Karolinska Institutet, Stockholm, Sweden.

Background and aims: Pancreatic β-cells are equipped with a developed endoplasmic reticulum (ER) in order to meet the high demand for synthesis of proteins destined for secretion, most notably insulin. To support the production, these cells express relatively large amounts of heat shock proteins with chaperone functions, protein disulfide isomerases (PDI) that catalyse formation of sulfide bridges and peptidylprolyl isomerases (PPI) which are responsible for isomerisation of proline peptide bonds. The ER is sensitive to alterations in homeostasis. For example, a reduction of ER Ca^{2+} levels elicits a signal response, the unfolded protein response (UPR), with the purpose to restore ER homeostasis by decreasing protein synthesis, increasing folding capacity and enhance protein degradation. In the present study we have focused on changes in protein levels of chaperones, PDIs and PPIs in INS-1E cells during thapsigargin (Th) treatment.
Materials and methods: INS-1E cells were treated with 200 nM Th for 0, 4, 16 or 24 h, cellular protein were isolated and subjected to iTRAQ labelling using 8 different isobaric tags. Protein identification and quantification was performed with LC/MS/MS. The phosphorylation status of eIF2α (p-eIF2α), protein levels of GRP78, CHOP, Bcl2 and cleaved caspase 3 were analysed by western blotting (wb). Protein synthesis was measured after incorporation of ^{35}S-labeled serine/methionine. Data is presented as means±sem. Differences were evaluated by Student's t-test.
Results: Quantitative iTRAQ proteomic analysis offers a way to identify and quantify 8 different samples in one homogenous assay. Two independent samples from each time point were combined in the analysis. From the positively identification of 91 unique proteins 8, 2 and 2 were classified as chaperones, PDIs or PPIs, respectively. Of the chaperones 4 localise to cytoplasm, 3 to mitochondria and 1 to ER. Heat shock protein 90β (cytoplasmic) and GRP78 (ER) decreased ($p<0.05$) with time. Other chaperones were unaffected. The PDIs, PDIA3 and PDIA6 (both localise to ER) decreased ($p<0.05$) with time ending at 73±6 % and 26±4 % of their baseline levels, respectively. Of the PPIs identified, PPIA (cytoplasmic) and PPIB (ER) levels were not affected by Th. The decreased level of GRP78 was unexpected since this chaperone is considered to be induced during UPR. The iTRAQ results could be verified in wb experiments. Treating cells with 30, 100, 200 or 300 nM Th dose-dependently decreased GRP78 levels with a maximal effect at 200 nM (45±4 %, $p<0.05$ *vs.* untreated cells). The time profile of Th-induced decrease in GRP78 was similar in the iTRAQ and wb analysis. Lowest levels, 35±2 % for iTRAQ and 51±4 % for wb, were seen after 16 h at 200 nM Th. In both dose and time series experiments, Th-induced decrease in GRP78 was paralleled by enhanced levels of p-eIF2α, CHOP and cleaved caspase 3 and decreased levels of Bcl2. We investigated if the lower levels of GRP78 after Th treatment were secondary to inhibition of protein synthesis. Exposing INS-1E cells to either 10 μM cycloheximide or 200 nM Th casued a similar inhibition of protein synthesis. However, cycloheximide only decreased GRP78 levels by 10±3 % ($p>0.05$) during a 24 h study period.
Conclusion: Disturbance of ER Ca^{2+} homeostasis leads to lower levels of GRP78, PDIA3 and PDIA6 in INS-1E cells which may contribute to the development of apoptosis.

Role of activating transcription factor 3 in low glucose- and thapsigargin-induced apoptosis in cultured mouse islets

J. Duprez, J.-C. Jonas;
Unit of Endocrinology and Metabolism, Faculty of Medicine, Université catholique de Louvain, Brussels, Belgium.

Background and aims: The Integrated Stress Response (ISR) results from the phosphorylation of eukaryotic initiation factor 2 alpha by various types of stress, including endoplasmic reticulum (ER) stress and amino acid deprivation. It is characterized by increased expression of Activating Transcription Factor 4 (ATF4)-target genes such as *Atf3, Growth arrest- and DNA damage-inducible gene 153 (Gadd153, or Chop)* and *Gadd34*, and of oxidative stress-response genes like *c-Myc*, *Heme-oxygenase 1* (*Hmox1*) and *Metallothionein 1a* (*Mt1a*). We recently reported that, after prolonged culture in low, intermediate and high glucose concentrations, rat islet cell apoptosis follows an asymmetric V-shaped profile with a minimum in 10 mM, a large increase in 2 mM and a moderate increase in 30 mM glucose. Interestingly, these changes were preceded by parallel changes in the mRNA levels of ISR and oxidative stress-response genes, suggesting that both types of stress could play a role in islet cell apoptosis during culture in low and high glucose. The aim of this study was to investigate the role of the pro-apoptotic transcriptional repressor ATF3 in the stimulation of islet cell apoptosis under conditions associated with ISR activation.
Materials and methods: Islets isolated from *Atf3* knockout mice (*Atf3*$^{-/-}$) and their wild-type C57BL6/J littermates (WT) were cultured in serum-free RPMI medium containing 5g/l BSA and 2-10-30 mM glucose (G2-G10-G30) or G10 + 1 μM thapsigargin (TG) as ER stress positive control. Insulin was measured by RIA. Islet gene mRNA levels were determined by RTq-PCR. Islet cell histone-associated DNA fragments (commercial ELISA kit) and the percentage of TUNEL positive islet cells were measured as indicators of islet cell apoptosis. Results are means ± SEM for at least 3 experiments.
Results: After 1 week preculture in G10, the glucose stimulation of insulin secretion during further 18h culture and the insulin to DNA content ratio at the end of culture were similar in *Atf3*$^{-/-}$ and WT islets. As in rat islets, culture of WT mouse islets in G2 or G10 + TG vs G10 rapidly (18h) increased *Atf3*, *Gadd153, Gadd34, c-Myc, Hmox1* and *Mt1a* to *Tbp* mRNA ratios and later (3-7 days) induced islet cell apoptosis. In contrast, culture in G30 only slightly increased the mRNA levels of ISR and oxidative stress response genes as well as islet cell apoptosis. In *Atf3*$^{-/-}$ islets, the effects of TG and G30 vs G10 on apoptosis and gene mRNA levels were not different from those in WT islets. In contrast, the level of apoptosis induced by one week culture in G2 was significantly lower in *Atf3*$^{-/-}$ vs WT islets in one third of the experiments (mean [range] reduction for 6 experiments ~20% [0-60%], unpaired t-test P=0.4), irrespective of mouse gender and age. This slight reduction in islet cell apoptosis in G2 vs G10 was preceded by a larger increase in *Mt1a* mRNA levels in *Atf3*$^{-/-}$ vs WT islets (50 fold vs 28 fold, P<0.001 by two-way ANOVA + test of Bonferroni) without significant changes in *Hmox1, c-Myc, Gadd153* or *Gadd34* mRNA levels.
Conclusion: The increase in *Atf3* gene expression induced by culture in a low glucose concentration only slightly contributes to the stimulation of islet cell apoptosis by a mechanism that may involve repression of *Mt1a* gene expression.

Nitrooxidative stress as a mechanism of cytokine-mediated toxicity in insulin-producing cells

S. Lenzen, S. Lortz, E. Gurgul-Convey;
Institute of Clinical Biochemistry, Hannover Medical School, Germany.

Background and aims: Both nitrosative and oxidative stress contribute to the toxic action of proinflammatory cytokines in insulin-producing cells during T1DM development and it is generally assumed that mitochondria play a crucial role in cytokine-mediated beta cell death. However, the interactions between reactive nitrogen (RNS) and oxygen (ROS) species in cytokine-mediated toxicity remain unclear. Therefore it was the aim of this study to unravel the mechanism of this interaction.
Materials and methods: Insulin-producing RINm5F cells were stably transfected with the pcDNA3-hMnSOD or with hMitoCat. Cells were treated with IL-1β 600 U/ml or with a cytokine mixture (IL-1β 60 U/ml, TNFα 185 U/ml, IFNγ 14 U/ml) in the absence or presence of an iNOS blocker (5 mM L-nitroarginine) for 72 h. Cell viability was estimated by MTT test, overall oxidative stress by DCFDA oxidation, nitrite by the Griess assay and hydroxyl radical-mediated 8-oxyguanine formation by an OxyDNA kit. Hydrogen peroxide generation was measured by HyPer protein oxidation.
Results: In the control cells IL-1β caused a 40 % and a cytokine mixture a 70 % reduction in cell viability. This was significantly counteracted by iNOS blocker (IL-1β 78 % and Mix 70 % viable cells). MitoCat cells overexpressing catalase in the mitochondrium were protected against cytokine toxicity (IL-1β 80 %, Mix 71 % viable cells), while MnSOD overexpressing cells were more sensitive to cytokine toxicity (IL-1β 49 %, Mix 10 % viable cells). No further protection was seen in MitoCat cells after addition of the iNOS blocker, while a significant prevention of cytokine toxicity was observed in the MnSOD cells (IL-1β 65 %, Mix 48 %). DCFDA oxidation after exposure to cytokines in the absence or presence of iNOS blocker indicated that IL-1β toxicity is mostly related to NO and cytokine Mix toxicity to both NO and ROS formation. Indeed, in control cells exposed to IL-1β nitrite formation was the same as after cytokine Mix (IL-1β 3.9±0.7, Mix 4.7±0.5 pmol/μg protein), but the hydrogen peroxide (Con: 0.94±0.03, IL-1β: 1.07±0.03, Mix 1.20±0.04) and hydroxyl radical (Con; 100 %, IL-1β 227 %, Mix 391 %) generation were significantly lower after IL-1β than after cytokine Mix. Mitochondrial overexpression of catalase as compared to control cells diminished nitrite formation (IL-1β 0.6±0.2, Mix 1.9±0.3) and completely prevented hydrogen peroxide (Con: 0.94±0.02, IL-1β: 0.85±0.02, Mix 0.88±0.03) and hydroxyl radical (IL-1β 101 %, Mix 123 %) generation. In contrast, MnSOD cells showed significantly higher nitrite levels (IL-1 6.4±0.8, Mix 29±7), hydrogen peroxide (Con: 1.11±0.05, IL-1β: 1.50±0.03, Mix 3.05±0.33) and hydroxyl radical (IL-1β 661 %, Mix 904 %) generation.
Conclusion: The results revealed that IL-1β toxicity is NO-related, while a mixture of cytokines, simulating the situation in T1DM, stimulates the generation of both NO and ROS. This duality results in an interaction between NO and H_2O_2 leading to the formation of the highly toxic hydroxyl radical, which provides a unifying hypothesis for the mechanism underlying cytokine toxicity leading to beta cell death in T1DM. Optimal protection against cytokine toxicity requires a H_2O_2 inactivating enzyme in the mitochondria, allowing effective detoxification of H_2O_2, thereby preventing stress through hydroxyl radical formation in the presence of NO. In conclusion, the studies prove that proinflammatory cytokine-mediated beta cell death is due to nitrooxidative stress.

361

Cytokines regulate both transcriptional and alternative splicing networks in primary beta cells

F. Ortis[1], N. Naamane[1], D. Flamez[1], L. Ladrière[1], F. Moore[1], D.A. Cunha[1], M.L. Colli[1], T. Thykjaer[2], K. Thorsen[2], T.F. Orntoft[2,3], D.L. Eizirik[1];
[1]Laboratory of Experimental Medicine, Université Libre de Bruxelles, Belgium, [2]Department of molecular Medicine, Aarhus University Hospital, Denmark, [3]CMO Aros Applied Biotechnology A/S, Aarhus, Denmark.

Background/rational: Cytokines contribute to insulitis and pancreatic beta cell death in Type 1 Diabetes. This effect is mediated by activation of complex gene networks that remain to be characterized. We presently utilized up-to-date array analysis to define the global pattern of genes, including spliced variants, modified by the cytokines IL-1β + IFNγ and TNFα + IFNγ in primary rat beta cells
Material and methods: FACS purified rat beta cells were exposed for 6 or 24h to IL-1β (50 U/ml) + IFNγ (100 U/mm) or TNFα (1000 U/ml) + IFNγ (100 U/ml) and then retrieved for array analysis using the GeneChip® Rat Genome 230 2.0 Array, containing > 31.000 probe sets. Three independent experiments were analyzed and gene expression considered as modified by cytokines when fold change was ≥ 1.5 and P ≤ 0.02 compared to controls. For identification of splice variants, cDNA from the three experiments were pooled and analysed using the exon array analysis GeneChip® Rat Exon 1.0 ST Array, containing ~ 1.000.000 probe sets. Most of the key results described below were confirmed by real time RT-PCR
Results: Nearly 16.000 transcripts were detected as present in control and cytokine-treated beta cells. TNF-α + IFNγ modified the expression of a higher number of genes compared to IL-1β + IFNγ at 6h (1.468 and 1.006 respectively), while at 24h this was inverted, with 2.531 and 1.929 genes modified by respectively IL-1β + IFNγ and TNF-α + IFNγ. TNF-α+IFNγ induced a higher expression of IRF1, IRF7, IL-15, IP-10 and CCL5, while IL-1β+IFNγ induced higher expression of CCL2 and CXCL1. Both treatments decreased the expression (20-80%; P ≤ 0.05, as confirmed by Real time RT-PCR) of genes involved in the maintenance of beta cell phenotype, including PDX-1, Mafa1, ins, isl1, foxo1, Glut2, PC1 and 2, NeuroD. Cytokines also decreased by > 80%

($P \leq 0.05$), as confirmed by Real time RT-PCR, the expression of receptors to the key growth/regeneration-inducing hormones GLP1, PRL and GH. Importantly, cytokines modified the expression of > 20 genes involved in RNA splicing. In line with this observation, exon array analysis showed cytokine-induced changes in alternative splicing of more than 40% of the cytokine-modified genes. This induction of alternative splicing was confirmed by PCR in three genes, namely iNOS, NF-κB2 and argininosuccinate synthetase.
Conclusion: The present study doubles the number of known genes modified by cytokines in primary rat beta cells, and suggests temporal and qualitative differences between the effects of TNF-α + IFN-γ and IL-1β + IFNγ in beta cells. Both IL-1β+IFNγ and TNF-α+IFNγ decrease the expression of genes related to beta cell function and growth/regeneration, suggesting that immune mediators of insulitis can "push back" newly developed beta cells into a de-differentiated state. Interestingly, cytokines modify alternative splicing in beta cells, indicating a new level of complexity in the beta cell responses to immune-mediated damage.

The effect of glucose variability on INS-1 cell apoptosis and the involvement of FOXO-SIRT system
M. Kim[1,2], H. Jung[2], C. Yoon[2], J. Ko[3], H. Jun[3], T. Kim[3], M. Kwon[3], S. Lee[3], K. Ko[3], B. Rhee[3], J. Park[3,2];
[1]Internal Medicine, Maryknoll General Hospital, [2]Molecular Therapy Lab, Paik Institute for Clinical Research, [3]Internal Medicine, College of Medicine, Inje University, Busan, Republic of Korea.

Background and aims: Glucose levels always change in some range in real life, and the degree of fluctuation would be more prominent in diabetes despite of meticulous control. Variable glucose levels have been reported to be more harmful than sustained high glucose in the vascular endothelial cells due to increased oxidative stress. Recent several studies reported that SIRT might regulate FOXO transcription factors under oxidative stress, and overexpression of SIRT could protect beta cells from cytokine induced apoptosis. But the effects of sustained and intermittent high glucose on the apoptosis and the changes of FOXO-SIRT system in pancreatic beta cells have not been studied so much. The purpose of our study is to clarify the effect of glucose variability on pancreatic beta cells, and the potential mechanisms related with FOXO-SIRT pathway.
Materials and methods: Cultured INS-1 cells were exposed to control (11mmol/l), SHG (sustained high glucose, 33mmol/l) or IHG (intermittent high glucose, 11 and 33mmol/l) alternating every 12 hours for 5 days. The degree of apoptosis was assessed by FACS and TUNEL assay. The levels of caspase-3, Mn-SOD, Bim and Bcl-2 were assessed via Western blot. The changes of FOXO-SIRT system were studied by Western blot and immuno-precipitation. The changes of glucose stimulated insulin secretion (GSIS) were also verified.
Results: INS-1 cells exposed to IHG for 5 days showed lower GSIS and the increased apoptosis than the cells in SHG. The changes of caspase-3 and Mn-SOD were compatible with the increased apoptosis in the cells exposed to IHG. The complex formations of SIRT and FOXO showed different patterns between IHG and SHG. The degree of acetylation of FOXO was lower in the cells exposed to SHG, but increased with SIRT inhibitor. Administration of SIRT inhibitor increased apoptosis, decreased caspase-3, MnSOD and Bcl-2 in the cells exposed to SHG.
Conclusion: IHG (Intermittent High Glucose) might be more harmful to the pancreatic beta cells than the SHG (Sustained High Glucose) causing increased apoptosis. FOXO-SIRT system might be closely involved in this process.

Transcriptome analysis of human type 2 diabetic islets
M. Bugliani[1], R. Liechti[2], L. Marselli[1], U. Boggi[1], F. Filipponi[1], I. Xenarios[2], P. Marchetti[1];
[1]Dept. Endocrinology and Metabolism, University of Pisa, Italy, [2]Swiss Institute of Bioinformatics, Lausanne, Switzerland.

Background and aims: Type 2 diabetes (T2D) is a multifactorial syndrome with beta-cell failure playing a major role. However, information on islets transcriptome in human T2D is scanty.
Materials and methods: We performed microarray analysis, followed by quantitative RT-PCR, of a few selected genes on six T2D (age: 71±9 yrs; gender: 3M/3F; BMI: 26.0±2.2 Kg/m^2) and seven non-diabetic (ND, age: 58±17 yrs; gender: 4M/3F; BMI: 24.8±2.5 Kg/m^2) isolated islet preparations. Standard RNA was hybridized on the Affymetrix platform (HG U133A). Gene expression intensities were normalized with RMA and differential expression was assessed by fitting a linear model on each gene using the limma package from bioconductor. Quantitative RT-PCR was performed using primers and probes from Applied Biosystems.
Results: When T2D islets were compared with ND samples, the expression of 5130 transcripts and variants resulted significantly ($p<0.01$) different; of these, 2927 were upregulated and 2203 downregulated. Changes included several genes involved in beta-cell function and turnover. By Gene Ontology and KEGG analysis it was observed that the differently expressed genes influence 81 processes and 13 pathways, including cell survival and secretion. Such findings were mostly confirmed by the Gene Set Enrichment Analysis, performed to evaluate how the overall gene expression profile could influence

intracellular processes. This analysis showed that out of 1412 gene sets studied, 144 were positively enriched and 234 negatively enriched in T2D islets. The expression of genes involved in oxidative phosphorylation and citrate cycle resulted consistently changed in T2D samples, and when quantitative RT-PCR analysis was performed, a significant reduction in the expression of pyruvate and succinate dehydrogenase complexes was found.
Conclusion: In conclusion, T2D islets show several alterations in the overall gene expression pattern; whereas it remains to understand what alterations may be cause or consequence of the diabetic condition, it is suggested that mitochondrial alterations might play an important role in T2D islet cell dysfunction.

The role of iron in IL-1β induced NFκB activity and iNOS expression in pancreatic beta cells
A.Ø. Nielsen[1], M.F. Tonnesen[1], N. Billestrup[1], T. Mandrup-Poulsen[1,2];
[1]Dept. of Translational Diabetology, Hagedorn Research Institution, Gentofte, [2]Core Unit for Medical Research Methodology, Institute of Biomedical Sciences, University of Copenhagen, Denmark.

Background and aims: Interleukin (IL)-1β mediated selective destruction of the pancreatic β-cells is believed to be a central element in the pathogenesis of type 1 diabetes. β-cell sensitivity to IL-1β is acquired during β-cell maturation and dependent on expression of the transcription factor pancreatic duodenal homeobox-1 (Pdx-1). Microarray analysis of Pdx-1 overexpressing compared to control cells revealed a gene cluster involved in nuclear factor κB (NFκB) activation, reactive oxygen species (ROS) formation, iron influx via the divalent metal transporter 1 (DMT1) and inducible nitric oxide synthase (iNOS) as important in the maturation-acquired sensitivity to IL-1β. This lead to the hypothesis that IL-1β induced NFκB activity and iNOS expression are iron dependent in that iron catalysed ROS contributes to sustained NFκB activity.
Materials and methods: The iron chelator desferoxamine (DFO) was used to reduce IL-1β induced iron uptake in the INS-1 cell line. The effect of iron chelation on NFκB and iNOS promoter activity was studied using the dual Luciferase assay. Protein levels of iNOS and IκB was examined using Western blotting and apoptosis shown with the Roche death detection kit. Newborn rat islets were used to confirm effects of DFO on total cell death and nitric oxide (NO) levels.
Results: In INS-1, DFO (25 μM) reduced IL-1β (160 pg/ml) induced apoptosis by 25% ($p<0.05$), NFκB activation by 30% ($p<0.05$), and decreased iNOS at the protein level by 50% ($p<0.01$), whereas iNOS promoter activity does not seem to be affected by DFO. Cytokine induced total cell death was significantly reduced 30-40% with DFO doses from 10-100 μM in rat islets. Concentration of NO in the media of rat islets was significantly reduced with 100 or 200 μM of DFO ($p<0.05$).
Conclusion: Lowering the iron levels in INS-1 cells by DFO reduced IL-1β induced apoptosis by inhibiting NFκB activation as well as lowering iNOS expression at the protein level. Cytokine induced cell death and NO release was also reduced in rat islets following DFO treatment. Iron chelation may be a therapeutic option in preventing inflammatory β-cell destruction in islet transplantation.

365

The orphan receptor GPR30 and pancreatic islet hormone secretion
A.F. Balhuizen, R. Kumar, S. Amisten, I. Lundquist, A.S. Salehi;
Department of Clinical Sciences, Lund University, Malmö, Sweden.

Background and aims: The role of the newly discovered estrogen receptor, GPR30 in islet physiology is unclear. We examined GPR30 expression in relation to hormone secretion and possible antiapoptotic effects in isolated mouse islets using the synthetic GPR30 ligand G1.
Materials and methods: GPR30 expression was analyzed by confocal microscopy, Western blot in islets from female mice and RT-PCR in islets from both female and male mice. Hormone secretion and cAMP content in islets were determined with RIA and apoptosis with the Annexin-V method.
Results: Confocal microscopy revealed GPR30 expression in insulin, glucagon and somatostatin cells. GPR30 mRNA and protein expression was markedly higher in female *vs* male islets ($p<0.01$). Dose-response studies of G1 *vs* 17β-estradiol in isolated islets at 12 mM glucose showed an almost identical pattern in increasing insulin and inhibiting glucagon and somatostatin secretion. The 17β-estradiol genomic receptor (ERα and ERβ) antagonist ICI-182,780 (Fulvestrant) did not influence the amplifying effect of G1 or 17β-estradiol on cAMP content ($p<0.001$) or insulin secretion from islets. Cytokine-induced (IL-1β 100ng/ml, TNFα and INFγ 125ng/ml) apoptosis in islets, cultured for 24 h at 5 mM glucose, was almost abolished by G1 or 17β-estradiol treatment ($p<0.001$). Addition of ICI-182,780 did not affect this beneficial effect of G1 or 17β-estradiol.
Conclusion: GPR30 is expressed in islet endocrine cells. The synthetic GPR30 ligand G1 mimics the nongenomic effects of 17β-estradiol on hormone secretion, cAMP content in islets and its antiapoptotic effects. G1 or analogs thereof might be new potential candidate in therapeutic strategy of type 2 diabetes in women.

Effect of angiotensin II on the insulin signalling pathway in NIT-1 cells
M.-T. Xu, L. Zhang, L.-D. Jiang, S. He, L. Yan, H. Cheng;
Department of Endocrinology, The Second Affiliated Hospital, Sun Yat-sen University, Guangzhou, China.

Background and aims: Angiotensin II (Ang II) can cause insulin resistance in peripheral insulin target tissues such as muscle, fat and liver. The mechanism is to damage the insulin signaling pathway in these cells by reducing the tyrosine phosphorylation levels of insulin receptor (InR) / insulin receptor substrate -1 (IRS-1) and increasing serine phosphorylation levels. Reactive oxygen species (ROS) play important roles on the damage of insulin signaling pathway by Ang II. Whether the effect of Ang II on insulin signaling pathway in islet β-cell is not known. In the present study, the effect of Ang II on insulin signaling pathway was evaluated in mouse insulin-secreting cells NIT-1 cells and the role of ROS involved was studied.
Materials and methods: NIT-1 cells were cultured in DMEM with 10% fetal bovine serum, and then divided into six groups acted as control group, Ang II group, insulin group (Ins), Ang II + Ins group (AI), Ang II + Ins + saralasin group (AIS), Ang II + Ins + DPI group (AID). Expression of InR-β tyrosine phosphorylation (InR-β-Tyr), IRS-1 serine phosphorylation(IRS-1-Ser) and IRS-1 tyrosine phosphorylation (IRS-1-Tyr), P47 were evaluated by Western blot. H_2O_2 were detected by FCM.
Results: Expression of InR-β-Tyr and IRS-1-Tyr was higher in Ins group compared to control group, whereas expression of IRS-1-Ser was not significantly different between Ins group and control group. Level of InR-β-Tyr and IRS-1-Tyr was not significantly different between Ang II group control group,but the level of IRS-1-Ser significant increased in Ang II group compared with control group. After AngII treatment, InR-β-Tyr and IRS-1-Tyr induced by insulin were lower compared with Ins group (InR-β-Tyr 1.32 vs 1.87; IRS-1-Tyr 0.67 vs 1.17, $P<0.05$). With presence of saralasin, InR-β-Tyr and IRS-1-Tyr in AIS group were higher than in AngII group (InR-β-Tyr 1.67 vs 0.96, IRS-1-Tyr 1.03 vs 0.59, $P<0.05$). The level of H_2O_2 and P47 in AII group significant increased compared with control group (H_2O_2 37.46 vs 27.55, P47 1.55 vs 0.87, $P<0.05$). With presence of DPI, level of InR-β-Tyr and IRS-1-Tyr increased in AID group compared with AngII group (InR-β-Tyr 1.61 vs 0.96, IRS-1-Tyr 1.01 vs 0.59, $P<0.05$) and the level of IRS-1-Ser changed adversely (IRS-1-Ser 0.70 vs 1.17, $P<0.05$).
Conclusion: In conclusion, Ang II can significantly increase the level of IRS-1 serine phosphorylation and inhibit insulin-stimulated InR-β tyrosine phosphorylation in NIT-1 cells. oxidative stress induced by NADPH oxidase may play an important role in the effect of Ang IIin NIT-1 cells.

Apoptosis in INS-1E cells after ZnT-3 and ZnT-8 knock-out
A.B. Petersen, K. Smidt, N.E. Magnusson, B. Brock, O. Schmitz, J. Rungby;
Department of Pharmacology, University of Aarhus, Denmark.

Background and aims: Insulin secreting β-cells contain large amounts of zinc. Intracellular metabolism of Zn^{2+} has to be subject to strict regulation due to its toxic potential at high concentrations. Transporters of the Slc30A-family (ZnT-1 to 10) regulate zinc efflux from the cytoplasm. Rising evidence connect ZnTs and diabetes. It has been shown that ZnT-8 is an antigen associated with the development of Type 1 diabetes. Furthermore, mutations in the same gene are associated with Type 2 diabetes. ZnT-3 KO mice have

decreased glucose tolerance which we have previously shown to be at least partly due to altered β-cell function. In this study we used siRNA-mediated knock-out to investigate the connection between the expression of these two zinc-transporters and INS-1E cell viability.
Materials and methods: 100 nM siRNA concentrations were used to perform single ZnT-3 and ZnT-8 knock-out in INS-1E cells. To avoid non-specific siRNA effects a total concentration of 100 nM was also used for the combined knock-out of ZnT-3 and ZnT-8. Knock-out of the two zinc-transporters at mRNA level was detected using Q-PCR. Following transfection and 48 hours of recovery the knock-out and control samples were stimulated with two different concentrations of glucose (5.0 and 16.7 mM) for 24 hours. Levels of apoptosis were then measured using an ELISA kit based on an enzyme-immunoassay-principle.
Results: A reduction of ZnT-3 expression to 30% ($p<0.01$) resulted in significantly increased apoptosis following stimulation with 5.0 mM glucose ($p<0.05$) and non-significantly at 16.7 mM glucose ($p=0.07$) when compared to mock-transfected controls. Knock-out of ZnT-8 to a level of 50% ($p<0.05$) resulted in increased apoptosis compared to controls only following stimulation with 16.7 mM glucose ($p<0.05$). Following combined knock-out we were able to reduce expression of ZnT-3 and ZnT-8 to 35 and 70%, respectively. The result was a significantly increased level of apoptosis following stimulation with both 5.0 and 16.7 mM glucose ($p<0.05$) (figure below).
Conclusion: The influence of ZnT-3 and ZnT-8 on INS-1E cell viability has until now not been described. Our results indicate that the presence of these two zinc-transporters, both separately and in combination is important for cell viability.

Systemic osteoprotegerin delivery induces pancreatic islet structural and functional alterations in non-diabetic mice
R. Candido[1], B. Toffoli[2], S. Bernardi[2], P. Secchiero[3], F. Corallini[3], E. Caroli[1], E. Manca[1], A. Petrucco[1], C. Montesi[1], R. Carretta[2], G. Zauli[3], B. Fabris[2];
[1]Diabetic Centre, A.S.S. 1 Triestina, [2]Department of Clinical Medicine and Neurology, University of Trieste, [3]Department of Morphology and Embryology, University of Ferrara, Trieste, Italy.

Background and aims: Osteoprotegerin (OPG), a secreted glycoprotein and member of the TNF receptor superfamily, is a soluble receptor activator of nuclear factor-κB (RANK) ligand (RANKL), and TNF-related apoptosis inducing ligand (TRAIL). Diabetic patients are characterized by elevated OPG, which is associated with subclinical atherosclerosis in both type 1 and type 2 diabetes. Recently, our group has demonstrated that OPG delivery leads to significant acceleration of atherosclerosis in diabetic apolipoprotein E-null mice. Although clinical studies have suggested that systemic levels of OPG are elevated in diabetes, the role of OPG in the endocrine pancreas has not been investigated. Therefore, the aim of this study was to examine the effects of OPG administration on pancreatic islet structure and function in mice.
Materials and methods: Three groups of C57B1/6J mice (n=20 for each group) were obtained at 10 weeks of age and studied for 12 weeks: 1. C57B1/6J mice treated with recombinant human OPG injected every 21 days intraperitoneally, 2. C57B1/6J mice treated with the vehicle alone, and 3. Untreated C57B1/6J mice. Tail cuff systolic blood pressure, fasting plasma glucose and insulin levels, pancreatic β-cell mass and density, β-cell apoptosis, peri- and intraislet fibrosis and macrophage infiltration, pancreatic gene expression of VCAM-1, MCP-1, CTGF and ACE were evaluated.
Results: Repeated intraperitoneal injections of recombinant human OPG in C57B1/6J mice significantly decreased β-cell mass (-28%; $p<0,005$) and density (-20%; $p<0,001$) and increased β-cell apoptosis (+38%; $p<0,001$), intraislet fibrosis (+24%; $p<0,001$) and peri- and intraislet macrophage infiltration (+44% and +66% respectively; $p< 0,001$) compared to untreated mice. OPG administration was also associated with hyperglycemia and reduced plasma insulin levels. In addition, OPG induced pancreatic gene overexpression of VCAM-1, MCP-1, CTGF and ACE.
Conclusion: The present study shows that OPG delivery leads to significant pancreatic islet structural and functional alterations, thus suggesting a possible role for OPG in the pathogenesis of diabetes.

PTPN2 and MDA5, two candidate genes for type 1 diabetes, modify beta cell responses to double-stranded RNA
M.L. Colli, F. Moore, E.N. Gurzov, F. Ortis, D.L. Eizirik;
Laboratory of Experimental Medicine, Université Libre de Bruxelles, Belgium.

Background and aims: Beta cell destruction in early type 1 diabetes (T1D) is at least in part the consequence of a "dialog" between beta cells and the immune system. This dialog may be affected by the individual's genetic background. We presently evaluated whether modulation of two candidate genes for T1D, namely PTPN2 and MDA5, affects beta cell responses to double-stranded RNA (dsRNA), a by-product of viral replication.
Materials and methods: Candidate genes to be tested were selected by comparison between known candidate genes for T1D and genes expressed in pancreatic beta cells, as identified in previous array analysis from our group. This search identified two genes, PTNP2 and MDA5. Next, INS-1E and primary FACS-purified rat beta cells were transfected with control or siRNAs targeting PTPN2 or MDA5 and then exposed to intracellular polyinosinic-polycytidylic acid (PIC), a synthetic dsRNA. Two different PICs, one with 100-2,000 bp and the other with >2,000 bp, were used. Real time RT-PCR, Western Blot, and viability assays (Hoechst/PI) were performed to characterize beta cell gene/protein expression and viability.
Results: PIC induced an increase in PTPN2 (>2-fold) and in MDA5 (>28-fold) mRNA expression in INS-1E cells ($n = 3$-4; $P<0.05$), which was inhibited by >80% using specific siRNAs ($n = 3$-4; $P<0.05$). Similar findings were observed in primary beta cells. PIC induced 20.0±1.7% and 31.5±3.2% cell death after 24 h, as compared to 4.0±0.5% and 4.3±0.8% cell death in respectively control INS-1E or primary beta cells ($P<0.05$). Cell death was increased by 83.9% and 23.3% ($n = 4$-6; $P<0.05$) by the siRNA targeting PTPN2 in respectively INS-1E and primary beta cells, while the siRNA against MDA5 failed to modify dsRNA-induced apoptosis. On the other hand, the siRNA targeting MDA5 decreased PIC-induced expression of mRNAs coding for interferon beta (13.5-fold), CXCL10 (4.9-fold), interleukin 15 (2.1-fold), CCL2 (42.9-fold) and CCL5 (6.9-fold) ($n = 4$; $P<0.05$), while the siRNA targeting PTPN2 produced only minor changes in CXCL10 (1.2-fold) and interleukin 15 (1.6-fold) ($n = 3$), without changing expression of interferon beta, CCL2 and CCL5 in INS-1E cells. In preliminary experiments ($n = 2$-4), similar results were obtained in primary beta cells.
Conclusion: The present findings indicate that changes in PTPN2 and MDA5 expression modify beta cell responses to dsRNA. While MDA5 modulates the pro-inflammatory signals induced by dsRNA, PTPN2 seems to function as a defence mechanism against the pro-apoptotic signals generated by dsRNA. This suggests that PTPN2 and MDA5, two candidate genes for type 1 diabetes, modulate beta cell apoptosis and/or insulitis independently of their presumed regulatory roles in the immune system.

XOMA 052, a monoclonal antibody that regulates interleukin-1 beta (IL-1 beta) activity: an example of a new class of regulatory antibody drugs that may confer a unique advantage in the treatment of type 2 diabetes mellitus

M.K. Roell, M. White, H. Issafras, K. Michelson, S. Vanegas, L. Gross, S. Lee, A. Mirza, J. Hunter, J. Corbin, S. Kantak, S. Doberstein;
Research, XOMA (US) LLC, Berkeley, United States.

Background and aims: IL-1 beta exerts biphasic effects on pancreatic beta cell function; it is beneficial at low concentrations and pathological at high concentrations. At low concentrations IL-1 beta acts as a stimulatory, growth, and survival factor for beta cells, leading to increased insulin secretion, increased proliferation, and reduced apoptosis. In type-II diabetes, increased secretion of IL-1 beta by beta cells results in macrophage infiltration which is hypothesized to contribute to loss of beta cell function and mass. Here we describe XOMA 052, an ultra-high affinity (0.3 pM) antibody that regulates, rather than blocks, IL-1 beta activity.
Materials and methods: XOMA 052 activity was characterized in vitro by analysis of binding kinetics for IL-1 beta and its receptors using surface plasmon resonance and kinetic exclusion assays. Neutralization of IL-1 beta mediated cytokine induction and proliferation by XOMA 052 was evaluated in multiple cell-based functional assays, including cell lines and whole blood assays.
Results: We demonstrate that XOMA 052 reduces the affinity of IL-1 beta for the soluble form of its signaling receptor, IL-1 Receptor I (RI) approximately ten-fold, and further reduces binding by IL-1 Receptor Accessory Protein (RAcP) extracellular domain another two-fold. Such a reduction in affinity would predict that binding of IL-1 beta by XOMA 052 will result in less efficient formation of the complex responsible for initiation of IL-1 beta-stimulated signal transduction, and thus a less sensitive dose-response to IL-1 beta stimulation. We have shown in multiple cell-based functional assays that XOMA 052 causes such a shift in the dose-response curve for IL-1 beta-stimulated responses. We have shown that XOMA 052 does not reduce the binding affinity of IL-1 beta to soluble IL-1 Receptor II (RII), which neutralizes IL-1 beta, and in its membrane bound form may facilitate clearance of IL-1 beta. We hypothesize that XOMA 052 may allow for low levels of beneficial IL-1 beta signaling while attenuating pathologically high levels and permitting the normal physiological mechanisms to clear IL-1 beta.
Conclusion: XOMA 052 regulates, rather than blocks IL-1 beta activity through its differential effects on the cytokine's binding to receptors responsible for signaling, neutralization, and clearance of IL-1 beta. This may be the first example of a new class of therapeutic antibodies that uses a novel strategy to regulate rather than shut down a targeted pathway to mitigate disease pathology while facilitating homeostatic regulation.

PS 14 Oxidative stress and ROS in beta cells

371

The role of mimitin in insulin-producing cells

K. Hanzelka[1], E. Gurgul-Convey[1], J. Jura[2], S. Lenzen[1];
[1]Institute of Clinical Biochemistry, Hannover Medical School, Germany, [2]Institute of Cell Biochemistry, Jagiellonian University, Cracow, Poland.

Background and aims: Proinflammatory cytokines, especially IL-1 are main mediators of pancreatic beta cell destruction and death in T1DM. Cytokines affect the expression of many genes and lead to both oxidative and nitrosative stress. Beta cell mitochondria are the central place of cytokine-induced beta cell death. Mimitin is a mitochondrial protein which has recently been discovered in human glioblastoma cells and was shown to be involved in cell proliferation. The expression, regulation and function of mimitin in insulin-producing cells is unknown. The aim of the study was to evaluate the role of mimitin in insulin-producing cells.
Materials and methods: Insulin-producing INS1E cells were were incubated with IL-1 600 U/ml or with a cytokine mixture (IL-1 60 U/ml, TNFα 185 U/ml und IFNγ 14 U/ml) in the absence or presence of an iNOS blocker (L-nitro-Arginine, 5 mM) for 6, 12 or 24 h. Thereafter RNA was isolated. Mimitin gene expression was analyzed by Real-Time PCR and corrected to beta actin levels. To study the localization of mimitin, cells were transiently transfected with pmaxFP™-green-Mimitin and incubated with a MitoTracker® Deep Red FM, and then analyzed by means of fluorescence microscopy. The pcDNA3-human mimitin vector was used to overexpress the protein in INS1E cells. The INS1E-hMimitin cells were incubated with cytokines for 72 h. Cell viability was measured by MTT assay and cell proliferation by BrdU ELISA. Insulin secretion was measured by RIA.
Results: Insulin-producing cells express mimitin on a very low level and the protein is expressed in the mitochondria. Cytokines downregulate mimitin expression after shorter incubations (6 h IL-1 87 %, cytokine mix 48 %; 12 h IL-1 72 %, cytokine mix 62 %, vs. untreated 100 %), but upregulate it after longer time periods (24 h IL-1 175 %, cytokine mix 147 %). Interestingly, the cytokine effects depend on NO, because the iNOS blocker counteracted cytokine-induced changes in mimitin expression (6 h IL-1 81 %, cytokine mix 85 %; 12 h IL-1 75 %, cytokine mix 107 %, 24 h IL-1 96 %, cytokine mix 78 %). INS1E-hMimitin cells show approximately 400-fold higher mimitin expression than untransfected cells. Overexpression of mimitin protected insulin-producing cells against cytokine toxicity (MTT 72 h: INS1E IL-1 57 %, cytokine mix 16 % vs. INS1E-hMimitin IL-1 85 %, cytokine mix 25 %). INS1E cells overexpressing mimitin exhibited a significantly higher basal proliferation rate compared to untransfected cells (160 % vs. control cells) and the suppressive effects of cytokines towards cell proliferation were successfully counteracted by mimitin overexpression (72 h: INS1E: IL-1 66%, cytokine mix 35%, INS1E-hMimitin IL-1 94%, cytokine mix 68 %). Basal insulin secretion was in INS1E 0.47±0.03 ng/ml/μg DNA and in INS1E-hMimitin 0.44±0.04. Glucose (30 mM) and KCl (25 mM) induced stronger insulin secretion in INS1E-hMimitin cells than in control cells (INS1E: 30 mM Glc 255%, KCl 430 %, INS1E-hMimitin 404 %, KCl 678 %). Mimitin overexpression counteracted completely IL-1 reduction in glucose- or KCl-induced insulin secretion, and the protective effect was weaker in the case of the cytokine mixture.
Conclusion: Mimitin is a novel, mitochondrial protein, its expression is regulated by cytokines and NO. Mimitin prevents cytokine-induced death of insulin-producing cells and stimulates cell proliferation. Importantly, mimitin counteracts also deleterious effects of cytokines on glucose-induced insulin secretion.

372

Modulation of K_{ATP} channels increases the activity of antioxidant enzyme systems and protects beta cells against ROS-induced cell damage

M. Düfer[1], B. Gier[1], P. Krippeit-Drews[1], L. Aguilar-Bryan[2], J. Bryan[2], G. Drews[1];
[1]Pharmazeutisches Institut, Universität Tübingen, Germany, [2]Pacific Northwest Research Institute, University of Washington, Seattle, United States.

Background and aims: We observed that K_{ATP} channel-deficient islet cells (SUR1-KO) were less sensitive to H_2O_2-induced alterations in membrane potential, $[Ca^{2+}]_c$ and insulin secretion compared to wildtype (WT) islets. In

addition SUR1-KO islet cells were protected against ROS-induced apoptosis. The aim of the present study was to elucidate whether similar effects could be evoked by modulation of K_{ATP} channel activity by sulfonylureas and to identify the underlying mechanisms.
Materials and methods: Apoptotic beta cells were identified by TUNEL and NucView™ (determination of active caspase3) labeling, respectively. Activity of catalase (Cat), superoxide dismutase (SOD) and glutathione peroxidase (GPx) was measured by suited enzyme assays.
Results: One hour incubation of WT islet cells with H_2O_2 or SNOC increased apoptotic cell death 3.0±0.4-fold (10 μM H_2O_2, n=3, P<0.01), 4.0±0.3-fold (25 μM H_2O_2, n=5, P<0.01) and 2.7±0.4-fold (100 μM SNOC, n=3, P<0.01), respectively. In contrast, the fraction of apoptotic cells was not affected by 10 μM H_2O_2 (n=3) or by 100 μM of the NO donor SNOC (n=3) in SUR1-KO islet cells and the effect of 25 μM H_2O_2 was much less pronounced vs WT (n=3). Protection against H_2O_2-induced loss of cell viability could also be achieved in WT islet cells by preincubation (4 hours) with tolbutamide (25 μM) or gliclazide (10 μM) (n=3). Next we tested whether KO or inhibition of K_{ATP} channels affected antioxidant enzyme systems. In SUR1-KO islets we observed an approximately 2-fold increase in the activity of SOD (n=4, P<0.05), Cat (n=3, P<0.001) and GPx (n=5, P<0.05), respectively, compared to WT islets. Importantly, treatment of WT islet cells with tolbutamide (100 μM) or gliclazide (10 μM) for four hours also elevated the activity of SOD (19±1 U/mg protein under control conditions vs. 34±3 U/mg protein after gliclazide treatment, n=3; P<0.01) and Cat (15±2 mU/mg protein vs. 26±2 mU/mg protein, n=3, P<0.05). The sulfonylurea-induced activation of SOD critically depended on $[Ca^{2+}]_c$ and was diminished by blocking Ca^{2+} influx through L-type Ca^{2+} channels (n=3).
Conclusion: Regarding ROS-induced cell damage the protective effects of K_{ATP} channel ablation is mimicked by pharmacological reduction of K_{ATP} channel activity. Both manoeuvres induced an up-regulation of antioxidant enzymes. The data indicate that modulation of K_{ATP} channel activity might provide a useful strategy to improve the resistance of pancreatic beta cells during periods of increased oxidative stress.

Endogenous production of hydrogen sulfide by beta cells protects against oxidative stress-mediated cell death
J.G. Mabley, W.-W. Li, P.K. Chatterjee;
School of Pharmacy & Biomolecular Sciences, University of Brighton, United Kingdom.

Background and aims: ß-cells produce hydrogen sulfide from L-cysteine via the enzyme cystathionine gamma-lyase (CSE). Hydrogen sulfide production in ß-cells has inhibitory effects on insulin secretion and as CSE expression increases in diabetes may participate in loss of ß-cell function. However, hydrogen sulfide is protective in a variety of disease states including those mediated by oxidative stress, the mechanisms involved range from induction of cytoprotective enzymes to direct interaction with reactive oxygen species. Hyperglycaemia increases cellular production of methylglyoxal leading to oxidative stress. Methylglyoxal levels are increased in Type I and II diabetics and may be involved in development of both diabetic complications and ß-cell dysfunction. The aim of this study was to examine whether endogenous ß-cell production of hydrogen sulfide protects against oxidative stress-mediated cell death induced by methylglyoxal.
Materials and methods: The BRIN-BD11 ß-cell line was exposed to methylglyoxal (MGO, 1 or 2 mM) or hydrogen peroxide (0.3 or 1 mM) for 4h either alone or in combination with 0.3, 1 or 3 mM L-cysteine or a hydrogen sulfide donor, sodium hydrogen sulfide. Cell viability was determined using the MTT assay and cell death assessed by propidium iodide and Hoechst staining. Inhibitors of CSE, DL-propargylgylcine (PAG, 3 mM), and glutathione synthesis, buthionine sulfoximine (BSO, 1 mM), were used in combination with L-cysteine.
Results: MGO exposure reduced ß-cell viability to 43±6% and 25±2% for 1 and 2 mM respectively (p<0.01). Simultaneous application of L-cysteine protected the ß-cells from MGO-mediated loss of cell viability; with 0.3, 1 and 3 mM L-cysteine in combination with 1 mM MGO increasing viability to 86±3%, 97±2% and 102±2% and in combination with 2 mM MGO to 59±8%, 63±7% and 86±3% (p<0.01 vs. MGO alone). This protective effect of 0.3 and 1 mM L-cysteine was blocked by 3 mM PAG (45±2% and 48±1% with 1 mM MGO, 28±1% and 27±4% with 2 mM MGO). BSO had no effect on the protective effect of L-cysteine ruling out the conversion of L-cysteine to glutathione as the mechanism of protection. MGO increased ß-cell apoptosis from 3±1% to 16±2% and 21±3% for 1 and 2 mM MGO respectively (p<0.01). L-cysteine treatment again protected against this MGO-mediated increase in apoptosis with 1 mM L-cysteine reducing apoptosis to 5±2% and 8±3% when applied in combination with 1 or 2 mM MGO, an effect which was again blocked by PAG but not BSO. Simultaneous application of exogenous hydrogen sulfide dose dependently protected ß-cells from MGO-mediated loss of cell viability; with 0.3, 1 and 3 mM hydrogen sulfide in combination with 1 mM MGO increasing cell viability to 71±6%, 71±5% and 73±4% respectively and in combination with 2 mM MGO to 62±7%, 67±7% and 71±5% (p<0.01 vs. MGO alone). Hydrogen sulfide (3 mM) also reduced the levels of apoptosis observed with 1 or 2 mM MGO to 8±2% and 11±3% respectively (p<0.05 vs. MGO alone). Similar results were observed when hydrogen peroxide was used as the oxidative stress inducer.
Conclusion: (i) Endogenous production of hydrogen sulfide from L-cysteine or exogenously applied hydrogen sulfide, via a donor, protects ß-cells against methylglyoxal-mediated ß-cell death and therefore may act as an anti-oxidant defence system for ß-cells. (ii) Increased production of hydrogen sulfide by ß-cells in diabetes may be detrimental to cellular function in the short term but may act to protect the ß-cell from cell death in the long term.

374

Protective effect of glucokinase activation against hydrogen peroxide-induced cell death in a model of pancreatic beta cells
M. Futamura[1], H. Maruki[1,2], H. Shimazaki[1], H. Hosaka[1], J. Kubota[1], T. Nakamura[1], R. Yamashita[1], T. Lino[1], T. Nishimura[1], B.B. Zhang[2], J.-I. Eiki[1]; [1]Banyu Pharmaceutical, Tsukuba, Japan, [2]Merck Research Laboratories, Rahway, United States.

Glucokinase (GK) functions as the glucose sensor in pancreatic β-cells to enhance insulin release. Recently, GK was found to form a complex with a pro apoptotic protein BAD in mitochondrial membrane, suggesting that GK is involved in apoptotic signaling pathway. We investigated the effect of a small molecule GK activator (Cpd B) on cell death in MIN6 cells, a mouse insulinoma cell line. Cpd B activates the recombinant GK with EC50 of 70 nM in the presence of 10 mM glucose. When incubated with MIN6 cells at 1 μM, Cpd B prevented hydrogen peroxide (H_2O_2)-induced acute cell death (% cell survival was 66±1.2 for the H2O2-treated group and 93±1.7 for Cpd B treated group, $p < 0.05$, n=3). Pyruvate, a metabolic intermediate of glycolysis, also protected MIN6 cells from H_2O_2-induced cell death. An increase of intracellular NADH level was observed by the treatment of Cpd B or pyruvate. In contrast, a sulfonylurea (SFU) agent glipizide did not show such protective effect, indicating that an autocrine effect of insulin does not account for the suppression of acute cell death. Furthermore, Cpd B suppressed apoptotic cell death caused by glucose depletion in cultured MIN6 cells. The anti-apoptotic effect of Cpd B was not affected by inhibitors of insulin release such as somatostatin and diazoxide, however, it was blocked by respiratory chain inhibitors. Investigation of glucose metabolism revealed that Cpd B but not SFU increased glucose metabolism, ATP content and mitochondrial membrane potential in the cells, suggesting that GK activation prevents apoptosis through preservation of mitochondrial oxidative phosphorylation activity and ATP production. Consistent with this finding, Cpd B remarkably increased the level of GK associated with mitochondria even under low glucose conditions. Taken together, activation of glucose metabolism pathway and increased GK association with mitochondria could account for the anti-apoptotic effect of Cpd B. GK activators may have a potential for protecting β-cells from deterioration typically associated with type 2 diabetes.

375

Role of oxidative stress in the alterations of pancreatic beta cell survival and function induced by prolonged culture in low glucose
S.M.A. Pascal, J.-C. Jonas;
Unit of Endocrinology and Metabolism, Faculty of Medicine, Université catholique de Louvain, Brussels, Belgium.

Background and aims: Prolonged exposure of rodent beta cells to extreme low glucose concentrations markedly reduces *preproinsulin* gene expression and glucose-stimulated insulin secretion (GSIS) while triggering apoptosis. The latter, which is prevented by antioxidants, likely results from an increase in oxidative stress. However, whether oxidative stress contributes to the reduction of GSIS under this condition is unknown. Here, we tested the effect

of the catalytic antioxidant Manganese (III)tetrakis (4-benzoic acid) porphyrin (MnTBAP) on the alterations of beta cell function and survival during prolonged culture in low glucose.
Materials and methods: Male Wistar rat islets were cultured for 1 week in RPMI medium containing 5g/l BSA and 5-10 mM glucose (G5-G10) with or without 50 μM MnTBAP. After culture, glucose-induced changes in intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$) and insulin secretion were measured in perifused islets. DNA fragmentation was measured with a commercial ELISA and gene mRNA levels by RT-qPCR. Results are means ± SEM for at least 8 islets from 3 experiments. Statistical significance of differences between groups was assessed by unpaired t-test or 2-way ANOVA followed by a test of Bonferroni.
Results: After culture in G10, acute stimulation from 0.5 to 20 mM glucose induced a transient decrease in $[Ca^{2+}]_i$ followed by a rapid rise in $[Ca^{2+}]_i$ and insulin secretion that was further increased by depolarizing islets with 30 mM extracellular K^+ (K30). In contrast, after culture in G5, the insulin secretory response to both stimuli was markedly reduced (by 99%, P<0.001), owing to a lack of glucose-induced rise in $[Ca^{2+}]_i$ (*P*<0.001) without changes in the response to K30, and to an ~70% reduction in islet insulin/DNA content ratio (*P*<0.001). These functional alterations were associated with an ~87% decrease in *preproinsulin* mRNA levels (*P*<0.001), a marked upregulation of the mRNA levels of the pro-apoptotic factor *c-Myc* (~16-fold, *P*<0.001) and of the oxidative stress-response genes *Heme oxygenase 1* (*Hmox1*) (~3-fold, *P*<0.001) and *Metallothionein 1a (Mt1a)* (~67-fold, *P*<0.001), and a 7-fold increase in islet cell apoptosis (*P*<0.001). As expected, the porphyrin derivative MnTBAP increased *Hmox1* mRNA levels under all culture conditions and did not affect beta-cell survival and function during culture in G10. In contrast, MnTBAP significantly reduced islet oxidative stress during culture in G5, as shown by a 50-70% reduction in *c-Myc* and *Mt1a* mRNA levels (*P*<0.001) and a 50% decrease in islet cell apoptosis (*P*<0.01). Despite these beneficial effects, MnTBAP only improved the glucose-induced $[Ca^{2+}]_i$ rise 2.5-fold (*P*<0.05), GSIS 4-fold (*P*=0.083), the insulin to DNA content ratio 1.5-fold (*P*<0.05) and *preproinsulin* mRNA levels 1.5-fold (*P*=0.062) in islets cultured in G5. As a result, the reduction in beta cell glucose responsiveness was still inhibited by ~97% as compared with islets cultured in G10 with or without MnTBAP.
Conclusion: An ~50-70% reduction in oxidative stress and islet cell apoptosis during culture in 5 vs 10 mM glucose is not sufficient to improve the beta cell ability to respond to a subsequent glucose challenge. These results suggests that beta cell function is more sensitive than islet cell survival to moderate levels of oxidative stress. Alternatively, the loss of GSIS after culture in G5 is mostly independent from the induction of islet cell oxidative stress and apoptosis.

Generation of oxidative stress is responsible for the sustained activation of the transcriptional repressor ICER in beta cells

D. Favre[1], F. Allagnat[1], G. Niederhäuser[1], V. Plaisance[1], J.-A. Haefliger[1], R. Regazzi[2], G. Waeber[1], A. Abderrahmani[1];
[1]Service of Internal Medicine, Centre Hospitalier Universitaire Vaudois (CHUV), [2]Department of Cell Biology and Morphology, University of Lausanne, Switzerland.

Background and aims: Type 2 diabetes (T2D) develops in patients whose pancreatic β-cells fail to secrete enough insulin to compensate for insulin resistance. Environmental stressors such as chronic hyperglycaemia and elevated levels of free fatty acids contribute to β-cell failure by generating oxidative stress (OS) and promoting sustained activation of the inducible cAMP early repressor (ICER). Oxidised LDL (oxLDL) are also thought to participate in the pathogenesis of T2D. The ratio of the plasma circulating levels of oxLDL-cholesterol particles over native LDL are increased in diabetic patients. Independent studies have shown the adverse effects of oxLDL on insulin synthesis, secretion and on β-cell survival. In this study, we investigated whether ICER activation is responsible for the oxLDL-induced β-cell dysfunction and, since these modified lipoproteins induce OS, we sought for a potential link between induction of ICER and OS.
Materials and methods: Native LDL fractions were freshly prepared from plasma of human healthy donors by sequential centrifugation. In vitro oxidization of LDL by copper was adjusted to obtain oxidised LDL qualitatively similar to those observed in patients. The lipoprotein preparations were dialyzed against phosphate-buffered saline and culture medium to remove copper and salts. Mouse MIN6 insulin-secreting cells and isolated rat islets were exposed to 2 mM oxLDL-cholesterol or 150 μM hydrogen peroxide (H_2O_2) in the presence or absence of 1mM of the antioxidant N-acetylcysteine (NAC).
Results: Exposure of MIN6 cells and rat isolated islets to 2mM of oxLDL-cholesterol particles induced a drastic rise in the content and activity of ICER. In line with the induction of ICER, the expression of target genes important for synthesis and secretion of insulin such as the exocytotic genes (Rab3a, granuphilin, Noc2 and Rab27) and connexin 36 were diminished and nutrients-induced insulin secretion was impaired. Islet brain 1 (IB1) is a JNK scaffold protein that preserves β-cells against JNK-mediated apoptosis provoked by many pro-apoptotic stressors. IB1 has been recently identified as an ICER target gene and its expression is reduced in the cells cultured with oxLDL. Suppression of ICER by small interfering RNAs prevented the loss of expression of all its target genes evoked by oxLDL and improved β-cell function. Implication of OS in the activation of ICER was demonstrated by the up-regulation of the transcriptional repressor in β-cells treated with H_2O_2. Co-incubation of the cells with 1mM of the antioxidant NAC abrogated induction of ICER, and restored nutrients-induced insulin release.
Conclusion: The data show that persistent induction of ICER mediates the harmful effects of oxLDL and emphasize OS as the mechanism involved in this dysregulation.

Cytoprotective effect of prostacyclin synthase overexpression in insulin-producing cells

E. Gurgul-Convey, S. Lenzen;
Institute of Clinical Biochemistry, Hannover Medical School, Germany.

Background and aims: Proinflammatory cytokines play a crucial role in the pathogenesis of type 1 diabetes, a disease with an inflammatory background. One of the cytokine-regulated pathways is the arachidonic acid metabolism pathway, comprising the induction of cyclooxygenases and the production of different prostaglandins. Through this pathway cytokine toxicity is mediated in many cell types, including pancreatic beta cells. Interestingly, some cell types have been shown to be insensitive to such toxicity and this correlated with a high expression of prostacyclin synthase. Therefore it was the aim of this study to evaluate the role of prostacyclin and the molecular mechanisms underlying its effects in insulin-producing cells.
Materials and methods: Insulin-producing cells were stably transfected with the pcDNA3.1-hPGIS. Cells were treated with IL-1β 600 U/ml or with a cytokine mixture (IL-1β 60 U/ml, TNFα 185 U/ml, IFNγ 14 U/ml) for 72 h and thereafter cell viability was measured by MTT test, proliferation by a BrdU ELISA and caspase-3 by a chemiluminescent method. NFκB and iNOS promoter were analyzed by a SEAP-reporter gene assay. iNOS WBs were performed and nitrite was measured by Griess assay. Glucose oxidation was estimated by use of [U-^{14}C]glucose.
Results: The endogenous prostacyclin synthase expression in rat pancreatic islets and in insulin-producing RINm5F cells is extremely low (around 5 and 1 %, respectively, of that found in rat liver). Cytokines were toxic in control cells (MTT, IL-1β 67 %, Mix 40 % viable cells), but not in PGIS overexpressing cells (MTT, IL-1β 91%, Mix 85 % viable cells). Cytokines slowed down proliferation of control cells (IL-1β 88 %, Mix 55 %), but not in PGIS overexpressing cells (IL-1β 102 %, Mix 84 %). Similarly, caspase-3 was significantly activated by cytokines in control cells (IL-1β 10-fold, Mix 5-fold induction), but this induction was counteracted by PGIS overexpression (IL-1β 13 %, Mix 200 %). This effect was specific for cytokines, because camptothecin induced caspase-3 activation in the same manner in control and PGIS cells (6-fold). NFκB and iNOS promoter were highly activated by cytokines in the control cells (NFκB IL-1β 217 %, Mix 190 %; iNOS promoter IL-1β 422 %, Mix 531 %) and, again, this activation was significantly lower in PGIS cells (NFκB IL-1β 111 %, Mix 119 %; iNOS promoter IL-1β 163 %, Mix 153 %). Also the cytokine-stimulated iNOS protein induction was high in control cells and extremely low in PGIS cells. Nitrite levels were elevated in control cells treated with cytokines (IL-1β 3.9±0.7 vs. Mix 4.7±0.5 pmol/μg protein), but there was virtually no nitrite in cytokine-treated PGIS cells. Cytokines significantly decreased glucose oxidation in control cells (IL-1β 63 %, Mix 34 % vs. untreated 100 %), and, in contrast, induced it in PGIS cells (IL-1β 286 %, Mix 376 %).
Conclusion: Prostacyclin synthase overexpression had a large protective effect against cytokine toxicity in insulin-producing cells. This protective effect of PGIS against cytokine toxicity correlated with a decreased activation of the transcription factor NFκB and the iNOS promoter as well as a reduced iNOS protein expression and nitrite production. Moreover, cytokine-induced caspase-3 activation and reduction of glucose oxidation and cell proliferation were suppressed by PGIS overexpression Thus, prostacyclin synthase overex-

pression may represent a novel strategy for protection of pancreatic beta cells against inflammation-based destruction during T1DM development.

378

Intermittent hypoxia-specific expression of CCL2, CXCL9, and CXCL10 genes via NFkappaB activation in pancreatic beta cells

H. Ota, S. Tamaki, A. Itaya-Hironaka, A. Yamauchi, S. Sakuramoto-Tsuchida, T. Morioka, Y. Dohi, S. Takasawa, H. Kimura; Nara Medical University, Kashihara, Japan.

Background and aims: Obstructive sleep apnea syndrome (OSAS) is a highly prevalent sleep disorder characterized by cyclic intermittent hypoxia. Metabolic syndrome characterized with obesity, hypertention, dyslipidemia, and hyperglycemia is prevalent in OSAS, which recently comes to be considered as an inflammatory systemic disease. Chemokines enhance the inflammatory response by recruiting immune-cells to sites of injury or inflammation. Although diabetes is frequently associated with OSAS, effects of intermittent hypoxia on chemokine gene expression in beta-cells are elusive.
Materials and methods: Rat insulinoma RINm5F cells were exposed to sustained hypoxia (1% O2) for 24 hours, 64 cycles of intermittent hypoxia (5 min hypoxia (1% O2)/10 min normoxia (21%O2)), or normoxia. Total RNA was prepared from sustained hypoxia-, intermittent hypoxia-, and normoxia-treated cells. Quantitative RT-PCR of CCL2, CCL20, CXCL2, CXCL9, CXCL10, and pancreatic derived factor (PANDER) was performed using sustained hypoxia-, intermittent hypoxia-, or normoxia-treated cell RNA as template. RINm5F cells were transiently transfected with reporter plasmid consisting of a luciferase reporter gene under the control of consensus binding sites for stress-related transcription factors, nuclear factor kappa B (NFkappaB), hypoxia induced factor (HIF), interferon regulatory factor 1, heat shock transcription factor (HSF), serum response factor (SRF), activator protein 1 (AP-1), or cyclic AMP responsive element binding protein (CREB). After transfection, cells were exposed to sustained hypoxia, intermittent hypoxia, or normoxia for 24 hours. Transcriptional activation was measured by luciferase activity of the cell extract.
Results: Quantitative RT-PCR revealed that mRNAs of CXCL10 (1.9 fold), CCL2 (6.3 fold), and CXCL9 (12 fold) were increased by intermittent hypoxia. By reporter assay, we found that NFkappaB was activated by intermittent hypoxia (% increase over normoxia; 40.1±10.6%, $p<0.05$) but not by sustained hypoxia. HSF (32.4±6.0%, $p<0.005$), SRF (44.9±6.6%, $p<0.005$), AP-1 (73.6±9.6%, $p<0.0005$), and CREB (115.0±11.9%, $p=0.0001$) were activated by sustained hypoxia.
Conclusion: NFkappaB but not HIF, HSF, SRF, AP-1 nor CREB was activated by intermittent hypoxia in pancreatic beta-cells to induce expression of CCL2, CXCL9, and CXCL10 genes. These chemokines could directly or indirectly damage beta-cells to induce apoptosis. In fact, CD95 mRNA was significantly induced by intermittent hypoxia in beta-cells. These results indicate that NFkappaB activation is a key step of chemokine induction in pancreatic beta-cells by intermittent hypoxia and suggest possible mechanism of hypoxia-reperfusion injury of beta-cells induced by cycles of hypoxia- reoxygenation in OSAS patients.

Is autophagy the mechanism of dioxin-induced cell death of the beta cell line INS-1E?

V. De Tata, M. Masini, L. Martino, M. Novelli, P. Masiello; Experimental Pathology, University of Pisa, Italy.

Background and aims: Several epidemiological studies have clearly demonstrated a positive correlation between dioxin exposure and type 2 diabetes incidence. In order to clarify the biological basis of this correlation we have previously demonstrated that 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) is highly toxic for INS-1E cells and that, even at very low doses, markedly impairs glucose-stimulated insulin secretion. The aim of this research has been to further investigate the mechanism of the acute TCDD citotoxicity in INS-1E cells.
Materials and methods: INS-1E cells were exposed for 1 hr to TCDD either alone or in the presence of different concentrations (0-300 μM) of epigallocatechin-3-gallate (EGCG), the main polyphenol component of green tea. We have then assayed: 1) cell survival by WST-1; 2) ultrastructural alterations by electron microscopy; 3) mitochondrial membrane potential by cytofluorimetry; 4) changes in intracellular calcium concentrations by fluo-3/AM-based fluorimetry; 5) glucose-stimulated insulin secretion.
Results: Our results show that EGCG was able to significantly increase, in a dose-related manner, the survival of INS-1E cells exposed for 1 h to 12.5 or 25 nM TCDD. Besides evidence of apoptosis or necrosis in many cells, one of the most interesting ultrastructural alterations induced by 1 h exposure to TCDD was a remarkable activation of autophagy, as indicated by the presence of several large autophagic vacuoles containing identifiable organelles, such as mitochondria or degraded membranes. Autophagy was further confirmed by monodansyl cadaverine fluorescence. In EGCG-protected cells, necrosis or apoptosis were significantly reduced and autophagic vacuoles were no longer found after 1 hr exposure to TCDD. Conversely, ultrastructural evidence of autophagy activation was found in both unprotected and EGCG-protected INS-1E cells after 10 and 30 min of exposure to TCDD. EGCG had no effect on TCDD-induced increase in intracellular calcium concentration, but significantly prevented TCDD-induced mitochondrial depolarization. Finally, EGCG was also able to fully prevent TCDD-induced impairment of glucose-stimulated insulin secretion.
Conclusion: Our study clearly shows that EGCG is highly effective in preventing TCDD toxicity in INS-1E cells, in terms of both cell survival and preservation of their functional properties. Moreover, our ultrastructural findings show that the protective effect of EGCG does not inhibit the early activation of autophagy induced by TCDD. Autophagy is a mechanism for bulk degradation of cytosolic proteins and organelles which has been claimed to be the hallmark of a new type of programmed cell death, the autophagic cell death. Our results rather indicate that in TCDD-induced cytotoxicity, autophagy could be interpreted as a pro-survival mechanism. The protective effect of EGCG could be likely related to its ability to preserve mitochondrial function in INS-1E cells, thus preventing apoptosis and impairment of glucose-stimulated insulin secretion.

380

Restoration of glucose stimulated insulin secretion by copper addition - a possible role of interleukin-1β and oxidative stress

G. Aharon-Hananel[1], S. Lenzen[2], A. Jorns[3], I. Raz[1], S. Weksler-Zangen[1]; [1]Diabetes Center, Hadassah University Hospital, Jerusalem, Israel, [2]Institute of Clinical Biochemistry, Hannover Medical School, Germany, [3]Centre of Anatomy, Hannover Medical School, Germany.

Background and aims: Cytokines are mediators of β-cell dysfunction in diabetes. When fed high-sucrose low-copper diet (HSD), Cohen diabetic sensitive (CDs) rats exhibit hyperglycemia while resistant (CDr) rats remain normoglycemic. Prevention of β-cell dysfunction was obtained in the CDs rats by addition of adequate (15ppm) copper (Cu) concentration to HSD (HSD-Cu). In the CDs-rat, hyperglycemia was associated with exocrine infiltration of macrophages secreting IL1-β which may promote the production of free radicals and a successive diminished glucose stimulated insulin secretion (GSIS).
Aim: To analyze the role of IL1-β, oxidative stress and Cu deficiency in the reduced GSIS of the CDs rats.
Materials and methods: Islets isolated from normoglycemic CDs and CDr rats were pre-incubated for 24h w/o IL1-β (1.25-10U/ml), w/o Cu-GHL (0.4-0.7umol/l) or L-NOARG (5mM). Islet insulin-secretion was evaluated (RIA) in KRB + 1.7 or 16.7 mmol/l glucose. In-vivo, OGTT (glucose, 3.5g/kg) and insulin tolerance test (ITT, insulin 0.25U/kg) were performed on CDs rats fed HSD-Cu or treated with aminoguanidine (50mg/kg, i.p.) for 15 days.
Results: In isolated islets, the initial GSIS of CDs was ~2fold lower than CDr (1103±178 vs. 2052±152pmol/l $P=0.001$, respectively). Low IL1- β (1.25U/ml) increased the GSIS of CDr (2581±84 pmol/l $p<0.05$) but had no effect on CDs. 2.5U/ml IL1-β markedly decreased GSIS of CDs but had no effect on CDr (620±97 vs. 2187±262pmo/l, $P<0.001$ respectively). Larger concentrations of IL1-β reduced GSIS of CDs and CDr but had a bigger effect on CDs. Cu completely restored the initial GSIS of CDs (2409±428pmol/l $p=0.02$) up-to the GSIS of CDr and prevented the reduction in GSIS induced by IL1-β in both CDs and CDr. Addition of iNOS inhibitor (L-NOARG) did not affect the reduced initial insulin secretion of CDs but prevented the reduction in GSIS induced by IL1-β in both CDs and CDr. In-vivo, CDs-HSD rats treated with the iNOS inhibitor aminoguanidine or fed HSD-Cu exhibited a reduction of the OGTT-AUC ($P=0.02$ and $P=0.001$ respectively) compared to vehicle treated CDs-HSD rats. Exogenous insulin produced a significant reduction in the ITT-AUC of aminoguanidine and HSD-Cu treated rats (2950±168 and 2549±303 mg/dl/min respectively) compared to vehicle treated rats (4533±531mg/dl/min, $p<0.05$).
Conclusion: In vitro, the initial lower capacity of the CDs-islets to secrete-insulin in response to glucose was restored by Cu but not by iNOS inhibi-

tion. CDs-islets are more sensitive to the deleterious effect of IL1-β compared to CDr. The IL1-β-induced reduction in insulin-secretion was reversed by both Cu and iNOS inhibition. In vivo, Cu and iNOS inhibitor significantly decreased the hyperglycemia of the CDs-HSD rats and increased their peripheral sensitivity to insulin. The ability of iNOS inhibitor to prevent the IL1-β induced reduction in insulin secretion provides a possible link between oxidative stress and β cell dysfunction. The fact that Cu protected the β-cells from the deleterious effect of IL1-β in a similar fashion as iNOS inhibitor suggest that the restoration of β cells function by Cu is at least partially obtained by reducing oxidative stress. Understanding the mechanisms regulating β-cell dysfunction is important for the development of novel disease modifying treatments.

Inhibition of MiR-375 supresses lipoapoptosis in mouse insulin-secreting cell line NIT-1
Y. Li, X.J. Xu, S.Y. Liu, Y. Liang, L. Yan, Z.Z. Fu;
Department of Endocrinology and Metabolism, The Second Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

Background and aims: Free fatty acids (FFAs) -induced apoptosis of pancreatic β-cells, namely lipoapoptosis, has been regarded as a critical determinant in the pathogenesis of Type 2 diabetes (T2D). MiR-375 is a evolutionarily conserved and islet-specific microRNA that is validated as a regulator of insulin secretion. The mechanism underlying the action of miR-375 is due to the reduction in expression of its target gene, myothophin. The purpose of this study was to investigate the role of miR-375 in the lipoapoptosis of a pancreatic β-cell line, NIT-1.
Materials and methods: We transfected mouse β-cell line NIT-1 with miR-375 or antisense oligonuleotide(2′ -O-me-375) to enhance or specifically inhibit miR-375 function .As negative controls ,NC-miR375 and liposome were also transfected. The change in the percentage of apoptotic cells upon palmitate challenge (incubated with 500uM palmitate for 48h) was evaluated by Hochest33342 and terminal deoxynucleotidyl transferase-mediated deoxyuridine triphosphate nick end-labeling (TUNEL) staining, respectively. Meanwhile,western blot for myothophin was performed.
Results: Results showed that overexpression of miR-375 was associated with enhanced pancreatic β-cell lipoapoptosis (TUNEL positive cells:from13.14±4.24%to 24.00±12.53%; hochest33342 stained apoptotic cells:from 14.90±3.52 % to 23.06±12.97%,$P < 0.001$). In contrast, inhibition of endogenous miR-375 function by 2′ -O-me-375 suppressed the lipoapoptosis(TUNEL positive cells:from 13.14±4.24% to 6.06±3.89 %, Hochest33342 stained apoptotic cells:from 14.90±3.52% to 7.86±3.48%,$P < 0.001$). We also found that the protein level of myotrophin is inversely correlated with the percentage of palmitate -induced apoptotic NIT-1 cell.
Conclusion: MiR-375 may serve as a regulator of pancreatic β-cell lipoapoptosis and a potential therapeutic target of Type 2 diabetes.

Palmitate triggers distinct cellular redistribution of PKCdelta and counteracts its degradation in isulin secreting INS-1 cells
F. Ranta, D. Michael, C. Klingler, R. Lammers, H.-U. Häring, S. Ullrich;
Internal Medicine and Clinical Chemistry, University Hospital Tübingen, Germany.

Background and aims: Previous work demonstrated that transgenic mice over-expressing a kinase dead PKCdelta (PKCdeltaKN) in beta-cells are protected from high fat diet - induced impaired glucose tolerance. However, the importance of PKCdelta and the molecular mechanisms underlying high fat diet - induced beta-cell failure are not completely understood. Upon stimulation, PKCdelta translocates to cellular compartments such as plasma membrane, nuclei, mitochondria and endoplasmic reticulum. This translocation is a prerequisite for the regulation of diverse cellular processes by PKCdelta. The present study examines changes in PKCdelta signalling induced by saturated free fatty acids.
Materials and methods: To follow palmitate-mediated subcellular redistribution of PKCdelta, INS-1E cells were transfected with a wild type PKCdelta (PKCdeltaWT) or a kinase dead PKCdelta (PKCdeltaKN) using a retroviral infection system. The expression of PKCdelta was assessed by Western blotting and its subcellular distribution by immunocytochemistry. The percentage of apoptotic cells was quantified by TUNEL versus TOPRO3 DNA staining.
Results: Short term treatment (1-10 min) with palmitate (600 μM) triggered a transient nuclear accumulation of PKCdeltaWT followed by a cytoplasmic redistribution of the kinase. After long term treatment (1 d) with palmitate cytosolic clustering of PKCdelta was observed without any visible degradation. More importantly, after depletion of PKCdelta by treating the cells with phorbol ester for 1 d (PMA, 100 nM) the addition of palmitate resulted in a

significant reappearance of cytosolic PKCdelta protein. In contrast to palmitate, PMA within the first min induced a rapid translocation of PKCdelta to the plasma membrane, followed by a transient nuclear accumulation and perinuclear localisation of the kinase. In INS-1 cells that over-expressed PKCdeltaKN, PKCdelta immunoreactivity accumulated in the nucleus after stimulation with palmitate or PMA without subsequent redistribution and any sign of degradation. Palmitate (600 μM for 2 d) treatment increased the percentage of apoptotic cells 2- to 3-fold in control INS-1 cells and in cells over-expressing PKCdeltaWT. This effect of palmitate was neither inhibited nor mimicked by the phorbol ester (PMA, 100 nM for 2 d).
Conclusion: The increased and sustained expression of PKCdelta in the presence of long term treatment with palmitate may explain that palmitate but not PMA stimulates apoptotic cell death. Nuclear extrusion and degradation of PKCdelta depends on intact kinase activity.

Over-expression of kinase-dead PKCdelta induces cell cycle arrest in insulin secreting INS-1 cells
J. Leveringhaus, F. Ranta, D. Michael, R. Lammers, H.-U. Häring, S. Ullrich;
Internal Medicine and Clinical Chemistry, University of Tübingen, Germany.

Background and aims: The serine/threonine protein kinase C delta (PKCdelta) is a ubiquitously expressed enzyme involved in opposing cellular processes such as apoptosis, cell survival and proliferation. In pancreatic beta-cells PKCdelta was proposed to mediate the pro-apoptotic effect of saturated free fatty acids, but the underlying mechanism is still a matter of debate. Beta-cell dysfunction involves long term transcriptional changes. One transcription factor important for beta-cell survival during oxidative stress is FoxO1. The aim of the present study was to analyse the impact of PKCdelta upon changes in FoxO1 activation and beta-cell survival during palmitate exposure.
Materials and methods: INS-1 cells were transfected with PKCdeltaWT or PKCdeltaKN using a retroviral infection system. Clones that highly over-express the transgene were selected. Cell growth was estimated by cell counting. DNA content of nuclei and the amount of fractionated DNA were assessed after propidium iodide staining (Nicoletti method) with fluorescence activated cell sorting (FACS). The expression and specific phosphorylation of proteins were quantified by Western blotting and their subcellular distribution followed by immunocytochemistry.
Results: INS-1 cells that over-express PKCdeltaKN display a significant reduced growth rate compared to control and PKCdeltaWT over-expressing cells. Both populations of control INS-1 cells and cells over-expressing PKCdeltaWT consist of about 30 % of cells in G1/Go and 70 % of cells in G2. In contrast, the G1/Go DNA peak is missing in the population of cells over-expressing PKCdeltaKN. Almost all intact nuclei of these cells exhibit the double amount of DNA reflecting cell cycle arrest in G2. The PKCdeltaKN over-expressing cells contain reduced amount of FoxO1 that displays increased phosphorylation at Ser256 a prerequisite for nuclear extrusion and degradation of FoxO1. PKCdeltaWT over-expressing cells contain increased amount of FoxO1 with significantly reduced phosphorylation at Ser256. Palmitate induces FoxO1 translocation to the nucleus in control and PKCdeltaWT over-expressing cells while over-expression of PKCdeltaKN counteracts palmitate-induced nuclear accumulation of FoxO1.
Conclusion: The observation that over-expression of PKCdeltaKN reduces cell growth and induces cell cycle arrest at G2 suggests that PKCdelta is involved in the modulation of beta-cell growth. The changes in palmitate-mediated and PKCdelta-dependent FoxO1 distribution disclose a signalling pathway important for free fatty acid-induced beta-cell dysfunction. This mechanism may explain at least in part adaptive changes in beta-cell mass during obesity.

Palmitate-induced dihydrosphingosine-1-phosphate production attenuates ceramide-dependent apoptosis of pancreatic beta cells
J. Veret[1], E.V. Berdyshev[2], A. Skobeleva[2], V. Natarajan[2], B. Portha[1], H. Le Stunff[1];
[1]Unité BFA et CNRS, Laboratoire de Biologie et Pathologie du Pancréas Endocrine, Paris, France, [2]Department of Medicine, Section of Pulmonary and Critical Care Medicine, Chicago, United States.

Background and aims: Type 2 diabetes (TD2) is characterised by beta-cell dysfunction, which correlates with increases in plasma lipids and beta-cell apoptosis. Different mechanisms for the detrimental effects of chronic exposure to long chain fatty acids, in particular palmitate, have been suggested, including the de novo synthesis of ceramide, a bioactive sphingolipid. In mammals, ceramide species differ by the size and the degree of saturation of their carbon chain, suggesting that specific species might have different biological effects. To further our understanding of the role of sphingolipids in the control of palmitate-induced beta-cell apoptosis, a mass spectrometry approach has been carried out to generate a sphingolipidomic profile of palmitate-treated beta-cells.
Materials and methods: INS-1 cells were cultured with 0.4 mM palmitate, various concentrations of glucose in the presence or absence of either sphingosine-1-phosphate (S1P) or N,N-dimethylsphingosine (DMS) for 24h. In some cases, INS-1 cells were transfected with sphingosine kinase 1 (SphK1). INS-1 cell viability was measured by MTT assay. INS-1 cell apoptosis was determined by chromatin condensation assessed by DAPI staining and caspase 3/7 activity assay. SphK activity and ceramide levels were measured by in vitro kinase assay and in vitro DAG kinase assay, respectively. Sphingolipid metabolites were analyzed by mass spectrometry (LC-MS/MS).
Results: Treatment of INS-1 cells with palmitate in the presence of high glucose concentrations (HG) resulted in a 7-fold increase of caspase 3/7 activity within 24 h, indicative of apoptosis. LC-MS/MS analysis showed that palmitate increased ceramide levels, especially N-C16:0 and N-C18:0 ceramides. Although HG did not induce apoptosis after 24h, it did upregulate the production of ceramides. The increase of ceramides induced by palmitate plus HG was associated with an increase in dihydrosphingosine (DHS) and dihydroceramide levels, suggesting an enhancement of the de novo sphingolipid biosynthesis. Interestingly, palmitate plus HG stimulated DHS phosphorylation into dihydrosphingosine-1-phosphate (DHS1P). To determine the role of DHS1P in beta-cell lipotoxicity, we used DMS to inhibit the activity of SphK, the enzyme responsible for DHS1P production. We showed that DMS increased by 2-fold palmitate plus HG-induced caspase activity. Furthermore, SphK1 over-expression in beta-cells drastically increased DHS1P levels, partially inhibited caspase activation and decreased palmitate-induced ceramide accumulation. Finally, we showed that addition of S1P, a DHS1P analog, inhibited beta-cell apoptosis induced by palmitate plus HG.
Conclusion: Together, these results indicate that lipotoxicity is associated with the increased generation of ceramides that correlates with beta-cell apoptosis. Interestingly, palmitate also induces de novo biosynthesis of another sphingolipid, DHS1P, which seems to attenuate beta cell apoptosis. Therefore, up-regulation of DHS1P biosynthesis opens novel therapeutic strategy for preventing beta-cell apoptosis during TD2.

Accumulation and oxidation of fatty acids modulate beta cell apoptosis but not the UPR
E. Sargsyan, P. Bergsten;
Medical Cell Biology, Uppsala University, Sweden.

Background and aims: Elevated levels of lipids are detrimental for beta-cell function and mass. Promoting lipid accumulation or oxidation has been connected with accentuation or attenuation of these effects on the β-cell, respectively. Different mechanisms of palmitate-induced beta-cell apoptosis have been proposed, where development of the unfolded protein response (UPR) has been studied intensely during recent times. The aim of the present study was to investigate if enhanced and reduced beta-cell apoptosis, observed in response to altered metabolism of lipids, involves modulation of the UPR. To address this issue beta-cells were exposed to AMPK-agonist AICAR or CPT1-inhibitior etomoxir.
Materials and methods: Insulin-secreting INS-1E cells were cultured for 3 or 24 hours in the presence of 0.5 mM palmitate complexed with 0.5% BSA and 1 mM AICAR or 0.2 mM etomoxir. Apoptosis was determined (cytoplasmic

oligonucleosomes and protein content) after 24 hours culture, whereas UPR markers phosphorylated (p) PERK, p-eIF2α, CHOP and BiP were measured (western blotting) in cells cultured for 3 and 24 hours.
Results: Apoptosis was induced 4-fold in cells cultured in the presence of palmitate compared to control. Presence of AICAR reduced apoptosis by 40%, whereas etomoxir accentuated apoptosis resulting in 15-fold induction in comparison to control. Protein content was reduced by 30% in the presence of palmitate. In the presence of AICAR the reduction was only 15%, whereas etomoxir reduced protein content by 50%. When UPR markers were examined, strong induction of PERK and eIF2α phosphorylation as well increased levels of BiP and CHOP were observed in the presence of palmitate. Expression levels of UPR markers were neither affected by AICAR nor etomoxir, however.
Conclusion: Development of the UPR is not dependent on the oxidation or accumulation of lipids in palmitate-exposed cells, which is in contrast to apoptosis.

Serine/threonine protein phosphatase 5 is involved in the regulation of fatty acid-induced beta cell apoptosis
N. Grankvist, R.E. Honkanen, H. Ortsäter, Å. Sjöholm;
Department of Clinical Science and Education, Södersjukhuset, Karolinska Institutet, Stockholm, Sweden.

Background and aims: In type 2 diabetes, where pancreatic β-cells are exposed to elevated glucose concentrations, a reduced β-cell mass is seen. Since type 2 diabetes is often linked to obesity, the β-cells are in conjunction with elevated glucose levels often also exposed to a hyperlipidemic environment, producing so-called glucolipotoxicity. Elevated levels of glucose and fatty acids are associated with increased production of reactive oxygen species that can cause cellular damage and initiate apoptosis. An important positive regulator of apoptosis is the mitogen-activated protein kinase (MAPK) signaling pathway. One mammalian MAPK is c-Jun N-terminal kinase (JNK), which can be activated by an apoptosis signal-regulating kinase. Serine/threonine protein phosphatase 5 (PP5) is a single polypeptide chain that are present both in the cytosol and the nucleus. It has been suggested that PP5 can act as a negative regulator of ASK1/JNK signalling. The aim of this study was to investigate the role of PP5 in the regulation of apoptosis signaling in MIN6 cells exposed to the fatty acid, palmitate.
Materials and methods: Clonal pancreatic MIN6 cells with reduced levels of PP5 were exposed to 0.5 mM palmitate together with 0.5 % BSA for 24 hours, or to 0.5 mM hydrogen peroxide for 15 min. Apoptosis induction was assessed by measuring the levels of cytoplasmic DNA-histone complexes. We also determined the protein phosphorylation levels of JNK, c-Jun, p38 and PP5 protein levels by western blotting. In order to reduce the PP5 expression level, MIN6 cells were treated with siRNA directed against PP5. We also analysed PP5 mRNA levels by quantitative PCR. Data is presented as mean±SEM.
Results: MIN6 cells treated with 0.5 mM palmitate for 24 hours showed a 5.8 ±0.2 fold induction of apoptosis compared to untreated cells. We next investigated the ability of palmitate to activate MAPK signalling by determining phosphorylation levels. This showed that both phosphorylated JNK levels increased by 135±19 % and the total c-Jun levels with 185±38 %, while the phosphorylation levels of p38 were not affected, compared to control after 24 hours of palmitate exposure. PP5 mRNA and protein levels were reduced by 60-70 %, 48 hours after siRNA treatment. The ability of palmitate to induce apoptosis was increased by 9.3±6.5 % in cells with reduced levels of PP5, compared to the control cells without reduced PP5 levels. MIN6 cells with reduced PP5 levels that were exposed to 0.5 mM hydrogen peroxide for 15 min, showed 78±25 % increased phosphorylation levels of JNK and phosphorylated c-Jun followed the same pattern, compared to the control cells without reduced levels of PP5.
Conclusion: The data presented here suggests that PP5 exerts an important role in the regulation of the apoptosis signalling cascade, since MIN6 cells treated with siRNA against PP5 showed increased levels of apoptosis after exposure to palmitate as compared to control cells. This effect, together with the finding that palmitate activates both JNK and c-Jun, suggest that enhancement of PP5 expression might be harnessed to advantage to reduce cellular damage induced by lipotoxicity and may prove valuable in efforts aimed at conferring β-cell protection against diabetic lipoapoptosis.

Comparative analysis of *db* and *ob* gene-related pancreatic beta cell function; evidence for a compensatory mechanism of cell protection in *ob/ob* mice
Y. Kanda, S. Hamamoto, M. Shimoda, K. Tawaramoto, M. Hashiramoto, K. Kaku;
Diabetes and Endocrine Division, Kawasaki Medical School, Kurashiki, Japan.

Background and aims: The *db* gene homozygous *db/db* mice develop diabetes with a marked obesity, severe insulin resistance, and limited capacity of insulin secretion. The *ob* gene homozygous *ob/ob* mice with a similar genetic background to *db/db* also develop severe obesity due to overeating, but hyperglycemia is not significant because of a compensatory hypersecretion of insulin. The molecular mechanism to explain a different phenotype for β cell function between 2 strains of mice has not clarified yet. In this study, we extensively analysed the β cell function and gene expression profile of pancreatic islets in *db/db*, *ob/ob*, and lean littermates *m/m* mice.
Materials and methods: Body weight (BW), fasted blood glucose (FBG), fasted insulin (FIRI), TG and FFA were measured at 8 and 12 weeks of age. The β cell mass and cell proliferation/apoptosis were assessed by histological analysis including PCNA and 4-HNE immunostaining of the islet tissue. Gene expressions specific for the core area of pancreatic islet were analyzed by Laser Capture Microdissection method and real time RT-PCR. Primer pairs encoding genes associated with pancreatic hormones, cell proliferation, apoptosis, cell cycle, and oxidative stress were prepared, and real-time RT-PCR with Sybr Green was applied.
Results: BW in *db/db* mice was significantly lower than those in *ob/ob* mice, but was significantly greater than in *m/m* mice. FBG in *db/db* mice was significantly greater than *ob/ob* and *m/m* mice (287.4±43.2, 93.1±3.5, 78.3±9.5 mg/dl at 12 weeks of age, $p<0.05$, respectively). FIRI in *db/db* and *ob/ob* mice were significantly higher than that in *m/m* mice, but no difference was observed between *db/db* and *ob/ob* mice. On the other hand, fed blood glucose (fBG) was significantly lower in *ob/ob* with significantly higher fIRI compared with *db/db* mice (fBG: 276.5±25.3, 470.4±40.3, $p<0.05$, fIRI: 31.3±3.9, 12.7±6.4, $p<0.05$). TG and FFA levels in *db/db* mice were significantly higher than those in *ob/ob* mice. The β cell mass was significantly larger in *ob/ob* than *db/db* or *m/m* mice, and the β cell ratio in *db/db* mice was reduced when compared to the other groups of mice at 12 weeks of age (cell mass: 3.48±0.59 in *ob/ob*, 2.30±0.42 in *db/db*, 0.62±0.10 mg in *m/m*, and β cell ratio: 87.2±0.26, 74.9±1.52, 80.5±2.8%, respectively). The β cell gene expression for insulinII were significantly increased in *db/db* and *ob/ob* mice. ERK1 gene related with cell proliferation was significantly up-regulated at 8 weeks of age both in *db/db* and *ob/ob* compared with *m/m* mice. At 12 weeks this gene expression was significantly down-regulated in *db/db* mice, whereas further up-regulated in *ob/ob* mice. The expression of CAD gene related with apoptosis promotion was already increased at 8 weeks and further accelerated at 12 weeks in *db/db*, but not in *ob/ob* mice. The gene expression of pdx-1 related with cell differentiation and SOD2 related with anti-oxidative stress was much less in *db/db* than in *m/m* mice at 12 weeks. In contrast, these genes were significantly up-regulated in *ob/ob* compared with *m/m* mice. Morphometric results for PCNA and 4-HNE corresponded with the data of gene expression analysis.
Conclusion: Our results strongly suggest that the *ob* gene, but not *db* gene, homozygote acquires a compensatory mechanism of β cell protection, resulting in suppression of cell apoptosis, and promotion of cell differentiation and proliferation probably through anti-oxidative stress mechanism.

OxLDL toxicity towards insulin secreting cells is mainly exerted extracellularly
A. Björklund[1], T. Wallin[1], D.F.J. Ketelhuth[2], C.B. Wollheim[3], V. Grill[1,4];
[1]Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden, [2]Department of Medicine, Karolinska Institutet, Stockholm, Sweden, [3]Department of Cell Physiology and Metabolism, University Medical Center, Geneva, Switzerland, [4]Department of Cancer Research and Molecular Medicine, Norwegian University of Science and Technology, Trondheim, Norway.

Background and aims: CD36 is known in many types of cells to scavenge oxidized LDL (oxLDL) and possibly native LDL (nLDL), thus increasing lipoprotein uptake. However, scavenging of oxLDL and/or nLDL has not been demonstrated in beta cells, nor whether putative scavenging affects beta cell functions.

Materials and methods: We evaluated by FACS the uptake of FITC-labeled oxLDL or nLDL, during 6h in a tet-on insulin secreting cell line (INS-1) over-expressing CD36. We quantified insulin secretion and content by RIA after 48 h of co-culture with oxLDL or nLDL. Viability of cells was evaluated by MTT assay.
Results: CD36 over-expression increased uptake of oxLDL 2.2±0.3 fold, p<0.01, n = 4, whereas over-expression did not affect uptake of nLDL, n = 4. Uptake was independent of ambient glucose concentrations (2.5, 10 or 21.5 mM). In acute experiments neither lipoproteins nor CD36 over-expression affected insulin secretion tested at 2.5 and 21.5 mmol/l glucose. In long-term experiments over-expression decreased glucose induced insulin secretion from 11.3±2 to 8.5±1 (% released of cellular insulin contents, p = 0.06, n=4) when cells were cultured with 20 μg/ml oxLDL for 48h. The corresponding decrease after culture with nLDL was from 7.8 ±1 to 6.3±1 %, p=0.063, n=4. Exposure to oxLDL (20 μg/ml) for 48h decreased insulin content similarly in control cells (-29 ± 7 %) and in CD36 over-expressing cells (-29 ± 6 %), p<0.02 for the oxLDL effect. An eqvimolar concentration of nLDL did not exert any significant effect (-2 ± 5% for control cells and -3±4% for CD36 over-expressing cells. Viability after 48h incubation with oxLDL were for control cells 101 ± 9 % with 20, 64 ±14 with 50 and 4±1 % with 100 μg/ml of oxLDL (expressed as % of no addition). Corresponding effects in CD36 over-expressing cells were 91±6, 64±12 and 3±1 %, n=3. Hence, CD36 over-expression did not potentiate the negative effect of oxLDL.
Conclusion: Over-expression of CD36 leads to a preferential uptake of ox-LDL which is independent of ambient glucose concentration. The increased uptake is not associated with aggravation of the inhibitory effects of oxLDL on insulin content and viability. These findings indicate that oxLDL toxicity towards insulin secreting cells is mainly exerted extracellularly.

Deterioration of islets structure and function in Zucker diabetic fatty (ZDF) rats during disease progression is prevented by pioglitazone but not by metformin

S. Uhles[1], A. Bénardeau[1], S. Sewing[1], M. Brecheisen[1], O. Ivanova[1], H. Wang[1], E. Sebokova[1], C.B. Wollheim[2], C. Migliorini[1];
[1]PRDM412, F-Hoffmann-La Roche, AG, Basel, [2]Department of Cell Physiology and Metabolism, University of Geneva, Switzerland.

Background and aims: The ZDF rat is a well accepted model to demonstrate the efficacy of anti-diabetic drugs, however the data evaluating the effect on disease progression and β-cell protection are rather limited. Our previous study in male ZDF rats looking at the age-dependent changes has shown that deterioration of islet structure and function precedes alterations of the metabolic profile. The aim of this study was to characterize the effect of the commonly used anti-diabetic drugs Metformin (MET) and Pioglitazone (PIO) on disease progression and prevention of β-cell failure.
Materials and methods: Measurement of metabolic parameters under basal and glucose challenge (oGTT at 2g/kg) together with quantitative analysis of islet morphology and *in situ* pancreas perfusion were performed after 4 weeks of treatment with MET (300 mg/kg p.o.) or PIO (10 mg/kg) in 6-week old male (ZDF-6w) rats and compared to age-matched Vehicle (V) or ZDF-6w rats. Pancreata were stained for insulin, glucagon and dapi.
Results: Treatment of ZDF rats with PIO and MET for 3 weeks led to a similar improvement of glucose levels during an oGTT ($AUC_{glu\text{-}2h}$ PIO: 1460 , MET: 1393 and V:1736) while only PIO significantly prevented hyperinsulinemia ($AUC_{ins\text{-}2h}$ PIO: 500, p<0.001, MET: 950, n.s. vs. V: 980 ng/mL*min). These changes were accompanied by a significant increase in insulin sensitivity (Matsuda Index: PIO: 400, p<0.01, MET: 200, n.s. vs. V: 130). In addition, PIO significantly decreased fasting blood glucose levels (PIO: 5.1, p<0.001, MET: 5.9, n.s. and V: 7.4 mM), fasting TG (PIO: 2.4, p<0.05, MET: 8.3, p<0.01 vs. V: 4.5 mM) and postprandial response of TG during oGTT ($AUC_{tg\text{-}2h}$ PIO: 210, p<0.01, MET: 800, p<0.01 vs. V: 500 mM*min). Quantitative immunohistochemistry analysis showed that MET was not able to prevent either islet area expansion (+70%, p<0.0001, V: +96%, p<0.0001) and/or loss of insulin staining intensity (-25%, p<0.0001, V: -38%, p<0.0001) when compared with ZDF-6w. PIO, on the contrary, prevented loss of insulin staining intensity (PIO: -0.5%, n.s.) without changing the islet area when compared with ZDF-6w (PIO: +22%, n.s.). These results were further supported by the total pancreatic insulin content, which was preserved with PIO (+9%, n.s.), but markedly reduced with MET (-37%, p<0.01, V: -40%, p<0.01), compared to ZDF-6w. PIO prevented α-cell invasion into the islet core better than MET (PIO: +109%, MET: +282% and V: +429%, all p<0.001) compared to ZDF-6w. *In situ* pancreas perfusion showed that PIO significantly reduced basal insulin secretion when compared to V and MET (-84% and -59%, respectively). While the profiles of phase I and II of insulin secretion were similar in both treatment groups, PIO attenuated the off-response to a greater extent than MET ($AUC_{off\text{-}response}$ PIO: -20%, MET: 15%).
Conclusion: Our data have clearly show that MET and PIO have different effects on disease progression and β-cell failure in the ZDF rat model. In particular, 4-week treatment with MET led to an improvement of glucose tolerance and insulin sensitivity but failed to protect the islets from the deterioration of their structure and function. On the contrary, PIO treatment protected the β-cell from exhaustion occurring during disease progression, which translated into a better metabolic profile and organ function.

PS 16 Experimental type 2 diabetes

Predicted targets of co-expressed microRNAs in pancreatic islets of GK rats are enriched for genes involved in regulation of beta cell mass and glucose-stimulated insulin secretion

J.L.S. Esguerra, C. Bolmeson, C.M. Cilio, L. Eliasson;
Clinical Sciences-Malmö, Lund University, Sweden.

Background and aims: The Goto-Kakizaki (GK) rat is a well-characterized animal model of non-obese spontaneous type 2 diabetes (T2D) with reduction in beta cell mass and impaired glucose-stimulated insulin secretion as main associated phenotypes. While mRNA expression and functional analyses of gene products implicated in the GK rat disease progression are abundant, the contribution of microRNAs (miRNAs) in eliciting the GK phenotype has not been fully explored. Previous studies with cultured insulin-secreting cell lines identified specific miRNAs important for proper beta cell function. We aimed to investigate whether these miRNAs are differentially-expressed in the pancreatic islets of the GK rat. Moreover we aimed to detect other miRNAs that could be involved in the development of the disease phenotype and identify their potential targets via bioinformatic approaches.
Materials and methods: We utilized LNA (locked nucleic acid)-based arrays to profile the miRNA expression levels in the pancreatic islets of GK rat *vs.* control Wistar rat (N=5 per group, 60 days old, females). Co-expressing miRNAs were then used as input to the meta mir-target inference (MAMI) web application combining the results of five miRNA target prediction tools (miRanda, PicTar, TargetScanS, microT and miRTarget). Gene enrichment analysis was performed to identify Gene Ontology (GO) categories associated with collective targets of co-expressed miRNAs (Fisher Exact p-value <0.005).
Results: We identified two distinct clusters consisting of 46 up-regulated and 32 down-regulated miRNAs in the GK rat using Significant Analysis of Microarrays (SAM). Enrichment for GO categories of the combined 2073 predicted targets of nine most upregulated miRNAs in GK rat yielded functional annotation clusters highly representative of genes in developmental process, cell differentiation, regulation of apoptosis among other GO terms potentially involved in the maintenance of beta cell mass. Interestingly, we found in the cell differentiation category the gene myotrophin, previously shown to be targeted by miR-375. Significant enrichment was also found for the GO category: vesicle-mediated transport, which include genes with central roles in glucose-stimulated insulin secretion such as RAB27A, RAB3A and granuphilin. We found in our arrays one of the most upregulated miRNAs in GK rat as being mir-124, known to regulate the expression of Rab27A and Rab3A. In addition we also observed increased expression of previously known negative regulators of insulin secretion such as mir-9 and mir-375 in GK rats relative to controls.
Conclusion: The predicted collective targets of co-expressed microRNAs upregulated in the GK rat were significantly enriched for genes involved in the maintenance of pancreatic beta cell mass and glucose-stimulated insulin secretion. The relatively higher expression of mir-9, mir-375 and mir-124 we observed indicates negative regulatory effects of these miRNAs in insulin secretion in the GK rat pancreatic islets, similar to previous reports in cultured insulin-secreting cell lines. Our bioinformatic analysis yielded testable hypotheses to support the notion that the GK diabetic phenotype could be caused by impaired miRNA regulation of targets involved in the maintenance of beta cell mass and insulin secretion.

Increased VEGF expression in beta cells leads to islet inflammation and diabetes

J. Agudo[1,2], E. Ayuso[1,2], A. Salavert[1,2], V. Jimenez[1,2], S. Tafuro[1,2], A. Casellas[1,2], M. Obach[1,2], A. Ruzo[1,2], X.M. Anguela[1,2], J. Ruberte[1,2], F. Bosch[1,2];
[1]CBATEG, University Autonoma of Barcelona, Bellaterra [2]CIBER de Diabetes y Enfermedades Metabolicas Asocidas (CIBERDEM), Barcelona, Spain.

Background and aims: Islets of Langerhans are abundantly vascularised and this vascularization is key to islet function. It regulates insulin access to systemic circulation, and the arrival of nutrients and secretagogs to endocrine cells. Furthermore, it has been recently described that islet endothelial cells directly regulate ß-cell proliferation and insulin gene expression. VEGF (Vascular Endothelial Growth Factor) is considered the main pro-angiogeneic factor and it can induce islet vessel formation and mantainance. Thus, VEGF may play an important role in controling insulin secretion and ß-cell mass.
Materials and methods: The effect of VEGF in islet vascularization and endocrine pancreas function was examined in transgenic mice overexpressing VEGF specifically in ß-cells and in animals treated with adeno-associated viral vectors carrying a RIP/VEGF gene (AAV/VEGF).
Results: Transgenic mice showed disorganised islets with increased vascularization. However, ß-cell mass, blood glucose levels, insulinemia and insulin secretion in vivo was not different between two-month-old transgenic mice and controls. Nevertheless, transgenic mice developed glucose intolerance overt diabetes with age. Moreover, these animals showed endocrine pancreas inflammation, with abundant macrophage infiltration and high levels of cytokine expression. To confirm these results and to avoid undesirable effects of the expression of the transgenic during embryonic development we used AAV vectors to transduce the islets of healthy adult mice. The AAV-mediated expression of VEGF in ß-cells in vivo also led to islet inflammation and glucose intolerance, suggesting a detrimental role of VEGF in pancreatic islet function.
Conclusion: Long-term VEGF overexpression in ß-cells may induce endocrine pancreas inflammation leading to islet dysfunction and diabetes.

IGF-II expression in beta cells induces susceptibility to develop diabetes

A. Casellas[1,2], A. Salavert[1,2], J. Agudo[1,2], M. Obach[1,2], V. Jimenez[1,2], E. Ayuso[1,2], F. Bosch[1,2];
[1]Center of Animal Biotechnology and Gene Therapy (CBATEG) and Dept Biochemestry, Universitat Autonoma De Barcelona, Bellaterra, [2]CIBER of Diabetes and Associated Metabolic Disease (CIBERDEM), Barcelona, Spain.

Background and aims: Both type 1 and type 2 diabetes are characterized by a deficit in ß-cell mass and increased ß-cell apoptosis. Replacing missing insulin-producing ß-cells to treat diabetes is a major challenge for regenerative medicine. A better understanding of the mechanisms involved in both ß-cell death and ß-cell regeneration in adult life is needed to develop means to increase ß-cell mass and revert diabetes. IGF-II induces ß-cell proliferation and differentiation in vitro and is involved in the regulation of islet growth and differentiation. We have shown that expression of IGF-II in ß-cells of transgenic mice (RIP-I/IGF-II) leads to increased ß-cell mass, hyperinsulinemia and altered glucose and insulin tolerance tests. Furthermore, polymorphic variants in locus IDDM2, which contains insulin and the growth factor IGF-II genes, have been described to be associated with type 1 diabetes risk. In addition, associations have been reported between IGF2BP2 (which encodes and IGF-II mRNA binding protein) and type 2 diabetes. These findings suggest a key role of IGF-II in diabetes susceptibility.
Materials and methods: IFN-ß/IGF-II double transgenic were obtained and phenotyped. Treatment with streptozotocin was performed in IGF-II transgenic mice. Expression profile analysis in islets from IGF-II transgenic mice was performed using GeneChip™ Affimetrix™ Technology.
Results: To determine whether IGF-II overexpression in ß cells could predispose transgenic mice to develop overt diabetes, we tested the susceptibility of RIP/IGF-II mice in front of several stimuli. Transgenic and control mice were treated with very low doses of streptozotocin (STZ) and after this treatment only transgenic mice became diabetic, indicating that IGF-II overexpression in ß cell increased sensitivity to STZ damage. Furthermore, IGF-II transgenic mice were crossed with RIP/IFN-ß transgenic mice, which show an important infiltration in their islets, mimicking an autoimmune process, a common feature in the diabetic pathology. We obtained IFN-ß/IGF-II double transgenic mice, which spontaneously developed diabetes during the first two months of age. All these findings suggest that an increase of IGF-II in ß cell may be key in the initiation of the diabetic process. Data from gene expression profile in islets from RIP/IGF-II showed a reduction in Glut2 and insulin gene expression in ß cells, probably due to a reduction in the transcription factors that regulate their expression, such as Pdx1 and HNF3ß. Transgenic islets also showed hyperexpression of molecules involved in the immune response, such as MHC class I and II, although no lymphocyte infiltration was observed. In addition, transgenic islets presented alteration of expression of genes involved in β-cell endoplasmic reticulum (ER) stress, characteristic of diabetic process.
Conclusion: These results indicate that local expression of IGF-II in ß-cells may increase susceptibility to develop diabetes by inducing metabolic and molecular alterations.

Diet-induced gene expression of isolated pancreatic islets from a polygenic mouse model for the metabolic syndrome

T. Dreja[1], Z. Jovanovic[2], A. Rasche[3], R. Kluge[1], R. Herwig[3], H.-G. Joost[1], G.S. Yeo[2], H. Al-Hasani[1];
[1]Department of Pharmacology, German Institute of Human Nutrition Potsdam-Rehbruecke, Nuthetal, Germany, [2]Institute of Metabolic Science, University of Cambridge, United Kingdom, [3]Department of Vertebrate Genomics, Max Planck Institute for Molecular Genetics, Berlin, Germany.

Background and aims: NZL mice are related with the New Zealand Obese (NZO) strain and develop juvenile-onset obesity and maturity-onset hyperglycemia. Exposure of these mice to a high-fat diet (HFD) results in rapid destruction of the pancreatic beta cells leading to frank diabetes. A carbohydrate free HF diet (CHFD), which still leads to the development of severe obesity and severe insulin resistance, prevents this destruction of beta cells. In order to investigate the contribution of dietary carbohydrates to pancreatic beta cell failure, we isolated pancreatic islets with laser capture microdissection and performed genome-wide expression analyses.
Materials and methods: Cryosections of pancreata from 8 week old, CHFD and HFD fed NZL-mice were briefly stained with Cresyl-Violet. Islet cells were isolated with laser capture microdissection (LCM). The RNA was purified and labelled cRNA was generated without an amplification step. The cRNAs were hybridised to Affymetrix Mouse 430 2.0 GeneChips. Differential expression of selected genes was validated by TaqMan-Realtime-PCR.
Results: By comparison of gene expression levels from isolated islets and total pancreas, we identified 230 transcripts that were highly enriched (>10-fold) in islets cells, many of those genes have an unknown function. In the early, pre-diabetic state of the animals, 786 islet transcripts were differentially regulated (>2-fold) between the two diets. Pathway analysis identified oxidative phosphorylation (OXPHOS) as the predominant gene set that was significantly up-regulated in response to the diabetogenic HFD. Moreover, HFD induces early changes in gene expression associated with increased cell cycle progression, proliferation, and differentiation of islet cells such as *Cdkn1b*,*Tmem27*, and *Pax6*. Regulators of the cellular redox state such as *Cat, Gpx1, Prdx4* and *Txnip* were also substantially increased in HFD islet, indicating that glucose-induced oxidative stress is relevant for disease progression. Furthermore, we identified 24 novel human candidate genes (e.g. *DACH1, CACNA1D, CHD2, CLIP2, IGFBP2*) for type 2 diabetes by correlating disease progression-associated genes in mouse islets with data from two publicly available genome-wide scans (DGI, WTCCC) for diabetes.
Conclusion: Our data clearly demonstrate the critical role of dietary carbohydrates in the pathophysiology of high fat-diet induced diabetes. LCM allows isolation of authentic pancreatic islet cells from their native tissue environment for genome-wide expression profiling. In islets, the diabetes-protective effect of a carbohydrate-free high-fat diet correlates with a reduced expression of genes for OXPHOS and antioxidants, implicating a major contribution of reactive oxygen species to diet-induced beta-cell failure.

Attenuation of Ca^{2+} microdomains and diet-induced diabetes in mice

S.C. Collins, M.B. Hoppa, J. Fearnside, Q. Zhang, S. Amisten, J.N. Walker, D. Gauguier, P. Rorsman;
Oxford University, United Kingdom.

Background and aims: Diet-induced diabetes in C57/Bl6 mice shows striking similarity to the evolution of diabetes in humans. The compensatory mechanisms put in place by the β- cell to overcome the increased demand in insulin are initially effective. However, by 15 weeks on high fat diet, β- cell function worsens together with glucose tolerance. Our aim was to pinpoint the cellular mechanisms leading to impaired glucose induced insulin secretion in the long run.
Materials and methods: Insulin release mesurements were combined with capacitance measurements and optical imaging of secretion by Total Internal Reflection Microscopy (TIRF) microscopy. Cytoplasmic $[Ca^{2+}]_i$ was measured by microfluorimetry. Intracellular ATP levels were determined by the luciferin/luciferase method. Membrane currents and potentials were recorded by the patch-clamp method. All results are based on at least 6 separate measurements from at least 3 different mice in each group.
Results: β-cell metabolism, electrical activity and $[Ca^{2+}]_i$ were unaltered by high fat feeding. Instead, a rapid component of exocytosis during capacitance measurements was decreased by up to 50%. This inhibition was confined to the first 500 ms of depolarization. These experiments were corroborated by TIRF microscopy which showed a strong inhibition of rapid (during first 300 ms) in the high fat diet (HFD) group of recombinant mIAPP-Cherry release. Using the perfused pancreas preparation, we demonstrated that this effect correlated with strong (>50%) inhibition of both 1st and 2nd phase insulin secretion. The inhibitory effect of the HFD was particularly strong for glucose-induced insulin secretion and the effect was less pronounced for insulin release evoked by high extracellular K^+**.** Thus, increasing the influx of calcium rescues insulin secretion. We consequently tested whether Ca^{2+} microdomains at the plasma membrane were affected. Evanescent-field illumination of voltage-clamped cells infused with EGTA (10 mM) and Calcium Green 6F (10 μM) stimulated by a single 50-ms depolarization from -70 mV to 0 mV showed that HFD results in a significant decrease in the clustering of calcium signal within microdomains. All differences stated are significant at the 0.05 level (at least).
Conclusion: Our results implicate that a reduction in Ca^{2+} microdomains within β-cells plays a part in the aetiology of diet induced type 2 diabetes.

Administration of a synthetic peptide demonstrating intrinsic kinase inhibitory properties increases residual pancreatic beta cell mass and improves glycaemic control in db/db mice

C. Gelber[1], J.R. Simms[2];
[1]Chief Scientific and Technology Officer, ATCC, Manassas, [2]Translational Research Group, ATCC, Manassas, United States.

Background and aims: Using proteomic analyses, we have previously identified a novel serum biomarker from the resistant strain of the Cohen diabetic rat model. Although the natural biological function of this marker (termed D3 peptide) is unknown, our studies indicate that it functions as a potent kinase inhibitor *in vitro*. In the present studies we assessed the efficacy of synthetic D3 peptide as a potential biotherapeutic using leptin receptor-deficient db/db mice as a model for type 2 diabetes.
Materials and methods: Seven week old db/db mice were purchased from the Jackson Laboratory (Bar Harbor, ME). Animals were administered 1 mg of D3 peptide in PBS, or PBS alone via the i.p. route twice weekly for 28 days. For a further 7 days, dosing frequency was increased to once every 48 hours. Body weights and non-fasting blood glucose levels were determined on a weekly basis. Plasma levels of glucose, insulin, IL-6, resistin, adiponectin and lipid profiling were performed on day 28. Following termination of the study, histological examination was conducted on hepatic, pancreatic, and adipose tissues.
Results: Treatment of db/db mice with D3 peptide reduced non-fasting blood glucose levels compared to control animals for the duration of the study. On day 28, despite observing only a slight increase in plasma insulin levels in the peptide treated group ($p>0.05$), fructosamine levels were significantly reduced compared to untreated controls ($p<0.01$). No significant differences in plasma lipid profiles or additional disease indicators were noted at this time. By day 35, mean blood glucose levels were reduced by approximately 30 % in peptide treated animals ($p<0.005$). Although the mass of both hepatic and pancreatic mass was increased in animals receiving D3 peptide, histological analysis revealed no significant differences between the treatment groups for insulitis, islet inflammation, acinar inflammation, islet hyperplasia, liver degeneration or liver inflammation. However, inflammation scores in both mesenteric and gonadal adipose tissues were approximately double in D3 peptide treated animals ($p<0.001$ in both instances). Interestingly, a marked increase in residual pancreatic beta cell mass was observed in peptide treated animals compared to PBS controls (3.80 ± 0.4 mg vs. 1.45 ± 0.2 mg respectively, $p<0.0001$).
Conclusion: The present study demonstrates that D3 peptide is efficacious at significantly reducing blood glucose and fructosamine levels in the db/db model of type 2 diabetes. Based on the current data set, we hypothesize that the peptide mediates its effect by regulation of kinase-dependent pathways causing a reduction in beta cell death, or the induction of beta cell proliferation leading to the observed increase in residual beta cell mass. However, as peptide treatment failed to cause a significant increase in plasma insulin levels, the peptide may also be contributing to improved glycemic control by upregulating systemic glucose uptake, or improving insulin sensitivity. Additional studies are planned to further explore the efficacy of D3 peptide using additional diabetic animal models, and to define its mechanism of action.

397

Exposure of human islets to palmitate mimics the mild inflammatory response observed in islets from type 2 diabetic individuals

M. Igoillo-Esteve[1], L. Marselli[2], D.A. Cunha[1], L. Ladrière[1], F. Ortis[1], G. Weir[3], P. Marchetti[2], D.L. Eizirik[1], M. Cnop[1];
[1]Laboratory of Experimental Medicine, Université Libre de Bruxelles, Belgium, [2]Department of Endocrinology and Metabolism, University of Pisa, Italy, [3]Joslin Diabetes Center, Harvard Medical school, Boston, United States.

Background and aims: Gluco- and lipotoxicity may contribute to β-cell dysfunction and apoptosis in type 2 diabetes (T2D). It has been proposed that increased circulating levels of IL-1β, TNF-α and IL-6 are independent risk factors for T2D, but the role of inflammation in the pathogenesis of T2D is controversial. Our aim was to analyze the expression of chemokines and cytokines in human islets from T2D patients and to evaluate *in vitro* the potential contribution of free fatty acids (FFAs) and high glucose to the putative inflammatory process.
Materials and methods: Chemokine and cytokine expression was studied by microarray analysis of laser capture microdissected β-cells from 10 non-diabetic and 10 T2D pancreata. Human islets were exposed to the FFAs oleate or palmitate (0.5 mM, 1%BSA) for 24 and 48h at 6 or 28 mM glucose. Chemokine and cytokine mRNA expression was measured by real time RT-PCR (n=6-9) and IL-6 and Gro-α protein secretion by ELISA (n=4-6). IL-1-receptor antagonist (IL-1ra) was used to block the IL-1R.
Results: The microarray analysis of human β-cells showed increased expression of several chemokines and cytokines in T2D compared to non-diabetic controls including: *IL-8* (2.2-fold induction vs control, p=0.015), *MCP-1* (3.7-fold, p=0.015), *eotaxin* (4.4-fold, p=0.063), *MCP-4* (3.4-fold, p=0.001), *Gro-α* (3.4-fold, p=0.09), *IL-6* (2.3-fold, p=0.48), *IL-1β* (1.9-fold, p=0.11). Exposure of human islets to palmitate, but not to oleate or high glucose, induced mRNA expression of *IL-8* (5.0±1.0-fold vs control after 24h, p<0.001; 7.4±1.8-fold after 48h, p<0.001), *MCP-1* (2.1±0.4 after 48h, p<0.001), *Gro-α* (7.6±2.9 after 24h, p<0.05; 7.1±2.4 after 48h, p<0.001), *IL-6* (4.7±0.8 after 24h, p<0.001; 6.5±0.9 after 48h, p<0.001), *IL-1β* (2.0±0.3 after 24h, p<0.01; 2.8±0.6 after 48h, p<0.05) and *TNF-α* (2.4±0.5 after 24h, p<0.01; 3.1±0.7 after 48h, p<0.01). mRNA induction by palmitate was similar at 6 and 28 mM glucose and was paralleled by protein secretion to the culture medium: IL-6 (2.0±0.3-fold vs control after 24h, p<0.05), Gro-α (2.7±1 after 48h, p<0.05). Multiple regression analysis of chemokine and cytokine mRNA expression suggested that IL-1β and TNF-α might regulate chemokine and cytokine expression. IL-1ra abolished palmitate-induced cytokine and chemokine expression at the mRNA and protein level but it did not prevent human islet cell death (control 5±0.7 % cell death; palmitate 13±1; palmitate + IL-1ra 14±2.1 after 3 days, n=4). Palmitate, but not oleate or high glucose, activated NF-κB in human islets, as evaluated by IκBα mRNA expression (2.4±0.6-fold induction vs control after 24h, p<0.05; 2.6±0.6 after 48h, p<0.01); this increase was abolished by IL-1ra. Immunofluorescence demonstrated that NF-κB nuclear translocation occurs in β- and non-β cells.
Conclusion: Islets from T2D patients have a mild increase in the expression of selected chemokines and cytokines. A similar mild inflammatory response is observed in human islets exposed in vitro to saturated FFAs, this response is at least in part dependent on IL-1β production; but it does not contribute to lipotoxicity. The mechanisms by which palmitate induces chemokines, and their potential role in β-cell dysfunction in T2D remain to be clarified.

Kir6.2 accumulation in adult Sur1-KO islet cells triggers only moderate oxidative stress without an endoplasmic reticulum stress response

I. Marhfour[1], J.-C. Jonas[2], J. Marchandise[1], J. Rahier[1], C. Sempoux[1], Y. Guiot[1];
[1]Pathology, Université Catholique de Louvain, [2]Endocrinology and Metabolism, Université Catholique de Louvain, Brussels, Belgium.

Background and aims: The K_{ATP} channel subunits SUR1 and Kir6.2 contain a retention signal in their amino-acid sequence that prevents their cell surface addressing until they are correctly assembled in functional hetero-octamers. It is therefore likely that, when expressed in the absence of their partner, each subunit accumulate in the endoplasmic reticulum (ER), thereby inducing an ER stress with eventual oxidative stress. To test this hypothesis, we investigated whether the absence of SUR1 in pancreatic endocrine cells alters the localization of Kir6.2 and induces ER stress- and oxidative stress-responses.
Materials and methods: We used islets from wild type (WT) and *Sur1* knockout (*Sur1*$^{-/-}$) mice in which 1) the sub-cellular localization of Kir6.2 and calreticulin (an ER marker) were determined by immunofluorescence and immunogold, 2) the rough ER (RER) length and Kir6.2 gold particle density were measured by morphometry (results are means ± SEM) and 3) the mRNA levels of several ER stress-response genes and antioxidant enzymes were evaluated by real-time RT-PCR.
Results: In WT islet cells, Kir6.2 immunostaining was diffuse in the cytoplasm and markedly enhanced at the plasma membrane. In contrast, Kir6.2 was mainly localized around the nucleus of *Sur1*$^{-/-}$ islet cells without positive immunoreactivity at their plasma membrane. This staining pattern was similar to that of calreticulin, suggesting ER localization of Kir6.2. Moreover, calreticulin staining intensity was higher in *Sur1*$^{-/-}$ than WT islet cells, suggesting a greater RER density. At electron microscopy, Kir6.2 gold particles were mainly localized on secretory granules of WT islet cells while they were mostly observed on the RER in *Sur1*$^{-/-}$ endocrine cells, leading to a significant increase in Kir6.2 gold particle density in the RER (0.053 ± 0.014 vs 0.027± 0.009 particles/μm in *Sur1*$^{-/-}$ vs WT beta cells, P<0.01). *Sur1*$^{-/-}$ islet cells also showed an increase in the length of the RER (32.6 ± 4.2 vs 8.5 ± 1.6 μm/cell in *Sur1*$^{-/-}$ vs WT beta cells, P<0.001) but no dilation of its lumen. Despite these multiple signs of Kir6.2 retention in the RER, Xbp1 mRNA splicing and the mRNA levels of the ER stress-response genes Bip, Edem and Gadd153 were not different between WT and *Sur1*$^{-/-}$ islets. In contrast, the mRNA levels of the antioxidant enzymes Sod1, Sod2, Gpx2 and Catalase were significantly up-regulated in *Sur1*$^{-/-}$ vs WT islets by 1.5, 1.9, 2.6 and 2.2-fold respectively.
Conclusion: Our results suggest that, in *Sur1*$^{-/-}$ islet cells, sequestration of the majority of Kir6.2 subunits in the RER is associated with an increase of RER length and mild oxidative stress without activation of the classical ER stress response.

Increased pancreatic islet GLP-1 content and release in mice with deletion of glucagon receptor

X. Li[1], L. Ge[1], S. Xu[1], G. Jiang[1], J. Mu[1], F. Liu[1], L. Wang[1], P. Fischer[1], M.J. Charron[2], Y.-P. Zhou[1], A.D. Howard[1], B.B. Zhang[1];
[1]Metabolic Disorders, Merck Research Laboratories, Rahway, United States, [2]Albert Einstein College of Medicine, Bronx, United States.

Glucagon-like peptide (GLP)-1 is an incretin hormone released from the intestine L-cells after ingestion of a mixed meal, exerting various effects on pancreas insulin and glucagon release as well as on gastrointestinal motility. Prior studies showed that mice with a null mutation of the glucagon receptor (GCGR KO) have increased circulating GLP-1 levels. However, the sources of this elevated GLP-1 have not been clearly defined. To address this outstanding question, we performed immunohistochemistry (IHC) analysis of the pancreas and assessed GLP-1 content and release using islets from wild type (WT) and GCGR KO mice. We observed a significant increase of GLP-1 positive cells in the pancreatic islets of GCGR KO mice relative to the WT mice. Likewise, the hormonal contents of glucagon and active GLP-1 were significantly increased in islets isolated from KO mice compared with WT mice (by 5 and 90 folds respectively, n=6). When islets were statically cultured in glucose-containing culture medium, release of active GLP-1 and glucagon from the KO islets markedly increased when compared with that of WT islets. This elevated hormone release by KO islets appeared to be unaffected by changes of glucose concentration in the culture medium from 3 mM to 15 mM. Microarray and real-time RT-PCR analyses revealed elevated mRNA levels of proglucagon (15 fold), PC2 (1.94 fold), ISL-1 (1.82 fold) and MafB (2.31 fold) genes, but decreased mRNA levels for MafA (0.49 fold), PC1 (0.5 fold) expression in the GCGR KO islets. Our data suggest that elevated plasma GLP-1 in GCGR KO mice is derived at least in part by the increased pancreatic islet GLP-1 synthesis and release possibly resulted from the compensatory amplification of the preproglucagon gene due to the absence of glucagon receptor signaling. Antagonizing glucagon receptor may yield additional benefits through the increase in GLP-1 production in pancreatic islets.

Effect of glucose abnormalities and pancreatic islet amyloidosis on the cell composition of the islets of Langerhans in non-human primates

F. Folli[1,2], A.M. Davalli[3], A.O. Chavez[1], G. Hubbard[2], E. Dick Jr.[2], G. Finzi[4], S. La Rosa[4], C. Capella[4], L.M. Jimenez-Ceja[1], S. Kamath[1], M. Palomo[1], G. Halff[5], A. Gastaldelli[1], R.A. DeFronzo[1], R. Guardado-Mendoza[1,6];
[1]Medicine/Diabetes, University of Texas Health Science Center at San Antonio, United States, [2]Southwest Foundation for Biomedical Research, San Antonio, United States, [3]San Raffaele Scientific Institute, Milan, Italy, [4]Pathology, Ospedale di Circolo and University of Insubria, Varese, Italy, [5]Surgery, University of Texas Health Science Center at San Antonio, United States, [6]University of Colima, Mexico.

Impaired insulin secretion is a major physiopathologic defect in type 2 diabetes mellitus (T2DM), and pancreatic islet amyloidosis (PIA) may play an important role in the development of beta cell dysfunction. We examined the relationship between beta and alpha cell volume versus with PIA and metabolic variables in non-human primates.
Methods: Forty baboons (matched by age, sex and weight) were divided into 5 groups based upon % islet volume occupied by PIA: 0, 1-25, 26-50, 51-75, >75%. Immunohistochemical staining for insulin, glucagon and somatostatin was performed in pancreatic sections to measure beta and alpha cell volume and size using a stereological approach (CAST-OLYMPUS). Plasma glucose, insulin, glucagon and FFA concentrations were determined before death in all baboons. ANOVA was used for comparisons between groups and Pearson Correlation coefficient to evaluate the relation between variables.
Results: Beta cell volume per islet indirectly correlated with FPG (R^2=-0.54, p<0.001), PIA (R^2=-0.76, p<0.001), Ln(FFA) (R^2= -0.24, p<0.001) and directly with HOMA-B (R^2= 0.61, p<0.001). Baboons with FPG >125mg/dl had 62% reduction in beta cell volume. Alpha cell volume and alpha/beta cell volume ratios were progressively elevated with increasing FPG and PIA (p<0.05). Baboons with FPG=95-125 mg/dl had a 21% increase in alpha cell volume, those with PIA >50% had a 30% increase in alpha cell volume and 44% decrease in delta cell volume. Individual beta and alpha cell size also increased accordingly to FPG and PIA (p<0.05). The sum of all islet components (amyloid and beta/alpha/delta cells) was 99.4±4.1% in baboons with FPG <80 mg/dl and PIA=0%, and it was slightly increased (13%) in baboons with PIA >25% and FPG >95mg/dl (p=NS), and this increase was around 50% when only the islet volume free of PIA was considered (p<0.05).
Conclusion: PIA and hyperglycemia are associated with reduced beta cell volume and function, and increased alpha cell volume and size. These histological abnormalities may explain the defect in insulin secretion and hyperglucagonemia in T2DM.

PS 17 Experimental insulin secretion

Melatonin receptor signalling is involved in insulin secretion in the INS-1 832/13 beta cell line

C.L.F. Nagorny, H. Mulder;
Clinical Sciences Malmö, Lund University, Sweden.

Background and aims: Genome-wide-association studies (GWAS) have recently suggested that a receptor (MTNR1B) for the pineal hormone melatonin is involved in the pathogenesis of Type 2 Diabetes Mellitus (T2DM). Melatonin binds predominantly to its receptors MTNR1A and MTNR1B, which are G-protein coupled receptors and are proposed to exert an inhibitory effect on insulin secretion. It remains uncertain which receptor mediates this effect. Here, we investigated which receptor exerts an effect on glucose stimulated insulin secretion (GSIS) and to what extent. Also, this study aimed at providing information about whether endogenous melatonin is present in the pancreatic β-cell and if it interferes with insulin secretion.
Materials and methods: To address this issue we knocked down the two different melatonin receptors (MTNR1A and MTNR1B) in the INS-1 832/13 β-cell line by RNA interference. The transfected cells were then stimulated with glucose alone and in combination with the cAMP-raising agent forskolin, given the suggested cAMP-lowering effect of melatonin.
Results: Both MTNR1A and MTNR1B were successfully knocked down by ~81% (n = 3) on the mRNA level. Upon knock down of MTNR1A in INS-1 832/13 β-cells, there was a trend towards an inhibitory effect on GSIS, whereas knock down of MTNR1B did not affect GSIS. A similar tendency was observed when β-cells were stimulated with high glucose (16.7mM) in combination with 35 mM potassium and 250 μM diazoxide to evoke K_{ATP}-independent insulin secretion. Stimulation with high glucose in combination with 2.5 μM forskolin provoked a 3-fold increase in GSIS compared to stimulation by 16.7 mM glucose alone. In contrast, knock down of MTNR1A significantly inhibited GSIS under these conditions (91 ±10 vs. 186 ±51 ng/mg/h; p = 0.03, n = 3). Silencing of MTNR1B was not associated with any inhibition of GSIS under the same conditions. mRNA for the enzyme arylalkylamine-N-acetyl transferase (AANAT), active in melatonin synthesis, was expressed in INS-1 832/13 β-cells.
Conclusion: Our data show that blocking melatonin receptor signaling in INS-1 832/13 β-cells reduces a full insulin secretory response, particularly that potentiated by cAMP. A block of MTNR1A exerts the strongest effect. Melatonin is likely to be synthesized in these cells since we were able to demonstrate expression of AANAT, the rate-limiting biosynthetic enzyme. Our data suggest that melatonin receptor signaling is involved in control of insulin secretion. It is possible that endogenous melatonin may play a role in these processes.

5-hydroxytryptamine exposure stimulates insulin secretion in clonal beta cells but not in islets of Langerhans

M. Fex[1], H. Bennet[1], C. Nagorny[2], M. Dekker Nitert[3], N. Wierup[4], Å. Lernmark[1];
[1]Diabetes and Celiac disease, Clinical Sciences, Malmö, [2]Molecular Metabolism, Clinical Sciences, Malmö, [3]Diabetes and Endocrinology, Clinical Sciences, Malmö, [4]Diabetes and Celiac disease, Experimental Medical Sciences, Lund, Sweden.

Background and aims: Receptors 5-HT1a (5-hydroxy-tryptophane receptor 1a) and 5-HT1a (5-hydroxy-tryptophane receptor 2b) are G-protein coupled receptors activated by 5-Hydroxytryptamine, also known as serotonin. 5-HT1a couples negatively to adenylate cyclase while 5-HT2b activates Gαq. This means that the receptors act by two distinct intracellular pathways and activate a cascade reaction, resulting in different cellular events. Both receptors have previously been found in islets of Langerhans from rodents. In addition, serotonin has been shown to be present in islets from several different animal species. As both receptors and amines are present, serotonin may potentially regulate hormone secretion from islets of Langerhans. We have therefore investigated the effect of a serotonin analogue (α-methyl serotonin) on insulin secretion in a clonal β-cell line and in islets of Langerhans from mouse and humans.
Materials and methods: We used RT PCR and sequence specific primers to detected expression of the receptors in the β-cell line (INS 832/13) and

in islets of Langerhans. Immuno-histochemical analysis was used to detect the receptors at the protein level in rodent islet and human islets. Islets from mouse was isolated by standard collagenase digestion and incubated with glucose and α-methyl serotonin at 37 ºC for 1h and assayed for insulin secretion. Insulin was measured either by radio-immuno assay or with insulin ELISA depending on the species of the islets of Langerhans.
Results: 5-HT2b mRNA was found in the 832/13 cells. We also found both 5-HT1a and 5-HT2b to be expressed in rodent and human islets, at both mRNA and protein level. Interestingly, 5-HT receptors in islets were localized in two different cell types in the islets. In rodent islets, 5-HT2b was predominantly expressed in β-cells while 5-HT1a was more abundant in the α-cells. In human, islets the situation was reversed. Stimulation with α-methyl serotonin provoked a significant increase in insulin secretion at stimulatory concentrations of glucose when the clonal β-cells were incubated with the analogue for 2h. In mouse and human islets, however, no difference between the control and α-methyl serotonin treated islets were detected at either concentrations of glucose.
Conclusion: Our results from the clonal cell line suggest a role for serotonin and its receptors in regulation of insulin secretion. Because both 5-HT1a and 5-HT2b are expressed in rodent and human islets and activate two very distinct cellular pathways, these receptors may in fact modulate secretion from both α and β-cells. This dual regulation of both insulin and glucagon secretion could obscure the actual effect of α-methyl serotonin on insulin secretion. This issue needs to be further investigated because these receptors may serve as potential drug targets to stimulate islet hormone secretion.

New paracrine role of pancreatic polypeptide in mouse and human pancreatic islets
F. Aragón[1], A. Novials[2], R. Maldonado[1], B. Rubí[1];
[1]Neuropharmacology laboratory, DCEXS, [2]Laboratory of Experimental Diabetes. Institut d'Investigacions August Pi i Sunyer -IDIBAPS-, CIBER de Diabetes y Enfermedades Metabólicas Asociadas -CIBERDEM-, Barcelona, Spain.

Background and aims: Pancreatic polypeptide (PP) is a hormone synthesized in pancreatic islet F-cells. PP is released in response to food ingestion and remains elevated for up to 6 h postprandially. It has recently received much attention for its metabolic role in humans, suppressing food intake and gastric emptying. For this reason, PP is nowadays in the spotlight for the development of treatments against obesity and diabetes in humans. We have explored the possible existence of additional paracrine roles of PP in the endocrine pancreas. Indeed, endocrine pancreatic hormones often exhibit paracrine roles in the regulation of islet secretion that are complementary to its extra-islet functions. Thus, insulin from beta cells negatively regulates glucagon secretion and somatostatin from delta cells negatively regulates both insulin and glucagon secretion. These paracrine regulations constitute a complex network necessary for a precise tuning of the endocrine pancreas in response to different metabolic states. Up to date, the possible intra-islet functions of PP are totally unknown.
Materials and methods: We have performed immunolocalization analysis of the PP receptor, NPY4R -also named as PP1R- in mouse and human pancreatic islets. Additionally, we have evaluated its role in the modification of pancreatic islet hormone secretion in vitro.
Results: Our data show the expression of PP receptor in both mouse and human models, were PP1R is exclusively expressed in glucagon-secreting alpha cells. In addition, our preliminary results indicate that these receptors are functional, and their activation by PP regulates glucagon secretion in isolated pancreatic islets.
Conclusion: Pancreatic polypeptide influences glucagon secretion by acting on PP1R present in pancreatic alpha cells in mouse and human islets. Our data reveal for the first time paracrine signalling of pancreatic polypeptide. Interestingly, it is known that glucagon modifies food intake in humans, probably by acting on central glucagon receptors. Our data indicate that some of the metabolic properties of PP may be mediated by changes in glucagon levels and suggest a possible functional parallelism on PP roles in CNS and endocrine pancreas.

Kisspeptin the endogenous ligand for the novel beta cell GPCR, GPR54, inhibits insulin secretion
J. Vikman, B. Ahrén;
Medicine, Clinical Sciences, Lund, Sweden.

Background and aim: Kisspeptins are a family of peptides that activates the G-protein coupled receptor GPR-54, which is a novel islet GPCR that couples to Gq and the PLC pathway. The KISS1 gene encodes for a hydrophobic 145 amino acid protein that can be cleaved into peptides of differing length e.g. kisspeptin 54 (KP54), kisspeptin 13 (KP13) and kisspeptin 10 (KP10). Both human and mouse islets express both the receptor, GPR54, and the gene encoding the ligand, KISS1. The function of kisspeptins in islet function and insulin secretion is however still unclear. We therefore explored the potential effect of kisspeptins on insulin secretion and expression of kisspeptin peptide in mouse islets.
Methods: Insulin secretion was measured in isolated islets after collagenase digestion of pancreata from C57BL/6J mice. The islets were divided in groups of three and incubated in HBSS with glucose concentrations of 2.8, 5.6, 8.3 and 11.1 mM, with or without 100 nM kisspeptin-13 for 60 min at 37 ºC. Insulin secretion was also measured during IVGTT where the mice were given an intravenous injection of with 0.35 g glucose with or without 3 nmol KP10 per kg. Insulin was determined with ELISA (Mercodia) or radioimmunochemically (Linco Res., St Charles, MO, USA). Finally, localization of KP10 in mouse islets was investigated using immunocytochemostry of mouse islet cells using an antibody directed against the N-terminal end of KP10.
Results: KP-13 inhibited insulin secretion in isolated mouse islets and the inhibitory action was most pronounced at glucose concentrations below 11.1 mM. At 5.6 mM glucose the insulin response was 121±15 pg/islet/h and in presence of KP13 the insulin response was reduced to 69±10 pg/islet/h (p=0.01, n=4). The inhibitory action was also seen at 8.3 mM glucose where the insulin response was 205±18 pg/islet/h in control islets and 152±16 pg/islet/h (p=0.04, n=4) in presence of KP13. In vivo, the insulin response to IV glucose was inhibited by the endogenous mouse kisspeptin, KP10. Thus the 1 min increase in plasma insulin after IV glucose was 715±200 pmol/l (n=9) and this was reduced by 60% to 290±94 pmol/l by KP10 (n=9, p=0.008). The presence of KP10 was shown in dispersed primary mouse beta cells using immunocytochemsitry.
Conclusion: Kisspeptins inhibit insulin secretion as evident both by in vivo and in vitro studies, and in vitro the effect was evident at glucose concentrations below 11.1 mM. This argues that signaling of GPR54 through kisspeptins is inhibiting regulating insulin secretion at physiological concentrations of glucose. Since kisspeptins are expressed in beta cells, as is GPR54, our results suggest a novel feed-back mechanism for restraining beta cell secretion. The mechanisms and physiological relevance of this remains now to be explored.

Palmitate-stimulated hormone secretion in relation to GPR40 expression in pancreatic islets of spontaneous obesity and type 2 diabetes in rats
A. Salehi, S. Meidute Abaraviciene, A. Balhuizen, R. Kumar, S. Amisten, B. Björn Olde, I. Lundquist;
Clinical Sciences, University of Lund, Malmö, Sweden.

Background and aims: The role of GPR40 in FFA-induced β-cell signalling is unclear. We examined GPR40 expression in relation to palmitate-induced hormone release in isolated islets from two rat models of spontaneous type 2 diabetes displaying either hyperlipidemia (fa/fa) or hyperglycemia (GK).
Materials and methods: GPR40 expression was analysed by confocal microscopy, Western blot and RT-PCR in islets from young prediabetic Zucker diabetic fatty (ZDF, fa/fa) rats or diabetic Goto-Kakizaki (GK) rats and their healthy controls. Palmitate-stimulated hormone secretion from isolated islets was analysed.
Results: Confocal microscopy of control islets showed expression of GPR40 protein in insulin, glucagon and somatostatin cells. This expression was strongly increased in islets of prediabetic fa/fa rats and had its functional counterpart in increased palmitate-induced release of insulin and glucagon and a pronounced inhibition of somatostatin release. Conversely, GK islets displayed an extremely faint expression of GPR40 as did high-glucose-cultured Wistar control islets. In GK islets this was reflected in an abolished hormone response to palmitate. In accordance, both Western blot and mRNA

expression of GPR40 showed a strong increase in fa/fa islets and a marked decrease in GK islets as compared to control islets and high-glucose cultured Wistar islets.
Conclusion: GPR40 is abundantly expressed in pancreatic islets and influences palmitate-induced secretion of insulin, glucagon and somatostatin. Mild hyperlipidemia increases GPR40 expression and palmitate-induced effects on hormone secretion, whereas hyperglycemia abrogated GPR40 expression and abolished palmitate-induced secretory effects. GPR40 could be a target for therapeutic approach in certain types of obesity and type 2 diabetes.

Evidence for inhibitory autocrine effects of proinsulin C-peptide on pancreatic beta cell function and insulin secretion
A.M. McKillop, M.T. Ng, P.R. Flatt, Y.H.A. Abdel-Wahab;
School of Biomedical Sciences, University of Ulster, Coleraine, United Kingdom.

Background and aims: There is evidence to suggest that proinsulin C-peptide may exert various physiological effects in addition to representing a component of proinsulin that is cleaved by proconvertase enzymes during insulin biosynthesis. C-peptide has been shown to affect several cellular processes and bind to cell membranes including insulin-secreting beta cells. However, very little attention has been given to the possible effects of C-peptide on insulin secretion. The present study was undertaken to explore the actions of various forms of proinsulin C-peptide on pancreatic beta cell function and insulin secretion.
Materials and methods: Insulin releasing activity of C-peptide (human, rat-1 and rat-2) was studied in the clonal pancreatic cell line, BRIN-BD11. Findings were substantiated by further studies in pancreatic islets isolated by collagenase digestion from normal Swiss TO mice (n=5). Acute insulin secretion studies were performed at 5.6mM and 16.7mM glucose. A range of C-peptide concentrations were tested with various stimulators of insulin release, and comparative studies performed with known inhibitors of beta cell function. Insulin release was measured by radioimmunoassay, and intracellular calcium ($[Ca^{2+}]_i$) determined by fluormetric assay kit using FLEXstation™.
Results: Acute exposure of clonal beta cells to human C-peptide (10^{-9}-10^{-6}M) resulted in concentration-dependent inhibitory effects on insulin secretion at 5.6mM (P<0.05-P<0.001) and 16.7mM (P<0.01-P<0.001) glucose. Inhibition of glucose-induced insulin secretion with C-peptide ($3x10^{-7}$M) was accompanied by suppression of the insulin-secretory responses to alanine (10mM, P<0.05), elevated Ca^{2+} (7.68mM, P<0.001), arginine (P<0.05), tolbutamide (P<0.001) and GLP-1 (P<0.001) at 5.6mM glucose. Likewise, C-peptide inhibited insulin release induced by KCl (30mM, P<0.05) and IBMX (200μM, P<0.01) at 16.7mM glucose. Additionally, the inhibitory effects of C-peptide were shown to be concentration dependent for alanine (10^{-8}-10^{-6}M, P<0.05-P<0.001) and IBMX (10^{-9}-10^{-6}M, P<0.01-P<0.001) stimulated insulin release at 5.6mM and 16.7mM glucose, respectively. Broadly similar results were found using isolated pancreatic islets as C-peptide ($3x10^{-7}$M) reduced insulin release at 5.6mM (P<0.001) and 16.7mM (P<0.001) glucose. In isolated islets C-peptide also inhibited alanine (10mM), GIP (10^{-8}M), IBMX (200μM) and tolbutamide (200μM) stimulated insulin release at 5.6mM glucose (P<0.01). Acute exposure of clonal beta cells to C-peptide ($3x10^{-7}$M) resulted in no modification of the changes in $[Ca^{2+}]_i$ induced by alanine, whereas inhibition of insulin secretion with diazoxide (300μM), clearly reduced $[Ca^{2+}]_i$ (P<0.001, n=6). Human C-peptide ($3x10^{-7}$M, P<0.01) and established inhibitors of insulin secretion, somatostatin-14 ($3x10^{-7}$M, P<0.001) and diazoxide (300μM, P<0.001) reduced glucose-stimulated insulin release in the acute studies performed at 5.6mM glucose in the presence of alanine. Glucose-induced insulin secretion was inhibited by 25% (somatostatin-14), 43% (C-peptide) and 48% (diazoxide). The various observations made with human C-peptide were reproduced using rat C-peptide I and II.
Conclusion: This study provides evidence that C-peptide is a biologically active endogenous peptide hormone that exerts tonic inhibitory effects on pancreatic beta cell function mediated through intracellular signalling pathways.

Silencing mitogen-activated protein 4 kinase 4 (MAP4K4) protects beta cells from TNF-alpha inhibition of glucose-stimulated insulin secretion
K. Bouzakri, P. Ribaux, P.A. Halban;
Department of Genetic Medicine and Development, CMU, Geneva, Switzerland.

Background and aims: Obesity and type 2 diabetes mellitus are widespread metabolic disorders characterized by an overlapping phenotype of insulin resistance with a relative deficiency in insulin secretion underlying hyperglycemia in type 2 diabetes. Systemic inflammation is also a feature of obesity and type 2 diabetes, raising the hypothesis that elevated cytokine levels may contribute to peripheral insulin resistance as well as decreased beta cell functional mass. In healthy humans, TNF-α infusion induces skeletal muscle insulin resistance. We now explore the impact of TNF-α on glucose-stimulated insulin secretion from primary beta cells and the underlying signalling pathways.
Materials and methods: Human and rat primary beta cells were sorted by FACS and cultured for 24h +/- 20 ng/ml TNF-α to explore the impact on apoptosis (TUNEL assay), proliferation (BrdU incorporation) and short-term insulin secretion (1h 2.8 mM glucose followed by 1h 16.7 mM glucose at the end of the 24h culture period) as well as key signalling protein phosphorylation and expression. siRNA was used to silence MAP4K4 expression: cells were transfected with liposome-siRNA (Lipofectamine 2000 and siRNA (100 nM)) 3 days prior to the experimental period to ensure knockdown of MAP4K4 before TNF-α treatment. Data are mean±SE, for n=4 independent experiments.
Results: Culture for 24h with TNF-α had no effect on either beta cell proliferation (rat) or apoptosis (rat and human). By contrast, TNF-α treatment decreased short-term glucose-stimulated insulin secretion (GSIS) by 42±6% (for human) and 49±8% (for rat) when compared to control (without TNF-α), with no significant effect on basal secretion. In rat primary beta-cells, 1h of glucose stimulation (16.7mM) induces phosphorylation of proteins from the insulin signalling pathway including Akt, AS160, other Akt Substrates, ERK and insulin receptor: 24h TNF-α treatment abolished this effect of glucose on these particular proteins. Strikingly, TNF-α treatment decreased IRS-2 protein levels by 46±7% vs. control, although mRNA expression was unchanged. TNF-α treatment also induced activation of p38, p70S6Kinase and JNK, as well as NF-κB in rat primary beta cells. In order to identify which kinases were responsible for TNF-α inhibition of GSIS, we used either a pharmacological approach or siRNA. Neither NF-κB (Bay 11-7032; 5μM) nor eNOS (LNMMA; 1mM) inhibition protected beta cells from the impact of TNF-α, whereas MAP4K4 knockdown using siRNA preserved GSIS and IRS-2 protein levels as well as the impact of glucose on components of the insulin signalling pathway. MAP4K4 knockdown also prevented activation of JNK and p70S6Kinase by TNF-α, whereas it had no influence on NF-κB or p38 activation.
Conclusion: We show here that 24h exposure to TNF-α inhibits GSIS in primary beta cells. This is associated with an alteration in phosphorylation of key proteins in the insulin signalling pathway after glucose stimulation as well as decreased levels of IRS-2 protein. We identify MAP4K4 as a key upstream mediator of TNF-α action on the beta cell, making it a potential therapeutic target for preservation of beta cell function in type 2 diabetes.

Targeting diabetes through multiple pathways using VPAC2 receptor selective peptide agonists
K. Bokvist[1], J. Alsina-Fernandez[1], M. Brenner[1], A. Cauvin[2], A. Delaunois[2], A. Köster[1], J. Mayer[1], L. Zhang[1];
[1]Eli Lilly & Co, Indianapolis, United States, [2]Eli Lilly Development Center, Mont-Saint-Guibert, Belgium.

Background and aims: Vasoactive intestinal polypeptide (VIP) is one of the most abundant neuropeptides in the pancreas. VIP potently enhances insulin secretion from pancreatic islets but may also stimulate glucagon secretion. VIP may act through either VPAC1 or VPAC2 receptors.
Materials and methods: We have used two different VPAC2R selective peptides, P17 and P104, to determine (1) if VPAC2R specific compounds can dissociate the VIP-mediated enhancements of glucagon and insulin secretion in *in vitro* and (2) to evaluate their efficacy on insulin secretion in normal or diabetic rats.

Results: Both peptides potently enhanced insulin secretion from isolated rat islets; for example, 30 nM P104 enhanced insulin secretion by 3.5-fold versus controls in the presence of 10 mM glucose. The same concentration of GLP-1 resulted in a 4-fold enhancement. In difference to PACAP-27 that activates both VPAC1 and VPAC2 receptors, neither GLP-1 nor P104 enhanced glucagon secretion from rat islets. This observation suggests that a VPAC2R selective compound may selectively enhance insulin secretion without stimulating glucagon release. P17 also protected ß-cells against apoptosis induced either by cytokines (IFNγ + IL1ß) or by H_2O_2. When given acutely in a rat intravenous glucose tolerance test (ivGTT), P104 enhanced the insulin response to an intravenous bolus of glucose by a factor of 4 (measured as the area under the insulin curve from 0 to 10 min after glucose). The half-maximal efficacious dose was 0.1 µg/kg. P104 was also efficacious in an ivGTT in diabetic GK rats, where 3 and 10 µg/kg stimulated insulin secretion by 3 and 4-fold, respectively. In order to assess to which extent VPAC2 receptors desensitize when chronically stimulated, P17 was subcutaneously infused in normal rats at a rate of 2.6 or 8 µg/kg/h for 72 h, after which insulin secretion was studied at two fixed iv glucose infusion rates (5 & 15 mg/kg/min). Both P17 doses enhanced insulin secretion by 4-fold compared to vehicle. The safety profile of P17 was assessed in a parallel study in healthy rats with infusion rates of 8 and 27 µg/kg/h for 72 h; which corresponded to 3- and 10-fold the maximal efficacious dose on insulin secretion. No adverse events were observed, but interestingly, plasma triglycerides and free fatty acids were dose-dependently reduced after the 72h infusion. Both doses reduced food intake by 20% and 50% for 8 and 27 µg/kg/h, respectively. No signs of liver damage or perturbations of plasma GH, corticosterone, prolactin or total cholesterol levels were observed.
Conclusion: VPAC2R-selective peptides enhanced insulin secretion in rat pancreatic islets, without effects on glucagon release. They also potently enhanced insulin secretion in both normal and diabetic rats, improved plasma lipid levels and reduced food intake; a set of properties which is particularly desirable for the treatment of type 2 diabetes.

Role of class 1A PI3-kinase in pancreatic beta cell functions and growth
K. Ueki[1], K. Kaneko[1], L.C. Cantley[2], T. Kadowaki[1];
[1]Department of Metabolic Diseases, The University of Tokyo, Japan, [2]Beth Israel Deaconess Medical Center, Center for Life Science, Harvard Medical School, Boston, United States.

Background and aims: Recent studies using several knockout models have shown that autocrine insulin (and/or IGF-1) regulates growth and some functions of pancreatic β cells through activation of insulin signaling. Downstream of insulin receptor signaling, Class IA phosphoinositide 3-kinase (PI3K) composed of a catalytic subunit (p110) and a regulatory subunit (p85) plays a pivotal role. Thus, in this, study, we tried to identify the role of Class IA PI3K in β cells.
Materials and methods: To this end, we have generated β cell specific Pik3r1 gene knockout encoding p85α and its splicing variants (βPik3r1KO) mice using Cre-LoxP system, and also ablated the genes of two major regulatory subunits, p85α and p85β, of PI3K by crossing mice lacking Pik3r1 in β cells with Pik3r2 (p85β gene) null mice, for creating pancreatic beta cell-specific double knockout mice (βDKO mice).
Results: βPik3r1KO mice were indistinguishable from control RIP-Cre transgenic mice. βPik3r1KO mice exhibited impaired glucose tolerance and suppressed glucose stimulated insulin secretion (GSIS) *in vivo* with decreased β cell mass. Moreover, βDKO mice showed more prominent glucose intolerance and decreased islet mass than βPik3r1KO mice. βDKO mice exhibited markedly blunted 1st phase insulin secretion in GSIS in vivo and in situ pancreatic perfusion test. Furthermore, apoptotic cells estimated by TUNEL assays were significantly increased in islets of βPik3r1KO and βDKO mice. We found that islets of βPik3r1KO and βDKO mice show impaired glucose-stimulated synchronized Ca influx and subsequent insulin secretion due to a reduction in Connexin 36, a key molecule of gap-junction. We also found that these mice show impaired insulin secretion even when intracellular Ca concentrations were elevated by caged Ca because these islets have reduced levels of SNARE protein complex. These reductions were normalized when the isolated islets were treated with the adenovirus expressing a constitutively active Akt.
Conclusion: These data suggest that Class IA PI3K is required for normal insulin secretion (especially in 1st phase secretion) and age-dependent islet growth, and that decreased Class IA PI3K activity causes postprandial hyperglycemia. Thus, these results may provide a novel therapeutic approach for diabetes by enhancing insulin/PI3K signaling in pancreatic β cells, leading to the normal insulin secretion and the normalization of postprandial hyperglycemia.

Deterioration of islet structure and function precedes alterations of metabolic profile in Zucker diabetic fatty (ZDF) rats
A. Bénardeau[1], S. Uhles[1], S. Sewing[1], M. Brecheisen[1], O. Ivanova[1], H. Wang[1], E. Sebokova[1], C.B. Wollheim[2], C. Migliorini[1];
[1]PRDM412, F-Hoffmann-La Roche, AG, Basel, [2]Department of Cell Physiology and Metabolism, University of Geneva, Switzerland.

Background and aims: The ZDF rat has been widely used to demonstrate preclinical efficacy of anti-diabetic drugs. In this study we investigated if the changes in islet function and morphology precede alterations in metabolic profile.
Materials and methods: Measurement of metabolic parameters under basal and glucose challenge (oGTT at 2g/kg) together with quantitative analysis of islet morphology and *in situ* pancreas perfusion were performed longitudinally for 6 weeks starting in 6-week old male ZDF (ZDF) and lean (Lean) rats. Pancreata were stained for insulin, glucagon and nuclei.
Results: Despite near normoglycemia (FBG: 6.5±0.3 vs. 4.1±0.1 mM) and normo triglyceridemia (1.2±0.1 vs. 1.6±0.2 mM), 6w-old ZDF rats were characterized by moderate glucose intolerance ($AUC_{Glu\text{-}2h}$=1138±57 vs 814±21 mM*min) compared to 6w-old Lean ($AUC_{Glu\text{-}2h}$=820±28 mM*min). However, the dynamic insulin secretion profile measured during in situ pancreas perfusion showed a tendency for a reduced phase II compared to Lean (AUC: 84.0±10.7 (n=3) vs 147.6±19.3 ng/ml*min (n=6), n.s.).Total pancreatic insulin content was significantly elevated (p<0.001) and an increase in islet area by ~40% (n.s.) could be observed vs. 6w-old Lean. At 8 weeks of age, ZDF rats were normoglycemic but exhibited hypertriglyceridemia (6.0±0.6 vs 1.2±0.1 mM, p<0.01) and fasting hyperinsulinemia (6.2±0.5 vs. 2.3±0.3 ng/ml, p<0.01) compared to 6w-old ZDF. In the perfused pancreas we observed increased basal insulin secretion (7.2±1.2 vs. 0.1±0.0 ng/m, p<0.01) and a tendency in increased phase I+II secretion (AUC: 116±14 vs. 155±24 ng/mL*min, n.s.) upon glucose stimulation to compensate for evolving insulin resistance (Matsuda: 130±10 vs 390±40, p<0.01). Analysis of islet morphology showed at this age disrupted islet architecture with increased islet area by ≥70% (p<0.001), reduced insulin staining intensity by 26% (p<0.0001) and a 240% (p<0.0001) increase of α-cell infiltration into the islet core compared to 6 w-old ZDF. At the age of 10 and 12 weeks, ZDF rats evolved toward type 2 diabetes showing severe hyperglycemia (FBG: 11.2±1.7, n.s. and 19.0±2.2 mM, p<0.01), hypertriglyceridemia (6.7±0.7, p<0.001 and 5.8±0.6 mM, p<0.001) and both peripheral and hepatic insulin resistance (Matsuda: 165±12, p<0.0001 and 176±16, p<0.0001) compared to 6-w old ZDF. In situ pancreas perfusion showed an insulin secretion profile characterized by a suppressed phase I amplitude and complete flat phase II leading to an overall suppression of insulin secretory capacity. Analysis of islet morphology at 10 and 12 weeks showed an increased islet area by ~90% (p<0.001) and ~114% (p<0.0001), decreased insulin staining intensity by 32% (p<0.0001) and ~48% (p<0.0001) and severe islet destruction measured by the increase in α-cell invasion in the islet core (+380%, p<0.0001 and +448%, p<0.0001).
Conclusion: Our results demonstrate that pre-diabetic 6-week ZDF rats show significant changes of islet structure and function compared to age-matched Lean. During disease progression, further functional and morphological islet changes compensating for insulin resistance precede the development of hyperglycemia and suggest that the ZDF rat model is suitable for preclinical characterization of anti-diabetic drugs modifying islet function and early disease progression.

Differential microRNA expression in human pancreatic islets from patients with type 2 diabetes

F. Dotta[1,2], A. Po[3], G. Sebastiani[1,2], A. Paganelli[3], F. Grieco[1,2], R. Gallo[1,2], M. Bugliani[4], A. Gulino[3], P. Marchetti[4], E. Ferretti[3];
[1]University of Siena, [2]Fondazione Umberto Di Mario, Siena, [3]University of Rome "La Sapienza", [4]University of Pisa, Italy.

Background and aims: MicroRNAs (miRNAs or miRs) are a recently identified class of small cellular RNAs, whose function is to pair the mRNAs of protein-coding genes with subsequent transcriptional and post-transcriptional regulation of gene expression. MicroRNAs have emerged as important regulatory factors involved in developmental processes, such as neural progenitor cell growth and differentiation and their altered expression has been observed in a large number of malignancies. In addition, increasing evidence has shown that miRNAs are involved in the development of endocrine pancreas as well as in the regulation of insulin secretion and insulin signaling. In the light that type 2 diabetes is characterized by a defective insulin secretion combined to impaired insulin signaling, we performed a miRNA expression profiling in isolated human pancreatic islets obtained from 5 type 2 diabetic and from 5 age-matched control multi-organ donors.
Materials and methods: To this end, RNA isolation from tissue samples was performed using TRIZOL reagent and quantitative analysis of 150 miRNAs was performed using the specific stem-loop primers for reverse transcription followed by real-time PCR. All values were normalized to endogenous controls U6 and U66. Hierarchical clustering analysis and dendrograms were performed on the Q-PCR expression levels of miRNAs employing Spotfire software.
Results: Among the 150 microRNAs analyzed, 142 were expressed in pancreatic islets and 16/142 resulted differently expressed in type 2 diabetic vs control human islets. An online search of miRNAs targets by miRanda and TargetScan databases revealed that a subset of these differently expressed miRs targeted several genes involved in regulation of beta cell development and function and in insulin signaling. We specifically studied miR-124 which resulted 30-fold hyperexpressed in type 2 vs control diabetic islets, by silencing its expression in MIN6 cells which, interestingly, resulted in increased expression of a number of predicted target genes such as myotrophin (involved in insulin exocytosis), Foxa-2 and NeuroD and in a 5-fold increase in basal insulin secretion (measured at 3.3mM glucose). Indeed, when over-expressed in 293T cells miR-124 was able to repress the translation of constructs in which the myotrophin -3'UTR and Foxa-2 -3'UTR were fused to the renilla-luciferase open reading frame.
Conclusion: In conclusion, we here report a differentially miRNA profiling in type 2 diabetic vs control human pancreatic islets which includes a major hyperexpression of miR-124, whose silencing resulted in increased insulin secretion and expression of genes involved in beta cell function and development, leading to the hypothesis that an altered miRNA expression may contribute to beta cell defects in type 2 diabetes.

Foxa1 and Foxa2 are critical regulators of glucagon gene expression and of genes controlling alpha-cell differentiation

A. Guérardel, A. Mamin, J. Philippe;
University Hospital and Faculty of Medecine, Geneva, Switzerland.

Background and aims: The Foxa1 and Foxa2 members of the Forkhead family are involved in glucose homeostasis, particularly in the protection against hypoglycaemia in mammals. Foxa proteins are expressed during embryonic development and in adulthood in liver and pancreas. They are essential for the regulation of hepatocyte-specific expression of several target genes and contribute to the specification of the pancreas. Gene ablation studies revealed a critical role for Foxa1 in the regulation of glucagon biosynthesis and in pancreatic islet function and for Foxa2 in the regulation of the terminal differentiation steps and the maturation of α-cells. The aims of the present study are to discriminate the respective role of the *foxa1* and *foxa2* genes on *glucagon* gene transcription by the precise identification of their cognate DNA elements and characterize their target genes to better understand the differentiation of the pancreatic α-cells.
Materials and methods: Specific inactivation of the *foxa1* and *foxa2* genes were performed by transient transfection with siRNA in islet hamster (InR1G9) glucagon-producing cells and by creating InR1G9-derived stable clones overexpressing a dominant negative (DN) form of Foxa2 lacking the transactivation domain.
Results: Both Foxa1 and Foxa2 activate the *glucagon* gene promoter in non islet BHK cells. *In vitro*, Foxa1 specifically interacts with G1, G2 and site A of the *glucagon* gene promoter whereas Foxa2 only with G1 and G2. *In vivo*, both factors also bind to the *glucagon* gene promoter as demonstrated by ChiP assay. SiRNA experiments in InR1G9 cells revealed that inhibition of the expression of Foxa1, Foxa2 or both factors 72h after transfection decreased glucagon mRNA levels respectively by 60%, 40% and 68% and that Foxa2 could not compensate Foxa1 inhibition and *vice versa*. Similarly, both glucagon and its mRNA levels were decreased in stable clones expressing the DNFoxa2. SiRNA directed against Foxa1, Foxa2 or both decreased *glucagon* promoter activity respectively by 63%, 62% and 77% and Foxa binding sites mutagenesis experiments indicated that the effects of Foxa1 and Foxa2 on *glucagon* gene expression are exerted independently through the binding to G2 but not G1 or site A. In addition to the *glucagon* gene, Foxa1 and Foxa2 regulate a number of genes which are important for the α-cell differentiation. Indeed, we found that inhibition of *foxa1* and *foxa2* genes down-regulate the genes coding the G protein-coupled receptor GPR40 affecting glucagon secretion, MafB involved in α-cell differentiation and function and *glucagon* gene expression and HNF4α which is known to be regulated by Foxa2 in pancreatic β-cells. The expression of transcription factors such as Pax6, cMAF and Glut1 was not affected.
Conclusion: These results highlight the critical importance of Foxa1 and Foxa2 in glucagon biosynthesis and secretion, α-cell differentiation and glucose homeostasis.

Functional effects of the common *SLC30A8* Arg325Trp polymorphism on isolated human pancreatic islets

S. Cauchi[1], S. Del Guerra[2], H. Choquet[1], V. D'Aleo[2], C. Groves[3], R. Lupi[2], M. McCarthy[3], P. Froguel[1], P. Marchetti[2];
[1]Genomics and Molecular Physiology of Metabolic Diseases, CNRS, Lille Cedex, France, [2]Department of Endocrinology and Metabolism, University of Pisa, Italy, [3]Endocrinology and Metabolism, Churchill Hospital, Headington, Oxford Centre for Diabetes, United Kingdom.

Background and aims: Genome-wide association studies have shown that Arg325Trp polymorphism in *SLC30A8* (rs13266634) is associated with type 2 diabetes (T2D) susceptibility. *SLC30A8* is mainly expressed in beta-cells and encodes a zinc transporter protein member 8 (ZnT-8) involved in insulin maturation, storage and secretion. The major risk C allele has been found to associate with decreased in-vivo insulin release in a few, but not all studies. To shed further light on this issue, we assessed the relationships between *SLC30A8* genotypes and some properties of isolated human islets.
Materials and methods: DNA from multiorgan donors (n: 82; age: 59.1±16.6 yrs; gender: 38 males and 44 females; body mass index: 24.8±4.2 kg/m2) was genotyped for the Arg325Trp polymorphism; then, pancreatic islets were isolated and insulin secretion in response to 3.3 mmol/l glucose (G), 16.7 mmol/l G, 3.3 mmol/l G plus 20 mmol/l arginine and 3.3 mmol/l G plus 100 μmol/l glibenclamide was determined by the batch incubation technique (45 min per stimulus). Finally, quantitative RT-PCR expression of ZnT-8, insulin and glucagon was assessed.
Results: Overall, 42 CC (51.2%), 36 CT (43.9%) and 4 TT (4.9%) samples were studied. When analyzed together, insulin release (μU/islet/min) was 0.040±0.018 at 3.3 mmol/l G and increased to 0.136±0.090 at 16.7 mmol/l G (stimulation index, SI: 3.42±1.75), 0.112±0.067 at 3.3 mmol/l G plus arginine (SI: 2.83±1.67), and 0.127±0.087 at 3.3 mmol/l G plus glibenclamide (SI: 3.13±1.57). Whatever the experimental condition, the release of insulin was similar in the CC, CT and TT genotype groups. Islet expression (2-ΔCt) of ZnT-8 did not differ significantly between the CC (0.194±0.272, n:17), CT (0.119±0.171, n: 10) and TT (0.361±0,646, n: 4) genotypes. Furthermore, insulin and glucagon gene expressions were similar in the three genotypic groups. Interestingly, *SLC30A8* expression was positively correlated with insulin (r: 0.39, p=0.03) and glucagon (r: 0.80, p<0.001) expressions. Electron microscopy of islet cells was performed in 3 CC and 1 CT cases. In the pres-

ence of the CT genotype, insulin granules ultrastructure appeared clearly different, with larger and less electrondense core; in addition, a lower amount of alpha-cells (< 5%) was observed.
Conclusion: In isolated human islets, the risk C allele of the Arg325Trp polymorphism does not affect ex-vivo insulin secretion and *SLC30A8* expression. However, the Arg325Trp genotype may be associated with changes of insulin granules ultrastructure.

The granular zinc transporter SLC30A8 in beta cells is linked to changes in expression of enzymes involved in proinsulin conversion
L.M. Sheridan[1], S. Sarkar[1], R.M. O'Brien[2], H.W. Davidson[1], J.C. Hutton[1];
[1]Barbara Davis Center for Childhood Diabetes, University of Colorado-Denver, Aurora, [2]Molecular Physiology and Biophysics Department, Vanderbilt University Medical Center, Nashville, United States.

Objective: ZnT8, the product of the SLC30A8 gene, has been implicated in perturbing the processing of proinsulin in non-diabetic relatives of Type 2 diabetic subjects. The common non-synonymous SNP encoding a W>R change at position 325 in the c-terminus confers genetic risk of developing disease. Our aim was to investigate whether the differences in the zinc transport in MIN6 beta cells were affected by overexpression or suppression of ZnT8 and how this might impact prohormone processing and secretory granule biogenesis and secretion.
Methods: MIN6 cells adenovirally expressing either human ZnT8(R325) or ZnT8(W325) variants or subjected to siRNA knockdown of endogenous ZnT8 were analyzed via western blot for protein expression, and ELISA for insulin secretion. Zinc-sensitive BHK cells were used to assess ZnT8 zinc transport ability.
Results: ZnT8 reduces cytoplasmic zinc in zinc-sensitive BHK cells compared to controls, but not as efficiently as the lysosomal ZnT2. Swapping the carboxyl terminus of ZnT2 with that of ZnT8 diminishes the zinc transport ability of ZnT2. siRNA knockdown of endogenous ZnT8 in MIN6 cells resulted in a decreased expression of insulin processing enzymes PC1, PC2 and CPE. Conversely, overexpression of ZnT8 in MIN6 cells resulted an increased expression of PC1, PC2, and CPE. Glucose-stimulated insulin secretion is enhanced in ZnT8-overexpressing MIN6 cells.
Conclusion: Changes in levels of transcription including the diabetes-associated R allele impact upon the levels and presumably activity of pro-protein convertases and provide a possible explanation for differences in circulating proinsulin/insulin ratios in pre-diabetes.

Whole genome profiling approaches to understand the function of Math6 during endocrine cell differentiation
M. Ejarque[1,2], G. Pujadas[1,2], J. Altirriba[1,2], L. Sanchez[1,2], F. Lynn[3], R. Gomis[1,2], R. Gasa[1,2];
[1]IDIBAPS-Hospital Clínic, Barcelona, Spain, [2]CIBERDEM, Barcelona, Spain, [3]Diabetes Center, San Francisco, United States.

Background and aims: Basic helix-loop-helix (bHLH) transcription factors often function in cascades to regulate cell fate decisions and differentiation programs in numerous tissues. In the pancreatic endocrine cell lineage, neurogenin3 (neurog3) turns on endocrine differentiation and activates neuroD1, which maintains the differentiation program. Another bHLH factor whose gene is induced by neurog3 is math6. We have recently shown that this factor is expressed in differentiating endocrine cells in the embryonic pancreas and, like neurog3, it is absent from mature islet cells. Math6 has a major non-redundant role in organismal development as demonstrated by early embryonic lethality of math6 knockout embryos. Yet, the precise function of math6 in pancreas formation remains elusive. This work aims to gain insight into the function of math6 in the endocrine transcriptional cascade through the identification of its gene targets.
Materials and methods: We have used math6 gain-of-function (ectopic expression) and loss-of-function (RNA interference) strategies in a neurog3-dependent cellular model of endocrine differentiation using mouse pancreatic duct cells. The effects of overexpressing or silencing math6 on the expression profile of duct cells have been assessed using Affymetrix expression microarrays.
Results: Overexpression of math6 alone has a minor impact on the transcriptome of mouse duct cells (28 genes were significantly different from B-galactosidase-expressing control cells), whereas concomitant expression of math6 and neurog3 results in the inhibition of 11 neurog3 gene targets. In contrast, silencing of math6 during the differentiation process promoted by neurog3 affects the expression of nearly 300 genes. Of these, 46% are also modulated by neurog3 and, remarkably, in many cases in an opposite way. Finally, gene ontology analysis of the identified math6 targets has revealed the potential involvement of this factor in the regulation of important developmental processes such as ubiquitination, chromatin remodelling and the wnt signalling pathway.
Conclusion: This study identifies for the first time a cohort of potential targets of math6 in the endocrine differentiation program. Remarkably, math6 and neurog3 appear to exert opposite effects on specific gene locus, raising the possibility that math6 may act as a regulatory component of neurog3 function. These data may be useful for the development of *in vitro* protocols for the generation of replacement beta cells for the treatment of diabetes.

Impact of c-Maf, one of the large Maf transcription factors, on pancreatic beta cell function
M. Yoshida[1], T. Kondo[1], Y. Hida[2], N. Yoshioka[1], T. Koike[1];
[1]Department of Medicine II, Hokkaido University Graduate School of Medicine, [2]Department of Diabetes and Endocrinology, Tonan Hospital, Sapporo, Japan.

Background and aims: Beta-cell specific transcription factors, such as PDX-1, BETA2, and MafA, play an important role in regulating insulin gene expression. MafA, a large-Maf factor, positively regulates insulin gene expression. We previously showed small-Maf factors (MafF, MafG and MafK), that lack an N-terminal transactivation domain present in the large-Maf factors, are also expressed in beta cells and thus, can function as a negative regulator of insulin gene expression. These observations suggest that both large- and small-Maf factors are important for the regulation of insulin gene expression through Maf Response Element (MARE) on insulin promoter. c-Maf, one of the large-Maf transcription factors, is reported to be expressed in helper T cell, chondrocyte, and lens, and involved in the differenciation of these cells. Recent studies have reported that not only MafA but also c-Maf was expressed in adult pancreatic beta-cells and could positively regulate insulin expression. However, physiological roles of c-Maf in pancreatic beta-cells is not known. To investigate the effect of c-Maf on insulin gene expression and the underlying mechanisms by which c-Maf expression is regulated in response to glucotoxicity, lipotoxicity, and oxidative stress in beta-cells.
Methods and results: Experiment 1): MIN6 cells, a mouse beta-cell line, were cultured and transfected with mouse c-Maf siRNA by lipofection. Control siRNA was used as negative control. Western blot analysis, real-time RT-PCR, and reporter assay using insulin promoter:luciferase reporter construct were performed to evaluate both cMaf mRNA and protein levels and to examine the effect on insulin promoter activity. Knockdown of c-Maf in MIN6 cells resulted in significant reduction of c-Maf, but not MafA, mRNA and protein levels and concomitant repression of insulin gene. Experiment 2): To investigate the impact of glucotoxicity, lipotoxicity, and oxidative stress on c-Maf expression in beta-cells, MIN6 cells were cultured in different concentrations of glucose, with palmitate or with tert-butyl hydroperoxide (tBHP). c-Maf expression was increased under lipotoxic condition. Experiment 3): To evaluate c-Maf expression in vivo, C57BL/6 mice were fed normal diet (ND) or high-fat diet (HFD) from 5 weeks of age. At 12 weeks of age, serum levels of total cholesterol, triglycerides (TG), free fatty acid (FFA), insulin and blood glucose level were analyzed. Islets were isolated and lysed for western blotting. Pancreatic sections were obtained for immunohistochemistry. Feeding HFD resulted in higher levels of TG, FFA, insulin and blood glucose, and increased beta-cell mass. cMaf expression level was unchanged, while MafA expression in a HFD group was significantly increased.
Conclusion: These data clearly demonstrate that c-Maf has an impact on insulin gene expression in beta-cells and reduction in c-Maf expression may cause beta-cell dysfunction. However, further studies are necessary for elucidation of the physiological roles in vivo.

417

Posttranslational modifications of Pax6 and Pax6(5a) in pancreatic beta cells

G. Wolf, A. Karkour, A. Ostmann, J. Seidel, R. Walther;
Department of Medical Biochemistry and Molecular Biology, University of Greifswald, Germany.

Background and aims: Pax6 is an important transcription factor of the glucagon gene expression in pancreatic alpha cells, while in beta cells the influence of Pax6 on insulin gene expression is discussed controversially. We identified Pax6 as an inhibitor on the rat insulin gene 2 promoter. However the impact of Pax6(5a), an alternative splice product, is still unclear. *In vitro* both Pax6 isoforms are phosphorylated by CaMK2 at S122 and CK2 at S206. Using starved and high glucose conditions we further studied posttranslational modifications by kinases and glycosyl-transferases of both isoforms in pancreatic beta cells.
Materials and methods: Microscopical and reporter gene analyses with overexpressed wild type or mutated (YFP-)Pax6 and (YFP-)Pax6(5a) were done to study their intracellular localization and effects on insulin gene expression in dependence on glucose. Glycosylation of both isoforms was investigated using specific antibodies after immunoprecipitations and Western Blots. Stably transfected BRIN-BD11 cells overexpressing siRNA against Pax6 transactivation domain or exon 5a were generated to verify the inhibitory actions of Pax6 in pancreatic beta cells using northern blots and radioimmunoassays.
Results: Co-Immunprecipitations confirmed a direct interaction between CK2 or CaMK2 and Pax6. CaMK2-phosphorylation site S122 was very sensitive to mutations, while mutation of S206 showed no effects on intracellular translocation and insulin gene expression. Glycosylation of Pax6 was only detectable in cells after glucose deprivation. Both constructs of siRNA diminished Pax6 expression and effects.
Conclusion: Pax6 and Pax6(5a) are posttranslational modified by phosphorylation and glycosylation which may modulate their functional activities.

418

Pax6 is crucial for beta cell functions and represents a component of glucose action on insulin biosynthesis and secretion

Y. Gosmain, L. S.Katz, A. Guérardel, J. Philippe;
Endocrinology/Diabetologia, HCUGE-Hopital Cantonal de Genève, Geneva, Switzerland.

Background and aims: Pax6 is a paired box homeodomain protein expressed in all cells of the endocrine pancreas during development and in the adult stage. We previously demonstrated that Pax6 exerts a major role in glucagon gene transcription and more widely in α-cell differentiation and functions. Pax6 is also involved in β-cell development. Inasmuch as specific knock-out for Pax6 in β-cells of mice leads to a marked decrease in insulin levels and diabetes. In humans, Pax6 heterozygous mutations are also associated with diabetes mellitus.To better understand the role of Pax6 in the differentiation and function of β-cells, we investigated the transcriptional network of Pax6 in HIT insulin-producing cells through a candidate gene approach study.
Materials and methods: We developed two Pax6-deficient models, a partial knock-down with specific siRNA and selected clones expressing a dominant negative form of Pax6 in HIT cells. We also investigated the effect of glucose on Pax6 gene expression in isolated rat islets.
Results: In both models, insulin gene expression was decreased by 50 %, reflecting the important role of Pax6 in insulin gene transcription. In addition to the insulin gene, we report that Pax6 deficiency in β-cells led to a significant decrease of Pdx1, Isl1, c-Maf and Sox4 mRNA levels which are all critical for β-cell differentiation and functions. Furthermore, we also identified several new Pax6 target-genes coding for key proteins involved in glucose metabolism and insulin biosynthesis among them glucokinase (GK), the insulin receptor (IR), the glucose transporter (GluT2) and the fatty-acids receptor GPR40. We further show that Pax6 controls directly or indirectly the promoter activities of these genes in insulin-producing cells.As Pax6 is involved in the control of several genes implicated in insulin biosynthesis and secretion, we examined whether Pax6 might be regulated by glucose in rat islets. We found that high glucose increases Pax6 mRNA levels 2-fold compared to low glucose.
Conclusion: We conclude that Pax6 regulates key genes involved in insulin biosynthesis and secretion and that Pax6 itself is regulated by glucose. These results underline the multiple steps at which glucose affects β-cell function and the critical role of Pax6 in this regulation.

Islet Brain 1 controls insulin secretion by maintaining the contents of annexin A2

N. Beeler[1,2], M. Ferdaoussi[1,2], J.-Y. Chatton[1,3], G. Niederhäuser[1,2], B. Riederer[1,4], R. Regazzi[1], G. Waeber[2], A. Abderrahmani[1,2];
[1]Department of Cell Biology and Morphology, [2]Service of Internal Medicine, Centre Hospitalier Universitaire Vaudoise-University of Lausanne, [3]Cellular Imaging Facility, [4]Center for Psychiatric Neuroscience, Proteomics Unit, CHUV, CERY, Prilly-Lausanne, Switzerland.

Background and aims: Islet Brain 1 (IB1) plays a key role in the beneficial effects of the long acting agonist of the glucagon-like peptide 1 receptor exendin 4 (ex-4) on pancreatic beta cells. IB1 is rather recognized as an inhibitor of the c-Jun N terminal Kinases (JNK) pathway in pancreatic beta cells and thereby, prevents inhibition of insulin expression and apoptosis induced by stress-activated JNK pathway. Several lines of evidence support an additional role for IB1 in beta cells as a regulator of insulin secretion. First, induction of IB1 expression parallels the stimulatory effects of ex-4 on insulin secretion. Second, impairment of IB1 dimerization diminishes glucose-induced insulin secretion. In the latter case, the loss of secretion is not linked to activation of the JNK pathway and subsequent apoptosis, suggesting that IB1 controls insulin secretion through a JNK-independent mechanism. The goal of this study was to clarify the role of IB1 in the control of insulin secretion.
Materials and methods: The short hairpin RNAs (shRNAs) directed against IB1 or scrambled shRNA were either cloned into plasmids or lentiviral vectors. Insulin secretion elicited by various secretagogues (glucose, KCl, IBMX and forskolin) was monitored by measuring either the release of insulin by the EIA kit (Spi-Bio) or by ELISA (Roche). mRNA and protein levels were assessed by quantitative real-time PCR and western blotting respectively. Proteomic analysis was performed by 2D-gel electrophoresis followed by protein sequencing. Calcium influx was measured by fluorescence microscopy.
Results: Suppressing IB1 expression markedly reduced glucose-induced insulin secretion in INS-1E, MIN6 and isolated rat islets. This effect was specific since the introduction of an IB1-encoding plasmid, resistant to shRNA, restored the capacity of the cells to secrete in response to glucose. Diminution in IB1 contents did not affect calcium influx but still impaired secretion in response to KCl, suggesting a defect in exocytosis. We then assessed whether activation of the JNK pathway could mediate the loss of this beta cell task. Co-treatment of the cells with either the JNK inhibitor peptide or the JNK catalytic activity inhibitor SP600125 did not prevent loss of insulin secretion evoked by silencing of IB1 expression. Proteomic analysis revealed a drastic reduction in the protein content of annexin A2 (Anxa2), a calcium-dependent phospholipid binding protein that regulates exocytosis of neuroendocrine cells. Suppression of Anxa2 in insulin-secreting cells with interference RNA impaired nutrients-induced hormone release, thus mimicking the effects of IB1 silencing.
Conclusion: IB1 is required for the control of nutrients-stimulated insulin secretion. This IB1-dependent function relies on the adequate levels of Anx2A.

Effects of nitric oxide on Cap-dependent and Cap-independent insulin biosynthesis in human islets

R.G. Fred, N. Welsh;
Medical Cell Biology, Uppsala University, Sweden.

Background and aims: Although insulin biosynthesis has been extensively studied, most of the work has been done in rodent islets. Due to the significant differences between rodent and human islets in islet structure, beta cell content and sensitivity to cytokines and stress, there might also be differences in the regulation of insulin biosynthesis. Based on the idea that polypyrimidine protein 1 (PTBP1) upon binding to the insulin mRNA 5'-UTR could induce cap-independent translation of insulin and that such a mechanism would uphold insulin production during cellular stress, we wanted to investigate both if insulin could be translated in a cap-independent manner and how nitric oxide induced cellular stress would affect the insulin mRNA translation.
Materials and methods: The affinity of PTBP1 to the human insulin mRNA 5'-UTR was measured using cytoplasmic extracts from human islets incubated in either 1.67 or 16.7 mM glucose for 2 hours w/wo 2.5 mM DETA/NO (a nitric oxide donor). These cytoplasmic extracts was then incubated with

biotinylated RNA oligonucleotides corresponding to the insulin mRNA 5'-UTR. The sequence specific proteins were then eluted, using dynabeads, and separated on SDS-PAGE for immunoblotting. Insulin biosynthesis was estimated by measuring the incorporation of L-[3,4,5-3H] leucine into insulin of 20 islets incubated for 2 h in KRBH. For the different experimental groups 1.67 or 16.7 mM glucose was added either in presence or absence of 1 mM DETA/NO and 0.1, 1.0, 10 mM hippuristanol (an eIF4A inhibitor that specifically inhibits cap-dependent translation). Labeled islet insulin was immunoprecipitated using guinea pig anti-insulin serum and protein A-sepharose while total protein was precipitated using trichloroacetic acid.
Results: The PTB pulldown experiments using RNA oligonucleotides corresponding to either the first 29 or the following 30 nucleotides of the 5'-UTR sequence clearly showed that PTB binds specifically to the second part of the insulin mRNA 5'-UTR. The insulin biosynthesis data show that a very high proportion of the insulin mRNA translation (93%) is cap-dependent at a high glucose concentration, but also that part of the insulin biosynthesis takes place through a cap-independent mechanism. Furthermore, DETA/NO treatment significantly decreased the translation of insulin by 83% and total protein biosynthesis by 73%. By expressing insulin biosynthesis as a percentage of total protein biosynthesis we observed that the percentage insulin biosynthesis was lower in DETA/NO treated islets than in control islets. In addition, DETA/NO-induced inhibition of insulin biosynthesis was less pronounced in the presence of hippuristanol. In low glucose, however, DETA/NO did not decrease insulin biosynthesis in relation to total protein.
Conclusion: Our studies shows that PTBP1 binds to the insulin mRNA 5'-UTR in vitro. The main bulk of the insulin synthesis occurs via cap-dependent translation and this process is preferentially inhibited by NO. We also show that cap-independent insulin translation occurs and that this event is to a lesser extent affected by NO. It is tempting to speculate that PTBP1 binding to insulin mRNA maintains a basal rate of insulin biosynthesis at conditions of low glucose or cellular stress.

Pancreatic duodenum homeobox-1 (PDX1) is phosphorylated in living pancreatic beta cells (MIN6) at serine 269
F. Semplici[1], R. An[1], G. daSilvaXavier[1], F. Meggio[2], M. Pagano[2], L.A. Pinna[2], G.A. Rutter[1];
[1]Section of Cell Biology, Division of Medicine, Imperial College, London, United Kingdom, [2]Biological Chemistry, University of Padova, Italy.

Background and aims: Pancreatic duodenum homeobox-1 (PDX1) is a crucial regulator of pancreatic development and mature β-cell function. At present, the molecular mechanisms, including post-translational modification(s), through which PDX1 nuclear uptake and DNA binding activity are regulated are poorly understood. In order to identify physiologically relevant phosphorylation sites for PDX1 we have undertaken phospho-proteomic analysis of the protein over-expressed in clonal β-cells.
Materials and methods: An adenovirus expressing wild type c-*myc*-tagged PDX1 was generated for infection and expression of pancreatic β-cell lines. PDX1 protein was immunoprecipitated from infected β-cells with an anti-c-*myc* antibody and separated on SDS-PAGE. A PDX1-containing band was identified and subjected to mass spectrometry for phosphorylation site mapping. A phospho-specific antibody was accordingly generated and validated.
Results: We revealed by mass spectrometric analysis of PDX1 expressed in INS1 (832/13) β-cells that Ser269 is a novel *in vivo* PDX1 phosphorylation site. Therefore we generated a phosphospecific antibody against phopsho-Ser269 and we used it to confirm further in MIN6 cells and in mouse islets that PDX1 is effectively phosphorylated *in vivo*. Wild type c-*myc*-tagged PDX1-expressing adenovirus was mutagenized to replace Ser269 either with an alanine, to produce a dephosphomimetic S269A mutant, or with a glutamic acid, producing a phosphomimetic S269E mutant. MIN6 cells were infected with either PDX1 wild type or the mutants and immunostained with anti-c-*myc* antibody. Whereas in response to an increase (3-30mM) in glucose concentration both the wild type and the S269A mutant translocated from the nuclear periphery to the nucleoplasm, the phosphomimetic S269E mutant localized preferentially to the nuclear periphery at both glucose concentrations. ^{35}S-Met/Cys pulse-chase analysis revealed that neither S269E nor S269A mutations displayed altered protein stability. Homeodomain Interacting Protein Kinase 2 (HIPK2) has recently been reported to be expressed in pancreatic endocrine cells and to directly phosphorylate the C-terminal domain of PDX1, which contains two potential phosphorylation sites that meet HIPK2 requirements: threonine^{214}-proline (Thr214), and serine^{269}-proline (Ser269). Hence, we postulated that this latter serine residue may be a specific target for HIPK2: indeed, the antiphospho-Ser269 antibody recognized recombinant PDX1 after it was subjected to *in vitro* phosphorylation by HIPK2 but not by several other kinases.
Conclusion: We demonstrate that Serine 269 is phosphorylated in living clonal pancreatic β-cells. We observed that a phosphomimetic S269E mutant of PDX1 failed to respond to glucose with translocation from the nuclear periphery to nucleoplasm. We identified HIPK2 as the most likely responsible kinase for phosphorylation at Ser269. Further investigations will be necessary to establish the physiological significance of this newly reported post translational modification of PDX1.

Conditional overexpression of Pax4 in pancreatic beta cells protects mice from developing streptozotocin-induced diabetes
K. Hu He, D. Aeberhard, P. Meda, B.R. Gauthier;
Physiology and metabolism, University Medical Center, Geneva, Switzerland.

Background and aims: We have previously shown that the forced expression of the diabetes-linked transcription factor Pax4 is crucial for islet beta-cell proliferation and survival *in vitro.* We have now generated the first animal model in which Pax4 expression can be specifically induced in beta-cells, allowing us to determine the protective role of Pax4, by challenging animals with streptozotocin, to induce a rapid and sustained hyperglycaemic state.

Material and methods: We generated two transgenic mouse lines harbouring either the wild type mouse Pax4 (mPax4WT) or a Type 2 diabetes-associated variant (mPax4R129W), under control of a doxycycline (DOX) inducible TRE-CMV promoter. Transgenic Pax4 animals were then bred to the Rat Insulin Promoter-Reverse Tetracycline Transactivator (RIP-rtTA) transgenic mouse line to restrict transgene expression to beta-cells. Pax4 expression and localization were determined by QT-PCR and immunohistochemistry respectively. Double transgenic animals were continuously given 1 g/L DOX in the drinking water and challenged once with 200 mg/Kg streptozotocin i.p., an agent that causes massive beta-cell death.
Results: QT-PCR revealed a 14.7 ± 6.5 fold increase in mPax4 mRNA levels in isolated islets from DOX-treated animals, as compared to those of control untreated animals. No expression was detected in other organs. Immunohistochemistry of pancreas sections confirmed Pax4 expression only in beta-cells of mice treated with DOX. Double transgenic animals exhibited normal glucose tolerance and insulin sensitivity, indicating that Pax4 expression did not alter glucose metabolism. Streptozotocin treated control animals developed a severe hyperglycaemia (n=9, 22.2 ± 2.1 mmol/L glucose) whereas double transgenic animals expressing Pax4WT maintained normal blood glucose (n=10, 8.17 ± 0.47 mmol/L glucose $P < 0.001$). Double transgenic animals expressing Pax4R129W developed an intermediate hyperglycaemia (n=6, 15.2 ± 3.5 mmol/L glucose). Immunofluorescence staining of sections of pancreas sampled 1 month after the streptozotocin treatment revealed a massive decrease in the number of beta-cells in control animals whereas Pax4WT overexpressing animals sustained a normal beta-cell mass.
Conclusion: When pancreatic beta-cells are challenged by a pharmacological insult such as streptozotocin, overexpression of Pax4WT confers increased protection against apoptosis to beta-cells, thus preventing the development of a hyperglycaemic state.

Regulation of the wnt signalling pathway by endocrine differentiation bHLH factors
G. Pujadas[1,2], M. Ejarque[1,2], L. Sánchez[1,2], J. Altirriba[1,2], R. Gomis[1,2], R. Gasa[1,2];
[1]Laboratori de Diabetis i Obesitat, Institut d'investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), [2]CIBER de Diabetes y Enfermedades Metabólicas Asociadas (CIBERDEM), Barcelona, Spain.

Background and aims: In the embryonic pancreas, the *atonal*-related bHLH gene neurogenin3 (ngn3) initiates the differentiation program that culminates in the formation of the endocrine cells of the islets of Langerhans. One of the genes activated by ngn3 is the gene for the bHLH factor math6. Math6 is expressed in ngn3+ endocrine progenitors and, like ngn3, is absent from differentiated endocrine cells. However, the specific role of math6 in the endocrine cascade is unknown. Using expression microarrays, we identified several genes related to the wingless (wnt) signalling pathway whose expression is modulated by a siRNA specific for math6 (simath6) in ngn3-expressing duct cells. These data raised the hypothesis that math6 may regulate this pathway during endocrine differentiation. However, while it is well established that activation of the canonical wnt/b-catenin pathway is needed for proper growth and progenitor proliferation in the embryonic pancreas, the involvement of wnt signals in the differentiation of the endocrine cell lineage remains controversial. Here, we have aimed at dissecting the potential link between endocrine differentiation bHLH factors, namely ngn3 and math6, and the wnt signalling pathway.
Material and methods: Overexpression and RNA interference using recombinant adenoviruses in mouse pancreatic duct cells. Gene expression profiles by Affymetrix. Gene expression quantitation by real time PCR. TOP-FLASH luciferase reporter system for measurement of canonical wnt activity.
Results: Microarray analysis reveals that knock-down of math6 activation by ngn3 results in significant changes in the expression of genes coding for several components of the wnt signalling pathway, including ligands, modulators, effectors and targets in duct cells. Likewise, microarray analysis has shown that ectopic expression of ngn3 alone promotes changes in the expression of a number of wnt-related genes in the same cellular context. Differential expression has been confirmed by real time PCR. Some of the identified genes are regulated by both ngn3 and simath6 (*wnt9a, bambi, igfbp4, cfos, tmem46* etc) whereas others are modulated by ngn3 alone (*wnt7b, dkk1*) or by simath6 alone (*TCF7L2*). It is noteworthy that math6 and ngn3 appear to exert opposite effects on the expression of many of the identified common gene targets, suggesting that these factors counter-regulate each other. In this regard, we demonstrate that ngn3 activates while math6 inhibits the activity of the canonical wnt activity as measured with a TCF-dependent luciferase reporter system. To this date, we have confirmed expression of all the identified genes in the embryonic pancreas at the time of endocrine cell differentiation. On-going work in the lab is aimed at understanding the molecular bases for the regulation of the activity of this pathway by ngn3 and math6.
Conclusion: Altogether, this work supports the existence of a link between endocrine bHLH factors and the wnt signalling pathway and points to the need of reassessing whether wnt signals participate in endocrine cell fate decisions during pancreatic organogenesis.

Wnt/Klotho interaction regulates the proliferation of pancreatic beta cells
S. Schinner, F. Ülgen, W.A. Scherbaum;
Endocrinology, University Hospital Düsseldorf, Germany.

Background and aims: Acute stimulation with Wnt-agonists induces beta-cell proliferation and insulin secretion. However, in fibroblasts chronic Wnt-stimulation represses cell proliferation and induces cellular aging. Klotho is a regulator of aging and has recently been identified as an extracellular Wnt-antagonist. The expression and function of klotho in pancreatic beta-cells is not known. Therefore, we investigated the effect of chronic Wnt-stimulation and the role of klotho on the proliferation of insulin-producing cells.
Materials and methods: Transient transfections of insulin-producing Ins-1 cells with a Wnt-reporter gene (TOPFLASH). Isolation, culture, mRNA- and protein extraction of primary murine beta-cells. PCR and Western Blot analysis of Ins-1 and primary beta-cells. Proliferation assays (3H-thymidine uptake). Immunohistochemistry of pancreata of wildtype and NZO (New-Zealand Obese) mice.
Results: We found klotho to act as an antagonist of canonical Wnt-signaling in Ins-1 beta-cells as recombinant klotho inhibited Wnt-mediated transcription (TOPFLASH reporter gene). In primary murine beta-cells we detected klotho expression on the mRNA and protein level. An obese pre-diabetic mouse model (NZO mice) showed an increase in the expression of Wnt4 and a decrease in the expression of klotho in pancreatic islets as compared to wildtype mice (assessed by immunohistochemistry). On the functional level, we found acute (24h) stimulation of Ins-1 cells wíth recombinant Wnt3a protein to induce beta-cell proliferation (129%; $p<0.001$) according to our previous findings. However, chronic Wnt-stimulation over 35 days repressed the proliferation of Ins-1 cells almost completely (to 18% as compared to untreated controls; $p<0.05$). The proliferation was restored by co-stimulation with klotho in addition to Wnt3a to 136% ($p<0.001$).
Conclusion: These data demonstrate the expression of endogenous Wnts and klotho in pancreatic beta-cells and their differential regulation in a pre-diabetic mouse model. Here we show that chronic Wnt-stimulation represses beta-cell proliferation and that klotho acts as a survival factor, suggesting that the Wnt/klotho interaction acts as a long-term regulator of the beta-cell mass.

β-catenin as a novel glucose-sensor in INS1E beta cells
E. Cognard, P.R. Shepherd;
Molecular Medicine and Pathology, University of Auckland, New Zealand.

Background and aims: Canonical Wnt signaling is a key feature of growth, differentiation and metabolism. Previous studies have already shown that the Wnt/ β-catenin pathway induces proliferation and insulin secretion in β-cells and can increase glucose-induced insulin secretion. In an earlier study, we have demonstrated that changes in glucose levels can acutely regulate the levels of β-catenin, in different cell lines and also *in vivo*, as β-catenin levels are increased in insulin sensitive tissues (liver, adipose tissue, skeletal muscle) of diabetic rats (unpublished data). Glucose-induced β-catenin increase involves autocrine Wnt activation and N-linked glycosylation. In our current study, we investigate the effect of glucose on the Wnt/ β-catenin pathway in a pancreatic β-cell line to see if these insulin-secreting cells respond to glucose in the same way as the insulin-sensitive tissues.
Materials and methods: As a model of β-cells, we use glucose-responsive and insulin-secreting INS1E cells. To explore the mechanisms, we treat INS1E β-cells with different kind of drugs, such as insulin secretion supressors, Hex-

osamine Biosynthesis Pathway (HBP) inhibitors, Wnt agonist or inhibitors, and also Wnt-conditioned-medium.
Results: Our most significant finding is that glucose itself increases β-catenin levels in INS1E β-cells. More precisely, glucose induces β-catenin translocation to the nucleus and the transcription of β-catenin target genes, such as CyclinD1. The Hexosamine Biosynthesis Pathway (HBP) is also involved as glucosamine can mimic the effect of glucose on β-catenin in INS1E cells. To check a potential autocrine Wnt activation, we looked at phosphorylation of Wnt-co-receptor LRP6 (low density lipoprotein receptor-related protein 6). We observed that in response to glucose, LRP6 phosphorylation is also increased in INS1E β-cells. Finally insulin secretion does not seem to be responsible for β-catenin stabilization as its inhibition in high or low glucose conditions does not affect β-catenin levels.
Conclusion: In this study, we present a new mechanism for pancreatic β-cells to sense glucose levels. Glucose increase stabilizes β-catenin and induces the canonical Wnt/β-catenin pathway via autocrine activation. This mechanism involves the HBP pathway but not insulin secretion. Taken together, these findings suggest that glucose-induced β-catenin increase occurs in insulin-secreting cells as observed in insulin-sensitive tissues such as skeletal muscle and liver. We will now focus on the precise mechanism leading glucose to activate Wnt/β-catenin pathway in β-cells and to regulate energy consumption and metabolism. The current findings establish β-catenin as a promising new sensor of energy availability within cells that regulate glucose levels in the whole body through insulin secretion.

Signalling in islets isolated from individuals with type 2 diabetes mellitus
P. Bergsten[1], H.K. Nyblom[1], M. Bugliani[2], E. Fung[3], U. Boggi[2], P. Marchetti[2], R. Zubarev[3];
[1]Department of Medical Cell Biology, Uppsala University, Sweden,
[2]Department of Endocrinology and Metabolism, University of Pisa, Italy,
[3]Department of Cell and Molecular Biology, Uppsala University, Sweden.

Background and aims: Type 2 diabetes mellitus (T2DM) is connected with β-cell failure. Cellular mechanisms responsible for this development have been proposed. The scarcity of human islets in general and islets from T2DM individuals in particular have led to that most studies addressing the T2DM islet pathophysiology have been conducted in animal or cellular models of the disease. We have optimized a gel- and label-free tandem mass spectrometry approach to generate protein expression data sets from approximately 100 islets. The aim was to use this approach to protein profile islets from T2DM and control individuals and analyze the expression data sets for changes in pathway signaling in T2DM islet.
Materials and methods: Islets were isolated from five T2DM and ten age- and weight-matched control individuals. Approximately 30 islets per donor were handpicked directly after isolation. Islets from the T2DM and control donors were pooled into two separate samples. From one T2DM individual approximately 150 islets were obtained which allowed that a separate sample and a matching control sample was prepared. Sample proteins were extracted and digested by trypsin. Generated peptides were separated by nano-liquid chromatography followed by mass determination by Fourier transform ion cyclotron mass spectrometry. Peptides were identified by comparing MS/MS data with the IPI Human database using the Mascot search engine. Identified proteins were mapped on known signaling networks using the databases TRANSPATH and TRANSFAC and analyzed for differential pathway activation.
Results: In samples from pooled T2DM and control islets the number of identified non-identical peptides was 2135 corresponding to 837 proteins. The data sets were analyzed for differential pathway signaling activation. In T2DM islets several pathways controlling β-cell arrest and apoptosis (p53, caspase, stress-associated, Apo2L/TRAIL) were activated. Pathways controlling islet regeneration and proliferation were both activated (E2F, EGF, PLK1, parkin associated) and inactivated (insulin, PRL, PDGF, mTOR, OSM). In addition, pathways involved in immunological responses were activated (Fas, RANKL and TLR3) and inactivated (IFN, LPS, TCR, BCR) in T2DM islets. Expression data sets were also generated from one T2DM and one control individual. Analysis of differential pathway activation of islets from this T2DM individual, who had accentuated functional impairment, revealed that several pathways of proliferation and immunological response were altered. In contrast, pathways of apoptosis and cell arrest were essentially the same.
Conclusion: Information about how signaling of specific pathway are altered in islets from T2DM individuals, once verified and validated, may be used to compare with and validate altered signaling in animal and cellular models of the disease. The differential signaling observed in T2DM islet may open for new ways of developing strategies aiming at maintaining or restoring islet function and survival in individuals with T2DM.

The protein tyrosine phosphatase, PTP-BL, interacts with the Wnt signalling pathway to regulate cell proliferation in INS-1 cells
A.R. Oknianska, H.J. Welters, N.G. Morgan;
Institute of Biomedical and Clinical Science, Peninsula Medical School, Plymouth, United Kingdom.

Introduction: The multifunctional protein tyrosine phosphatase, PTP-BL, has been shown recently to regulate pancreatic β-cell proliferation by interacting with components of the Wnt signalling pathway, resulting in altered β-catenin levels. B-catenin exists in various cellular pools and can also be present in active and inactive forms but the effects of altered expression of PTP-BL on the various pools of β-catenin and its activation state have not been characterised. Therefore, changes in the localisation and activation of β-catenin have been studied in the present work, after treatment of β-cells with activators of Wnt signalling and following induction of PTP-BL expression.
Methods: The rat β cell line INS-1 was used to generate clones stably expressing either wild type (WT) PTP-BL or a tyrosine phosphatase deficient mutant (PTP-BL-CS) under the control of an inducible promoter. INS-1 cells were grown to 80-90% confluence and treated with either purified Wnt3a, a low molecualr weight synthetic Wnt agonist (2-Amino-4-(3,4-(methylenedioxy)benzylamino)-6-(3-methoxyphenyl)pirimidine) and/or the Wnt co-ligand, R-spondin-1, to activate Wnt signalling. In some experiments, Exendin-4 was also used as this has been reported to regulate β-catenin responsive genes in β-cells. Whole cell protein extracts were analysed by Western blotting with anti-total β-catenin and anti-active β-catenin antibodies and with antibodies against Cyclin-D1. Subcellular fractionation of the cells was also performed to reveal the distribution of PTP-BL, total β-catenin and active β-catenin.
Results: Conditional expression of PTP-BL and PTP-BL-CS in INS-1 cells was confirmed by Western blotting. Induction of WT PTP-BL decreased the amount of active β-catenin in unstimulated INS-1 cells and it also antagonised the rise caused by Wnt 3a, Wnt3a+ R-spondin 1 or Exendin-4. These effects were not seen with the phosphatase deficient mutant, PTP-BL-CS. Surprisingly, although INS-1 cell growth was attenuated by induction of PTP-BL (uninduced: 0.30±0.02 A_{490} units at 72h; induced: 0.14±0.01 units; ($p<0.001$)) the increase in cyclin D1 caused by Wnt3a or Exendin-4 was not reduced following induction of PTB-BL. Thus, the attenuation in proliferation was apparently not mediated via Cyclin-D1. In unstimulated INS-1 cells, active β-catenin was found mainly in the nuclear and cytoskeletal fractions. Active β-catenin was also seen in the nucleus and cytoskeleton of the cells over-expressing PTP-BL and, additionally, it accumulated in the membrane fraction under these conditions.
Conclusion: The protein tyrosine phosphatase, PTP-BL, regulates the Wnt signalling pathway by modulating active β-catenin levels in pancreatic β cells but the attendant attenuation of cell proliferation appears to be independent of changes in cyclin-D1 expression.

Evaluation of histology pattern recognition and color deconvolution image analysis of beta cell and islet area
K.L. Lillard-Wetherell;
Aperio Technologies, Vista, United States.

Background and aims: The etiology of diabetes varies and there are a number of rodent models which mimic type 1 (T1D) and type 2 (T2D) forms of the disease. Evidence indicates that reduced functional beta-cell mass underlies insulin insufficiency in both conditions; thus, new therapies are increasingly being targeted towards the restoration or preservation of beta cell mass. In order for rodent models to be useful for the evaluation of new therapies, islet morphology and insulin positive area (beta cell area) need to be well characterized using histological approaches. Manual morphometric approaches can be tedious and time-intensive; therefore, most labs are now calculating beta cell area using immunohistochemistry (IHC) with an insulin antibody and image analysis using color separation to estimate insulin stained area. The

objective of the current study is to analyze results for beta cell & islet area using manual morphometry, color separation, and histology pattern recognition image analysis.
Materials and methods: Analysis was performed on an established T2D mouse model, Tallyho (TH), and age, gender-matched control mice. Representative pancreatic sections from six TH and six wild-type animals were compared. Two parameters were analyzed, insulin positive area and total islet area. Pancreas sections were processed for histology using hematoxylin and eosin (H&E) or an insulin antibody, detected by DAB. Whole slide images were captured using an Aperio Scanscope and were analyzed with ImageScope tools and algorithms. Histology pattern recognition was accomplished using a genetic algorithm which uses multiple features, such as color, shape, cell morphology, and staining texture, to separate tissue into "classes".
Results: We report strong concordance between results obtained with histology pattern recognition and manual morphometry for both beta cell area and islet area. There was no significant difference in beta cell area calculated using the two methods. While color separation showed similar trending, the values for beta cell area were much higher than those obtained with either manual morphometry or histology pattern recognition (2-6% vs. 0-2% for other methodologies). Presumably, this increase is due to presence of background IHC staining which is inadequately removed by thresholding; therefore, it is included as positive area in the data.
Conclusion: These results suggest that automated histology pattern recognition is a quicker alternative to manual morphometry and is more reliable than color separation alone for analyzing islet morphology in animal models.

429

Human beta cell sorting for characterisation of beta cell specific transcripts and functions

C. Kirkpatrick[1], P. Marchetti[2], M. Bugliani[2], F. Pattou[3], J. Kerr-Conte[3], C. Wollheim[1];
[1]Dept. of Cell Physiology and Metabolism, University of Geneva, Switzerland, [2]Dept. of Endocrinology and Metabolism, University of Pisa, Italy, [3]INSERM U859, Lille, France.

Background and aims: For some years, researchers have been able to isolate rat and mouse beta cells for studying in isolation based on endogenous fluorescence of the beta cells relative to the non-beta cells, but this has not been possible in human islet cells until recently. We have used a method for sorting beta and non-beta human islet cells based on labeling with a zinc-binding fluorescent dye (Newport Green), which labels the insulin granules of the beta cells allowing separation of the beta and non-beta populations. This study aimed to first characterise the beta and non-beta cell fractions obtained by this method and then to identify beta cell-specific transcripts that may be associated with beta cell dysfunction or proliferation.
Materials and methods: Human islets were dissociated with trypsin and DNAse I and sequentially labelled with an antibody marker for ductal cells, Newport Green to identify the beta cells and 7-aminoactinomycin D to label dead cells. The sorting protocol discards ductal and dead cells and sorts the remaining population on the basis of size and Newport Green fluorescence to give two populations of endocrine beta and non-beta cells. RNA was extracted immediately after sorting and reverse transcribed to cDNA for quantitative PCR. For immunofluorescence, cells were fixed to slides by Cytospin followed by 2 % paraformaldehyde fixation. For insulin secretion measurements, beta cells were seeded on 804G extracellular matrix, and insulin secretion and content measured during 1hr incubation with glucose or KCl with an enzyme-linked immunoassay.
Results: This method successfully sorts human beta cells with a purity of consistently 90 % or greater. However, the non-beta cell fraction was more variable between different islet donors with varying amounts of glucagon transcript, as measured by Q-PCR. We also observed by immunofluorescence varying proportions of glucagon-positive to glucagon and insulin double negative cells in the non-beta fraction. Total RNA yields per cell were significantly higher in the beta cell fraction (4.58 pg/cell for non-beta versus 8.77 pg/cell for the beta cells, $n > 4$, $p < 0.01$) possibly indicating higher protein synthetic activity in this fraction. The beta cell fraction retained an insulin secretory response to high glucose and to KCl after sorting and monolayer culture, confirming their functional identity and demonstrating that they are still capable of insulin secretion in the absence of other endocrine cells. Gene profiling of the beta cell fractions from multiple donors suggested possible genes that could correlate with donor body mass index (BMI), which may be associated either with beta cell dysfunction or proliferation.
Conclusion: This method provides a means of acquiring purified beta and non-beta cells from human islets in larger quantities than can be obtained with other current methods such as laser capture microdissection. This will enable functional analysis of beta cells in the absence of other endocrine cells and allow comparisons to be made between diabetic and non-diabetic beta cells. Identification of beta cell enriched transcripts in these cells may provide novel targets for diabetes therapy.

Orexin-A stimulates insulin secretion and proinsulin gene expression

E. Göncz[1], S. Mergler[1], F. Hofmann[1], B.F. El-Zayat[2], B. Wiedenmann[1], M.Z. Strowski[1];
[1]Hepatologie, Gastroenterologie & Interdisziplinäres Stoffwechsel-Centrum/ Endokrinologie und Diabetes, Charité - Universitätsmedizin, Berlin, [2]Philipps Universität, Marburg, Germany.

Background and aims: Orexin-A (OXA) regulates food intake and energy homeostasis. We recently demonstrated that OXA inhibits glucagon secretion and gene expression via forkhead-1 (foxo1)-dependent pathway. Discrepant observations were reported regarding the effects of OXA on insulin secretion in vivo. We therefore aimed to characterize the role of OXA in regulating pancreatic B-cell function.
Methods: Orexin receptor 1 (OX1R) expression in the endocrine pancreas, isolated pancreatic islets and INS-1 cells was identified by Western blots and confirmed immunohistochemically. Intracellular signalling encompassed the measurement of cyclic AMP, calcium, proinsulin gene expression and insulin secretion by ELISA, RIA, Fura-2, Western blots and real-time PCR. In situ pancreas perfusion studies were performed on anaesthetized male rats.
Results: OXR1 was expressed on pancreatic B-cells. OXA stimulated insulin secretion from in situ perfused rat pancreas and INS-1 cells. The changes were accompanied by an increase of intracellular cyclic AMP and calcium concentrations. OXA raised proinsulin mRNA-levels with a maximum after 24 hours of exposure.
Conclusion: Our study provides the first evidence for OXA as a stimulus of insulin secretion and proinsulin gene expression. In addition we identify cAMP/AKT/PDK-1 and calcium as intracellular target molecules for OXA action in pancreatic B-cells.

Gliquidone features different from glibenclamide in the insulin secretion pattern and closing the K_{ATP} channels profiles in HIT-T15 cells

S.Y. Liu[1], Z. Xiao[1], Z.M. Tang[1], J.M. Zhang[1], X.Y. Li[2], H.M. Tian[1], X.J. Li[1];
[1]Department of Endocrinology and Metabolism, West China Hospital, ,
[2]West China College of Stomatology, Sichuan University, Chengdu, China.

Background and aims: The aim of this study is to determine whether gliquidone has any different effect on the insulin-secretory profiles of HIT-T15 cells in response to glucose stimuli and the closing ATP-sensitive potassium (K_{ATP}) channels profiles in this βcells membrane from the other two sulphonylureas i.e. gliclazide and glibenclamide.
Materials and methods: HIT-T15 cells (β-cells line) were cultured for 8h in RPMI-1640 with three different glucose concentrations (5, 10, 15mmol/l), the cells were re-cultured with gliquidone ,gliclazide and glibenclamide in physiological concentrations ,and then, insulin levels in the medium at 0,10,20,30,45,60,120 and 180 minutes were measured by radiommunoassay(RIA). The action of the drugs with the therapeutic concentrations was studied by whole-cell current recording of K_{ATP} channels in single HIT-T15 cells.
Results: In this study , all three sulpholureas strongly stimulated the insulin release by β-cells in the presence of glucose in different patterns. Gliquidone and gliclazide induced a similarly rapid biphasic insulin secretion, reaching the first peak at 10 minutes and the second lower peak at 30 minutes, followed by gradual decline to near the basal values at the third hours. In contrast, glibenclamide induced a strong but monophasic insulin release, reaching its peak at 45 minutes followed by somewhat decline of the hormone release but did not return to basal values in 3 hours later. Gliquidone blocked the whole-cell βcells K_{ATP} current rapidly, the mean time of the 50% K_{ATP} channels closing is much shorter than that of glibenclamide (2.5min Vs 6.8 min. P<0.001),but is similar to gliclazide (2.5min Vs 2.4 min. P>0.05)
Conclusion: Gliquidone stimulates insulin release of HIT-T15 cells in biphasic secretion which similar to gliclazide, but different from glibenclamide. gliquidone closes the K_{ATP} channels of βcells more quickly than glibenclamide. This unique feature in insulin secretion of gliquidone may have important implications in its clinical use.

Excessive expression and activity of Kv2.1 channels in islet beta cells of type 2 diabetic GK rats

K. Dezaki[1], B. Damdindorj[1], A. Ando[1], M. Yoshida[2], M. Kakei[2], T. Yada[1];
[1]Physiology, Jichi Medical University, Tochigi, [2]Saitama Medical Center, Jichi Medical University, Saitama, Japan.

Background and aims: Voltage-dependent delayed rectifier K^+ (Kv) channels are involved in repolarization of excitable cells. In pancreatic β-cells, activation of Kv channels might repolarize cells and attenuate glucose-stimulated action potentials to suppress insulin secretion. Among Kv channel families, Kv2.1 is reportedly expressed in islet β-cells as the major component of Kv currents in rodents. This study aimed to determine the pathophysiological role of Kv2.1 channels in the impaired glucose-induced insulin release in islet β-cells of type 2 diabetic rats.
Materials and methods: Expression of Kv2.1 channels in the pancreas of male normal Wistar and type 2 diabetic Goto-Kakizaki (GK) rats was measured by immunohistochemistry. Islets were isolated from these rats by collagenase digestion, and insulin release was determined by ELISA. In rat single β-cells, whole cell Kv channel currents were measured in the presence of tolbutamide by patch-clamp technique, and cytosolic Ca^{2+} concentration ($[Ca^{2+}]_i$) was measured by fura-2 microfluorometry.
Results: Immunohistochemical analysis revealed that Kv2.1 channels were expressed in islet β-cells, but not exocrine part, of the pancreas. The Kv2.1 immunofluorescence intensity in the islets of diabetic GK rats was stronger than that in normal Wistar rats. In isolated islets of Wistar and GK rats, tetraethylammonium, a non-selective blocker of Kv channels, increased glucose (8.3 mM)-induced insulin release. Moreover, Kv2.1 channel blockers, stromatoxin-1 (ScTx) and guangxitoxin-1E (GxTx), significantly increased glucose-induced insulin release, without altering basal insulin release at 2.8 mM glucose. Kv channel current density in β-cells was larger in GK rats than Wistar rats. Kv2.1 channel blockers markedly attenuated Kv channel currents in β-cells, and the channel currents that remained in the presence of GxTx were identical between Wistar and GK rats. Blockade of Kv2.1 channels by ScTx and GxTx potentiated glucose (8.3 mM)-induced $[Ca^{2+}]_i$ increases in β-cells of normal and diabetic rats, whereas basal $[Ca^{2+}]_i$ levels and KCl (25 mM)-induced $[Ca^{2+}]_i$ increases at 2.8 mM glucose were not affected by these channel blockers.
Conclusion: Kv2.1 channels may physiologically limit glucose-induced Ca^{2+} influx and thereby attenuate insulin secretion in β-cells. Excessive expression and/or activity of Kv2.1 channel may be causally related to impaired insulin secretion in diabetic GK rats. Blockade of this channel can promote glucose-induced insulin release in diabetic as well as normal rats, providing a potential therapeutic tool to treat type 2 diabetes.

Essential role of NAADP-evoked calcium release in glucose-mediated depolarization, [Ca2+]i spiking and insulin secretion in mouse pancreatic beta cell

A. Arredouani, R. Parkesh, T. Pillinger, G. Coltart, F. Clough, K. Shimomura, F. Aschcroft, G. Churchill, A. Galione;
Oxford University, United Kingdom.

Background and aims: Current mechanisms of stimulus-secretion coupling in pancreatic β-cells emphasize a role for glucose-enhanced plasma membrane ion fluxes as a consequence of the closure of KATP (Kir6.2/SUR1) channels. However, glucose may still evoke Ca2+ signals and insulin exocytosis in β-cells from Kir6.2 or SUR1 knockout mice by KATP-independent pathways. We have investigated the role of the NAADP-targeted acidic Ca2+ stores in glucose-mediated Ca2+ oscillations and insulin secretion in primary mouse β-cell.
Materials and methods: We have used Ca2+ imaging, electrophysiology and insulin secretion measurement.
Results: We found that the release of Ca2+ from acidic Ca2+ stores plays a critical role in triggering and shaping glucose-evoked Ca2+ signals since these signals are abolished by the vacuolar proton pump inhibitor, bafilomycin. Using new membrane-permeant probes, we further show that the intracellular messenger NAADP mobilizes Ca2+ from acidic stores, but not the endoplasmic reticulum, depolarizes the plasma membrane by activating a cation current. Inhibition of NAADP-evoked Ca2+ release, either by Ned-19, a selective NAADP antagonist, or self-desensitization, abolishes not only glucose-induced depolarization, Ca2+ signals and insulin secretion but also tolbutamide-induced insulin secretion. We have recently discovered that the two-pore channel (TPC2) located on acidic stores is the target receptor of NAADP (Nature, in Press). We show that glucose-induced [Ca2+]i signalling is dramatically altered in TPC2 knockout mice
Conclusion: We propose that NAADP-mediated Ca2+ mobilization from acidic stores is a key step in triggering stimulus-secretion coupling in mouse pancreatic β-cells. In turn this activates a calcium-dependent cation current which, when KATP channels close, can depolarize the membrane potential allowing the activation of voltage-gated Ca2+ channels, Ca2+ influx and exocytosis of insulin granules.

Analysis of membrane potential oscillation mechanism in the novel pancreatic beta cell simulation model

Y. Nakamura[1,2], S. Fujimoto[1,2], J.-W. Wang[1,2], Y. Himeno[1,2], C. Cha[3,2], T. Shimayoshi[3,2], A. Noma[3,2], N. Inagaki[1,2];
[1]Department of Diabetes and Clinical Nutrition, Kyoto University, [2]Biomedical Cluster Kansai, Kobe, [3]Department of Bioscience and Bioinformatics, Ritsumeikan University, Kusatsu, Japan.

Background and aims: Several types of pancreatic beta cell models have been published. However, the application of these models is still very limited because of very simplified ionic channel models. We aim at developing an electrophysiological pancreatic beta cell model to analyze the role of ion channels and transporters in the oscillation mechanisms of membrane potential oscillation underlying in the regulation of insulin secretion.
Materials and methods: Mathematical models of twelve ion channels (INa, ICaL, IKr, Ito, IKATP, IKCa, IKb, ICRAN, ITRPM4) and transporters (INa/K,

IPMCa, INa/Ca) were developed according to electrophysiological studies, and were implemented into a novel beta cell computer model based on the framework of previous cell models. Then we examine contributions of ion channels and transporters to oscillatory membrane potential response using this new model.
Results: The model was quiescent at glucose([G]) below 6 mM with a most negative resting potential of about -70 mV at 0 [G]. Brief bursts of action potential with an overshoot = ~ -10 mV and a plateau level = ~ -40 mV were initiated at [G] higher than 6.5 mM accompanied with an increase in intracellular Ca2+ ([Ca2+]). The burst duration was prolonged with increasing [G] as observed in experimental studies. The burst of action potentials was generated by alternating activation of L-type Ca2+ channel and the delayed rectifier K+ channels. The open probability of the ATP-sensitive K+ channel is gradually increased because of increased consumption of ATP during the burst, and the increased outward current finally terminated the burst. The mechanisms underlying the cyclic burst activity is explained along the sequential events as described below. During the inter-burst period, the glucose-dependent ATP production exceeds the ATP consumption and decreases the [ADP] / [ATP] ratio. Thereby, the open probability of ATP-sensitive K+ current is decreased and the membrane potential is depolarized with time. Finally at around -55 mV, the bust of action potential is triggered. During the burst of repetitive Ca2+ spikes, [Ca2+] accumulate, which then leads to acceleration in the ATP consumption and an increase in the [ADP] / [ATP] ratio. As a result, outward current through the ATP-sensitive K+ channel is increased and the burst is terminated. With increasing [G], the ATP production rate is increased in a dose-dependent manner, and the burst duration is prolonged because of the delayed increase in the [ADP] / [ATP] ratio. At [G] higher 12 mM, the increase in [ADP] / [ATP] ratio becomes much depressed. Under this condition, the role of the ATP-sensitive K+ channel is replaced by the increase in the Na+/K+ pump current. Namely, the accumulation of Ca2+ is converted to a Na+ accumulation by the Na+/Ca2+ exchange. Thereby, the outward Na+/K+ pump current is enhanced to finally terminate the burst activity after more than ~90 sec burst. Switching the terminatory role from the ATP-sensitive K+ channel to the Na+/K+ pump current is achieved smoothly through the ultra slow inactivation of the Ca2+ channel.
Conclusion: We concluded that the new B cell model is relevant for analyzing mechanisms underlying the [G]-dependent activation of the cell.

Oscillations of Zn^{2+} beneath the plasma membrane in glucose-stimulated beta cells

O. Dyachok, O. Idevall, A. Tengholm, E. Gylfe;
Department of Medical Cell Biology, Uppsala University, Sweden.

Background and aims: Glucose is the main physiological stimulus of insulin secretion from pancreatic β-cells. Glucose increases the cytoplasmic Ca^{2+} and cAMP concentrations in β-cells, and cAMP is an important amplifier of Ca^{2+}-triggered pulsatile insulin release. Insulin is stored in secretory vesicles as a crystalline zinc complex and Zn^{2+} is co-secreted with insulin. Zn^{2+} has been proposed to exert a negative feedback on insulin secretion as a potent and reversible activator of hyperpolarizing K^{+}_{ATP} channels. Zn^{2+} has also been found to interfere with cAMP turnover in β-cells. We therefore studied how glucose affects Zn^{2+} in insulin-secreting β-cells.
Materials and methods: MIN6 β-cells were transfected with a fluorescent translocation biosensor reporting phosphatidylinositol-3,4,5-trisphosphate in the plasma membrane ($[PIP_3]_{pm}$) in response to autocrine insulin receptor activation. This assay was used as readout for insulin secretion from single cells. The cytoplasmic cAMP concentration beneath the plasma membrane ($[cAMP]_{pm}$) was detected by another translocation biosensor based on fluorescence-labeled protein kinase A subunits. Measurements of intracellular Zn^{2+} and Ca^{2+} concentrations were performed in cells loaded with the fluorescent indicators FluoZin-3 and Indo-1, respectively. Conventional epifluorescence microscopy was used to detect the global changes of Zn^{2+} and Ca^{2+} in the cell cytoplasm ($[Zn^{2+}]_i$, $[Ca^{2+}]_i$). Local changes of these cations in the sub-membrane space ($[Zn^{2+}]_{pm}$, $[Ca^{2+}]_{pm}$) as well as changes in $[PIP_3]_{pm}$ and $[cAMP]_{pm}$ were recorded with evanescent wave microscopy.
Results: MIN6 cells reacted to glucose stimulation with pronounced $[Ca^{2+}]_i$, $[Ca^{2+}]_{pm}$ and $[cAMP]_{pm}$ as well as $[PIP_3]_{pm}$ oscillations reflecting pulsatile insulin release. Glucose stimulation did not affect $[Zn^{2+}]_i$ but induced oscillations of $[Zn^{2+}]_{pm}$, which were heterogeneous with irregular amplitude and frequency. Hyperpolarization with 250 μmol/l diazoxide or inhibition of voltage-dependent Ca^{2+} channels with 100 μmol/l methoxyverapamil prevented the glucose-induced $[Ca^{2+}]_i$ and $[Ca^{2+}]_{pm}$ signaling without affecting the $[Zn^{2+}]_{pm}$ oscillations. Also chelation of extracellular Zn^{2+} with 2 mmol/l Ca-EDTA failed to affect the glucose-induced $[Zn^{2+}]_{pm}$ and $[cAMP]_{pm}$ oscillations. However, the membrane permeable Zn^{2+} chelator TPEN (50 μmol/l) abolished the Zn^{2+} signal and much amplified the $[cAMP]_{pm}$ and $[PIP_3]_{pm}$ responses to glucose stimulation. Application of 30 μM Zn^{2+} to glucose-stimulated MIN6 cells resulted in an increase of $[Zn^{2+}]_{pm}$ and markedly inhibited $[cAMP]_{pm}$ and $[PIP_3]_{pm}$ responses as well as suppressed insulin release detected by ELISA.
Conclusion: These data provide support for intracellular Zn^{2+} as inhibitory messenger affecting cAMP and insulin secretion from β-cells.

Rapid changes in surface expression of L-type Cav1.2 channels in stimulated INS-1 cells

E. Zhang[1], T. Reinbothe[1], S. Andersson[1], L. Eliasson[1], M. Brauns[2], J. Striessnig[2], E. Renström[1];
[1]Lund University Diabetes Centre, Malmo, Sweden, [2]Institute of Pharmacy, University of Innsbruck, Austria.

Background and aims: Voltage gated calcium channels (VGCCs) in the plasma membrane (PM) play an essential role in linking glucose metabolism to insulin secretion. Under resting condition, the number of VGCCs in the PM (surface expression) maintains a dynamic equilibrium that is controlled by trafficking to and from the cell interior. eIF3e (eukaryotic translation initiation factor 3, subunit E) is widely expressed in eukaryotic cells and is involved in both initiation of protein translation and degradation. Interestingly, eIF3e has been suggested to be involved in the regulation of activity-dependent internalization of L-type Cav1.2 channels in neurons. However, it remains unclear whether eIF3e plays a similar role in pancreatic beta-cells.
Materials and methods: Cav1.2 clusters were observed by 3D confocal imaging in INS-1 cells. Cluster internalization was quantified using the ImageJ and Matlab programs. To assess the rate of Cav1.2 transport to plasma membrane, the Fluorescence Recovery After Photobleaching (FRAP) technology was used.
Results: Depolarization causes internalization of Cav1.2. Cav1.2 is expressed in clusters in Cav1.2-EGFP transfected INS-1 cells. The ratio of the cluster number in the PM over clusters residing in the cytosol was calculated in time-lapse series taken from the middle section of the cells, which decreased from 4.1±1.09 to 1.36±0.18. Double labeling experiments with Cav1.2 and the PM indicator FM-64, verified that the number of Cav1.2 clusters in the PM decreased by 50% upon glucose stimulation. To allow a careful quantification of Cav1.2 cluster internalization, we calculated the geometrical centre of the cluster scatter and measured the distance from that point to each cluster, which decreased from 6.2±0.11 to 5.2±0.16 μm after 30 min stimulation with glucose ($P<0.001$).
Cav1.2 cluster internalization can be detected also in native cells. To validate the physiological significance of our initial results, we measured Cav1.2 expression by immunostaining in INS-1 cells before and after 15-30 min stimulation with glucose. The ratio of the number of clusters in the PM over clusters in the cytosol amounted 3.32±0.48 which decreased to 0.83±0.14 after glucose stimulation ($P<0.01$). Similarly, Cav1.2 redistribution from the PM to intracellular membranes upon glucose stimulation could be detected by Cav1.2 immunoblotting in fractionated cells.
eIF3e silencing reduces surface expression of Cav1.2 and inhibit their internalization upon stimulation. After knockdown of eIF3e by RNAi, the number of Cav1.2 cluster in the PM was reduced by 40% in resting condition ($p<0.05$). Interestingly, stimulation with HK or glucose now failed to internalize Cav1.2 to the cell interior.
eIF3e silencing decreases the rate of Cav1.2 supply to the PM. A FRAP approach was used to investigate the dynamics of Cav1.2 clusters in the PM. The average recovery intensity was fitted by an exponential curve and the time constant (τ) indicates how slow the Cav1.2 moves to PM. eIF3e silencing increased τ for Cav1.2 transport to the PM from 0.79 s to 1.51 s under non-stimulatory conditions. Under stimulation with HK, eIF3e silencing increased τ from 0.21 s to 0.63 s.
Conclusion: Depolarization causes internalization of Cav1.2 clusters in INS-1 cells. eIF3e enhances Cav1.2 surface expression under resting condition, and
eIF3e is also required for activity-dependent internalization of Cav1.2 clusters.

Ca^{2+}/Calcineurin/NFAT signalling pathway regulates glucose-induced IRS-2 expression in rat pancreatic beta cells

D. Demozay, S. Tsunekawa, J.F. Mc Cuaig, C.J. Rhodes;
Department of Medicine, Endocrinology, University of Chicago, United States.

Background and aims: Insulin receptor substrate 2 (IRS-2) plays an essential role in pancreatic beta-cells by promoting cell growth and survival and so represents an interesting target for therapeutic means in type 2 diabetes. We have previously shown that glucose induces a rapid increase in IRS-2 expression in rat pancreatic islet beta-cells, mediated at the transcriptional level and requiring presence of Ca^{2+}. However how Ca^{2+} regulates IRS-2 gene expression remains unknown.
Materials and methods: Rat pancreatic islet beta-cells or INS-1E cell line were exposed to various inhibitors and/or infected with adenovirus expressing CAIN or VIVIT. IRS-2 expression was analyzed by RT-PCR and Western blot. NFAT activation and translocation were analyzed by Western blot and confocal immunofluorescent microscopy.
Results: Using nifedipine, a selective inhibitor of L-type Ca^{2+} channels, we showed that elevated intracellular concentration of Ca^{2+} is required for glucose-induced IRS-2 gene expression in isolated rat islet beta-cells. Moreover, in rat islets beta-cells exposed to 30 mM KCl, which leads to an $[Ca^{2+}]_i$ increase via depolarization, specific increased in IRS-2 mRNA and protein levels was observed at stimulatory glucose concentrations (≥5 mM). Inhibition of Ca^{2+}/calmodulin-dependent phosphatase 2B (calcineurin) by FK506 or Cyclosporin A inhibitors markedly blocked the glucose-induced IRS-2 expression at both mRNA and protein levels in both INS-1E cells and rat islet beta-cells. Moreover, infection of islets beta-cells with the adenovirus expressing CAIN (Adv-CAIN; a selective peptide inhibitor of calcineurin), totally suppresses glucose-induced IRS-2 gene expression compare to cells infected with an adenovirus control expressing luciferase. As expected, decrease in IRS-2 protein level correlates with mRNA decrease in presence of these inhibitors. The transcription factor nuclear of activated T cells (NFAT) is well known to be activated by the Ca^{2+}/calcineurin pathway which induces its dephosphorylation and then translocation to the nucleus. NFAT protein phosphorylation state and localization are modified by glucose in INS-1E cells. Four putative NFAT binding sites within the proximal region of the rat IRS-2 promoter (-1250 to +1 bp) were identified in the IRS-2 promoter sequence. To investigate the potential role of NFAT in IRS-2 expression, we infected INS-1E cells with an adenovirus to express VIVIT (Adv-VIVIT; a selective peptide inhibitor of calcineurin-mediated NFAT activation). We found that selective NFAT inhibition abolished glucose-induced IRS-2 expression at the mRNA and protein levels compare to control cells. Furthermore, direct binding of NFAT on IRS-2 promoter was demonstrated by a chromatin immunoprecipitation assay.
Conclusion: Taken together, these results clearly suggest that Ca^{2+}/calcineurin/NFAT pathway in islets beta-cells is implicated in IRS-2 gene expression in response to glucose. Considering the pivotal role that IRS-2 plays in pancreatic beta-cells, a better understanding of the IRS-2 transcriptional regulation could eventually provide novel therapeutic means in type 2 diabetes by improving beta-cells survival and proliferation.

BLX-1002, a novel thiazolidinedione with no PPAR affinity, selectively enhances insulin secretion in diabetic animal islets stimulated with high glucose, GLP-1 or tolbutamide

F. Zhang[1], D. Dey[2], R. Bränström[3], L. Forsberg[3], M. Lu[3], Q. Zhang[1], Å. Sjöholm[1];
[1]Department of Clinical Science and Education, Karolinska Institutet, Stockholm, Sweden, [2]Bexel Pharmaceuticals, Inc., Union City, United States, [3]Department of Molecular Medicine and Surgery, Unit of Endocrine Surgery, Karolinska Institutet, Stockholm, Sweden.

BLX-1002 is a novel amino acid conjugated, small thiazolidinedione with no apparent affinity to peroxisome proliferator-activated receptors (PPAR) that was shown to reduce glycemia in type 2 diabetes without adipogenic effects. We have investigated the actions of the drug on insulin secretion in pancreatic islet cells from diabetic and non-diabetic animal models. In the obese, leptin-deficient ob/ob mice, BLX-1002 enhanced insulin secretion stimulated by high (20 mM), but not low or intermediate (3 or 8 mM) glucose concentrations during a 20 min-incubation, while its major metabolite BLX-1015 had no effect. BLX-1002 also potentiated pioglitazone-, but not fenofibrate-induced insulin secretion. BLX-1002, but not BLX-1015, restored glucose-sensitive insulin secretion in pancreatic islets from type 2 diabetic, leptin receptor-deficient db/db mice. Under perifusion conditions, BLX-1002 significantly potentiated insulin secretion induced by GLP-1 or the sulfonylurea tolbutamide in pancreatic islets from type 2 diabetic Goto-Kakizaki (GK) rats, effects that were not observed in islets from non-diabetic Wistar rats. In contrast, BLX-1015 was without effect. Studies in single islet cells from ob/ob mice revealed that BLX-1002 augmented [Ca2+]i at high glucose, which was abolished either by the L-type Ca2+ channel blocker nifedipine or by pre-treatment of the cells with the Ca2+-ATPase inhibitor thapsigargin. The BLX-1002-induced rise in [Ca2+]i was significantly suppressed by the selective phosphatidylinositol (PI) 3-kinase (PI3K) inhibitor LY294002. However, BLX-1002 interfered neither with voltage-gated Ca2+ channel nor with KATP channel activities as demonstrated using patch-clamp technique. In addition, cellular NAD(P)H stimulated by glucose was not affected by the drug. The stimulatory effect of BLX-1002 on insulin secretion at high glucose was completely abolished by treatment of the cells with the PI3K inhibitors wortmannin or LY294002. Furthermore, stimulation of the b-cells with BLX-1002 induced activation of AMPK at high glucose. Our study suggests that BLX-1002 selectively potentiates insulin secretion induced by high glucose, GLP-1 or tolbutamide in b-cells from obese or diabetic animal models, but not from healthy animals. The effect of BLX-1002 on glucose-induced insulin secretion is dependent on PI3K activity and is associated with an increased [Ca2+]i and AMPK activation. The glucose-sensitive stimulatory impact of BLX-1002 on b-cell function may translate into substantial clinical benefits of the drug in the management of type 2 diabetes, by avoidance of hypoglycemia.

Roles of the GDP-dependent Rab27a effector coronin 3 in membrane traffic in the pancreatic beta cell

T. Kimura[1], S. Taniguchi[1], K. Toya[2], I. Niki[1];
[1]Pharmacology, Oita University, Faculty of Medicine, [2]Anatomy, Kansai University of Health Sciences, Osaka, Japan

Background and aims: Membrane trafficking is crucial for the regulation of the size of the readily releasable pool of the secretory granules and for the recovery of the granule membranes. Although many proteins have been found to participate in membrane trafficking, knowledge about its regulatory mechanisms is still limited. Rab27a is involved in the control of membrane traffic in the beta cell typically through its GTP-dependent effectors. We have recently identified the actin-bundling protein coronin 3 as a novel Rab27a effector which paradoxically bound GDP-Rab27a in the pancreatic beta-cell line, MIN6. In the present study, we investigated GDP-dependent roles of Rab27a via its interaction with coronin 3 in the pancreatic beta cell.
Materials and methods: A pull-down assay was performed to quantify GTP- and GDP-bound Rab27a. The slp homology domain of the GTP-dependent Rab27a effector and the GDP-dependent Rab27a binding site of coronin 3 were used as specific affinity ligands. For immunostaining and live imaging, MIN6 cells were transfected with plasmid DNAs or siRNA using Lipofectamine 2000. After 24 h of transfection, the cells were analyzed with a confocal laser microscopy system. For the observation of endocytosis, cells were incubated in culture media containing the endocytosis marker FM4-64 or anti-phogrin antibody which reacts with its extracellular domain. The rate of cells with cytoplasmic pattern was evaluated.
Results: Glucose stimulation promptly shifted Rab27a from the GTP- to GDP-bound form and redistributed coronin 3 to the cell periphery. The redistribution was inhibited in Rab27a-silenced MIN6 cells. Coronin-3-silencing inhibited FM4-64 uptake and phogrin recycling. Disruption of the coronin-3-GDP-Rab27a interaction with the dominant-negative coronin 3 reproduced these changes, which were restored by co-expression of the GDP-Rab27a mutant.
Conclusion: The interaction of GDP-Rab27a with coronin 3 regulates endocytosis of the insulin granule membranes. We propose a model where Rab27a is a key protein in stimulus-endocytosis coupling in the pancreatic beta cell, and plays a pivotal role in membrane recycling of the insulin granules.

Sorting nexin 19 regulates the number of insulin-containing secretory vesicle and insulin content by affecting IA-2 expression

S. Harashima[1], M. Sasaki[1], Y. Seino[1,2], N. Inagaki[1];
[1]Department of Diabetes and Clinical Nutrition, Graduate School of Medicine, Kyoto University, [2]Kansai Electric Power Hospital, Osaka, Japan.

Background and aims: IA-2 is a member of the transmembrane protein tyrosine phosphatase (PTP) family and a major autoantigen in type 1 diabetes. Autoatibodies to it are positive in about 70 % of newly diagnosed patients. They also are a predictive marker of the disease because of appearance years before the onset of the clinical disease. This molecule is 979 amino acids in length consisting of an intracellular, transmembrane and luminal domain. IA-2 is an intrinsic transmembrane component of dense core secretory vesicles. Studies of knockout in mice and knocked down in a mouse beta-cell line MIN6 showed that IA-2 is a regulator of insulin secretion. In addition, overexpression of IA-2 in MIN6 cells increases insulin content and insulin containing secretory vesicle numbers in part through stabilizing half-life of the vesicles. However, it is not fully understood how IA-2 regulates insulin content or insulin-containing secretory vesicle numbers. To address this question, we examine the involvement of sorting nexin 19 (SNX19), an IA-2 interacting protein identified by yeast two-hybrid system. SNX19 is a member of the SNX family which has a phospholipid binding motif, phox domain, and is proposed to regulate intracellular trafficking.
Materials and methods: Endogenous interaction of SNX19 and IA-2 was confirmed by immunoprecipitation analysis and Western blot analysis using anti-SNX19 antibody and/or anti-IA-2 antibody. Binding of SNX19 to phospholipids were determined by protein/lipid overlay assay. Permanent SNX19-knocked-down cell lines were established by transfection of SNX19 siRNA expression vector and selection by limit dilution with hygromycin. Insulin content was measured by insulin ELISA kit. Numbers and size of insulin-containing secretory vesicles in SNX19-knocked-down or control cells were measured by electron microscopy.
Results: SNX19 was endogenously expressed in MIN6 cells and pancreatic islets isolated from *C57BL/6 mice* and *Wister rats*. Immunoprecipitation analysis revealed endogenous interaction of SNX19 and IA-2 in MIN6 cells. Protein/lipid overlay assay indicated that SNX19 could mainly bind phosphatidylinositol-3-, or -4-, or -5- phosphate, and phosphatidylinositol-(3,5)-bipospate. In SNX19-knocked-down MIN6 cells, SNX19 expression was decreased by one-fifth with a parallel decrease of insulin content as compared to that in control siRNA-transfected MIN6 cells. Interestingly IA-2 expression also was decreased in SNX19-knocked-down MIN6 cells. Electron microscopy revealed that the number of insulin-containing secretory vesicle were about 75% decreased and the average size of the vesicles was about 40% smaller in SNX19-knocked-down MIN6 cells as compared to that in control siRNA-transfected MIN6 cells, respectively.
Conclusion: SNX19 regulates the number of insulin-containing secretory vesicle and insulin content in pancreatic beta-cells via modulating IA-2 expression.

Protein expression and distribution of syntaxin isoforms in INS-1 cells, mouse, rat and human pancreas

R.D. Fernández-Montes[1], V. Barceló[2], M. Nacher[2], E. Montanya[2], J. Blasi[1];
[1]Department of Pathology and Experimental Therapeutics, University of Barcelona-IDIBELL-CIBERNET, [2]Endocrine Unit, Hospital Universitari Bellvitge and Department of Clinical Science, University of Barcelona-IDIBELL-CIBERDEM, Barcelona, Spain.

Background and aims: In previous studies we showed the differential expression of SNARE proteins at different glucose concentrations in the insulin secretory cell line INS1. At high glucose concentration (20mM), the expression of several key proteins for insulin secretion, syntaxin1, VAMP2, synaptotagmin I and connexin36 was reduced. In contrast, the expression of t-SNARE proteins, SNAP25 and SNAP23 augmented suggesting a specific effect of high glucose concentration on the expression of proteins involved in the exocytic molecular machinery. Plasma membrane syntaxin (sytx) isoforms (1, 2, 3 and 4) have been related to insulin secretion, but their particular differential implication is still obscure and poorly studied. The aim of this study was to define both the distribution of syntaxin isoforms in mouse, rat and human pancreas and in the cell line INS-1, and the expression pattern of syntaxin isoforms (1 to 4) at different glucose concentrations in the cell line INS1 and rat isolated islets.
Materials and methods: The distribution of syntaxin isoforms was analyzed by immunofluorescence and confocal microscopy using isoform specific antibodies. The level of protein expression at different glucose concentrations was determined by western blot. Cell line INS1 was cultured for 1, 3 and 7 days at 3,3; 11,1; 20 and 33,3 mM glucose in RPMI medium 10%FBS. Sprague-Dawley rats of 150-175 g were used for studies on pancreas and isolated islets. Rat isolated islets were cultured for 6 days at the same glucose concentration used in the experiments with INS1cell line. Human pancreas were obtained from brain-dead donors and processed for immunofluorescence and confocal microscopy.
Results: A) Syntaxin isoform distribution: Sytx1 was found in the beta-cell plasma membrane in all models used while sytx 2, 3 and 4 showed a cytosolic distribution in the endocrine tissue. Sytx3 was also present in the plasma membrane in cells from the rat exocrine tissue. Sytx4 was mainly found in the alpha-cells from mouse and rat pancreas. None of the studied sytx isoforms showed immunofluorescence signal in a human diabetic pancreas, with the exception of sytx2.
B) Protein expression at different glucose concentrations: 1- INS-1: expression of sytx2 was decreased (44±15%, $p \leq 0.05$) after 7 days at high glucose concentration; sytx3 was increased at 3,3, 20, and 33,3 mM compared with 11,1 mM glucose, and sytx4 was increased (114±37%, $p \leq 0.05$) after 7 days at high glucose concentration. 2- Rat isolated islets: expression of sytxs 2 and 3 showed a tendency to increase at 3,3, 20, and 33,3 mM compared with 11,1mM glucose; sytx4 showed a tendency to decrease at high glucose concentration. Western blot results were confirmed by immunofluorescence and confocal microscopy.
Conclusion: The isoforms of syntaxin (1, 2, 3 and 4) studied in mouse, rat and human pancreas showed differential distribution patterns and protein expression at different glucose concentrations. The differential distribution

and expression of syntaxin isoforms in islet pancreatic cells indicates the presence of different pathways for intracellular membrane trafficking. However, further studies are required to establish the functional significance of these differences.

Both rapid exocytosis and granule mobilization in glucagon secreting cells are reduced by antibodies against synaptosomal protein of 25 kDa (SNAP-25) and Syntaxin 1
S.A. Andersson[1], J. Vikman[2], L. Eliasson[1];
[1]Dept. of Clinical Sciences, Lund University, Malmö, [2]Dept. of Clinical Sciences, Lund University, Lund, Sweden.

Introduction and aims: Glucagon is important for regulation of glucose metabolism by enhancing synthesis and mobilization of glucose in the liver. Glucagon resides within granules in the alpha-cells (A-cells) of the pancreas that upon A-cell activation fuses with the plasma membrane whereby glucagon is released into the bloodstream. A crucial mechanism behind the fine tuned release of glucagon is a functional exocytotic machinery constituting the SNARE-complex including the two target-SNARE proteins on the plasma membrane, syntaxin 1A and SNAP-25. We have previously shown that the SNARE-proteins are key players in the exocytotic process in beta-cells: Our aim is to investigate whether this is also true for A-cell exocytosis.
Material and methods: Primary A-cells extracted from mouse pancreas were identified by their small size and Ca^{2+} current inactivation properties using the standard whole-cell configuration of the patch-clamp technique. Exocytosis was measured as an increase in membrane capacitance following membrane depolarisations.
Results: The exocytotic granules are differently positioned within the cell where the granules most approximate to the plasma membrane are called the readily releasable pool (RRP), also constituting an immediately releasable pool (IRP), which are primed to the plasma membrane so that glucagon release may occur. The larger portion of the granules is contained in a non-releasable reserve pool that needs to be mobilized and primed prior to release, and is responsible for the refilling of the RRP. Single A-cells were stimulated by a train of ten 500-ms depolarisations from -70 mV to 0 mV. The total increase in membrane capacitance evoked by a train was 691 ± 67 fF (n=17) under control conditions. This response was reduced to 304 ± 112 fF (n=8; p<0.01) when anti-SNAP-25 was included in the pipette solution. Close inspection of the responses revealed that exocytosis during the first two depolarisations, correlating to RRP, was significantly decreased from 322 ± 32fF to 160 ± 41 fF (p<0.01). The release of mobilized granules as defined by the exocytotic response evoked by pulses 2-10, was also significantly decreased from 371 ± 54 fF to 145 ± 74 fF (p<0.05). It was controlled using IgG that antibodies do not affect exocytosis through steric hindrance. A similar setup showed a reduction in total membrane capacitance from 1615 ± 123 fF (n =18) in control to 798 ± 176 fF following immunoneutralization of Syntaxin 1 (n=18; p<0.001). Likewise, the release of the RRP was significantly reduced by 40% (p<0.001) and the mobilized granules were reduced by 47% (p<0.001). In addition, pulse length- measurements were performed to create an image of the rapid exocytosis occurring during the fast exocytosis and to get an estimate of IRP. In the presence of the Syntaxin 1 antibody (n= 13), there was a 50% (p<0.001) reduction of the exocytosis evoked by a 50-ms depolarisation as compared to the control (n=17), and a 45% (p<0.05) reduction in the plateau reached at 250 ms corresponding to a decrease in IRP.
Conclusion: Investigating the effect of SNARE-proteins on the processes involved in the exocytotic machinery of glucagon secreting A-cells revealed that SNAP-25 and Syntaxin 1 are important for both rapid exocytosis and refilling of IRP/RRP by granule mobilization. Thus, we suggest that SNAP-25 and Syntaxin 1 are necessary for glucagon exocytosis in A-cells.

Evidence for PKA-independent priming of insulin secretory granules: insight from mathematical modeling
M.G. Pedersen[1], L. Eliasson[2];
[1]Department of Information Engineering, University of Padova, Italy,
[2]Diabetes Centre, Lund University, Malmö, Sweden.

Background and aims: Incretins, such as GLP-1 and glucagon, raise the concentration of cAMP in beta-cells. cAMP acts through both Epac-dependent and PKA-dependent pathways and is believed to be an important player in the maturation of secretory granules leading to calcium triggered exocytosis and insulin release. The aim of this study was to investigate the interplay between cAMP and calcium in the final steps preceding membrane fusion by estimating the size of the immediately releasable pool, calcium sensitivity of exocytosis, maximal rate of exocytosis and the rate of priming from capacitance data from single beta-cells under various conditions using a biophysical model.
Materials and methods: We developed a mathematical model of calcium induced exocytosis of insulin secretory granules, and applied it to experimentally obtained whole cell patch clamp capacitance data from single beta-cells. The model includes the immediately releasable pool, priming of granules, measured calcium currents and exocytosis. The simulations were done by solving numerically the ordinary differential equations of the model, and parameter estimation was done using Levenberg-Marquardt nonlinear regression, as implemented in the software Octave.
Results: The measured calcium currents were used as input to the mathematical model, and the predicted capacitance increases were fitted to the experimental data. To obtain insight in the role of cAMP for priming and fusion of secretory granules, we analyzed data from groups of cells stimulated with various concentrations of cAMP (0-500 μM) in the patch pipette, as well as from cells where PKA was inhibited by including Rp-cAMPS (0.5 μM) in addition to cAMP. The outcome of the model demonstrated that the differences between groups could be explained by varying just three parameters: Addition of 100 μM cAMP increased the priming rate 12-fold with respect to the control group (from 1.26 (+/- estimated standard deviation=0.05) fF/s to 15.2 (+/-1.9) fF/s). This rate was not changed by further addition of Rp-cAMPS (14.7 (+/-0.6) fF/s). The increased priming rate is thus PKA-independent, likely mediated by Epac2/cAMP-GEFII. Since the size of the immediately releasable pool is assumed to be proportional to the priming rate, we also estimated a 12-fold PKA-independent increase in pool size. The EC50 value of exocytosis with respect to calcium was slightly lowered by addition of 100 μM cAMP (to 12.6 (+/-0.8) from 14.7(+/-0.7) pA) but increased to 30.1(+/-0.7) by further addition of Rp-cAMPS. 100 μM cAMP + Rp-cAMPS did not change the maximal exocytosis rate (2.5 (+/-0.1) pr. sec in both cases), but was only 0.8(+/-0.1) pr. sec with 100 μM cAMP alone. In spite of the lower exocytosis rate, the group with 100 μM cAMP showed the largest total capacitance increase. Inspection revealed that this was due to a PKA-dependent increase in calcium currents in this group.
Conclusion: Our results differ from estimates using simpler analytical methods on the same data set and demonstrates that it is important to include calcium currents directly in the analysis of capacitance data. This is best done by mathematical modeling due to the nonlinear dependence of the exocytosis rate on the calcium concentration. The model strengthens the suggestion that priming of insulin secretory granules is largely mediated by Epac2/cAMP-GEFII. The PKA-dependent modified fusion properties might reflect the shift to a highly calcium sensitive state of the granules.

Membrane depolarization: a fail-safe parameter to assess the triggering pathway of insulin secretion?
M. Willenborg, K. Hatlapatka, U. Panten, I. Rustenbeck;
Institute of Pharmacology and Toxicology, Technical University of Braunschweig, Germany.

Background and aims: A classical experimental manoeuver to elicit insulin exocytosis is to subject pancreatic B-cells to depolarization by increasing the external K^+ concentration or by current injection. Typically, the extent of depolarization is made equal or even larger than the peak values of the action potentials resulting from K_{ATP} channel closure by nutrient and non-nutrient secretagogues. We tested whether this procedure is appropriate to gain insight into the physiological regulation of insulin secretion.
Materials and methods: NMRI mouse islets and beta cells were used to measure insulin secretion by perifusion and ELISA, membrane potential by patch clamping (perforated patch mode).
Results: When the blocker of voltage-dependent K^+ channels, TEA (10 mM), was added to a maximally effective concentration of the K_{ATP} channel blocker glipizide (2.7 μM) in the absence of glucose, an increase in action potential amplitude by 11.7 ± 4.1 mV was noted. Addition of KIC (10 mM) to glipizide led to a transient repolarization of the B-cell, thereafter an elevated plateau depolarization was observed. Again, the additional presence of TEA led to a significant increase in action potential amplitude (8.1 ± 1.4 mV). When

secretion of perifused islets was measured using the same experimental protocol, the presence of TEA did not increase secretion rather the secretory effect of glipizide in absence of glucose was reduced by 46.8%. When the fuel secretagogue KIC (10 mM) was added to the perifusion in both cases (presence or absence of TEA) a fast increase in secretion was elicited. When the data were normalized to the last value prior to addition of KIC, the increase in the absence of TEA was not significantly different and from that in the presence of TEA. When the blocker of K_{ATP} channels, tolbutamide (50 μM) was added to high KCl (15 mM), the moderate membrane depolarization (20.7 mV) established by KCl was further enhanced and action potentials ocurred. The difference in plateau depolarization was 5.5 ± 1.8 mV. Here, the enhanced depolarization had a corresponding effect on secretion in that the amount of insulin secreted during 30 min was increased 2.5fold.
Conclusion: The extent of depolarization of the B-cell membrane per se does not define the strength of a secretory stimulus. Rather, the underlying mechanisms have to be taken into account. Action potential amplitude is largely determined by membrane resistance and an increased amplitude does not necessarily transduce into a proportionate increase of secretion. Depolarization methods circumventing K_{ATP} channel closure may represent unphysiologically strong stimuli when depolarization levels equal to action potential peaks are attained.

Involvement of protein kinase A and Epac in initiation and maintenance of glucose-stimulated pulsatile release of insulin
O. Idevall-Hagren, E. Gylfe, A. Tengholm;
Medical Cell Biology, Uppsala University, Sweden.

Background and aims: Glucose stimulation of β-cells results in pulsatile release of insulin. This process is controlled by synchronized oscillations of the Ca^{2+} and cAMP concentrations beneath the plasma membrane ($[Ca^{2+}]_{pm}$ and $[cAMP]_{pm}$). The effects and mediators of glucose-induced cAMP signals in β-cells are poorly characterized, and the aim of the present study was to clarify the contribution of protein kinase A (PKA) and the cAMP-regulated guanine nucleotide exchange factor Epac to pulsatile insulin secretion from glucose-stimulated MIN6 β-cells.
Materials and methods: Evanescent wave fluorescence imaging was used to record $[cAMP]_{pm}$ or $[Ca^{2+}]_{pm}$ in parallel with phosphatidylinositol-3,4,5-trisphosphate (PIP_3). This membrane lipid is formed by autocrine insulin receptor activation and was used as readout for insulin secretion from single MIN6 β-cells.
Results: Elevation of the glucose concentration from 3 to 11 mM induced oscillations of $[Ca^{2+}]_{pm}$ and $[cAMP]_{pm}$. The second messenger signals were tightly associated with PIP_3 oscillations reflecting pulsatile release of insulin. After inhibition of PKA with 100 μM Rp-8-CPT-cAMPS or 2 μM KT5720 the PIP_3 response to a subsequent glucose challenge was reduced by 30±7% (n=37 cells, P<0.05) and 59±10% (n=19, P<0.01), respectively, without corresponding changes in $[Ca^{2+}]_{pm}$. In contrast, already manifested PIP_3 oscillations in glucose-stimulated cells were little affected by PKA inhibition. cAMP was nevertheless required for the glucose-induced PIP_3 oscillations, and inhibition of adenylyl cyclases with 100 μM 2',5'-dideoxyadenosine or 400 μM SQ22,536 (SQ) reduced the time-average PIP_3 response by 66±5% (n=54, P<0.001) and 42±3% (n=101, P<0.001), respectively. This inhibition was partially reversed by 1 μM of the Epac-selective nucleotide analogue 8-pCPT-2'-O-Me-cAMP-AM restoring the PIP_3 response in SQ-treated cells to 80±5% (n=78, P<0.001 vs SQ) of that obtained with 11 mM glucose alone.
Conclusion: cAMP contributes significantly to pulsatile insulin release from glucose-stimulated β-cells. While PKA is required for appropriate initiation of the secretory response, the cAMP-dependence of maintained pulsatility is mediated by Epac.

Secretagogue-induced elevation of the plasma membrane PtdIns4*P* concentration in individual insulin-secreting cells
A. Wuttke, A. Tengholm;
Medical Cell Biology, Uppsala University, Sweden.

Background and aims: The phospholipid phosphatidylinositol 4-phosphate (PtdIns4*P*) is a critical regulator of a variety of cellular processes, including membrane and vesicle trafficking. Generation of PtdIns4*P* by phosphatidylinositol 4-kinases has been implicated in the priming of secretory granules in pancreatic β-cells. However, it is unknown whether stimulators of insulin secretion regulate plasma membrane PtdIns4*P*. The aim of this study was to clarify how glucose and the phospholipase C-activating agonist carbachol affect plasma membrane PtdIns4*P* concentration, $[PtdIns4P]_{PM}$, by real-time monitoring of the lipid in individual insulin-secreting cells.
Materials and methods: The PtdIns4*P*-binding pleckstrin homology domain from the oxysterol binding protein fused to cyan fluorescent protein (OSBP-CFP) was used as a biosensor for PtdIns4*P* in individual MIN6 β-cells. The subcellular distribution and plasma membrane localization of the biosensor were monitored with confocal and evanescent wave microscopy, respectively. Response amplitudes were expressed as the ratio of OSBP-CFP over membrane bound yellow fluorescent protein signal.
Results: Confocal imaging of MIN6 β-cells expressing OSBP-CFP showed distinct localization of the biosensor at intracellular membranes, whereas the plasma membrane fluorescence was only slightly brighter than the diffuse fluorescence from unbound biosensor in the cytoplasm. However, background reduction by release of free cytoplasmic OSBP-CFP after membrane permeabilization with digitonin revealed a clear plasma membrane localization of the PtdIns4*P* biosensor (n=13). This membrane localization was specific, since a PtdIns4*P* binding-deficient biosensor mutant was localized exclusively in the cytoplasm (n=9). Evanescent wave microscopy recording of plasma membrane OSBP-CFP fluorescence showed that elevation of the glucose concentration from 3 to11 mM induced a prompt increase of $[PtdIns4P]_{PM}$ (22.2 ± 0.1% increase of the fluorescence ratio; n=56), which was transient, sustained or oscillatory in 39%, 35% and 26% of the cells, respectively. The glucose-induced elevation of $[PtdIns4P]_{PM}$ was prevented by inhibition of type III PI4-kinases with LY-294002, by removal of extracellular Ca^{2+} (n=24), hyperpolarization with 250 μM diazoxide (n=21) or blockage of L-type voltage-gated Ca^{2+} channels with 50 μM methoxyverapamil (n=41). Elevation of the cytoplasmic Ca^{2+} concentration by depolarization with 30 mM K^+ (n=9) or 1 mM tolbutamide (n=7) triggered a similar rise in $[PtdIns4P]_{PM}$ as glucose. Activation of phospholipase C with 100 μM of the muscarinic receptor agonist carbachol induced sustained elevation of $[PtdIns4P]_{PM}$ (12.5 ± 0.7% increase of the fluorescence ratio; n=52). In contrast to the glucose-induced elevation of $[PtdIns4P]_{PM}$, the carbachol response persisted even after removal of extracellular Ca^{2+} and depletion of intracellular Ca^{2+} stores.
Conclusion: Glucose and carbachol stimulation of insulin-secreting cells is associated with elevation of the plasma membrane PtdIns4*P* concentration. Whereas the glucose effect is mediated by Ca^{2+}, carbachol operates via a Ca^{2+}-independent mechanism. The demonstration of stimulus-induced changes of the plasma membrane PtdIns4*P* pool reinforces the importance of this lipid in signaling underlying insulin secretion.

Glucose models cAMP-linked signalling pathways in pancreatic beta cells
J. Papin[1], B. Roger[1], P. Vacher[2], A. Mulot[1], G. Charpentier[1], M. Raoux[1], F. Pattou[3], B. Vandewalle[3], J.-C. Jonas[4], N. Moustaïd-Moussa[5], J. Lang[1];
[1]Umr cnrs 5248, Institut Européen de Chimie et Biologie, Université de Bordeaux, Pessac, France, [2]Inserm u916, Institut Bergonié, Université de Bordeaux, France, [3]Inserm u859, Laboratoire de Thérapie Cellulaire du Diabète, Faculté de Médecine, Lille, France, [4]Unité d'Endocrinologie et Métabolisme, Faculté de Médecine, Université Catholique de Louvain, Bruxelles, Belgium, [5]Department of Animal Science and University of Tennessee Obesity Research Center, Knoxville, United States.

Background and aims: Glucose regulates gene expression in pancreatic β-cells and prolonged exposure to elevated levels induces considerable changes in acute effects of the hexose. In this study, we are investigating the long-term effects of glucose on cell signalling pathways namely GPCR- and cAMP ; these effects are determined using the physiologically relevant hormone glucagon-like peptide 1 (GLP-1) as well as forskolin (FSK), a general activator of adenylyl cyclases (ADCYs) and IBMX, a general inhibitor of phosphodiesterases.
Materials and methods: INS-1E cells or pancreatic islets were cultured for 24 to 72h at 5.5, 11 or 20 mM glucose (G5.5, G11, G20). Intracellular calcium concentration ($[Ca^{2+}]_i$) was determined in single cells using microspectrofluorimetry and Indo-1 as fluorescent probe, cAMP and insulin were measured by commercial assays. Microarray analysis was performed on Affymetrix arrays (REA 230 2.0) and analyzed by ARRAY-Assist or INGENUITY. Exocytosis was determined by capacitance measurements.
Results: GLP-1- or FSK-induced $[Ca^{2+}]_i$ increases were abolished or largely reduced by culture of INS-1E cells for 72h at G11 or G20 as compared to G5.5. Similarly, increases in cAMP levels by FSK/IBMX were reduced at G20

and amplification of glucose effects on insulin secretion by GLP-1 or FSK were lost. Microarray analysis revealed profound changes at G11 and at G20 within several canonical pathways and ranked pyruvate metabolism, glycolysis, cAMP- and GPCR-mediated signalling as the most significantly affected ($p<0.005$, Fischer's exact test). The latter two showed a loss in GLP-1 receptor already at G11 and a major reduction in the calcium-sensitive adenylyl cyclase 8 (ADCY8) at G11 and at G20. Other ADCYs including ADCY10 or cAMP targets were not altered. Expression profiles were validated by quantitative PCR as well as immunoblots and similar changes were observed in rat or human islets. Interestingly, transient re-expression of ADCY8, but not of GLP-1 receptor, restored GLP-1-induced calcium signalling in cells cultured at G20. In line with these observations, knock-down of ADCY8 in cells cultured at G5.5 abolished GLP-1-induced changes in $[Ca^{2+}]_i$ and reduced by two-thirds the glucose response. In contrast, thapsigargin- or KCl-induced changes in $[Ca^{2+}]_i$ remained unchanged. Moreover, this knock-down abolished amplification of calcium-induced exocytosis by FSK/IBMX.
Conclusion: The expression of key proteins involved in GPCR- and cAMP-linked signalling, such as ADCY8 and GLP1R, is controlled by glucose. These findings strongly suggest a central role for ADCY8 in glucotoxicity.

Protein GAS6 and its receptor Axl are expressed and operate in pancreatic beta cells
V.V. Sharoyko[1], C. Ekman[2], N. Wierup[3], F. Sundler[3], B. Dahlbäck[2], H. Mulder[1];
[1]Clinical Sciences, Lund University, Malmo, [2]Department of Laboratory Medicine, Section for Clinical Chemistry, Wallenberg Laboratory, Lund University, Malmo, [3]Department of Experimental Medical Science, Lund University, Lund, Sweden.

Background and aims: Growth arrest-specific protein 6 (GAS6) belongs to the family of plasma vitamin K-dependent proteins. It shows homology (~40%) to the plasma anticoagulant protein S, another gamma-carboxylated protein. GAS6 exhibits growth factor-like effects, as it interacts with a receptor tyrosine kinase: Axl. GAS6 and the Axl have further been implicated in inflammation and immune responses, hemostasis, and cancer. Here, we studied whether this system occurs in pancreatic islets.
Materials and methods: TaqMan qRT-PCR was used to quantify mRNA levels. GAS6 and Axl were detected by immunoblotting, immunocytochemistry and ELISA in pancreatic beta-cells. Insulin secretion was determined by RIA.
Results: Quantitative RT-PCR analysis demonstrated a low level of Axl mRNA expression in INS-1 832/13 clonal beta-cells. In contrast, expression of GAS6 mRNA was abundant in INS-1 832/13 cells. Immunoblotting of protein extracted from INS-1 832/13 cells with an antibody to GAS6 showed an immunoreactive band of the expected molecular weight (75 kD). Furthermore, immunoblotting with an antibody to Axl detected expression of full length Axl receptor. Immunocytochemical analysis revealed that GAS6 and Axl are expressed in mouse and rat islets. Secretion of GAS6 from INS-1 832/13 cells was analysed in conditioned RPMI-1640 medium containing 11.1 mM glucose in which INS-1 832/13 cells had been cultured for 24 h, using a highly sensitive ELISA. The level of GAS6 protein was 100 pg/ml in the medium (corrected for concentration of medium); this was several-fold higher than that in medium alone, ensuring that it is not a constituent of serum. Next, we observed that glucose affects Axl receptor expression in INS-1 832/13 cells: Axl mRNA was upregulated two-fold upon 48 h culture of INS-1 832/13 cells in 16.7 mM glucose compared to cells cultured with 2.8 mM glucose. Axl mRNA levels were reduced by 92-98% using three different siRNAs to Axl. Knockdown of Axl resulted in a significant decrease in glucose-stimulated insulin secretion, whereas basal insulin secretion did not change. GAS6 induces Axl-mediated PI3-kinase/Akt signalling in INS-1 832/13 beta-cells. Immunoblotting with an antibody to Axl[pY779] and Akt/PKB[pS473] detected phosphorylation of Axl and Akt/PKB induced by 400 ng/ml GAS6. Axl-phosphorylation was blocked by preincubation GAS6 with soluble Axl-receptor or GAS6 antibody. Akt-phosphorylation was inhibited by 100 nM wortmannin (inhibitor of PI3-kinase).
Conclusion: By using different methods we identified protein GAS6 and its receptor Axl in clonal beta-cells and pancreatic islets. For the first time we showed that GAS6/Axl system operates in pancreatic beta-cells: 1) Axl knockdown resulted in impairment in glucose-stimulated insulin secretion in beta-cells; 2) GAS6 activates Axl/PI3-kinase/Akt signalling in INS-1 832/13 beta-cells. Studying the GAS6/Axl system opens a new avenue for research in pancreatic islet cell biology.

Role of mitochondrial fission and fusion in beta cell stimulus secretion coupling
H. Schmitt[1], S. Lenzen[1], S. Baltrusch[1,2];
[1]Institut of Clinical Biochemistry, Hannover Medical School, [2]Institute of Medical Biochemistry and Molecular Biology, University of Rostock, Germany.

Background and aims: In pancreatic beta cells glucose-induced insulin secretion is mediated by the glucose sensor enzyme glucokinase (GK) and accompanied by mitochondrial membrane potential (MMP) hyperpolarization. Previous studies show, that mitochondrial fission followed by selective fusion segregates dysfunctional mitochondria and permits their removal by autophagy. Thus, this machinery is vital to maintain mitochondrial morphol-

ogy and ATP generation. The aim of the study was to determine fusion and fission events in beta cells with respect to the glucose metabolism and MMP.
Materials and methods: Insulin-producing RINm5F-R-GK, expressing GK in response to the synthetic inducer RSL1 and primary rat beta cells were incubated at different glucose concentrations. The MMP was measured using the potentiometric dye TMRE in combination with MitoTracker Green. The change of MMP induced by 10 mmol/l glucose was analyzed over 60 min by fluorescence microscopy. The slope of the TMRE/MitoTracker Green ratio change of individual cells and mitochondria was calculated. Fission and fusion events were determined by the use of the green to red photoconvertible fluorescent protein Dendra2 fused to cytochrome-c-oxidase (Dendra2-Mito). Photoconversion of a single mitochondrium was performed with a confocal microscope equipped with a second scan unit. Mitochondrial dynamics were analyzed with Imaris software.
Results: RINm5F-R-GK cells were pre-cultured for 48 h at 10 mmol/l glucose without or in the presence of 500 nmol/l of the inducer RSL 1. Thereafter the increase in the MMP after 90 min starvation in response to 10 mmol/l glucose was significantly faster in cells with GK expression. Interestingly, RINm5F-R-GK cells pre-cultured at 30 mmol/l glucose for 48 h showed also a faster increase in MMP in comparison to cells pre-cultured at 10 mmol/l. This increase was further amplified by GK expression during pre-culture at 30 mmol/l glucose. Likewise, in primary rat beta cells pre-culture for 48 h at 30 mmol/l glucose resulted in a significantly faster increase in the MMP in comparison to cells pre-cultured at 5 mmol/l. Furthermore pre-culture at 30 mmol/l glucose resulted in a higher cellular MMP homogeneity. Visualized mitochondrial morphology by Dendra2-Mito in RINm5F-R-GK cells was comparable to that observed with MitoTracker Green and thus, feasible to describe mitochondrial dynamics. Mitochondrial fusion and fission was not affected by GK expression, but occurs more frequently in cells pre-cultured at 30 mmol/l glucose.
Conclusion: GK expression temporally activates MMP hyperpolarization after glucose stimulation, but is not involved in the regulation of the mitochondrial morphology and maintenance of the functional network. Mitochondrial adaptation to high glucose exposure acts in beta cells of healthy rats. Analysis of mitochondrial fusion and fission with Dendra2-Mito will be a useful tool to analyze mitochondrial dysfunction in type 2 diabetes.

Isocitrate dehydrogenase 1 knockdown in INS 832/13 cells by siRNA increases glucose-induced insulin secretion
C. Guay, É. Pepin, M. Guèvremont, M. Madiraju, É. Joly, M. Prentki;
Montreal Diabetes Research Center, Centre de Recherche du Centre Hospitalier de l'Université de Montréal, Canada.

In pancreatic β-cells, metabolic coupling factors produced by glucose metabolism regulate insulin secretion. Recent studies have suggested that NADPH could act as a metabolic coupling factor since NADPH concentration correlates with glucose-induced insulin secretion (GIIS). In β-cell, very low amount of glucose is metabolised via the pentose phosphate pathway, such that cytosolic NADPH level is thought to be controlled primarily by the activity of the cytosolic isoform of malic enzyme (ME1) and of isocitrate dehydrogenase (IDH1). In a previous study, we have shown that ME1 expression is important for appropriate insulin secretion in response to glucose. To investigate the role of IDH1 in GIIS, we transfected INS 832/13 cells with siRNA directed against IDH1. IDH1 expression at mRNA level was reduced by 70 % using siRNA, correlating with more than 35% decrease in IDHc activity. Surprisingly, siRNA knockdown (KD) of IDH1 expression led to a 58% increase in insulin secretion at intermediate (5 mM) glucose and of 46% at high (10 mM) glucose. This effect on GIIS was mediated via the K_{ATP}-independent/amplification pathway. Basal and KCl-induced secretion were not affected by IDH1 KD. IDH1 KD cells showed an elevation of glucose incorporation into fatty acids. Taking together, the results suggest that metabolic flux through IDH1 may not be critical for GIIS as previously thought, and that a decrease in the metabolic flux through IDH1 is compensated by an elevation of pyruvate/citrate cycling possibly linked to enhance production of metabolic coupling factors such as NADPH and malonyl-CoA. Current experiments aim at assessing the metabolic consequence of IDH1 KD.

Q268X mutation of HNF4α/MODY1 gene affects the mitochondrial function in cultured living beta cells; evaluation by a new original system
M. Ogata[1], N. Iwasaki[1], T. Awaji[2], M. Takizawa[1], R. Fujimaki[1], K. Maruyama[2], Y. Iwamoto[1];
[1]Diabetes Center, Tokyo Women's Medical University, [2]Department of Pharmacology, Saitama Medical School, Japan.

Background and aims: Mitochondrial pH is known to reflect its functional viability. However, there has been no useful system to measure quantitative and serial mitochondrial pH to date. Recently, a pH of organum has been successfully calculated by using fluorescence GFP, but still it is not a direct quantitative calculation. Here, we developed a new system to calculate mitochondrial pH of living cell with fluorescence. Since mitochondrial function of the β−cell is a key step for insulin secretion, we aimed to measure a mitochondrial pH of the β-cell carrying the mutation of the hepatocyte nuclear factor (HNF)-4α/ MODY1 gene characterized by impaired insulin secretion, using this unique system.
Materials and methods: A pH calculation probe consists of two probes, a pH dependent fluorescence Venus of which pKa ranged 7.2-8.0, and a pH independent fluorescence mutational GFP. Mitochondrial pH calculated probe made by cytochrome-C subunit IV gene was fused with the pH measurement probe, then transfected stably in cultured β−cells, INS-1 and MIN6 cells, by lipofectum method. Insulin stimulating substance: glucose, tolbutamide, arginine, and potassium are applied to these cells, and calculate mitochondrial pH. Since Q268X mutation of the HNF4α gene is a causative mutation in human diabetes of autosomal dominant inheritance, we have introduced this mutational gene fused with JRED. These mutational genes were transfected to the mitochondrial pH measurement β−cells. Mitochondrial pH was calculated serially and quantitatively under the stimulation of insulin secretion using these cells.
Results: In the wild cultured β−cells, the mitochondrial pH decreased quickly by glucose and potassium, and leisurely decreased by arginine and tolbutamide. A basal level of the mitochondrial pH of β−cells increased by aeration in a cultured medium. Interestingly, in the β−cells with Q268X mutation of HNF4α gene, a response to glucose was clearly disappeared, but a response to arginine was still shown.
Conclusion: Mitochondrial pH is decreased by insulinotropic stimulation in cultured β−cells. We have observed that Q268X mutation of the HNF4α affected mitochondrial function in the living β−cells. This new system worked well and is thought to be a useful tool for evaluation of the mitochondrial function in the living cells.

Mitochondrial matrix alkalinisation serves as an essential signal for nutrient-induced second phase insulin secretion
A.C. Wiederkehr, C.B. Wollheim;
Department of Cell Physiology and Metabolism, University of Geneva, Switzerland.

Background and aims: The mitochondrial matrix pH is more alkaline than the close to neutral cytosolic pH. We recently demonstrated that in the pancreatic beta-cell matrix pH under resting conditions is very low but increased substantially during nutrient stimulation. Furthermore we found matrix alkalinisation to be essential for nutrient-dependent mitochondrial ATP synthesis in alpha toxin permeabilised INS-1E cells. Here we have tested whether mitochondrial matrix alkalinisation serves as a mitochondrial activation signal necessary for metabolism-secretion coupling.
Materials and methods: INS-1E cells or intact rat islets were infected with Adenoviruses expressing reporter proteins to measure mitochondrial pH (mitoAlpHi), ATP (cytosolic Luciferase), mitochondrial calcium (mitochondrial Aequorin) or cytosolic calcium (cytosolic YC3.6). The different parameters were measured using either single cell fluorescence imaging or by following luminescence changes. Nigericin was utilized to clamp nutrient-dependent matrix alkalinisation. This ionophore can be used to equilibrate proton gradients across biological membranes with only little impact on the much larger potassium gradients.
Results: Nigericin (500nM) attenuated glucose-induced mitochondrial matrix alkalinisation, whereas cytosolic pH remained constant close to 7.1. Preventing mitochondrial alkalinisation and the associated increase in ΔpH lowered glucose-stimulated insulin secretion by more than 70%, whereas basal release was unchanged. In rat islet perifusion experiments second phase

insulin secretion was almost abolished by nigericin. Insulin secretion per se was not affected as insulin exocytosis to PKC activation (independent of mitochondrial function) was normal in the presence of the ionophore. Nigercin also strongly reduced the glucose-mediated net increase of cytosolic ATP and the amplitude and frequency of cytosolic calcium transients consistent with the observed pronounced secretion defect. In contrast, the cytosolic calcium response to tolbutamide was unaffected by nigericin, demonstrating that nigericin did not clamp the plasma membrane potential. We find however that tolbutamide may in part act as a secretagogue via mitochondria as cytosolic ATP levels were increased by 12% in response to tolbutamide at basal glucose concentration. Nigericin prevented this increase and consequently lowered insulin secretion to tolbutamide despite a normal cytosolic calcium response.

Conclusion: Attenuation of mitochondrial alkalinisation not only inhibits mitochondrial ATP synthesis preventing closure of KATP channels, but may also affect other energy-dependent aspects of insulin exocytosis. Our results demonstrate that matrix alkalinisation is an essential signal in metabolism-secretion coupling.

Hyperthyroidism decreases islet pyruvate dehydrogenase kinase 1 (PDHK1) expression and attenuates islet starvation adaptations

M.J. Holness[1], H. Mulder[2], O. Kotova[2], U. Bryborn[2], G.K. Greenwood[1], M.C. Sugden[1];
[1]Centre for Diabetes and Metabolic Medicine, ICMS, Queen Mary University of London, United Kingdom, [2]Unit of Molecular Metabolism, Department of Clinical Sciences, Lund University Diabetes Center, Lund, Sweden.

Background and aims: Glucose metabolism in the pancreatic β-cell controls glucose-stimulated insulin secretion (GSIS), the routes by which carbons enter and exit the TCA cycle being critical. Two major regulatory fates are reactions catalyzed by pyruvate carboxylase (PC) and pyruvate dehydrogenase (PDH), respectively. PC controls the major anaplerotic pathway in β-cells, and its inhibition results in impaired GSIS. Inhibitory phosphorylation of PDC by the PDH kinases (PDHKs) conserves pyruvate for PC-mediated entry into the TCA cycle during starvation. Here, we aimed to determine whether reports of increased glucose oxidation by pancreatic islets in the hyperthyroid state reflected altered islet PDK expression.

Materials and methods: Insulin secretion, PDHK expression and GSIS were examined in rat islets after 72 h of *in vivo* treatment with tri-iodothyronine.

Results: Islet PDHK1 protein expression was reduced by 61% ($P<0.001$), and PDHK2 protein expression was decreased by 27% ($P<0.001$), as assessed by Western Blot. At basal glucose (2 mM), insulin secretion by islets was unaffected by hyperthyroidism. The GSIS response to hyperthyroidism differed depending on dietary status. Insulin secretion was decreased (by up to 58%) in the fed state, but the insulin secretory response to starvation (associated with enhanced expression of PDHK4) was attenuated.

Conclusion: We suggest that augmented PDH activity in response to hyperthyroidism in the fed state lowers GSIS via suppression of PC flux and pyruvate cycling; however, through maintenance of low PDHK1 and PDHK2 expression, keeping PDH in a relatively dephosphorylated and active state, hyperthyroidism opposes the response of GSIS of pancreatic β-cells to fasting.

Differences in metabolic regulation between glucose responsive INS-1 832/13 and its glucose non-responsive INS-1 832/2 sister clonal rat beta cell line decides their beta cell functionality

S. Malmgren[1], V.V. Sharoyko[1], D. Nicholls[2], H. Mulder[1];
[1]Department of Clinical Sciences in Malmö, Lund University, Sweden, [2]Department of Experimental Medical in Lund, Lund University, Sweden.

Background and aims: The biochemical mechanisms underlying glucose-stimulated insulin secretion from pancreatic beta-cells are not completely understood. The main coupling signal is a rise in ATP:ADP ratio, mainly accounted for by the mitochondrion. This closes ATP-dependent K+ channels, depolarizating the plasma membrane. Voltage-gated Ca2+ channels opens and allow Ca2+ ions to flow into the cell triggering insulin vesicles to merge with the plasma membrane. In order to investigate the putative metabolic disturbances in β-cells that affects glucose-stimulated insulin secretion we investigated two subclones of INS-1 exhibiting different properties: 832/13 cells are glucose-responsive while the 832/2 cells are glucose-nonresponsive. The insulin content of the cells is the same and ATP-independent closing of K+ channels evokes insulin release in both cell types. This leads us to hypothesize that the difference in insulin response could have a metabolic origin.

Materials and methods: Insulin secretion for one hour in static incubation was measured by RIA. Differences in glucose metabolism were assessed by Extracellular flux analyzer XF24 (Seahorse Bioscience, Billerica, MA). Lactate in the cells incubated at 2.8 and 16.7 mM glucose was measured using a colorimetric lactate assay kit (Biovision, Mountain view, CA, USA). ATP production was measured by using an ATP monitoring reagent based on firefly luciferase (BioThema AB, Handen, Sweden)

Results: The INS-1 832/13 were robust secretors of insulin (>8-fold) when stimulated by an elevation in glucose from 2.8 mM (low glucose) to 16.7 mM (high glucose) whereas the same settings failed to release insulin in INS-1 832/2. The Oxygen Consumption Rate (OCR) is basically a measurement of the respiratory rate in the mitochondrion. INS-1 832/13 cells showed a considerable increase in OCR when stimulated with high glucose; this effect was abundant in INS-1 832/2. They also displayed a poorer response to the metabolic modulators oligomycin, FCCP and Rotenone. The ATP production rate of the INS-1 832/13 was more than twice that of the INS-1 832/2 in a 14 mM glutamate/succinate buffer. INS-1 832/2 cells secreted 140 nmol/mg prot/h of lactate at high glucose while lactate secretion from the INS-1 832/13 was not detected. Extracellular acidification rates (ECAR) can be attributed to lactate and/or CO2 production. The ECAR of 832/13 cells basically paralleled the OCR, suggesting that it is mainly accounted for by CO2 production. In the 832/2 cells, the ECAR was 3.6 fold higher, and increased in response to oligomycin and FCCP. This suggests that increased glycolytic rate compensates for the inhibition of ATP production caused by these drugs.

Conclusion: We conclude that tight coupling between the glucose stimulus, via glycolysis, and the rate of oxygen consumption determines ATP production. This aspect of mitochondrial metabolism is crucial for the ability of the β-cell to respond to high glucose with insulin secretion. The INS-1 832/2 cells which express LDH have regained their ability to speed up glycolysis to reflect energy demands and substrate levels. This gives them an advantage as it makes them less vulnerable but occurs at the expense of β-cell functionality, such as their ability to secrete insulin in response to glucose.

Complement factors are expressed in pancreatic islets and affect glucose induced insulin secretion

V. Nagaraj[1], U. Bryborn[1], J. Sjölander[2], A. Blom[2], E. Renström[1];
[1]Lund University Diabetes Centre, Malmo, [2]Department of Laboratory Medicine, Lund University, Malmo, Sweden.

Background and aims: Complement factors form an important part of the humoral innate immune system and have been implicated in the pathogenesis of autoimmune diseases, including type 1-diabetes. There is however accumulating evidence that the complement system may also be an important player in the development of type 2-diabetes. First, the complement system modulating peptide adrenomedullin is increased in patients with type 2-diabetes. This peptide, together with its binding partner the complement inhibitor factor H, has been reported to affect insulin secretion. Furthermore, patients with type 2-diabetes exhibit increased neutrophil levels of complement factor 5a. C5a is produced as a result of complement activation and exerts its effect by binding to its receptor C5aR. In this study we have addressed the expression of the complement system in human pancreatic islets and the effects of adrenomedullin, Factor H and C5a on islet function.

Materials and methods: Expression in human islets: Total RNA was isolated from pancreatic islets islets from 17 non-diabetic donors (6 female, 11 male aged 26-73, BMI 17.7-29 kg/m2) using the AllPrep DNA/RNA Mini Kit (Qiagen) and analyzed using Gene 1.0 ST whole transcript based assays (Affymetrix).

Expression in rat islets and INS1 832/13 cells: Isolated rat pancreatic islets and cDNA from liver were used to study the complement gene expression by Q-RT-PCR technique with specific primers. Secretion assay: The role of C5a, factor H and adrenomedullin on insulin secretion was identified by insulin secretion assay in the presence of 2.8mM and 16.7mM glucose in Ins1 823/13 cells.

Results: The microarray data confirmed the presence of all the complement genes in human pancreatic islets. Complement genes C2, C3, C5aR, factor H and factor I were selected for validation in rat. The rat-derived clonal Ins1 832/13 cells expressed low levels of the transcripts for the selected complement genes. Rat pancreatic islets exhibited higher transcript levels. Of the selected transcripts expression was highest for factor H and complement component 2 (C2) relative HPRT. The mRNA relative HPRT expression values of C2, factor H, C3, C5aR, and factor I were 0.047, 0.043, 0.018, 0.014, 0.0026 respectively, with 0.00336, 0.00127, 0.00045, 0.00107, 0.00018 respective standard error means. Liver is considered as a rich source for the complement factors and we therefore compared expression of complement in islet with liver. Interestingly, it was observed that the expression of C5a mRNA was higher in islets than in liver. Next, we evaluated effects of factor H, adrenomedullin and C5a on glucose evoked insulin secretion in Ins1 832/13 cells. Adrenomedullin and factor H both stimulated glucose-induced insulin secretion by 75% and 52%, respectively with P=0.003 and 0.003, respectively. Their simultaneous presence did not stimulate secretion any further. Interestingly, C5a also had a stimulatory action in the absence of the complement factor glucose stimulated insulin secretion 2.6-fold, whereas in the presence of C5a a 5.6-fold stimulation was observed.
Conclusion: Most, if not all, complement factors are expressed in human and rat pancreas. Adrenomedullin, factor H and C5a all appear to stimulate insulin secretion. Signalling via the C5a receptor (C5aR) is a particularly interesting signalling pathway that may be involved in type 2-diabetes.

Non beta cell progenitors of beta cells in pregnant mice
S. Abouna[1], R.W. Old[1], S. Pelengaris[2], D. Epstein[3], V. Ifandi[1], I. Sweeney[1], M. Khan[1];
[1]Biological Sciences, University of Warwick, [2]Warwick Medical School, University of Warwick, [3]Department of Mathematics, University of Warwick, Coventry, United Kingdom.

Objective: Pregnancy is a physiological condition associated with a near doubling in maternal beta cell mass, in a relatively short period of time. In this state, replication of pre-existing beta cells is often presented as the main mechanism responsible for this expansion. The aim of this study was to critically examine whether a non-beta cell source might be also involved in the increase in beta cell mass.
Research design and methods: We used a double transgenic mouse (RIP-CreER^{TAM}/ZAP) of Dor and Melton. In this lineage tracing system, the cre-recombinase is expressed only in beta cells and is activated only upon tamoxifen exposure, leading to a conditional deletion of the translational stop sequence, flanked by two *loxP* sites, upstream of the human placental alkaline phosphatase (HPAP) region in the Z/AP transgene. As a result, the beta cells are irreversibly and heritably labelled with the HPAP reporter, in response to a pulse of tamoxifen before pregnancy.
Results: Following the tamoxifen-pulse, first we conclude that the lineage tracing system was highly specific for β-cells. Secondly, we compared the proportion of the β-cells as HPAP positive during a subsequent chase period in pregnant and non-pregnant females. We observed a dilution in this labelling index in pregnant animal pancreata (0.33±0.06), compared to non-pregnant controls (0.44±0.05). This difference was statistically significant (P =0.021, paired two-tailed t-test). We counted the numbers of HPAP-positive or HPAP-negative insulin-positive cells in the duct epithelium and in several islets in the same sections, to give the labelling index for islets and ductal cells. The labelling indices of insulin-positive ductal cells (0.25, n=44) and islets (0.31, n=5459) from pregnant animals were not significantly dissimilar (2x2 contingency table, Fisher's exact test, P= 0.455). Consequently, we concluded that β-cells associated with the pancreatic ducts were not a preferential source of new β-cells. Finally, there was no transdifferention of β-cells to other cell types in a two and half month period following labelling, including the period of pregnancy.
Conclusion: For the first time in a normal physiological condition we demonstrate that pregnancy is associated not only with β-cell duplication, but importantly also with the activation of a non- β-cell progenitor population.

Modulation of islet cell mass by fetal low-calorie diet and glucocorticoid exposure
V.M. Schwitzgebel, E. Somm, D. Vauthay, M.L. Aubert;
Pediatrics, University of Geneva, Switzerland.

Background and aims: Fetal adverse environment, such as insufficient maternal nutrition, placental insufficiency and stress, alters organ development and leads to poor fetal growth, also called intrauterine growth retardation (IUGR). IUGR is associated with an increased risk of perinatal mortality and morbidity as well as late-onset metabolic diseases, such as obesity, diabetes and hypertension in adulthood. In the rodent model, IUGR is induced by fetal caloric restriction, by isocaloric protein restriction, by restricted placental blood supply or by exposure to high levels of glucocorticoids. Such experimental IUGR models show a decreased beta cell mass and glucose intolerance with aging. To date, the mechanisms responsible for the loss of beta cells are still poorly understood. The aims of the present study were: (1) to examine the effects of intrauterine caloric restriction and dexamethasone exposure on pancreatic islet gene expression in rats; and (2) to characterize changes in gene expression during postnatal catch-up growth.
Materials and methods: To induce IUGR, pregnant rats were subjected to a 70% caloric restriction (CR) or exposed to dexamethasone (Dexa) (100 µg/kg/d for 7 days). Islet cells were then obtained in the offspring at postnatal days P7 and P21 and gene expression profiles compared to cells harvested

from pancreases of rats with a normal birth weight. Using real-time PCR, we quantified the relative changes in gene expression and confirmed the microarray results for a group of selected genes.
Results: At P7, islet cell area and insulin content of the pancreas were significantly reduced in the CR group in comparison to controls ($p<0.05$) and mRNAs of insulin and several beta cell markers (Pdx1, Kir6.2, Glut2 and glucokinase) were down regulated by 50% to 60%. In the Dexa-exposed group the islet cell area was also reduced compared to controls, while the difference for insulin mRNA did not reach significance. At P21 the islet cell area normalized in both groups. The expression of the cell cycle gene, cyclin D1, was significantly decreased at P7 (by 20%), but increased markedly by P21 (230%) in the CR group and paralleled the increase of beta cell markers such as insulin, Pdx1 and Glut2. In the Dexa-exposed group cyclin D1 did not change significantly at P7 or P21. There was no difference in the expression of cyclin D2 in both groups compared to controls. We also tested P16Ink4a to assess premature aging after IUGR, no expression was found at P7 or P21. At P21 the gene profile was different from P7, showing mostly a decrease in transcriptional regulators such as hepatocyte nuclear factor 6 (HNF6) and Krüppel-like factor 5 (KLF5).
Conclusion: In conclusion, we show that postnatal recovery of the islet cell mass after fetal stress exposure is linked to a complex regulation of different groups of genes, including transcription factors involved in prenatal pancreas development and cell cycle genes known to regulate postnatal beta cell expansion.

Liraglutide induces human beta cell proliferation, counteracts low density lipoprotein anti-proliferative effects and protects from IL-1beta induced apoptosis
S. Rütti[1], R. Prazak[1], H. Ellingsgaard[1], R. Sibler[1], L.B. Knudsen[2], A. Von Eckardstein[3], M.Y. Donath[1];
[1]Endocrinology and Diabetology, University Hospital, Zürich, Switzerland, [2]Novo Nordisk A/S, Malov, Denmark, [3]Institute for Clinical Chemistry, University Hospital, Zürich, Switzerland.

Background and aims: Glucagon-like peptide 1 (GLP-1) analogs induce β-cell proliferation and have anti-apoptotic effects in rodent islets. However, the proliferative capacity of human β-cell and its modulation by GLP-1 analogs remain to be fully investigated. The aim of this study was to determine whether the GLP-1 analog liraglutide affects β-cell proliferation and to investigate whether liraglutide is able to counteract the anti-proliferative effect of low density lipoprotein (LDL) and the pro-apoptotic effect of interleukine-1β (IL-1β).
Materials and methods: Human islets from cadaveric organ donors were dispersed into single cells and exposed to liraglutide for 2 days and co-stained for Ki-67 or BrdU incorporation and insulin, allowing the determination of proliferative β-cells. The anti-apoptotic effects of liraglutide against 2 ng/ml IL-1β were tested in human islets cultured for 4 days and analyzed for cell death by the TUNEL assay. Mouse islets were cultured for 4 days in the presence of liraglutide and 3.1 mM LDL, isolated from healthy human plasma. Proliferation was assessed by analyzing BrdU incorporation.
Results: After 2 days incubation, liraglutide increased human β-cell proliferation (unequivocally identified by insulin staining), in a dose dependent manner up to 3 fold. Moreover, 4 days incubation with liraglutide protected human islet cells from IL-1β induced apoptosis. LDL decreased mouse islet cell proliferation and this anti-proliferative effect of LDL was counteracted by the presence of liraglutide.
Conclusion: These results indicate that human β-cell can proliferate in vitro in response to liraglutide. Furthermore, liraglutide protects human islet cells from IL-1β induced apoptosis and counteracts the anti-proliferative effect of LDL in mouse islets, suggesting additional mechanisms for the anti-diabetogenic effects of liraglutide.

The downregulation of Raf-1 Kinase Inhibitor Protein (RKIP) allows the formation of new beta cell cluster
F.N. Pardo[1,2], J. Altirriba[3,4], A. Garcia[3], A. Barbera[1], A. Yañez[2], A. Novials[1,3], R. Gomis[1,3];
[1]Laboratorio de Diabetes y Obesidad, IDIBAPS, Barcelona, Spain, [2]Instituto de Bioquimica, Universidad Austral de Chile, Valdivia, Chile, [3]CIBER de Diabetes y Enfermedades Metabólicas Asociadas, CIBERDEM, Barcelona, Spain, [4]Fundació Clinic per a la Recerca Biomèdica, Barcelona, Spain.

Backgrounds and aims: RKIP (raf-1 kinase inhibitor protein) is a docking protein that regulates different signaling pathways involved in cell proliferation and apoptosis. Previous studies, performed in our laboratory, have demonstrated a downregulated expression of RKIP in a model of beta cell regeneration. To understand the role of RKIP in the plasticity of the beta cell, and a possible role in the inhibition in the replication, we have studied the pancreas in the whole knock out (KO) mouse of RKIP.
Material and methods: Morphometric studies have been performed in samples of pancreas fixed in formalin of 8-weeks old male mice, determining pancreas mass, beta cell mass and area. Intraperitoneal glucose tolerance test was performed in 8-weeks old male mice.
Results: The KO mouse shows a bigger pancreas than the wild type (1% of the body weight in KO and a 0.8% in WT; $p<0.05$). There are no differences between WT and KO animals in the total beta cell mass and pancreatic islet distribution (number of islets/mm^2) but there are significant differences in the distribution of different beta cell area, KO animals present a higher percentage of insulin-positive cluster cells smaller than 1.000 um^2 (KO: 71% ± 4.5, WT: 38.4% ± 5.3; $p<0.001$) and a lower percentage of bigger islets. These smaller clusters represent an 11.28% (± 2.8) of the total mass of beta cell in the KO pancreas compare to the WT who has a 5.16 % ± 0.75. For otherwise, in response to the i.p. glucose tolerance test, KO mice have not elevated the glucose, showing lower glycemia levels at 15 and 30 minutes ($p<0.05$) than WT mice.
Conclusion: With these results, we suggest that RKIP is involved in beta cell plasticity and its absence increases the formation of new insulin-positive clusters. Therefore RKIP should be considered as a new gene which controls formation of beta cell cluster processes in the pancreas and its modulation with some pharmacologic agents could be considered as a new target for the treatment of diabetes.

Novel transgenic mice for inducible gene overexpression in pancreatic precursors or mature beta cells
B. Blondeau[1], I. Sahly[2], E. Massourides[2], A. Singh-Estivalet[1], D. Dorchene[1], F. Tronche[2], B. Breant[1];
[1]INSERM UMRS 872, [2]CNRS UMR7148, Paris, France.

Background and aims: The use of genetically modified mice for conditional gene inactivation or gene overexpression in specific cell populations has helped identifying the precise role of genes in pancreatic beta cells. Previously, we have shown that the absence of glucocorticoid receptor in pancreatic precursor cells led to a doubled beta-cell mass while its absence in mature beta cells had no consequence on beta-cell mass. These results showed that genes may have crucial functions at precise developmental windows and that genetic modifications have to be controlled not only in specific cell populations but also during specific time frames. Thus, the aim of the present project was to generate new transgenic mice using the inducible Tetracycline system to overexpress genes of interest either in pancreatic precursor cells or in mature beta cells and during precise time frames.
Materials and methods: We have created two lines of mice : one with the expression of the tetracycline Transactivator (tTA) under the control of the mouse insulin 1 gene promoter (Ins-tTA, expression in mature beta cells), the second with the tTA under the control of Pdx-1 promoter (Pdx-tTA, expression in pancreatic precursor cells). Because minimal promoters may lead to ectopic expression, we used Bacterial Artificial Chromosomes containing large portions (>150 Kb) of the gene environment to drive the tTA expression. Mice from each line were crossed with mice that express the LacZ reporter gene under the control of the tetracycline response element. We then analyzed the sites of expression of the transgenes for each mouse line by determining where the reporter gene is expressed. Since this system can be turned off by the use of Doxycycline (Dox), we have tested if gene expression could be controlled during various developmental windows.

Results: Our results show that in the Pdx-tTA mice, the transgene is expressed as early as embryonic (E) day 11.5 in the two pancreatic buds and at E13.5 and E15.5 in all pancreatic precursor cells. In the adult pancreas, the transgene is present in mature beta, delta and PP cells and in some acinar cells. Transgene expression was also found in the duodenum and stomach. In the Ins-tTA mice, the transgene is expressed from E13.5 but is restricted to beta cells. No expression in other organs than the pancreas was found. Next, we showed in both mouse lines that a 4 week-Dox treatment to adult mice was able to turn off the expression of the reporter gene. Moreover, when Dox was given from conception until postnatal age, the turned off system could be re-induced upon removal of Dox.
Conclusion: In conclusion, we have generated transgenic mice in which the transgene is correctly targeted to precursor cells, mature beta and some acinar cells for Pdx-tTA mice and only to beta cells for Ins-tTA mice. The transgene overexpression can be controlled in time, thus providing new useful tools to overexpress genes in pancreatic cells during defined development periods.

First generation adenovirus vectors affect differentiation of human mesenchymal stem cells
A. Zaldumbide, F. Carlotti, I. Van der Velde-van Dijke, S. Knaän-Shanzer, R.C. Hoeben;
Molecular Cell Biology - Virus and Stem Cell Biology, Leiden University Medical Center, Netherlands.

Background and aims: Type 1 diabetes results from a specific destruction of β-cell by the immune system. The restoration of the damaged β-cell population represents an attractive challenge. In that prospect, the use of adult mesenchymal stem cells (MSC) would represent an attractive therapeutic option since they are easy to isolate and their plasticity allows them to differentiate into the endoderm, mesoderm and ectoderm lineage. Despite these attractive properties, the number of studies documenting efficient endocrine differentiation remains rather limited compared to embryonic stem cell based strategies for instance. Our previous data showed that the use of lentivirus vectors to force expression of Pdx-1 and Ngn3 does not lead to robust expression of any endocrine hormones. However, many studies have reported some evidences of endocrine differentiation by Pdx-1 overexpression used an adenoviral vector. In this study we want to investigate the putative effect of viral carrier on BM-MSC differentiation capacities.
Materials and methods: Functionality of the Pdx-1 lentivirus has been assessed by luciferase assay after co-expression in HepG2 cells of a reporter construct where the luciferase gene is driven by the human insulin gene promoter. Lentiviral and adenoviral transduction efficiency in BM-MSC have been evaluated by FACS and endocrine differentiation progression determined by RT-PCR/qPCR analysis.
Results: After a first transduction with a lentivirus carrying Pdx-1, modified BM-MSC cells were transduced with an irrelevant and replication-deficient first-generation human adenovirus type 5 vector endowed with the fiber of serotype 50. The cells were maintained in high glucose containing media for 4 additional days. Whereas Pdx-1 modified BM-MSC cells did not show any robust sign of differentiation, the subsequent transduction with the adenovirus leads to expression of insulin, glucagon and somatostatin. qPCR and FACS analysis demonstrated that the adenoviral transduction had little or no effect on the CMV promoter that drives expression Pdx-1 in the lentiviral vector, demonstrating that the effect observed was independent on the level of expression of Pdx-1. Moreover, we confirmed by qPCR that the combined treatment LV-Pdx-1 / irrelevant adenovirus trigger BM-MSC to the endocrine pathway since amylase level, used here as control for exocrine pancreas, was not affected. Although the molecular mechanism is still unclear it appears that an adenoviral gene product is involved in this process since no modifications have been observed after Helper-Dependent (HD) adenovirus transduction. Finally, making use of human pancreatic-islet derived MSC, which poorly differentiate into adipocytes, we demonstrate that infection of these cells with a E1-deleted adenovirus vector carrying an irrelevant transgene resulted in robust adipogenic differentiation.
Conclusion: These data demonstrate that subsequent transduction of lentivirally modified BM-MSC with an irrelevant first-generation human adenovirus type 5 fibers 50 (HAdV5-fib50) leads to expression of insulin, glucagon, and somatostatin. Thus, first-generation E1-deleted adenoviruses are not inert gene transfer vectors and can have a broad effect on differentiation capacity of stem cells in vitro. Epigenetic modifications associated with adenoviral transduction could explain the effect of Pdx-1 on its target promoters.

Regulation of beta cell regeneration by the autonomous nervous system in pancreatectomized rat
J. Movassat, J. Pakradouni, D. Bailbé, M. Faro, B. Portha;
University Paris Diderot, France.

Background and aim: The autonomous nervous system (ANS) regulates the activity of endocrine and exocrine pancreatic cells. Numerous in vitro and in vivo studies have shown that acetylcholine, the main neurotransmitter of the parasympathetic nervous system, enhances glucose-stimulated insulin secretion from pancreatic beta cells while activation of sympathetic nerves inhibits insulin release from the islets. However the role of ANS in the growth and proliferation of pancreatic cells is not clearly identified.
Material and methods: We investigated the role of ANS in a model of compensatory beta cell growth after 90% pancreatectomy in adult rat. In order to determine the impact of parasympathetic system on the regulation of beta cell regeneration, we performed sub-diaphragmatic vagotomy on pancreatectomized adult Wistar rats. The beta cell mass was morphometrically measured 7 days after surgery. The processes of cell replication, cell neogenesis and apoptosis were assessed in the time period preceding the partial recovery of beta cell mass after pancreatectomy i.e. 8h, 24h and 48h after surgery.
Results: The follow up of the beta cell mass 7 days after pancreatectomy showed that beta cell regeneration was reduced by 40% in the vagotomized/pancreatectomized group compared to the pancreatectomized group. We showed that during the first 48h following the pancreatectomy, the tremendous increase in ductal cell proliferation normally occurring in this model is significantly reduced in rats with sub-diaphragmatic vagotomy. PDX-1 expression in ductal cells, a feature of beta cell neogenesis, was also reduced in pancreatecomized/vagotomised rats 48h after surgery when compared to pancreatectomized rat. Moreover, vaogotomy associated with pancreatectomy significantly increased the rate of acinar cell apoptosis in the pancreas. Finally, beta cell replication was decreased as a consequence of vagotomy.
Conclusion: Taken together, our data show that vagotomy significantly alters beta cell regeneration in pancreatectomized rats suggesting that neurotransmitters released by parasympathetic nervous system are important for the compensatory growth of beta cells in adult rats.

Upregulation of cell differentiation-related genes in 90%-pancreatectomized rats treated with gastrin
N. Tellez[1,2], G. Joanny[1,2], J. Escoriza[1,2], E. Montanya[1,2];
[1]Lab. Diabetes and Experimental Endocrinology, IDIBELL-University of Barcelona, Hospital Universitari Bellvitge, L'Hospitalet de Llobregat, [2]CIBERDEM, Barcelona, Spain.

Background and aim: We have recently found that gastrin treatment improved glucose tolerance and increased beta cell regeneration in pancreatectomized rats through stimulation of beta cell proliferation and neogenesis. Here, we aimed to study the gene expression profile of beta cell neogenesis-related genes induced by gastrin in pancreatectomized rats.
Material and Methods: Sprague-Dawley rats underwent 90% partial pancreatectomy (90%-Px), a well established model of beta cell regeneration, and were treated with [15 leu] gastrin-17 (Px+Gast, n=18) or with vehicle (Px+V; n=17). A sham operated group was added as control (Sham, n=6). Pancreatic remnants were harvested on days 1, 3 (early Px) and 5, 7 (late Px) after pancreatectomy and processed for total RNA extraction. Gene expression was determined by quantitative real time PCR. **Results:** 90%-Px rats developed mild hyperglycemia after surgery with similar blood glucose concentrations between Px+V and Px+Gast groups (Blood glucose on day 7 after Px: Px+V=149 ± 11 mg/dl; Px+Gast=163±37 mg/dl). Gastrin treatment increased *ngn3* and *neurod1* expression on day 1 and *pdx-1, nkx6.1* and *tcf1* on day 3 after Px ($p < 0.05$ compared to sham animals). In late Px, *pdx-1*, *nkx6.1* and *pax6* gene expression levels were dramatically decreased in vehicle treated rats ($p < 0.05$ compared to sham animals). The lower expression of these transcription factors, which are crucial for maintaining the mature/functional beta cell phenotype, was consistent with the downregulation of the insulin gene expression in Px+V rats on day 7 ($p < 0.05$) compared to sham animals. In contrast, pancreatic remnants of Px+Gast rats showed sustained gene expression of all these transcription factors. Accordingly, *insulin2* and *glucagon* gene expression levels were also similar in Px+Gast and normal pancreas of sham animals, and significantly higher than in Px+V group ($p<0.05$).

Summary/Conclusion: Gastrin treatment stimulated the expression of the crucial transcription factors *ngn3*, *neuroD*, *pdx-1* and *nkx6.1* required for beta cell differentiation during the early phase of regeneration after 90%-Px. Moreover, gastrin administration resulted in the maintenance of the mature/functional beta cell phenotype preventing *pdx-1*, *nkx6.1* and *insulin2* gene expression downregulation found in late Px+V rats.

Combined loss of the cell cycle inhibitors p21cip1 and p27kip1 reveals that both are dispensable for maintaining adult beta cell mass and function

I. Cozar-Castellano[1,2], J. Kleinberger[2], K. Selk[2], E. Cherok[2], A.F. Stewart[2];
[1]Hospital Universitario Puerta del Mar, Cadiz, Spain, [2]Division of Endocrinology, University of Pittsburgh, United States.

Background and aims: β-cell replication is partially responsible for developing and maintaining beta cell mass and function. The "pRb pathway" is the final regulation step of the G1/S checkpoint in the β-cell cycle. In addition to cyclins and cyclin-dependent kinases, upstream control at the G1/S checkpoint also includes cell cycle inhibitors, the CIP/KIPs and the INK4s. On the CIP/KIP side, p27kip1 play a role in maintaining cell cycle arrest, which becomes apparent only when p27kip1-null mice are placed on a high-fat diet, or on insulin-resistant backgrounds. p21cip1 is also a cell cycle inhibitor, but its loss in mice results in no obvious β-cell phenotype. Since p21 and p27 are functional homologues, we have investigated if it is possible that loss of one is compensated by the other. Three hypotheses are feasible: 1) since p21 and p27 are required for assembly and nuclear import of cdks and D-cyclins, their loss will lead to dramatic beta cell failure, reductions in β-cell proliferation and mass, and diabetes; 2) since p21 and p27 are functional and structural homologues, and are important cell cycle inhibitors, their combined loss will lead to robust β-cell replication, increases in beta cell mass, and marked hypoglycemia; or, 3) since the G1/S checkpoint has multiple layers of redundancy and compensation, combined loss of p21 and p27 will have no important effect.
Matherial and methods: To address these hypothesis, we generated mice that are doubly deficient for p21 and p27.
Results: Mice doubly deficient for p21 and p27 prepared by two different breeding strategies and studied at 2 and 6 months of age, display no striking abnormalities in β-cell mass, islet number, fasting or postprandial glucose or insulin concentrations, intraperitoneal glucose tolerance or any other evidence of metabolic or β-cell dysfunction. Preliminary examination of beta cell proliferation also discloses no abnormalities.
Conclusion: Together, these findings suggest that combined p21 and p27 loss do not have striking effects on β-cell mass or function, and support hypothesis #3 above. Further, they suggest that other cell cycle inhibitors may compensate for this loss. This possibility is currently under investigation.

Selective removal of undifferentiated embryonic stem cells during differentiation towards insulin-producing cells

J.M. Gorska, S. Lenzen, O. Naujok;
Institute of Clinical Biochemistry, Hannover Medical School, Germany.

Background and aims: Embryonic stem cells (ESCs) are attractive candidates for generation of surrogate insulin-producing cells for cell replacement therapy in type 1 diabetes. However, the major limitation to their approval for clinical use is the risk of uncontrolled proliferation and teratoma formation after transplantation. This form of cellular misbehaviour constitutes a health risk and may contribute to functional failure of the graft. Therefore, a selection process must be developed for removal of residual ESCs from differentiation cultures and for tumour prevention. To tackle this problem we combined an efficient protocol for differentiation of insulin-producing cells with negative selection of undifferentiated cells. Our aim was to establish an embryonic stem cell line expressing a suicide gene HSV-1 thymidine kinase (HSVtk) that renders cells sensitive to the prodrug Ganciclovir (GCV). HSVtk cloned under the promoter of the human *Pou5f1* gene (Oct4), the master regulator of stem cell pluripotency, allows specific elimination of embryonic cells and leaves differentiated populations insensitive to GCV treatment.
Materials and methods: Mouse ES-D3 cells were transfected with an expression vector carrying the HSVtk gene and eGFP under the control of the Oct4 promoter. The clonal cell line eHSVtk was subjected to a new 4-stage differentiation protocol into insulin-producing cells, comprising 7 or 14 days of 1 μM GCV incubation. GCV-treated and untreated cells were analyzed by RT-PCR, flow cytometry, Western blot and immunocytochemistry.
Results: ES cells were successfully transfected with the pOct4-HSVtk-eGFP construct. The clonal cell line eHSVtk remained similar to wild type cells in terms of morphology, ESC marker expression (SSEA-1, alkaline phosphatase, Oct4, Nanog) as well as the potential to follow the differentiation protocol into insulin-producing cells. 19 days of differentiation, including 7 days of 1 μM GCV incubation, showed a very quick loss of eGFP fluorescence and only negligible populations of SSEA-1-positive cells. In contrast, untreated cultures were composed of up to 40 % of eGFP- and SSEA-1-positive cells. Selective ablation of ESCs after GCV treatment was also documented by reduction in expression of many important stem cell markers: alkaline phosphatase, Oct4, Nanog, ERas, Sox2, Rex1, Dax1, Klf4 and Nac1, both on the mRNA and protein level. After an additional 7 days of 1 μM GCV incubation, the percentage of eGFP- and SSEA-1-positive cells further decreased from 1.8 % to less than 0.3 %. Also, a further significant drop in the expression of other embryonic markers was observed. Immunocytochemical staining of Oct4, Nanog, and ERas revealed barely detectable levels, unlike that of untreated cells with a typical embryonic pattern of staining. Finally, cells supplemented with GCV showed higher insulin content than those cultured without GCV.
Conclusion: The results indicate that the suicide gene HSVtk driven by the stem cell-specific Oct4 promoter can be used to specifically target undifferentiated stem cells with teratogenic potential and effectively remove them from the differentiation culture. This technique, together with a new protocol for differentiation of ES cells into insulin-producing cells, provides the basis for a future application of differentiated stem cells in diabetes treatment.

PS 24 Islet and pancreas transplantation

Improved metabolic control and quality of life in 10 patients with type 1 diabetes following islet after kidney transplantation: results of the GRAGIL 1 trial

A. Wojtusciszyn[1], C. Brault[2], L. Guittard-Millat[2], N. Niklauss[3], L. Badet[4], S. Demuylder[3], A. Penfornis[5], C. Thivolet[6], C. Colin[2], E. Renard[1], L. Frimat[7], F. Bayle[8], L. Kessler[9], T. Berney[10], P. Benhamou[11];
[1]Endocrinology department, Lapeyronie hospital, Montpellier, France, [2]Pôle Information Médicale Evaluation Recherche clinique de Lyon, France, [3]Centre médical universitaire, Laboratoire d'isolement et de transplantation cellulaire, Geneva, Switzerland, [4]Surgery department, CHRU Edouard Hériot, Lyon, France, [5]Endocrinology department, CHRU, Besançon, France, [6]Endocrinology department, CHRU Edouard Hériot, Lyon, France, [7]Nephrology department, CHRU, Nancy, France, [8]Nephrology department, CHRU, Grenoble, France, [9]Endocrinology department, CHRU, Strasbourg, France, [10]Surgery department, laboratoire d'isolement et de therapie cellulaire, Geneva, Switzerland, [11]Endocrinology department, CHU, Grenoble, France

Background and aims: Islet transplantation with Edmonton protocol has proven its efficiency in non-uremic brittle diabetic patients. We report here the results of islet grafts with this same immunosuppression protocol in type 1 diabetic patients with previous kidney transplantation within the GRAGIL group.
Patients and methods: Sixteen intra-portal islets infusions were performed in 10 type 1 diabetic patients with functional kidney transplant. Target islet equivalent number (IEQ) was 10'000/Kg of body weight administered in two infusions if necessary. Immunosuppression was switched on the day of transplantation to regimen associating sirolimus-tacrolimus-daclizumab. Metabolic results were assessed by HbA1c, fasting glycaemia and C-peptide levels. Insulin needs and hypoglycaemic events were quantified. Quality of life was evaluated by SF36 and DQOL scores.
Results: Patients were 43 years-old (median) with median diabetes duration of 36 years. They had received a kidney graft 7 years before. At 12 months post transplantation, 9/10 patients had a functional islet graft (C-peptide level> 0.5 ng/ml). HbA1c significantly decreased from 7.1%[6.4-7.8] to 6.5%[6.4-6.7] at 6 months and to 6.6%[5.8-6.8] at 12 months ($p<0.05$). Four patients were insulin independent at 6 months but only one at 12 months. However, insulin needs decreased, with a significant decrease of hypoglycaemic events, from 30IU/day to 8IU/day ($p<0.01$) and 9/10 patients needed less than 30% of their previous insulin dose. Global quality of life scores did not reach significant improvement but physical activity and health perception scores were significantly better at 12 months post transplantation. Adverse events included one minor peritoneal effusion, mouth ulceration (n=1) and diarrhea (n=2) with a need for switching sirolimus to mycophenolate mofetil in one patient.
Conclusion: Islet after kidney transplantation can restore good glycaemic control with a reduced occurrence of hypoglycaemia thanks to very low dose of insulin. Impact of this control on kidney transplant function needs further evaluation.

Islet cell aggregates are superior to islets for transplantation in microcapsules

E.S. O'Sullivan[1], A.S. Johnson[2], A. Omer[1], J. Hollister-Lock[1], S. Bonner-Weir[1], C.K. Colton[2], G.C. Weir[1];
[1]Islet Transplantation and Cell Biology, Joslin Diabetes Center, Boston, [2]Chemical Engineering, Massachusetts Institute of Technology, Cambridge, United States.

Background and aims: Small islet-cell aggregates were studied to determine if their survival and function were superior to intact islets within microcapsules during low oxygen culture and transplantation.
Materials and methods: Islet-cell aggregates were generated by dispersing rat islets into single cells and allowing them to reaggregate in culture. Islets and islet-cell aggregates were encapsulated in barium alginate capsules and cultured in low (0.5% or 2%) or normal (20%) oxygen, or transplanted. Following culture, tissue was assessed with measurements of oxygen consumption rate (OCR), nuclei counts, insulin to DNA content ratio, glucose-stimulated insulin secretion (GSIS), and gene expression. Syngeneic transplantation experiments were carried out to assess tissue survival in the transplantation setting without an immune response, and xenogeneic transplants were performed to assess whether islet-cell aggregates were superior in their ability to reverse diabetes in streptozocin diabetic mice.
Results: After low oxygen culture islet-cell aggregates were able to survive and function better than intact islets in terms of OCR, nuclei counts, insulin to DNA ratio, and GSIS. Culture in low oxygen (2%) resulted in maintenance of pre-culture levels of viable tissue (determined by OCR) in aggregates, but for whole islets only 61% of pre-culture viable tissue remained, $p < 0.01$. In terms of nuclei counts there was a substantial loss of tissue in the islets cultured at 0.5% oxygen when compared to pre-culture values (59%; $p < 0.05$) but only modest loss of tissue in the aggregate capsules (87% of pre-culture values, $p < 0.05$). The ratio of insulin to DNA content (an index of beta cell viability) decreased markedly in islets cultured in 0.5% oxygen for 2 days, in contrast to no decline in aggregates. After 2 days of culture in 2% oxygen there was no difference in insulin output between low and high glucose with islets, whereas islet cell aggregates showed differential increased secretion to high glucose. Pro-inflammatory genes MCP-1 and tissue factor were expressed at significantly lower levels in islet cell aggregates than in whole islets ($36 \pm 9\%$ and $59\% \pm 11\%$, $p < 0.01$ and 0.05, respectively) after overnight culture in 2% oxygen. Two weeks after encapsulated islets and aggregates were transplanted into syngeneic (Lewis rat) recipients, large areas of central necrosis were apparent in many of the islets and were especially prominent in the larger islets. In contrast, encapsulated aggregates remained healthy in appearance. Encapsulated aggregates cured a greater proportion of diabetic xenogeneic transplant recipients (83%) compared to encapsulated islets (30%) ($p < 0.03$ Fisher exact test, and the overall average blood glucose concentration was substantially lower with encapsulated aggregates. IPGTTs performed on the cured transplant recipients showed aggregates were as responsive as islets to a glucose load in terms of insulin secretion and similar to the normoglycemic controls.
Conclusion: The use of islet-cell aggregates with a smaller diameter than an intact islet reduces oxygen transport limitations to encapsulated tissue. These aggregates were superior to intact islets in terms of survival and function in low oxygen culture and under transplantation conditions.

Effect of hypoxia-inducible timely VEGF gene overexpression in islet transplantation

S.-H. Ihm[1], C.-S. Kim[1], M.-G. Choi[1], H.-J. Yoo[1], B.-W. Lee[2], M. Lee[3], J. Ihm[4];
[1]Internal Medicine, Hallym University, Anyang, [2]Internal Medicine, Yonsei University, Seoul, [3]Bioengineering, Hanyang University, Seoul, [4]Biochemistry, Kyonggi University, Suwon, Republic of Korea.

Background and aims: Hypoxic damage is one of the major causes of early islet graft failure. Vascular endothelial growth factor (VEGF) is known to induce a pleiotropic response in favor of angiogenesis and has been investigated as a therapeutic gene for revascularization of islets. In particular, timely and localized overexpression of VEGF in hypoxic cells is desirable, since unregulated VEGF expression in normal cells may induce overgrowth of endothelial cells. In this study, we determined the effect of hypoxia-inducible VEGF gene transfer on the function and revascularization of transplanted islets using a syngeneic mouse model.
Materials and methods: Mouse islets were transfected with hypoxia-inducible gene expression vector, pRTP801-hVEGF or control vector, pSV40-hVEGF using a non-viral carrier, Effectene. After transfection, the islets were incubated at the desired concentration of oxygen (normoxia, 20% oxygen; hypoxia, 1% oxygen) for 20 hrs, and then hVEGF expression was assessed by ELISA. One hundred mouse islets transfected with pRTP801-hVEGF or pSV40-hVEGF were transplanted under the left renal capsule of syngeneic STZ-induced diabetic recipients. At 7-weeks posttransplant, IPGTT and left nephrectomy were performed.
Results: The hVEGF level was significantly induced in the islets transfected with pRTP801-hVEGF and left under hypoxia condition. However, this effect was not observed in the islets transfected with pSV40-hVEGF, suggesting that the RTP801 promoter increased VEGF expression specifically in islets under hypoxia. When 100 mouse islets were transplanted into renal subcapsular space of STZ-induced diabetic syngeneic mouse, AUC in IPGTT at 7-weeks after transplantation was significantly lower in recipients of pRTP801-

hVEGF transfected islets than in recipients of pSV40-hVEGF transfected islets (Fig.).
Conclusion: Theses results indicate that the delivery of pRTP801-VEGF using Effectene induces VEGF level specifically under hypoxia and further enhances islet engraftment and preserves islet function in transplants compared with the pSV40-VEGF delivery. Our results suggest that the construction of plasmids with cytoprotective target genes and the RTP801 promotor combined with nonviral delivery with Effectene may be a useful strategy for ex vivo gene therapy in clinical islet transplantation.

Influence of donor age on islet isolation and transplantation outcome
N. Niclauss[1], D. Bosco[1], P. Morel[1], S. Demuylder-Mischler[1], C. Brault[2], P.-Y. Benhamou[3], T. Berney[1];
[1]Department of Surgery, Hospitals and University of Geneva, Switzerland, [2]Department of Medical Information, Hospices Civiles, Lyon, France, [3]Department of Nephrology and Endocrinology, University Hospital Center, Grenoble, France.

Background: It has been suggested that the age of human organ donors might influence islet isolation and transplantation outcome in a negative way due to a decrease of in vivo function in islets isolated from older donors.
Methods: We retrospectively analyzed 332 islet isolations performed in our facilities and divided them into two groups depending on donor age (n=187 and n=145 for below and above 50 years, respectively). Pancreata were procured and processed according to established protocols. Isolation outcome was determined by islet yield, success rate (>250'000 IEQ) and transplantation rate. Beta cell function was assessed in vitro by stimulation indices in static incubation assays. Transplanted patients were divided into two groups depending on donor age of islet preparations (n=49 and n= 31 patients that received just islets from 50 year-old donors, respectively). In vivo function was assessed by the newly developed secretory units of islets in transplantation (SUIT) index and the C-peptide/glucose ratio 1 month after transplantation.
Results: There was no difference in islet yields between the two groups (249'200 ± 11'400 and 245,900 ± 9'800 IEQ for 50 year-old donors, respectively). Success rates were 45% for both groups, respectively. Overall, 85 (45%) islet preparations were transplanted from <50 year-old donors and 56 (39%) islet preparations were transplanted from >50 year-old donors. Stimulation indices were similar for both groups. SUIT indices and C-peptide/glucose ratios one month after transplantation were significantly higher in patients that received islets only from the younger donor population (41 ± 4 vs. 26 ± 4, p=0.008 and 1.38 ± 0.12 vs. 0.87 ± 0.1, p=0.003, respectively).
Conclusion: Our study shows that, in our donor population, donor age does not influence islet isolation outcome, in contrast to islet graft function.

Transendoscopic islet transplantation to gastric submucosa (eGSM-ITx) of pigs with streptozotocine induced diabetes - preliminary results
M. Wszola[1], A. Berman[1], M. Fabisiak[2], M. Zmudzka[2], P. Domagala[1], R. Kieszek[1], A. Perkowska-Ptasinska[3], M. Sabat[4], K. Pawelec[1], L. Kownacki[5], K. Ostrowski[1], O. Rowinski[5], L. Paczek[4], A. Kwiatkowski[1], A. Chmura[1];
[1]Department of General and Transplantation Surgery, Warsaw Medical University, [2]Veterinary Medicine, Warsaw University of Life Sciences, [3]Nephrology, Warsaw Medical University, [4]Immunology, Warsaw Medical University, [5]Radiology, Warsaw Medical University, Poland.

Islets and pancreas transplantation have become standard treatments of patients with diabetic complications.However pancreas transplantation is associated with high incidence of complications and the long-term results of islet transplantation are still unsatisfactory.Loss of pancreatic islets grafts is not only caused by immunological reactions but also due to the site of grafting and IBMIR.Gastric submucosal space might be an alternative site for transplantation.
The aim of this study was to assess the possibility of endoscopic islets transplantation into the gastric submucosa-its efficacy and complications.
Materials and methods: 20Landrace pigs weighing 19-24kg were obtained for the study.7 animals were controls(C-group)and 13 were Transplantation group(TX group).In both groups diabetes was induced by streptozotocine (stz)infusion at 200 mg/kg.At 7 days post stz infusion pigs of both groups underwent endoscopy-in group-C to assess the feasibility of gastroscopic examination under general anesthesia in pigs with diabetes and to study the influence of basiliximab infusion on pigs,in Tx-group to perform eGSM-ITx. Immunosuppression consisted of tacrolimus 0,2 mg/kg and sirolimus 6mg/m^2.At 7 days post transplantation, control gastroscopy was performed to assess the gastric mucosa and to take biopsies for histopathology.10 to30 days after eGSM-ITx Magnetic Resonance(MRI)examination was performed and pigs were euthanized.Stomach and pancreas were obtained at autopsy for histopathology.C-peptide level was assessed prior to diabetes induction, at 7 days post induction and 3,10,30days post eGSM-ITx.Glycemia was assessed twice daily during the experiment.For 10 days after diabetes induction(up to three days after eGSM-ITx)in both groups,insulin was given to reach glyc-

emia between 150-200mg/dl,after that period insulin was given only when glycemia exceeded 600 mg/dl.
Results: There were no differences in insulin requirement and glycemia up to the day of eGSM-ITx between the groups.Tx-group animals received a mean of 6000±3170 IEQ/kg.Tx-group animals had a significantly lower insulin requirement and significantly lower mean glycemia since the first day post transplantation.This trend was observed till the end of study at 1 month. Beginning at day 4 post eGSM-ITx pigs from the ITx-group did not receive insulin-in 7 cases(63 %)mean glycemia remained below 250 mg/dl;in 4 cases it did not exceed 450 mg/dl.C-group animals all required insulin once daily to keep glycemia below 600 mg/dl. There were no signs of perforation,ulceration or bleeding after the eGSM-ITx on gastroscopy and histopathological examination.In MRI scans unspecific thickening of gastric wall was observed at sites of islet deposition.
Conclusion: Transendoscopic islets transplantation into gastric submucosa is feasible and a safe procedure in an experimental animal setting. Its potential for clinical application in human subjects needs further studies.

Type 1 diabetic patients after successful pancreas kidney transplantation exhibit normal fasting and postprandial liver glycogen content despite systemic insulin secretion
M. Stadler[1,2], C. Anderwald[3], C. Göbl[3], M. Krssak[4], Y. Winhofer[3], G. Pacini[5], M. Bischof[3], M. Haidinger[3], M. Saemann[3], F. Mühlbacher[6], A. Luger[3], R. Prager[1,2], M. Krebs[3];
[1]3rd Medical Department of Metabolic Diseases and Nephrology, Hietzing Hospital Vienna, Austria, [2]Metabolic Diseases and Nephrology, Karl Landsteiner Institute, Vienna, Austria, [3]Internal Medicine III, Medical University Vienna, Austria, [4]Department of Radiology, Medical University Vienna, Austria, [5]Metabolic Unit, ISIB-CNR, Padova, Italy, [6]Deparment of Surgery, Medical University Vienna, Austria.

Background and aims: Insulin replacement in Type 1 diabetes mellitus (T1DM) is usually performed via a systemic (subcutaneous) instead of the physiologic portal route. So far it is unclear whether this systemic route of insulin delivery might contribute to metabolic defects in these patients. This hypothesis is supported by the finding that T1DM with poor glycemic control exhibit reduced hepatic glycogen stores. Successful pancreas kidney transplantation (PKT) with systemic venous drainage is an ideal model of optimized systemic insulin therapy. Therefore, the aim of the present study was to investigate the effects of PKT on fasting and postprandial liver glycogen content.
Materials and methods: Using ^{13}C-nuclear magnetic resonance spectroscopy (^{13}C-NMR), liver glycogen concentrations were assessed in 6 T1DM patients after successful PKT (26±2kg/m², 49±3yrs, 2f/4m, fasting glucose 86±4mg/dl, HbA1c 5.2±0.2%) with systemic venous drainage and in 4 matching nondiabetic controls (CON) (25±2 kg/m², 52±3yrs, 2f/2m, 86±3 mg/dl, 5.5±0.2%) at fasting and after two standardized mixed meals. Fasting insulin sensitivity was assessed using the QUICKI-Index.
Results: Liver glycogen concentrations at fasting (PKT:185±15, CON:191±15mM), after breakfast (PKT:207±10, CON:205±14mM) and after lunch (PKT:233±17 vs. CON:233±11mM) were comparable in PKT and CON. Mean and fasting concentrations of glucose, insulin, C-peptide and glucagon and QUICKI were similar in PKT vs. CON.
Conclusion:Despite systemic insulin secretion, T1DM after successful PKT exhibit unchanged fasting and postprandial liver glycogen stores in comparison with age-and BMI-matched non-diabetic controls. Thus, this study indicates that systemic insulin substitution does not cause alterations of hepatic glycogen storage.

Immunosuppressive drugs inhibit rat islet cell proliferation *in vitro*
G. Parnaud, D. Bosco, T. Berney;
Cell Isolation and Transplantation Center, Department of Surgery, Geneva University Hospital and University of Geneva, Switzerland.

Background and aims: Beta-cell replication is thought to play a significant role in maintaining pancreatic beta-cell mass. Whether immunosuppressive drugs affect replication of beta-cells in transplanted islets is not fully understood. The aim of this study was to determine the effects of immunosuppressive drugs, used in islet transplant recipients, on islet cell replication, *in vitro*.
Materials and methods: Rat pancreatic islet cells were incubated with BrdU (10μM) in the presence or absence of different concentrations of cyclosporine A (CsA), tacrolimus, sirolimus or mycophenolate mofetil (MMF). Cell replication was determined by BrdU incorporation after 1 to 7 days of culture. Data are expressed as % of positive BrdU cells and as mean ± SEM for 3 or more independent experiments.
Results: Sirolimus (10 ng/ml) blocked almost completely islet cell proliferation from 24h (0.17±0.17 vs. 2.00±0.51; sirolimus vs. control, $p<0.001$) until 7 days of treatment (0.14±0.10 vs. 23.80±3.63; sirolimus vs. control, $p<0.01$). Additionally, the inhibitory effect of sirolimus was also observed at low concentrations from 0.1 ng/ml (2.75±0.97 vs. 13.43±0.76; sirolimus vs. control, $p<0.001$). After 2 days of treatment, MMF also inhibited cell proliferation in a dose-dependent manner (control: 12.08±1.53; MMF 1μg/ml: 5.74±0.80; MMF 5μg/ml: 1.83±0.30; MMF 25μg/ml: 1.33±0.35%). Treatment with CsA (200 ng/ml) and tacrolimus (10 ng/ml) during 5 days significantly reduced islet cell proliferation (2.52±0.94; 3.68±1.06; 21.13±2.47 for CsA, tacrolimus and control, respectively ($p<0.01$)). None of the immunosuppressive drugs induced a significant increase of apoptosis. Furthermore, effect of immunosuppressive drugs on cell proliferation was reversible.
Conclusion: Our results indicate that immunosuppressive drugs, at therapeutic target concentrations, inhibit pancreatic islet cell proliferation *in vitro*. It is therefore suggested that progressive graft islet dysfunction may result, in part, from an impairment of beta cell replication induced by immunosuppressive drugs.

Simultaneous pancreas kidney transplant (SPK) improves cardiovascular risk factors in type 1 diabetes mellitus
M.M. Teh[1], S. Paramanathan[1], S. Cohen[2], S. Thomas[1], P. Carroll[1], J. Powrie[1], J. Taylor[2], J. Karalliedde[1];
[1]Department of Diabetes and Endocrinology, Guy's and St Thomas' Hospital, [2]Renal and Transplantation, Guy's and St Thomas' Hospital, London, United Kingdom.

Background and aims: SPK is the treatment of choice in patients with type 1 diabetes and stage 4 and 5 chronic kidney disease (CKD). Long term haemodynamic and biochemical outcomes following SPK in a UK population are not well defined. The aim is to evaluate metabolic and biochemical variables in patients with type 1 diabetes following SPK in a tertiary renal centre.
Materials and methods: A retrospective analyses of successful SPK transplant patients over the last 12 years. Successful SPK was defined as insulin and dialysis independence at most recent clinic visit. Clinical and biochemical measures were obtained from patient records prior to SPK (V1) and at the most recent clinic visit (V2).
Results: 47 patients (32 M, 15F) were included with a follow up of 4.2 (1.2-11) yrs (median & range). The age at the time of SPK was 41±7 yrs (mean±SD) and the duration of diabetes was 26.5±8.5 yrs. V1 to V2, systolic blood pressure fell from 139±18 to 127±16mmHg and diastolic blood pressure from 78±12 to 72±10mmHg, HbA1c (n=22) improved from 8.3±1.6 % to 5.6±0.6% and serum creatinine fell from 695±285 to 113± 25μmol/l ($p<0.01$ for all variables). There was a reduction in the number of anti-hypertensive and lipid lowering agents at V2 ($p<0.05$).
Conclusion: Successful SPK not only removes need for insulin and dialysis but also improves cardiovascular risk factors.

PS 25 Immunoprevention in type 1 diabetes

GAD_{65} treatment induces high GADA but no changes in epitopes or adverse signs/symptoms in type 1 diabetic children

J. Ludvigsson[1], C. Skoglund[1], M. Cheramy[1], R. Casas[1], C. Hampe[2];
[1]Department of Clinical and Experimental Medicine, Linköping University, Sweden, [2]Department of Medicine, Seattle, United States.

Background and aims: GAD_{65} treatment (Diamyd) has been shown to preserve residual insulin secretion in children and adolescents with recent onset Type 1 diabetes (T1D), and to cause an increase of GAD auto-antibodies (GADA). High GADA may be associated with risks for neurological adverse events and we have therefore performed a clinical follow-up of patients 4 years after GAD_{65}-treatment, as well as studied GADA and its binding in more detail.
Methods: 70 T1D patients (10-18 years old) with diagnosis within the previous 18 months, were included in a double-blind, randomised, controlled trial receiving a primary injection on day 1 of 20 µg recombinant human GAD_{65}-alum (Diamyd) (n=35) or placebo (n=35) and a booster dose after 4 weeks. Blood samples were collected before the first injection and after 1, 3, 9, 15, 21, and 30 months. The serum levels and the epitope binding pattern of GADA were analysed. A 48 months follow-up is on-going.
Results: There were no clinical adverse events after 30 months, and none is seen so far in the 48 month follow-up. Patients receiving GAD_{65}-alum or placebo had similar levels of GADA at baseline, but GADA were higher in GAD_{65}-alum treated patients after 3 months ($p=0.001$), and remained so still after 30 months ($p<0.05$). There were no differences in the binding pattern of GADA to a number of selected epitopes of GAD. High GADA, seen in both groups, were not related to any signs of neurological or other clinical adverse events. To further clarify the effect of treatment in the induced GADA, analyses of enzymatic inhibition, anti-idiotypic antibodies and subclasses of GADA are ongoing.
Conclusion: The effect of GAD_{65}- treatment on the humoral response was antigen specific and induced a long lasting specific B cell memory, without inducing epitope spreading or adverse clinical events, seen so far after 48 months follow-up.

Effect of combined oral protease and flavonol treatment in persons at risk for type 1 diabetes

N.C. Schloot[1], K. Kempf[1], G. Manzo[1], P. Hanifi-Moghaddam[1], S. Kappler[1], J. Seissler[2], C. Jaeger[3], B. Boehm[4], M. Roden[1], H. Kolb[1], S. Martin[5];
[1]Heinrich-Heine University, Institute for Clinical Diabetology, Düsseldorf, [2]Medical Clinic Innenstadt, Munich, [3]Third Medical Department, Giessen, [4]Ulm University, Division of Endocrinology and Diabetes, Graduate School Molecular Endocrinology and Diabetes, [5]Sana Clinics Düsseldorf GmbH, West-German Centre of Diabetes and Health, Germany.

Background and aims: Past regimens for preventing diabetes have failed in individuals with family history of type 1 diabetes (T1D). We examined in a pilot study, whether combined treatment with proteases and flavonols decreases the incidence of diabetes and affects immune and inflammatory markers.
Materials and methods: This randomised, prospective, multicenter, placebo-controlled, double-blind study included 21 islet antibody positive first-degree relatives of patients with T1D, with one participant dropping out before start of medication. Eleven subjects (age: 12.0±8.0 years) received daily oral treatment with 48mg trypsin, 90mg bromelain and 100mg rutoside, nine subjects (10.2±3.7 years) received placebo for at least 24 months. Serum cytokines and chemokines were measured at 0, 1, 3, 6 and 12 months and diabetes incidence was monitored for 8 years.
Results: During a total of 8 years follow up, 6 of 9 (67%) subjects on placebo and 4 of 11 (36%) on proteases/flavonol developed diabetes (Hazard ratio 2.1 [0.6-7.9]). Serum concentrations of cytokines (IFN-g, IL-10, IL-13, MIF) and chemokines (IL-8, MIP-1ß [CCL4], MCP-1 [CCL2]) were unchanged during 12 months in both groups. Immune mediators measured at study entry were not predictive of later development of T1D. No side effects were reported upon proteases/ flavonol treatment.
Conclusion: Proteases/flavonol treatment was found to be safe and well tolerated but did not significantly decrease diabetes incidence in this small group of subjects at increased risk for T1D. Circulating cytokines were neither related to treatment nor to later manifestation of T1D. Large clinical trials are needed to recognise smaller size effects of the protease/flavonol mixture on the progression towards T1D.

Evaluation of different regimens of a chimeric/humanized aglycosylated anti-CD3 monoclonal antibody (MAb), otelixizumab, in subjects with type 1 diabetes mellitus

M. Rosenzweig, D. Mehta, D. Forman, C. McKee, L. Vaickus;
Tolerx, Cambridge, United States.

Background and aims: Otelixizumab is an Fc-disabled IgG1 MAb directed against the mature T cell antigen CD3ε. Otelixizumab is being developed for the treatment of autoimmune disorders, including type 1 diabetes mellitus (T1DM). Phase 1b/2 open-label dose-escalation studies were conducted to identify a regimen that minimized pro-inflammatory cytokine (PIC) release, immunogenicity, and perturbation of Epstein Barr Virus (EBV) immunity (PEI), yet preserved clinical activity and pharmacokinetic (PK) and pharmacodynamic (PD) parameters. A prior Phase 2 study and studies in the NOD mouse model guided dose optimization.
Materials and methods: Over 100 T1DM adult subjects were enrolled in 3-, 4-, and 8-day dosing studies. Eleven different regimens with total doses ranging from 0.3 mg to 6.85 mg otelixizumab were assessed. Serum concentrations of cytokines, otelixizumab, and anti-otelixizumab antibodies were measured along with standard safety parameters. PD parameters were monitored using flow cytometry; EBV viral load was measured by a validated, quantitative PCR method.
Results: A cumulative dose of 3.1 mg otelixizumab administered over 8 days was identified for use in a Phase 3 clinical trial in new onset T1DM adult subjects (DEFEND-1). This regimen utilizes increasing doses on the first 3 days, followed by 5 subsequent doses that are higher but without significant PIC release (suggesting that at least partial conditioning is achieved in the first 3 days). This regimen resulted in no lymphocyte depletion or other cytopenias, no electrolyte abnormalities, no clinically significant changes in liver function tests, no rash or unexpected AEs, no SAEs, and no significant immunogenicity or PEI. CD3/TCR modulation during the last 5 days of dosing ranged from between 25% to 40% prior to dosing and 70% to 80% just after dosing. This was accompanied by 30% to 40% saturation prior to dosing and 90% saturation just after dosing. The pattern of CD3/TCR modulation mirrored results seen with efficacious dose regimens in the NOD mice. In the peripheral blood of T1DM subjects, increases in CD4+CD25+FOXP3+ T regulatory cells were observed. Lastly, preliminary results show that new onset T1DM subjects, beta cell function appeared to be comparable to that previously published with higher doses of otelixizumab (Belgian Diabetes Registry Study). Higher cumulative doses resulted in similar but more pronounced PK/PD changes and modest dose-dependent increases in immunogenicity and PIC release.
Conclusion: An optimized 8-day otelixizumab regimen was identified that resulted in targeted PK/PD changes, had no significant safety issues, and was relatively well tolerated. These data provided the support for choosing this dose regimen for evaluation in an ongoing Phase 3 clinical trial (DEFEND-1).

C-Peptide response and HLA genotypes in subjects with recent onset type 1 diabetes following immunotherapy with diapep277

R. Buzzetti[1], S. Cernea[2], A. Petrone[1], M. Spoletini[1], S. Zampetti[1], C. Guglielmi[2], C. Venditti[1], P. Pozzilli[2];
[1]Clinical Sciences Department, Sapienza, University of Rome, [2]Endocrinology, Campus Bio-Medico, Rome, Italy.

Background and aims: In immunotherapy trials of type 1 diabetes (T1D) response to treatment has not been analysed according to different HLA genotypes (high, moderate or low risk genotypes) due to the low number of enrolled subjects.
Materials and methods: This analysis was carried out in 120 consecutive T1D subjects enrolled in double blind trials with DiaPep277. Age of patients ranged from 4 to 59 years (mean age 19.9 yrs. ± 10.8). Fasting C-peptide, glucagon-stimulated peak C-peptide (Max Cpep) and area under the curve

(AUC Cpep) were evaluated at study initiation (Baseline) and after 12 months therapy. The variances of fasting C-peptide, Max Cpep and AUC Cpep were analyzed using the general linear model repeated-measures procedure. This provided the analysis of groups of related variables representing different measurements of the same attribute (within-subjects factor). The model includes between-subjects factors that divides the population into groups according to their HLA risk groups genotype and treatment (DiaPep277 treatment vs. placebo).
Results: Fasting C-peptide, Max Cpep and AUC Cpep values in T1D subjects with low risk HLA genotypes were significantly higher than those in subjects with high/moderate risk HLA genotypes from baseline through 12 month follow up (p=0.001, p=0.02, p=0.04, respectively). These findings were independent of age at onset. Nonetheless changes in fasting C-peptide, Max Cpep and AUC Cpep over the observational period did not differ significantly between subjects with low or high /moderate risk HLA risk genotypes (for all comparisons). No interactions were observed between HLA genotypes and type of treatment (Diapep277 vs. placebo) on Cpep Max Cpep and AUC Cpep changes from baseline through 12 month follow up.
Conclusion: T1D subjects with low risk HLA genotypes maintain higher C-peptide secretion irrespective of type of therapy (Diapep277 vs. placebo), however a different outcome might result from an analysis separating pediatric vs. adult patients.

Treatment with alum-formulated GAD65 in type 1 diabetic children results in early induction of Th2 responses
S. Axelsson, M. Hjorth, L. Åkerman, J. Ludvigsson, R. Casas;
Clinical and Experimental Medicine, Linköping University, Sweden.

Background and aims: Animal studies have shown that treatment with GAD65 can prevent destruction of the β-cells, by induction of immunological tolerance and shifting the normal Th1/Th2 balance toward a Th2 response. In a phase II study, injection of alum-formulated GAD65 (GAD-alum) to children with T1D resulted in the preservation of β-cell function. Here we studied the immunomodulatory effect of the treatment on the early GAD65-induced cytokine and chemokine response.
Materials and methods: Peripheral blood mononuclear cells (PBMC) from patients (n=70) included in the study, collected at day 0 and after 1, 3 and 9 months, were stimulated *in vitro* with antigens (e.g. GAD65, IA-2 peptide, insulin peptide, PHA) for 72 hours. Secretion of cytokines and chemokines was analyzed in cell supernatants and serum samples using Luminex. Expression of transcription factor FOXP3 was analyzed with real-time RT-PCR.
Results: Treatment with GAD-alum expanded a GAD65-specific T-cell population in the periphery that secreted the Th2 associated cytokines IL-5 ($p<0.05$) and IL-13 ($p<0.01$), and expressed FOXP3 ($p<0.05$) one month after injection. The recall response was characterized by a broader range of cytokines and chemokines in samples collected 3 and 9 months later. Remarkably, IL-5 and IL-13 were the only GAD65-induced cytokines that increased over time in the treated group ($p<0.001$). Similar secretion of all cytokines and chemokines was seen in the two groups after stimulation with placebo, IA-2 peptide, insulin peptide and PHA. No difference was detected in serum samples between the two groups.
Conclusion: Immunotherapy with GAD-alum in humans with T1D induces an early Th2-type specific immune response.

GAD-alum treatment induces GAD-specific FOXP3$^+$ cells in type 1 diabetic children
M. Hjorth, S. Axelsson, J. Ludvigsson, R. Casas;
Clinical and Experimental Medicine, Linköping University, Sweden.

Background and aims: We have recently shown that alum-formulated GAD_{65} contributes to preservation of residual insulin secretion in newly diagnosed type 1 diabetic children. In parallel, the treatment induced an antigen-specific T cell population with a recall response including a broad range of cytokines. Here we study the immunomodulatory effect on T cells with focus on CD4CD25^{hi} cells after GAD-alum treatment.
Materials and methods: Seventy children (age 10-18) recently diagnosed with T1D (<18 months), fasting C-peptide >0.1 nmol/L and presence of GADA were randomly assigned 20μg GAD-alum (n=35) or placebo (n=35) at two occasions, one month apart. Twelve healthy children (age 11-15) were included as reference. Peripheral blood mononuclear cells (PBMC) were stained with antibodies (CD4, CD25, CTLA-4, Neuropilin, FOXP3) for flow cytometry. At 21 months PBMC were cultured over-night with GAD_{65} and medium alone and thereafter treated as previous samples. As the receptor expression was not normally distributed, two groups were compared with Mann-Whitney U-Test and three or more groups with Kruskal-Wallis test for unpaired observations.
Results: Three months after the initial injection, GAD-alum treated children had lower percentages of CD4CD25^{hi} cells co-expressing Neuropilin and CTLA-4 ($p=0.01$) than the placebo group. Further, median intensity of CD-4CD25^{hi} cells was lower in samples from children receiving GAD-alum compared to placebo ($p<0.05$). Interestingly, at 21 months increased percentage ($p=0.04$) and intensity ($p=0.006$) of GAD_{65}-induced CD4CD25^{hi} FOXP3+ cells were detected in samples from GAD-alum treated children.
Conclusion: Treatment with GAD-alum seems to decrease the inflammatory process in parallel to an induction of GAD_{65}-specific CD4CD25^{hi} cells expressing FOXP3.

Characterisation of patients with new onset diabetes and prospective follow-up from birth to diabetes onset
M. Hummel, H. Boerschmann, E. Storz, A.G. Ziegler;
Diabetes Research Institute, Munich, Germany.

Background and aims: Type 1 diabetes (T1D) is preceded by islet autoimmunity. Aim of the study is to characterize patients who have developed T1D at onset and compare the autoimmunity status at onset to the prediabetic period.
Materials and Methods: 55 children who developed T1D between age 1 and age 16 years were investigated. Unique in this cohort was that all children were prospectively followed from birth with repeated blood sample collection. Antibodies to insulin (IAA), GAD, and IA2, were measured in all available samples until diabetes onset.
Results: At diabetes onset, 56% of cases were positive for 3 islet autoantibodies (ab), 33% of cases were positive for 2 islet abs, 11% were positive for 1 islet ab, and no cases were autoantibody negative. At diabetes onset, IAA was present in 91% of the cases, GADA in 73%, and IA-2A in 71% of the cases. 9 of the 18 children with 2 antibodies at onset had all three antibodies during the prediabetic period. 1 of the 6 children with 1 antibody at onset had 2 antibodies and none had 3 antibodies in the prediabetic period. Two offspring lost IAA before onset, 5 offspring lost GADA, and 3 offspring lost IA2A before onset, resectively. The maximum titer of IAA was found 2.7 ± 3.2 yrs prior to T1D onset (mean peak titer 69 U, mean onset titer 55 U), the maximum titer of GADA 2.4 ± 2.3 yrs (mean peak titer 191 U, mean onset titer 137 U), and the maximum titer of IA2A 2.0 ± 2.7 yrs (mean peak titer 170 U, mean onset titer 82 U) prior to T1D onset, respectively. Of the 55 cases, 22 had developed rapid progressive diabetes defined by progression from first autoantibody positivity to T1D within 2 yrs. In those cases T1D onset age ranged from 0.7 to 9.9 yrs, indicating that they were younger than slow progressors (mean onset age 3.1 ± 2.0 yrs vs. 8.9 ± 3.4 yrs, $p<0.001$).
Conclusions: Maximum expression of autoantibodies usually occurs prior to diabetes onset. A subgroup of rapid progressors differs by younger onset age and higher IAA titers from slow progressors.

Prevention of autoimmune diabetes mellitus by modulatory antibodies in the LEW.1AR1-*iddm* rat: protective effects of CD4 modulation and diabetes aggravation by CTLA-4 agonism
H. Weiss, A. Siepert, M. Lehmann, M. Tiedge;
University of Rostock, Institute of Medical Biochemistry and Molecular Biology, Germany.

Background and aims: The LEW.1AR1-*iddm* rat is an animal model of autoimmune diabetes mellitus with a strong genetic component and an incidence of 60 %. Modulation of CD4+ T cells by monoclonal antibodies (mabs) is a promising approach to induce immune tolerance. It was the aim of this study to test whether (1) the modulating anti CD4+ antibody (RIB5/2) or (2) the agonistic CTLA-4 antibody (H4) could prevent autoim-

mune diabetes and affect the cellular immune state when applied during the prediabetic period.
Materials and methods: Normoglycaemic LEW.1AR1-*iddm* rats were treated on day 40, 42, 44, 46 and 48 after birth with the mabs (5 x 5 mg/kg b.w.) RIB5/2 (n = 17) or H4 (n = 16). Blood glucose was measured biweekly and blood samples were taken on day 50, 60, 75 and 120 for flow cytometry (FACS) analysis. Animals were killed on day 120 (normoglycaemia) or after diabetes manifestation (blood glucose > 10 mmol/l). Blood samples were analyzed for immune status via FACS for the T-cell markers CD4, CD8, CTLA-4 and CD25. FACS data were expressed as % of monuclear cell population. Pancreas samples were examined for beta cell destruction and immune cell infiltration.
Results: Application of RIB5/2 mab resulted in a 40 % reduction of T helper cells within 48 h and a 91 % reduction of CD4+ fluorescence intensity on T helper cells indicating modulatory receptor internalization. RIB5/2 treatment significantly ($p<0.01$) reduced diabetes incidence from 60 % to 11 %. Diabetes manifestation was delayed from d 60 to d 68 ($p<0.05$). RIB5/2 antibody treatment significantly reduced the portion of CD4+ T-cells in blood on day 50 (16 % vs. 48 %, $p<0.001$), day 60 (normoglycaemic 29 % vs. 46 %, $p<0.001$; diabetic 30 % vs. 48 %, $p<0.05$) and day 75 (36 % vs. 43 %, $p<0.05$) (RIB5/2 treated cohort vs. untreated control). Blood CD8+ T-cells were increased at day 50 in RIB5/2 treated animals who eventually developed diabetes (39 % vs. 30 %, $p<0.05$). Interestingly, regulatory CD4+/CD25+ cells were significantly increased in diabetic RIB5/2 treated animals on day 50 (6.2 % vs. 1.6 %, $p<0.05$). H4 treatment slightly reduced the portion of blood CD8+ T-cells at day 50 but did not affect the portion of CD4+ T cells. The time point of diabetes manifestation was not different to that of the control cohort. At day 50 regulatory CD4+/CD25+ T-cells were significantly reduced in H4-treated animals. The portion of CTLA-4+ T-cells was significantly increased after H4 treatment at day 50 but significantly decreased after day 60 in rats developing diabetes. Treatment with the RIB5/2 or H4 mab did not affect the degree of islet infiltration in diabetic animals in comparison to untreated controls.
Conclusion: The modulatory downregulation of CD4 by the RIB5/2 mab during the critical period of islet infiltration proved to be a promising strategy to induce persisting tolerance against autoimmune diabetes. The increase of regulatory T cells could be at least in part a possible mechanism to control autoimmunity. Stimulation of the CTLA-4 feedback pathway showed aggravating effects upon beta cell autoimmunity. Thus, modulation of costimulatory pathways appears problematic as prevential strategy of tolerance induction in type 1 diabetes.

482

Specific immunomodulatory effect of GAD_{65} in type 1 diabetics
R. Casas, M. Hjorth, S. Axelsson, M. Chéramy, M. Pihl, J. Ludvigsson;
Div of Paediatrics and Diabetes Research Center, Linköping University, Sweden.

Background and aims: In animals prevention of autoimmunity with GAD_{65} induced immunological tolerance and shifting toward Th2 responses. We intended to clarify the effect of GAD_{65}-alum in the immune responses of type 1 diabetic (T1D) patients.
Materials and methods: Samples from T1D children receiving 20µg rh-GAD_{65}-alum (n=35) or placebo (n=35) and a booster after 4 weeks were collected at baseline and at 1, 3, 9, 15, 21 and 30 months. Isolated PBMC were stained for flow cytometry with anti-CD4, CD25, CTLA-4, Neuropilin and FOXP3. At 21 months cells were cultured over-night with GAD_{65} before staining. After 72 hours stimulation, cytokines IL-5, -6, -10, -12, -13, -17, TNF- α, IFN- γ were analyzed by Luminex, FOXP3 by RT-PCR and serum GADA, IA-2A, tetanus toxoid and IgE by RIA.
Results: After one month GAD_{65} induced IL-5,-13 and FOXP3 ($p<0.05$) in GAD-alum treated. At three and nine months, IL-17, TNF-α and IFN-γ ($p<0.05$) were additionally induced, and GADA titers increased ($p<0.001$). At nine months also IL-10 was higher in GAD-alum group. Reduction of C D4+$CD25^{high}$Neuropilin+CTLA-4+ cells ($p=0.01$) and lower CD4+$CD25^{high}$ MFI ($p<0.05$) detected at three months was at nine months only observed in children with shorter disease duration. At 21 months GAD_{65} induced CD4+$CD25^{high}$FOXP3+ cells ($p<0.05$) while CD4+CD25+ ($p<0.005$) were reduced. No differences in IA-2A, tetanus antibody or IgE were observed
Conclusion: GAD-alum induced long-lasting specific T and B cell memory, and a specific T cell population characterized by early Th2 and regulatory immune responses that increased over time, in parallel to reduction of the inflammatory process.

Distinct phenotype and function of natural killer cells in the pancreas of non obese diabetic mice
H. Brauner[1], M. Elemans[1], S. Lemos[1], C. Broberger[2], D. Holmberg[3], M. Flodström-Tullberg[4], K. Kärre[1], P. Höglund[1];
[1]Microbiology, Tumor and Cellbiology, Karolinska Institutet, Stockholm, [2]Neuroscience, Karolinska Institutet, Stockholm, [3]Medical Biosciences, Umeå University, [4]Medicine, Center for Infectious Medicine, Karolinska Institutet, Stockholm, Sweden.

Background and aims: Natural Killer (NK) cells are part of the early innate immune response and play an important role in fighting certain viruses, tumours and in rejection of bone marrow transplants. A role for NK cells in autoimmune disease has been suggested, but the literature is conflicting. The objective of this study was to investigate the presence, phenotype and function of NK cells in the pancreas of non obese diabetic (NOD) mice.
Materials and methods: NK cells from NOD mice pancreases were analysed by immunohistochemistry and flow cytometry. Proliferation was assessed by BrdU-incorporation. Functional responses were recorded using antibody-mediated stimulations and measurements of intracellular cytokines. Adoptive transfers were performed to investigate NK cell homing to the pancreas.
Results: NK cells infiltrated the pancreas of NOD mice at young age, had a distinct phenotype and proliferated more compared to spleen and pancreatic lymph node NK cells. NK cells could home to the pancreas in a T and B cell-independent fashion and adoptive transfer experiments showed that the spleen contained NK cells or precursors that could traffic to the pancreas, where they displayed the typical phenotype. Despite expression of activation markers, most pancreatic NK cells showed diminished IFN-γ secretion and degranulation compared to spleen NK cells after stimulation in vitro, reflecting exhaustion. However, some pancreatic NK cells produced IFN-γ spontaneously, suggesting that the pancreas contains both NK cells mediating ongoing effector responses and NK cells rendered hyporesponsive due to chronic stimulation. Pancreases from mouse strains not prone to develop diabetes also contained NK cells. Compared to NOD mouse pancreatic NK cells, they displayed less killer cell lectin-like receptor G1 (KLRG1), a marker for mature NK cells that have undergone proliferation, and a lower rate of proliferation as measured by BrdU incorporation.
Conclusion: In conclusion we show that NK cells are present in the pancreas of several mouse strains but show distinct properties in the NOD mouse. This suggests that pancreatic NK cells may be sentinel cells, which under inflammatory conditions could become activated, proliferate and contribute to the development of organ-specific autoimmune diseases such as type 1 diabetes.

Expressions of phagocyte surface receptors for apoptotic cells in the bone marrow-derived dendritic cells from non-obese diabetic mice
K. Takahashi, J. Satoh;
Department of Diabetes and Metabolism, Iwate Medical University, Morioka, Japan.

Background and aims: Dendritic cells (DC) are professional antigen presenting cells. In type 1 diabetes, DC play pivotal roles in the pathogenesis of this disease. When cells apoptose, they are engulfed by DC. Constituents of the corpse survive the intracellular processing and are recycled to the membrane of DC. The presentation of yielded antigens to T cells is a central event in the induction and the maintenance of peripheral immune tolerance. Conversely, errors in this pathway contribute to the pathogenesis of autoimmune diseases. A variety of signals distinguish apoptotic cells from those alive, and a significant number of phagocyte receptors have been shown to be involved in sensing the presence and the uptake of apoptotic cells, which include scavenger receptors (SR), Fc gamma receptors (FcgR), integerins, and C-type lectin-like receptors (Clec). To characterise molecular changes in $CD11c^{+}$ bone marrow (BM)-derived DC from non-obese diabetic (NOD) mice, we recently compared transcript profiles of BMDC with those from the sister strain, non-obese non-diabetic (NON) mice. In the present study, we analaysed our microarray data focusing on these receptors for apoptotic cells, which possibly play critical roles in triggering anti-islet autoimmunity.

Materials and methods: BM cells from 4-week-old female NOD and NON mice were cultivated in the presence of GM-CSF and IL-4 over 5 days, and of LPS for additional 2 days. The $CD11c^+$ DC were then sorted by magnetic beads-conjugated anti-CD11c antibodies (MACS, Miltenyi Biotech Inc). RNA extracted from the $CD11c^+$ DC from 3 independent mice (10 micrograms/ mouse) was pooled, and used to prepare targets for hybridization to the GeneChip Mouse Genome 430A Arrays (Affymetrix).
Results: Among the known receptors for apoptotic cells expressed on DC, CD36, MSR1/ CD204, integrin beta 5, Fcgr1, CD93/ C1qR, c-mer proto-oncogene tyrosine kinase (Mer), hepatitis A virus cellular receptor 2 / Tim-3, Clec4n/ dectin1, and Clec 4d/ dectin2 were noted to be more strongly expressed in the BMDC from NOD mice than those from NON mice (Table). On the contrary, the expressions of CD68, SRB1, integrin alpha M/ CR3, integrin alpha v, Fcgr2b, Fcgr3, low density lipoprotein receptor-related protein 1/ CD91, CD14, jumonji domain containing 6, TYRO3 protein tyrosine kinase 3, and Clec13b/ CD205 showed about equal intensity of expression between these strains.
Conclusion: In the present study, we showed that BMDC from NOD mice displayed elevated expressions of various receptors to uptake apoptotic cells compared to those from NON mice. Defects in apoptotic cell clearance reportedly contribute to the development of a lupus-like disease in the Mer-knockout mice. Contrarily in NOD mice with autoimmune-prone background, we propose that these receptors highly expressed in BMDC from NOD mice possibly lead to active uptake of self-antigens, and then to the predisposition to autoimmune diseases.

Table. Expressions of phagocyte receptors for apoptotic cells in DC

Surface receptors	NOD	NON	NOD/NON (%)
CD36	668.6	1384.1	207.0
macrophage scavenger receptor 1/ CD204	65.8	316.2	480.5
integrin beta 5	24.6	62.6	254.5
Fc receptor, IgG, high affinity I	25.2	115.0	456.3
CD93/ C1qR	78.4	192.5	245.5
c-mer proto-oncogene tyrosine kinase	45.4	154.7	340.7
hepatitis A virus cellular receptor 2 / Tim-3	29.1	68.4	235.1
C-type lectin domain family 4, member n/ dectin1	671	1552.6	231.4
C-type lectin domain family 4, member d / dectin2	154.3	365.8	237.1

485

The monocytes of type 1 diabetic patients (newly-diagnosed and long-standing) express significantly lower intensity of cell membrane HLA-DQ molecules compared to controls, while in long-standing patients very few monocytes express the surface markers CD122 (IL-2Rβ) and CD152 (CTLA-4)

[1]Endocrinology Clinic, University of Ioannina Regional Hospital, [2]Haematology Laboratory, Molecular Biology Unit, University of Ioannina Regional Hospital, [3]Department of Nursing, Epirus Institute of Technology, Ioannina, [4]Haematology Laboratory, University of Ioannina Regional Hospital, [5]Laboratory of Biochemistry and Biophysics, Epirus Institute of Technology, Arta, Greece.

Background and aims: The monocytes are the main antigen-presenting cells in the body, playing an important role in autoimmunity. We have investigated the expression of key markers on monocytes (presence and intensity) that are important hereditary factors for type 1 diabetes (HLA-DQ, CTLA-4), and important in immune function (IL-2Rβ, CD122, TGFβ, and TGFβRII), particularly the generation and maintenance of Tregs, in type 1 diabetes (t1d) patients and controls.
Materials and methods: Peripheral blood from 13 newly-diagnosed type 1 diabetes patients (mean age 12.5 +/- 9.4 years, 9M/4F), including 5 followed-up 2 years later, 26 patients with long-standing disease (mean disease duration 13.8 years, mean age 26.7 +/- 9.2 years 12M/14F) and 32 healthy controls having no first or second degree relatives suffering from autoimmune diseases (mean age 25.3 +/-11 years,13M/19F), was analyzed via flow cytometry for the above characteristics of the monocyte population.
Results: Monocytes from all three groups uniformly expressed to high intensity HLA-DR molecules, with little differences in percent or intensity. By contrast, there was a significantly lower level of expression of HLA-DQ in the monocytes of t1d patients (MFI 111.53 +/- 40.02, 100.6 +/- 50.58, 157.70 +/- 104.41), of long-term, newly-diagnosed patients, and controls, respectively ($p=0.032$ and $p=0.02$, compared to controls, respectively). Very few monocytes of patients with long-lasting diabetes expressed IL-2Rβ (1.11 +/- 2.35 % vs. 23.12 +/- 22.52 % of newly-diagnosed patients and 23.56 +/- 25.90 % of controls; $p=0.006$ and $p<0.001$, respectively), or CTLA-4 (8.89 +/- 6.49 % vs. 25.31 +/- 28.79 % of newly-diagnosed patients and 23.67 +/- 27.17 of controls; $p=0.064$ and $p=0.007$, respectively). By contrast, cell surface expression of TGFβ, and TGFβRII was found in 23.77%, 32.39% and 36.42%, as well as 59.42%, 46.42% and 52.58% of long-term, newly-diagnosed t1d patients and controls, respectively (ns). In the 5 newly-diagnosed patients followed 2-years post onset, the surface expression of IL-2Rβ was significantly decreased to 0.24 +/- 0.19% of the monocytes ($p=0.005$), while CTLA-4 expression was non-significantly decreased.
Conclusion: The decrease in HLA-DQ monocyte cell membrane density in t1d patients may be due to the specific susceptibility alleles expressed by these patients and must be pursued along this line. By contrast, the significantly lower percent of monocytes bearing IL-2Rβ or CTLA-4 in long-standing t1d patients, appears to be manifested as early as 2 years post onset, and may signify decreased ability to participate in immune-regulatory networks. The documented presence of cell membrane TGFβ and TGFβRII, may signify additional factors in these networks.

Association of adiponectin, IL-1ra, IP10 and number of islet autoantibodies with progression patterns of type 1 diabetes the first year after diagnosis

A. Kaas[1], C. Pfleger[2], P. Hougaard[3], L. Hansen[1], N.C. Schloot[4,5], B.O. Roep[6], H.B. Mortensen[1], Hvidøre Study Group on Childhood Diabetes;
[1]Department of Paediatrics, Glostrup University Hospital, Denmark, [2]Institute for Clinical Diabetology at the German Diabetes Centre, Leibniz center for Diabetes research at the Heinrich-Heine Universität Düsseldorf, Germany, [3]Statistics, University of Southern Denmark, Odense, Denmark, [4]Clinic for Internal Medicine/ Metabolic diseases, University Hospital, Düsseldorf, Germany, [5]Institute for Clinical Diabetology at the German Diabetes Centre, Leibniz center for Diabetes research at the Heinrich-Heine University Düsseldorf, Germany, [6]Department of Immunohaematology and Blood Transfusion, Leiden University Medical Center, Netherlands.

Background and aims: Progression of type 1 diabetes after diagnosis is poorly understood. Our aim was to define distinct patterns of disease progression of juvenile-onset type 1 diabetes determined by preserved β-cell function, and further to assess the relation between disease progression and systemic cytokine concentrations and number of autoantibodies, the first year after diagnosis.
Materials and methods: Juvenile patients were subjected to a meal-stimulated C-peptide-test 1, 6, and 12 months after diagnosis with type 1 diabetes. On basis of C-peptide course from 1-6 months four progression groups were defined: patients with persistently low β-cell function ("stable-low"), patients with a rapid loss in β-cell function (rapid progressers), a slow loss in β-cell function (slow progressers) and patients with increased β-cell function (remitters). Serum concentrations of adiponectin, IL-1ra and IP10 were measured at 1, 6, and 12 months. GAD, IA-2A and ICA, were measured at 1 month.
Results: Serum adiponectin concentrations measured at 1 month predict disease progression at 6 months ($p=0.04$). Patients with adiponectin within the lowest quartile had a significant higher probability of becoming remitters than rapid progressers, OR 3.1 (1.3-7.6). At 6 and 12 months adiponectin differed significant between the groups ($p=0.03$ and $p=0.006$) with highest concentrations among stable-low and rapid progressers. IL-1ra and IP10 did not differ between the groups at any time point. Yet, rapid progressers showed significant decreases of IP10 from 1-6 months ($p=0.0007$). Number of autoantibodies differed significantly between the groups at 1 month ($p=0.05$), with rapid progressers having the highest number.
Conclusion: We defined distinct progression patterns distinguishing patients progressing rapidly from those diagnosed with low β-cell function, as well as patients with slow disease from those with actually improving β-cell function, pointing to different mechanisms of disease progression. We found that adiponectin concentration at 1 month predicts and associate with particular patterns of progression at 6 and 12 months. This indicates that adiponectin could be a potential biomarker for disease progression.

487

Latent autoimmune diabetes in adults vs recent-onset type 1 diabetes: differences in autoantibody levels, clinical and metabolic parameters were independent of the age of type 1 diabetes onset

L.Z. Lukic, N.M. Lalic, A. Jotic, T. Milicic, M. Zamaklar, K. Lalic, N. Rajkovic, J.P. Seferovic-Mitrovic, M. Macesic;
Institute for Endocrinology, Belgrade, Serbia.

Background and aims: Previous studies have shown that Latent Autoimmune Diabetes in Adults (LADA) represents slowly developing form of Type 1 Diabetes (T1D), exhibiting similar as well as discrepant immunological, clinical and metabolic characteristics compared to recent-onset T1D. These similarities and differences between the two disorders were suggested to depend on the age of onset of T1D but they have not yet been clarified. Therefore the aim of this study was to compare: (a) the incidence of glutamic acid decarboxilase (GAD) and thyrosin phosphatase (IA2) autoantibody positivity, (b) clinical course and (c) insulin secretory capacity during the first year of the disease in: (A) LADA patients (group A) and (B) adult recent-onset T1D patients (group B) divided into subgroups in accordance to different age of onset (age < 20 yrs, group B1, n=22; age 20-25 yrs, group B2, n=39; age > 26 yrs, group B3, n=29).
Materials and methods: LADA was defined as diabetes without the need for insulin treatment during first 6 months after the onset of disease in patients aged > 35yrs. T1D was diagnosed in accordance to the WHO criteria. All patients were analysed in insulin requiring state. The GADA and IA2 positivity was determined by RIA. The clinical course was evaluated using the following parameters: duration of simptoms before diagnosis, frequency of ketosis, weight loss and incidence of clinical remission (CR). The CR was defined as optimal metabolic control without insulin lasting >30 days. The insulin secretion capacity was evaluated by determining C-peptide levels (RIA) before and after 1 mg i.v. glucagon stimulation (0/6 min).
Results: We found that percentages both of GADA and IA2 positive patients were lower in group A compared to all subgroups of the group B (A:3.7% vs B1:63.6; B2:59.3; B3:14.3%; p<0.001). However, the percentage of single positivity for GADA was higher in group A in comparison to all subgroups of the group B (A: 92.6% vs B1:4.5; B2:10.3; B3:65.3%, p<0.001). On the other hand, the percentage of single positivity for IA2 was lower in group A than in the B subgroups (A:3.7% vs B1:28.2; B2:27.3%, p<0.001, B3:3.6%, p=NS). Simultaneously, we detected significantly longer duration of simptoms (A:7.57±0.87 vs B1:2.73±1.67; B2 2.12±1.64; B3 2.83±197 months, p<0.01), lower frequency of ketosis (A:19.2% vs B1:61.9; B2:53.8; B3:50%, p<0.01), and smaller weight loss (A:4.03±2.18 vs B1:7.80±3.47; B2:6.34±3.26; B3: 6.73±3.64 kg, p<0.05) in group A than in all B subgroups. However, the basal and stimulated C peptide levels were significantly higher in group A than in all B subgroups (0 min A: 0.37 vs B1:0.18; B2:0.19; B3:0.20 nmol/l, p<0.01; 6 min A: 0.53 vs B1:0.2; B2:0.33; B3:0.35 nmol/l, p<0.01). In addition, the incidence of clinical remission was significantly lower in group A than in all B subgroups (A:13.8% vs B1:63.6; B2:59.0; B3:41.4%, p<0.05).
Conclusion: Our results have demonstrated that patients with LADA exhibited lower autoantibody response, together with milder clinical course and better preserved insulin secretion capacity, as well as less frequent CR in comparison to the recent-onset T1D. In additon, our results have shown that these differences were not dependent on the age of onset of T1D.

Association of immune reactivity with metabolic control in new-onset type 1 diabetes patients

C. Pfleger[1], G. Meierhoff[1,2], N.C. Schloot[1];
[1]Institute of Clinical Diabetology, German Diabetes Center, Leibniz Institute for Diabetes Research at Heinrich-Heine-University, [2]Center for Internal Medicine, Heinrich-Heine-University, Düsseldorf, Germany.

Background and aims: Previously, we reported an association of T-cell reactivity measured by ELISPOT with ß-cell function determined by stimulated C-peptide in the context of a prospective placebo controlled intervention trial in recent type 1 diabetes.
In a sub analysis, we have tested independently for additional associations of T-cell reactivity with metabolic control as determined by A1C and blood glucose.
Materials and methods: 50 adult (mean age 27.26 ±8.1 years) and 49 pediatric patients (mean age 10.9 ±2.8 years) with recent onset type 1 diabetes were included in the DiaPep277 Trial. We investigated secretion of IFN-γ (Th1), interleukin (IL)-5 and IL-13 (Th2) and IL-10 (Treg) by peripheral mononuclear cells (PBMC) upon stimulation with islet antigens peptide fragment of Islet Antigen 2 (pIA2), heat shock protein 60 (hsp60) or glutamic acid decarboxylase (GAD65) by ELISPOT according to the Peakman protocol. Cytokine responses entered regression analysis corrected for background signal as stimulation indices. Regression analysis included cytokine responses as dependent variable, A1c and blood glucose as independent variable. Analysis was adjusted for confounding factors such as sex, age, BMI, DiaPep277 treatment, HLA and AUC C-peptide.
Results: Cytokine secretion of PBMC upon islet antigen stimulation showed associations with A1C and blood glucose in adults and children.
In adults, response of Th1 related IFN-γ upon stimulation with GAD65 was positively associated with A1C (p=0.027) but negatively with blood glucose (p=0.002) at week 30. In addition, secretion of IL-10 upon stimulation with GAD65 was positively associated with A1C (p=0.042) at week 8.
In children, IL-13 showed negative associations with A1C but positive associations with blood glucose upon stimulation with GAD65 and pIA2 at week 8 (all, p<0.05). In addition, IL-13 showed negative associations with A1C upon stimulation with GAD65 at week 30 and 78 and hsp60 at week 78 (all, p<0.05). As in adults, IL-10 response showed positive association with A1C but negative association with blood glucose upon stimulation with hsp60 and GAD65 at week 0 and 8, respectively (all, p<0.05).
Conclusion: Cytokine secretion of PBMC upon stimulation with islet antigens was associated with metabolic control as determined by A1C and blood glucose in both adults and children. The association of A1C with immune response may give a basis for the observation by others that worse metabolic control leads to worse clinical outcome. Higher A1c was associated with increased response of Th1 related IFN-γ in adults and with decreased response of Th2 related IL-13 in children. IL-10 response was positively associated with A1c in paediatric and adult patients which may reflect a counter-regulatory attempt of the immune system to regulate immune reactivity.
We thank ANDROMEDA for providing DiaPep277

Positive correlation between the serum DPP-4 enzymatic activity and the CD3+ lymphocyte membrane bound CD26 expression in patients with type 1 diabetes mellitus

V. Timea, A. Somogyi, G. Nagy, Z. Tulassay, G. Firneisz;
Semmelweis University 2nd Department of Medicine, Budapest, Hungary.

Background and aims: Serum dipeptidyl peptidase-4 (identical to CD26) has an important role in carbohydrate metabolism with the degradation of incretin-hormones (GIP, GLP-1). Membrane bound CD26 is widely present in the human body among many other cell types it is also expressed on the surface of lymphocytes. Both the soluble and the membrane bound form of CD26 can modulate in vitro T-cell proliferation and the serum enzymatic activity is also sometimes used as a marker of T-cell activation. DPP-4 inhibitors have convincingly demonstrated their beneficial effect in the treatment of type 2 diabetes, however little amount of data are available on the role of CD26 in type 1 diabetes mellitus.
Materials and methods: Thirty-five (F/M=17/18, mean age: 34.7yrs) patients with T1DM, and 27 (F/M=15/12 mean age:28.4yrs) young healthy volunteers were included in the study. Fasting serum DPP-4 activity was assessed in all the 62 individuals. Years from diagnosis of diabetes: 14.39 yrs, (95%CI: 10.6-18.2yrs). Serum DPP-4 activity was measured by microplate-based (Multiskan-Plus-MKII, Labsystem at 405 nm, 25°C for 30 min) kinetic assay. Gly-Pro-pNA (Bachem, Bubendorf, Switzerland) was used as substrate. Results are expressed in nmol/ml/min (U/L) pNA hydrolysis. Membrane bound CD26 expression was evaluated on CD3+ and CD4+ lymphocytes by Fluorescence Activated Cell Sorting method in a FACS Excalibur System. Results are expressed in fluorescens unit (FU). Kolmogorov-Smirnov normality test, two tailed T-test and Pearson correlation was used.
Results: We experienced a significant increase in the fasting serum DPP-4 enzyme activity in type 1 diabetes (30.35U/L, 95%CI: 28.1-32.6) compared to healthy individuals (23.18U/L, 95%CI: 21.26- 25.1, two-tailed p< 0.0001). CD26 expression on CD3+ and on its subpopulation CD4+ lymphocytes was not increased in T1DM compared to healthy subjects. However we found significant positive correlation between the CD26 expression on CD3+ lymphocytes and the serum DPP-4 enzyme activity within the T1DM group (r^2=0.14; r=0.38; p = 0.036; Figure 1).
Conclusion: The significant positive correlation between the CD3+ lymphocyte membrane bound CD26 expression and the fasting serum DPP-4 enzymatic activity in type 1 diabetes mellitus might support the hypothesis

that the excess DPP-4 activity in the serum of patients with T1DM might in part be the consequence of the autoimmune process. However the low r^2 value indicates that this correlation could not entirely be taken into consideration for the significant increase in serum DPP-4 activity in T1DM.

Zinc transporter 8 autoantibody in Chinese type 1 diabetes

L. Yang[1], S. Luo[1], G. Huang[1], J. Peng[1], X. Li[1], J. Lin[1], X. Yan[1], H.W. Davidson[2], J.C. Hutton[2], Z. Zhou[1];
[1]Endocrinology of Second Xiangya Hospital, Diabetes Center of Central South University, Changsha, China, [2]Barbara Davis Center for Childhood Diabetes, University of Colorado at Denver and Health Sciences Center, Aurora, United States.

Background and aims: Zinc transporter 8 (ZnT8) is a member of the SLC30A family that play a critical role in insulin maturation, storage and secretion in β cells. ZnT8 was recently identified as a major autoantigen in the development of Caucasian type 1 diabetes (T1D). The present study aimed to evaluate the diagnostic utility of ZnT8A for autoimmune T1D in Chinese patients.
Materials and methods: Radioligand binding assays based on human ZnT8 carboxytermini (amino acids 268-369) carrying 325Arg (CR) and a dimeric construct of 325Arg and 325Trp (CW-CR) were used to evaluate ZnT8A in a group of 429 T1D diabetic patients, 555 type 2 diabetic (T2D) patients and 405 healthy controls. T1D patients were divided into Ab+ and Ab- T1D subsets according to their glutamate decarboxylase antibody (GADA) and protein tyrosine phosphatase antibody (IA-2A) status and the ZnT8A distributions were analyzed in the two subsets. The clinical characteristics were also compared among GADA+, IA-2A+, ZnT8A+ alone and Ab- groups.
Results: The prevalence of ZnT8A in T1D patients of 24.2% (105/429), was markedly higher than that in T2D 1.9% (10/555) and controls 1.0% (4/405) (both P <0.001). ZnT8A and IA-2A in newly diagnosed Chinese T1D patients were less prevalent than in Caucasian populations (both P<0.001) , though not different from that in Japanese. Moreover, ZnT8A were more prevalent in the leaner cases in Ab-T1D subset. ZnT8A levels were correlated with IA2-A (R=0.211, P=0.001) but not with GADA (R= -0.107, P=0.093). The diagnostic sensitivity of autoimmune diabetes reached 65.3% when combining 3 antibodies (GADA, IA-2A and ZnT8A). About16 % (28/177) of T1D cases, who were negative for GADA and/or IA-2A, tested ZnT8A positive. Such individuals had longer duration of disease, a higher requirement for insulin (both P<0.05), yet presented with lower glycemia, higher fasting C-peptide and higher body weight than GADA+ or IA-2A+ subjects alone (P<0.05~0.001).
Conclusion: ZnT8A is an independent marker of ß-cell autoimmunity in GADA /IA-2A negative T1D cases and improved the diagnostic sensitivity of immune-mediated T1D when combined with GADA and/or IA-2A. Moreover, ZnT8A identified a milder T1D subset, intermediate between the phenotypes of GADA+/IA-2A+ alone T1D and Ab-T1D.

Epitope analysis of GAD65 autoantibodies in type 1 diabetes and LADA patients with thyroid autoimmunity

P. Jin, G. Huang, W.-D. Zhou, Y.-F. Xiang, Z.-G. Zhou;
Diabetes Center, Metabolic Syndrome Research Center,Institute of Metabolism and Endorcrinology, 2nd Xiangya Hospital, Central South University, Changsha, Hunan, China.

Background and aims: Type 1 diabetes (T1DM) is frequently associated with autoimmune thyroid diseases (AITD). Latent autoimmune diabetes in adults (LADA) is a slowly progressive form of autoimmune diabetes, which also has high risk for thyroid autoimmunity. GAD65Ab is one important antibody in T1DM and LADA patients, but it also found in AITDs. This study was aimed to investigate the epitopes of GAD65 autoantibodies in T1DM and LADA patients with and without thyroid autoimmunity.
Materials and methods: The GADAb levels and their relative epitope reactivities to N-terminal (GAD65-N), Middle (GAD65-M) and C-terminal (GAD65-C) regions of human GAD65 were measured by radioligand immunoassay in 112 T1DM, 107 LADA patients. TPO-Ab and TG-Ab were measured by radioimmunoassay.
Results: Antibodies reactivity to N-terminal,Middle,C-terminal epitope of GAD65 was 11.6%,31.2%,68.8% in T1DM patients and 22.4%,31.8%,47.7% in LADA patients respectively. GAD65Ab reacting with the N-terminal epitope were more common in LADA than in T1DM patients (22.4% *vs* 11.6%, P=0.002). More T1DM patients recognized C- terminal of GAD65 than LADA patients (68.8% *vs* 47.7%, P=0.002). LADA patients with M+C-predominant GAD65Ab reactivity have higher risk for thyroid autoimmunity, lower C-peptide level and the requirement for insulin therapy compared with non-M+C-reactive patients (P<0.05). Compared with those without thyroid autoimmunity, more T1DM patients and LADA patients with thyroid autoimmunity had antibodies directed to both GAD65-M and GAD65-C (46.0% *vs* 14.5% and 51.6% *vs* 18.4% respectively, P<0.001).Multiple logistic regression shown that GAD65-M+CAb positivity was significantly associated with thyroid autoimmunity in T1DM and LADA patients (OR=5.016 and 4.724 respectively, P<0.05).
Conclusion: The majority of T1DM and LADA patients had antibodies directed to Middle and C-terminal epitopes of GAD65. LADA patients with M+C-predominant GAD65 reactivity have clinical features similar to those of T1DM patient. T1DM and LADA patients with GAD65-M+C epitopes specific reactivity showed an increase risk for thyroid autoimmunity.

Common and unique environmental events associated with innate and adaptive immunity in type 1 diabetes

H. Beyan[1], H. Riese[2], M.I. Hawa[1], G. Beretta[1,3], H.W. Davidson[3], J.C. Hutton[3], H. Snieder[2], B.O. Boehm[4], R.D. Leslie[1];
[1]Centre for Diabetes and Metabolic Medicine, St Bartholomew's Hospital, London, United Kingdom, [2]Unit of Genetic Epidemiology & Bioinformatics, Department of Epidemiology, University Medical Center Groningen, University of Groningen, Netherlands, [3]University of Colorado, Denver, United States, [4]Division of Endocrinology and Diabetes, University Medical Center Ulm, Germany.

Background and aims: Type 1 diabetes mellitus is caused by destructive adaptive and innate immune responses. Serum diabetes-associated autoantibodies, to glutamic acid decarboxylase (GADA), insulinoma-associated antigen-2 (IA-2A) and zinc transporter-8 (ZnT8A), reflect adaptive immunity, while carboxy-methyl-lysine (CML), an advanced glycation end-product, is associated with proinflammation and innate immunity. We assessed whether genetic or environmental factors determine serum autoantibodies and CML levels in type 1 diabetes.
Materials and methods: Serum autoantibodies and CML were determined in two prospective studies: a classical twin study of twins discordant for type 1 diabetes (32 monozygotic (MZ), 32 dizygotic (DZ) pairs) and a population study of 7,287 normal subjects. CML levels were determined by ELISA, autoantibodies by radio-immunoprecipitation,

Results: Baseline CML and autoantibodies predicted diabetes additively. CML levels were increased in diabetic and non-diabetic twins, population-based autoantibody positive and pre-diabetic subjects (all p<0.001). Twin CML correlations were strong, irrespective of zygosity: r(MZ) = 0.70, r(DZ) = 0.66; model fitting showed common environmental factors explained 66% of variance. Autoantibodies occurred more frequently in diabetic than non-diabetic twins (p<0.001); but twin correlations (r) were weak, irrespective of zygosity: e.g. IA-2A, r(MZ)=0.06, r(DZ)=-0.03; model fitting showed unique environment explained all variance.
Conclusion: In twin studies, environmental factors were strong determinants of two diabetes-associated features, which predicted type 1 diabetes additively in a large population study. Common environmental factors determined serum CML levels, while unique factors determined diabetes-associated autoantibodies. We postulate that distinct, additive, environmental events are associated with type 1 diabetes, common events activating innate immunity, unique events inducing adaptive immune responses.

Modulation of innate immunity in enterovirus-infected human pancreatic islets
O. Skog[1], M. Hodik[1], O. Korsgren[2], G. Frisk[1];
[1]Dept. of Women's and Children's Health, [2]Dept. of Oncology, Radiology, and Clinical Immunology, Uppsala University, Sweden.

Background and aims: Type 1 diabetes (T1D) is a chronic disease characterized by the selective destruction of insulin-producing cells in the pancreas. Enterovirus (EV) is the prime candidate to initiate this destruction and several inflammatory chemokines are induced by EV infection, potentially involved in the induction of insulitis. A protective effect of the female sex hormone 17β-estradiol on isolated human islets has been shown. The aim of this study was to evaluate the effect of 17β-estradiol on EV-induced chemokine secretion and cytolysis of human islet cells. In addition, the islet response to EV infection was compared to the response to the synthetic dsRNA analogue polyinosinic:polycytidylic acid (Poly I:C).
Materials and methods: Human islets, cultured with or without the addition of 17β-estradiol, were exposed to synthetic dsRNA (poly(I:C)) or infected with an EV strain isolated from a diabetic child at T1D onset. Secretion and gene expression of several cytokines were analyzed with ELISA and real-time quantative PCR (RT-qPCR) respectively. Virus replication was determined by tissue culture infectious dose 50 ($TCID_{50}$) titrations on green monkey kidney cells.
Results: The results confirm previous findings that EV infection induces high level IP-10 and MCP-1 secretion from human islets and show that this secretion is markedly reduced by addition of 17β-estradiol to the culture medium. In contrast, the IP-10 and MCP-1 secretion induced by treatment of islets with poly(I:C) is not affected by 17β-estradiol, suggesting that separate signalling pathways are responsible for the innate immune response triggered by EV and poly(I:C). 17β-estradiol did not affect viral replication but reduced the cytopathic effect of the virus on the islets. Exposure of the islets to poly(I:C) 24 h prior to EV infection either blocked (2 donors), reduced (3 donors), or had no effect (1 donor) on EV replication. A negative effect of poly(I:C) on EV replication correlated with a high induced expression level of genes involved in the innate immune response to virus infection (interferon-β, MDA-5, TLR3, and RIG-I). Surprisingly, interferon-α was not induced by any of the treatments. The antiviral effect of poly(I:C) could not be reduced by addition of 17β-estradiol, which is in line with the finding that 17β-estradiol had no effect on poly(I:C)-induced chemokine secretion.
Conclusion: The reported findings might have direct implications for the understanding of the etiology and forthcoming prevention of T1D. It also highlights the importance of genetic diversity in shaping the innate immune response to EV in islets, which most likely is involved in controlling the later antigen-specific adaptive immune response. Further studies on the genetically determined differences in response to acute EV infection need to be performed in order to explain the interplay between infection and genetic predisposition to T1D.

Effects of metformin vs sulphonylurea on immune activity of Natural Killer (NK) cells in individuals with newly diagnosed type 2 diabetes
P.J. Piatkiewicz[1], A. Czech[1], M. Kniotek[2], M. Nowaczyk[2];
[1]Chair and Department of Internal Diseases and Diabetology, [2]Department of Clinical Immunology, Warsaw Medical University, Poland.

Background and aims: Diabetic hyperglycemia may suppress the function of peripheral blood NK cells which represent the first line defense in the immune system. The earlier obtained results revealed significant impairment in activity of NK cells of diabetic patients in comparison to healthy control subjects (CS). Hypoglycemic drugs may influence and improve the immune activity of NK cells. In order to explore this hypothesis we evaluated the number and activity of NK cells obtained from newly diagnosed Type 2 diabetic patients (T2DP) before and after the administration of either metformin or sulphonylurea in comparison with CS.
Materials and methods: Incubation tests were performed at baseline in 25 newly-diagnosed T2DP, naive to any hypoglycaemic drugs and 20 carefully matched CS; in the diabetic patients, the tests were repeated after 6 and 12 months of therapy either with metformin (13 persons) or sulphonylurea - gliclazide (12 persons) accordingly to clinical indications. Peripheral blood mononuclear cells (PBMC) were isolated by Ficoll gradient centrifugation. The K562 human erythroleukemia cell line was used as the standard target for human NK cytotoxicity assay. K562 were labelled with DIO(3,3-dioctadecyloxacarbocyanine perchlorate). Target and effector cells were added to reach effector/target rations: 50:1 ,12:1. Dead target cells were stained with PI (propidium iodide). After 4 hours of incubation data were collected for analysis on the Becton-Dickinson FACScalibur flow cytometer. Immunofluorescent phenotyping of NK ($CD16^+$) cells in PBMC was performed using specific murine anti-human CD16 PE-conjugated monoclonal antibodies. The data was analyzed using Cell Quest software.
Results: The T2DP at baseline in comparison to CS had an increased number (14,27±6,2% vs 9,59±4,8%) but decreased activity (3,0±2,4% vs 9,1±3,8%) of NK cells (p<0,01). Treatment with metformin resulted in reduction in fasting plasma glucose (FPG) of 1.65 mmol/L (P<0.001) and in HbA_{1C} of 0.82% (P<0.001) after 6 months and further reduction of 0.48 mmol/L in FPG and of 0.34% in HbA_{1C} after 12 months of therapy. The T2DP treated 6 months with metformin demonstrated substantially decreased number and increased activity of NK cells in comparison to baseline values(10,91±4,7% vs 14,69±5,1% and 5,6±2,9% vs 2,9±2,0%)(p<0,01). Further 6 months of metformin therapy resulted in not statistically significant differences of these parameters (10,59±4,0% and 6,0±3,2%, respectively). Treatment with gliclazide resulted in reduction in FPG of 1,77 mmol/L (p<0,001) and in HbA1c of 0,69% (p<0,001) after 6 months and further reduction of 0.26 mmol/L in FPG and of 0.14% in HbA1c after 12 months of therapy. The T2DP after 6 months of gliclazide administration demonstrated decreased number and increased activity of NK cells in comparison to baseline values (12,13±3,9% vs 13,93±4,8% and 6,5±3,0% vs 3,1±2,2%)(p<0,01). This tendency became more intense after 12 months of therapy (10,12±4,2% and 7,3±3,5%, respectively)(p<0.05).
Conclusion: Both metformin and gliclazide improve immune activity of NK cells in Type 2 diabetes. The beneficial influence of metformin on NK cells number is accelerated and more pronounced than gliclazide. These findings constitute immune response as a new potential target of oral hypoglycemic drugs in type 2 diabetes mellitus.

Protection of the beta cell function by treatment with a rat specific CD3 antibody alone or in combination with the immunomodulatory agent FTY720 in the IDDM rat, an animal model of human type 1 diabetes
A. Jörns[1], M. Akin[1], T. Taivankhuu[1], A. Meyer zu Vilsendorf[2], S. Lenzen[1];
[1]Institute of Clinical Biochemistry, [2]Visceral- and Transplantation Surgery, Hannover Medical School, Germany.

Background and aims: The IDDM (LEW.1AR1-*iddm*) rat is an animal model of type 1 diabetes mellitus (T1DM) without lymphopenia. The aim of the treatment with CD3-antibody (AB) alone or in combination with the immunomodulatory agent FTY7220 was to prevent clinical manifestation of diabetes or to protect the remaining pancreatic beta cells from autoimmune destruction after onset of the disease. The CD3-AB interacts with the T-cell receptor to inhibit proliferation and cytokine production of T-lymphocytes, while the sphingosin-1-phosphate receptor antagonist FTY720 retains the lymphocytes in the organ draining lymph nodes.

Materials and methods: For the purpose of primary or secondary prevention the animals were treated with CD3-AB (0.5 mg/kg body weight) consecutively over 5 days and additionally in the combined therapy over 40 days with FTY720 (1 mg/kg body weight). Gene and protein expression of pro- and anti-inflammatory cytokines, MCP-1 and iNOS were analysed in pancreatic biopsies and the pancreas-draining lymph nodes at the time point of diabetes manifestation, at the end of therapy, and 60 days after the end of treatment.
Results: Primary prevention therapy with CD3-AB initiated before diabetes manifestation suppressed clinical diabetes manifestation. However, 60 days after CD3-AB treatment 60 % of the CD3-AB treated animals showed signs of immune cell infiltration, as documented by infiltration with macrophages and CD4 and CD8 T lymphocytes in the islets. But there was no increased beta cell apoptosis in the infiltrated islets. Ultrastructurally, the beta cells in the infiltrated islets showed signs of an unfolded protein response which were absent in beta cells of non infiltrated islets. The immune cells of the infiltrated islets in the treated animals expressed no pro-inflammatory cytokines, neither IL-1β, IFN-γ, nor TNF-α, on the gene and protein level. In the secondary prevention therapy with CD3-AB initiated after overt diabetes manifestation there was a sluggish increase of the blood glucose concentration over the first three weeks after treatment in comparison to the spontaneous development. The slower increase of the blood glucose was accompanied by a strong decrease of the pro-inflammatory cytokine protein concentrations in the peripheral blood. The remaining beta cells after diabetes manifestation could not be protected permanently against the autoimmune attack by CD3-AB alone. The combined treatment of CD3-AB and FTY720 induced a permanent normoglycaemia over 60 days after therapy. The remaining beta cells in the islets were ultrastructurally well preserved and the immune cell infiltration was restricted to the perivascular region.
Conclusion: The findings after CD3-AB treatment in the IDDM rat confirmed earlier observations in NOD mice and in humans with T1DM and illustrate the problem with a single compound therapy approach. In a combined therapy with CD3-AB and FTY720, however, the later compound retains the lymphocytes in the pancreas draining lymph nodes and thereby makes the therapy success permanent by prevention of pancreatic islet immune cell infiltration.

496

Preservation of residual beta cell function in newly diagnosed type 1 diabetes by treatment with atorvastatin: the DIATOR trial

S. Martin[1,2], C. Herder[1], N.C. Schloot[1], T. Heise[3], L. Heinemann[3], H. Kolb[1,4], DIATOR Study Group;
[1]German Diabetes Center at the University of Düsseldorf, Germany, [2]West-German Centre of Diabetes and Health, Düsseldorf, Germany, [3]Profil Institute for Metabolic Research, Neuss, Germany, [4]Hagedorn Research Institute, Gentofte, Denmark.

Background and aims: The lipid-lowering agent atorvastatin is also a potent immunomodulator. We therefore investigated the effect of atorvastatin on the progressive decline of residual beta cell function in patients with newly diagnosed type 1 diabetes.
Materials and methods: Adult patients with newly diagnosed type 1 diabetes and islet autoantibodies were randomly assigned to treatment with either atorvastatin or placebo in a multi-centre, outpatient, parallel group study. During a run-in period of 6 weeks the daily dose was increased from 20 mg to 80 g/day, which was to be reduced to 40 mg/day in case of side-effects (e.g. myalgia). Efficacy on beta cell preservation was assessed by means of two-hour standardised mixed-meal tests at baseline and after 12 and 18 months of treatment. A tight glycaemic control was aimed at with a target of HbA1c ≤ 6.5 %.
Results: Eighty-nine patients (mean age 30 years, median BMI 24 kg/m², 40 % females) participated in this study, 21 dropped out before the one year visit (8 placebo, 13 atorvastatin). The intention-to-treat analysis showed a significant drop in total serum cholesterol concentrations with atorvastatin treatment (median from 156 to 106 mg/dl). Median HbA1c levels at 18 months were 6.8 % in the placebo and 6.5 % in the atorvastatin group, the corresponding insulin doses were 0.34 vs 0.43 IU/kg (differences not significant). Median autoantibody levels (GADA, IA-2A, ICA) changed little during the study period. Median fasting C-peptide levels dropped from baseline to 12 and 18 months in the placebo group (from 0. 34 to 0.23 and 0.20 pmol/ml, $p < 0.001$) whereas they remained stable in the atorvastatin group (from 0.34 to 0.27 and 0.30 pmol/ml, ns). Median mixed-meal stimulated C-peptide concentrations dropped slightly between baseline and 12 months in both groups (placebo from 0.89 to 0.71, atorvastatin from 0.88 to 0.73 pmol/ml, $p < 0.01$ each) followed by a major loss in the placebo group (to 0.48 pmol/ml) but not in the atorvastatin group (to 0.71 pmol/ml, ns). Atorvastatin treatment was well tolerated and serious drug-related adverse events were not observed.
Conclusion: Daily treatment with atorvastatin slowed the loss of residual beta cell function in people with newly diagnosed type 1 diabetes over the study period of 18 months. Atorvastatin appears to interfere with mechanisms of autoimmune or inflammatory beta cell destruction.

Adiponectin receptor expression on peripheral blood mononuclear cells is reduced in autoimmune diabetes and can be upregulated with lifestyle intervention

T.T.L. Pang[1], E. Goble[1], K. Weaver[1], M. Chinem[1], S.A. Eldershaw[1], S.C. Gough[1], R. Andrews[2], P. Narendran[1];
[1]School of Clinical and Experimental Medicine, University of Birmingham, [2]Joint Clinical Research Unit, University of Bristol, United Kingdom.

Background and aims: Studies of patients with genetic predisposition for T1D show that insulin resistance (IR) is an independent risk factor for T1D. We are interested in defining the mechanisms that link IR with progression to T1D, and in particular the potential role of adipocytokines such as adiponectin. Adiponectin is an anti-inflammatory and insulin sensitising cytokine whose levels are inversely associated with IR. It signals through receptors AdipoR1 & AdipoR2, whose expression levels are increased by manoevres that reduce IR. These receptors have previously been found on peripheral blood mononuclear cells (PBMC) where stimulation reduces their proliferation and cytotoxicity, and increases their secretion of anti-inflammatory cytokines. We hypothesise that adiponectin has an anti-inflammatory effect on human islet autoimmunity. Our initial aim was to assess the expression of adiponectin receptors on PBMC in healthy and T1D subjects, and whether these expression levels could be modulated by exercise.
Materials and methods: PBMC expression of AdipoR1 & AdipoR2 was quantified by flow cytometry and qPCR on 26 T1D subjects and 14 age and anthropometrically matched healthy male Caucasian volunteers. The proportion of cells expressing each receptor, and the mean fluorescence intensity (MFI) were calculated by subtracting from subject-specific isotype control staining. The estimated glucose disposal rate (eGDR) of T1D subjects was calculated using waist hip ratio, blood pressure and HbA1C as previously described. In addition, we measured the effect of 6 months of diet and exercise training on adiponectin receptor expression by PBMC using qPCR, in 9 subjects with autoimmune diabetes.
Results: AdipoR1 & AdipoR2 are expressed on monocytes and lymphocytes in both healthy and T1D subjects. On average, 47% of monocytes and 11% of lymphocytes expressed AdipoR1 and AdipoR2. AdipoR1 & AdipoR2 expression is decreased on monocytes (with a tendency to decrease in lymphocytes) in T1D compared to healthy subjects (figure). AdipoR1 & AdipoR2 expression by both monocytes and lymphcytes, measured by MFI, correlated significantly with eGDR in subjects with T1D (monocytes AdipoR1 $r = 0.475$, AdipoR2 $r = 0.512$; lymphocytes AdipoR1 $r = 0.292$, AdipoR2 $r = 0.420$). Lifestyle intervention increases AdipoR1 & AdipoR2 gene expression at 6 months (Fold change: AdipoR1 2.6 $p = 0.02$, AdipoR2 1.5, $p = 0.07$).
Conclusion: Adiponectin receptor expression is decreased on PBMC from T1D subjects. These findings are consistent with adiponectin playing an anti-inflammatory role on islet autoimmunity, and may explain the association between insulin resistance and the development of T1D. Furthermore, therapies that reduce IR may also modulate the development of this disease.

Protection against spontaneous immune-mediated diabetes in the IDDM rat by CD8+ T cell transfer correlates with an anti-inflammatory cytokine shift within the pancreas-draining lymph nodes

T. Arndt[1], D. Wedekind[2], H. Weiss[3], M. Tiedge[3], S. Lenzen[1], H.-J. Hedrich[2], A. Jörns[1];
[1]Hannover Medical School, Institute of Clinical Biochemistry, [2]Hannover Medical School, Institute for Laboratory Animal Science, [3]University of Rostock, Department of Medical Biochemistry and Molecular Biology, Germany.

Background and aims: The IDDM (LEW.1AR1-*iddm*) rat is an animal model of spontaneous human type 1 diabetes mellitus. This study analysed how adoptive transfer of selective T cell subpopulations affects the incidence of diabetes and the infiltration stages in the islets.
Materials and methods: $CD4^+$ or $CD8^+$ T cells were isolated from diabetic IDDM rats or the diabetes-resistant background strain LEW.1AR1. Lymphocytes were selectively transferred into athymic LEW.1AR1-*Whn*^{rnu} or prediabetic IDDM rats. The animals were monitored for blood glucose, islet infiltration and immune cell composition of pancreas-draining lymph nodes.
Results: After adoptive transfer of $CD4^+$ T cells from diabetic IDDM rats into athymic LEW.1AR1-*Whn*^{rnu} rats, 50% of the recipients developed diabetes. Transfer of $CD8^+$ T cells failed to induce diabetes. Only 10% of the athymic recipients became diabetic after co-transfer of $CD4^+$ and $CD8^+$ T cells. Adoptive transfer of $CD8^+$ T cells from LEW.1AR1 or diabetic IDDM rats into prediabetic IDDM rats halved the incidence of diabetes. In the protected normoglycaemic animals without any immune cell infiltration in the pancreatic islets regulatory $CD8^+/CD25^+$ and $CD4^+/CD25^+$ T cell subpopulations co-expressing FOXP3 accumulated in the pancreas-draining lymph nodes. Corresponding to the increased accumulation of both regulatory T cell subpopulations gene and protein expression shifted from a pro-inflammatory to an anti-inflammatory cytokine profile in comparison with the lymph nodes from diabetic rats after transfer of $CD8^+$ T cells.
Conclusion: Our results show that adoptive transfer of $CD4^+$ but not $CD8^+$ T cells from diabetic IDDM rats induced diabetes development. Importantly, $CD8^+$ T cells from diabetic IDDM rats and diabetes-resistant LEW.1AR1 rats provided protection against immune cell infiltration leading to beta cell destruction in the islets. The additional accumulation of regulatory T cells in the pancreas-draining lymph nodes from protected rats indicates that transferred $CD8^+$ T cells may have beneficial effects in the control of beta cell autoimmunity.

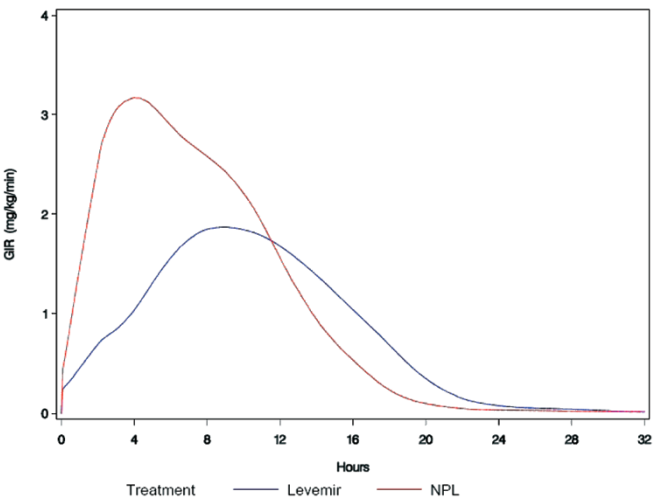
PS 28 Action of insulin and its analogues

499

A direct comparison of pharmacodynamics and pharmacokinetics of insulin detemir and neutral protamine lispro (NPL) insulin in subjects with type 1 diabetes

S. Korsatko[1], K. Glettler[1], K.J. Olsen[2], A. Wutte[1], G. Bock[1], G. Koehler[1], J.K. Mader[1], B. Semlitsch[1], T.R. Pieber[1];
[1]Departement of Internal Medicine, Medical University of Graz, Austria, [2]Larix ApS, Balerup, Denmark.

Background and aims: Basal insulin preparations attempt to recreate the low and constant plasma insulin levels seen between meals and overnight in normal physiology. For the insulin analogues detemir and glargine, comparable flat time-action profiles over 24 hours have been described. The aim of this study was to compare the pharmacodynamic and pharmacokinetic properties of a new insulin analogue, neutral protamine lispro (NPL) with those of insulin detemir in a euglycaemic glucose clamp trial.
Materials and methods: 30 subjects with C-peptide negative type 1 diabetes (42±11 years, BMI 25.4±3.0 kg/m², HbA1c 7.7±1.1 %, mean±SD) were randomly allocated to single dose administration of insulin detemir and NPL insulin. After normalization of plasma glucose with a variable insulin infusion, 0.4 U/kg BW of either insulin was administered on 2 separate dosing visits in a double-blind fashion. Insulin infusion was stepwise decreased and a euglycaemic clamp was initiated with a plasma glucose target of 5.5mmol/l over 32 hours. Duration of action was defined as the time from dosing until plasma glucose consistently exceeded 8.3mmol/l without glucose infusion.
Results: The primary endpoint "duration of action" was similar for insulin detemir and for NPL insulin (23.6±6.2h vs. 22.6±7.2h; p=0.557), with detemir showing a lower inter-subject variability. Compared to NPL insulin, insulin detemir exhibited a flatter pharmacodynamic profile reflected by significantly different glucose infusion rate (GIR) results [AUCGIR(0-32h) 1326 mg/kg (insulin detemir) vs. 1841 mg/kg (NPL insulin); p<0.01; AUCGIR(0-12h) 784 mg/kg vs. 1392 mg/kg; p<0.001; AUCGIR(12-32h) 455 mg/kg vs. 274 mg/kg; p<0.02) and a higher GIRlate(12-32)/GIRearly(0-12) ratio (0.33 vs. 0.04; p<0.01). Consequently detemir showed a lower peak action (GIRmax 2.0 mg/kg/min vs. 3.2 mg/kg/min, p<0.005) as well as a later peak of action (Tmax 7.2±2.4h vs. 6.2±4.5h)) when compared with NPL insulin.
Conclusion: The results of this study indicate that - using a single dose of 0.4U/kg - both basal insulin analogues have duration of action of approximately 24 hours and are hence both suitable for once daily dosing. That said, insulin detemir exhibited a flatter profile with a more even distribution of the metabolic effect over the 32 hours, whereas for NPL the main effect was observed in the first 12 hours. Furthermore, insulin detemir had lower GIRmax and less variability. Clinical trials with head to head comparison are thus needed to establish the superiority of one or more analogue preparations.



500

Impact of alternative splicing of insulin receptor to binding and signalling of insulin analogues

M. Sommerfeld, K. Klein, S. Welte, N. Tennagels;
TD Metabolism, sanofi-aventis, Frankfurt am Main, Germany.

Background & aims: The human insulin receptor is expressed as two isoforms that are generated by alternative splicing. The two mature proteins differ by the presence or absence of 12 amino acids encoded by exon 11 at the C terminus of the extracellular α-subunit. The aim of the present study was to explore the impact of the presence or absence of exon 11 to binding and signaling of the insulin analogs glargine, glulisine, and insulin AspB10.
Materials & methods: The affinity of insulin, insulin analogs, IGF-I, and IGF-II to the IR isoforms A and B was analysed in a competitive binding assay using SPA technology. IR autophosphorylation was measured via in-cell western (ICW) in CHO cells overexpressing either human IR-A or -B. Dephosphorylation kinetics were analysed using a Luminex XMAP System.
Results: Analysis of the binding of human insulin to the two IR splice variants A and B did not reveal a significant difference in the measured IC50 values (0.49±0.04 vs. 0.57±0.02 nmol/L, p=0.27). In contrast both IGF-I and IGF-II showed a higher affinity to IR-A. IGF-I binds 2.7x (64.5±5.1 vs. 171±50 nmol/L, p<0.05), and IGF-II 8.8x (6.2±0.34 vs. 46.6±7.8 nmol/L, p<0.05) better to IR-A, respectively. Measuring the binding of the insulin analogs glargine, glulisine and AspB10 resulted in the following IC50 values - glargine: 0.83±0.08 vs. 1.10±0.12 nmol/L, p=0.1015; glulisine: 0.88±0.07 vs. 1.08±0.25 nmol/L, p=0.5077; AspB10: 0.06±0.01 vs. 0.21±0.03 nmol/L, p<0.05.
Analysing IR autophosphorylation in CHO-IR-A or IR-B cells via ICW resulted in EC50 values as follows for IR-A and IR-B, respectively - insulin: 11.95±1.65 vs. 11.67±1.43 nmol/L; IGF-I: 449±61.7 vs. >1,000 nmol/L; IGF-II: 85.4±5.5 vs. 384±68.4 nmol/L; glargine: 19.03±3.39 vs. 26.39±3.34 nmol/L; glulisine: 49.6±6.05 vs. 51.7±7.22 nmol/L; AspB10: 5.12±0.69 vs. 3.32±0.78 nmol/L.
To assess dephosphorylation kinetics CHO cells expressing either IR-A or IR-B were stimulated for 10 min with insulin or analogs, then the medium was replaced and the IR phosphorylation was analysed at various time points. From these data half-lifes for IR-A were calculated: insulin 6.87 min, glargine 4.87 min, glulisine 6.54 min, and AspB10 17.7 min, and also for IR-B: insulin 12.04 min, glargine 10.74 min, glulisine 12.91 min, and AspB10 298 min.
Conclusion: Presence or absence of the 12 amino acids of exon 11 in the α-subunit of the IR results in different binding properties, especially IGF-I and IGF-II have a considerable higher affinity to IR-A. Analysing the binding properties of insulin analogs revealed that only insulin AspB10 has a significant unique profile with a 3.5x higher affinity to IR-A. Autophosphorylation of the IR kinase domain after ligand binding is the first step of the insulin signaling cascade. Analysis of this event via ICW reflected the observed higher binding of IGF-I/II to IR-A in a more potent activation of IR-A than IR-B. However, no special characteristics were found for insulin or the studied analogs. Dephosphorylation of IR-A occurs twice as fast as of IR-B after a stimulus with insulin, glargine or glulisine, respectively. Both IR splice variants show an extreme elongated dephosphorylation profile with AspB10. This protracted dephosphorylation of IR has been discussed as causative for increased mitogenic activity of AspB10 via the IR. Taken together these data show that in contrast to AspB10 the interaction of insulin glargine and glulisine with IR-A and IR-B is very similar to human insulin.

Glycaemic basis for reduced feeding by intact and diabetic rats in response to injections of insulin detemir

J.R. Vasselli[1], P.J. Currie[2], F.X. Pi-Sunyer[1];
[1]Medicine, St. Luke's-Roosevelt Hospital Center, New York, [2]Psychology, Reed College, Portland, United States.

Background and aims: Insulin detemir (DET) is a long-acting insulin analog that binds reversibly to albumin in the serum and interstitial fluid. Numerous studies indicate that the clinical use of DET in diabetic patients results in more stable long-term glycemia, fewer episodes of hypoglycemia, and decreased weight gain, in comparison with long-acting protamine (NPH) forms of insulin. The mechanisms for the weight-gain-sparing effect of DET are however unknown. We tested whether the glycemic effects of these two forms of insulin alter food intake (FI) in intact and diabetic rats in a manner that may influence body weight (BW) gain on a long-term basis.
Materials and methods: Groups of intact (INT) and mildly streptozotocin-diabetic (STZD) female Sprague-Dawley rats (n = 6-8) with 3-hr fasting glucose levels of 112±10.3 vs. 200±34.6 mg/dl, respectively, were maintained continuously in on-line feeding-monitoring chambers (BioDaq) with access to laboratory chow ad libitum. For testing, groups were administered a single s.c. injection of biologically equivalent doses of either 15U/kg NPH or 26.25U/kg DET at mid-morning (for dose equivalency see Diabetes 2008 V57: 746-756). Blood was sampled at 0 (Baseline), 2, 4, 6, 8, 10, 12 and 24 hrs post-injection, and FI was continuously monitored electronically.
Results: Results for STZD rats are shown in Fig 1. Significant differences of glucose level ($p < 0.05$) were seen between the groups at hrs 2, 4, 6, and 8 (Fig. 1A), with NPH rats displaying frank hypoglycemia during the first 4 hrs post-injection. In contrast, glucose levels of STZD DET rats remained moderate and stable over the first 8 hrs post-injection. Significantly greater cumulative FI ($p < 0.01$) was seen in NPH- vs. DET-injected STZD rats during each 2-hr interval from hrs 4 - 12 (Fig. 1B). Blood glucose levels did not differ between the groups from hr 10 onward, nor did cumulative FI from hr 14 onward. Similar significant differences in glucose level and cumulative FI were observed over the same intervals in DET vs. NPH-injected INT groups, and a tendency for decreased BW gain was seen in the INT DET group at 24 hrs (ns). At higher doses of DET and NPH that led to similar reductions of glycemia in INT and STZD rats, no differences of cumulative FI were observed.
Conclusion: Our results indicate that the more moderate and consistent glucose-lowering effects of DET eliminate episodes of hypoglycemia and glucoprivic feeding in INT and diabetic rats, and may predispose to reduced BW gain with repeated DET administration.

Effects of intranasal insulin on neuronal processing of food pictures in lean and obese subjects: a magnetoencephalographic study

M. Guthoff[1], M. Heni[1], K. Stingl[2], O. Tschritter[1], M. Hallschmid[3], H.-U. Häring[1], A.M. Hennige[1], H. Preissl[2,4], A. Fritsche[1];
[1]Department of Diabetes, Endocrinology, Nephrology, Angiology and Clinical Chemistry, Medical Clinic, Tübingen, Germany, [2]Institute of Medical Psychology and Behavioral Neurobiology, Tübingen, Germany, [3]Department of Neuroendocrinology, University of Lübeck, Germany, [4]Department of Obstetrics and Gynecology, Medical College, Little Rock, United States.

Background and aims: Insulin is known to be an anorexigenic hormone to the central nervous system (CNS) that contributes to the termination of food-intake in the postprandial state. In obese, however, diminished cortical activity was described both in animals and humans implicating insulin resistance in the brain. Intranasally administered insulin enters the brain via the olfactory nerve and bulb, and was shown to raise insulin concentrations in the cerebrospinal fluid without altering levels in the systemic blood circulation. Thereby, a potential malfunction of the blood-brain barrier as an underlying cause of insulin resistance in the brain in obese subjects can be disregarded, and insulin action in the brain can be monitored apart from effects in the periphery. In the present study, we therefore investigated whether neuronal activity modulated by intranasal insulin behaves differently in lean and obese subjects.
Materials and methods: We determined evoked potentials by magnetoencephalography measurements in 10 lean and 10 obese subjects for both in the basal state and after applying insulin or placebo spray. Neuronal stimulation was achieved by matched food and non-food pictures in randomized order, and multiple blood-samples were drawn to determine parameters of peripheral glucose metabolism.
Results: Intranasal insulin had no significant effect on glucose, insulin or C-peptide concentrations over a 60-minute period after application of insulin spray. However, insulin increased the amplitude of the evoked potentials in response to food pictures in lean subjects (10 ± 8 femtoTesla (fT)), while this effect was absent in obese (multivariate regression analysis: p=0.003). Moreover, in lean, the increase in the amplitude was observed in the components of evoked fields related to identification and categorization of incoming pictures at around 170 ms post-stimuli in the visual ventral stream.
Conclusion: Our data suggest that insulin-dependent processing of food pictures is decreased in obese subjects compared to lean, and therefore support the idea that insulin in the brain of obese is not sufficient to terminate food intake and might aggravate overeating and obesity.

Evidence of an impaired transcapillary insulin transport in obese females showing postprandial hyperglycaemia

M.M. Sandqvist, L.E. Strindberg, P.N. Lönnroth, P.-A.E. Jansson;
The Lundberg Laboratory for Diabetes Research, Department of Molecular and Clinical Medicine, Institute of Medicine, Gothenburg, Sweden.

Background and aims: An endothelial barrier for the transport of insulin to the target tissues has been suggested to contribute to insulin resistance in obese subjects. However, the interstitial insulin concentration (I-Insulin) in adipose tissue and skeletal muscle has so far not been studied during physiological hyperinsulinemia in obese subjects characterized by postprandial hyperglycemia.
Materials and methods: Seven obese postmenopausal females without type 2 diabetes, but with signs of postprandial hyperglycemia (P-Glucose ≥9.7 mmol/l 60 min after an OGTT), and 9 postmenopausal lean glucose tolerant females were studied after fasting overnight (Age 61±2 vs 60±1 yrs, ns, (Mean±SEM); BMI 32.9±0.8 vs 22.8±0.6 kg/m^2, p<0.005; fS-Insulin 7.0±0.2 vs 3.9±0.5 mU/l, p<0.005; fP-Glucose 5.2±0.1 vs 4.7±0.1 mmol/l, p<0.05; P-Glucose 120 min after OGTT 9.0±0.4 vs 6.1±0.3 mmol/l, p<0.005 in obese and lean subjects, respectively) The microdialysis technique was applied to study I-Insulin in the subcutaneous (sc) adipose tissue and the brachioradialis muscle in the forearm, as well as to study the sc I-glycerol concentration. To achieve physiological hyperinsulinemia the measurements were performed during an OGTT. Adipose tissue blood flow (ATBF) was studied by ^{133}Xe-clearance.
Results: After the OGTT there were higher serum insulin concentrations (S-Insulin) in the obese, as compared to the lean group. However, I-Insulin did not differ significantly between the groups, neither in the sc adipose tissue (Fig 1), nor in the skeletal muscle (data not shown). Accordingly, the proportion of insulin passing from the circulation to the interstitial fluid in the sc adipose tissue was significantly lower in the obese as compared to the lean subjects (42±2% vs 79±4%, p<0.001) (mean during 2 hours after the OGTT). A similar relationship was seen in the skeletal muscle (37±3% vs 51±3%, p<0.005), although the difference between obese and lean subjects was more pronounced in the sc adipose tissue. As expected, the sc Interstitial-Arterial glycerol concentration difference (marker for lipolysis) (138±18 vs 81±9 µmol/l, p<0.05, at 60 min after the OGTT), as well as the P-Glycerol (38±5 vs 21±2 µmol/l, p<0.05, at 60 min), was significantly higher in the obese group, indicating insulin resistance. Furthermore, ATBF was higher in the lean group during the first 90 min after the OGTT (2.0±0.2 vs 3.8±0.6 ml x 100 g^{-1}x min^{-1}, p<0.05, at 90 min).
Conclusion: Obese females showing postprandial hyperglycemia need higher circulating insulin than lean controls to achieve similar interstitial insulin levels in sc adipose tissue and skeletal muscle, indicating a defective transcapillary transport for insulin. The endothelial barrier for insulin might counteract insulin´s ability to compensate for insulin resistance at the cellular level resulting in impaired sc antilipolysis and decreased muscle glucose uptake.

The identification and characterisation of compounds with insulin-like properties

A.R. Cameron, J. Harthill, G. Rena;
Centre for Neuroscience, University of Dundee, United Kingdom.

Background and aims: Insulin resistance is a key hallmark of type 2 diabetes (T2D). Emerging evidence suggests that defects in information processing by signal transduction pathways may contribute to insulin resistance. If this is correct, drugs may be designed that can overcome and therefore restore signalling to downstream effectors such as the transcription factor FOXO1a and the key gluconeogenic regulatory enzymes phosphoenolpyruvate carboxykinase (PEPCK) and glucose 6-phosphatase (G 6-Pase) that become poorly responsive to insulin in T2D. We recently identified three theaflavins as novel mimics of insulin/IGF-1 action on FOXO1a and PEPCK. Theaflavins are large molecules which contain a structural motif which is also present in much smaller molecules that I have recently discovered to have insulin-like signalling properties. Characterisation of one particular smaller compound and some of its derivatives is presented here.
Materials and methods: HEK293 cells were stimulated with various compounds and lysates underwent SDS-PAGE and Western blotting then probed with phosphospecific FOXO1a antibodies. RT-PCR assays of the genes PEPCK and G 6-Pase were carried out in HL1c cells. Statistical siginificance on average mRNA expression was calculated using one way ANOVA followed by Bonferroni's post hoc test.
Results: The compound elicits insulin-like effects on FOXO1a, PEPCK and G 6-Pase. The compound induces phosphorylation of FOXOs by PtdIns 3-kinase-sensitive and PKB-dependent phosphorylation of Thr24, Ser256 and Ser319, the latter residue then priming a further CK1 mediated phosphorylation of Ser322 and Ser325. The compound required a concentration of 50 μM to induce maximal phosphorylation and a minimum application of 15 minutes. The use of the inhibitors PI-103, wortmannin, PD98059, rapamycin and the PKB inhibitor, Akti, indictated the compound induced phosphorylation of FOXOs by a PtdIns 3-kinase-sensitive and PKB-dependent manner. The effect of derivitisation of the compound is discussed. The repression of hepatic gluconeogenesis by reduced expression of PEPCK and G 6-Pase is recognized as a key aspect of the anti-hyperglycaemic action of insulin so the effect of the novel compound was also investigated. The compound reduced average mRNA expression (as a % of Dex/cAMP expression) of both genes ($n=3$, $p<0.001$).
Conclusion: We have found a small compound that mimics the insulin-like action of black tea theaflavins on FOXO1a and gluconeogenesis. Further investigation might provide novel strategies for the treatment or deferral of T2D.

VVP808 is a novel insulin sensitising agent that reduces endogenous glucose production

K.R. Walder[1], J.C. Molero[2], N. Konstantopoulos[2], K. Windmill[2], G.Y. Krippner[3], G.R. Collier[3];
[1]School of Medicine and Institute for Technology Research and Innovation, Deakin University, Waurn Ponds, [2]School of Medicine, Deakin University, Waurn Ponds, [3]Verva Pharmaceuticals, Geelong, Australia.

Background and aims: We previously showed that VVP808 reduced fasting blood glucose concentration ($p=0.00004$) and HbA1c levels ($p=0.04$) in db/db mice, and improved glucose tolerance in diet-induced obese (DIO) mice ($p<0.05$). The aims of the current study were to determine the mechanism by which VVP808 exerts these antidiabetic effects.
Materials and methods: FAO liver cells were treated in glucose-free media with VVP808 (100 μM) or Metformin (200 μM), and known activators of glucose production (dexamethasone and CPT-cAMP), both in the absence and presence of sub-maximal insulin (0.5 nM). After 24 h, glucose concentration was determined in the media. 10-week-old male Sprague-Dawley rats ($n=10$ per group) were made diabetic by IV injection of streptozotocin (65 mg/kg). Male C57Bl/6 mice ($n=10$ per group) were given free access to a diet containing 45% energy from fat for 10 weeks to induce mild obesity and insulin resistance. Both rats and mice were administered VVP808 (50 mg/kg/d) or vehicle control by single daily oral gavage for 12 or 14 days. Clamps and insulin tolerance tests were performed using standard procedures.
Results: VVP808 inhibited activated glucose production both in the absence and presence of insulin by 35 and 45% respectively ($p<0.05$, $n=5$-7). Under the same experimental conditions, VVP808 decreased PEPCK and G6Pase gene expression levels by 20 and 27% respectively ($p<0.05$, $n=3$). Administration of VVP808 (50 mg/kg/d for 12 days) had no effect on fasting blood glucose concentration in STZ rats. However, VVP808 significantly enhanced the glucose-lowering effects of insulin (0.5U/kg) in an insulin tolerance test (by 2.2-fold after 30 min ($p=0.045$) and by 2.4-fold after 60 min ($p=0.038$)). Data from hyperinsulinemic-euglycemic clamp studies in DIO mice showed that treatment with VVP808 (50 mg/kg/d for 14 days) increased the glucose infusion rate by 27% ($p=0.005$), and this associated with a 23% decrease in endogenous glucose production ($p=0.04$).
Conclusion: In these studies we demonstrated that VVP808 acts as an insulin sensitising agent. VVP808 reduced PEPCK and G6Pase gene expression, and lowered glucose production from cultured FAO cells. VVP808 significantly enhanced the glucose-lowering effects of insulin in STZ rats, and increased the glucose infusion rate during the clamp procedure in mice. We also showed that VVP808 appears to act predominantly by reducing endogenous glucose production. These results confirm the potential of VVP808 for development as an anti-diabetic agent.

Malaysian herb *Labisia pumila var alata* improved insulin sensitivity and lipid profile in a rat model of polycystic ovary syndrome

M. Fazliana[1], L. Mannerås[2], W. Wan Nazaimoon[3], M. Lönn[2], H.F. Gu[1], C.-G. Östenson[1], E. Stener-Victorin[2];
[1]Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden, [2]Department of Physiology, Göteborg University, Sweden, [3]Cardiovascular, Diabetes and Nutrition Research Centre, Institute for Medical Research, Kuala Lumpur, Malaysia.

Background and aims: Labisia pumila var alata (LPva), a Malaysian herb thought to have phytoestrogenic effects, has shown promising results regarding body weight and insulin sensitivity in our previous study on ovariectomized rats. Here we investigated if LPva extracts have effects on metabolic features and body composition in rat model of polycystic ovary syndrome (PCOS) which incorporates ovarian and metabolic characteristics of the syndrome. PCOS is a complex endocrine and metabolic disorder associated with ovulatory dysfunction, hyperandrogenism, abdominal obesity and insulin resistance.
Materials and methods: Twenty-two female rats were given a continuous dose of dihydrotestosterone (7.5 mg/90days; PCOS groups) starting at 21 days of age, to induce PCOS. At 9 weeks of age, rats were randomly divided into 2 groups: i) PCOS Labisia pumila (50mg/kg body weight) and ii) PCOS control (1 ml deionised water) daily during 4 to 5 weeks by oral administration.
Results: Treatment with LPva in PCOS rats resulted in improved insulin sensitivity measured by euglycemic hyperinsulinemic clamp (1.4-fold increase, $p<0.05$). Total cholesterol and triglycerides levels were decreased in LPva treated rats (15% and 14% respectively, $p<0.05$). Plasma resistin levels increased in LPva (25.32 ± 0.92 vs. 20.72 ± 1.54 ng/ml for LPva vs. PCOS control, $p<0.05$). On the other hand, adiponectin levels showed a tendency of increased level in LPva group (24.02 ± 2.00 vs. 18.26 ± 2.02 μg/ml for LPva vs. PCOS control, $p= 0.07$). However, no effect on body weight, body composition or plasma leptin levels was observed. Despite no effects on plasma leptin level, relative mRNA expression in LPva treated group was significantly decreased (4.4 ± 0.7 vs. 8.4 ± 1.1 for LPva vs. PCOS control, $p<0.01$). Furthermore, uterine weight was increased by 29% ($p<0.05$), which indicated estrogenic effects of LPva.
Conclusion: Treatment with LPva extracts in PCOS rats improves insulin sensitivity and lipid profile without affecting body composition.

The *Ginkgo biloba* extract EGb761 prevents palmitate-induced insulin resistance in C2 myotube via activation of 5' AMP-activated protein kinase (AMPK)

E.-S. Ha[1], S.-E. Choi[1], J. Jung[1], S. Yi[1], S. Han[1], H. Kim[1], D. Kim[1], Y. Kang[2], K.-W. Lee[1];
[1]Endocrinology and Metabolism, [2]Institute for Medical Science, Ajou University School of Medicine, Suwon, Republic of Korea.

Background and aims: EGb761, a standardized form of *Ginkgo biloba* leaf extract, was recently reported to mitigate various diseases, including cognitive dysfunction and Alzheimer's disease. But the effect of EGb761 on insulin resistance has not been intensively studied. In this study, we found a phenomenon that EGb761 prevented palmitate-induced insulin resistance and investigated the molecular and cellular mechanisms of the protective effect of EGb761 on palmitate-induced insulin resistance.
Materials and methods: We used differentiated C2 myotubes as an in vitro skeletal muscle model under the differentiation medium for 4 day. To investigate whether EGb761 ameliorates palmitate-induced insulin resistance in C2 myotubes, we treated palmitate, with or without EGb761, on C2 myotubes. After treatment of insulin, we investigated molecules of insulin signaling pathways and insulin stimulated glucose uptake. To elucidate the preventing mechanism of EGb761 on palmitate-induced insulin resistance in C2 myotube, we performed immunoblotting with IR(Insulin Receptor), IRS-1(Insulin Receptor Substrate), Protein kinase B (PKB/AKT), JNK(c-jun N-terminal kinase), p38, AMP-activated protein kinase (AMPK), acetyl-coenzyme A carboxylase (ACC) antibodies, and palmitate beta-oxidation assay.
Results: A 16 h exposure of C2 myotubes to palmitate, reduced insulin stimulated glucose uptake by 25%, IRS-1 tyrosine phosphorylation by 40%, and AKT phosphorylation by 30%. To determine the effect of EGb761 on insulin resistance, before palmitate treatment, we pretreated with EGb761 on C2 myotubes and then measured insulin-stimulate glucose uptake and insulin signaling. EGb761 prevented palmitate-induced reduction of insulin stimulated glucose uptake by 30%. But molecules of insulin signalling pathways, such as tyrosine phosphorylation of IRS-1 and phosphorylation of AKT were not changed. It has been well known EGb761 stimulate mitochondrial metabolism, so we measured palmitate oxidation, with or without EGb761, and monitored the activation of AMPK. EGb761 induced phosphorylation of AMPK in a time and dose dependent manner. Also EGb761 recovered palmitate-reduced beta-oxidation in a dose dependent manner. EGb761 prevented palmitate-reduced expression of glucose transporter 4.
Conclusion: Our data suggest that EGb761 prevented palmitate-induced insulin resistance through improvement of beta-oxidation by activation of AMPK.

DSP-8658, a novel PPAR α/γ modulator, with favorable anti-diabetic profile distinct from that of thiazolidinediones

K. Hirota, M. Yamanaka, M. Takata, J. Nagamine, T. Takazawa, Y. Hirose, A. Tsuchida, M. Taiji;
Pharmacology Research Laboratories, Dainippon Sumitomo Pharma Co., Ltd., Osaka, Japan.

Background and aims: Thiazolidinediones (TZDs), such as pioglitazone and rosiglitazone ameliorate insulin resistance, but cause side effects, including body weight gain, edema and congestive heart failure. In our search for new anti-diabetic agents with beneficial effects on insulin resistance-associated dyslipidemia and minimal side effects, we have found DSP-8658, a selective peroxisome proliferator-activated receptor (PPAR) α/γ modulator. DSP-8658 is currently under clinical development for the treatment of type 2 diabetes. Our aim in this study is to evaluate the beneficial effects of DSP-8658 on metabolic abnormalities in mice models and, characterize the mechanism of these effects and compare it to that of TZDs.
Materials and methods: Transactivation assays were conducted using COS-1 cells transiently transfected with a vector containing PPAR α or γ ligand binding domain as well as a vector containing a reporter gene. Mammalian-2-hybrid assays using HEK293 cells were also conducted to examine PPARγ interaction with cofactors, such as NCoR and P300. The effects of DSP-8658 on glucose metabolism were evaluated in diet-induced obese (DIO) and genetically diabetic KK-A^{y} mice. In addition, the anti-lipidemic action of DSP-8658 was evaluated in human ApoA1 transgenic mice. Finally, to examine regulatory effect of DSP-8658 on gene expression, mRNAs from white adipose tissue (WAT), peripheral blood leucocytes (PBLs), and adipose tissue macrophages (ATMs) in diabetic mice were subjected to RT-PCR analysis.
Results: In transactivation assays, DSP-8658 exhibited comparable EC_{50} values for human PPARα (1.08 μM) and human PPARγ (1.01 μM), and partial activation of human PPARγ (76% compared to that of pioglitazone). In mammalian-2-hybrid assays, DSP-8658 induced dissociation of the corepressor NCoR from PPARγ, but did not affect recruitment of the coactivator P300 to PPARγ. In oral glucose tolerance test, DSP-8658 reduced blood glucose level in DIO mice with an ED_{25} value of 6.2 mg/kg, but did not cause body weight gain or fluid retention even at a dose of 100 mg/kg. In addition, DSP-8658, but not pioglitazone, increased serum HDL-cholesterol concentration, possibly through PPARα activation, in human ApoA1 transgenic mice. In high-fat diet-fed KK-A^{y} mice, DSP-8658 decreased white adipose tissue (WAT) weight, while pioglitazone increased it. Pioglitazone also increased mRNA levels of genes related to both glucose metabolism (Glut4) and fat accumulation (glycerol kinase and FATP1) in WAT. In contrast, DSP-8658 increased mRNA level of Glut4 but had no effect on glycerol kinase and FATP1 in WAT. It is increasingly recognized that low-grade inflammation in metabolic tissues caused by imbalance between classically activated macrophages (M1) and alternatively activated macrophages (M2) underlies obesity-induced insulin resistance. Interestingly, DSP-8658 increased mRNA level of the M2 marker gene arginase 1 in PBLs of DIO mice, and decreased mRNA level of the M1 marker gene TNFα in ATMs, suggesting that DSP-8658 induces macrophages polarization toward M2 and suppresses inflammation.
Conclusion: Unlike pioglitazone, DSP-8658, a PPAR α/γ modulator, selectively modulates cofactor recruitment to PPARγ and exhibits differential gene regulation. DSP-8658 has therefore a highly promising therapeutic profile in the treatment of type 2 diabetes.

Fish oil minimizes insulin resistance and decreases food intake in Zucker fa/fa rats

C. Corporeau[1], C. Crucianni-Guglielmacci[2], V. Le Guen[3], C. Le Foll[1], G. Allain[3], C. Magnan[2], J. Delarue[3];
[1]Laboratoire Régional de Nutrition Humaine, Faculté de Médecine, Brest, [2]Equipe HERGE, CNRS-University Paris Diderot, [3]Laboratoire Régional de Nutrition Humaine, Faculté de Médecine, CHU, Brest, France.

Background and aims: Dietary fish oil (FO) rich in n-3 polyunsaturated fatty acids, i.e EPA + DHA, can modulate insulin-resistance in rats depending on the dose given, the duration of its administration and on the cause of insulin resistance. High dose of FO (20% w/w) over 4 weeks prevents the decrease in phosphatidyl-inositol 3'-kinase (PI3K) activity and GLUT4 content in muscle and adipose tissue induced by a high n-6 PUFA diet (60% w/w). At low dose (7% w/w) over 8 weeks, FO reversed insulin resistance in sucrose-fed rats and increased plasma leptin and adiponectin levels. In contrast, lower dose of fish oil (4.4% w/w) over 4 weeks was unable to prevent dexamethasone-induced insulin resistance and defects of PI3K activity, probably because of too potent effects of dexamethasone.
In this study, we used Zucker fa-/fa- rats. These rats become spontaneously obese and insulin resistant because of a genetic mutation in leptin receptor gene. We aimed to study the effects of a low dietary intake of FO (7% w/w) on food intake and development of insulin resistance in Zucker rats.
Materials and methods: 24 male Zucker rats were fed over 9 weeks either a control diet containing 8 % of fat as corn oil (CO diet) or a n-3 diet containing 7% FO plus 1% CO (FO diet). Food intake was recorded daily and weight gain twice a week. In 12 rats, insulin sensitivity was estimated from both an oral glucose tolerance test (OGTT) and glycaemic response to IP insulin (IPITT). In 12 other rats, hyperinsulinemic-euglycemic clamp plus tritiated glucose infusion were performed to assess both hepatic glucose production and plasma glucose peripheral utilization. Glucose transport in peripheral tissues was determined from infusion of radiolabelled 2-deoxyglucose (2-DOG) during the clamp. Hypothalamus were harvested and analysed for ceramide and diacyglycerol (DAG) quantitation.
Results: At end of week 9, FO had decreased both food intake (- 8.4%, $p< 0.01$) and weight gain (- 6.6%, $p < 0.05$). During OGTT, area under the curve (AUC) of glycaemic response was not altered by FO (FO = 1643 ± 116 vs. CO = 1698 ± 210 mmol.l-1.2h-1) but AUC of insulinaemic response was decreased by 25% (FO = 3009 ± 216 vs. CO = 4006 ± 253 ng.ml-1.2h-1, $p<0.01$). During IPITT, FO induced a greater decrease in glycaemia after insulin injection (glycemia: FO = 8.24 ± 0.62 vs. CO = 11.06 ± 1.51 mM, $p < 0.01$). During clamp, FO did alter neither peripheral glucose utilization nor glucose

transport in tissues but decreased hepatic glucose production by 35% as compared to CO ($p< 0.02$). Ceramide and DAG content did not differ whatever the diet.
Conclusion: These results demonstrate that, in a genetic rat model, where insulin resistance and obesity develop progressively overtime, FO decreased both food intake and weight gain, probably independently from leptin action because Zucker rats are deficient for leptin receptor. Moreover, we demonstrated that FO minimized specifically liver insulin resistance.

Possible effect of endogenous cannabinoids and rimonabant upon insulin resistance and beta cell function

L.E. Flores[1], M.E. Alzugaray[1], A.M. Suburo[2], M.A. Raschia[1], H. Del Zotto[1], M.E. García[1], M.I. Borelli[1], B. Maiztegui[1], V. Madrid[1], M.L. Massa[1], F. Francini[1], J.J. Gagliardino[1];
[1]CENEXA (UNLP-CONICET), La Plata, [2]Facultad de Ciencias Biomédicas, Universidad Austral, Buenos Aires, Argentina.

Background and aims: Obesity produces a decrease in insulin sensitivity and a compensatory increase in β-cell function. Anandamide (AEA, endocannabinoid) regulates appetite and other metabolic functions; thus, drugs interacting with its specific CB1 and CB2 receptors have been used to treat obese people. We studied the possible regulatory role of the general and local (pancreatic islets) cannabinoid system upon insulin secretion in rats with insulin resistance (IR) induced by administration of a fructose-rich diet (FRD).
Materials and methods: Normal male Wistar rats were divided into 4 groups and fed for 21 days as follows: *Control* (C): standard commercial powder diet and tap water *ad libitum*; *Fructose* (F): C plus 10% w/v fructose in the drinking water; *Rimonabant control* (RC): C plus 2 mg/rat Rimonabant; and *Fructose Rimonabant* (FR): RC plus the same amount of fructose as F. Blood samples were drawn at the time of sacrifice to measure glucose, insulin, thiobarbituric acid reactive substances (T-bars) and triglyceride levels. Serum glucose and insulin values were used to calculate insulin sensitivity (HOMA-IR). After sacrifice, pancreases from each animal were removed to isolate islets (collagenase digestion). Expression of insular CB1 and CB2 receptor genes was checked by RT-PCR and immunocytochemistry (confocal microscopy). We measured insulin secretion from isolated islets incubated with 2.8, 8.3 or 16.7 mM glucose with or without 0.1-200 μM AEA, 0.1-20 μM ACEA (CB1 agonist), or 0.1-20 μM JWH (CB2 agonist) (RIA).
Results: The presence of CB1 and CB2 receptors in normal rat islets was demonstrated by RT-PCR and immunocytochemistry. While CB1 receptors were selectively expressed in glucagon-producing cells, CB2 were expressed in both insulin- and somatostatin-producing cells. AEA at 10 μM enhanced significantly the release of insulin induced by 8.3 mM glucose (3.5 ± 1.0 *vs.* 7.4 ± 1.5 ng/islet/h; $p<0.05$), but these effect was observed with 100 μM at 16.7 mM glucose at (8.2 ± 0.7 *vs.* 10.8 ± 0.5 ng/islet/h; $p<0.05$). ACEA and JWH affected insulin secretion in the presence of 16.7 mM glucose in a dual way: they enhanced and inhibited the secretion at 1 μM and at 20 μM, respectively (ACEA: 9.7 ± 0.6, 11.8 ± 0.8 and 6.8 ± 0.8 ng/islet/h at 0, 1 and 20 μM, respectively. JWH: 10.4 ± 0.7, 15.1 ± 1.2 and 6.2 ± 0.8 ng/islet/h at 0, 1 and 20 μM, respectively; $p<0.05$ in all cases). FRD increased significantly daily caloric intake, body weight, serum glucose, triglyceride, T-bars, insulin concentration and IR state ($p<0.05$ in all cases). Rimonabant administration corrected significantly (except T-bars), all these abnormalities ($p<0.05$).
Conclusion: Islets have a specific distribution of CB1 CB2 receptors that modulate insulin secretion. Blockage of the endocannabinoid pathway *in vivo* corrected most metabolic abnormalities and FRD-induced IR.

D-chiro-inositol acts as an insulin mimetic to attenuate epinephrine-stimulated hepatic glucose output in the isolated perfused rat liver

K.M. Loomes[1,2], L. Whiting[1], R.N. Danaher[1], K. Ruggiero[1], T. Mulvey[1], A.R.J. Phillips[1,2];
[1]School of Biological Sciences, University of Auckland, [2]Maurice Wilkin's Centre for Molecular Biodiscovery, Auckland, New Zealand.

Background and aims: D-chiro-inositol is an inositol compound present in comparatively low abundance in vivo compared to its stereoisomer, myo-inositol. Chronic administration of D-chiro-inositol in animal models of diabetes attenuates hyperglycaemia, and in polycystic ovary syndrome, a condition where insulin resistance is a primary feature, D-chiro-inositol administration also improves glucose tolerance and ovulatory function in human patients. The underlying mechanisms and sites of action involved are largely undefined, however, we hypothesised that attenuating effects on hepatic glucose output (HGO) by D-chiro-inositol could potentially explain these observations. Our aim was therefore to investigate whether D-chiro-inositol could in fact modulate HGO in an isolated perfused liver.
Materials and methods: Isolated rat livers (12-15g) from fed animals (220g-250g) were perfused with plasma-free buffer containing 5 mM glucose in a non-recirculating set-up. The perfusion protocol comprised a 40 minute equilibration period followed by a 30 min infusion with either insulin (1 nM), D-chiro-inositol (200 micromolar), myo-inositol (200 micromolar), or saline. Within the background of each of these experimental groups, an epinephrine infusion (50 nM) was then performed for a further 30 minutes. A final glucagon infusion (1.2 nM) was then performed to demonstrate hormonal responsiveness. Glucose, lactate and portal pressure were monitored continuously.
Results: Prior to epinephrine infusion there were no significant baseline differences in HGO between the four experimental groups. In the saline group (n=9), epinephrine evoked an acute (within 2 minutes) and approx. 3-fold increase in HGO that was largely sustained throughout the following 30 min infusion period. As expected, this increased HGO was substantially attenuated in livers co-infused with insulin (n=10). Co-infusion with D-chiro-inositol (n=10) also significantly attenuated epinephrine-stimulated HGO over 30 minutes to a degree intermediate between saline and insulin infusions. HGO in the myo-inositol-infused livers (n=8) also mimicked the attenuating effects of D-chiro-inositol over the first 10 minutes but then stabilised and by 30 minutes was not significantly different from the saline infusion.
Conclusion: These findings show that D-chiro-inositol has an intrinsic site of action on the liver and can reduce epinephrine-stimulated HGO. This insulin mimetic activity provides a potential mechanism by which D-chiro-inositol could mediate some of its observed therapeutic actions in diabetes and polycystic ovary syndrome.

The $VO(dmpp)_2$, a promising insulin mimetic vanadium compound

M. Passadouro[1], E. Carvalho[1], A.M. Metelo[1,2], H. Faneca[1], M.C.P. Lima[1,2], M. Castro[1,2];
[1]Centro de Neurociências de Coimbra, [2]Biochemistry Dept., University of Coimbra, Portugal.

Background and aims: The importance of Vanadium Compounds (VCs) has greatly increased in the last years since they have shown pharmacological properties. In particular, their potential use as oral insulin mimetic has been demonstrated by in vivo and ex vivo studies, as well as in clinical trials. Thus, research has been carried out to develop VCs to be used in the treatment of Diabetes Millitus (DM) at an effective non toxic dose. Type 2 DM and other metabolic syndromes are characterized by insulin resistance originating high plasma insulin and glucose levels due to reduction of insulin action and glucose uptake. In this work we report some biochemical studies with a vanadium complex with a pyridinone ligand, the VO(dmpp)2, concerning glucose uptake in primary cultures of rat adipocytes, to prove its capacity to withdraw insulin resistance in these cells.
Materials and methods: The experiments were carried out with primary cultures of 6-8 weeks old Wistar rat adipocytes. Glucose uptake studies were performed using a radioactive assay by measuring the 14C-glucose in the extracellular medium after 45 minutes incubation with and without insulin, in the presence and absence of different concentrations of VO(dmpp)2 (0.1-

1mM). Alamar Blue test was used to assess cell viability when the adipocytes were incubated with the tested concentrations of the VC.
Results: The results obtained showed that when adipocytes were incubated with VO(dmpp)2 in concentrations of 0.1 mM and 0.5 mM, the increase in glucose uptake relative to basal value was respectively 85% and 131% ($p<0.001$), being the value obtained with insulin alone of 123% ($p<0.001$). Incubations in the presence of 10 nM of insulin, the concentrations of 0.1 mM and 0.5 mM of the VC originated an additional effect of 45% ($p<0.001$) and 32% ($p<0.01$), respectively, above the insulin value. Both concentrations of the VO(dmpp)2 tested are below acceptable cytotoxicity, as demonstrated by the Alamar Blue assay. These results were compared with those obtained with another VC with a similar structure, the BMOV, which is now in clinical trials. This compound also showed a dose dependent response, but none of the concentrations tested (up to 1.5 mM) showed a glucose uptake rate significantly different from basal or close to insulin values, In fact, for the concentration of 1.5 mM, which is the higher response obtained, the glucose uptake value is 33% below the insulin response ($p<0.001$).
Conclusion: Our results demonstrate that VO(dmpp)2, is able by itself to mimic insulin action on glucose uptake in adipocyte tissue. Moreover, when cells are treated with this VC along with insulin, an accumulative effect is observed, being effective at lower concentrations, thus minimizing the toxic effects on cells. Therefore VO(dmpp)2, may represent a major candidate as a powerful drug to treat DM.

PS 30 Insulin sensitivity in adipose tissue and muscle - human studies

513

Adipose tissue expression of retinoic acid receptor-related orphan receptors gamma (RORg) is altered in morbid obesity and insulin resistance

M. Macias Gonzalez[1], J. Vendrell[2], E. Garcia Fuentes[1], F. Tinahones[3]; [1]Laboratorio Medicina Regenerativa, Ciber Fisiopatologia Obesidad Y Nutricion, Malaga, [2]Ciber Diabetes Y Enfermedades Metabolicas, Tarragona, [3]Servicio Edocrinologia, Ciber Fisiopatologia Obesidad Y Nutricion, Malaga, Spain.

Background: Adipose tissue is an active endocrine and paracrine organ due to the production of secreted proteins and lipid indicators collectively called adipokines. These observations have spurred interest in the identification of the transcriptional and other regulatory pathways of adipocyte differentiation. The orphan nuclear receptor, peroxisome proliferator-activated receptor gamma (PPARg) and retinoic acid receptor-related orphan receptors gamma (RORg), are central mediators controlling adipocyte differentiation.
Aims: The aim of the study was to evaluate whether RORg and PPARg mRNA and protein expression levels in human adipose tissues and its relationship with insulin resistance in morbid obese versus non obese patients.
Material and methods: Visceral adipose tissue (VAT) and subcutaneous adipose tissue (SAT) biopsies were obtained from 26 morbidly obese patients undergoing bariatric surgery procedures. VAT and SAT samples were also obtained from otherwise non obese patients during surgical repair of hiatus hernias. RORg and PPARg mRNA and protein expression levels were measured in the tissues obtained by quantitative RT-PCR and western blotting respectively. The MO patients were divided into two groups: those with a low homeostasis model assessment of insulin resistance (HOMA-IR<5) (MO nonIR) and those with a high HOMA-IR (HOMA-IR≥8) (MO-IR).
Results: RORg mRNA and protein expression in VAT was significantly higher in the MO patients ($P<0.05$) than the non obese subjects, but there were no significant differences between the expression of PPARg in MO patients in comparison with non obese subjects. In addition, PPARg mRNA and protein expression levels were similar in VAT and SAT from the MO patients and not dependent on IR. In contrast, the RORg mRNA expression was higher in VAT ($P<0.05$), in the MO-IR than the MO nonIR group. Finally, the MO patients showed a significant positive correlation between mRNA and protein RORg expression and insulin resistance in VAT ($r=0.357$, $p=0.045$) and in SAT ($r=0.396$, $p=0.030$).
Conclusion: Expression of RORg, is up regulated in morbid obesity and showed to be related with the insulin resistance. Future studies are warranted to elucidate the role of this orphan nuclear receptor in the pathogenesis of insulin resistance in morbid obesity

Investigating *PTEN* expression in tissues of insulin action illustrates reduced mRNA expression in adipose tissue of patients with type 2 diabetes

L.J. McCulloch, M. Neville, J.P. Grew, M.I. McCarthy, A.L. Gloyn; Oxford Centre for Diabetes, Endocrinology & Metabolism, University of Oxford, United Kingdom.

Background and aims: Phosphatase and tensin homologue deleted on chromosome 10 (PTEN) is a critical regulator of cell growth and metabolism via its antagonisation of PI3K and control of the AKT/PKB pathway. Insulin signalling utilises the AKT pathway and this has generated interest in the tissue specific roles of PTEN in glucose homeostasis. Murine studies have shown that *Pten* is expressed in pancreatic islets, liver, muscle and adipose tissue. Tissue specific Pten deletion in both muscle and adipose tissue of mice leads to insulin hypersensitivity and protection against diabetes. We hypothesised that PTEN plays a critical role in tissues of insulin action in humans and that elevation of *PTEN* mRNA in both adipose tissue and muscle may contribute to the insulin resistance seen in patients with Type 2 diabetes (T2D).
Materials and methods: *PTEN* expression in human tissues (including liver, muscle, adipose tissue, pancreatic islets) was determined. Adipose tissue (omental & subcutaneous) was available for 16 patients (9 male, 8 female)

with T2D and 16 age, gender & BMI matched normoglycaemic controls. Muscle tissue was available from 3 patients with T2D and 3 age, gender & BMI matched controls. RNA was extracted from all tissues using TRI reagent, cDNA synthesised from a total of 2ug RNA and *PTEN* expression determined on an ABI7900HT system. Analysis was performed using the ΔΔCt method, normalising to 2 housekeeping genes (UBC & PPIA) and significance determined using a paired t-test.
Results: *PTEN* is highly expressed in human tissues of insulin secretion and action (liver, adipose tissue, muscle, islets). *PTEN* expression is reduced 1.48 fold (35%) in the subcutaneous adipose tissue of T2D subjects when compared to matched controls ($p = 7.9x10^{-4}$). Further analysis demonstrated that this reduction is more pronounced (1.57 fold, $p=4.7x10^{-3}$) in T2D males compared to T2D females (1.39 fold, p=0.07). *PTEN* expression was also reduced 1.3 fold in the omental adipose tissue of diabetic subjects, although this did not reach statistical significance (p=0.06). Gender specific analysis in this depot however reveals that there is a 1.55 fold (36%) reduction in *PTEN* expression in the T2D males (p=0.02) when compared to controls. Our data indicates there is only a minimal 1.06 fold reduction between T2D females and matched controls at the level of omental adipose tissue (p=ns). No difference in *PTEN* expression was seen in muscle, although numbers are currently limiting (n=3).
Conclusion: We have demonstrated that *PTEN* gene expression is reduced in adipose tissue from patients with T2D when compared with matched controls and suggests that the reduction in both fat depots may be more pronounced in males. Our data are in conflict with our initial hypothesis and suggests that there are compensatory mechanisms in adipose tissue whereby *PTEN* is down regulated to maximise insulin stimulated glucose uptake in this depot. Replication of our finding is required in further datasets along with studies to confirm that PTEN protein expression is also reduced.

Insulin resistance is induced by endoplasmic reticulum stress in the human adipocytes
C.J.H. van der Kallen[1,2], M.M.J. van Greevenbroek[1,2], M.G. Robertus[1,2], M. Wabitsch[3], C.D.A. Stehouwer[1,2], C.G. Schalkwijk[1,2];
[1]Dept of Internal Medicine, Maastricht University, Netherlands, [2]CARIM, Maastricht University, Netherlands, [3]Division of Pediatric Endocrinology and Diabetes, University of Ulm, Germany.

Background and aims: Obesity is associated with insulin resistance and type 2 diabetes. However, the mechanisms linking these pathologies remain not completely understood. Recent studies in rodent models revealed endoplasmic reticulum (ER) stress in adipose and liver tissues and demonstrated that ER stress could cause insulin resistance. Morover, studies in human adipose tissue suggest a relationship between obesity-related ER stress and metabolic dysfunction in obese humans, such as insulin resistance. The aim of this study was to test the effect of ER stress on insulin resistance in human adipocytes.
Materials and methods: In this study we used a human preadipocyte cell strain derived from subcutaneous white adipose tissue of a patient with Simpson-Golabi-Behmel syndrome (SGBS). The SGBS cell strain exhibits a high capacity for adipose differentiation, resulting in mature fat cells which are biochemically and functionally similar to human adipocytes. Differentiated SGBS cells were incubated with (or without) thapsigargin for 1, 2, 4, 6, or 18 hours to induce ER stress. ER stress in our system was monitored by an increase in the protein expression of GRP94 and GRP78. Insulin sensitivity was measured as induction of Akt phosphorylation by 100 nM insulin for 15 min (at the end of 1, 2, 4, 6 or 18 hours incubations). The readout of insulin sensitivity is determined by the ratio phosphorylated AKT (phospho-Akt) vs Akt (ratio phospho-Akt/Akt).
Results: Thapsigargin induced ER stress, as measured by a 1.2 to 2.3 fold increase in GRP78 and 1.1 to 1.3 fold increase in GRP94. Insulin induced Akt phosphorylation at all time points (1.4 to 2.6 fold increase in phospho-Akt/Akt ratio). After 1, 2, 4, 6 hours of incubation with thapsigargin, insulin-induced Akt phosporylation was 1.3 fold higher compared to incubations without thapsigargin, suggesting improved insulin sensitivity. In contrast, a 18 hours incubation of cells with thapsigargin, reduced the effect of insulin on Akt phosphorylation compared to incubations without thapsigargin with 28%, indicating an induction of insulin resistance.
Conclusion: In human adipocytes (SGBS cells), short term induction of ER stress cells, resulted in an increase in insulin sensitivity, while adipocytes exposed to ER stress for a long period showed insulin resistance. This SGBS adipocyte model may be a useful tool to study the role of ER stress in human adipocyte biology.

Regulation of plasma metabolome and subcutaneous adipose transcriptome by insulin in the clamp study
O. Pivovarova[1,2], L. Willmitzer[3], A.F.H. Pfeiffer[1,2], V.J. Nikiforova[3,4], N. Rudovich[1,2];
[1]Department of Clinical Nutrition, German Institute of Human Nutrition Potsdam-Rehbruecke, Nuthetal, [2]Department of Endocrinology, Diabetes and Nutrition, Charité University Medicine, Campus Benjamin Franklin, Berlin, [3]Department of Molecular Physiology, Max Planck Institute of Molecular Plant Physiology, Potsdam, Germany, [4]Timiryazev Institute of Plant Physiology, Moscow, Russian Federation.

Background and aims: Insulin, the dominant anabolic hormone, suppresses endogenous glucose production, stimulates glucose utilization by insulin-sensitive tissues and inhibits the lipolysis in fat. Few studies describe insulin-dependent transcriptome changes and no data exist for metabolome. In this pilot study we examined acute insulin effects on plasma metabolites and subcutaneous adipose tissue (SAT) transcriptome under clamped euglycemia and hyperglycemia.
Materials and methods: Healthy obese men (n=14) underwent a placebo infusion test (0.9% NaCl-infusion for 4 h) and/or a hyperinsulinemic, euglycemic clamp (EC), and/or a hyperinsulinemic, hyperglycemic clamp (HC). SAT biopsy and plasma samples were taken at -40 min and 240 min of the tests. Full human genome Agilent chips were used for transcript profiling, and GC/MS analysis was applied to get the metabolome of plasma. An explorative analysis of insulin-induced changes with calculating 240 to basal ratio was conducted. We proposed "non-changed values" as range of 1.2 to 0.8 in these ratios with p>0.06. To evaluate a trend of changes, we estimated the proportion of up and down regulated genes and metabolites ("up-to-down ratio").
Results: The highest insulin and blood glucose levels were observed in the HC test (p<0.001). In EC, insulin levels were higher then these of placebo tests under similar blood glucose levels.

Plasma metabolome and SAT transcriptome changes

Tests	Metabolites changes (%), n_{total}=3199	Up-to-down ratio	Gene expression changes (%), n_{total}=38662	Up-to-down ratio
Placebo infusion	2.15	0.19	2.80	1.72
EC	16.30	0.025	3.50	2.82
HC	15.75	0.66	4.01	3.20

Conclusion: Insulin down regulates a big portion of plasma metabolome under euglycemia, while simultaneous expressional changes are only minor. This observation reflects possible prevalence of stoichiometric-driven changes in insulin-dependent metabolome.

Level of TLR-4, IL-6, TNF-*a*, but not TLR-2 was elevated in skeletal muscles from non-obese subjects with impaired glucose tolerance (IGT) compared to normal subjects
S.-E. Choi[1], E.-S. Ha[1], S. Han[1], H. Kim[1], D. Kim[1], Y. Kang[2], K.-W. Lee[1];
[1]Endocrinology and Metabolism, Ajou University School of Medicine, [2]Institute for Medical Science, Ajou University School of Medicine, Suwon, Republic of Korea.

Background and aims: In obese subjects and type 2 diabetes, insulin resistance has been shown to be associated with chronic inflammatory states. Recent studies have suggested that Toll-like receptors, which are components of the innate immune system, and inflammatory signals may play a critical role in saturated fatty acid-induced insulin resistance in skeletal muscles of obese subjects and type 2 diabetes. However, the relation between inflammation and insulin resistance has not been intensively studied in non-obese patients with IGT. In this study, we investigated TLR gene expression, inflammatory cytokine, and insulin signaling in skeletal muscles from non-obese patients with IGT.
Materials and methods: Ten IGT subjects and 15 control subjects were recruited for this study. Whole-body insulin-mediated glucose uptake was de-

termined using a euglycemic hyperinsulinemic clamp test. Muscle biopsies were obtained from the vastus lateralis muscle before and after insulin stimulation. Next we determined TLR gene expression, levels of several inflammatory cytokine, and insulin signaling using immunoblotting.
Results: Subjects with IGT had significantly higher fasting blood glucose and HbA1c levels in comparison with control subjects. Total-cholesterol, triglyceride, and high-density lipoprotein levels were not significantly different between the groups. Insulin stimulated glucose infusion rates were 39% lower in the IGT group than the control group (control: 7.33 + 0.5 vs. IGT: 4.54+ 0.6, $p < 0.01$). Also the activity of insulin signaling molecules such as IR-β, IRS-1, AKT, and GSK-3β were reduced in the IGT group compared to the control group. To investigate involvement of inflammation in skeletal muscle from non-obese subjects with IGT, we measured levels of TLR-2, TLR-4, IL-6, and TNF-α. Interestingly, the level of TLR-4 significantly increased by 200% in the IGT group. But TLR-2 did not. Increased level of IL-6 and TNF-α were 600% and 200%, respectively, in the IGT group compared to the normal group. We then investigated intracellular signaling molecules related with inflammation. Phosphorylation of NFκB, mTOR, and STST3 were observed in the IGT group compared to the control group. But phosphorylation of JNK, p38 and ERK did not.
Conclusion: Levels of TLR-4, IL-6, and TNF-α were increased in skeletal muscles of non-obese subjects with IGT compared to normal subjects. Our data suggested that inflammation may associate with insulin resistance in non-obese subjects with IGT, as well as obese subjects.

Histone variant H2A.Z is enriched in the vicinity of the transcriptional start site of insulin-modulated genes. A possible epigenetic link to insulin-dependent transcription
L. Pirola, A. El-Osta;
Baker IDI Heart and Diabetes Institute, Melbourne, Australia.

Background and aims: Besides its metabolic effects, insulin controls gene expression in insulin-responsive tissues. In insulin resistance, extensive transcriptional alterations occur in skeletal muscle and adipose tissue, due to impaired insulin signalling. As insulin-dependent transcriptional control is regulated by the mutual interplay between the transcriptional machinery and its chromatin template, we sought to investigate whether known insulin-regulated genes bear specific chromatin signatures using L6 myotubes as a model system.
Materials and methods: Differentiation of L6 cells was carried out under normoglycaemic conditions (5.5 mM glucose). Fully differentiated myotubes were incubated for 6 hours in the presence of 100 nM insulin or 100 nM insulin in 25 mM glucose containing medium. Gene expression levels were compared to unstimulated myotubes in normoglycaemic conditions. Primer pairs around the hexokinase 2 (HK2) transcriptional start site (TSS) spanned a region from - 4000 bp to +500 bp. Primers for genes of the insulin signalling cascade were designed within 1 kb from the start codon. Chromatin immunoprecipitation (ChIP) was performed with antibodies directed to H2A, H2A.Z and acetylated H3K9/14. mRNA levels and DNA enrichment in ChIP were measured by real time PCR.
Results: As a paradigm for insulin-regulated genes in L6 myotubes we studied HK2, insulin receptor substrate 1 (IRS1) and IRS2. HK2 mRNA was increased > 2-fold following 6-hours insulin stimulation, while IRS1/2 mRNAs were downregulated. ChIP to H2A and H2A.Z showed that the histone 2A variant H2A.Z is specifically accumulated around the TSS of insulin modulated genes, including HK2, IRS1, IRS2. By contrast, H2A.Z enrichment was not observed distally to the TSS (i.e. 4 kb upstream) in the HK2 promoter, nor in the vicinity of the TSS in the HPRT1 housekeeping gene. The ratio between H2A and H2A.Z deposition was not sensibly affected by insulin treatment. However, H2A.Z deposition along the HK2 gene positively correlated with H3K9/14 acetylation levels, both in the basal and in the insulin-stimulated condition, in which H3K9/14 acetylation was further enhanced. Whether H2A.Z also coordinates the occurrence of other histone post-translational modifications on insulin-regulated genes, such as transcriptionally-promoting H3K4 methylation and transcriptionally-repressive H3K9 methylation, is currently under investigation.
Conclusion: Our findings on a selected subset of insulin-responsive genes in L6 myotubes suggest that they bear a common "epigenetic signature", consisting in enrichment of the H2A.Z histone variant around the TSS. We hypothesize that enriched H2A.Z deposition may be instrumental in conferring insulin-responsiveness to these genes, by facilitating the occurrence of histone post-translational modification. As an example we show a correlation between increased H2A.Z deposition along the HK2 gene and increased H3K9/14 acetylation following exposure to insulin. Further investigation is warranted to determine whether H2A.Z deposition may be dysregulated in insulin resistance and type 2 diabetes.
LP has been supported by the Franco-Australian INSERM-NHMRC cooperation programme

Insulin and glucose promote expression of CD36 and phagocytosis of oxidized-LDL in monocytes from lean insulin sensitive and obese insulin resistant subjects
M. Sarigianni[1], K. Paletas[1], A. Tsapas[1], M. Kaloyianni[2], K. Topouridou[3], G. Koliakos[3];
[1]Metabolic Diseases Unit, 2nd Department of Internal Medicine Clinic, Aristotle University, Medical School, [2]Laboratory of Animal Physiology, Department of Zoology, Aristotle University, Biology School, [3]Department of Biological Chemistry, Aristotle University, Medical School, Thessaloniki, Greece.

Background and aims: Obesity and insulin resistance are atherosclerosis risk factors and commonly associate with hyperinsulinemia and hyperglycemia. Expression of CD36 on monocytes and phagocytosis of oxidized-LDL are an essential part of the process of atherosclerosis. The aim of the present study was to investigate whether insulin sensitivity associate with the atherosclerotic properties of monocytes in lean and obese with or without insulin resistance subjects in the environment of hyperinsulinemia and hyperglycemia.
Materials and methods: Monocytes were isolated from whole blood of 8 lean insulin sensitive, 6 obese insulin resistant and 6 obese insulin sensitive subjects. Insulin sensitivity was estimated with euglycemic hyperinsulinemic clamp. For the estimation of CD36 scavenger receptor density on monocytes surface, a fluorescein isothiocyanate (FITC)-linked monoclonal antibody was used. LDL was oxidised and labeled with DiI towards DiI-oxi-LDL and phagocytosis from monocytes was estimated through the measurement of fluorescence after 1h and 3h of incubation. All experiments were repeated after pre-incubation of monocytes with insulin or glucose. The SPSS 15.0 was used for the statistical analysis.
Results: The 3 groups did not differ in the age ($p=0.9$) but there was significant difference in BMI (Kg/m^2) (20.3± 0.9 lean, 32.1±0.9 insulin sensitive obese and 33.3±1.4 insulin resistant obese) and glucose disposal rate (mg/Kg*min) (10.9±1 lean, 7.1±1.5 insulin sensitive obese and 2.3±1.5 insulin resistant obese). The surface density of CD36 on monocytes after incubation with glucose was increased in the groups of the lean ($p=0.035$) and the obese insulin resistant ($p=0.002$) subjects compared to the control samples. The same result was observed when monocytes were pre-incubated with insulin ($p=0.004$, lean subjects and $p=0.006$, obese insulin resistant subjects). Phagocytosis of oxi-LDL in lean subjects increases after monocyte incubation for 1h and 3h with glucose ($p=0.02$ and $p=0.032$, respectively) and with insulin ($p=0.015$ and $p=0.041$, respectively) compared to the control samples. In the obese insulin sensitive subjects an increase was observed only after 1h of monocyte incubation with glucose and insulin ($p<0.001$) while in obese insulin resistant patients phagocytosis of oxi-LDL was increased after 1h of monocyte incubation with insulin ($p=0.027$) and after 3h with glucose ($p<0.001$). A correlation between insulin sensitivity and CD36 surface density (Spearman's rho=0.343, $p=0.026$) and oxi-LDL phagocytosis (Spearman's rho=0.578, $p<0.001$), after monocyte incubation with insulin, was observed.
Conclusion: Insulin and glucose can influence CD36 surface density and oxi-LDL phagocytosis on human monocytes and an association between these properties and insulin sensitivity was observed in the hyperinsulinemic state. The differences noted among obese insulin sensitive subjects could be attributed to a cofounding factor possibly associated with the maintenance of "inappropriate" (according to their obesity) insulin sensitivity.

Insulin and GH signalling in human skeletal muscle *in vivo* following exogenous GH exposure: impact of an oral glucose load

T. Krusenstjerna-Hafstrøm, M. Madsen, M. Vendelbo, N. Jessen, N. Møller, J.O.L. Jørgensen;
Medical Department M (Endocrinology and Diabetes), Aarhus University, Denmark.

Background and aims: GH acutely induces insulin resistance in skeletal muscle in vivo but the underlying molecular mechanisms remain unknown. We tested the hypothesis that GH suppresses glucose-stimulated insulin signalling pathways
Materials and methods: Eight healthy young men (age 25 +/- 2 yrs) were studied in a single-blinded, randomised, crossover design. Each subject was studied in the morning after an overnight fast on three different days: 1) after an intravenous GH bolus (0.5 mg), 2) after an intravenous GH bolus plus and oral glucose load (75 g.), and 3) after intravenous saline plus oral glucose. Muscle biopsies were obtained at 0 min, 30 min, 60 min, 120 min and blood samples at regular intervals during each study day.
Results: GH increased $AUC_{glucose}$ (P= 0.05) without significant changes in blood insulin levels. GH induced phosphorylation of STAT5b independently of oral glucose intake. Conversely, oral glucose induced phosphorylation of the insulin signalling proteins Akt and AS160 independently of GH exposure.
Conclusion: 1) Insulin signalling pathways in human skeletal muscle in vivo are acutely activated by an oral glucose load. 2) A physiological GH bolus activates STAT5b signalling pathways acutely in skeletal muscle irrespective of ambient circulalting glucose and insulin levels.3) GH-induced insulin resistance in human subjects does not seem to be mediated by down regulation of insulin signalling pathways.

Influence of insulin kinetics on the post receptor signal transduction of insulin in patients with type 2 diabetes

A. Weise[1], E. Pfützner[2], A. Krasner[3], F. Flacke[3], M.M. Weber[2], S.S. Steiner[3], T. Forst[1], A. Pfützner[1];
[1]R&D, IKFE Institute for Clinical Research and Development, Mainz, Germany, [2]University Hospital, Mainz, Germany, [3]Biodel Inc., Danbury, United States.

Background and aims: Next to its glucose lowering effects, insulin also exerts a specific activity when binding to insulin receptors on the endothelial cell. The nature of these effects is dependent on the insulin concentration and the degree of resistance of the insulin receptor. Dependent on the underlying conditions, insulin can lead to cardio-protective production of nitric-oxide or can induce atherogenic growth hormone effects. This pilot study was performed to investigate the impact of insulin pharmacokinetics on vaso-protective and atherogenic insulin signal transduction pathways in patients with type 2 diabetes mellitus.
Materials and methods: Seven patients with type 2 diabetes who participated in a prospective, randomized three-way crossover study could be included into this analysis (5 male, 2 female, age: 63±7 yrs., HbA1c: 7.1±0.6 %, BMI: 30.1±3.3 kg/m²). They received an individually calculated dose of regular human insulin (RHI) to cover a standardized liquid meal, or 90 % of this dose as the fast-acting insulin analog lispro (LP) and the ultra-rapid regular human insulin VIAject (VJ) on separate occasions. Next to glucose measurement, the mRNA of peripheral circulating monocytes, used as indicator cells for the endothelial insulin response, was isolated and subjected to quantitative determination of the expression of eNOS (anti-oxidative insulin effect) and MAPK-1 (atherogenic/growth hormone effect of insulin) by means of the LightCycler real-time PCR technology at 0, 30, 60, 90, 120 and 180 min.
Results: There was no difference in postprandial glycemic control between the three treatment arms. Treatment with RHI was associated with indications of atherogenic activity: increased postprandial expression of MAPK-1 (AUC of changes from baseline (0-240min): 80±124 AU), and decreased eNOS expression (-177±268 AU). In contrast, VJ showed a vasoprotective expression profile (MAPK-1: -50±78 AU, p<0.05 vs. RHI, eNOS: 98±134 AU, p=0.063). Intermediate results were obtained with LP (MAPK-1: 24±78 AU, p=0.084 vs. VJ, eNOS: -10±31 AU, p<0.05 vs. VJ).
Conclusion: In this pilot experiment, treatment with the ultra-fast regular human insulin formulation VIAject resulted in an improved endothelial function profile independent of glycemic control, while regular human insulin had atherogenic effects. These results suggest that the pharmacokinetic profile of insulin may have a major influence in the control of vasoprotective vs. atherogenic effects of insulin in patients with type 2 diabetes mellitus. Our results may be of help for the interpretation of recent outcome study results with insulin.

AICAR stimulats insulin signalling pathway independent of AMPK activation in L6 myotubes

Z. Zhou, S. Huang, Y. Wang, Y. Leng;
Shanghai Institute of Materia Medica, Chinese Academy of Sciences, China.

Background and aims: AICAR is widely used as a pharmacological activator of AMPK and has been reported to increase glucose uptake and improve insulin sensitivity in skeletal muscle by activation of AMPK. Here, we observed the incremental effect of AICAR on insulin signaling pathway independent of AMPK activation in L6 myotubes.
Materials and methods: 2-deoxy [^{3}H] glucose uptake was performed in L6 myotubes to examine the effect of AICAR in the presence or absence of compound C or/and wortmanin under both basal and insulin stimulated states. Phosphorylation of AMPK and Akt were detected by western blot. Tyrosine phosphorylation of IR and IRS1 were detected by immunopricipitation. RNA interference was performed to silence AMPK gene expression.
Results: AICAR increased basal or insulin stimulated glucose uptake in L6 myotubes. The AICAR enhanced glucose uptake under basal condition could not be suppressed by preincubation with either compound C or wortmanin, but could be fully blocked by the combination of compound C and wortmanin. AICAR increased Akt phosphorylation in L6 myotubes with a time and dose dependent manner, and this effect could not be blocked by pretreatment with compound C or AMPK silencing using *si*RNA, which suggested that AICAR stimulated Akt phosphorylation independent on AMPK activation. Moreover, AICAR dose dependently increased tyrosine phosphorylation of IR and IRS1, which suggested that AICAR could activate insulin signaling pathway.
Conclusion: ACIAR could activate insulin signaling pathway independent on AMPK activation in L6 myotubes. The enhanced glucose uptake induced by AICAR might be not only due to the activation of AMPK, but also the activation of insulin signaling pathway.

Gender effect on insulin sensitivity and secretion in different categories of glucose tolerance

A. Kautzky-Willer[1], A.R. Brazzale[2], A. Tura[3], J. Vrbikova[4], B. Bendlova[4], E. Moro[5], G. Pacini[3];
[1]Internal Medicine III, Medical University of Vienna, Austria, [2]Social Cognitive Quantitative Sciences, University of Modena and Reggio Emilia, Italy, [3]Metabolic Unit, ISIB-CNR, Padova, Italy, [4]Institute of Endocrinology, Prague, Czech Republic, [5]Internal Medicine, Regional Hospital, Venice, Italy.

Background and aims: It is not yet clear whether parameters on insulin resistance and insulin secretion extracted from metabolic tests depend upon the sex of the subject. With this study, we aimed to evaluate the gender effect on insulin sensitivity and beta cell function in a large population of subjects divided according to main categories of glucose tolerance. Gender effect was assessed after having accounted for age and body mass index (BMI).
Materials and methods: A total of 2130 subjects of both genders (F=females; M=males) were studied with a 3h-75g oral glucose tolerance test (OGTT) with samples every 30 min. Subjects were divided into three categories according to their fasting and 2h glucose level: normal tolerance (NGT; 611/362 F/M; age 37±1/40±1 (mean±SE) [range 10-77] years; BMI=25.6±0.2/25.9±0.2 [16.3-57.3] kg/m^2; fasting glucose, G_b 4.7±0.02/4.9±0.02 mmol/l; fasting insulin, I_b 52±1/56±2 pmol/l); impaired fasting glucose or glucose tolerance (IGM; 301/441; age 55±1/54±1 [11-78]; BMI 28.6±0.3/27.5±0.2 [15.5-53.0]; G_b 6.1±0.03/6.2±0.02; I_b 74±3/73±2) and type 2 diabetes (T2D; 180/235; age 60±1/58±1 [25-79]; BMI 28.9±0.4/28.2±0.3 [17.3-62.9]; G_b 7.4±0.09/7.3±0.06; I_b 92±5/92±5). From OGTT data, we calculated the insulinogenic index as beta cell function [BCF=$(I_{30}-I_b)/(G_{30}-G_b)$, where I_{30} and G_{30} are insulin and glucose measured at 30 min], insulin sensitivity [IS=10000/$\sqrt{(I_b \times G_b \times \text{mean(I)} \times \text{mean(G)})}$, Matsuda Index] and glucose clearance (OGIS from mathematical modeling). Statistical analysis was a pooled analysis of 3 homogeneous data-sets performed using multiple regression, ANOVA and 2-sample t-test in suitably defined strata.
Results: BCF is reduced with age and increased with BMI independently of the tolerance category and sex ($p<0.0001$). Taken all together, BCF is higher in F than in M (103±6 *vs.* 79±10 pmol/mmol, $p<0.001$) after having accounted for age and BMI. Precisely, F have a significantly higher BCF only in NGT ($p<0.0001$), while BCF was not different by sex in IGM ($p=0.11$) and T2D ($p=0.30$). IS is markedly reduced with increasing BMI in every category ($p<0.0001$), while it does not change with sex ($p=0.46$) and age ($p=0.14$). When the gender effect is evaluated, after having accounted for age and BMI, F have a higher IS only in NGT (7.2±0.2 *vs.* 6.7±0.3, $p=0.015$), being $p=0.68$ in IGM and $p=0.21$ in T2D. OGIS depends upon age and BMI, decreasing when they augment ($p<0.001$), but only marginally related to sex ($p=0.081$). When dividing into categories, again, the difference between sex is observed only in NGT (F 473±3 *vs.* M 454±3 ml/min/m^2, $p<0.005$), being $p=0.66$ in IGM and $p=0.18$ in T2D.
Conclusion: Beta cell function is highly dependent on age and BMI, while sex related differences are present only in NGT. Also insulin sensitivity, highly dependent on BMI, is higher in F than in M only in NGT, when calculated accounting for age and BMI. In general, beta cell function and insulin sensitivity are influenced by gender only in individuals with normal glucose tolerance; with deterioration of metabolic control, as observed in impaired tolerance and type 2 diabetes, the effect of gender vanishes.

Association of elevated serum ferritin concentration with insulin resistance and impaired glucose metabolism in Koreans

C.-H. Kim[1], H.-K. Kim[2], J.-Y. Park[3], K.-U. Lee[3];
[1]Internal Medicine, Soonchunhyang University Bucheon Hospital, Kyeonggi-do, [2]Health Promotion Center, Asan Medical Center, Seoul, [3]Internal Medicine, University of Ulsan College of Medicine, Seoul, Republic of Korea.

Background and aims: Iron overload in patients with hemochromatosis or hematologic diseases, is reported to be associated with insulin resistance and development of diabetes. However, data concerning relationship between serum ferritin levels and glucose metabolism abnormalities in non-pathologic conditions are scanty. This study investigated the association of serum ferritin levels with insulin resistance and impaired glucose metabolism.
Materials and methods: We analyzed the clinical and laboratory data of 12,090 subjects (age 18-90 years, 6,387 men and 5,703 women) who underwent routine medical check-ups. Those included 1,084 subjects with type 2 diabetes (DM), 3,783 with impaired fasting glucose (IFG), and 7,223 with normal fasting glucose (NFG). Serum ferritin, HbA1c, fasting glucose, and insulin levels were measured. Insulin resistance (HOMA-IR) and beta-cell function (HOMA%B) indices were derived from homeostasis model assessment.
Results: Since the average serum levels of ferritin was higher in men than in women, we analyzed the data of men and women separately. Ferritin concentrations were the highest in DM group, followed by the IFG group, and the NFG group in both men and women (160 ± 98, 181 ± 116, 195 ± 139 ng/ml, respectively, in men; 59 ± 54, 76 ± 60, 91 ± 66 ng/ml, respectively, in women; $p < 0.01$ for all). In multiple regression analysis, serum ferritin levels were associated with BMI, waist circumference, fasting glucose, serum triglycerides, aspartate aminotransferase, alanine aminotransferase (ALT), gamma-glutamyl transferase (GGT), high sensitivity CRP (hsCRP), and HOMA-IR in men. In women, age, fasting glucose, triglycerides, ALT, GGT, and hsCRP levels were related to serum ferritin concentration. After adjustment for age, BMI, waist circumference, and blood pressure, the odds ratio (OR) for T2DM, comparing the fourth quartile of ferritin with the first quartile, was 1.60 (95% confidence interval 1.29-1.99) in men and 1.40 (0.98-2.01) in women. In men, after further adjustment for ALT, GGT, triglyceride, and hsCRP, the OR was attenuated to 1.28 (1.02-1.61). In non-diabetic subjects, after adjustment for age, BMI, waist circumference, and blood pressure, OR for IFG in the fourth quartile of ferritin was 1.64 (1.40-1.92) in men and 1.68 (1.39-2.03) in women. After further adjustment for ALT, GGT, triglyceride, and hsCRP, the OR was slightly attenuated to 1.36 (1.15-1.61) for men, and 1.52 (1.25-1.85) for women. In NFG subjects, the OR for metabolic syndrome in the fourth quartile of ferritin after adjustment for age and BMI, was 1.99 (1.36-2.92) in men and 1.19 (0.80-1.76) in women. In men, after further adjustment for ALT, GGT, and hsCRP, the OR was slightly attenuated to 1.61 (1.08-2.41).
Conclusion: Increased serum level of ferritin was associated with insulin resistance, type 2 diabetes, IFG, and metabolic syndrome in men, but only with IFG in women. These results suggest that iron overload is strongly associated with insulin resistance in men, but not clearly in women.

525

Ferritin concentrations, type 2 diabetes, metabolic syndrome and insulin resistance in a Chinese population

Y. Ren, Y.Y. Liu;
Division of Endocrinology and Metabolism, West China Hospital of Sichuan University, Chengdu, China.

Background and aims: Inflammation may play a key role in the development of Diabetes Mellitus (DM), metabolic syndrome and insulin resistance. High level of the acute phase reactant ferritin has been reported to positively correlate with DM and insulin resistance. In this study we examined the association among serum ferritin concentrations, DM, metabolic syndrome and insulin resistance in a Chinese population in Sichuan province.
Materials and methods: We conducted a cross-sectional study in 3040 subjects over 18 years old from three communities in Sichuan province. Serum ferritin concentrations, glucose tolerance status, plasma lipids, alanine aminotransferase, aspartate aminotransferase, uric acids and creatinine were determined in all subjects. Blood pressure, BMI and waist circumferences were also measured. Metabolic syndrome was diagnosed using the IDF criteria.
Results: Individuals with newly diagnosed diabetes, previously diagnosed diabetes and prediabetes (including IGT and IFG) had elevated serum ferritin concentrations compared with those of normal glucose tolerance (191.13±114.96μg/l vs. 184.63±109.51μg/l vs. 164.77±116.25μg/l vs. 119.58±97.57μg/l, $P<0.05$). After adjusting for age, race, BMI, smoking, alcohol consumption, activity, family history, education, residential district, waist circumferences, waist-to-hip ratio (WHR), blood pressure, plasma lipids and uric acids, (the odds ratio of prediabetes and DM was 1.54 (95% CI: 1.08-2.19) in men with ferritin concentrations ≥300μg/l and was 1.80 (95% CI: 1.36-2.39) in women with ferritin concentrations ≥150μg/l, respectively.) the odds ratio of prediabetes and diabetes was 1.46 (95% CI 1.05-2.03) in men with elevated ferritin concentrations in the highest quartile (≥271.1μg), and 1.76 (95% CI 1.34-2.33) in women with elevated ferritin concentrations(≥141.5μg).

The prevalence of metabolic syndrome in subjects with serum ferritin concentrations in the highest quartile was significantly higher than those whose serum ferritin concentrations were in the lowest quartile, either in men (32.2% vs 10.1%, P<0.001) or women (38.8% vs 10.7%, P<0.001). After adjusting for age, race, BMI, smoking, alcohol consumption, activity, family history, education and residential district, the odds ratios of metabolic syndrome in subjects with serum ferrtin concentrations in the highest quartile were 1.71 (95% CI 0.92-3.19) in men and 1.67 (95% CI 1.03-2.70) in women when compared with those in the lowest quartile. In all subjects, the serum ferritin concentrations increased gradually with the increasing numbers of co-existing metabolic components accordingly (P<0.001). This positive relationship between the numbers of co-existing metabolic components and serum ferritin concentrations remained significant when male and female subjects were analyzed separately (P<0.001). A positive association was found between serum ferritin concentrations and HOMA-IR. HOMA-IR (≥1.98) was associated with a higher level of ferritin and uric acid.
Conclusion: Serum ferritin concentrations increased remarkably in diabetic patients, and elevated serum ferritin concentrations were associated with an increased risk of prediabetes(including IGT and IFG) and diabetes. Furthermore, we found a positive association between serum ferritin concentrations and metabolic syndrome. Also elevated level of ferritin was positively associated with insulin resistance.

526

Independent association between the renin angiotensin aldosterone system and insulin resistance

A. Tomaschitz[1], S. Pilz[1], B.R. Winkelmann[2], B.O. Boehm[3], W. Maerz[4];
[1]Internal Medicine, Medical University of Graz, Austria, [2]Cardiology Group, Frankfurt-Sachsenhausen, Germany, [3]Department of Medicine/Division of Endocrinology, University Hospital Ulm, Germany, [4]Clinical Institute of Medical and Chemical Laboratory Diagnostics, Medical University of Graz, Austria.

Background and aims: The nonsuppressed activity of the Renin Angiotensin Aldosterone System (RAAS) in the presence of high salt diet is increasingly implicated to play a key role in the development and progression of insulin resistance (IR). With the present analysis, we aimed to investigate the impact of plasma renin (PRC), aldosterone (PAC) and angiotensin 2 (ang2) concentrations on IR in a large cohort of patients (on usual western diet) of type 2 diabetic and nondiabetic individuals referred to coronary angiography.
Materials and methods: We performed multivariate adjusted statistical analysis to investigate the cross-sectional relations between mediators of the RAAS to IR. IR was assessed from fasting insulin and glucose levels and the validated homeostasis model assessment (HOMA-IR). We measured plasma renin (PRC), angiotensin2 (ang2) and aldosterone concentrations (PAC) reflecting systemic RAAS as wells as several circulating biomarkers reflecting inflammation (CRP), endothelial dysfunction (homocysteine), lipid metabolism (HDL-, LDL-cholesterol, free fatty acids, triglycerides, adiponectin and leptin), renal function (cystatin C), hemostasis (PAI-1 and fibrinogen) and neurohormonal activation (NT-pBNP).
Results: The mean age of the study population (n = 3153; 31.9% women) was 62.7 (± 10.6 years) and type 2 diabetes was present in 999 (31.7%) individuals studied. Fasting insulin (U/L) and HOMA-IR (U), were significantly different between diabetic and nondiabetic probands (11.9± 10.8 versus 15.8 ± 15.1 U/L, P<0.001; and 3.22 ± 4.5 U versus 5.1 ± 5.8, P<0.001, respectively). In regard of the RAAS, only PRC (pg/mL) was elevated in diabetic compared to nondiabetic individuals (46.7 ± 137.7 versus 39.8 ± 165.2; P=0.006). We performed (log-transformed) multivariable adjusted one-way analysis of variance to compare distribution of fasting insulin and HOMA-IR within quartiles of PRC, ang2 and PAC levels. Overall, we observed a steadily and significant absolute rise in mean fasting insulin across PRC-, ang2- and PAC-quartiles (Q) (mean increase: 3.24 U/L, P<0.001 (PRC-Q); 1.36 U/L, P<0.001 (ang2-Q) and 3.36 U/L, P<0.001 (PAC-Q), respectively). Accordingly, median HOMA-IR increased steadily from the bottom Q of PRC, ang2 and PAC-levels to the upper Q of each RAAS mediator (from 1.91 U (PRC-Q1) to 2.88 U (Q4), P<0.0001; from 2.19 U (ang2-Q1) to 2.55 U (Q4), P<0.001; and from 1.79 U (PAC-Q1) to 2.76 U (Q4), P<0.001). In a multivariate stepwise regression model after plasma leptin (β=0.299, P<0.001), PRC (β=0.170, P<0.001) and PAC (β=0.129, P<0.001) emerged as strongest predictors for fasting insulin. With this in line, plasma leptin, PRC, BMI, PAI-1, HDL-cholesterol and PAC (for all variables p<0.001) emerged as most important predictors for HOMA-IR. The overall models used explained 29.1% and 32.1% of the interindividual variability of fasting insulin and HOMA-IR, respectively.
Conclusion: Our findings suggest that inappropriate RAAS activity contributes considerably to an increased IR and may therefore provide a feasible mechanism for target organ damage in patients with impaired glucose metabolism.

The effect on insulin action of the angiotensin converting enzyme inhibitor captopril combined with either a calcium channel blocker, amlodipine, or low dose thiazide, bendroflumethiazide

C.M. McHenry[1], C.N. Ennis[2], S.J. Hunter[1], A.B. Atkinson[1], P.M. Bell[1];
[1]Regional Centre Endocrinology and Diabetes, [2]Regional Endocrine Laboratory, Royal Victoria Hospital, Belfast, United Kingdom.

Background and aims: Combinations of antihypertensive agents are needed to meet stringent blood pressure (BP) targets in patients with diabetes. Concern exists regarding deleterious metabolic effects of some of these drugs. Angiotensin converting enzyme (ACE) inhibitors are neutral or maybe beneficial with regard to insulin action, whereas thiazide diuretics may cause insulin resistance unless used in low dose. Calcium channel blockers are often used first line or as part of combination regimens, but less is known about their metabolic effects. In this study we compared the effects on insulin action of two commonly used regimens; the ACE inhibitor captopril combined with low dose diuretic bendroflumethiazide, or captopril combined with the calcium channel blocker amlodipine.
Materials and methods: We performed a randomised cross over trial in 13 hypertensive patients with type 2 diabetes. Following six week placebo run in, patients were assigned captopril 50 mg twice daily combined with either amlodipine 10 mg once daily (CA) or captopril combined with bendroflumethiazide 1.25 mg once daily (CB) for 12 weeks. The primary outcome, insulin sensitivity, was assessed by the isoglycaemic hyperinsulinaemic clamp after placebo run in and following the two 12 week treatment periods. The power of the study, based on previous clamp data, gave a 90% chance of detecting a 20% difference in action of insulin at the 5% level of significance. Analysis was as recommended by Hills and Armitage for crossover studies.
Results: Both combinations led to a reduction in BP from baseline (CA 140/82 to 131/76 mmHg; p<0.05: CB 144/81 to 126/76 mmHg; systolic reduction p<0.05 and diastolic p=0.08). Systolic BP was lower following CB compared to CA (126 vs. 131 mmHg; p=0.004). Fasting glucose (CA 7.7 ± 0.4 mmol/l vs. 8.0 ± 0.5 mmol/l, p=0.35), HbA1c (CA 6.9 ± 0.4 vs. CB 7.2 ± 0.4 %; p=0.14) and fasting insulin concentrations (CA 9.4 ± 1.1 mU/l vs. CB 11.04 ± 1.42 mU/l, p=0.07) all tended to be higher following CB compared to CA, but none of these differences reached statistical significance. Exogenous glucose infusion rates required to maintain isoglycaemia during hyperinsulinaemia were similar after CA compared to CB (28.8 ± 4.2 vs. 25.3 ± 3.8 μmol/kg/min; p=0.12). There was also no difference between treatment periods in basal endogenous glucose production (CA 10.0 ± 0.7 vs. CB 10.9 μmol/kg/min; p=0.64), nor was there any change from baseline (10.0 ± 0.8 μmol/kg/min). Suppression of endogenous glucose production, an index of hepatic insulin sensitivity, was similar between therapies (p=0.74).
Conclusion: Whilst both combinations were effective in lowering BP from baseline, the captopril/bendroflumethiazide combination lowered BP to a greater extent than captopril/amlodipine. Although there was a tendency towards negative metabolic effects with the captopril/bendroflumethiazide combination, the differences did not reach the predetermined level deemed clinically significant. A small negative effect of captopril/bendroflumethiazide could be uncovered in a larger trial.
CMcH was funded for research by the R&D Office of the DHSS, Northern Ireland

A double-blind, placebo-controlled, crossover study to evaluate the effects of multiple doses of prednisone on insulin sensitivity in healthy lean males

E.A. Kauh[1], M. Hompesch[2], L.M. Mixson[3], J. McCarthy[4], V. Maridakis[1], L. Morrow[2], S. Shankar[4], G.A. Herman[4];
[1]Experimental Medicine, Merck & Co., Inc., North Wales, [2]Profil Institute for Clinical Research, Chula Vista, [3]Biostatistics and Research Decision Sciences, Merck & Co., Inc., Rahway, [4]Experimental Medicine, Merck & Co., Inc., Rahway, United States.

Background and aims: Supraphysiologic endogenous or exogenous glucocorticoid activity has been well established as a cause of impaired glucose

tolerance. To date, no single study has evaluated the dose-dependent effects of the widely used glucocorticoid, prednisone, on glucose disposal during short-term oral administration. The objective of the study was to use the hyperinsulinemic euglycemic clamp to assess the effects of commonly used prednisone doses on insulin action.
Materials and methods: Following one week of daily administration of 10 mg and 25 mg prednisone or placebo in a double-blinded, randomized, crossover study design of 17 healthy, nondiabetic, lean males (age 31.5 ± 9.2 years, BMI 23.2 ± 1.4 kg/m^2); glucose disposal was assessed using a two-step hyperinsulinemic euglycemic clamp with insulin infusion rates of 0.5 mU/kg·min for step 1 and 2.0 mU/kg·min for step 2. The amount of glucose infused during the final 30 minutes of each step ("steady state"), to maintain a stable serum glucose level (90 mg/dl) was used as a biomarker for insulin sensitivity and was used to calculate whole body glucose disposal (M), glucose metabolic clearance rate (MCR), M/I ratio and the insulin-sensitivity index ($S_{i)}$. The drug effect, as measured by a decrease in insulin sensitivity for each dose of prednisone as compared to placebo, was estimated and compared for the difference between doses and the associated one-sided P-value from an analysis of covariance (ANCOVA) mixed-effects model for 3 period crossover design. Results from each step of the clamp (i.e. the different insulin infusion rates) were analyzed separately.
Results: During Step 1 of the clamp, M and MCR were both reduced by 35% (p=0.003) while M/I was reduced by 29% (p=0.025) for 25 mg prednisone compared to placebo. No appreciable effect of 10 mg prednisone was observed. During Step 2 of the clamp, M was reduced by 33% (p=0.001) and by 15% (p=0.006), respectively for 25 mg and 10 mg prednisone compared to placebo; MCR was reduced by 32% (p<0.001) and 14% (p=0.008), respectively for 25 mg and 10 mg prednisone compared to placebo; M/I ratio was reduced by 31% (p<0.001) and 13% (p=0.026), respectively for 25 mg and 10 mg prednisone compared to placebo. Compared to placebo, S_i decreased by 33% (p<0.001) and 19% (p<0.014) for 25 mg and 10 mg prednisone, respectively. For 25 mg prednisone compared to 10 mg prednisone, S_i decreased by 17% (p=0.049).
Conclusion: Based on the analyses of these indices of insulin sensitivity, short-term prednisone administration results in dose-dependent inhibitory effects on insulin action in healthy, lean males, indicating that gluco-metabolic abnormalities may occur following treatment with even low to moderate doses of prednisone.

529

Evaluating effect of insulin resistance and beta cell function in a pioglitazone and metformin fixed-dose combination study
R. Spanheimer[1], Z. Zhao[2], A. Perez[2];
[1]Medical & Scientific Affairs, Takeda Pharmaceuticals North America, Inc., Deerfield, [2]Takeda Global Research & Development Center, Inc., Lake Forest, United States.

Background and aims: Insulin resistance and failure of the ß-cell to adapt to increasing insulin needs are the two core defects in type 2 diabetes mellitus (T2DM). Homeostatic model assessment (HOMA) is a method used to quantify insulin resistance or ß-cell function. Pioglitazone (PIO) improves glycemic control primarily by reducing insulin resistance, whereas metformin (MET) exerts its effect primarily by decreasing hepatic glucose output. In addition, thiazolidinediones may also have direct effects on ß-cell preservation and ß-cell function improvement.
Materials and methods: In this double-blind trial comparing fixed-dose combination (FDC) of PIO/MET vs respective monotherapies, the efficacy and safety of PIO/MET FDC therapy in T2DM patients during a 24-week trial period were studied. Patients were on no antidiabetes medications for 12 weeks and had a hemoglobin A1c (A1c) ≥7.5% and ≤10%. The primary endpoint was change from Baseline in A1c of PIO/MET FDC (N=201) vs PIO (N=189) or MET (N=210) monotherapy. Change from Baseline in HOMA-IR was evaluated as a secondary endpoint using fasting glucose and insulin levels.
Results: In all treatment groups, compared with Baseline (P<0.05), A1c was improved. A significant decrease in HOMA-IR was observed in Week 16 through 24 for the PIO/MET FDC, which was comparable to PIO monotherapy at Week 16 and 20, with a smaller decrease in HOMA-IR observed in the MET group. At Final Visit (Week 24), the greatest decrease in HOMA-IR was seen in those receiving PIO/MET FDC (Figure).
Conclusion: The improvement in HOMA-IR was most in PIO/MET FDC and PIO monotherapy, and PIO appeared to be the major contributing factor. Analysis of overall treatment-emergent adverse events showed no increase in the combination group with 50.7% for PIO/MET FDC and 52.1% and 53.1% for PIO and MET monotherapy, respectively.

Pioglitazone and sitagliptin compared to pioglitazone and metfomin therapy on glycaemic control and on insulin resistance in type 2 diabetic patients
G. Derosa, A. Cicero, P. Ragonesi, S. Salvadeo, I. Ferrari, F. Querci, I. Franzetti, G. Gadaleta, L. Ciccarelli, M. Piccinni, A. D'Angelo, R. Fogari; Internal Medicine and Therapeutics, University of Pavia, Italy.

Background and aims: our study aimed to compare the effects of pioglitazone (P) plus sitagliptin (S) vs pioglitazone (P) plus metformin (M) on glycemic control and on insulin resistance related-parameters in type 2 diabetic patients.
Materials and methods: ninety-nine type 2 diabetic patients with uncontrolled type 2 diabetes mellitus (HbA1c > 7.5 %) were randomised to P 30 mg o.d. and S 100 mg o.d. or to P 15 mg b.i.d. and M 850 mg b.i.d. All type 2 diabetic patients were resulted not well controlled with diet and physical activity and P at dosage of 30 mg/day. The treatment period had a 9 months duration. We evaluated BMI, HbA1c, FPG, PPG, FPI, Homa index and collected plasma samples of adiponectin (ADN), resistin (R), tumor necrosis factor-alpha (TNF-α), and high-sensitivity C reactive protein (Hs-CRP) at baseline, and after 9 months.
Results: ninety-two patients completed the study (46 in PS and 46 in PM group). BMI was significantly reduced by PM, but not by PS (from 27.8±1.4 to 27.4±1.1 Kg/m^2, ns vs baseline, and from 27.6±1.2 to 26.8±0.9 Kg/m^2, p< 0.05 vs PS, respectively). HbA1c was decreased by 1.1±0.07 % (p< 0.01), and by 1.3±0.09 % (p< 0.01); FPG was reduced by 17±3 mg/dl (p< 0.01), and by 23±4 mg/dl (p< 0.01); PPG was decreased by 29±5 mg/dl (p< 0.01), and by 31±6 mg/dl (p< 0.01), in PS and PM group, respectively. FPI was decreased by 3.0±0.2 μU/ml (p< 0.05), and by 3.9±0.3 μU/ml (p< 0.01 vs baseline, p< 0.05 vs PS), and Homa index by 1.6±0.5 (p< 0.05), and by 2.1±0.6 (p< 0.01 vs baseline, p< 0.05 vs PS) in PS and PM group, respectively. ADN was increased by 0.2±0.002 μg/ml (ns vs baseline), and by 1.2±0.2 μg/ml (p< 0.05 vs baseline, p< 0.05 vs PS), in PS and PM group, respectively. Resistin was reduced by 0.2±0.001 ng/ml (ns vs baseline), and by 2.2±0.3 ng/ml (p< 0.05 vs baseline, p< 0.05 vs PS), TNF-α by 0.2±0.001 ng/ml (ns vs baseline), and by 1.0±0.3 ng/ml (p< 0.05 vs baseline, p< 0.05 vs PS), and Hs-CRP by 0.7±0.005 mg/l (p< 0.05), and by 0.7±0.005 mg/l (p< 0.05), in PS and PM group, respectively. There was a significant correlation between Homa index decrease and ADN increase (r= -0.57, p< 0.01), R decrease (r= 0.55, p< 0.01), and TNF-α decrease (r= 0.53, p< 0.01).
Conclusion: both combinations ameliorated diabetes control, but only PM improved insulin resistance related-parameters. The ADN increase, R and TNF-α decrease seem to be related to Homa index improvement.

531

A comparison between metabolic and vascular effects of simvastatin and rosuvastatin in patients with type 2 diabetes

A. Bellia, A. Galli, S. Rizza, R. Fabiano, R. Rossi, M. Lombardo, M. Tesauro, M. Federici, P. Sbraccia, D. Lauro;
Department of Internal Medicine, University of Rome, Italy.

Background and aims: Type 2 diabetes (T2D) is frequently characterized by metabolic and vascular abnormalities, like insulin-resistance, endothelial dysfunction and low-grade systemic inflammation, leading to an increased risk of coronary heart diseases. Statins have been largely reported to reduce cardiovascular events, with a distinctive benefit for patients with T2D. Beside variations in lipid profile, this beneficial effect might be attributable to a number of vascular actions of statins, including effects on endothelial dysfunction and inflammation. However, the potential effects of statins on insulin-resistance and glucose tolerance in diabetic patients are still controversial. The present randomized, parallel, single-blind, intervention study has been direct to compare the effects of treatment with rosuvastatin or simvastatin on glucose control, insulin-resistance and endothelial dysfunction in individuals with T2D**.**
Materials and methods: After a run-in period of 3 weeks, twenty-nine dyslipidemic T2 diabetic (non obese) patients (aged 56±8, mean±SD) treated with oral antidiabetic drug (OAD) were randomly assigned to rosuvastatin 20 mg/daily (Group R, n=14) or simvastatin 20 mg/daily (Group S, n=15) for six months. The following data were collected before and after treatment period: BMI, waist circumference, fasting glucose, HbA1c, lipid profile, hs CRP, fibrinogen, TNF-alpha, glucose disposal assessed by euglycemic hyperinsulinemic clamp and flow-mediated vasodilation (FMD) evaluated by brachial artery reactivity technique (BART). We used Student t-test for paired data to compare values (mean±SD) before and after treatment.
Results: No patients changed OAD therapy or modified their own life-style habits during the study. After six months of treatment, LDL decreased of 55% in Group R (56±13 mg/dl, p<0.001) and 40% in Group S (81±12 mg/dl, p<0.001). Faced to this improvement in LDL levels, we observed a change in glucose tolerance and insulin-resistance in both groups (baseline vs treatment): fasting glucose (Group R 135±20 vs 149±23 mg/dl, p=0.004; Group S 136±24 vs 142±19 mg/dl, p<0.05); HbA1c (Group R 6.6±0.7 vs 7.1±0.4%, p<0.001; Group S 6.7±0.2 vs 7.0±0.4%, p<0.05); peripheral glucose disposal (Group R 5.1±0.6 vs 3.8±0.9 mg/kg/min, p=0.02; Group S 5.9±0.7 vs 5.2±0.5 mg/Kg/min, p=NS). FMD improved from baseline both in patients taking rosuvastatin (9.2±3.4 vs 12.7±4.5%, p=0.01) and in patients taking simvastatin (6.7±2.4 vs 12.3±4.6%, p=0.002). Only subjects in Group R showed a significant change from baseline in hs CRP (3.4±1.5 vs 1.1±0.9 mg/l, p=0.03), fibrinogen (343±27 vs 287±26 mg/dl, p=0.04) and TNF-alpha (12.2±6.5 vs 8.9±4.3 pg/ml, p=0.02).
Conclusion: In T2 diabetic patients treated for six months with Rosuvastatin 20 mg/daily or Simvastatin 20 mg/daily it has been reported an increased defect in fasting glucose concentration and HbA1c levels. In patients taking rosuvastatin the alterations in glucose homeostasis are related to an impaired insulin sensitivity. By contrast, both statins improved vascular reactivity, with a significant change in inflammation biomarkers in the rosuvastatin arm. More data are requested to better elucidate the relationships between metabolic and vascular actions of different statins, in order to verify whether certain drugs could be more appropriate than others to treat T2D dyslipidemia.

PS 32 Insulin sensitivity and lipids

The relationship of liver fat content, glucose fluctuation and components of metabolic syndrome

M. Liu[1], R. You[1], S.X. Rao[2], X.Z. Yao[2], M.S. Zeng[2], X. Gao[1];
[1]Endocrinology & Metabolism, [2]Radiology, Zhongshan Hospital, Shanghai, China.

Background and aims: Both lean and obese insulin resistant individuals have an excess of fat in the liver. Liver fat is highly significantly and linearly correlated with all components of the metabolic syndrome independent of obesity. Excess accumulation of fat in liver increases the risk of type 2 diabetes and cardiovascular disease, but the association of liver fat content and character of glucose fluctuation is unknown. This study aims to observe the association of liver fat content, character of glucose fluctuation and main metabolic parameters in 47 subjects with normal metabolic parameters monitored using the Continuous Glucose Monitoring System(CGMS) and 34 patients with non-alcoholic fatty liver disease (NAFLD) tested the same metabolic parameters but without CGMS in China.
Materials and methods: 47 subjects with normal metabolic parameters were involved in the study by standard interview, anthropometrics (height, weight, waist circumference, hip circumference and blood pressure) measurement, Laboratory tests included liver enzymes, renal function, lipid profile, serum glucose and insulin in oral 75g glucose tolerance test. All subjects were monitored using the CGMS for 3 days.34 patients with NAFLD were tested the same metabolic parameters but the CGMS. The liver fat content was measured by proton magnetic resonance spectroscopy (^{1}H MRS).
Results: 37 subjects (78%) with liver fat content<5% (1.98%±1.17%), 10 subjects (22%) with liver fat content>5%(14.48%±12.22%). All subjects were divided into two groups according the median of liver fat content tested by ^{1}H MRS. The levels of serum triglyceride, fasting C peptide, insulin, HOMA-IR, area under curve of insulin and Insulin-plus of the 30th minute in OGTT in 23 subjects with liver fat content ≥2.21% were higher, but the HDL-c was lower than those of the group with liver fat content <2.21%.(P<0.05). Liver fat content was positive correlated with the level of BMI (r=0.547), ALT(r=0.676), AST(r=0.514), GGT(r=0.474), ALP(r=0.358), TG(r=0.577), fasting blood glucose (r=0.281) (all P<0.05), but was negative correlated with the level of HDL-c (r=-0.315, P=0.004) in all 81 subjects including 47 subjects with normal metabolic parameters and 34 patient with NAFLD. 35 valid data of CGMS were involved in the analysis. The MBG was 5.75±0.09 mmol/L, MAGE was 2.32±0.83 mmol/L. The liver fat content was positively correlated with MBG (r=0.338, P=0.047), AUC of blood glucose >5.6mmol/L(r=0.408, P=0.015), AUC of blood glucose>6.1mmol/L(r=0.409, P=0.015), and was not correlated with the highest blood glucose, the lowest blood glucose and MAGE.
Conclusion: 22% subjects with normal metabolic parameters have increased accumulation of liver fat and hepatic insulin resistance. Disorder of metabolism existed in the subjects with excess accumulation of liver fat. The glucose fluctuation was found in the subjects with liver fat content>2.21%.

Lipid accumulation product is strongly associated with surrogates of insulin resistance, metabolic syndrome and cardiovascular disease risk in healthy men

M.J. Taverna[1], F. Aranguren[2], G.D. Frechtel[3];
[1]IDEHU, CONICET (National Research Council), Buenos Aires, [2]Division of Diabetology, Clinical Hospital of the University of Buenos Aires, [3]Division of Genetics, Clinical Hospital of the University of Buenos Aires, Argentina.

Background and aims: lipid accumulation product (LAP), a novel index of central lipid accumulation, has been associated with diabetes and cardiovascular risk. LAP is based on a combination of waist circumference (WC) and triglyceride (TG) [LAP = (WC - 65) × TG for men, and (WC - 58) × TG for women]. Because insulin resistance (IR) is extremely common and its prevalence is increasing, early detection of high-risk individuals could be useful to predict and prevent diabetes and cardiovascular disease (CVD). We performed a population cross-sectional study in order to identify simple parameters, as LAP, with high ability in predicting IR, metabolic syndrome (MS) and CVD risk.
Materials and methods: 601 unrelated healthy men were recruited at our hospital. All subjects were non-diabetic blood donors with normal findings on medical examination and blood count, and free from any medication. Their ages ranged between 18 to 65 years (36.9 ± 10.8 years). The study was carried out in accordance with the Declaration of Helsinki, and approved by the ethic committee of our hospital. MS was determined according to the International Diabetes Federation criteria (IDF-MS). Fasting insulin levels were measured using a human specific radioimmunoassay kit (cross-reactivity is less than 0.2% to intact human proinsulin and the primary circulating split form (des 31, 32)). HOMA-IR, QUICKI and LAP were calculated. Cardiovascular risk was determined using the Framingham risk score.
Results: LAP was positively correlated with HOMA-IR (P <0.0001) and fasting insulin (P <0.0001), and negatively correlated with QUICKI (P <0.0001). LAP showed high areas under the curves (AUCs) for ROC (receiver operating characteristic) curves for cutoff values of HOMA-IR (above 75th percentile, AUC 0.76 ± 0.01 [95% CI 0.72-0.81]), QUICKI (below 25th percentile, AUC 0.76 ± 0.01 [0.71-0.81]) and fasting insulin levels (above 75th percentile, AUC 0.76 ± 0.01 [0.72-0.81]). The prevalence of IDF-MS was 38.6%. LAP was strongly associated with IDF-MS (P <0.0001) and their individual components (P <0.0001 for every component). LAP showed the highest diagnostic accuracy for IDF-MS (AUC 0.89 ± 0.01 [0.86-0.92]) in comparison with other parameters such as HOMA-IR (AUC 0.71) among others. These findings were confirmed by internal validation using 32,000 bootstrap samples. The best cut-off value for prediction of IDF-MS was LAP 47.3 (sensitivity 0.76; specificity 0.82; predictive value of positive test 0.73; predictive value of negative test 0.85; correct classification rate 0.80). LAP was positively correlated with the cardiovascular Framingham risk score (P <0.0001).
Conclusion: This is the first report finding, in Argentinian healthy men, that LAP is strongly associated with IR, has the highest diagnostic accuracy for IDF-MS, and is strongly positively correlated with the cardiovascular Framingham risk score. LAP could be associated with a dysfunctional and lipolytic adipose tissue which is a central abnormality behind IR, MS, type 2 diabetes and CVD. The reliability of LAP in early identification of high-risk individuals for IR, MS and CVD requires further investigation using longitudinal designs.

Effects of fish oil on metabolic alterations induced by carbohydrate overfeeding in healthy volunteers

G. Allain[1], V. Le Guen[1], S. Lesven[1], J. Mansourati[2], F. Guerrero[2], H. Kerspern[3], J. Delarue[1];
[1]Laboratoire Régional de Nutrition Humaine, CHU, [2]Université de Bretagne, EA-4324 Orphy, [3]CHU, Laboratoire de Biochimie, Brest, France.

Background and aims: Long-term positive energy balance could induce metabolic alterations that lead to metabolic syndrome (MS). The aim of our study was to assess if fish oil (FO) supplementation could partially or completely prevent the metabolic alterations induced by 4-day carbohydrate overfeeding (O).
Materials and methods: 32 volunteers were randomized in 2 groups: one group without o (C) (10 W and 6 M, 44.1 ± 1.5 y, BMI: 22.30 ± 0.42 kg/m^2) and one group with O (7 W and 9 M, 44.1 ± 1.6 y, BMI: 22.63 ± 0.36 kg/m^2). Group C was studied once while absorbing usual diet; group O was studied 6-w apart while absorbing over 4-d prior to each experiment 75% energy from CHO/d in addition of their daily energy expenditure. One test was made on each volunteer from C. The volunteers from O have been submitted to 2 periods of O 6 weeks apart. During these 6 weeks, after randomization, 8 volunteers received 3g/d of FO (Epax 6000 TG QualitySilver®, Polaris, Pleuven, France: 1.7g/d of EPA + DHA), the other 8 received 3g/d of paraffin oil (placebo P). Parameters studied: Glucose Infusion Rate (GIR) (euglycaemic hyperinsulinaemic clamp: insulin infusion rate = 1 mU/kg/min), mean arterial blood pressure (MBP), heart frequency (HF), plasma FFA, HDL, triglycerides (TG), insulin concentrations and cutaneous endothelium independent vasodilatation.
Results: mean±SEM (ANOVA and Student's t-test). Comparison of O (n=16) vs. C (n=16): Basal state: O did not alter BMI (22.95 ± 0.31 vs. 22.63 ± 0.36 kg/m^2), increased basal insulinemia (5.5 ± 0.6 vs. 4.7 ± 0.3 mU/L ; p<0.05), TG (2.11 ± 0.29 vs. 0.72 ± 0.07 mmol/L; p<0.0001), decreased HDL cholesterol (1.02 ± 0.08 vs. 1.46 ± 0.09 mmol/L; p<0.001) and FFA (176 ± 35 vs. 446 ± 44 µmol/L ; p<0.0001). O increased DEE (1.08 ± 0.04 vs. 1.00 ± 0.03 kcal/min; p<0.05) and carbohydrates oxidation (3.09 ± 0.20 vs. 1.32 ± 0.09 mg/kg/min; p<0.0001) and decreased fatty oxidation (0.11 ± 0.04 vs. 0.62 ± 0.06 mg/kg/min; p<0.0001). HF tended to increase (65 ± 2 vs. 61 ± 2 bt/min; p= 0.055). Vasodilatation was not altered by O. During the clamp: O decreased the GIR (9.71 ± 0.47 vs. 11.45 ± 0.60 mg/kg/min; p<0.05). DEE was increased (1.20 ± 0.04 vs. 1.15 ± 0.05 kcal/min; p<0.05), carbohydrate oxidation was increased (4.02 ± 0.23 vs. 3.45 ± 0.18 mg/kg/min; p<0.0001) and fatty oxidation was decreased (0.00 ± 0.00 vs. 0.04 ± 0.03 mg/kg/min; p<0.0001). FFA were less inhibited (48 ± 6 vs. 17 ± 4 µmol/L; p<0.0001). MBP was increased (90.4 ± 1.4 vs. 87.0 ± 1.4 mmHg; p<0.05). Comparison of O + FO (n=8) vs. O + P (n=8): The P had no effect on each studied parameter. Basal state: FO decreased TG (1.58 ± 0.41 vs. 2.12 ± 0.58 mmol/L; p<0.05) without changing HDL cholesterol and LDL. FO decreased MBP (84.0 ± 6.8 vs. 86.4 ± 2.0 mmHg; p<0.0001) and increased vasodilatation (6.39 ± 0.59 vs. 5.45 ± 0.44 UA; p<0.05). During the clamp: FO increased the GIR (10.05 ± 0.70 vs. 8.84 ± 0.68 mg/kg/min; p<0.01), decreased MBP (85.3 ± 2.9 vs. 89.4 ± 1.7 mmHg; p<0.0001). FO had no effect on the other studied parameters.
Conclusion: A short term (4d) carbohydrate O reproduces without weight gain some metabolic alterations characteristic of the MS (increase in TG and of MBP, decrease in HDL cholesterol and insulin sensitivity). FO supplementation (1.7 g/d of EPA+DHA) over 6 weeks prevents the emergence of some

alterations: better insulin sensitivity, decrease in TAG and normalization of MBP.

Paradoxal effect of chronic treatment with extended-release nicotinic acid on insulin sensitivity in patients with abdominal obesity and mixed dyslipidaemia

E. Blond[1], S. Lambert-Porcheron[1], A.-C. De Gouville[2], H. Vidal[3], M. Laville[1];
[1]Centre de Recherche en Nutrition Humaine Rhône Alpes,
[2]GlaxoSmithKline, Les Ulis, [3]INSERM unité 870, Lyon, France.

Background and aims: Nicotinic acid (NA) is used to regulate lipid abnormalities by reducing triglyceride (TG) level and LDL cholesterol. It is the most potent available lipid regulating agent to increase HDL cholesterol. However, its global therapeutic benefit could be questioned as an increase in glycaemia has been reported after chronic treatment. Thus, we wanted to investigate the effects of NA on insulin sensitivity as well as on non esterified fatty acids (NEFA) evolution during both acute and chronic administration of extended release NA (ENA).
Materials and methods: We performed a cross over, randomized, double blind study of twice 8 weeks (wash out 3 weeks); 8 men, 18-65 years old, with abdominal obesity and mixed dyslipidemia (without diabetes and hypertension), received ENA at 2g/day after an escalation dose of 500mg/week during 4 weeks or placebo with 300mg of lysine acetylsalicylate. A euglycemic hyperinsulinemic clamp with 2 levels of insulin (0.2 and 1mUI/kg/min) associated to glucose tracer infusion was performed on day 53. Substrate oxidation was also measured by indirect calorimetry. Glycerol, NEFA, TG, β-hydroxybutyrate (β-OH), insulin and glycemia were monitored. Glucose, insulin, TG, NEFA, glycerol and β-OH kinetic were assessed for 8 hours on day 42 after a supplementary placebo administration and on day 56 after supplementary immediate release NA (INA) ingestion. This allows to appreciate acute and chronic effect of NA vs placebo.
Results: After 8 weeks of treatment, LDL cholesterol was decreased by 18.7% (3.63 ± 0.89 vs 2.99 ± 0.58 mM (p=0.028)) and HDL cholesterol increased by 5.9% (1.23 ± 0.20 vs 1.16± 0.22mM) but not significantly (NS). TG were significantly decreased during chronic treatment (3.03 ± 1.88 vs 1.31 ± 0.68 mM (p=0.012)). Chronic treatment with ENA significantly increase glycemia and insulinemia and HOMA was doubled (3.15 ± 0.52 vs 6.24 ± 2.24 (p=0.017)). During clamp, glucose utilisation tend to be decreased at the 2nd insulin dose with NA (4.44 ± 1.92 vs 3.73 ± 0.96 mg/kg/min (NS)). No change was observed on basal hepatic glucose production which was similarly inhibited during the clamp. Baselines NEFA were slightly increased with ENA (437 ± 267 vs 501 ± 264 µM (NS)) and similarly inhibited during the clamp as were glycerol and β-OH. After INA ingestion, we observed a decrease in NEFA followed by a rebound effect (basal value: 464 ± 217 µM; p=0.61 - nadir: 177 ± 123 µM; p=0.012 - peak: 987 ± 246µM; p=0.017). During chronic treatment, we observed a non significant increase in NEFA. Same kinetics were observed for glycerol and β-OH.
Conclusion: We demonstrate that chronic administration of ENA was associated with dramatically changes in glucose metabolism and in insulin resistance profile. This occurs despite a significant decrease in TG but with a trend to increase in NEFA. This insulin resistance seems to occur at the peripheral level (muscle) as hepatic glucose production inhibition was not altered. Relative risk-benefit of extended release NA should be assessed taking into account the HDL increase and deleterious change in glucose metabolism.

The role of lipid subfractionation in predicting insulin sensitivity in normal glucose tolerant subjects

B. Buday[1], E. Kulcsár[1], É. Péterfai[1], M. Vitai[1], B. Literati-Nagy[1], P. Hamar[2], L. Koltay[3], L. Korányi[1];
[1]Department of Metabolism, Drug Research Center, Balatonfüred, [2]Institute of Pathophysiology, Semmelweis University, Budapest, [3]Department of Mathematics and Computer Science, Pannon University, Veszprém, Hungary.

Background and aims: Insulin resistance (IR) is associated with alterations of lipoprotein particle size especially with small-dense LDL, preceeding all other lipoprotein modifications and is associated with increased cardiovascular risk. The predictive value of lipoprotein particle size for IR is unknown. In the present study, we analyzed the predictive value of lipoprotein size-subfractions to hyperinsulinemic normogycemic clamp (HNC) measured glcuose disposal rate adjusted for muscle mass (M_m) in both normal and impaired glucose tolerant subjects compared to other fasting parameters well known to predict IR.
Materials and methods: 159 previously healthy (H), medically non-treated individuals (83 males and 76 females, mean age: 44 ± 2 years) underwent a HNC to measure M_m. Individuals were categorized as healthy (NGT, n=80) or glucose intolerant (GI: n= 79; IFG/IGT or drug-naïve 2DM) based on an OGTT. Lipoprotein size-subfractions were determined electrophoretically with the lipoprint system (Quantrimetrix). Basic anthropometric and metabolic parameters (fasting insulin, glucose, conventional lipids), free fatty acid (FFA), adiponectin, leptin, resistin, TNF-alpha, IL-6, apoprotein B and A1 were measured, percent body fat (PBF) and muscle mass were determined by DEXA.
Results: In H subjects, after adjusting with BMI, age, gender and PB, bivariate correlations with M_m stayed significant only in case of adiponectin (r=+ 0.407, p=0.006), leptin/adiponectin ratio (r = -0.268, p = 0.01), large and small IDL subfractions (IDL-A and IDL-C, r = +0.232, p = 0.014 and r = +0.247, p = 0.033) but not of conventional lipid and other parameters. According to a multivariate regression model BMI (p<0.0001), adiponectin (p<0.0001), VLDL% (p=0.0009), large (buoyant) LDL (LDL-1%, p=0.003), small-dense LDL (LDL2-7%)-to- total-LDL (LDL1-7%) ratio, total-LDL-to-HDL ratio (p<0.0001) and small-dense LDL% (p<0.0001) were independent predictors of M_m (R^2=0.51), but not fasting insulin, which only had a week bivariate correlation with the M_m (r = -0.259, p=0.018), similar to HOMA-IS (r= +0.28, p=0.014). In the GI group independent predictors of M_m (R^2=0.50) were fasting insulin (p<0.0001), FFA (p=0.005), adiponectin (p=0.005) and triglyceride (p=0.031). HOMA-IS showed week bivariate correlation with the M_m value in GI subjects (r=+0.36, p=0.003).
Conclusion: In healthy subjects adiponectin and lipoprotein subfractionation predicted clamp measured IS better than the HOMA model. Decreased number of large buoyant LDL and IDL particles along with the increase of small-dense LDL may indicate IR before hyperinsulinemia and dyslipidemia occurs. Conventional lipid panel (hypertriglycerdemia) and hyperinsulinemia (i.e. the HOMA model) only indicated IR in glucose intolerant subjects.

The antioxidant N-Acetyl-L-cysteine does not reverse hepatic insulin resistance induced by prolonged (48h) lipid infusion

S. Pereira, C. Lee, L. Lam, A. Giacca;
Physiology, University of Toronto, Canada.

Background and aims: Our group has previously demonstrated that the antioxidant N-Acetyl-L-Cysteine (NAC) and the anti-inflammatory sodium salicylate completely prevent hepatic and peripheral insulin resistance induced by short-term (7h) i.v. lipid infusion. To determine if the mediators of hepatic insulin resistance differ depending on the duration of lipid infusion, we also established a prolonged (48h) lipid infusion protocol. The prolonged lipid infusion model mimics the chronically elevated plasma free fatty acids (FFAs) and increased FFA tissue availability characteristic of obesity. We have previously found that i.v. infusion of sodium salicylate at the same dosage as for the short-term lipid infusion model prevents peripheral but not hepatic insulin resistance. We wished to determine whether NAC is effective at the same dosage as in the short-term lipid infusion model.
Materials and methods: Wistar rats (250-310g, n=7-13/group) were chronically cannulated and given i.v. saline control or Intralipid plus heparin (IH; 20% Intralipid plus 20 U/ml heparin at 5.5 µl/min), with or without NAC

(0.35 mg kg^{-1} min^{-1}) for 48h; the rate of IH infusion was the same as for the 7h protocol. During the last 2h of treatment, a hyperinsulinemic (5 mU kg^{-1} min^{-1}) euglycemic clamp with concomitant tritiated glucose methodology was performed to determine hepatic and peripheral insulin sensitivity.
Results: IH administration resulted in hepatic insulin resistance, as indicated by blunted insulin-mediated suppression of endogenous glucose production (EGP) (% change of EGP from basal: Saline, -69.4±10.6%; IH, -21.0±6.7%, p<0.05), and peripheral insulin resistance, as indicated by a modest reduction in clamp glucose utilization (GU) (Saline, 30.9±2.0 mg kg^{-1} min^{-1}; IH, 26.0±1.1 mg kg^{-1} min^{-1}, p<0.05). Similar to sodium salicylate, NAC co-infusion completely prevented peripheral insulin resistance (GU: IH+NAC, 31.9±1.2 mg kg^{-1} min^{-1}, p<0.05 vs. IH alone), but did not prevent IH-induced hepatic insulin resistance (% change of EGP from basal: IH+NAC, -13.5±9.6%, not significant vs. IH alone).
Conclusion: Similar to sodium salicylate, NAC, which completely prevented hepatic insulin resistance in the 7h lipid infusion model, is not effective in preventing IH-induced hepatic insulin resistance caused by prolonged lipid infusion. Unlike the short-term lipid infusion model, which is characterized by hepatic and peripheral insulin resistance, prolonged lipid infusion is a more selective model of hepatic insulin resistance, with minimal peripheral insulin resistance. Our findings indicate that either a greater dosage of IKKbeta inhibitor (sodium salicylate) or antioxidant is required in this model, perhaps in combination, or more likely that unknown mediators, other than IKKβ and oxidative stress, are important. These results highlight the difficulties in target identification for the treatment of fat-induced insulin resistance in obesity.

The lipid peroxidation product 4-hydroxynonenal uncouples insulin-stimulated Akt phosphorylation from its activation, resulting in adipocyte insulin resistance
A. Osnis, N. Bashan, A. Rudich;
Biochemistry, Ben Gurion University, Beer Sheva, Israel.

Introduction: Although it is accepted that diabetes and obesity are associated with increased oxidative stress, and oxidative stress as an isolated factor can cause insulin resistance, the exact oxidative mediators and molecular mechanisms are poorly understood, particularly in fat cells. 4-hydroxynonenal (HNE) is a major peroxidation end-product of unsaturated fatty acids, which has been shown to be elevated in patients with diabetes and obesity. Moreover, its conjugation to proteins was suggested to constitute the major carbonyl modification in adipose tissue in these conditions. The aim of the present study was to characterize whether and how HNE impairs insulin signaling in adipocytes, with emaphasis on activation of Akt/PKB, a step particularly affected in adipocytes by other oxidants.
Methods: Differentiated 3T3-L1 adipocytes were exposed to 0-100 μM HNE for up to 4h, rinsed, and insulin signaling and action were studied after stimulation with 100 nM insulin. GLUT4 translocation and fusion was studied using confocal microscopy after introducing (by electroporation) a GFP-GLUT4myc plasmid, and assessing externalization of the myc epitope in non-permeabilized cells using anti-myc Ab.
Results: Treatment of 3T3-L1 adipocytes with HNE increased total protein corabonylation, as assessed by a Protein Oxidation Detection Kit (COMPANY). Consistent with previous reports, HNE impaired insulin actions including the stimulation of glucose uptake in 3T3-L1 adipocytes, in a time and dose dependent manner. This was mediated by impaired capacity of the hormone to stimulate GLUT4 fusion with the plasma membrane, though translocation (GFP rims) seemed to be less affected. Intriguingly, insulin-stimulated phosphorylation of Akt on both Ser473 and Thr308 residues was increased 3-4 fold (p<0.05) following HNE pre-treatment, despite a time and dose-dependent decrease in total Akt content (p<0.05). HNE increased Akt phosphorylation by 3 fold also in the absence of insulin (p<0.05). To determine whether insulin resistance induced by HNE occurred downstream of normal or even exaggerated Akt activation by the hormone, phosphorylation of Akt substrates was assessed. Although basal phosphorylation of GSK3 on residues 9/21 mirrored basal Akt phosphorylation, it suggested a discrepancy between Akt phosphorylation and activation at higher doses in response to insulin. We next utilized the anti-phospho-Akt substrate (PAS) antibody generated against the phosphorylated Akt consensus sequence on target proteins. The notable increase in basal Akt phosphorylation was associated with a mild elevation in phosphorylation of various Akt substrates. Yet, despite the robust elevation in insulin-stimulated Akt phosphorylation induced by HNE, Akt-mediated phosphorylation of its various target proteins, including AS160, was markedly diminished.
Conclusion: These results suggest that the lipid peroxidation product 4-HNE can cause adipocyte insulin resistance by uncoupling Akt phosphorylation from the enzyme's activity in response to insulin stimulation.

N-acetylcysteine reduces gluconeogenesis without altering hepatic lipid accumulation or mitochondrial superoxide production in an *in vitro* model of NAFLD
K.A. Lockman[1], C.J. Pemberton[2], J.P. Baren[2], C. Filippi[3], P. Cowan[2], P. Lee[2], A. Pryde[2], F. Howie[4], P.C. Hayes[2], A.J. Jaap[1], J.N. Plevris[2];
[1]Department of Diabetes and Endocrinology, Royal Infirmary of Edinburgh, [2]Department of Hepatology, University of Edinburgh, [3]MRC Scottish Centre of Regenerative Medicine, University of Edinburgh, [4]Department of Biochemistry, University of Edinburgh, United Kingdom.

Background and aims: Reactive oxygen species and insulin resistance are implicated in the progression of simple hepatic steatosis to steatohepatitis. Free radical scavenger, N-Acetylcysteine (NAC) is a thiol compound that has been proposed to prevent oxidative stress, thus protecting hepatocytes from injury in steatohepatitis. The aim of this study is to elucidate the effect of NAC on hepatic lipid accumulation, hepatic mitochondrial superoxide production and hepatic endogenous glucose production (EGP) as a marker of insulin resistance.
Materials and methods: C3A cells, a clonal derivative of HepG2 cell line, were incubated for 3 days with Lactate (L), Pyruvate (P), Octanoate (O) and Ammonia (N), as previously described with or without NAC (0.1mM). After a 3 day preconditioning, the presence of intracellular lipid was determined by oil red O staining. Triglyceride concentrations were measured using an enzymatic assay. Mitochondrial superoxide were detected by fluorescent microscopy using MitoSox Red and quantified by FACS. Total glucose production in the supernatant and glucose concentrations after 4 hour incubation with gluconeogenic substrates were measured using Bergmeyers method. Cell viability was assessed using propidium iodide staining followed by FACS. Experiments were done for n=3 in triplicate.
Results: Incubation with LPON and NAC did not affect cellular viability in all groups. LPON induced significant triglyceride accumulation when compared with control (Control (mean±SEM) 89.3±9.6 vs LPON 248.8±11.04 μg/g protein, P<0.01). LPON cells had higher mitochondrial superoxide formation (peak intensity LPON 31.5±2.9 vs control 16.5±4.1, P<0.05). Addition of NAC to LPON cells did not alter triglyceride concentrations (P=0.25) or superoxide production (P=0.40). In contrast, NAC caused a significant reduction in EGP (LPON:6799±231 vs LPON+NAC:5896±127.1 μmol/gTP; P=0.003), and this was also associated with a lower gluconeogenic capacity (LPON:7.1±0.8 vs LPON+NAC:4.9±0.6 μmol/gTP; P=0.04).
Conclusion: NAC treatment caused reduction in EGP, and presumably insulin resistance. This decrease was not associated with alteration in intracellular lipid accumulation or dependent on reduction of mitochondrial superoxide production. However, it is possible that the effect of NAC on mitochondrial hydrogen peroxide (H_2O_2) may underlie the observed reduction in EGP. In addition, our data showed that the degree of intracellular lipid accumulation was not related to the EGP or gluconeogenic capacity, hence hepatic insulin resistance.

Dysregulation of intracellular triacylglycerol breakdown in fatty liver contributes to the development of hepatic insulin resistance
M. Cahova, J. Ždychova, H. Dankova, L. Kazdova;
Department of Metabolism of Diabetes, Institute for Clinical and Experimental Medicine, Prague, Czech Republic.

Background and aims: Hepatic steatosis is associated with the development of hepatic insulin resistance (HIR). This study was designed to test the hypothesis that steatosis-associated HIR is causally linked with dysregulation of endogenous triacylglycerol (TAG) degradation in fatty liver.
Materials and methods: Hepatic steatosis was induced by 2-week high-fat diet (HFD, 69 cal% as lard) administration to male Wistar rats (300±15 g). Hepatic lipase, (HL), triacylglycerolhydrolase (TGH)and lysosomal acid lipase (LAL) were identified according to their different pH optimum and their activity was measured on either emulgated ^{3}H-labeled triolein (^{3}H-TO) or

endogenous TAG in liver homogenate. Activated phagolysosomes (PhL) were prepared from 20% liver homogenate (H) by differential centrifugation.
Results: All three lipases exhibited measurable activities on 3H-TO substrate LAL > HL >> TGH (not shown) but the only lipase capable significantly degrade endogenous TAG was LAL. In rats fed SD total LAL activity in homogenate was higher in fasted animals and lower in fed ones. Corresponding changes were found in mRNA expression. HFD administration resulted in significant stimulation of LAL activity in homogenate in fed animals but LAL mRNA and total LAL protein expression were not significantly different compared with SD group (tab-H). This contradiction could be explained by specific intracellular localisation of LAL that is functional only in lysosomes activated by substrate ingestion - fagolysosomes. While in homogenate no correlation between LAL protein expression and LAL activity was found, in phagolysosomal fraction these two variables changed in accordance with each other. We propose an additional mechanism of LAL activation independent on mRNA and protein synthesis when the increased amount of intracellular fat droplets in steatosis makes their contact with lysosomes more frequent and the probability of fagolysosomal formation increases. The tissue concentration of DAG was elevated in fatty liver (56±12 vs 154±21 nmol. g-1). The data obtained in experiments designed to measure the production of DAG from endogenous TAG by LAL in vitro (SD vs HFD fasted: 85±9 vs137±14 p<0,01; fed: 56±8 vs129±10 p<0,01 nmol.mg-1.60 min-1) indicate that stimulated lipolysis in HFD group is an important one source of liver DAG. HFD feeding led to the impairment of insulin signal transduction in liver (attenuated insulin-stimulated IRS, PKB and mTOR phosphorylation) and to the increased activation of PKCε.
Conclusion: The lipolysis of intracellular TAG is increased in fatty liver due to the substrate-dependent stimulation of LAL activity and leads to the overproduction of DAG. Recent data indicate that PKCε activation is an important mechanism in HIR development. DAG, as a recognized activator of PKCε, may represent the causal link between fat-induced hepatic TAG accumulation and hepatic insulin resistance via the PKCε activation.

Relationships of TNF-alpha system with glucose and lipid oxidation in lean and obese subjects

A. Adamska, M. Karczewska-Kupczewska, I. Kowalska, A. Nikolajuk, M. Gorska, M. Straczkowski;
Department of Endocrinology, Diabetology and Internal Medicine, Medical University of Bialystok, Poland.

Background and aim: One of the key actions of insulin is the regulation of glucose and lipid oxidation. Disturbances in substrate oxidation play an important role in the development of insulin resistance. Insulin action is inversely associated with circulating pro-inflammatory cytokines such as soluble TNF-α receptors (sTNFR1 and sTNFR2). The aim of the present study was to analyze the associations between serum sTNFR1 and sTNFR2 concentrations and glucose and lipid oxidation and non-oxidative glucose metabolism in lean and obese subjects with normal glucose tolerance.
Materials and methods: We examined 42 subjects (30 females and 12 males), 22 lean (BMI<25 kg x m-2, 16 females and 6 males) and 20 with overweight or obesity (BMI>25 kg x m-2, 14 females and 6 males) with normal glucose tolerance. Insulin sensitivity was measured with the hyperinsulinemic euglycemic clamp technique. Glucose and lipid oxidation was evaluated with indirect calorimetry in the baseline state and during the last 30 minutes of the clamp. Non-oxidative glucose metabolism in the hyperinsulinemic state was calculated by subtracting glucose oxidation from the total glucose metabolism. Metabolic flexibility was assessed as an increase in respiratory quotient (deltaRQ) in response to insulin.
Results: Serum sTNFR1 concentrations were higher in the obese in comparison with the lean group (p<0.0001). Insulin sensitivity was negatively related with serum sTNFR1 (r=-0.38, p=0.014), whereas the relationship with sTNFR2 was approaching the level of significance (r=-0.30, p=0.057). Serum sTNFR1 concentration was positively associated with the baseline glucose oxidation (r=0.32, p=0.043) and negatively - with the increase in glucose oxidation in response to insulin (r=-0.40, p=0.01) and with non-oxidative glucose metabolism (r=-0.35, p=0.022). Significant negative correlation between serum sTNFR1 and metabolic flexibility was observed (r=-0.36, p=0.019). Serum sTNFR2 was positively related to baseline respiratory quotient (r=0.36, p=0.018).
Conclusion: Our data suggest that TNFα system is associated with multiple metabolic pathways regulated by insulin.

Evaluating the insulin sensitivity and secretion function from the 2-hour OGTT by mathematical model

B. Li[1], Q. Li[2], Y. Xie[3];
[1]Tianjin Normal University, [2]Department of Endocrinology, First Affiliated Hospital, Chongqing Medical University, [3]Metabolic Disease Hospital, Tianjin Medical University, China.

Background and aims: To assess insulin sensitivity and secretion function from the 2-hour oral glucose tolerance test (OGTT), the mathematical model LMM (linear minimal model) was established from five physiological assumptions in this paper.
Materials and methods: The insulin sensitivity index LMM-ISI and secretion function index LMM-BCI could be calculated simultaneously from the values of plasma glucose and insulin at four time points (0, 30, 60 and 120 min) during the 2-hour OGTT by model LMM. .Eighty Chinese female volunteers in Chongqing area (50 subjects for NGT and 30 subjects for IGR) were involved in this study, aged 27.04±4.77 and BMI 22.59±3.59. Using the data from the Botnia clamp test and the 2-hour OGTT, the feasibility of LMM-ISI and LMM-BCI was studied in this paper.
Results: The Pearson's linear correlation coefficient between LMM-ISI and GIR (glucose infusion rate at steady state of the Botnia clamp test) was 0.740 (P<0.001) , which was larger than those corresponding values calculated from QUICKI, HOMA-ISI, HOMA2-%S, Cederholm-ISI and Composite-ISI, the respective values of which were 0.452, 0.493, 0.503, 0.610 and 0.678. After removing the effect of GIR, the partial correlation between LMM-BCI and G_{120} (plasma glucose concentration at 120 minute after ingestion of the oral load) in the OGTT was most significant (r=-0.642, P<0.001) among the six insulin secretion function indices (HOMA-β, HOMA2-%B, $\Delta I_{30}/\Delta G_{30}$, $\Delta I_{60}/\Delta G_{60}$, MBCI and LMM-BCI) derived from the OGTT.
Conclusion: So LMM-ISI and LMM-BCI is a relatively good pair of insulin sensitivity index and secretion function index derived from the 2-hour OGTT.

Inflexion of the glucose disposition vector among insulin resistant children may be an early sign of beta cell insufficiency

T.J. Wilkin[1], B. Storey[2], A. Jeffery[1], B. Metcalf[1], L. Voss[1];
[1]University Medicine, Derriford Hospital, Plymouth, [2]Physics, University of Dundee, United Kingdom.

Background and aims: Blood glucose is controlled by the interaction between insulin sensitivity (S) and insulin secretion (B), whose vector can be plotted over time. We tracked the vector of children who were insulin sensitive, and compared it with that of children who were insulin resistant.
Materials and methods: BMI (kg/m2), fasting glucose, insulin, HOMA-%S and HOMA-%B were recorded annually from 5-12y in 258 healthy children (144 boys) from the EarlyBird cohort, grouped according to quartile of insulin sensitivity at 5y (highest Q4, lowest Q1).
Results: BMI SDS (+0.16 Kg/m^2, p<0.01) and glucose (+0.6 mmol/l, p<0.001) rose progressively from 5-12y. The BMI of Q4 was lower than Q1 (p<0.02), HOMA-%S (predictably) higher (p<0.02), and HOMA-%B lower (p<0.03) throughout. The vector of Q4 shifted only slightly in response to the loss of S associated with puberty. The vector of Q1, on the other hand, suggested early loss of B cell function (with compensatory increase in insulin sensitivity), followed by an acute switch in direction at 7y to indicate falling insulin sensitivity (with only partial beta cell compensation).
Conclusion: The inflexion appears to be a feature of early insulin resistance, and may correspond to a weakening of glucose control associated with adjustment to beta cell loss. Importantly, it does not appear to be a normal event, and could represent early beta cell pathology among contemporary children.

Insulin resistance is associated with metabolic syndrome but not with angiographically determined coronary artery disease

J. Breuss[1], A. Vonbank[1,2], C.H. Saely[1,2], P. Rein[1,3], S. Beer[1,2], H. Drexel[1,2];
[1]VIVIT Institute, Feldkirch, Austria, [2]Department of Internal Medicine, Academic Teaching Hospital Feldkirch, Austria, [3]Private University in the Principality of Liechtenstein, Triesen, Liechtenstein.

Background and aims: Insulin resistance (IR) is the key feature of the metabolic syndrome (MetS) and in prospective studies predicts atherothrombotic events. Its association with directly visualised coronary atherosclerosis is unclear. We hypothesised that IR is associated with both angiographically determined coronary artery disease (CAD) and with the MetS.
Material and methods: We enrolled 986 consecutive patients undergoing coronary angiography for the evaluation of suspected or established stable CAD; significant CAD was diagnosed in the presence of ignificant coronary stenoses with lumen narrowing ≥50%. IR was determined by the HOMA index; the MetS was defined according to ATPIII criteria.
Results: HOMA IR scores were significantly higher in MetS patients than in subjects without the MetS (6.4 ± 2.1 vs. 2.2 ± 2.0; p <0.001). In contrast HOMA-IR did not differ significantly between patients with significant CAD and those who did not have significant CAD (3.9 ± 14 vs. 3.2 ± 4; p = 0.490). When both, the presence of MetS and of significant CAD were considered, HOMA-IR was significantly higher in patients with the MetS both among those who had significant CAD (7.2 ± 28 vs. 2.3 ± 2.1; p <0.001) and among those who did not have significant CAD (5.3 ± 5.7 vs. 2.1 ± 1.4; p <0.001) whereas it did not differ significantly between patients with significant CAD and subjects without significant CAD in patients with the MetS (7.2 ± 28 vs. 5.3 ± 5.7; p = 0.679) nor in those without MetS (2.1 ± 1.4 vs. 2.3 ± 2.1; p = 0.411). Similar results were obtained with the IDF definition of the metabolic syndrome.
Conclusion: IR is significantly associated with the MetS but not with angiographically determined coronary atherosclerosis.

545

Relation between cardiac autonomic dysfunction and insulin resistance in non diabetic obese patients

I. Banu, S. Chiheb, M. Nguyen, E. Cosson, P. Valensi;
Endocrinology diabetology nutrition, Jean Verdier Hospital, Bondy, France.

Background and aims: Obesity is often associated with cardiac autonomic dysfunction (CAD). The role of insulin resistance in CAD has been suggested in diabetic patients. The aim of the present study was to evaluate the role of insulin resistance in CAD in non diabetic obese patients and whether metabolic disorders are more common and blood pressure higher in patients with both insulin resistance and CAD.
Materials and methods: 394 overweighed or obese patients, aged 38,1 ± 14,4 years, BMI 38;5 ± 7 kg/m², were included. An OGTT was performed, HOMA insulin resistance index was calculated and metabolic syndrome was assessed according to IDF criteria. CAD was defined by at least one abnormal out of 3 cardiac autonomic function tests (deep breathing, lying-to-standing, Valsalva).
Results: CAD was present in 213/394 patients. Insulin resistance was defined by HOMA index ≥ 2.93 (median value). Insulin resistance was associated with a higher rate of CAD (63% vs 49% in the patients with HOMA < 2.93 ; p = 0.006) and severe CAD as defined by 2 or 3 abnormal tests (23% vs 14% ; OR 1.86 [1.10-3.15] ; p = 0.02). The population was divided in 4 groups : HOMA < 2.93 with either 0-1 abnormal CAD test or 2-3 abnormal CAD tests (groups 1 and 2), HOMA ≥ 2.93 with either 0-1 abnormal CAD test or 2-3 abnormal CAD tests (groups 3 and 4). There was a regular increase in BMI, waist and hip circumferences, waist/hip circumference ratio, systolic and pulsed blood pressure, blood glucose and serum insulin 2 hours after glucose intake, HbA1c, triglycerides from group 1 to group 4 (p = 0.02 to 0.0001). Similarly, the prevalence of impaired glucose tolerance and type 2 diabetes according to OGTT and the prevalence and severity of metabolic syndrome increased regularly from group 1 to group 4 (p < 0.0001 for all comparisons).
Conclusion: These data strongly suggest that in non diabetic obese patients insulin resistance is associated with a higher prevalence of CAD and a more severe CAD and that CAD aggravates the consequences of insulin resistance on metabolic disorders including glucose dysregulation and on blood pressure elevation.

546

Metabolic flexibility in the postprandial phase: a global assessment of metabolic defects in type 2 diabetes

J.-A. Nazare[1], E. Disse[1], C. Maitrepierre[1], S. Normand[1], V. Sauvinet[1], M. Desage[1], L. Chardon[2], R. Cohen[2], M. Laville[1];
[1]Centre de Recherche en Nutrition Humaine Rhone-Alpes, [2]Fédération de Biochimie et Biologie Spécialisée/Hôpital Edouard Herriot, Lyon, France.

Background and aims: Impaired metabolic flexibility has been highlighted in type 2 diabetes using a euglycemic-hyperinsulinemic clamp. Our aim was to assess such an impaired metabolic flexibility in more physiological insulin-induced conditions following a meal and to connect it with the postprandial metabolic pattern.
Materials and methods: Using indirect calorimetry and the percent relative cumulative frequency curve (PRCF) analysis for respiratory quotient (RQ), metabolic flexibility (as defined by H: slope of PRCF curve of RQ) and nutrient oxidation were evaluated postprandially after an oral glucose load in 11 type 2 diabetic subjects (DT group) and 9 control healthy subjects (C group). In parallel, insulinemia, glycemia, non-esterified fatty acids (NEFA) concentration and total and endogenous glucose kinetics were assessed.
Results: Metabolic flexibility was significantly lower in the DT group (p<0.0001). Insulin concentration kinetics differed dramatically in the DT group, with no first acute phase but a longer-lasting response associated to a prolonged inhibition of lipolysis. In the DT group, $EGP_{0\text{-}120min}$ (Endogenous Glucose Production) was significantly higher, $RaT_{120\text{-}300min}$ (Appearance of Total glucose) significantly lower and $RdT_{120\text{-}300min}$ (Disappearance of Total glucose) significantly higher (p<0.05). H was significantly correlated to the insulinemic response, the glycemic peak, the total and endogenous glucose kinetics and to NEFA suppression.
Conclusion: H is an original marker of metabolic flexibility in the dynamic postprandial conditions and presently characterized the impaired ability to match fuel availability and utilization in type 2 diabetes. H integrates the interaction between metabolic flexibility and the defects in both insulin-sensitivity and insulin kinetics and showed that nutrient availability pattern significantly determine metabolic flexibility.

Association of restrictive ventilatory dysfunction with insulin resistance and type 2 diabetes

H.-K. Kim[1], Y.-J. Jung[1], S.-J. Bae[1], J.-Y. Park[2], K.-U. Lee[2], C.-H. Kim[3];
[1]Health Promotion Center, Asan Medical Center, Seoul, [2]Internal Medicine, University of Ulsan College of Medicine, Seoul, [3]Internal Medicine, Soonchunhyang University College of Medicine, Bucheon, Republic of Korea.

Background and aims: It has been suggested that early life exposures which affect lung growth could also be associated with insulin resistance. This study was performed to investigate the association of ventilatory dysfunction with insulin resistance and type 2 diabetes.
Materials and methods: We cross-sectionally examined clinical, laboratory and pulmonary function data on 35,456 Korean adults (age 18-93 years, 40% women) which were recorded for routine health check-ups. Insulin resistance was estimated by fasting serum insulin concentration and homeostasis model assessment (HOMA IR).
Results: Type 2 diabetes group and pre-diabetes (impaired fasting glucose) group showed higher prevalence of restrictive ventilatory dysfunction (18% and 11%, respectively, vs. 8%; p < 0.01) and obstructive ventilatory dysfunction (4.3% and 3.2%, respectively, vs. 2.3%; p < 0.01) than normal glucose group. Compared with subjects with normal ventilatory function, the subjects with restrictive or obstructive ventilatory dysfunction had older age, higher fasting glucose, HbA1c, systolic and diastolic blood pressure, and greater proportion of smokers. Serum triglyceride, fasting insulin levels, and HOMA IR were higher only in restrictive ventilatory dysfunction group than in normal or obstructive ventilatory dysfunction group. On logistic regression analysis, age and sex-adjusted odds ratio (OR) of type 2 diabetes for restrictive ventilatory dysfunction was 1.59 (95% confidence interval, 1.43-1.78). After controlling exercise, drinking, and smoking habits, presence of hypertension, BMI, and waist circumference, the OR was 1.38 (1.23-1.55). However, further adjustment for HOMA IR attenuated the OR (1.12 [0.97-1.29]) to become insignificant. In contrast, obstructive ventilatory dysfunction was not independently related with type 2 diabetes.
Conclusion: Our results indicate that restrictive ventilatory dysfunction is independently associated with type 2 diabetes, probably via insulin resistance.

548

Algorithm based on HMW multimers of adiponectin strongly correlates with parameters of insulin resistance in non diabetic severe obese patients who are candidates for bariatric surgery

L. Valera[1], E. Renard[2,3], S. Roche[1], V. Moulin[1], N. Salvetat[1], E. Dupas[1], D. Laune[1], B. Jardin[1];
[1]CNRS UMR 3145 Sysdiag, Montpellier, [2]Endocrinology Department, Lapeyronie Hospital, [3]University of Montpellier I, France.

Background and aims: Because insulin resistance is associated with an increased risk of metabolic and cardiovascular morbidities, its identification in severe obese patients can argue in favour of bariatric surgery. The homeostasis model assessment (HOMA-R) is often used to evaluate insulin resistance, although suffering from limitations due to the specificity of plasma insulin assays and impairments of insulin secretion in case of abnormal glucose tolerance. We investigated the correlation between the various isoforms of adiponectin (LMW, MMW, HMW), total adiponectin, leptin and parameters of insulin resistance in non diabetic severe obese patients in order to assess whether these proteins (or a combination) could represent valuable markers of insulin resistance.
Materials and methods: In this study, 112 severe obese subjects (41 men and 71 women, BMI range: 33-87 kg/m²) with normal glucose tolerance were investigated as candidates for bariatric surgery. Blood glucose and plasma insulin assays allowed the calculation of HOMA-R value. The patients were considered as insulin sensitive when HOMA-R was < 2.6 (n=53) and insulin resistant when HOMA-R was > 2.6 (n=59). The serum concentrations of each isoform of adiponectin and leptin were measured by ELISA (Daiichi Pure Chemicals, Tokyo, Japan; Alpco, Salem, United States, respectively). All statistical analyses were performed with the R software for statistical computing.
Results: Differential statistics using Wilcoxon test revealed clinical or biochemical parameters able to discriminate between insulin resistant (IR) subjects and insulin sensitive (IS) subjects. The most significant parameters

were a) leptin/ HMW isoforms of adiponectin ratio (p=0.0001; Nfoldmedian (IR/IS subjects = 2.09)); b) leptin/total adiponectin ratio (p=0.0001; Nfold median (IR/IS subjects = 1.82)); c) HMW isoforms of adiponectin (p=0.0001; Nfold median (IS/ IR subjects = 1.82)). Analyses of univariate ROC curves showed that leptin/HMW ratio allowed a discrimination between IS and IR patients with a sensitivity of 74.6 and a specificity of 71.7 (Area under curve (AUC) = 0.775). Besides, AUCs were 0.746, 0.739 and 0.732 for leptin/total adiponectin ratio, HMW isoforms of adiponectin and BMI, respectively. Finally, analyses of multivariate ROC curves based on the association of clinical and biochemical parameters showed that the combination of BMI, adiponectin HMW and leptin is the best method to discriminate between IR and IS subjects. Thus, we found an algorithm based on these three parameters allowing a significant discrimination between IR and IS subjects, with 80% sensitivity and 74% specificity (AUC = 0.803). Omission of leptin led to a slightly reduced AUC of 0.790, but sensitivity was increased to 85% while specificity remained at 70%.
Conclusion: Our data disclose the specific value of assessing circulating HMW isoforms of adiponectin in order to identify insulin resistance in non diabetic severe obese patients. The measurement of this parameter, combined to BMI in our algorithm, could represent a useful tool to further estimate the metabolic and cardiovascular risk of overweight patients; it should support the development of easier methods of specific assays to be extended in routine practice.

PS 34 Insulin sensitivity - animal studies

549

Opposing effects of ROCK1 deficiency in liver and adipose tissue on insulin action
D. Lee[1,2], J. Shi[3], L. Wei[3], Y.-B. Kim[1];
[1]Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, United States, [2]Department of Medicine, Jeju National University College of Medicine, Republic of Korea, [3]Indiana University, School of Medicine, Indianapolis, United States.

Background and aims: Rho-kinase (ROCK) isoforms have been shown to modulate insulin signaling and glucose metabolism. Deficiency of ROCK1 causes systemic insulin resistance by impairing insulin signaling in skeletal muscle. The current study was designed to further determine the mechanism(s) for insulin resistance induced by absence of ROCK1.
Materials and methods: Mice with global knock out of ROCK1 ($ROCK1^{-/-}$) were injected with insulin (10U/kg) or saline and sacrificed 10 min later. Molecular parameters of insulin signaling in liver and adipose tissue were measured.
Results: Insulin-stimulated PI3K activity associated with IRS-2 was reduced ~35% without any alteration in tyrosine phosphorylation of insulin receptor in liver of $ROCK1^{-/-}$ mice. ROCK1 deficiency also resulted in impaired insulin action on Akt, S6K and S6 in liver. In addition, $ROCK1^{-/-}$ mice displayed dysregulation of liver glycogen metabolism, as evidenced by the decreased expression of glycogen synthase and the defective phosphorylation of GSK3. Despite the fact that $ROCK1^{-/-}$ mice are insulin-resistant, the ability of insulin to activate PI3K was dramatically enhanced in adipose tissue of ROCK1 deficient mice compared with wild type mice. This increase corresponded closely with an elevation in IRS-1 tyrosine 612 phosphorylation, the binding site for the p85 subunit of PI3K, in $ROCK1^{-/-}$ mice. These effects are mainly due to increased insulin action at the level of insulin receptor. Insulin-stimulated phosphorylation of S6K and S6 in adipose tissue was unaltered by ROCK1 deletion.
Conclusion: These data suggest, combined with our previous data on impaired insulin action in skeletal muscle, that defective IRS/PI3K signaling could contribute to the pathogenesis of insulin resistance caused by ROCK1 deficiency. However, increased action of insulin in adipose tissue could not mask whole body insulin resistance.

550

RANKL affects insulin signalling in vascular smooth muscle cells
M. Olesen[1,2], V. Skov[2], T. Ledet[3], L.M. Rasmussen[2];
[1]Physiology and Pharmacology, University of Southern Denmark, Odense, [2]Biochemistry, Pharmacology and Genetics, Odense University Hospital, [3]Laboratory for Biochemical Pathology, Aarhus University Hospital, Denmark.

Background and aims: Osteoprotegerin (OPG), a soluble decoy receptor for receptor activator of nuclear factor-κB ligand (RANKL), accumulates in the arterial wall in patients with diabetes. RANKL is almost absent in normal vasculature but is upregulated in atherosclerotic and calcified lesions. Insulin has been shown to affect OPG production and calcification of vascular smooth muscle cells. However, possible interactions between the OPG-RANKL system and insulin have not previously been considered. The aim of the present study was to investigate the effects of RANKL and OPG on gene expressions in vascular smooth muscle cells, and particularly putative interactions with effects of insulin.
Materials and methods: Primary human vascular smooth muscle cells (HVSMCs) were used for global gene expression studies using Affymetrix microarrays. Three individual studies were performed: Study one: HVSMCs were treated with RANKL (six hours) or vehicle. Study two: Cells were treated with negative control or OPG siRNA for reduction of the OPG production (30 hours). Study three included four experimental groups: HVSMCs treated with RANKL (nine hours), insulin (three hours), RANKL (nine hours) and insulin (three hours), or vehicle.
Results: To investigate the effects of RANKL on gene expressions in HVSMCs, global pathway analysis was applied to study one. Surprisingly, it was found that RANKL downregulated the insulin signaling pathway. OPG knock down (study two) did not affect the insulin signaling pathway but upregulated the

electron transport chain and the ubiquinone biosynthesis pathway. Next, it was investigated whether the observed RANKL-mediated downregulation of the insulin signaling pathway attenuates insulin's effects on HVSMCs (study three). It was found that insulin upregulated 52 genes in HVSMCs (P<0.05, FC >1.2). RANKL inhibited the insulin-mediated upregulation of 16 of the 52 genes. RANKL itself did not downregulate the 16 genes. Therefore, the result showed that RANKL attenuates some of insulin's effects in the arterial wall.
Conclusion: These data demonstrated that RANKL disturbs insulin signaling in HVSMCs. Since insulin upregulates genes through different pathways we suggest that RANKL only has an impact on one or some of these pathways. These results indicate that RANKL has an impact on insulin signaling in the arterial wall and this may be important in relation to the development of vascular calcifications, observed with a high frequency in patients with diabetes.

Palmitate affects insulin signalling in pancreatic alpha cells
S. Piro, E.T. Maniscalchi, A. Monello, G. Pandini, L.G. Mascali, A.M. Rabuazzo, F. Purrello;
Department of Internal Medicine, University of Catania, Italy.

Background and aims: Under physiological conditions high glucose or insulin levels inhibit glucagon secretion, but this regulation is altered in T2DM. Since insulin directly affects glucagon secretion by binding to specific receptors in alpha cells, an alteration in insulin receptor function or signaling could impair this regulatory effect. In this study we investigated the effects of chronic exposure to palmitate on insulin receptor (IR) phosphorylation and insulin signaling in pancreatic alpha cells.
Materials and methods: We cultured α-TC1 (a mouse glucagonoma cell line) with palmitate (0,5 mM) for 48 h. After chronic palmitate exposure, we acutely stimulated the cells with insulin (10-9 M) for different times (from 1 to 20 minutes). At the end of insulin stimulation the IR downstream was investigated. In particular, we studied the insulin receptor phosphorylation (IR-P), the IRS-1 and IRS-2 phosphorylations and the expression of AKT.
Results: After 48 h of palmitate exposure, insulin (10-9 M for 5 minutes) determined an increase of whole IR-P/IGF-1R-P (654±5 AU) significantly higher than in control cells (227±2 AU, n=5, p<0.05). In contrast, the specific immunoprecipitation of IR and the subsequent blot with anti-phosphotyrosine showed a decrease of phosphorylation in palmitate groups (28±2 vs. 229±5 AU in control cells, n=5, p<0.05). To investigate IRS-1 we measured its phosphorylation in Tyr-612 (the most active form). In cells cultured with palmitate we found a decrease of IRS-1-P (Tyr-612) (46 ± 4 AU vs 420 ± 2 AU in control cells; n=5, p<0.01). In addition, we found an increase of IRS-2-P in palmitate groups (102±2 AU in control cells vs 279±3 AU in palmitate cells, n=5, p<0.05). The AKT phosphorylation levels were also decreased in palmitate groups (64 ± 3 AU vs 182 ± 6 AU in control cells; n=5, p<0.05).
Conclusion: In α-TC1, a mouse pancreatic alpha cell line, the chronic exposure to palmitate affects the intracellular insulin pathway. In particular, the phosphorylation of IR and IRS-1 (Tyr-612) were impaired, thus suggesting that trough this mechanism FFA might induce insulin resistance in alpha cells. The increased IRS-2 phosphorylation might drive the insulin signals through the mitogenic pathway.

Post-natal diet-induced programming of insulin resistance in rats alters *in vitro* aortic reactivity
C. Sanchez[1], S. Tanguy[2], O. Georgelin[1], V. Tassistro[1], P. Obert[2], M. Grino[1], M.-C. Alessi[1];
[1]Inserm UMR626, Aix-Marseille University, [2]Physiopathologie des adaptations cardiovasculaires à l'Exercice (EA 2426), Université d'Avignon, France.

Background and aims: Endothelial dysfunction, an independent predictor of cardiovascular events, is associated with the metabolic syndrome in part in relation with insulin resistance. We have shown that immediate postnatal overfeeding in rats, obtained by reducing the size of the litter, programs insulin resistance and adipose tissue metabolism in adulthood. These alterations being further enhanced by high-fat diet. The purpose of the present study was to characterize in this experimental model the endothelial function in relation with the hemodynamic actions of insulin.
Materials and methods: We investigated, using a technique of isolated organ, the dynamic properties of thoracic aorta obtained from adult control (C) or postnatally programmed (P) rats subsequently fed low- (LF) or high-fat diet (HF). Organ were isolated, pretreated with 10^{-6} M epinephrine, and the vasoreactivity to acetylcholine (Ach, 10^{-9}-$10^{-4\,M}$), in the absence or presence to N^{ω}-nitro-L-arginine methyl ester (a nitric oxyde synthase inhibitor, LNAME, 100 μM) or Wortmannin (a PI3-kinase inhibitor, 50 μM) was determined. The effects of insulin alone or during Ach-induced relaxation with or without Wortmannin were also studied.
Results: P or HF induced insulin resistance, this effect being more marked when both paradigms were associated. Inhibition of nitric oxide synthase significantly decreased ACh-induced relaxation, with lower potency in arteries from rats fed HF as compared to LF ($P < 0.01$). Aorta of PHF rats exhibited lower maximal relaxation to ACh and higher EC_{50} for ACh than did those of the other groups ($P < 0.02$). Inhibition of PI3-kinase reduced Ach-induced relaxation in C, but not in P animals ($P < 0.03$), whatever the diet, indicating the existence of a P-induced impairement of PI3-kinase. Insulin (0.035-35 nM) alone was devoid of effect either under a basal state or after epinephrine-induced vasoconstriction. Pre-incubation with insulin (150 nM) decreased ACh-induced aortic relaxation, this effect being less potent in P rats ($P < 0.005$ vs C rats). Pre-incubation with Wortmannin did not affect the above mentioned inhibitory effect of insulin.
Conclusion: Whereas HF alone was ineffective, its association with postnatal programming reduced the ACh-induced vasodilatation partly due to ineffective PI3-kinase pathway. Interestingly insulin reversed Ach-induced vasodilatation whatever the group, and this effect was not affected by PI3-kinase inhibition. This indicates that adult rats exhibit an insulin resistant state with defective PI3-kinase pathway leading to a prominent vasoconstrictive effect of insulin. Surprisingly this vasoconstrictive effect was less pronounced in P rats suggesting the development of compensatory mechanism(s). The reduced effect of NO synthase blockade in high fat-fed animals is in favor of regimen-induced endothelium-independent alterations. The expression level and phosphorylation status of the various proteins involved in insulin and ACh pathways and smooth vascular cells function are currently investigated.

Glucosamine-induced endoplasmic reticulum stress causes insulin-resistance in L6 skeletal muscle cells
C. Iadicicco[1,2], G.A. Raciti[1,2], L. Ulianich[1,2], V. Vinci[1,2], A. Coppola[1,2], S. Petruolo[1,2], F. Andreozzi[3], P. Formisano[1,2], F. Beguinot[1,2], C. Miele[1,2];
[1]DBPCM, University of Naples "Federico II", [2]IEOS-CNR, Naples, Italy, [3]DMSC, University of Catanzaro "Magna Graecia", Italy.

Background and aims: Endoplasmic reticulum (ER) stress might play an important role in the pathogenesis of insulin-resistance and Type 2 Diabetes. Hyperglycaemia (HG) causes insulin resistance and this process appears to be linked to ER stress. Glucosamine (GlcN), generated by the hexosamine pathway (HP) during HG, also causes insulin resistance and disturbances similar to glucose toxicity. In this work, we sought to evaluate the role of HG- and GlcN- induced ER stress on the insulin-resistance in L6 skeletal muscle cells.
Materials and methods: L6 skeletal muscle cells were incubated either with 10mM GlcN or with 0.5μM thapsigargin (Thap), a well known ER stressing agent, pretreated or not with either 10mM 4-Phenyl Butyric Acid (PBA) or 5mM Tauroursodeoxycholic Acid (TUDCA) for 1 hour.
Results: In L6 cells, 24 hours incubation with either 25mM glucose (HG) or 10mM GlcN, increased the mRNA levels of the ER stress marker *BiP* by 2- and 6-fold, respectively. Azaserine (20μM), an inhibitor of the HP, was able to prevent HG-induced ER stress, suggesting that HG effect on *BiP* was mainly due to the rate of glucose converted into GlcN through the HP. GlcN caused a 2-fold increase of *ATF-6* mRNA ($p < 0.001$), a 3-fold increase of *ATF-3* mRNA levels ($p < 0.001$) and an increase of *XBP-1* spliced form. Furthermore, GlcN significantly impaired insulin-induced 2-deoxy-D-[^{14}C]-glucose (2DG) uptake. These effects were paralleled by a 70% decrease of both mRNA and protein levels of the insulin-sensitive glucose transporter GLUT4. Time-course experiments showed that *GLUT4* mRNA levels were reduced by 30% after 4 hours ($p < 0.001$), and by 70% after 8 hours ($p < 0.001$) of GlcN treatment. *GLUT4* regulation occurred, very likely, at the transcriptional level, as demonstrated by the decrease of the mRNA levels of the two transcription factors known to regulate its expression, MEF2A and PGC1. Moreover, the reduction of *MEF2A* and *PGC1* mRNA observed upon GlcN treatment was paralleled by a 50% and a 45% decrease in their binding to *GLUT4* promoter respectively . Interestingly, the use of the chemical chaperones PBA and TUDCA, known to alleviate ER stress, prevented both *BiP* induction and

GLUT4 downregulation. As for *GLUT4*, also *MEF2A* and *PGC1* mRNA levels did not show any appreciable variation when L6 cells were treated with GlcN in the presence of PBA or TUDCA. Furthermore, PBA or TUDCA pre-treatment restored insulin-induced 2DG uptake in L6 cells treated with GlcN to levels comparable to those measured in L6 control cells. To understand the molecular mechanism involved in the transcriptional inhibition of *GLUT4* induced by ER stress, we analyzed the expression of the inhibitory transcription factor *SHP* that is induced upon stress conditions. *SHP* expression was increased by 2-fold upon GlcN treatment suggesting that it could be involved in *GLUT4* regulation.
Conclusion: In L6 skeletal muscle cells GlcN induces insulin resistance by inhibiting insulin-stimulated glucose uptake and by decreasing *GLUT4* expression through ER stress activation.

Leptin infusion in lateral ventricle enhances the insulin sensitivity in hypothalamus and liver despite the induction of PTP1B
F. Berthou[1], C. Rouch[2], A. Gertler[3], K. Gerozissis[1], M. Taouis[1];
[1]UMR 1197 - INRA / Université Paris Sud 11, Orsay, [2]UMR 7059 CNRS-Université Paris 7, France, [3]The Institute of Biochemistry, Food Science, and Nutrition, Rehovot, Israel.

Background and aims: Leptin and insulin increase energy expenditure and reduce food intake by act on the hypothalamic arcuate nucleus. However, a leptin resistance state has been described in obese humans as mirrored by an increase of appetite, a reduced energy expenditure and high leptin plasma levels. Leptin resistance is frequently associated to other metabolic diseases such as type 2 diabetes characterized by an insulin-resistance. The molecular mechanisms underlying the onset of the two resistances at the central level are still misunderstood. Recently in rat hypothalamus, we have shown that leptin is able to induce the expression of phosphotyrosine phosphatase 1B (PTP1B), which plays a crucial role in leptin and insulin signalling by dephosphorylation of JAK-2 (Janus kinase) and insulin receptor. The present study aims to investigate the consequences of a chronic central overexposure to leptin on the PTP1B expression and on insulin sensitivity in hypothalamus and liver.
Materials and methods: Adult male Wistar rats were stereotaxicaly implanted in lateral ventricle with Alzet osmotic pumps and received for 2 weeks saline or leptin (0, 25 µg/µl). At the end of the infusion, animals were treated with saline or insulin (1U/kg/rat) by intraperitoneal (IP) injection, 30 minutes before euthanasia. Hypothalamus and liver were removed and solubilised proteins were subjected to Western-blots analysis using adequate antibodies.
Results: A 2-weeks central leptin infusion increases significantly the basal STAT-3 phosphorylation (+250%) but not MAPK in hypothalamus. In controls rats, insulin treatment is not able to activate insulin signalling pathways in the hypothalamus but interestingly and despite PTP1B induction, leptin infusion potentiates insulin action on the phosphorylation of STAT-3 (+450%), and MAPK (+180%). In liver of leptin-infused rats, the insulin-dependent phosphorylation of Akt was also strongly potentiated (+300%) as compared to control rats (+200%). This increase of insulin sensitivity could be attributed to the overexpression of IR and/or to the leptin-dependent decrease of potential negative regulators of insulin signaling such as serine phosphorylated IRS1/2.
Conclusion: A chronic central leptin infusion for 14 days induces the hypothalamic PTP1B expression which was unable to alter insulin action. This chronic leptin treatment seems to potentiate the insulin action at both hypothalamic and hepatic levels. This suggests that during early stage of leptin-resistance onset and despite PTP1B increase, insulin signaling pathways are not yet impaired and probably leptin-resistance will lead to insulin-resistance later when the leptin resistance will be clearly established with weight gain and increased food intake.

Postprandial glucose disposal is subject to hepatic parasympathetic control
A.B. Fernandes[1], P.A. Videira[2], N. Bonito[1], R.S. Patarrao[1,3], R.A. Afonso[1,3], M.P. Macedo[1,4];
[1]Physiology, Faculty of Medical Sciences, [2]Imunology, Faculty of Medical Sciences, [3]Biochemistry, Faculty of Medical Sciences, [4]Associação Protectora dos Diabeticos de Portugal (APDP), Lisbon, Portugal.

Background and aims: In the last few years it has emerged a new post prandial mechanism suggesting that besides insulin from the pancreas, the liver produces a humoral factor known as Hepatic Insulin Sensitizing Substance - HISS, which doubles total glucose uptake. The major site of action for this factor is still unknown, but it was observed that changes in response to insulin before and after parasympathetic denervation resulted in unaltered effect of insulin on net glucose balance across the hepatic and splanchnic region. However, significant changes were observed in hindlimb responses. These results highlighted the importance of a new study to evaluate the specific site of action of HISS, which is the aim of this work. Our hypothesis is that HISS acts selectively at the skeletal muscle.
Material and methods: Male fed Sprague-Dawley rats (9weeks-old) were used. To measure insulin sensitivity the Rapid Insulin sensitivity Test (RIST) was used. The RIST is an euglyceamic clamp that quantifies the glucose infused after an insulin bolus (50mU/kg, 5 min). The rate of glucose infusion is adjusted in order to maintain euglycemia and it is the parameter used to evaluate insulin sensitivity/resistance. This study was carried out in the presence and absence of HISS (denervated vs non-denervated animals). Insulin sensitivity was determined before and after each intervention (denervation or sham), using the RIST. The plasma [3H]2-deoxy-glucose ([3H]2DG) rate of disappearance was also quantified during the RIST and incorporation of [3H]2DG uptake into the following individual tissues was measured: skeletal muscle (gastrocnemius, extensor digitorium longus (EDL) and soleus), liver, adipose tissue, heart and kidney. For this purpose, a bolus of 250µCi/kg [3H]2DG was injected at t=9 min of the second RIST.
Results: In the non-denervated group, the first RIST was 228.9±15.3 mg glucose/kg and the second RIST was 221.2±12.3mg glucose/kg (n=5). In the denervated group the control RIST (before denervation) was 251.6±27.5 and after the denervation process (after blocking the HISS pathway) the RIST decreased to 153.5±12.3 ($p<0.01$, n=6). The denervated animals showed a decreased rate of plasma [3H]2DG disappearance, and when we evaluated the tissues we observed that the skeletal muscle, specifically the soleus and the EDL, were affected by 35% ($p<0.05$) and 48% ($p<0.01$), respectively, in the denervated group. The cardiomyocytes also were affected in the denervated group, in this case the decrease was 46% ($p<0.05$) when compared to the sham group.
Conclusion: When we block the HISS pathway, there is a significant decrease in insulin action (observed by the RIST Indexes). In the *in vivo* incorporation of [3H]2DG uptake into individual tissues we observed that the tissues that were affected by the HISS manipulation was the skeletal muscle, mainly the soleus and the EDL muscles and the cardiomyocytes. These observations suggest that when the hepatic parasympathetic nerves are compromised glucose uptake is only decreased in the skeletal muscle and cardiomyocytes.

Knockdown of CHOP, an inducer of cellular apoptosis upon excessive endoplasmic reticulum stress, in liver ameliorates insulin resistance and glucose homeostasis in mice model of type 2 diabetes
T. Kondo[1], H. Adachi[1], R. Ogawa[2], K. Sasaki[1], K. Tsuruzoe[1], N. Furukawa[1], H. Motoshima[1], M. Sakakida[2], E. Araki[1];
[1]Metabolic Medicine, Kumamoto University, [2]Environmental & Symbiotic Sciences, Prefectural University of Kumamoto, Japan.

Background and aims: Transcription factor CHOP (C/EBP homologous protein), is known as a strong inducer of cellular apoptosis in response to excessive endoplasmic reticulum (ER) stress. CHOP is also associated with pancreatic β-cell apoptosis and insulin secretory dysfunction in diabetic condition. CHOP is specifically induced upon severe ER stress, when cells can no longer adapt to survive using unfolded protein response pathways, and contribute to cell death to eliminate dysfunctioning ones. However, it is yet known the function of CHOP in insulin resistance, especially in liver.

Materials and methods: We utilized younger age db/db (BKS.Cg-m +/+ Leprdb/J; 5w old~) mice to determine the impact of CHOP on insulin resistance. CHOP expression was down-regulated by CHOP siRNA expression plasmid which was delivered using in vivo jetPEI intraperitoneally. Injection of CHOP siRNA and control siRNA were performed once a week from 5 to 15 weeks old mice.
Results: The followings were observed in CHOP siRNA treated group (Control v.s. CHOP siRNA group).
1) Suppression of body weight increments (43.2g v.s. 39.1g at 10 weeks old, $p< 0.05$),
2) Reduction of fasting and random fed glucose levels (Fasting: 644 mg/dL v.s. 309 mg/dL at 15 weeks old, $p< 0.05$; Random fed: 721 mg/dL v.s. 505 mg/dL at 13 weeks old, $p< 0.05$),
3) Comparable fasting insulin levels (8.2 ng/mL v.s. 9.4 ng/mL at 11 weeks old),
4) Significant reduction of HOMA-IR (13.03 v.s. 7.17, $p< 0.05$),
5) Improvement of glucose tolerance upon GTT and insulin resistance upon ITT,
6) Suppression of glucose elevation upon pyruvate loading test,
7) Strong suppression of CHOP induction in liver by 95%,
8) Attenuation of ER stress marker, Bip expression in liver,
9) No significant alteration of CHOP expression in muscle and pancreatic islets.
These observations suggest that CHOP silencing in liver is associated with amelioration of insulin resistance and glucose homeostasis in vivo. It is known that CHOP activates interleulin (IL)-1β via caspase-11 induction. Systemic administration of IL-1 β can cause insulin resistance.
Conclusion: CHOP may have a significant role in deterioration of insulin resistance by the induction of inflammatory signals in db/db mice.

Regulatory role of mouse SIRT5 in metabolism
M. Ogura, Y. Nakamura, D. Tanaka, Z. Xiaotong, Y. Fujita, A. Obara, A. Abudukadier, A. Hamasaki, M. Hosokawa, N. Inagaki;
Diabetes and Clinical Nutrition, Kyoto University Graduate School, Japan.

Background and aims: The nuclear protein SIR2, an NAD dependent deacetylase, is known to be involved in life span extension in yeast. In mammalian, there are seven SIR2 homologues, SIRT1-7. SIRT1 is localized in nucleus and regulates the activity of critical transcriptional regulators of metabolism, including FOXO1 and PGC1α. SIRT3, SIRT4 and SIRT5 are localized in mitochondria. SIRT3 deacetylates and regulates acetyl CoA synthetase 2. SIRT4 ADP-ribosylates glutamate dehydrogenase and inhibits its activity in pancreatic beta-cells. However, the function of SIRT5 is still unknown. In this study, to understand the function of SIRT5 in metabolism, we examined the expression level of SIRT5 in different nutrient status, and determined the molecules which are regulated by SIRT5 protein.
Materials and methods: Eleven-week-old C57/BL6 mice were fed *ad libium*, fasted for 24 hours, and re-fed for 24 hours, sequentially. Total RNA was extracted from various organs including liver. SIRT5 mRNA level was determined by qutantitive RT-PCR. SIRT5-overexpressing transgenic (SIRT5 Tg) mice were generated, in which mouse SIRT5 cDNA fused with FLAG tag was expressed by CAG promoter. Overexpression of SIRT5 protein was confirmed by western blotting with anti-FLAG antibody. The liver mitochondrial protein samples from the SIRT5 Tg mice and the littermates were applied for isoelectric electrophoresis, and then separated by SDS-PAGE. The obtained gels were stained with SYPRO Ruby strain kit, and the images were captured with a laser scanner. Then the protein whose position was altered between SIRT5 Tg mice and the littermates was identified using MALDI-TOF-MASS.
Results: SIRT5 mRNA level was increased in liver at fasting condition and decreased at re-feeding up to *ad libium* condition. We established two independent SIRT5 Tg mouse lines on the C57BL/6 inbred background. The SIRT5 Tg mice of both sexes were normally fertile and showed normal appearance. No histological abnormalities were observed in light microscopic analysis in all organs examined. Two-dimension electrophoresis of liver mitochondrial protein was performed and the protein whose position was altered was identified using MALDI-TOF-MASS. The protein is known to be an acetylated enzyme which is involved in metabolism, and its activity was increased in liver of the SIRT5 Tg mice.
Conclusion: SIRT5 may be involved in the regulation of metabolism by modulating the activity of liver enzyme through deacetylaion.

S-nitrosothiols as insulin resistance reversers
M.P. Macedo[1,2], N. Bonito[1], A.B. Fernandes[1];
[1]Physiology, Faculty of Medical Sciences, [2]Associação Protectora dos Diabeticos de Portugal (APDP), Lisbon, Portugal.

Background and aims: Hepatic parasympathetic nerves mediate peripheral insulin action. In the post prandial state the hepatic parasympathetic nerves (HPN) are activated leading to an increase in glucose uptake by insulin action. This HPN activation seems to occur through a new mechanism to which optimal levels of hepatic glutathione (GSH) and nitric oxide (NO) are essential.
Prandial stages are related to different insulin sensitivities. In the fasted state the response to an insulin bolus is decreased when compared to the response of the same insulin bolus in the fed state. Administration of S-nitrosothiols to fasted animals increased the response of an insulin bolus to similar values as observed in the fed state. Our aim was assess the effect of RSNOs in the insulin action dependency on the HPN pathway. Our hypothesis is that blockade of the hepatic parasympathetic nerves leads to an insulin resistance state, which is reversed by RSNOs administration.
Material and methods: Male Wistar rats (9 weeks-old) were used. Insulin action was measured by the Rapid Insulin Sensitivity Test (RIST). The RIST is an euglycemic clamp that quantifies the amount of glucose necessary to infuse after an insulin bolus (50mU/kg over 5 min). The quantity of glucose infused to maintain the euglycemia is refered as the RIST Index and is the parameter used to evaluate insulin sensitivity/resistance. The animals were fasted for 22h and refed for 2h. Three RISTs were done. In the first test, insulin sensitivity was measured in the post prandial state. In a second RIST, insulin sensitivity was evaluated after denervation of the hepatic parasympathetic nerves. The third RIST was done after the administration of a nitrosothiol, the S-nitroso-N-acetylpenicillamine (SNAP). The SNAP was administered intravenously in a dose that was shown previously to be effective in fasted animals (15 mg/kg).
Results: The control RIST Index was 265.3±15.8 mg glucose/kg. After the ablation of the hepatic nerves the RIST Index decreased to 153.9±16.1 mg glucose/kg ($p<0.01$). This decrease was reversed by the administration of SNAP to values similar to the ones observed in the control RIST, 274.3±24.2 mg glucose/kg ($p<0.01$).
Conclusion: In this study it was observed the involvement of the hepatic parasympathetic nerves in insulin action. Moreover the insulin resistance observed with surgical denervation of the HPN was totally reversed by the administration of RSNOs. This observation suggests RSNOs as potential tools to treat dysfunctions related to insulin resistance.

PS 35 Glucagon - secretion and effects

559

Preserved inhibitory potency of glucagon-like peptide-1 on glucagon secretion in type 2 diabetes mellitus

K.J. Hare[1,2], F.K. Knop[1], M. Asmar[2], S. Madsbad[3], C.F. Deacon[2], J.J. Holst[2], T. Vilsbøll[1];
[1]Department of Internal Medicin F, Gentofte Hospital, Hellerup, [2]Department of Biomedical Sciences, University of Copenhagen, [3]Department of Endocrinology, Hvidovre Hospital, Denmark.

Background and aims: The incretin glucagon-like peptide-1 (GLP-1) stimulates insulin secretion and inhibits glucagon release from pancreatic alpha cells. A dose-response relationship for GLP-1's insulinotropic properties has been established; whereas the effect on alpha cells remains less well described. We investigated the dose-response relationship for GLP-1-induced glucagon suppression in healthy subjects and in patients with type 2 diabetes mellitus (T2DM) during hyperglycaemia and after normalization of plasma glucose (PG) levels.
Materials and methods: Ten patients with T2DM (duration of DM: 4±1 years; HbA_1c: 7.1±0.3%; fasting plasma glucose (FPG): 10.3±1 mM; BMI: 31±1.1 kg/m^2) were studied on 2 separate days, after 1 week wash-out of oral antidiabetic drugs, with stepwise increasing GLP-1 infusions (0.25, 0.5, 1.0 and 2.0 pmol/kg/min-each infusion was maintained for 45 minutes) (Day 1) or saline infusion (Day 2) with PG clamped at fasting level. On a Day 3 PG was normalized over-night ($FPG_{t=-30}$: 5.9±0.3 mM) using a variable intravenous insulin infusion. The insulin infusion was stopped 30 minutes before initiation of a stepwise GLP-1 infusion ($FPG_{t=0}$ 6.7±0.2 mM) as on Day 1. Ten matched glucose tolerant subjects were examined with the same protocol as the patients with T2DM on Day 1 and 2 including clamping at FPG levels.
Results: We observed a dose-dependent stepwise suppression of glucagon secretion in both patients and control subjects. Significant suppression was observed at a infusion rate resulting in physiologic GLP-1 plasma levels (0.25 pmol/kg/min) as early as time 15 minutes in control subjects and time 30 minutes in patients with T2DM (Day 1 and Day 3). Area under the curve (AUC) for glucagon during the 3-hour GLP-1 infusion was significantly reduced on Day 1 and Day 3 (1096±109 and 1116±108 pmol/l·3h; P=NS) as compared to Day 2 (1733±193 pmol/l·3h; P<0.01) in the patients. A similar reduction in AUC was observed in control subjects 1122±186 pmol/l·3h (Day 1) vs. 1733±312 pmol/l·3h (Day 2) (P<0.001).
Conclusion: We conclude that the alpha cells in patients with T2DM appear to be fully sensitive to the inhibitory action of GLP-1 both during high and near-normalized PG levels, but respond with a significant delay compared to glucose tolerant control subjects.

Hepatic knockdown of glucagon receptor via siRNA improves glucose homeostasis in mice

T. Akiyama[1], E. Asante-Appiah[2], S. Bartz[3], J.P. Berger[1], G.J. Eiermann[1], C. Li[1], X. Li[1], Q. Shao[1], N. Sharma[1], M. Shin[1], W. Strapps[3], M. Trujillo[1], C. Wang[1], B.B. Zhang[1];
[1]Merck Research Laboratories, Rahway, United States, [2]Merck Research Laboratories, Kirkland, Canada, [3]Merck Research Laboratories, San Francisco, United States.

Glucagon is an important counter-regulatory hormone of insulin that plays a key role in the maintenance of glucose homeostasis by stimulating glycogenolysis and gluconeogenesis in liver. The physiological effects of glucagon are mediated by the glucagon receptor (GCGR), a G-protein coupled receptor predominantly located on the plasma membranes of hepatocytes. Pharmacological and genetic interventions to suppress glucagon receptor signaling have been reported to reverse hyperglycemia in animal models. Here, we examine the extent to which siRNA lipid nanoparticle (LNP)-mediated knockdown (KD) of *Gcgr* in the livers of high fat diet-fed C57BL/6N (DIO) and *db/db* mice results in an improvement in glucose control. Intravenous (IV) administration of GCGR siRNA LNP at a dosage of 3 mg/kg resulted in a 65% KD of *Gcgr* expression in the livers of DIO mice 4 days post-injection, concomitant with 1) significant reductions in ambient and fasted glucose levels, 2) ~2-fold increases in circulating glucagon, 3) improved oral glucose tolerance, and 4) diminished hyperglycemic response to glucagon. In *db/db* mice, two independent *Gcgr* siRNA oligos also achieved significant hepatic KD of *Gcgr* (~65% versus control siRNA LNP) 4 days following an IV injection at a dosage of 3 mg/kg, accompanied by a 75-80% normalization of ambient glucose levels relative to lean controls with no effect on plasma insulin levels (glucose levels were 480.4 +/- 23.0 mg/dl in the control group and 271.0 +/- 18.0 mg/dl or 286.7 +/- 13.0 mg/dl for each of the two GCGR siRNA treatment groups). Elevations in circulating levels of glucagon (3.7-fold) and total GLP-1 (1.9 to 2.3-fold) were also observed, consistent with a 5-fold elevation in the mRNA levels of *preproglucagon* in islets. Together, these data confirm that the attenuation of glucagon signaling improves glucose homeostasis in diabetic mouse models. Importantly, the use of siRNA provides an alternative modality and a powerful tool to interrogate the role of hepatic pathways in glucose control.

Role of glucagon receptor in energy metabolism and body weight regulation

J. Mu[1], K. Lu[1], Z. Li[1], C. Li[1], M.J. Charron[2], B.B. Zhang[1];
[1]Metabolic Disorders, Merck Research Laboratories, Rahway, [2]Albert Einstein College of Medicine, Bronx, United States.

Glucagon, the counter-regulatory hormone of insulin, plays a key role in maintaining glucose homeostasis. In contrast to its role in glycemic control, the relevance of glucagon receptor (GCGR) in the regulation of body weight is less clear. Our recent studies of GCGR knockout (KO) mice demonstrated GCGR deletion improves metabolic control by multiple mechanisms, including inhibition of hepatic glucose output as well as elevation of GLP-1 and FGF21 in circulation. These findings suggest that GCGR signaling is also important for the control of adiposity and insulin sensitivity. To further investigate its role in energy metabolism, GCGR homozygous (KO) and heterozygous mutant mice of both sexes were evaluated for changes in their metabolic phenotype while the mice were maintained on a chow diet or a high fat diet (HFD). As reported previously, male KO mice on chow diet were slightly leaner but maintained similar body weight as wild type (WT) littermates. These KO mice showed a partial resistance to diet induced obesity (DIO). In comparison with their male counterpart, the female KO mice exhibited a lean phenotype to a greater degree. When fed a chow diet, female KO mice displayed significantly increased body weight than their WT littermates (27.5±0.7 vs. 24.5±0.6 g, week 21 of age), largely due to a >10% increase of lean mass. On HFD, female KO mice were completely resistant to DIO during the study period (5-28 weeks of age). Reduced body weight gain in KO mice under HFD was solely due to a decrease of body fat content (lean mass 23.6±0.9 vs. 25.0±1.0 g, p=0.15; fat mass 3.4±0.8 vs. 29.7±1.4 g, p<0.001; week 28, KO vs. WT, n=16). Accompanying reduced adiposity under HFD, ambient glucose levels, plasma and liver triglyceride contents were significantly decreased in KO mice of both sexes. These correlated well with enhanced glucose tolerance and insulin sensitivity seen in KO mice. In contrast to complete GCGR deletion, heterozygous mice of both sexes were non-distinguishable from their WT littermates with respect to body weight and metabolic parameters. In summary, these results demonstrate that GCGR plays a critical role in body weight regulation in rodents, which is more apparent in female mice.

Dual effects of low and high concentrations of cAMP on glucagon secretion from mouse pancreatic A-cells

L. Eliasson[1], Y.Z. De Marinis[1], R. Ramracheya[2], A. Salehi[1], E. Zhang[1], P. Rorsman[2];
[1]Dept. of Clinical Sciences, Lund University, Malmö, Sweden, [2]OCDEM, Oxford University, United Kingdom.

Background and aim: Hyperglycemia is a result from a combination of impaired insulin secretion and insulin resistance at the target tissue. In addition it is associated with oversecretion of glucagon. Normally glucagon is secreted from the pancreatic alpha-cells (A-cells) in response to low glucose levels and it is under neuronal and hormonal control by agonists such as adrenaline, GIP and GLP-1. They all increase the cAMP-concentration of the A-cell, but still GLP-1 inhibits and adrenaline and GIP stimulates glucagon secretion. The aim of this study is to investigate the cellular mechanisms behind cAMP-dependent inhibition and stimulation within the pancreatic A-cells.
Material and methods: Glucagon secretion was measured on freshly isolated mouse islets and analyzed using radioimmunoassay (RIA). The electrical

properties of the A-cells such as ion channel currents and electrical activity was measured on single A-cells using the perforated patch configuration of the patch clamp technique.
Results: First we confirmed that glucagon secretion stimulated at 1 mM glucose (10±0.5 pg/islet/h, n=38) is inhibited by GLP-1 (6±0.6 pg/islet/h; P<0.0001; n=16) and stimulated by adrenaline (34±7 pg/islet/h; p=0.0001; n=10). The inhibitory action of GLP-1 was almost totally reversed in the presence of the PKA-inhibitor 8-Br-Rp-cAMPS (11±1 pg/islet/h; P< 0.0001 vs GLP-1 alone; n=8) and the stimulatory effect of adrenaline was partially antagonist by Rp-cAMPS (19±2 pg/islet/h; P<0.05 vs adrenaline alone; n=10). The observed effects by GLP-1 and adrenaline on glucagon secretion could be mimicked by low (1-10 nM) and high (10 μM) concentrations of forskolin. Likewise Rp-cAMPS counteracted the inhibitory effect of 3 nM forskolin (P<0.01; n=6-11) and did not reduce (n=8-10) the potentiating effect of 10 μM forskolin. Measuring the cAMP concentration ([cAMP]) in presence of different concentrations of forskolin revealed that 1 nM forskolin increased [cAMP] to 7±1 fmol/islet compared to 91±8 fmol/islet in the presence 10 μM forskolin. Together these data suggests that low [cAMP] is responsible for the inhibitory action on glucagon secretion and the high [cAMP] for the potentiating effect. Interestingly, there exist two isoforms of PKA, PKAI and PKAII, where PKAI have been demonstrated to be activated at a lower [cAMP] than PKAII. Using immunocytochemistry we could demonstrate the presence of both these PKA-isoforms in A-cells. Patch-clamp experiments on single A-cells revealed that the PKA-dependent suppressive action of GLP-1 on glucagon secretion act through inhibition of the N-type Ca^{2+}-currents (P<0.001; n=7) and reduced electrical activity (P<0.01; n=4).
Conclusion: We conclude that GLP-1 and adrenaline increase [cAMP] inside the A-cell to a low and high level, respectively. We further suggest that 1) low concentrations of cAMP activates PKAI leading to inhibition of N-type Ca^{2+}-currents and electrical activity and 2) high [cAMP] activate PKAII and PKA-independently the cAMP-binding protein Epac2 resulting in amplification of glucagon secretion.

Glucose inhibits glucagon secretion from mouse pancreatic islets independently from insulin release and by mechanisms that are distinct from those elicited by K_{ATP} channel modulators
R. Cheng-Xue, M.A. Ravier, P. Gilon;
Université Catholique de Louvain, Brussels, Belgium.

Background and aims: Glucagon secretion by pancreatic α-cells is normally inhibited by hyperglycemia and stimulated by hypoglycemia. The mechanisms by which glucose (G) inhibits glucagon secretion are still unclear. In particular, it is unknown if G influences glucagon secretion by modulating K_{ATP} channels as in β-cells and if a β-cell derived factor is responsible for the G-induced inhibition of glucagon secretion. These questions were studied here.
Materials and methods: NMRI mouse islets were isolated by collagenase digestion of the pancreas and cultured overnight in RPMI 1640 medium containing 7 mM G. Glucagon and insulin secretion from islets were measured in perifusion experiments. A 5 mM mixture of amino-acids (1 mM alanine, 1 mM leucine, 1.5 mM glutamine and 1.5 mM lysin) was added to all perifusion media to better mimic the physiological conditions and have a detectable glucagon secretion. Because glucagon secretion is Ca^{2+}-dependent, the free cytosolic Ca^{2+} concentration ($[Ca^{2+}]_c$) of α-cells was also measured in some experiments by using a Ca^{2+}-sensitive probe (D3cpv) specifically targeted to α-cells within islets.
Results: Increasing stepwise the glucose (G) concentration of the perifusion medium from 0 to 20 mM (2, 5, 7, 10, 15, 20 mM) showed that inhibition of glucagon secretion was already of large amplitude at G2 (64%), and maximal at G7 (69%), whereas stimulation of insulin secretion started at G5. A high concentration of the K_{ATP} channel opener diazoxide (250 μM) decreased glucagon secretion without affecting insulin release during perifusion with G0, whereas it did not affect glucagon secretion but decreased insulin release during perifusion with G7. By contrast, a high concentration of the K_{ATP} channel blocker tolbutamide (500 μM) stimulated glucagon secretion during perifusion with G7 and did not affect it in G0, whereas it strongly stimulated insulin secretion at both [G]. Low concentrations of diazoxide (5μM) and tolbutamide (2μM) did not affect glucagon and insulin secretion, except for a small stimulation of insulin release by tolbutamide at G7. To test if G inhibits glucagon secretion by decreasing the efficacy of $[Ca^{2+}]_c$ on exocytosis, the effect of G was tested during perifusion with a medium containing 30 mM K^+ and 250 μM diazoxide, a condition where α- and β-cell $[Ca^{2+}]_c$, and glucagon and insulin secretion were steadily elevated. Under this condition, increasing the [G] from 0 to 7 mM did neither affect α-cell $[Ca^{2+}]_c$ nor glucagon release whereas it strongly stimulated insulin release by the well documented amplifying pathway of G-induced insulin secretion.
Conclusions: The lack of association between inhibition of glucagon secretion and stimulation of insulin secretion under various experimental conditions refutes the proposal that insulin or a β-cell derived factor coreleased with insulin is the paracrine factor responsible for G-induced inhibition of glucagon secretion. The distinct effects of G and K_{ATP} channel modulators on glucagon and insulin secretion suggest that G does not inhibit glucagon secretion by modulating K_{ATP} channels in α-cells as in β-cells. The lack of effect of G on glucagon secretion when α-cell $[Ca^{2+}]_c$ was steadily elevated demonstrates that G does not inhibit glucagon secretion by decreasing the efficacy of Ca^{2+} on exocytosis.

***In situ* α-cell electrophysiological characterizations using a novel whole pancreas tissue slice approach**
Y.-C. Huang[1], M. Rupnik[2], H.Y. Gaisano[1];
[1]Medical Science, University of Toronto, Canada, [2]Faculty of Medicine, University of Maribor, Slovenia.

Background and aims: The mechanism underlying glucagon secretion remains elusive. Despite a recent surge in α-cell studies, large body of reports have been conflicting because selected α-cell populations or properties could have been inadvertently induced or selected during the conventional islet isolation procedures. An assay specifically designed to overcome these technical limitations is therefore urgently required to reveal insights into α-cell biology and to provide therapeutic targets for treatment of type 1& 2 diabetes.
Material and methods: A novel pancreas slice preparation was developed to surmount enzymatic and mechanical perturbations inherent in conventional islet cell isolation procedures. Mice pancreata were agarose gel-infused and sectioned into slices, wherein intact islets were embedded. Intra-islet cellular communication and islet architecture can be well-preserved and α-cells within slices are easily reachable by a patch pipette. Along with standard patch clamp techniques, we developed electrophysiological protocols to rapidly distinguish α-cells, thereby, enabling large sampling and unbiased examination of high quality α-cells.
Results: Mouse α-cells in slices revealed classical features including readily-activated A-type I_K, voltage-gated I_{Na}, small size (~4 pF), low resting membrane conductance (<0.5nS), and inducible low/high voltage-activated I_{Ca} at -80mV. I_{Ca} influx correlated with glucagon exocytosis as either train of depolarization (train) or UV photo-release of intracellular-loaded caged-Ca^{2+} stimulated C_m increase. N-type Ca^{2+} channels modulated α-cell secretion predominantly because ω-conotoxin GVIA (GVIA) pre-treated α-cells revealed diminished C_m increase in response to a train. Consistently, GVIA-sensitive I_{Ca} became significantly reduced after applying a train to α-cells without pretreatment, which also likely suggests cycling of N-type Ca^{2+} channels on the membrane from active to inactive states or between insertion and internalization. We frequently encountered widely-deviated α-cell parameters, including I_{Na} amplitude (100-900pA), amount of K_{ATP} conductance (0-22 nS), specific subtypes of I_{Ca} in different α-cells, and multiple phases of train-induced C_m change (endo-, no change and exocytosis) in a pool of α-cells. Furthermore, some of these parameters displayed a bell-shaped distribution along with a "window" of maximal activity. More remarkably, when applying multiple trains on individual α-cells at different time points, C_m changes revealed an oscillatory pattern of glucagon secretion.
Conclusion: α-cell ion channel properties examined in slices were largely consistent with previous reports, validating the feasibility of using pancreas slice approach to specifically investigate α-cells. The pattern of wide-range data distribution, cycling of ion channel activities, multiple secretory responses (endo-, no change and exocytosis) within a pool of α-cells, and windows of maximal channel activities within a bell-shaped curve led us to postulate that these properties collectively contribute to the waveform-like oscillatory pattern of glucagon release observed in α-cells. Within this secretory pattern, glucagon secretes maximally when K_{ATP}, Na^+, Ca^{2+} channels reached their optimal "window" of activities (at the peak of a wave cycle). Outside this window, at the upstroke or downstroke of the wave, glucagon secretion declines.

Structure function studies with glucagon related peptides reveal glucagon receptor antagonist activities *in vitro* and *in vivo*

F.P.M. O'Harte, P.L. McClean, N. Irwin;
School of Biomedical Sciences, University of Ulster, Coleraine, United Kingdom.

Background: The impact of abnormally elevated postprandial glucagon responses has been shown to contribute to the increased hepatic glucose output and overall hyperglycaemia associated with type 2 diabetes. Glucagon receptor antagonists have the potential to alleviate this unwanted hyperglycaemia.
Aims: In this study we examined the effects of structural modification of glucagon on peptide stability in the presence of dipeptidylpeptidase-4 (DPP-4). Furthermore, the functional ability of glucagon peptide analogues to block glucagon mediated effects in cultured rodent pancreatic beta cells and in normal mice was examined.
Methods: Two structural analogues of glucagon, namely desHis^{1}Glu^{9}glucagon-amide and desHis^{1}Glu^{9}Lys^{30}Pal-glucagon were synthesised. The stability of these two analogues and native glucagon to DPP-4 was examined *in vitro*. Peptides were incubated with DPP-4 (pH 7.8, final peptide concentration 2 µmol/l) at 37°C for 0, 2, 8 and 24 h. Enzymatic reactions were stopped by the addition of 10% (v/v) trifluoroacetic acid and degradation products were then analysed using reversed-phase HPLC. Acute insulin secretion studies (20 min) were performed with control (5.6 mM glucose), glucagon alone or glucagon in the presence of either desHis^{1}Glu^{9}-glucagon or desHis^{1}Glu^{9}Lys^{30}Pal-glucagon in pancreatic BRIN-BD11 cells. *In vivo* studies were performed with groups of fasted mice (n=9-10, aged 10-14 weeks) injected i.p. with saline, glucagon alone (25 nmol/kg) or desHis^{1}Glu^{9}-glucagon in the presence or absence of glucagon. Blood samples were collected by tail venepuncture at 0, 15, 30, 60 and 105 min.
Results: Glucagon was progressively degraded following incubation with DPP-4 and the primary degradation product was identified as glucagon(3-29) by MALDI-MS. After 8 h incubation only 20% of glucagon remained intact, whereas 60% of desHis^{1}Glu^{9}-glucagon remained intact. In contrast, 100% of desHis^{1}Glu^{9}Lys^{30}Pal-glucagon remained intact up to and including 24 h. Glucagon dose-dependently (10^{-12} to 10^{-7} M) increased insulin secretion (P<0.05-P<0.001, Students t-test) compared to 5.6 mM glucose controls in BRIN-BD11 cells. In contrast, both desHis^{1}Glu^{9}-glucagon and desHis^{1}Glu^{9}Lys^{30}Pal-glucagon failed to promote insulin secretion in these cells over the entire range of concentrations tested (10^{-12}-10^{-7} M) at 5.6 mM glucose. Both desHis^{1}Glu^{9}-glucagon and desHis^{1}Glu^{9}Lys^{30}Pal-glucagon effectively antagonised 10^{-7} M glucagon-induced insulin secretion over the concentration range (10^{-12} to 10^{-7} M) causing a 65-78% decrease in glucagon stimulated insulin secretion (P<0.001). *In vivo* studies demonstrated that plasma glucose responses to glucagon were significantly enhanced (P<0.001) compared with saline (Area Under Curve, AUC 0-105 min) in normal mice. DesHis^{1}Glu^{9}-glucagon showed a reduced overall glucose excursion (P<0.01) compared with glucagon alone. In addition, when combined with glucagon, desHis^{1}Glu^{9}-glucagon effectively antagonised glucagon-induced glucose production, 0-105 min AUC excursion (P<0.001).
Conclusion: These studies demonstrate that desHis^{1}Glu^{9}-glucagon and desHis^{1}Glu^{9}Lys^{30}Pal-glucagon are more stable than native glucagon and are specific glucagon receptor antagonist candidate molecules with potential in alleviating glucagon-induced hyperglycaemia in normal mice. Further studies are required to investigate the efficacy of these peptide analogues in animal models of diabetes.

Impaired glucose-induced glucagon suppression after 50% partial pancreatectomy in humans

B.A. Menge[1], H. Schrader[1], P.R. Ritter[1], W.E. Schmidt[1], T.G.K. Breuer[1], W. Uhl[2], J.J. Holst[3], J.J. Meier[1];
[1]Department of Medicine I, St.Josef-Hospital, Bochum, Germany, [2]Department of Surgery, St. Josef Hospital, Bochum, Germany, [3]The Panum-Institute, Copenhagen, Denmark.

Background and aims: The glucose-induced decline in glucagon levels is often lost in patients with type 2 diabetes. It is unclear, whether this is due to an independent defect in alpha-cell function or secondary to the impairment in insulin secretion. We examined, whether a 50% partial pancreatectomy in humans would also impair post-challenge glucagon concentrations, and if so, whether this could be attributed to the reduction in insulin levels.
Materials and methods: 36 patients were studied before and after an ~50% partial pancreatectomy with a 240 min oral glucose challenge, and the plasma concentrations of glucose, insulin, C-peptide, and glucagon were determined.
Results: Fasting glucose concentrations increased significantly after the partial pancreatectomy (p<0.0001). This was accompanied by a reduction in both fasting and post-challenge insulin and C-peptide levels (p < 0.0001). Fasting glucagon concentrations were not altered by the intervention (p = 0.11). Oral glucose ingestion elicited a decline in glucagon concentrations before surgery (p < 0.0001), but this was lost after partial pancreatectomy (p < 0.01 vs. pre OP values). Likewise, the absolute mean difference in glucagon levels from baseline, and the reduction in the integrated incremental glucagon concentrations were lower after partial pancreatectomy (p<0.01). The loss of glucose-induced glucagon suppression was found after both pancreatic head (p < 0.001) and tail (p < 0.05) resection. The glucose-induced changes in glucagon levels were closely correlated to the respective increments in insulin and C-peptide concentrations (p < 0.01).
Conclusion: The glucose-induced suppression in glucagon levels is lost after a 50% partial pancreatectomy in humans, most likely as a consequence of reduced insulin levels. This suggest that impaired alpha-cell function in patients with type 2 diabetes may also be secondary to reduced beta-cell mass. Alterations in glucagon regulation should be considered as a potential side effect of partial pancreatectomies.

PS 36 Incretin secretion in humans

The postprandial response of the anorexigenic gut hormones PYY and GLP-1 is affected by eating rate

A. Kokkinos[1], C.W. leRoux[2], K. Alexiadou[1], N. Tentolouris[1], R.P. Vincent[2], D. Kyriaki[1], D. Perrea[1], M.A. Ghatei[2], S.R. Bloom[2], N. Katsilambros[1];
[1]First Department of Propaedeutic Medicine, University of Athens Medical School, Greece, [2]Department of Metabolic Medicine, Imperial College, London, United Kingdom.

Background and aims: The rate at which people eat has been suggested to be positively associated with obesity. However, there are no studies examining how eating rate affects appetite and related gut hormones. The present study assessed whether eating the same meal at varying speeds elicits different postprandial orexigenic and anorexigenic gut peptide responses.
Materials and methods: Seventeen healthy adult male volunteers (age: 29.7 ±1.2 years, BMI: 26.1 ±0.9 kg/m2) were consecutively recruited and examined in a crossover design. They consumed a test meal consisting of 300 ml ice-cream (675 kcal, 59% of kcal fat, 33% carbohydrates, 8% protein) at two different rates. In one session, the meal was divided in equal portions and consumed within 5 minutes, while in the other it was consumed in 30 minutes. Blood samples for the measurement of glucose, insulin, plasma lipids, the orexigenic gut hormone ghrelin, and the anorexigenic hormones PYY and GLP-1 were drawn before the meal and at 30 minute intervals after the beginning of meal consumption, until the end of the session, 210 minutes later. Visual analogue scales (VAS) for assessment of the subjective feelings of hunger and fullness were completed during the meal and at 30 minute intervals after meal termination until the end of the study session. The postprandial ghrelin, PYY and GLP-1 responses were assessed and expressed as area under the curve of their plasma concentrations for each session.
Results: PYY levels were higher for the 30 minute meal than for the 5 minute meal 90, 120 and 150 minutes after meal initiation, as were GLP-1 concentrations 60 minutes after the start of the 30 minute meal and until the end of the session. PYY area under the curve (AUC) was higher after the 30 minute meal than after the 5 minute meal (mean ±SEM AUC-5 min meal: 4133 ± 324, AUC-30 min meal: 5250 ± 330 pmol/L*min, p=0.004). The same was true for GLP-1 AUC (mean ±SEM AUC-5 min meal: 6219 ± 256, AUC-30 min meal: 8794 ± 656 pmol/L*min, p=0.001). There was no difference in ghrelin, insulin or glucose response between the sessions, either between specific time points after meal initiation or in terms of AUC. There was a trend for higher VAS fullness ratings immediately after the end of the 30 minute meal compared to immediately after the 5 minute meal (mean ±SEM: 51.7 ±4.9 vs 43.4 ±4.6 mm, p=0.09).
Conclusion: Eating at a physiologically moderate pace leads to a more pronounced anorexigenic gut peptide response than eating very fast, and may thus favor earlier satiety.

Differential reduction in incretin hormone response to different macronutrients in obese vs lean healthy subjects

O. Lindgren[1], J. Vikman[1], C.F. Deacon[2], B. Ahrén[1];
[1]Department of Clinical Sciences, Lund University, Lund, Sweden, [2]Dept of Biomedical Sciences, Copenhagen University, Denmark.

Background and aims: The incretin hormones, glucagon-like peptide-1 (GLP-1) and glucose-dependent insulinotropic polypeptide (GIP) are released after meal ingestion and potentiate glucose-stimulated insulin secretion. Although it is hypothesized that GLP-1 secretion is reduced in obese subjects after ingestion of a mixed meal, it is not known whether the GLP-1 response to individual macronutrients is similarly reduced. This study therefore examined the incretin hormone responses (total and active forms) to isocaloric glucose, fat and protein challenges in obese (OV) and lean (LV) healthy subjects.
Materials and methods: The study was undertaken in healthy male human volunteers that were either lean (BMI 20-25kg/m^2; n=12;LV) or obese (BMI 30-35kg/m^2; n=12;OV). After an overnight fast, the subjects at three different occasions consumed 2g glucose/kg b wt, 0.88g olive oil/kg b wt or 2.22g protein mix (85% whey protein)/kg b wt. Blood samples were collected before and up to five hours after intake of each macronutrient for measurements of insulin and intact GLP-1 and GIP. Early insulin and incretin hormone response were estimated as suprabasal area under the curve (AUC) for the first 30 minutes (AUC30) whereas total hormon responses were assessed as AUC300 over the entore 300 minutes study period.
Results: GLP-1 and GIP secretion increased after glucose, protein and fat in both lean and obese subjects. OV had a significantly lower AUC30 for total GLP-1 compared to LV (0.4±0.1 vs. 0.7±0.1nM*min, P=0.04). In contrast, there was no difference in total GLP-1 response between OV and LV after protein or fat. No Differences were found for AUC300. By contrast, OV had significant reduction of both AUC30 (0.9±0.2 vs. 1.7±0.3nM*min, P=0.03) and AUC300 (18±3 vs. 10±3nM*min, P=0.046) of total GIP after oral protein, whereas there was no difference in GIP secretion after intake of glucose and fat. No differences were found for the early secretion of the intact forms of the incretins. For insulin there were no difference in the early secretion but significantly higher AUC300 in OV after glucose (80±9 vs. 268±41nM*min, P=0.0005) and protein 37±3 vs. 114±16nM*min, P=0.0007).
Conclusion: Our results showed that obesity is associated with reduced early GLP-1 secretion after oral glucose and reduced early and total GIP secretion after oral protein. Our data suggests that incretin hormone secretion is differentially perturbed in obesity depending on the specific macronutrient ingested.

Deterioration of glucose homeostasis induces impaired incretin effect in healthy normal glucose tolerant subjects

K.B. Hansen[1,2], T. Vilsbøll[3], J.J. Holst[2], F.K. Knop[3];
[1]Clinical Physiological, Glostrup Hospital, [2]Biomedical Science, the Panum Institute, Copenhagen, [3]Internal Medicine F, Gentofte Hospital, Denmark.

Background and aims: The incretin effect is severely reduced in patients with type 2 diabetes. It remains unclear whether this deficiency can be induced temporarily in healthy subjects by a short period of glucose homeostatic dysregulation. We aimed to investigate the incretin effect before and after 10 days of prednisolone (a corticosteroid drug) administration, high energy diet and physical inactivity in healthy male subjects
Materials and methods: The incretin effect was measured using 75-g OGTT and isoglycaemic i.v. glucose infusion in 10 healthy Caucasian male subjects without family history of diabetes (age: 24±3 years (mean±SD); BMI: 23±2 kg/m^2; fasting plasma glucose: 5.2±0.4 mM, HbA_1c:5.4±0.1%) before and after dysregulation of glucose homeostasis using high calorie diet, physical inactivity and administration of prednisolone (37.5 mg/day) for 10 days.
Results: No significant change in body weight was observed whereas insulin resistance according to HOMA (1.3±0.1 *vs* 2.9±0.3, (mean±SEM) p=0.0003) and glucose tolerance as assessed by the 120-min plasma glucose-value during the OGTT (4.9±0.4 *vs* 7.8±0.8 mM, p<0.0001) and $AUC_{PG\text{-}OGTT}$ (152±45 *vs* 384±53 mM·4h, p=0.002) deteriorated following the 10-day interventional period. The intervention had a significant negative impact on the incretin effect as assessed by the formula: 100% ($AUC_{insulin,OGTT}$ - $AUC_{insulin,i.v.}$) / $AUC_{insulin,OGTT}$ (72±5 *vs* 43±7%, p=0.002)
Conclusion: These data show that the reduced incretin effect observed in patients with type 2 diabetes is a phenomenon that can be induced in healthy male subjects without risk factors for type 2 diabetes. This finding indicates that the deficient incretin effect in type 2 diabetes is a consequence of a glucose intolerant state rather than a primary event causing type 2 diabetes.

Reduced incretin effect in dexamethasone-induced insulin resistance and glucose intolerance in diabetic offspring

D.H. Jensen[1], K. Aaboe[2], J.E. Henriksen[3], S. Madsbad[4], T. Krarup[1];
[1]Department of Internal Medicine, Bispebjerg Hospital, Copenhagen, [2]Department of Internal Medicine, Herlev Hospital, [3]Department of Endocrinology and Metabolism, Odense University Hospital, [4]Department of Endocrinology, Hvidovre Hospital, Denmark.

Background and aims: Insulin resistance and impaired glucose tolerance characterize pre-diabetes. We wanted to evaluate the incretin effect before and after the development of insulin resistance and glucose intolerance. We used a model where we increased insulin resistance, which in some patients also induced glucose intolerance, by short-term dexamethasone treatment.

Materials and methods: 12 healthy, 1st degree relatives to type 2 diabetic patients, with normal glucose tolerance, were examined on 2 occasions before and after a steroid treatment. We performed a 75g OGTT with frequent blood samples to obtain a glucose profile. On day 2 we made an isoglycemic duplication of the glucose curve by an i.v. glucose infusion. The subjects were then treated with 2mg dexamethasone bid for 5 days, and the tests were repeated. During the tests we drew blood to measure insulin and C-peptide. We calculated the incretin effect by relating the incremental insulin response during the OGTT to the incremental insulin response during the i.v. glucose infusion by the following formula: $((iAUC_{insulin,OGTT}-iAUC_{insulin,i.v.})/iAUC_{insulin,OGTT}) \bullet 100\%$. Insulin resistance was evaluated using the $HOMA_{IR}$ index.
Results: The dexamethasone treatment increased the insulin resistance in all the subjects, of which 7 became glucose intolerant. The group that remained glucose tolerant, ((BMI 22±1 kg/m^2) (mean±SEM), 2 men, 3 women), had a change in $HOMA_{IR}$ from 0,88±0,12 to 1,8±0,30 ($p < 0,05$). This group also had a reduction in the incretin effect from 71±5,4% to 61±4,6% ($p < 0,05$). The glucose intolerant group ((BMI 25±0,6 kg/m^2), 5 men, 2 women) had a change in $HOMA_{IR}$ from 0,97±0,16 to 2,5±0,44 ($p < 0,05$). This group had a reduction in the incretin effect from 70±6,2% to 33±11,8% ($p < 0,05$). Comparison between the two groups showed a significantly larger reduction in the incretin effect in the glucose intolerant group as compared with the tolerant group ($p < 0.05$). The increase in $HOMA_{IR}$ did not differ between the groups. A correlation analysis showed no correlation between the increase in insulin resistance and the decrease in the incretin effect ($p = 0,4$).
Conclusion: Our results point to a reduced incretin effect in relatives to patients with type 2 diabetes after an increase in insulin resistance despite a normal glucose tolerance. Nevertheless the reduction in the incretin effect was significantly more pronounced in subjects, who both developed insulin resistance and glucose intolerance. We therefore hypothesize that the diminished incretin effect seen in type 2 diabetes is the end product of a process already beginning with the development of insulin resistance.

The capability increase the incretin effect in response to increasing oral glucose loads is impaired in patients with type 2 diabetes
J.O. Bagger[1,2], F.K. Knop[3], A. Lund[1,2], H. Vestergaard[1], J.J. Holst[2], T. Vilsbøll[1,3];
[1]Endocrinology J, Herlev Hospital, [2]Biomedical Sciences, University of Copenhagen, [3]Internal Medicin F, Gentofte Hospital, Hellerup, Denmark.

Background and aims: The incretin effect (the enhancement of glucose-induced insulin secretion following OGTT compared to isoglycaemic intravenous glucose infusion (IIGI)) is reduced in patients with type 2 diabetes mellitus (T2DM). In healthy subjects the incretin effect increases concurrently with the size of the oral glucose load resulting in similar glucose excursions independently of the size of the glucose load. Whether patients with T2DM are able to regulate their incretin effect in this manner is unknown. We aimed at elucidating this uncertainty.
Materials and methods: The incretin effect was measured over six days by means of three 4-hour OGTTs with increasing glucose loads (25 g, 75 g and 125 g) and three corresponding IIGIs in two groups of volunteers: 1) Eight patients with T2DM (fasting plasma glucose (FPG): 7.7 (7.0-8.9) mmol/l (mean(range)); HbA_{1c}: 7.0 (6.2-8.4)%); and 2) eight healthy control subjects (CTRLs) matched for sex, age and BMI (FPG: 5.3 (4.8-5.7) mmol/l; HbA_{1c}: 5.4 (5.0-5.7)%) were studied.
Results: As opposed to patients with T2DM the CTRLs did not exhibit any difference in glucose excursions in response to the different oral glucose loads. In contrast to the CTRLs, the patients with T2DM only exhibited a tendency to augmentation of their incretin effect ($100\% \cdot (AUC_{insulin,OGTT} - AUC_{insulin,i.v.}) / AUC_{insulin,OGTT}$) in response to increasing oral glucose loads (Table 1). During all three OGTTs the incretin effect was lower in the T2DM group as compared to the CTRLs (Table 1).
Conclusion: Our data suggest that regulation (increase) of the incretin effect in response to increasing oral glucose loads is crucial for controlling postprandial glucose excursions in healthy subjects, and that this regulatory capability is impaired in patients with T2DM.

Reduced postprandial GLP-1 response in gestational diabetes mellitus is a fully reversible phenomenon
L. Bonde[1], T. Vilsbøl[2], T. Nielsen[1], J. Svare[3], J.J. Holst[4], S. Larsen[1], F.K. Knop[2];
[1]Internal Medicine, Copenhagen University Hospital, Glostrup, [2]Internal Medicine F, Copenhagen University Hospital, Gentofte, Hellerup, [3]Gynecology and Obstetrics, Copenhagen University Hospital, Glostrup, [4]Biomedical Sciences, The Panum Institute, University of Copenhagen, Denmark.

Background and aims: Patients with type 2 diabetes exhibit reduced postprandial secretion of glucagon-like peptide-1 (GLP-1). The causality and potential reversibility of this pathophysiological trait are unclear. We aimed to investigate whether women with gestational diabetes mellitus (GDM) exhibit decreased postprandial GLP-1 responses, and if so, whether this deficiency ceases following delivery when normal glucose tolerance is reestablished.
Materials and methods: Eleven women with GDM (plasma glucose concentration at 120 min after 75-g OGTT: 10.0±0.3 mM (mean±SEM); age: 31±2 years; BMI: 31.6±1.9 kg/m2; HbA1c: 5.6±0.2%) and eight pregnant women with normal glucose tolerance (NGT) (age: 27.7±1.0 years; BMI: 29.7±1.7 kg/m2; HbA1c: 5.4±0.1%) were investigated with a 4-hour liquid meal test (100g NAN1: 2170 kJ) during pregnancy (third trimester) and 3-4 months post partum. All patients with GDM reestablished a normal glucose tolerance within 2-3 months following delivery.
Results: Patients with GDM exhibited reduced postprandial GLP-1 responses as compared to their postpartum levels (Table 1) and as compared to healthy non-pregnant women (AUC: 1445±293 vs. 3461±811 pM•4h (mean±SEM), $p<0.0001$). The difference between third trimester and post partum GLP-1 responses among NGT women did not reach statistical significance. However, no differenc-es between the two groups during pregnancy and postpartum, respectively, were observed (Table 1). Pregnancy did not have any impact on postprandial responses of the other incretin hormone, glu-cose-dependent insulinotropic polypeptide, in either of the two groups.
Conclusion: Patients with GDM exhibit reduced postprandial GLP-1 responses and the deficiency is fully reversible alongside the restoration of NGT. GLP-1 responses in healthy pregnant women showed the same tendency, suggesting that reduced postprandial GLP-1 response is a characteristic of type 2 diabetes and most likely occurs as a consequence of an insulin resistant state and worsen alongside the development of overt glucose intolerance.

Table 1. Mean incremental AUC for GLP-1 (pM<font face=

	GDM (n=11)	GDM (n=11)	Difference, unpaired T-test (P-value)
Third trimester	1445±293	1616±870	0.836
Post partum	4520±828	3461±811	0.388
Difference, paired T-test (P-value)	0.002	0.069

GIP and GLP-1 concentration are prescribed by different factors during oral glucose load in Asian subjects
A. Hamasaki, N. Harada, A. Muraoka, S. Yamane, X. Liu, A. Okumachi, K. Toyoda, N. Inagaki;
Diabetes and Clinical Nutrition, Kyoto University, Japan.

Background and aims: It is well known that incretin effect contributes to as much as half of insulin secretory response to oral glucose load and that this effect reduces along with worsening of glucose tolerance. Several studies have shown relations between incretin effect, incretin concentration and other endogeneous factors. These findings are, however, almost based on European subjects, and little is known on Asian subjects who have different genetic background resulting in much lower insulin secretory capacity. Thus, in this study, we aimed to investigate whether Asian subjects show similar incretin effect as previously reported, and to show which factor prescribes incretin secretion.
Materials and methods: Isoglycemic 3-hour oral (75g oral glucose tolerance test (OGTT)) and intraveneous glucose administration was performed in thirteen Japanese subjects (age: 33.8±5.6 years; body mass indx (BMI):

23.2±3.5 kg/m2 (mean±S.D.)) who consists of the NGT and the IGT. In the isoglycemic test, intraveneous glucose infusion (20% wt/vol) was performed aiming to reproduce the plasma glucose profile at OGTT using artificial pancreas system STG-22 (Nikkoso, Tokyo, Japan). Plasma or serum levels of glucose, insulin, C-peptide, glucagon, free fatty acids (FFA), gastric inhibitory polypeptide (GIP) and glucagons-like polypeptide-1 (GLP-1) were determined.
Results: Plasma concentrations of GIP and GLP-1 increased significantly after oral glucose load. The integrated GIP concentration during OGTT (area-under-curve (AUC)-GIP) was not correlated with glucose concentrations but with AUC-FFA and fasting glucagon concentration positively (r= 0.75, P<0.01 and r= 0.62, P<0.05 respectively). There also was a significant strong relationship between GIP levels and BMI (r= 0.79, P<0.005). On the other hand, the AUC-GLP-1 was inversely correlated with fasting glucose level and AUC-glucose significantly (r= -0.68, P<0.05 and r= -0.69, P<0.01 respectively), and was not correlated with FFA, glucogon, or BMI. The AUC-glucose during OGTT was closely reproduced by intravenous glucose infusion. Incretin effect caliculated from the integrated β-cell cell secretory response (of insulin and C-peptide) was comparable to that reported in previously (57.9±4.8 % and 44.7±4.0 % respectively).
Conclusion: In this study, we show for the first time that incretin effect in the Asian subjects is comparable to that in the European subjects. In addition, our findings revealed that GIP and GLP-1 concentrations are prescribed by clearly different factors. Furthermore, glucose metabolism appears to be affected by GLP-1 rather than by GIP even in normal to near-normal glucose tolerant subjects, while GIP appears to be more important in lipid metabolism.

574

Beta cell responsiveness to GLP-1 in nondiabetic lean and obese adults
B.A. Aulinger, M. Salehi, D.A. D'Alessio;
Division of Endocrinology, University of Cincinnati, United States.

Background and aims: The incretin effect describes the enhancement of insulin secretion after ingestion of meals due to the gut factors Glucose-dependent insulinotropic polypeptide (GIP) and Glucagon-like peptide-1 (GLP-1). Recent studies suggest that the incretin effect is not only impaired in patients with T2DM but also in obese subjects without history of diabetes. However it is unclear whether this is due to an impaired beta-cell response to GIP or GLP-1. Therefore we sought to determine a dose-response relationship between GLP-1 and insulin secretion in a cohort of lean and obese subjects.
Materials and methods: For this purpose 8 lean (BMI 23.0±0.8; M/F, 4/4) and 6 obese (36.7±0.8; M/F, 3/3)) healthy subjects with no personal or family history of diabetes were studied. Subjects received a variable glucose infusion to achieve stable blood glucose of 7.3 mmol/l that was clamped for 240 minutes. After 60 min of hyperglycaemia, a step wise infusion of GLP-1 was given at rates of 0, 15, 45, 90, 150, 300, and 400 ng/kg (lean mass)/h for 25 minutes each.
Results: The fasting glucose levels in all subjects were < 5.3 mmol/L and slightly higher in the obese than lean group (4.8±0.1 vs 4.5±0.1, p = 0.05). Obese subjects had a significantly higher fasting insulin than lean subjects consistent with insulin resistance (169±32 vs. 57±3 pM; p<0.001). During hyperglycaemia alone, plasma insulin rose to 688±61 pM in the obese subjects and to 201±25 pM in the lean subjects (p<0.001). At the highest rate of GLP-1 subjects in the obese cohort still secreted significantly more insulin compared to the lean (12579±4218 vs. 6062±579 pM; p<0.05), although the individual responsiveness to GLP-1 was more variable (CV 59 vs. 29%). The relative increment of GLP-1 stimulated insulin secretion over glucose alone was not significantly different between the groups.
Conclusion: While the subjects in the obese cohort were obviously insulin resistant their basal insulin secretion was appropriate with only modestly higher fasting glucose compared to the lean subjects. Both glucose and GLP-1 stimulated insulin secretion was significantly higher in the obese subjects and was proportional compared to the response in leans. In this cohort of obese subjects with insulin resistance but adequate beta-cell function there was no impairment of beta-cell responsiveness to GLP-1.

Bromocriptine acutely decreases glucose-stimulated insulin secretion in mice
J.E. de Leeuw van Weenen[1], E.T. Parlevliet[1], M. Ouwens[2], P. Maechler[3], J.A. Romijn[1], H. Pijl[1], B. Guigas[2];
[1]Department of Endocrinology and Metabolic Diseases, Leiden University Medical Center, Netherlands, [2]Department of Molecular Cell Biology, Leiden University Medical Center, Netherlands, [3]Department of Cell Physiology and Metabolism, University of Geneva, Switzerland.

Background and aims: Long term treatment with Bromocriptine, a dopamine receptor D2 agonist, improves glucose tolerance and decreases fasting plasma insulin levels in both obese diabetic patients and animal models by a still unknown mechanism. Since dopamine D2 receptors are expressed in pancreatic beta-cells, we hypothesized that Bromocriptine might modulate insulin secretion by a direct action on the pancreas. We therefore investigated the acute effect of therapeutic concentrations of Bromocriptine on insulin release, both *in vivo* and *in vitro*.
Materials and methods: Male C57BL/6 mice were subjected to an intraperitoneal glucose tolerance test (ipGTT) or a hyperglycemic clamp (20 mM) 60 min after they received a single intraperitoneal injection with Bromocriptine (10 or 25 mg/kg BW) or vehicle. Basal and glucose-stimulated insulin secretion (GSIS) was also measured in pancreatic INS-1E beta-cells after acute treatment (60 min) with Bromocriptine (1, 5, 50 and 500 nM) or vehicle.
Results: One hour after a single intraperitoneal injection of 10 or 25 mg/kg BW Bromocriptine the basal glucose levels were dose-dependently increased by 35% and 136% (p<0.01) compared to vehicle, while insulin levels remained unaffected. In addition, Bromocriptine significantly increased the area under the curve of glucose levels by 40% and 46% (p<0.001) and delayed the rise in insulin levels during the ipGTT, indicating glucose intolerance. During the hyperglycemic clamp, Bromocriptine strongly reduced the first-phase (-76% and -74% at 1 min; p<0.01) and second-phase insulin response (-55% and -63%; p<0.01), underlining a clear alteration of GSIS. Additional experiments in INS-1E beta-cells also showed a dose-dependent inhibition of GSIS by Bromocriptine at concentrations above 1 nM (from -14% to -61%; p<0.01), while basal insulin secretion was not modified.
Conclusion: In contrast with the previously reported beneficial effect of long-term Bromocriptine treatment on glucose homeostasis, we report here that acute administration leads to glucose intolerance, provoked by the inhibition of GSIS. Our *in vitro* data suggests that the Bromocriptine-induced decrease in GSIS is the result of a direct effect on pancreatic beta-cells, through activation of dopamine D2 receptors.

Nateglinide stimulated oral glucose tolerance test for functional assessment of residual beta cell capacity in type 2 diabetes
J. Reusch, A. Wilms, S. Boehncke, K. Badenhoop;
Department of Internal medicine 1, Division Endocrinology, Goethe University, Frankfurt, Germany.

Background and aims: There is no simple clinical tool for testing beta-cell-capacity in patients with type 2 diabetes. The clamp requires continuous monitoring and is not feasible in an out-patient setting.
Nateglinide is a derivative of the amino acid D-phenylalanine, which acts directly on the pancreatic beta-cells to stimulate insulin secretion particualrly in the the early phase. Our aim was to evaluate a combined nateglinide-/OGT test to assess beta-cell capacity in an out-patient setting.
Materials and methods: We examined in a 79 individuals (30 healthy controls (HC) and 49 type 2 diabetes patients (T2DP) either on dietetic control or treated with OAD (excluding sulfonylurea derivatives) during a modified 3 hour OGTT (50g) combined with 120 mg of nateglinide (Starlix®). We measured glucose, insulin and C-peptide at baseline and after 30, 60, 120 and 180 minutes and calculated HOMA-IR, AUCinsulin, AUCc-peptide and AUCglucose. In order to assess the intraindividual variability 10 HC were tested twice.
Results: Significantly lower serum glucose level were found in HC than in the T2DP at any time points (e.g. max glucose: 6.94±1.44 vs 13.03±3.58mmol/l, AUC glucose: 4.69±0.86 vs 9.45±3.70 mmol*h/l) who reached maximum

level later (35.25±17.61 vs. 63.33±31.76 min). In 18 T2DP we observed normal 2h glucose levels (7 had levels compatible with IGT and 20 had glucose >11.1mmol/l). T2DP can be devided into A leading insulin resistence (HOMA-IR>2,5, n=29) and B secretory deficiency (max. c-peptide < 4ng/mL or increase in c-peptide < 2fold, n=21). Patients with secretory deficiency had higher HbA1c (7.79%±1.80 vs. 6.23%±1,58 p<0.001), AUCglucose (1756.91±766 vs.1612 06±663.21.p.05 n.s) and blood glucose at 30min (12.99mmol/l±2.19 vs. 10.38mmol/l±4.38 n.s.) and 120min (11.14mmol/l±5.05 vs. 9.86mmol/l±4.07 n.s.).
Conclusion: The nateglinide/OGT test is a feasible tool for a routine outpatient clinic to assess the residual beta-cell capacity. Insulin and C-peptide values at 30 and 120 minutes distinguish between normal and deficient insulin secretion. Based on the limited numbers analysed we diagnose relevant insulin deficiency in T2DP if the nateglinide/OGT test shows: - 120 min blood glucose levels > 11.1 mmol/l or - > 7.8 mmol/l < 11.1 mmol/l and maximum c-peptide < 4 ng/mL or stimulated c-peptide is smaller than twofold. We will increase the number of investigated patients in order to confirm these cut-off levels.

577

Stimulation of insulin secretion and enhancement of insulin action, *in vivo*, by a small molecule glucokinase activator
R.C. Camacho[1], S. Qureshi[1], X. Yang[1], J.-I. Eiki[2], B.B. Zhang[1];
[1]Metabolic Disorders, Merck Research Laboratories, Rahway, United States, [2]Banyu Pharmaceutical, Tsukuba, Japan.

Glucokinase (GK) is a critical element of glucose metabolism in both the β-cell and hepatocyte, making it an attractive type 2 diabetes drug target. In the β-cell, GK functions as the glucose sensor, determining the threshold for insulin secretion. In the hepatocyte, GK facilitates hepatic glucose uptake during hyperglycemia. The aim of this study was to assess the effects of a GK activator (Cpd C) on *in vivo* insulin secretion and insulin action. Cpd C activates recombinant human GK with an EC_{50} of 50 nM in the presence of 10 mM glucose. Studies were conducted in overnight fasted 10 week old male Sprague-Dawley rats that had underwent arterial and venous catheterization, for sampling and infusion, respectively, 1 week prior to study. In the first set of studies, either vehicle (0.5% methylcellulose, V, n=7) or Cpd C (10 mg/kg, n=5) was dosed orally, followed by an immediate maintenance of euglycemia by an exogenous glucose infusion. Cpd C increased plasma insulin levels (1.8±0.3 vs. 0.8±0.2 ng/mL, p<0.05). As a result, Cpd C also increased the glucose infusion rate (GIR) required to clamp glucose (36±2 vs. 3±1 mg/kg/min, p<0.05). To isolate (insulin-independent) hepatic effects of Cpd C, a second group of rats were dosed orally with either V (n=8) or Cpd C (10 mg/kg, n=8), and then immediately underwent a pancreatic (SRIF+basal glucagon) hyperinsulinemic (2 mU/kg/min) hyperglycemic (190 mg/dL) clamp. Glucagon was clamped at basal levels, and both insulin and glucose were increased similarly (to 1.7 ng/mL and 190 mg/dL, respectively) in both groups. Cpd C significantly increased GIR requirements (30±2 vs. 20±3 mg/kg/min), insulin's stimulation of glucose utilization (29±1 vs. 24±2 mg/kg/min) and suppression of glucose production (-2±4 vs. 4±2 mg/kg/min), and increased liver glycogen (127±13 vs. 71±9 mg/g liver). Thus we have shown that Cpd C stimulates insulin secretion, and independently, also increases hepatic glucose uptake and glycogen synthesis *in vivo*. These data suggest that GK activators hold great potential as novel type 2 diabetes therapeutic agents.

578

Decreased insulin hepatic extraction in women with polycystic ovary syndrome and study of influence of *TCF7L2* gene variant
M. Vankova[1], J. Vcelak[1], P. Lukasova[1], K. Dvorakova[1], J. Vrbikova[1], B. Bendlova[1], G. Pacini[2];
[1]Depart. of Molecular Endocrinology, Institute of Endocrinology, Prague, Czech Republic, [2]ISIB, CNR, Padova, Italy.

Background and aims: The liver is the principal site of insulin degradation. The evaluation of its ability to extract insulin is important to understand pathological states such as impaired glucose tolerance, obesity and diabetes. Polycystic ovary syndrome (PCOS) is considered as a risk factor for diabetes type 2, it is often associated with obesity and beta cell dysfunction as well as insulin resistance. Insulin secretion and hepatic extraction can be calculated from OGTT derived data. Common variants of *TCF7L2* gene are associated with overexpression of this transcription factor and increased insulin gene expression in pancreatic islets, but surprisingly with lower insulin secretion. The aim of study was to assess using functional tests' derived indices the insulin secretion, sensitivity and hepatic extraction and to evaluate the possible influence of *TCF7L2* gene variants in PCOS patients and controls.
Materials and methods: The study involved 109 PCOS patients diagnosed according to ESHRE criteria and 192 control women with different glucose tolerance and body mass index. OGTT was performed in all subjects, in subgroup of 50 PCOS and 23 control women arginin secretion test and euglycemic hyperinsulinemic clamp were performed. The SNPs rs12255372, rs7901695, rs7903146 in the *TCF7L2* gene were assessed by ABI TaqMan SNP Genotyping Assays. Statistics (Kruskal-Wallis one-way ANOVA) was done using NCSS 2004 programme.
Results: PCOS patients vs. controls had higher body mass index (p=0.00), insulin resistance (HOMAR p=0.0004; 1/Matsuda index p=0.00) and insulin secretion (HOMAF p=0.0001; insulinogenic index p=0.00). Insulin hepatic extraction was significantly lower in PCOS patients vs. controls (p=0.00). Independently on study groups, insulin hepatic extraction was higher in lean women (BMI < 25 kg/m^2) compared to overweight women (BMI ≥ 25 kg/m^2). With respect to *TCF7L2* gene variants, PCOS and control women differed only in rs12255372 (G/T) genotypic frequencies (Chi square test, p=0.04). PCOS carriers of the risk T-allele had lower insulin secretion (insulinogenic index p=0.03) and increased insulin hepatic extraction (p=0.02), mainly in lean women. In lean T-allele carriers, acute insulin response (AIR) to arginine during arginine test tended to lower fasting values (AIRf: carriers vs. non-carriers, medians 155 vs. 190 mIU/l, p=0.1) and glucose-potentiated values (AIR_{14}: 768 vs. 965 mIU/l, p=0.2). Euglycemic hyperinsulinemic clamp as well as OGTT derived indices did not detect any difference in insulin sensitivity with respect to genotype.
Conclusion: The study revealed the association of rs12255372 of the *TCF7L2* gene not only with insulin secretion, but also with insulin hepatic extraction in PCOS patients.

Common variant on 1q24.2 (187cM) affects insulin secretion of beta cells and lipid spectrum in French-Canadian and Czech populations
J. Vcelak[1], O. Seda[2], M. Vankova[1], P. Lukasova[1], J. Vrbikova[1], J. Tremblay[2], B. Bendlova[1], P. Hamet[2];
[1]Institute of Endocrinology, Prague, Czech Republic, [2]Research Centre, CHUM, Montreal, Canada.

Background and aims: In order to search for sequence variants conferring risk of type 2 diabetes mellitus (T2DM) we previously conducted a genome-wide linkage study in 108 French-Canadian families from the Saguenay-Lac-St-Jean (SLSJ) region of Quebec (Canada) as we reported on the 43rd EASD Meeting. One of the most significant statistical results was a linkage of insulin resistance index HOMA-IR with locus on chr. 1 (187cM), LOD=2.97. Subsequent FBAT analysis revealed the association of this locus with LDL-cholesterol levels in these families. Our aim was to validate these results by replication in the case/control association study in Czech population.
Materials and methods: The study involved 1465 Czech Caucasian subjects: 347 patients with T2DM (M/F 116/231; age 61.54±7.58/58.37±9.32 years; BMI 29.67±4.63/31.77±5.64 kg/m^2); 327 women with PCOS defined according to ESHRE consensus (age 27.49±6.33 years; BMI 26.96±6.62 kg/m^2); 263 gestational diabetics (age 32.79±4.91 years; BMI 23.82±4.16 kg/m^2); 149 offspring of T2DM (M/F 50/99; age 38.80±10.22/37.24±12.78 years; BMI 26.61±4.52/25.17±4.38 kg/m^2) and 379 controls (M/F 125/254; age 29.39±7.79/29.85±10.77 years; BMI 24.10±2.96/23.27±4.38 kg/m^2) were collected. For better assessment of insulin secretion and sensitivity, the oral glucose tolerance test (oGTT) and insulin tolerance test (ITT) were performed (except of T2DM patients). Moreover, 16 anthropometric parameters, 29 biochemical parameters and hormones, 32 oGTT-derived indices were evaluated. The rs4656671 (G>A) was assessed by TaqMan SNP Genotyping Assay. Statistics was done using nonparametric Mann-Whitney test and χ^2-test (NCSS 2004 software).
Results: The allelic and genotypic distribution was not significantly different among groups and was independent on sex (χ^2-test). The A allele carriers and non-carriers did not differ in age and BMI within these groups. Only results with the highest statistical significances for associations of the A allele (AA + AG vs. GG) with screened parameters in control and offspring of T2DM groups are presented. In spite of the similar oGTT stimulated glucose levels, the carriers of the A allele had significantly lower insulin and C-peptide secretion (Areas Under Curves (AUCs) are presented) and lower levels of total-

and LDL-cholesterol in comparison with non-carriers. Results from T2DM, PCOS and gestational diabetics groups were not significant.
$AUC_{oGTT\ 0\text{-}180min.}$IRI *[mIU/l*180 min.]* Controls: 5377±3567 vs. 5998±3560, *p=0.025*
Offspring of T2DM: 5429±3361 vs. 6495±4233, *p=0.0073*
$AUC_{oGTT\ 0\text{-}180min.}$C-peptide *[nmol/l*180min.]* Controls: 358±120 vs. 384±120, *p=0.024*
Offspring of T2DM: 370±129 vs. 397±132, *p=0.0128*
Total Cholesterol *[mmol/l]* Controls: 4.27±0.79 vs. 4.59±0.90, *p=0.0006*
Offspring of T2DM: 4.42±0.87 vs. 4.62±0.93, *p=0.028*
LDL-Cholesterol *[mmol/l]* Controls: 2.30±0.71 vs. 2.58±0.83, *p=0.001*
Offspring of T2DM: 2.46±0.80 vs. 2.62±0.86, *p=0.033*
Conclusion: In this study on a sample set from the general Czech population we show that SNP rs4656671 that was previously found by linkage study in French-Canadian families, is associated with lower insulin secretion of beta cells and is accompanied with change in lipid spectrum.

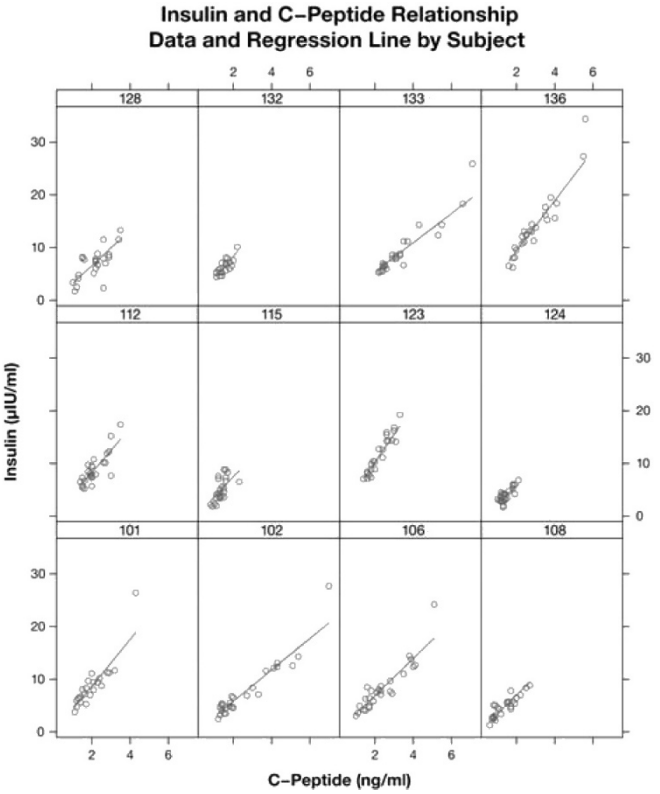
C-Peptide correction method to determine exogenous insulin levels in pharmacokinetic studies using Technosphere insulin
A. Boss, M. Marino, J. Cassidy, R. Baughman, P. Richardson;
MannKind Corporation, Valencia, United States.

Background and aims: Determining the concentration time profile of exogenous-administered insulin in pharmacokinetic studies usually requires the use of patients with poor or absent β-cell function (type 1 diabetes mellitus), labeled insulin, or insulin clamp studies. These methodologies are difficult and limit the ability to explore the kinetics of novel insulins in broad populations. Although baseline C-peptide corrections have been used, they are not robust or precise.
Materials and methods: We report here the use of repeated intraindividual correlations between insulin and C-peptide to assess exogenous insulin contribution in individuals with intact β-cell function analyzed in several clinical trials (69 subjects from 3 trials). C-peptide and insulin are secreted in a 1:1 molar ratio by the pancreas, but while insulin is removed by the liver, C-peptide is not. The clearance, and ultimate ratio, differs among individuals. Data for the analysis were obtained when exogenous insulin was cleared from the plasma (ie, prior to dosing and 6 h or more after dosing with TI). The relationship was analyzed with a linear mixed effect model where the fixed effect was the population mean for intercept and slope and the random effect was the individual deviation from those means.
Results: As expected, a general linear relationship was found to exist between C-peptide and insulin, but the slope varied by individual.
$Insulin_{i,j} = Intercept_i + Slope_i$ X $C\text{-}Peptide_{i,j}$
C-peptide concentrations allow the estimation of an individual's endogenous insulin concentration from the equation above. Exogenous insulin is then calculated by subtracting the endogenous insulin from the total insulin measured as per the equation below.
$TI\ Insulin_{i,j} = Measured\ Insulin_{i,j} - Insulin_{i,j}$
An example of the C-peptide insulin relationship is displayed below.
Conclusion: We suggest that this novel method may be used to replace determination of individuals' C-peptide elimination experimentally.



PS 38 Incretin secretion - studies in animals

Different insulinotropic effecs of GLP-1 and GIP before and during IVGTT with and without systemic DPP4 inhibition in Wistar rats

S. Berg, P. Heinke, E. Salzsieder, K. Kohnert, E. Freyse
Institute of Diabetes, Karlsburg, Germany.

Background and aims: Data on insulinotropic potency of GLP-1 and GIP are controversial and systematic investigations are missing. We had therefore performed glucose and insulin measurements in catheter-wearing rats receiving placebo (P), 1, 2, 4 and 8 nmol/kg GIP and 4 and 8 nmol/kg b.w. GLP-1 5 min before an IVGTT. The GLP-1 dose of 4.0 nmol/kg b.w. produced an insulinotropic effect comparable to that of 2.0 nmol/kg b.w. GIP - I-AUC0-25min: 179± 76* vs. 164±63* ng•min•ml-1, insulinogenic Index (iI): 1.11±0.50* vs. 0.97±0.37* ng/mmol. The glucose efflux was less effective after GLP-1 administration - KG: 14.0±1.6 vs. 21.8±5.5* %/min; *p<0.05 vs. placebo). Since the generated data in the tests could be influenced by a) early insulin liberation and b) action of systemic DPP4 activity immediately after incretin injection and before IVGTT, the effects of both these components should be investigated more in detail.
Materials and methods: a) Catheterized Wistar rats were injected with P, 4.0 nmol/kg GLP-1 (GLP-1,(7-36) amide; Neo MPS; Strasbourg, France) and 2.0 nmol/kg GIP (GIP, Probiodrug AG, Halle/Saale, Germany). Incretins were solved in 0.1 % BSA in saline and were injected at 0 min. Arterial blood for blood glucose (BG) and plasma insulin (I) were taken (-5, 0 min and 1, 2, 3, 5, 7, 10, 15 and 20 min). Reactive and absolute G- and I-AUC from 0-20min was calculated.
b) The DPP4 inhibitor P32/98 was injected at -20 min (dose: 30 µmol/kg), the respective incretin at -5 min and the IVGTT (0.4 g glucose/kg) at ± 0 min. Blood sampling was extended to 60 min and AUC from 0-25min were calculated. To compare treatment groups with the control, the two-tailed t-test with Bonferroni-Holm correction was chosen. Within-group changes were tested by t-test, a *p<0.05 was considered significant.
Results: a) Both GLP-1 and GIP induced an insulin increase under basal blood glucose - GLP-1: reactive I-AUC 10.6±6.0*, absolute I-AUC 16.9±4.1* ng•min•mL-1; GIP: reactive I-AUC 8.8±3.4*, absolute I-AUC 16.5±4.7* ng•min•mL-1. 33.9 % and 34.5 % of insulin increase occurred within 3 min in both the tests. Reactive G-AUC was unchanged after 4 nmol/kg GLP-1 vs. P (10.1±6.2 vs. 4.6±4.1 mmol•min•mL-1) but declined after 2 nmol/kg GIP (-1.7±4.2 mmol•min•mL-1*).
b) DPP4 inhibitor declined always plasma DPP4 activity to 25-20 % during the IVGTT. GIP improved more efficient glucose tolerance (G-AUC: GIP, reactive: 24.6±26.1, absolute: 159.0±31.5*; GLP-1, reacive: 64.7±29.9, absolute: 204.2±33.2; P, reacive: 47.7±12.2, absolute: 183.8±17.1 mmol•min•mL-1) and insulin response (I-AUC: GIP, reacive: 76.4±52.9, absolute: 139.9±40.95*; GLP-1, reactive: 61.5±18.6, absolute: 71.4±25.4; P, reactive: 46.7±19.3, absolute: 54.2±22.3 ng•min•mL-1).
Conclusion: Both, 4 nmol/kg GLP-1 and 2 nmol/kg GIP induce an early insulin increase under basal conditions in healthy Wistar rats. Only the incretin GIP exerts a blood glucose decline.
The plasma DPP4 activity on GLP-1 and GIP for a short time may not explain the different insulinotropic potency of GLP-1 and GIP in the IVGTT in rats and especially the great difference in glucose efflux.
We thank Prosidion Ltd. and Probiodrug AG for donation of DPP4 inhibitor and GIP compound

Chronic treatment with a glucagon receptor antagonist reduces blood glucose and elevates circulating GLP-1 in diet-induced obese mice

B.B. Zhang[1], E. Brady[2], Q. Dallas-Yang[2], F. Liu[2], J. Woods[1], E. Zycband[1], L. Tota[1], M. Wright[1], L. Zhu[1], R. Sinha Roy[1], S. Qureshi[1], D.-M. Shen[1], F. Zhang[1], E.R. Parmee[1], G. Jiang[1];
[1]Merck Research Laboratories, [2]Metabolic Disorders, Merck Research Laboratories, Rahway, United States.

Glucagon plays a key role in maintaining glucose homeostasis and hyperglucagonemia has been implicated in the pathophysiology of type 2 diabetes. Antagonism of glucagon receptor (GCGR) signaling therefore represents a potential approach for treating diabetes. Cpd 15 is a small molecule GCGR antagonist (GRA) that blocks glucagon binding to the hGCGR with an IC_{50} of 34 nM and antagonizes glucagon-induced cAMP accumulation in CHO. hGCGR cells with IC_{50} of 92 nM. The compound blocks glucagon-induced glucose excursion in hGCGR mice whose endogenous murine GCGR was replaced with the human receptor. Cpd 15 also blocks glucagon induced glycogen breakdown in a real-time NMR based assay to monitor glycogenolysis in perfused liver from hGCGR mice. In a chronic study of 82 days in duration, Cpd 15 dosed daily as admixture to chow resulted in effective and sustained glucose lowering in high fat diet induced obese (DIO) hGCGR mice. Treatment with Cpd 15 also resulted in stable and moderate elevation of both glucagon and GLP-1 that was completely reversible upon washout of the compound. Importantly, there was no hyperglycemic overshoot upon termination of the treatment. Immuohistochemical analysis of pancreatic tissue showed that while GCGR KO mice demonstrated severe α-cell hyperplasia, treatment with Cpd 15 normalized the densities of both insulin positive β-cells and glucagon-positive α-cells in the pancreas of DIO hGCGR mice to the levels observed in lean hGCGR mice without apparent α-cell hyperplasia. Finally, whereas the pancreatic tissue of GCGR knockout mice had 16-fold higher preproglucagon mRNA levels compared to wild type mice, treatment with Cpd 15 caused a 2-fold increase in pancreatic preproglucagon mRNA. Thus, GRA treatment can effectively improve glucose homeostasis and increase total GLP-1 levels without eliciting severe hyperglucagonemia. These results suggest the possibility that combination of a GRA with a DPP-4 inhibitor will lead to improved efficacy in glucose lowering by not only blocking the hepatic action of glucagon but also by providing significantly higher levels of active GLP-1 than could be achieved with either therapy alone.

Regulation of proliferation and hormone production of GLP-1 and glucagon-secreting cells

C. Kappe[1], J.J. Holst[2], Q. Zhang[1], Å. Sjöholm[1];
[1]Department of Clinical Science and Education, Södersjukhuset, Karolinska Institutet, Stockholm, Sweden, [2]Department of Biomedical Science, The Panum Institute, University of Copenhagen, Denmark.

Background and aims: Glucagon-like peptide-1 (GLP-1) is an incretin hormone, secreted from gut L-cells upon nutrient intake, and forms the basis for novel drugs against type 2 diabetes. Secretion of GLP-1 is impaired in type 2 diabetes. Glucagon, secreted from pancreatic α-cells, acts as the counterpart of insulin. Abnormalities in α-cell function contribute to hyperglycemia and insulin resistance in diabetes. Little is known about the influence of antidiabetic drugs on α- and L-cell function and regeneration. The aim of this study was to investigate the long term impact of anti-diabetic agents on the proliferation and hormone production of GLP-1- and glucagon-secreting cells and mechanisms underlying such effects.
Materials and methods: The GLP-1-secreting cell line GLUTag and glucagon-secreting αTC1-9 cells were cultured in DMEM media. Cell proliferation was evaluated by ^{3}H-thymidine incorporation and MTT assay after a 48 h-incubation with the anti-diabetic agents. GLP-1 and glucagon were measured by specific ELISAs.
Results: In the GLP-1-secreting GLUTag cells, insulin and the stable GLP-1 analogue Exendin-4 stimulated proliferation at a basal (3 mM), but not high (11 mM) concentration of glucose. A similar effect was also observed by applying ATP. Unexpectedly, the proliferation of the cells was suppressed by the cAMP agonist Sp-cAMP. The DPP-IV inhibitor sitagliptin selectively promoted proliferation of GLUTag cells at high glucose, but not at basal concentration of the sugar. In contrast, proliferation of the glucagon-secreting αTC1-9 cells was not affected by the agents under the same conditions. Metformin significantly inhibited proliferation of both GLUTag and αTC1-9 cells, while pioglitazone inhibited proliferation of GLUTag, but not αTC1-9 cells.
Conclusion: The present study shows that insulin, Exendin-4 and sitagliptin stimulate proliferation of GLP-1-secreting cells without effects on glucagon-secreting cells. Metformin suppresses proliferation of both GLP-1- and glucagon-secreting cells. Since serum GLP-1 levels are decreased in type 2 diabetic patients, the mitogenic stimulation of GLP-1-producing cells by insulin, Exendin-4 and sitagliptin noted here suggests a novel beneficial long term effect of these antidiabetic drugs in clinical practice, *i.e.* by augmenting the incretin effect, and understanding the mechanism of this stimulation would be of great importance for the treatment of diabetes. Likewise, the inhibitory influence of metformin on the proliferation of glucagon-secreting cells may benefit diabetic patients treated with this drug, as relative hyperglucagonemia contributes to impaired glycemic control in type 2 diabetes.

GPR119 activation regulates glucose homeostasis through mechanisms requiring incretin receptor activation

G.B. Flock[1], D. Holland[1], D.J. Drucker[2];
[1]Samuel Lunenfeld Res Institute, [2]IMS, Samuel Lunenfeld Res Institute, Toronto, Canada.

Background and aims: The mechanisms through which nutrients regulate peptide hormone secretion from enteroendocrine cells remains poorly understood. Oleoylethanolamide (OEA) activates incretin secretion via the GPR119 G protein coupled receptor originally detected on islet beta-cells. Although administration of OEA and synthetic GPR119 agonists (GPR119A) reduces glycemic excursion in preclinical studies in association with enhanced incretin and insulin secretion, the importance of GLP-1 and GIP for the glucoregulatory actions transduced through GPR119 remain unclear. We have now examined the importance of GIP and GLP-1 receptor signaling for glucoregulation and satiety mediated by GPR119A through studies of the mechanisms of action of GPR119 agonists in WT and double incretin receptor knockout (DIRKO) mice.
Materials and methods: The actions of a selective GPR119 agonist(GPR119A) were assessed in oral and intra-peritoneal glucose tolerance tests in DIRKO and age and sex-matched C57Bl6 mice. Experimental endpoints included plasma glucose, insulin, GLP-1, GIP and glucagon. Gastric emptying rate was assessed by the acetaminophen assay in mice treated acutely with GPR119A in the presence or absence of the DPP-4 inhibitor Sitagliptin. The effect of GPR119 activation on food intake was assessed in WT C57Bl6, Glp1r-/- and littermate control mice. Statistical analysis was determined using ANOVA.
Results: Oral administration of GPR119A improved glucose homeostasis and augmented plasma levels of both GLP-1 and insulin during an OGTT in WT mice. In contrast, although enteral glucose stimulated GLP-1 and insulin secretion in DIRKO mice, concomitant treatment with GPR119A failed to lower glucose in DIRKO mice. Unexpectedly, oral administration of GPR119A failed to control glucose homeostasis in WT mice during an IPGTT despite an increase in circulating insulin and GLP-1. Acute GPR119 activation significantly reduced the rate of gastric emptying when co-administered with the DPP-4 inhibitor sitagliptin and this effect was independent of GLP-1 action as it remained detectable in Glp1r-/- mice. Moreover, GPR119A significantly but transiently reduced food intake in WT C57Bl6 mice however GPR119A failed to reduce food intake in mice on a metformin-sitagliptin diet.
Conclusion: Our findings suggest that oral administration of nutrients (glucose), together with intact incretin receptor signaling, is required for transduction of the glucoregulatory actions of GPR119A. Hence, under the experimental conditions utilized, direct GPR119A activation of the islet beta-cell is not sufficient to fully control glucose homeostasis in the absence of functional incretin receptors in mice.

Ileal interposition surgery increases circulating GLP-1 and PYY responses and delays diabetes onset in a novel rat model of type 2 diabetes mellitus, the UCD-T2DM rat

B. Cummings[1], A.D. Strader[2], J.L. Graham[1], K.L. Stanhope[1], P.J. Havel[1];
[1]Veterinary Medicine: Molecular Biosciences, University of California, Davis, [2]Department of Physiology, Southern Illinois University School of Medicine, Carbondale, United States.

Background and aims: Bariatric surgery often results in resolution of type 2 diabetes mellitus (T2DM). While the mechanisms for diabetes resolution remain undefined, recent studies suggest that endocrine mechanisms may have an important role. Bypass of the proximal intestine increases secretion of glucagon-like peptide-1 (GLP-1) and peptide YY (PYY), gut hormones that influence energy and glucose homeostasis, in part by increasing the delivery of less completely digested nutrients to the distal intestine. Ileal interposition (IT) surgery involves transposing a 10 cm segment of ileum into the proximal intestine and provides a model whereby the effects of bariatric surgery on gut hormones can be isolated. We hypothesized that IT surgery would delay the onset T2DM in UCD-T2DM rats, a model of polygenetic obese T2DM more similar to T2DM in humans than other existing rodent models, in part by increasing nutrient-stimulated GLP-1 and PYY release.
Materials and methods: IT (n=18) or sham surgery (n=19) was performed on 4 month old UCD-T2DM rats weighing ~580 g. All animals underwent an oral glucose tolerance test (OGTT) 1 month after surgery. 10 animals from each group were euthanized 2 months after surgery for tissue analyses. The rest were followed until onset and underwent insulin tolerance (ITT) and oral fat tolerance tests (OFTT) at 2.5 and 3.5 months after surgery, respectively. Diabetes onset was determined by weekly non-fasted blood glucose (<200 mg/dl).
Results: At this point in the study, sham animals have higher diabetes incidence (78%) and earlier age of onset (262 ± 12 days) compared with IT (63% and 349 ± 22 days; P<0.01). Body weight and food intake do not differ between groups. During OGTT, IT animals exhibited lower glucose (AUC: Sham = 15141 ± 1317, IT = 10972 ± 790 mg/dl x 120 min; P<0.01) and insulin excursions (AUC: Sham = 142 ± 17, IT = 115 ± 11 ng/ml x 120 min; P<0.01) and greater active GLP-1 secretion (AUC: Sham = 53 ± 14, IT = 211 ± 23 pM x 60 min; P<0.01). Since the position of the duodenum remains unchanged after both surgeries, as expected, GIP excursions were not different between groups (AUC: Sham = 9863 ± 537, IT = 10121 ± 447 pg/ml x 60 min). IT animals also exhibit improved insulin sensitivity. Plasma glucose levels fall by 19 ± 3% in IT animals compared with 8±4% in Sham animals 45 min after insulin administration (P<0.05). Total PYY excursions during OFTT were 4-fold greater in IT animals (AUC: Sham = 4704 ± 1175, IT = 19670 ± 3367 pg/ml x 180 min; P<0.01). While body weight only tended to be lower in IT animals, the retroperitoneal (Sham: 12 ± 1 g, IT: 9 ± 1 g; P<0.05) and epididymal (Sham: 9 ± 1 g, IT: 7 ± 1 g, P<0.05) fat pads weighed significantly less in IT animals. In addition, peak mesenteric adipocyte volume was almost two-fold smaller in IT animals (Sham: 409 ± 31, IT: 268 ± 27 pl; P<0.01), whereas subcutaneous adipocyte size did not differ between groups.
Conclusion: Thus, IT surgery improves glucose tolerance and insulin sensitivity and delays the onset of T2DM in UCD-T2DM rats, which may in part be due to increased nutrient-stimulated release of GLP-1 and PYY, and decreased mesenteric adipocyte size.

PS 39 Hypoglycaemia in type 1 diabetes

586

Do patients with greater glycaemic variability on continuous glucose monitoring have a greater risk of subsequent hypoglycaemia?

P. Choudhary[1], A. Finlayson[1], S. Heller[2], S.A. Amiel[1];
[1]Department of Diabetes, King's College London, [2]Department of Diabetes, University of Sheffield, United Kingdom.

Background and aims: Measures of glycaemic variability derived from 1 month of home capillary glucose testing are reported to predict risk of subsequent hypoglycaemia. It is not known if much shorter (48 hours) exposure to much more detailed glucose information available with continuous glucose monitoring (CGM) will likewise predict risk of hypoglycaemia. . There is also no consensus on which measure of variability provides the best indicator of an individual's subsequent hypoglycaemia risk. Aims: To determine if 3 days of CGM (a single sensor) can identify patients at an increased risk of hypoglycaemia in the following year.
Materials and methods: 75 patients with type 1 diabetes from the UK Hypoglycaemia study [HbA1c 7.5 (0.9%) diabetes duration either <5 years or >15 years] had a session of CGM and prospective documentation of severe and symptomatic hypoglycaemia over the subsequent 9 months From the first complete 48 hours of CGM from each subject, measures of variability (Low Blood Glucose Risk Index (LBGI); High Blood Glucose Risk index (HBGI); Blood glucose Risk Index (BGRI) and Continuous Overall Net Glycaemic action (CONGA)) were calculated. Correlations between different measures of variability, HbA1c and subsequent hypoglycaemia risk were calculated.
Results: Glycaemic variability was greater in the longer duration group and was significantly correlated with HbA1c (CONGA1 r= 0.35; p=0.003). CONGA and BGRI showed strong correlation with each other (r= 0.691; p<0.001) but there was poor agreement between measures of variability in identifying those with the highest degree of variability (kappa 0.3 between BGRI and CONGA), with both measures only agreeing in 9/17 of those in the highest quartile of variability.. Only glycaemic variability measured by CONGA was significantly correlated with risk of severe (r = 0.3; p= 0.016) and symptomatic (r = 0.41; p< 0.001) hypoglycaemia CONGA1 < 30 was associated with minimal risk of severe hypoglycaemia over the following year.
Conclusion: Some measures of variability taken from 48 hours of CGM can identify patients at high risk of severe hypoglycaemia over the next 9 months and may identify patients needing treatment to be focussed towards avoidance of hypoglycaemia and reduction of hypoglycaemia risk.

587

Improvement in hypoglycaemia awareness and amelioration if glycaemic profile using CSII in type 1 diabetic subjects with repeated severe hypoglycaemia

I. Conget[1,2], M. Lara[1,2], M. Mora[1], M. Giménez[1,2];
[1]Endocrinology and Diabetes Unit, Hospital Clínic i Universitari, [2]CIBER de Diabetes y Enfermedades Metabólicas Asociadas (CIBERDEM), Barcelona, Spain.

Intensive insulin therapy significantly reduces the risk of complications in subjects with type 1 Diabetes (T1D) and represents the standard treatment from the onset of the disease. However, it is associated with a higher risk of non-severe (NS) and severe hypoglycaemic episodes (SH).
Aim: To evaluate the long-term effect of CSII on hypoglycaemia awareness and on glucose profile in T1D subjects with repeated NS/SH.
Methods: Subjects with: Age ≥18-years, T1D duration >5 years, on multiple doses of insulin, with an absence of micro/macrovascular complications and >4 NS/week (last 8-weeks) and >2 SH (last 2-years) were included. The number of NS/SH episodes were registered. Hypoglycaemia awareness was also evaluated (Clarke's test). A 72h continuous glucose monitoring (CGM) was performed before starting CSII. Quality of life (QoL) assessment was also performed. After 6, 12 and 18-months, all the subjects were reevaluated.
Results: 29 subjects were included. Twenty started CSII (aged 34.4±7.5 years; 13 women, A_{1c} 6.7±1.1%) and 9 declined. At baseline 19/20 subjects displayed hypoglycaemia unawareness which diminished significantly during the follow-up (3/20). NS episodes/week diminished from 5.40±2.09 at baseline to 3.80±2.23 at the end of the study (p<0.02). SH episodes fell from 1.30±0.47 per-subject-year at baseline to 0.05±0.22 after 18-months (p<0.001). HbA_{1c} remained unaltered. Considering CGM, the percentage of values within 70-180mg/dl significantly increased (53.1±10.9 to 65.9±17.6; p<0.01), the percentage below 70mg/dl significantly decreased (13.7±9.4 to 9.5±5.5; p<0.05) and the area <70mg/dl significantly decreased (2.45±1.90 to 1.36±1.61; p<0.05) after 18-months. In addition, considering SD from CGMS it also decreased at the end of follow-up (63.7±14.5 to 52.3±14.5; p<0.05). An improvement in nearly all the aspects of QoL was observed. In the group of 9 subjects who declined CSII we did not observe any change neither in the number of NS/SH, nor in hypoglycemia awareness.
Conclusion: CSII prevents hypoglycaemic episodes, improves hypoglycaemia awareness and ameliorates glycaemic profile for a lasting period in T1D subjects with repeated NS/SH. Likewise; its use is associated with an improvement in diabetes QoL.

ACTH stimulation test in patients with type 1 diabetes and recurrent severe hypoglycaemia

P.L. Kristensen[1], U. Pedersen-Bjergaard[1], H. Beck-Nielsen[2], K. Nørgaard[3], H. Perrild[4], J.S. Christiansen[5], T. Jensen[6], H.-H. Parving[6], B. Thorsteinsson[1], L. Tarnow[7];
[1]Department of Cardiology and Endocrinology, Hillerød Hospital, [2]Department of Endocrinology, Odense University Hospital, [3]Department of Endocrinology, Hvidovre University Hospital, Copenhagen, [4]Department of Endocrinology, Bispebjerg University Hospital, Copenhagen, [5]Department of Endocrinology, Aarhus University Hospital, [6]Department of Medical Endocrinology, Rigshospitalet, Copenhagen, [7]Steno Diabetes Center, Gentofte, Denmark.

Background and aims: Adrenal insufficiency increases insulin sensitivity. This may increase the risk of hypoglycaemia in patients with type 1 diabetes. However, data on the prevalence of adrenal insufficiency are very limited. The primary aim of the study was to determine the prevalence of undiagnosed adrenal insufficiency in patients with type 1 diabetes and recurrent severe hypoglycaemia.
Materials and methods: Cross-sectional data from a clinical trial investigating the effect of human insulin vs. insulin analogues on the frequency of severe hypoglycaemia. Patients with type 1 diabetes for minimum five years and at least two episodes of severe hypoglycaemia (defined as the need of assistance from another person to normalise blood glucose) in the previous year were enrolled in the study. At entry, an ACTH stimulation test (Synacthen®, 0,25 mg i.v.) was performed. Basal and stimulated (after 30 minutes) serum cortisol was measured in all patients.
Results: 128 patients were included (age 53 (13) years (mean (SD)), age at diagnosis of diabetes 23 (13) years, duration of diabetes 30 (13) years, 60% men). Mean (SD, range) basal serum cortisol concentration was 452 nM (120; 119-894). Mean stimulated serum cortisol concentration was 731 nM (125; 515-1134). Delta cortisol was 279 nM (95; 74-614). None of the patients had adrenal insufficiency (defined as stimulated serum cortisol < 500 nM). Stimulated but not basal serum cortisol was significantly higher in women than in men (2 women taking oral contraceptives excluded), p=0.001. Basal and stimulated serum cortisol were neither associated with age (r^2=0.02, p=0.1 and r^2=0.028, p=0.06, respectively) nor with duration of diabetes (r^2=0.002, p=0.59 and r^2=0.0002, p=0.87, respectively). In an analysis adjusted for sex, age and duration of diabetes as explanatory variables basal serum cortisol was significantly positively associated with age (1.97 nM/year, p=0.039), while stimulated serum cortisol was significantly associated with age (1.94 nM/year, p=0.038) and sex (75 nM/female, p=0.001).
Conclusion: Adrenal insufficiency as a contributory factor in development of recurrent severe hypoglycaemia is rare. ACTH stimulation test seems justified only when other signs of adrenal insufficiency are present (e.g. increased insulin sensitivity, common symptoms and signs, etc).

Sustained reduction of biochemical, clinical and severe hypoglycaemia with extended CGM use: results of JDRF CGM six month extension study

B. Bode[1], I.B. Hirsch[2], the Juvenile Diabetes Research Foundation Continuous Glucose Monitoring Research Group;
[1]Atlanta Diabetes Associates, [2]University of Washington, Seattle, United States.

Background and aims: A potential value of continuous glucose monitoring (CGM) is to reduce biochemical hypoglycemia, which is commonly observed in patients with well-controlled type 1 diabetes.
Materials and methods: 83 of 86 subjects ≥25 years old randomized to CGM use in the JDRF CGM randomized clinical trial were followed for 12 months. After 12 months, all but one subject was still using CGM, averaging 6.0±1.6 days/week. HbA1c levels (7.1% at baseline) were reduced to 6.8% at 6 and 6.9% at 12 months (P<0.001 at each time point compared with baseline).
Results: The mean amount of time (minutes) per day in the hypoglycemic range decreased from baseline to 6 months and remained decreased at 12 months (see table below).

	Baseline	6 months	12 months	p-value*
CGM Glucose (min/day)				
≤70 mg/dL	81	69	65	0.06
≤60 mg/dL	44	30	28	0.003
≤50 mg/dL	23	12	11	0.002

*comparing change from baseline to 12 months

A similar trend was seen both in subjects whose baseline HbA1c was ≥7.0% and in those whose baseline HbA1c was <7.0%. A decrease in time in the hypoglycemic range occurred both for daytime and nighttime. The decrease in the frequency of biochemical hypoglycemia was accompanied by a reduction in the rate of severe hypoglycemic events. The rate of severe hypoglycemia was 21.8 events per 100 person-years in the first 6 months and 7.1 events per 100 person-years in the last six months. Indeed, in subjects with baseline HbA1c <7.0 % who had 23.6 events per 100 person-years during the first 6 months, there were no episodes of severe hypoglycemia during the last 6 months even though mean HbA1c levels remained unchanged at 6.4%.
Conclusions: CGM provides an effective means to achieve and maintain target HbA1c levels for up to 12 months in association with a substantial reduction in the frequency of biochemical hypoglycemia in intensively treated adults with type 1 diabetes. More experience with the devices and reduced exposure to biochemical hypoglycemia with associated improvements in counter-regulatory response may have contributed, in turn, to the extraordinarily low rates of severe hypoglycemic events that were observed during the second 6 months of sensor use.

Insulin-like growth factor-1 as a risk marker for severe hypoglycaemia in type 1 diabetes

L. Færch[1], A. Juul[2], U. Pedersen-Bjergaard[1], B. Thorsteinsson[1];
[1]Dept of Cardiology and Endocrinology, Hillerød University Hospital, [2]Rigshospitalet, University of Copenhagen, Denmark.

Background and aims: Low levels of circulating insulin-like growth factor-1 (IGF-1) are associated with increased risk of severe hypoglycaemia (SH) in pregnant women with type 1 diabetes, especially in early pregnancy. We studied whether a similar relationship between IGF-1 and SH exists in non-pregnant people with type 1 diabetes.
Materials and methods: A total of 267 patients with type 1 diabetes were recruited from our outpatient clinic. Information about demography and diabetes was collected at baseline along with blood samples. The participants were followed for one year during usual diabetes treatment. Participants were instructed to phone a trained diabetes nurse within 24h in case of severe hypoglycaemia. The nurse performed a detailed interview with the participant to validate if the episode was actually caused by severe hypoglycaemia. Also, participants were interviewed about mild hypoglycaemia and hypoglycaemia awareness. Biochemical hypoglycaemia (blood glucose < 3.0 mmol/l) was assessed by monthly self-monitored 5-point blood glucose profiles.
Results: During the study 257 episodes of severe hypoglycaemia (1.0 episode per patient-year) were reported by 89 patients (33%). Serum IGF-1 was 112 (36-479) ng/ml (median (range)). IGF-1 was not associated with occurrence of severe hypoglycaemia in the entire cohort (r^2=0.002, p=0.52) or in any of the two sexes when analysed separately. Median serum IGF-1 levels were 112, 101, and 119 ng/ml in patients without SH (n=177), with 1 SH (n=43), and with ≥2 SH (n=47), respectively. Levels of IGF-1 were positively, but weakly, associated with frequency of biochemical hypoglycaemia (p=0.045), but not when corrected for HbA1c level. IGF-1 levels were neither associated with frequency of mild hypoglycaemia (p=0.36) nor hypoglycaemia awareness (p=0.37).
Conclusion: Although low levels of IGF-1 are associated with increased risk of SH in pregnant women with type 1 diabetes, IGF-1 levels are not associated with a hypoglycaemic phenotype in non-pregnant people with type 1 diabetes.

Hypoglycaemia unawareness in patients with diabetes - could galvanic skin response (GSR) measurements provide the answer?

B. Krishnan, D.E.H. Flanagan;
Diabetes and Endocrinology, Derriford Hospital, Plymouth, United Kingdom.

Background and aims: Hypoglycaemia Unawareness (HU), which occurs in approximately 25% of patients with type 1 Diabetes (T1DM), is the main limiting factor in obtaining tight blood sugar control and therefore, preventing or delaying onset of complications related to diabetes in these patients. Reduced autonomic nervous system (ANS) responses, presumed to be secondary to recurrent exposure to cortisol and / Corticotrophin releasing hormone are two of the several theories implicated in the pathogenesis of HU. Measurements of GSR can be used to represent the ANS function, especially the peripheral sympathetic system. The aim of this study was to measure differences in GSR and therefore, the differences in ANS responses to recurrent hypoglycaemia, in healthy subjects and those with disorders of the hypothalamic-pituitary-adrenal (HPA) axis.
Materials and methods: We used a 2 day model of recurrent hypoglycaemia using the hyperinsulinaemic hypoglycaemic clamp technique in two groups of subjects. Group 1 included 11 healthy subjects (age - 41.77 ± 13.72 years, BMI - 24.08 ± 2.86). Group 2 included 7 patients with abnormalities of the HPA axis (age - 46.77 ± 10.87, BMI 26.18 ±2.27). Group 2 included 1 patient with secondary adrenal failure and 6 patients with primary adrenal failure. All patients were on appropriate replacement therapy and took double their normal hydrocortisone dose on both the days of the study. All subjects provided written consent for the study, which was approved by the regional and local research ethics committee. GSR was measured using GSR100C module of the MP150 BIOPAC system. Two Ag-AgCl skin conductance electrodes (TSD203) were attached to the pulps of second and third fingers and GSR recorded using a portable system. Biopac isotonic gel (GEL 101) was used to ensure good contact and the subjects wore the electrodes for minimum of 5 minutes before registration was commenced. The data thus sampled was stored and analyzed digitally using AcqKnowledge software. All subjects underwent clamp studies lasting for 4 hours; this included 30 minutes of euglycaemia (Blood sugar ≈ 4.5 mmol/l), 120 minutes of hypoglycaemia (Blood sugar ≈ 2.5 mmol/l) and the final 60 minutes of euglycaemia. Both the initial shift from euglycaemia to hypoglycaemia and the recovery phase from hypoglycaemia to euglycaemia lasted 15 minutes.
GSR was recorded on 3 occasions during each study - 1) at baseline prior to starting the study 2) during the phase of hypoglycaemia and 3) during the second phase of euglycaemia. Peak GSR responses refers to the maximum GSR responses recorded for any subject during each day of the study.
Results: The peak GSR responses between day 1 and day 2 were significantly different in healthy subjects (p = 0.04) compared to patients (p = 0.18) with the responses being higher on day 2 than day 1 (10.58 ± 5.19 μmho vs 8.59 ± 4.94 μmho). In the patients, the peak GSR on day 1 was 6.33 ± 2.42 μmho and on day 2 was 5.11 ± 2.81 μmho.
Conclusion: The reduced GSR responses to hypoglycaemia in patients with disorders of the HPA axis following exposure to recurrent hypoglycaemia, suggest that their altered HPA axis may be responsible for their reduced ANS responses. This supports the theory that HPA axis dysregulation could account for HU in those with recurrent hypoglycaemia. GSR measurements could therefore be potentially used to study altered ANS responses in patients with diabetes.

Severity of self-reported hypoglycaemia and quality of life in patients with type 2 diabetes mellitus treated with oral anti-hyperglycaemic agents

E. Marrett, L. Radican, Q. Zhang;
Global Outcomes Research, Merck & Co., Whitehouse Station, United States.

Background and aims: Oral anti-hyperglycemic agents (OAHAs), especially sulfonylureas (SU), may increase risk of hypoglycemia and thereby reduce patient quality of life. Our objective was to assess the impact of self-reported hypoglycemia on health-related quality of life (HRQoL) among patients with type 2 diabetes mellitus (T2DM) treated with OAHAs.
Materials and methods: A follow-up survey was conducted among 2008 participants with self-reported T2DM treated with OAHAs only from the US National Health and Wellness Survey 2007.Data were collected on the severity and frequency of hypoglycemic episodes with severity defined as mild (no interruption of activities), moderate (some interruption of activities), severe (needed assistance of others), or very severe (needed medical attention). HRQoL was assessed using the EQ-5D US weighted summary score (utility) and Worry subscale of the Hypoglycemia Fear Survey (HFS).
Results: Mean age was 58 (± 11) years, 57% were male, and 72.2% reported HbA_{1C} goal attainment (<7%). The proportions of patients on SU monotherapy, SU combination therapy, and other treatment regimens were 10.7%, 39.7%, and 49.6%, respectively. Hypoglycemic episodes, in the 6 months prior to the survey, were reported by 61.6% of patients (45.6% mild, 37.4% moderate, 13.2% severe and 3.8% very severe). For patients reporting hypoglycemia, mean utility score was 0.08 lower (0.78 versus 0.86, p<.0001), and mean HFS score was 11.3 higher (17.5 versus 6.2, p<.0001), compared to patients with no symptoms. Differences in mean scores between those with and without hypoglycemia increased with severity for utility (0.03, 0.09, 0.18, 0.23) and HFS (6.1, 13.9, 20.1, 25.6). After adjusting for age, gender, weight gain, microvascular and macrovascular complications, the utility decrement was 0.045 (by severity: 0.008, 0.055, 0.131, 0.209), and the HFS increase was 9.6 (by severity: 5.3, 12.4, 17.6, 23.2). HRQoL further decreased with higher frequency of hypoglycemic episodes.
Conclusion: Self-reported hypoglycemia is independently associated with lower HRQoL, and the magnitude of this reduction increases with both severity and frequency of episodes.

^{13}C magnetic resonance spectroscopy of cerebral glucose metabolism during acute mild hypoglycaemia in humans

K.C.C. van de Ven[1], B.E. de Galan[2], M. van der Graaf[1], A. Heerschap[1], C.J.J. Tack[2];
[1]Radiology, Radboud University Nijmegen Medical Centre, [2]General Internal Medicine, Radboud University Nijmegen Medical Centre, Netherlands.

Background and aims: Normal brain function requires constant supply of glucose and may thus be jeopardized by insulin-induced hypoglycemia. Hypoglycemia causes profound effects on brain physiology, however its effect on metabolism of glucose in the brain is largely unknown. The aim of this study was to investigate the effect of acute hypoglycemia on cerebral glucose metabolism in humans in vivo using 13C magnetic resonance spectroscopy (MRS).
Materials and methods: Eight healthy volunteers underwent ^{13}C MRS measurements during 120-minute hyperinsulinemic (60 mU/min/m^2) euglycemic and hypoglycemic glucose clamps, performed in random order on separate days. [1-^{13}C]glucose was infused during the clamps to increase plasma ^{13}C isotopic enrichment, required to enable ^{13}C MRS. Measurements were performed at a magnetic field strength of 3T in a 125 ml voxel in occipital brain tissue, with a TR of 2s and a duration of 2.5 minutes per scan. Arterial blood was sampled every 5 minutes for the measurement of plasma glucose and plasma ^{13}C enrichment, and every 30 minutes for the measurement of counterregulatory hormone levels. MR spectra were analyzed to assess cerebral concentrations of the glucose metabolite isotopomers glutamate, glutamine, aspartate and lactate. All metabolite concentrations were corrected for plasma ^{13}C enrichment.
Results: Plasma glucose levels were 5.2±0.1 mmol/l during euglycemia and 3.0±0.2 mmol/l during hypoglycemia. Arterial plasma levels of glucagon (77.0±41.9 vs. 27.6±5.1 pmol/L), adrenaline (4.84±2.51 vs. 0.41±0.12 nmol/L), noradrenaline (1.96±0.64 vs. 1.14±0.31 nmol/L) and cortisol (0.89±0.21 vs. 0.42±0.13 µmol/L) were all significantly higher under hypoglycemic than under euglycemic conditions (all P<0.01). Plasma ^{13}C isotopic enrichment remained stable at 35±1% during euglycemia and at 30±1% during hypoglycemia. The quality of the ^{13}C-MR spectra was good under both conditions. After correction for plasma isotopic enrichment, label incorporation into the first glucose-derived metabolites Glutamate C4 and Glutamine C4 did not differ between euglycemia and hypoglycemia (figure). There were also no differences for glutamate C_3 and C_2, glutamine C_3 and C_2, aspartate and lactate.
Conclusion: Despite significant enhancement of counterregulatory hormone responses, overall cerebral glucose metabolism appears unaltered during insulin-induced hypoglycemia in vivo in healthy humans. These data indicate that the human brain is able to maintain normal overall glucose metabolism despite a considerable fall in glucose delivery.

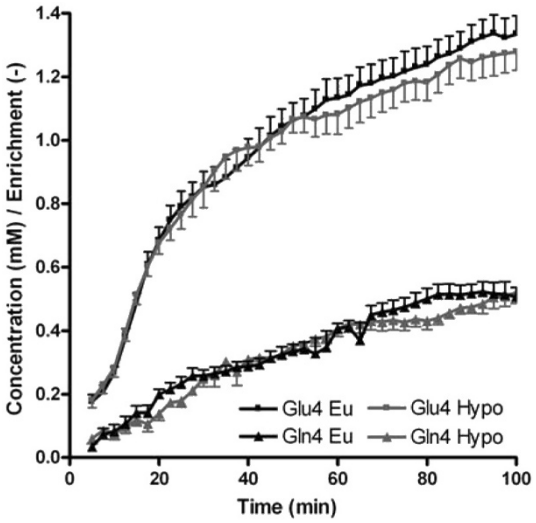

Figure: Incorporation of the 13C label inglutamate C4 (diamonds) and glutamine C4 (triangle) for a euglycemic (black) and hypoglycemic (grey) clamp, corrected for 13C enrichment of plasma glucose. Mean ±SEM.

Somatostatin type 2 receptor antagonism improves glucagon and corticosterone counterregulation to hypoglycaemia in STZ-diabetic rats

J.T.Y. Yue[1], E. Burdett[1], D.H. Coy[2], S. Efendic[3], M. Vranic[1];
[1]Physiology, University of Toronto, Canada, [2]Medicine, Tulane University, New Orleans, United States, [3]Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden.

Background and aims: The pancreatic α-cell glucagon response to a variety of stimuli including exercise, arginine, and neurogenic stress is normal, or even excessive, in diabetic subjects. However, we suggest that the markedly diminished glucagon responsiveness to *hypoglycemia* is mainly due to excessive insulin delivery since insulin suppresses glucagon release. The lack of glucagon response may be due to a lack of decrement of intraislet insulin, increased α-cell sensitivity to exogenous insulin, or chronic hyperglycemia. The impaired α-cell response to hypoglycemia may also be due, in part, to augmented circulating and especially pancreatic somatostatin (SST) in diabetic humans and animals. Presently, we hypothesize that since glucagon release is inhibited in part due to the inhibitory effect of excessive SST, a SST receptor type 2 antagonist (SSTR2a), BIM23458, will normalize the glucagon response to hypoglycemia. SST inhibits glucagon secretion via SSTR2 on α-cells.
Materials and methods: Non-diabetic (N) and STZ-diabetic (D) Sprague-Dawley rats underwent 3h of insulin-induced hypoglycemia (10 U/kg, sc) clamped at 2.5±0.5 mM.
Results: Expectedly, D rats had a greatly attenuated glucagon response to hypoglycemia (P<0.007). To evaluate the inhibition of SST suppression on glucagon release during hypoglycemia, diabetic rats were given iv SSTR2a (D+SSTR2a) at both 1.5 or 3.0 mmol/kg/h for 1h before and 3h after insulin

injection. These groups showed a dose-dependent increase of glucagon such that the latter dose fully restored the glucagon response (N: 325±63, n=9; D: 98±19, n=9; D+SSTR2a: 384±67, n=18; AUC responses, $P<0.002$). Furthermore, the attenuated corticosterone response in D rats ($P<0.002$) was also enhanced by SSTR2a (N: 59±5; D: 30±3; D+SSTR2a: 46±9; AUC responses, $P<0.05$), presumably because SST inhibits the secretions of hormones of the hypothalamo-pituitary-adrenal axis, CRH and ACTH. Thus, antagonism of SSTR2 potentiates not only glucagon but also corticosterone counterregulation. To evaluate the effect of 4h SSTR2a infusion *per se*, plasma glucagon, corticosterone, and glycemia were measured in N, D, and D+SSTR2a (n=6/group) without hypoglycemia. Glucagon, corticosterone, and glycemia were unaltered in these groups. It is known that SSTR2 in the α-cell is coupled to the *L*-type high threshold calcium channel, which is responsible for stimulated secretion of glucagon, but not the *N*-type calcium channel, which mediates basal glucagon secretion, and we presently demonstrate that *antagonism of SSTR2 enhances hypoglycemia-stimulated, but not basal, glucagon or corticosterone release in diabetic rats and that SSTR2a does not affect glycemia in the absence of hypoglycemia*. D exhibit 60-70% more plasma and pancreatic SST than N, regardless of hypoglycemia. SSTR2a did not significantly affect plasma or pancreatic content of SST.

Conclusion: This data supports our hypothesis that *increased SST may contribute to impaired glucagon and corticosterone responsiveness to hypoglycemia and that its selective inhibition normalizes glucagon, and improves corticosterone, counterregulation*. Intervention to improve counterregulation will decrease the threat in those at risk of hypoglycemia.

The cingulate cortex is activated by acute but not recurrent hypoglycaemia in rats - evidence for a role of limbic system in impaired responses to hypoglycaemia?

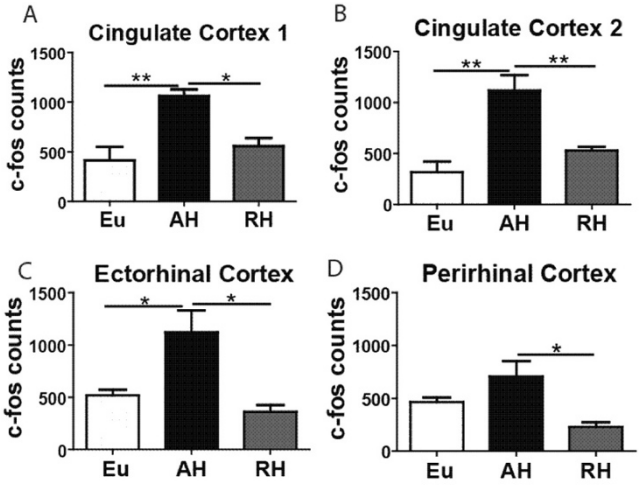
P.S. Hurst, S. Moore, P. Markkula, D. Lam, J. Shaw, C. Riches, L.K. Heisler, M.L. Evans;
Metabolic research laboratories, Cambridge University, United Kingdom.

Background and aims: Some patients, particularly those with exposure to recurrent hypoglycaemia (RH) develop a debilitating loss of counterregulatory (CR) neurohumoral defences to low glucose associated with symptomatic unawareness of hypoglycaemia (HU). Although hypoglycaemia sensing probably occurs predominantly in hypothalamus, it is unclear whether impaired CR/ HU is a consequence simply of altered hypothalamic glucose sensing or whether other brain areas, for example the limbic system contribute. We hypothesized that the cingulate cortex (CC), a cortical/limbic area involved in monitoring the internal milieu, would be activated by acute hypoglycaemia (AH) and, if so, that this activation would be abrogated with RH.

Materials and methods: 3 groups (n=4-5 for each) of male Sprague Dawley rats (250-300g) were injected s.c. on three consecutive days as follows; (i) control (CON) had day 1-3 saline (ii) AH had day 1-2 saline and insulin (humulin S, 10 U/kg) on day 3 (iii) RH had day 1-3 insulin (humulin S, 10-6 U/kg). The RH protocol was selected from our previous studies showing that this results in impaired CR. 120 minutes after injection on day 3, rats were perfused transcardially with fixative and brains were extracted and processed immunohistochemically for c-fos, a marker of neuronal activation, using a monoclonal antibody against rabbit c-Fos (1:10,000, Calbiochem) with one-way ANOVA analysis and post hoc Tukey's for multiple comparisons. The CC was subdivided into 2 anatomically separated areas (CC1 and CC2).

Results: As shown in the figure, AH induced an increase in c-fos staining within both the CC1 and CC2 compared with CON. In keeping with our hypothesis, this activation was markedly attenuated following RH. Looking for a similar pattern in other non-hypothalamic areas, we found a significant increase in c-fos activation with AH in the ectorhinal cortex, an area with projections to the CC, which was attenuated with RH. The adjacent perirhinal cortex also demonstrated decreased c-fos activation with RH compared with AH.

Conclusion: In summary, our data show that the CC and connected brain areas are activated by hypoglycaemia with these responses being lost with RH, a pattern mimicking that of the development of impaired CR. These areas are not known to be direct glucose sensing areas but collectively are involved in memory and perception and sensing of physiological danger. We speculate that altered function in limbic areas may either contribute to the development of impaired CR and/ or contribute to the associated hypoglycemia unawareness.



AH induces c-fos expression whilst RH attenuates such a response. (A-D) Quantitative comparison of c-fos cell counts following AH and RH in the CC1 (A), CC2 (B), Ectorhinal (C) and Perirhinal (D) cortices. Data are mean ± SEM, * P<0.05, ** P<0.01.

Hypoglycaemia is related to mortality in the ICU

J.B.L. Hoekstra[1], J. Hermanides[1], R.J. Bosman[2], T.M. Vriesendorp[1], R. Dotsch[3], F.R. Rosendaal[4], D.F. Zandstra[2], J.H. DeVries[1];
[1]Academic Medical Centre, Amsterdam, [2]Onze Lieve Vrouwe Gasthuis, Amsterdam, [3]Radboud University, Nijmegen, [4]Leiden University Medical Center, Netherlands.

Background and aims: The world wide implementation of intensive insulin therapy in the intensive care unit (ICU) is accompanied by increased risk of hypoglycaemia. However, evidence about the impact of hypoglycaemia on ICU mortality is scarce and issue of ongoing debate.

Materials and methods: All 291 first episodes of hypoglycaemia (Glucose ≤ 2.5 mmol/l) were derived from 155,195 glucose values in 5,983 patients admitted to an 18-bed medical/surgical ICU from 2004 to 2007. Readmissions and patients with a withholding care policy were excluded. Patients were treated with a computerized insulin algorithm (target glucose range 4-7 mmol/l). Using Poisson regression, the incidence rates (IR) for ICU death and incidence rate ratio (IRR) comparing exposure and non-exposure to hypoglycaemia, were calculated. To investigate whether hypoglycaemia might have a causal role in worsening patient outcome or might rather be a marker of severe disease, we corrected for severity of disease using daily Sequential Organ Failure Assessment (SOFA) score. Furthermore, age, sex and diabetes mellitus were included as possible confounders.

Results: Mean age was 65 ± 14 years, 35% was female and 6.7% of patients died in the ICU. The overall IR of ICU death was 18.8/1000 person days (PD). The IR of death in patients exposed to hypoglycaemia was 35.6/1000 PD, as compared to 16.9/1000 PD in patients without hypoglycaemia exposure. The corrected IRR was 1.6 (95% CI 1.2.-2.1), $P< 0.001$.

Conclusion: Hypoglycaemia is a strong predictor of ICU death, independent of severity of disease. This suggests a causal role for hypoglycaemia in ICU mortality. Hypoglycaemia is the prime side effect of intensive insulin therapy in the ICU.

597

Mechanisms of insulin resistance following hypoglycaemia in humans: the role of lipolysis induced by hypoglycaemia counterregulation

P. Rossetti, F. Porcellati, S. Pampanelli, P. Lucidi, P. Candeloro, A. Marinelli Andreoli, G. Perriello, G.B. Bolli, C.G. Fanelli;
Internal Medicine, University of Perugia, Italy.

Background and aims: Changes in glucose metabolism that occur during counterregulation are, in part, mediated by increased plasma FFA as result of

hypoglycemia-activated lipolysis. However, it is not known whether FFA play a role in the development of post-hypoglycemic insulin resistance as well. To test the hypothesis that hypoglycemia-induced lipolysis plays a role in the pathogenesis of post-hypoglycemic insulin resistance, we conducted a series of studies in 8 healthy volunteers using acipimox, an inhibitor of lipolysis, in order to determine the metabolic effects on insulin action of prevention of increase in FFA during hypoglycemia in normal volunteers. Insulin action was measured during 2 h hyperinsulinemic-euglycemic clamp (plasma glucose, PG, 5.1 mmo/l) from 5 to 7 pm, after volunteers had undergone a 3 h morning hyperinsulinemic glucose clamp (from 10 am to 1 pm) either euglycemic (*S1*) or hypoglycemic (PG 3.2 mmol/l, *S2, S3, and S4*) during which FFA levels were either allowed to increase (*S2*) or suppressed by acipimox (*S3*) or replaced by infusing lipids (*S4*). [6,6-2H2]glucose was infused to measure PG fluxes in all studies.

Results: Plasma adrenaline, noradrenaline, GH and cortisol levels were not different (P>0.2). Glucose infusion rates (GIR) during the euglycemic clamp was reduced by morning hypoglycemia in *S2* vs *S1* (16.8±2.3 vs 34.1±2.2 μmol.Kg^{-1}.min^{-1}, respectively, p<0.001). The effect was largely removed by blockade of lipolysis during hypoglycemia in *S3* (28.9±2.6 μmol.Kg^{-1}.min^{-1}, p>0.2 vs *SI*), and substantially reproduced by replacement of FFA in *S4* (22.3±2.8 μmol.Kg^{-1}.min^{-1}, p<0.03 vs *SI*). Compared to *S2*, blockade of lipolysis in *S3* decreased endogenous glucose production (2±0.3 vs 0.85±0.1 μmol.Kg^{-1}.min^{-1}, p<0.05) and increased glucose utilization (16.9±1.85 vs 28.5±2.7 μmol.Kg^{-1}.min^{-1}, p<0.05). In *S4* GIR fell by ~ 23% (22.3±2.8 μmol.Kg^{-1}.min^{-1}, vs *S3*, p=0.058) indicating a role of acipimox *per se* on insulin action.

Conclusion: In conclusion, lipolysis induced by hypoglycemia counterregulation largely mediates post-hypoglycemic insulin resistance in healthy subjects, with an estimate overall contribution of ~ 50%.

Visualisation of protein-protein interactions of glucokinase in living cells

C. Arden[1], K.S. Langlands[1], T.K. Kerppola[2], F.M. Matschinsky[3], L. Agius[1];
[1]Institute of Cellular Medicine, Newcastle University, Newcastle Upon Tyne, United Kingdom, [2]Department of Biological Chemistry, University of Michigan, Ann Arbor, [3]Department of Biochemistry, University of Pennsylvania School of Medicine, Philadephia, United States.

Background and aims: Several binding proteins of glucokinase (GK) have been identified from independent studies. The liver-specific regulatory protein GKRP sequesters GK in the nucleus at basal glucose concentrations, whilst PFK2/FBPase2 is thought to interact with GK in the cytoplasm in both liver and pancreatic beta cells. However, little is known regarding the regulation of the GK-PFK2/FBPase2 interaction at the cellular level.

Materials and methods: The interaction between GK and PFK2/FBPase2 was investigated using Bimolecular Fluorescence Complementation (BiFC). GK, FBPase2 and PFK2/FBPase2 were tagged with either N- (YN155) or C-terminal (YC155) YFP halves at the C-terminus and transiently co-expressed in Cos1, WRL68 and MIN6 cells. Interactions between GK and PFK2/FBPase2 were also investigated in primary hepatocytes and MIN6 using a proximity ligation assay.

Results: Using the BiFC assay a direct interaction between GK and PFK2/FBPase was visualised as a clear fluorescent signal in the cytoplasm of Cos1, WRL68 and MIN6 cell lines. Removal of the PFK2 domain did not alter the interaction, consistent with binding of GK to the FBPase2 domain. Deletion of the GK interaction interface on FBPase2 (SLKVWT) eliminated the cytoplasmic signal confirming specificity. Two MODY-2 GK mutants which show decreased cellular stability when expressed in a beta-cell system, showed lower levels of interaction with PFK2/FBPase2, quantified as <50% of wild-type GK with respect to YFP intensity and frequency of signal. Studies of the adaptive changes in binding of GK to PFK2/FBPase2 in hepatocytes and MIN6 showed that in primary hepatocytes expressing endogenous GKRP, binding of GK to PFK2/FBPase2 was enhanced by high glucose and pharmacological GK activators and counteracted by resorcinol, which counteracts translocation of GK from the nucleus, and by dibutyryl-cAMP, which lowers fructose 2,6-bisphosphate. The interaction between GK and PFK2/FBPase2 in MIN6 beta cells was also enhanced by high glucose and counteracted by dibutyryl-cAMP, indicating adaptive changes in binding of GK to PFK2 independently of GKRP.

Conclusion: This study shows a direct interaction between GK and PFK2/FBPase2 in mammalian cells. The adaptive nature of this interaction, which is responsive to glucose and GK activators, and the finding that MODY-2 GK mutants show decreased interaction with PFK2/FBPase2, support a role for the GK-PFK2/FBPase2 interaction in the glucose-mediated control of GK activity.

Indirect pathway contribution to hepatic glycogen synthesis is underestimated by enrichment of glucuronide position 3 from deuterated water

C. Barosa[1], M. Caldeira[2], M. Carvalheiro[3], L. Barros[3], A. Fagulha[3], M. Bastos[3], C. Baptista[3], C. Silva[1], J. Jones[1];
[1]Dept of Biochemistry, Center for Neurosciences, [2]Dept of Chemistry, University of Coimbra, [3]Department of Endocrinology, University Hospital of Coimbra, Portugal.

Background and aims: Analysis of urinary glucuronide enrichment from deuterated water (^2H_2O) is a simple method for assaying direct and indirect pathway contributions to hepatic glycogen synthesis (Fig 1). The method assumes that glucuronide derived via indirect pathway is enriched in position 5 (H5) while that derived via direct pathway is not. With transaldolase-mediated exchange (TA), direct pathway precursors are enriched in H5. Thus when TA is active, H5 overestimates the indirect pathway contribution. Since TA does not alter position 3 enrichment (H3), we reasoned that H3 represents the real indirect pathway contribution and that TA accounts for the increased

H5 enrichment relative to H3, (i.e. H5/H3 > 1.0). To test this hypothesis, TA was measured using [U-d_7]glucose and theoretical H5/H3 ratios from ^2H_2O enrichment were calculated. These were compared to real H5/H3 ratios obtained from subjects administered with ^2H_2O.
Methods: 14 Overnight-fasted healthy subjects took breakfast (540 Kcal, 60% CHO/20% fat/20% protein) at 08:00. The CHO portion included 10 grams of glucose. Peppermint oil (200 mg) was taken at 04:00 and 08:00 and urine was collected from 10:00-12:00. TA exchange was measured in 6 of these subjects by enriching the meal glucose with 30% [U-d_7]glucose and quantifying H5 and H3 from urinary menthol glucuronide. H5 and H3 from ^2H_2O was measured in the remaining 8 subjects by providing ^2H_2O (0.3% of body water) 8 hours before the breakfast meal. In all cases menthol glucuronide was isolated by solid phase extraction-preparative HPLC and directly analyzed by ^2H NMR.
Results and discussion: ^2H NMR analysis of glucuronide enrichment from [U-d_7]glucose revealed that 23 ± 5 % of direct pathway flux underwent TA exchange. From this TA activity, a theoretical H5/H3 ratio of 1.31 ± 0.05 was obtained. Real H5/H3 ratios from ^2H_2O was significantly higher than the theoretical value (2.12 ± 0.30, $p < 0.05$) indicating that the H3 and H5 enrichment differences from ^2H_2O were not all accounted for by TA. The lower than expected H3 is likely due to a primary kinetic isotope effect that discriminates against ^2H-incorporation into hexose position 3 at the level of triose phosphate isomerase. Consequently, H3 underestimates the indirect pathway contribution to hepatic glycogen synthesis.
Conclusion: The indirect pathway contribution to hepatic glycogen synthesis can be noninvasively quantified by ^2H NMR analysis of urinary menthol glucuronide ^2H-enrichment following ingestion of ^2H_2O and Peppermint oil. Position 5 enrichment over-estimates the indirect pathway contribution because of transaldolase exchange activity. Glucuronide H3 underestimates the indirect pathway contribution possibly because of isotopic discrimination at the level of triose phosphate isomerase.

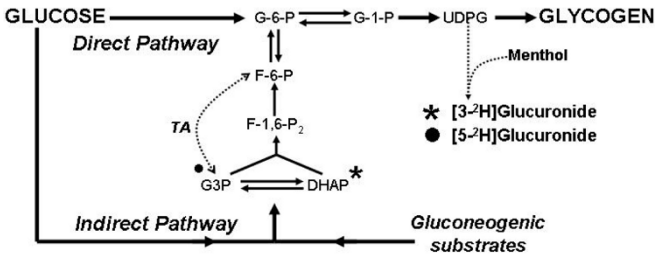

Figure 1: Labeling of menthol glucuronide from ^2H_2O via the indirect pathway. At the triose-P level, glyceraldehyde-3-phosphate (G3P) is labeled with ^2H such that it subsequently forms [5-^{2}H]glucuronide (•) and dihydroxyacetone phosphate (DHAP) is labeled with ^2H such that it forms [3-^{2}H]glucuronide (*). Transaldolase exchange activity (TA) increases the amount of [5-^{2}H]glucuronide independently of indirect pathway flux but has no effect on the production of [3-^{2}H]glucuronide.

Metabolic profiling of hepatic glycogen and lipid synthesis in spontaneously feeding rats: effects of switching from solid to liquid diet
D.R. Pinheiro, P.M. Nunes, J.G. Jones;
Center for Neurosciences and Cell Biology, University of Coimbra, Portugal.

Background and aims: The liver has a central role in glucose and lipid homeostasis and disarrangements of hepatic glucose and lipid fluxes are early defining events in the development of insulin resistance and Type II diabetes (T2D). Under normal conditions, hepatic carbohydrate and lipid metabolic fluxes are highly coordinated with respect to each other and to overall nutritional state. To better understand how this is altered in T2D requires an integrated analysis of hepatic glucose and lipid metabolic fluxes. The analysis cannot perturb feeding habits since such changes can also acutely modify hepatic glucose and lipid fluxes. This is difficult to achieve in rodent models since metabolic flux assays usually involve invasive catheterization procedures whose effects *per se* on the animal´s nutritional status may be significant. We are developing methods for integrating hepatic glucose and lipid fluxes in spontaneously feeding animals. Tracers are delivered via diet and as a single injection of deuterated water (^2H_2O). As an important first step towards an integrated metabolic profile of hepatic glucose and lipid fluxes, of we present simultaneous measurements of hepatic glycogen synthesis and *de novo* lipogenesis (DNL) in spontaneously feeding animals.
Materials and methods: Male Wistar rats raised on standard chow solid diet (SD) were randomly divided in two groups of 7. One group was placed for 7 days on a liquid diet (LD) that was isocaloric with SD. The control group was maintained on SD for this period. Animals were maintained with a constant light/dark cycle of 12/12 h. At 20:00 of day 6 rats were injected with 2.1 ml/100 g body wt of 99% ^2H_2O. At 08:00 on day 7, rats were sacrificed and the liver was excised, frozen and lyophilized. Glycogen was extracted by alkali method and hydrolysed to glucose by α-amyloglucosidase. Extracts were dried and glucose was derivatized to monoacetone glucose (MAG) for NMR analysis of ^2H-enrichment and glycogen quantification. Lipids were extracted by Folch method and triglyceride ^2H-enrichment was analyzed by ^2H NMR. Body water ^2H-enrichment was directly determined from plasma by ^2H NMR. From a single ^2H NMR spectrum of MAG, total hepatic glycogen was determined by an internal standard. The fraction of total glycogen synthesized overnight was determined from enrichment of glycogen position 2 relative to body water (H2/BW). The contribution of direct and indirect pathways to overnight glycogen synthesis was determined from enrichment in position 5 relative to position 2 (H5/H2). From the triglyceride ^1H and ^2H NMR spectra, total hepatic triglyceride content and the contribution of DNL to hepatic triglycerides during overnight feeding was determined.
Results: Total glycogen synthesized was significantly lower in LD group (3.1 ± 0.7 mg) than in SD group (17.8 ± 4.3 mg), $p<0.01$. Indirect pathway accounted for 5.7 ± 2.2 and 1.1 ± 0.4 ($p<0.01$), of the total glycogen synthesised, in SD and LD groups respectively. In contrast, DNL was not affected by the diet formulation: SD group synthesized 85.1 ± 11.5 μmol/g*dw*, whereas LD group synthesized 85.7 ± 15.2 μmol/g*dw*. Total hepatic triglycerides levels were also similar for both groups (255.4 ± 30.7 μmol/g*dw* for SD and 286.5 ± 22.4 μmol/g*dw* for LD).
Conclusion: Seven days weaning from solid to liquid diet induced significant alterations in overnight hepatic glycogen synthesis but not for triglyceride synthesis.

Effects of resistin on glucose metabolism in C2C12 myocytes
F.P. Li, Z.Z. Li, M. Zhang, L. Yan, Z.Z. Fu;
Department of Endocrinology and Metabolism, The Second Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

Background and aims: Resistin is an adipokine highly related to insulin resistance (IR). Our study is to investigate how resistin influences skeletal glucose metabolism and explore its mechanisms.
Materials and methods: The recombinant plasmids PcDNA3.1 expressing resistin were constructed and then transfected into C2C12 myocytes. The expression of resistin in C2C12myocytes was detected by Western blotting. Glucose uptake was measured by ^3H labeled glucose; glucose oxidation and glycogen synthesis were detected with ^{14}C-labeled glucose. GLUT-4 mRNA was measured by reverse transcript polymerase chain reactions (RT-PCR).
Results: Resistin was expressed in transfected myocytes. Resistin decreased insulin stimulated glucose uptake rate by 28%~31% and inhibited the expression of GLUT4 mRNA. However, there were no significant differences in basal glucose uptake, and glucose oxidation and glycogen synthesis remained unchanged in all groups.
Conclusion: Resistin inhibited insulin stimulated glucose uptake in myocytes by downregulating the expression of GLUT-4 and it had no effects on glucose oxidation and glycogensynthesis. Our findings may provide a clue to understand the roles of resistin in the pathogenesis of skeletal IR.

Regulation of hepatic glucose homeostasis by glucokinase localization
S. Langer[1], M.T. Kaminski[1], S. Lenzen[1], S. Baltrusch[1,2];
[1]Institute of Clinical Biochemistry, Hannover Medical School, [2]Institute of Medical Biochemistry and Molecular Biology, University of Rostock, Germany.

Background and aims: Glucokinase (GK) acts as a glucose sensor for coupling millimolar glucose concentrations to metabolism. A specific glucokinase regulatory protein (GRP) inhibits GK activity in liver and mediates the translocation of GK between nucleus and cytoplasm in dependence on glucose and fructose metabolites. While the GK nuclear import is clearly mediated by the GRP, the mechanism of GK nuclear export remains open. It has

been shown, that GK activators recently described as a potential new class of drugs for the treatment of type 2 diabetes modulate GK localization in liver. Thus, the elucidation of the underlying molecular mechanisms of GK shuttling is also important for an appropriate pharmacotherapeutic intervention. Therefore the aim of this study was to analyze the GK-GRP interaction and the GK nuclear export mechanism with respect to hepatic glucose homeostasis.
Materials and methods: Interaction between GK and GRP was analyzed in COS cells using a fluorescence based mammalian two-hybrid system (MMTHS) and in primary rat hepatocytes via fluorescence resonance energy transfer (FRET). The glucose concentration in the cytoplasm and nucleus was determined by a recently established FRET based glucose specific nanosensor (FLIPglu). Primary rat hepatocytes were transduced with a recombinant adenovirus expressing the FLIPglu sensor and a nucleus localized FLIPglu (FLIPglu-nuc). COS cells were transiently transfected with FLIPglu and FLIPglu-nuc constructs.
Results: The MMTHS allowed monitoring of the effects of environmental changes on the GK-GRP interaction. In medium supplemented with 5 mmol/l glucose an interaction between GK and GRP was measured. Increasing the glucose concentration in the cell culture medium significantly decreased the interaction between the proteins. Using an antibody based acceptor photobleaching FRET technique in primary rat hepatocytes differences in the GK-GRP association strength were detectable. Interaction of endogenous GK and GRP in the nucleus of hepatocytes was tenfold higher after incubation at 5 mmol/l glucose than at 20 mmol/l glucose. Addition of fructose-6-phosphate further induced the interaction. The cytoplasmic and nuclear glucose concentration upon changes in the extracellular glucose concentration could be determined expressing the FLIPglu sensor and calculating the EYFP/ECFP ratio upon ECFP excitation. After addition of glucose containing Krebs Ringer medium the intracellular glucose concentration significantly increased. In both primary rat hepatocytes and COS cells the cytoplasmic glucose rise was accompanied by a comparable increase in the nucleus.
Conclusion: Subcellular alterations in glucose homeostasis in primary cells could be monitored using the FLIPglu sensor. Glucose plays a major role in the GK compartmentation by dissolving the GK-GRP complex. As there is a simultaneous rise of the glucose concentration in the nucleus, paralleling this in the cytosolic compartment, it is likely that GK leaves the nucleus at least partially in a GRP independent manner. This newly established cellular system will allow the elucidation of the effect of GK activators on this process in future studies.

603

Measuring glucokinase in fresh and frozen liver
S.P. Burns, A. Smith;
Chemical and Biological Sciences, University of Huddersfield, United Kingdom.

Background and aims: Glucokinase (GK) is a key enzyme of glucose homeostasis influencing both insulin secretion and control of hepatic glucose balance, especially when post-prandial glycemia increases. The absolute activity of GK is key to both processes as illustrated by numerous studies on man and in animal models. Mutation of the gene for this enzyme can result in GK protein with increased or decreased activity, contributing to chronic hyperglycemia (MODY2) or familial hypoglycemia respectively. Activity of the liver enzyme can be readily measured in fresh liver samples. However, we are unaware of data derived from frozen liver samples: there is no reason in principle why activity of the enzyme should be impaired by freezing. Our initial attempts at preparing a 10% liver homogenate from frozen rat liver gave activities of glucokinase significantly higher than literature values reported both by ourselves and others. Because of the potentially important physiological implications of this finding with respect to understanding of the mechanisms of normal glucose homeostasis, and especially that of liver glycogen synthesis we began a systematic review of the methodology used to determine activity of this enzyme, and a preliminary report of key findings to date is reported here.
Materials and methods: GK and HK activity were determined as previously described: briefly, samples of both fresh and thawed frozen liver were homogenized by hand using a glass homogenizer and samples ultra-centrifuged at 100,000g to obtain a clear supernatant: the fatty layer was removed and supernatant assayed for GK and HK by the G6PDH NAD-linked assay.
Results: Activity of GK was significantly higher in frozen liver sections compared with fresh liver, and hexokinase activity significantly decreased. The enzymes were separated by gel filtration to investigate their kinetic parameters independently: GK demonstrated unchanged sigmoidal and HK, Michaelis-Menten, kinetics with respect to glucose. The Vmax for GK was obtained at about half the glucose concentration used by previous workers in both fresh and frozen liver tissue, and S0.5 was unchanged (approximately 8mM).
Conclusion: Since the increased activity of GK in frozen liver was not the result of altered kinetics of the enzyme we postulate that freezing the tissue from ad libitum fed rats results in more efficient liberation of the enzyme from a nuclear pool sequestered by the glucokinase regulatory protein (GKRP). In fresh liver tissue it is possible that some of this pool escapes mechanical release during homogenization and ultra-centrifugation and is then pelleted and lost to the supernatant. This would indicate that the nutritional conditions under which animals are killed for study of glucokinase activity using fresh liver samples could influence measures of GK activity, and hence the conclusions drawn. Such data might also explain why measured activity of GK appears to change remarkably quickly under differing nutritional circumstances.

Short term and long term disease mathematical modelling of diabetes in Zucker and ZDF rats
E.M. Watson[1,2], S.M. Poucher[1], M.J. Chappell[2], J. Teague[1];
[1]CVGI R&D, AstraZeneca, Macclesfield, [2]School of Engineering, University of Warwick, Coventry, United Kingdom.

Background and aims: The aim is to create a universal mathematical model for glucose and insulin dynamics in rats both in the short term, for example to model meal feeding, and also in the long term, to model disease progression.There have been several attempts to model the glucose and insulin system before, but very few of these have tried to combine both short- and long-term dynamics. This new model takes elements from previous mathematical models in an attempt to create a universally applicable model.
Materials and methods: The model was created using a combination of features from existing models, such as beta cell mass from the beta cell mass model, and newly-designed elements to characterise both short- and long-term dynamics of the glucose and insulin system. The model incorporates elements that allow the simulation of short-term aspects which include feedback between insulin and glucose dynamics. Long-term dynamics display elevated levels of glucose, stimulating an increase in insulin secretion capacity, but very high levels of glucose can cause damage and reduce insulin secretion capacity. The model additionally allows simulation of gut delay of glucose absorption, as well as incorporating increased glucose as a result of feeding. The model can be numerically simulated within MATLAB, using a stiff equation solver, and an interface was created to enable easy use of the model by researchers and other interested parties.
Results: Simulations show that the long-term progression into diabetes can be modelled by decreasing both insulin sensitivity and the first phase of insulin secretion. The wider applicability of the model is demonstrated by its ability to simulate the adaptation of the system to the change in insulin secretion to cope with a decay in insulin sensitivity. The data used to perform model fitting and validation were from Zucker and Zucker Diabetic Fatty (ZDF) rats which were meal fed for 4 hours per 24 hour period over 40 days, with glucose and insulin profile measurements taken on days 3, 14, 28 and 38 of the study. The figure shows a model fit for glucose data, with black denoting the real data, showing the model responses for each day.
Conclusion: A mathematical model has been developed that can characterise the disease status of the glucose and insulin system in rats, incorporating both short- and long-term aspects. The model can produce dynamic responses that compare well with real data.

Islet-cell secretion of pancreatic polypeptide in response to ghrelin and obestatin acting on distinct receptors

R. Kumar[1], A.F. Balhuizen[1], A.S. Salehi[1], J.F. Rehfeld[2], P. Höglundc[1], R. Håkanson[1];
[1]Clinical Science, Lund University, Malmo, Sweden, [2]Clinical Science, Rigshospitalet Copenhagen University Hospital, Denmark.

Background and aims: Des-acyl ghrelin (28 a.a. residues) and obestatin (23 a.a.) are hormonal cleavage products of proghrelin, which is synthesized in endocrine A-like cells in the gastric mucosa.
During processing, a fraction of des-acyl ghrelin is octanoylated in position 3 (serine) to form acyl ghrelin. Being cleavage products of proghrelin, obestatin and the two ghrelin peptides are likely to be released together from the A-like cells, conceivably affecting their targets in concert. In the present study we used isolated pancreatic islets from the mouse to study whether acylghrelin and obestatin act on the same or on distinct receptors to inhibit the secretion of pancreatic polypeptide (PP).
Materials and methods: Isolated mouse pancreatic islets were used to study the dose dependent response of acylghrelin & obestatin in absence and presence of des-acylghrelin on islets hormone secretion.
Results: Both acyl ghrelin and obestatin abolished PP release by dose-dependent manner with marked effect at concentrations of 10^{-10} M. Des-acyl ghrelin was without effect.The inhibitory effect of 10^{-10} M acyl ghrelin was counteracted by des-acyl ghrelin in a concentration-dependent manner, while the inhibitory effect of 10^{-10} M obestatin was not.. Under these circumstances the IC_{50} value for des-acyl ghrelin was $4.1\pm 1 \times 10^{-8}$ M. This means that quite high concentrations of des-acyl ghrelin were needed to impair the inhibition of PP release induced by 10^{-10} M acyl ghrelin. The IC_{50} value for acyl ghrelin was calculated to be $4.1 \pm 1 \times 10^{-12}$ M (n=6), while the IC_{50} value for obestatin was $3.2 \pm 1 \times 10^{-12}$ M (n=8). The concentration-response curve for acyl ghrelin was greatly affected by different concentrations of des-acyl ghrelin, shifting the curve to the right with increasing concentrations of des-acyl ghrelin, in a manner suggestive of competitive inhibition and the effect of obestatin was unaffected by the presence of des-acyl ghrelin.
Conclusion: Our data suggest that des-acylghrelin per se was found no effect on PP cells while the inhibitory effect of acylghrelin on PP secretion was reversed by des-acylghrelin, the suppressive effect of obestatin on PP cells was unchanged. This observation indicates that acylghrelin and obestatin act on PP cells through distinct receptors. Understanding the mechanisms that control PP release might help to clarify the physiological significance of PP cells.

Vitamin D and glucose metabolism in polycystic ovary syndrome

B. Obermayer-Pietsch[1], S. Pilz[1], N. Schweighofer[1], T.R. Pieber[1,2], E. Wehr[1];
[1]Department of Internal Medicine, Division of Endocrinology and Nuclear Medicine, Medical University Graz, [2]Joanneum Research Forschungsgesellschaft mbH, Graz, Austria.

Background and aims: Several studies suggest an association of low 25-OH vitamin D [25(OH)D] levels with impaired β cell function and type 2 diabetes. Women affected by polycystic ovary syndrome (PCOS) frequently present with insulin resistance and are at an increased risk for the development of type 2 diabetes. The aim of this study was to investigate the relationship between 25(OH)D levels and parameters of glucose metabolism in PCOS women.
Materials and methods: 25(OH)D levels were measured by means of ELISA in 205 women affected by PCOS. Metabolic, endocrine, and anthropometric measurements and oral glucose tolerance tests were performed. Metabolic syndrome was defined in accordance with National Cholesterol Education Program/Adult treatment panel III criteria.
Results: PCOS women with hypovitaminosis D (<29.9 ng/ml) had significantly higher BMI, waist circumference, HOMA-IR, HOMA-β, AUCgluc, 1h glucose, fasting insulin, and triglycerides and lower levels of QUICKI and HDL (p<0.05 for all). In turn, PCOS women with impaired glucose tolerance had significantly lower 25(OH)D levels than PCOS women with normal glucose tolerance (p=0.006). In multivariate regression analysis, 25(OH)D and BMI were independent predictors of HOMA-IR and QUICKI (p<0.05 for all). PCOS women with impaired glucose tolerance and metabolic syndrome (MS) had lower 25(OH)D levels than PCOS women without these features (p<0.05 for all). In logistic regression analysis, 25(OH)D (OR 0.86, p=0.021) and BMI (OR 1.3, p<0.001) were independent predictors of MS in PCOS women.
Conclusion: We present evidence that low 25(OH)D levels are associated with obesity, IR, impaired β cell function, impaired glucose tolerance, and MS in PCOS women. Large intervention trials are warranted to evaluate the possible beneficial role of vitamin D supplementation on disturbances in glucose metabolism in PCOS women.

Altered plasma leptin level is associated with low stearoyl-CoA desaturase-1 activity in type 2 diabetes

H.S. Chaudhury[1], S. Akter[2], S. Murshed[2], Q. Nahar[2], S. Salim[2], I. Khan[2], M.K. Rahman[2], L. Ali[2];
[1]Dept of Biochemistry, M Bhasani Medical College, [2]Biomedical Research Group, BIRDEM, Dhaka, Bangladesh.

Background and aims: Leptin is a multifunctional hormone which may be involved in the pathogenesis of type 2 diabetes mellitus (T2DM) by influencing insulin production or sensitivity. The exact mechanism of insulin secretory dysfunction associated with altered plasma leptin level in T2DM is still under investigation. One hypothesis is that the hypoleptinemia induced insulin secretory defect is caused by steatosis of β-cells of pancreas resulting from altered fatty acid metabolism. The present study was designed to determine any change in fatty acid metabolism associated with altered leptin level in type 2 diabetes.
Materials and methods: A total of 119 subjects were included. In Group I (Case), 59 newly diagnosed T2DM and in Group II (Comparison), 60 age (year, 36±4 vs. 35±4, M±SD) and Body Mass Index (BMI) matched (kg/m^2, 24.0±3.1 in Group I vs. 23.6±2.0 in Group II) healthy control subjects were included in this cross sectional analytical study. Plasma insulin (fasting and 30 min post glucose) and leptin were estimated by Enzyme Immunoassay. Insulin secretory capacity (HOMA-B%) and insulin sensitivity (HOMA-S%) were calculated by Homeostasis Model Assessment using HOMA-CIGMA software. Fasting serum non-esterified fatty acid (NEFA) was measured by enzymatic colorimetric method. Plasma fatty acid composition (%) was analyzed by gas liquid chromatography. Stearoyl-CoA desaturase-1 (SCD-1) activity was calculated by plasma palmitoleic/palmitic (C16:1/C16:0) ratio.
Results: The diabetic subjects showed highly significant β-cell dysfunction and also insulin resistance as evident from HOMA B% [20.2(4.2-89.6) in diabetic vs. 78.4(35.5-365.7) in control, p<0.001] and HOMA S% [84.6(39.1-226.4) vs. 118.8(22.0-3573.0), p<0.004]. Serum fat normalized leptin level was found significantly lower in diabetic subjects [ng/ml, 5.44 (0.65-34.7)] compared to controls [8.35 (1.36-55), p=0.012]. The serum leptin level inversely correlated with insulin secretory dysfunction. The total NEFA level in the diabetic subjects was higher than control (mmol/l, 0.652±0.196 vs. 0.42±0.15, p<0.001). NEFA was inversely correlated with HOMA S% (r=-0.369, p<0.01). HOMA S% was positively associated with eicosapentaenoic (20:5) acid (r=0.354, p=0.001). HOMA B% was inversely associated with palmitic (16:0) acid (r=-0.577, p=<0.01). Leptin level was positively correlated with stearoyl-CoA desaturase-1 activity (r=0.185, p=0.04), erusic (22:1) acid, (r=0.561, p=0.046), as well as the ratio of linoleic/linolenic (C18:2/C18:3) acid (r=0.165, p=0.05), and inversely correlated with behenic acid (r=-0.319, p=0.039).
Conclusion: The data suggest that a) Serum fat normalized leptin level in normal to mildly overweight Bangladeshi type 2 diabetic subjects is lower compared to age and BMI-matched healthy population; b) Lower plasma leptin in type 2 diabetes mellitus subjects is associated with insulin secretory dysfunction; c) Lowered plasma leptin level in Type 2 diabetes is associated with lower levels of stearoyl-CoA desaturase-1 (SCD-1) activity, linoleic/linolenic (C18:2/C18:3) ratio and plasma erusic acid level, and higher level of plasma behenic acid.

Plasma thyroid hormone levels are positively associated with insulin resistance at all stages of type 2 diabetes

V. Lambadiari[1], G. Dimitriadis[1], P. Mitrou[2], E. Boutati[1], E. Maratou[2], A. Raptis[1], N. Tountas[1], T. Economopoulos[1], S.A. Raptis[1,2];
[1]2nd Dpt Internal Medicine, Athens University, Attikon University Hospital, [2]Hellenic National Diabetes Center, Attikon University Hospital, Athens, Greece.

Background and aims: Thyroid hormone levels have generally been found normal in diabetic patients. Whether variation in those levels within the euthyroid range influence insulin sensitivity at the various stages of type 2 diabetes remains to be established.
Materials and methods: A meal was given to four groups of subjects (age 34+2.6, 37+2.7, 46+4.2, 51+2.2 yrs, respectively, and BMI 23.1+0.63, 23.9+0.53, 24.9+0.8, 24.9+0.56 kg/m^2, respectively) whose baseline characteristics are shown in Table 1. Blood was withdrawn for 360 min from the radial artery for measurements of glucose and insulin. Fasting plasma free T4 (FT4) and free T3 (FT3) levels were also measured. Fasting and postprandial insulin resistance was assessed by HOMA and ISI indices respectively.
Results: FT4 levels were lower in controls versus relatives, IGT and DM (p=0.048). FT3 levels were also lower in controls versus relatives, IGT and DM subjects (p=0.005). HOMA was positively associated with FT4 and FT3 levels (β-co-efficient=0.110±0.33, p=0.001 and 0.521±0.160, p=0.002 respectively). ISI was negatively associated with FT4 and FT3 levels (β-co-efficient=-6.597±1.449, p=0.001 and -21.036±6.152, p=0.001, respectively).
Conclusion: In type 2 diabetes, increases of thyroid hormone levels within the normal range associate positively with insulin resistance. These data suggest that thyroid hormones may be part of the pathogenetic mechanism to explain metabolic derangement at all stages of type 2 diabetes.
RELATIVES: 1st degree relatives of diabetic patients with a normal glucose tolerance test, IGT: subjects with impaired glucose tolerance, DM: subjects with type 2 diabetes.

Growth hormone deficiency and rhGH-therapy to individuals with low IGF-1 levels contribute to the regulation of STAMP2 gene in subcutaneous adipose tissue

B. Ukropcova[1], T. Kurdiova[1], A. Penesova[2], Z. Radikova[2], M. Vlcek[2], R. Imrich[2], S. Zorad[3], M. Pura[4], P. Vanuga[4], V. Belan[5], J. Payer[6], S.R. Smith[7], J. Ukropec[1], I. Klimes[1], D. Gasperikova[1];
[1]Diabetes Laboratory, Inst. of Exp Endocrinology, [2]Laboratory of Human Endocrinology, Inst. of Exp Endocrinology, [3]Laboratory of Adipocyte Endocrinology, Inst. of Exp Endocrinology, Bratislava, [4]National Institue of Endocrinology and Diabetology, Lubochna, [5]Department of Radiology, Comenius University School of Medicine, [6]The 5th Department of Internal Medicine, Comenius University School of Medicine, Bratislava, Slovakia, [7]Pennington Biomedical Research Center, Baton Rouge, United States.

Introduction: Growth hormone deficiency (GHD) is known to be associated with metabolic dysregulation, increased inflammation and compromised growth and differentiation of adipose tissue. We investigated the effect of GHD as well as GH supplementation in patients with low IGF-1 levels on the expression of six-transmembrane protein of prostate 2 (STAMP2), the potential coordinator of nutrient and inflammatory response in human subcutaneous adipose tissue (SAT).
Methods: The first cohort consisted of 20 GHD patients (age 30.7±7 yrs, M/F 12/8, BMI 21.7-36.8 kg.m^{-2}) and 19 healthy age, gender and BMI-matched controls. Insulin sensitivity (IS) was measured by euglycemic hyperinsulinemic clamp (EHC). Abdominal fat mass and distribution was determined using MRI. Samples of SAT were taken by needle biopsy and fat cell size (FCS) was assessed by light microscopy. Gene and protein expressions were measured by qRT-PCR and immunoblotting, respectively. The second cohort consisted of ten 40-70yrs old sedentary male subjects with waist circumference >102 cm, BMI 27 - 35 kg.m^{-2}, and blood levels of IGF-1 bellow 241 ng/ml who were for a period of 24 wks treated by pharmacological levels (0.95 mg/day) of rhGH (Genentech, CA, USA).
Results: GHD patients displayed lower IS, increased FCS and visceral obesity. GHD was associated with a significant decrease in STAMP2 gene and protein expressions, the change in mRNA being more pronounced during the EHC (2.2-fold, p<0.0001) compared to the fasting state (1.4-fold, p<0.05). STAMP2 was positively correlated to the protein expression of adipokines regulating growth and differentiation of adipose tissue (PDGF, SDF1, GRO; r=0.59, r=0.41, r=0.62; p<0.05; n=24). A strong positive association was found between STAMP2 and adiponectin gene expression during fasting state and the euglycemic hyperinsulinemia (r=0.52, r=0.67; p<0.01; n=34). Furthermore, patients receiving GH-supplementation displayed 1.4-fold increase (p=0.02) in the expression of STAMP2 gene in SAT.
Conclusion: Our results demonstrate that STAMP2 is decreased in GHD associated with whole-body metabolic derangements and upregulated by rhGH therapy of obese individuals with low IGF-1 levels. The relationships of STAMP2 to adipokines regulating adipose tissue growth, differentiation and inflammation support a positive role this protein might play in human metabolic health.

Type 2 diabetes mellitus and primary hypothyroidism. TSH test in all diabetic patients?

H.E. Tamez[1], A.L. Tamez[1], E. Martinez[2], J. Barquet[2];
[1]Investigation, School of Medicine, [2]Internal Medicine, Nova Clinic, Monterrey, Mexico.

Background and aims: Type 2 diabetes mellitus (DM) and primary hypothyroidism are recognized risk factors for atherosclerotic cardiovascular disease. This study is an effort to identify the high prevalence of association between these two diseases in our population.
Materials and methods: A cross-sectional study from an outpatient clinic in Monterrey, Nuevo Leon, México. 1848 adult patients with DM were included in the study group and were compared with 33732 matched controls without a diagnosis of type 2 DM. Primary hypothyroidism was defined in all patients using thyroid medication. Subjects with thyroid neoplasm, surgery complications, or other pathologies were excluded.
Results: The two groups were similar respect to demographic characteristics. Of the 1743 patients of the study group, 105 had hypothyroidism, and the

control group 33,131 patients, 601 had hypothyroidism, OR 3.32 (95% IC 2.64-4.10). Cholesterol, triglycerides, systolic and diastolic pressure values were significantly higher in the study group.
Conclusion: We demonstrated an elevated association between DM and hypothyroidism. These findings are consistent with increased cardiovascular risk. Thyroid profile measurement should be a diagnostic test in all patients with DM, similar as type 1 diabetes mellitus.

Background and aims: Two US randomized trials found a lower incidence of type 2 diabetes among women treated by menopausal hormone therapy (MHT) with oral conjugated equine estrogen combined with medroxyprogesterone acetate. The purpose of this study was to evaluate the influence of various MHTs, according to their formulation and route of administration, on new-onset diabetes in a cohort of postmenopausal women.
Materials and methods: E3N is a cohort study of 98,995 French women born in 1925-1950 and followed by questionnaire every 2 years. We included only the women who responded to a dietary history questionnaire sent in 1993, and who were postmenopausal when they replied to the 8th questionnaire sent in 2005. We excluded women with non validated diabetes, prevalent diabetes, no follow-up or lack of information on MHT use, leaving 63,624 postmenopausal women for analysis. Cases of diabetes were identified through self-report or drug reimbursement record linkage, and further validated. The association between MHT use and new-onset diabetes was investigated by Cox regression analysis.
Results: A total of 1220 new-onset diabetes were validated. We observed a lower risk of diabetes among women having ever used MHT (Hazard Ratio: HR=0.82 [0.72 - 0.93]), compared to MHT never users. Adjustment for BMI during follow-up did not substantially modify this association. An oral route of estrogen administration was associated with higher decrease in diabetes risk than cutaneous route (HR=0.68 [0.55-0.85] vs. 0.87 [0.75-1.00], p for homogeneity=0.028). When further taking into account the type of progestagen used in combined MHT, there was no statistically significant heterogeneity between progestagens, neither between route of estrogen administration, with regard to diabetes risk.
Conclusion: MHT might decrease the risk of diabetes, independent of BMI. Further studies are needed to confirm the stronger effect of oral administration of estrogen compared to cutaneous administration.

Hyperandrogenism is associated with an increased risk for type 2 diabetes and metabolic disturbances in a large cohort of postmenopausal women

E. Wehr[1], N. Schweighofer[1], S. Pilz[1], M. Winfried[2,3], B.O. Boehm[4], B.R. Winkelmann[5], B. Obermayer-Pietsch[1];
[1]Department of Internal Medicine, Division of Endocrinology and Nuclear Medicine, Medical University Graz, Austria, [2]Department of Public Health, Social and Preventive Medicine, Mannheim Medical Faculty, University of Heidelberg, Mannheim, Germany, [3]Clinical Institute of Medical and Chemical Laboratory Diagnostics, Medical University Graz, Austria, [4]Department of Internal Medicine, Division of Endocrinology and Diabetes, Ulm University, Germany, [5]Department of Cardiology, Heart Center, Ludwigshafen, Germany.

Background and aims: Women with polycystic ovary syndrome present with hyperandrogenism and are frequently affected by insulin resistance and impaired glucose tolerance. However, the association of hyperandrogenism with type 2 diabetes is incompletely described in postmenopausal women. The aim of this study was to evaluate the relation between testosterone and type 2 diabetes and metabolic disturbances in postmenopausal women.
Materials and methods: We measured testosterone [µg/l], estradiol [ng/l], and metabolic parameters in 728 postmenopausal women not using hormone therapy enrolled in the Ludwigshafen Risk and Cardiovascular Health (LURIC) study.
Results: Median testosterone levels were significantly higher in postmenopausal women with type 2 diabetes (0.8 [0.5-1.0]) than in women without type 2 diabetes (0.7 [0.5-1.0]) (p=0.019) whereas median estradiol levels were

similar (27 [21-36.5] vs 26 [20-44). Postmenopausal women were stratified into 2 groups (higher or lower than the median testosterone level of the study sample). Postmenopausal women with higher testosterone levels had a 37.5 % higher risk of type 2 diabetes (RR 1.38; 95% CI [1.02-1.86]; p=0.039] than women with lower testosterone levels. Postmenopausal women with testosterone levels >0.7 µg/l had higher weight, waist circumference, fasting glucose, fasting insulin, fasting proinsulin, HOMA-IR, LDL, and CRP and lower HDL levels than women with lower testosterone levels (all p<0.05).
Conclusion: These data suggest that endogenous testosterone levels are associated with type 2 diabetes and metabolic disturbances in postmenopausal women. Identification of postmenopausal women with hyperandrogenism may be important for prevention and treatment of type 2 diabetes.

Progesterone directly affects mitochondrial function - a mechanism relevant to gestational adaptations of glucose metabolism?
C. Fürnsinn[1], K. Staniek[2], K. Stadlbauer[1], Z. Szöcs[1], A. Luger[1], B. Brunmair[1];
[1]Department of Medicine III, Division of Endocrinology & Metabolism, Medical University of Vienna, [2]Department of Biomedical Sciences, Molecular Pharmacology & Toxicology Unit, University of Veterinary Medicine Vienna, Austria.

Background and aims: Late pregnancy is associated with adaptations of glucose metabolism, which have been attributed, at least in part, to high concentrations of circulating progesterone. In preceding studies, we found that progesterone directly and immediately modulates glucose handling by isolated specimens of rat skeletal muscle via a non-genomic mechanism of action. The results revealed not only inhibitory action on glucose transport, but also that progesterone impairs cell respiration. 1 µmol/l progesterone, a concentration that can be reached in plasma of pregnant humans and rats, reduced the rate of pyruvate oxidation by specimens of skeletal muscle by 28±2% (p<0.0001). Based on this finding, the present study investigated, if progesterone can affect respiratory function of mitochondria directly.
Materials and methods: Mitochondria were isolated from rat liver by tissue homogenization and differential centrifugation. They were incubated without or with 1, 3, 10, or 30 µmol/l progesterone in the presence of glutamate plus malate (substrates for respiratory complex I) or in the presence of succinate (substrate for complex II; complex I was blocked by rotenone). Oxygen consumption was measured after addition of inorganic phosphate and ADP, which allows oxidative phosphorylation (state 3), and after quantitative consumption of added ADP (i.e. without oxidative phosphorylation; state 4).
Results: In the presence of glutamate and malate, progesterone dose-dependently inhibited oxygen consumption in state 3 (control = 100%; 1 µmol/l progesterone, 89.5±5.6%, p=0.12, ns; 3 µmol/l, 93.9±5.3%, p=0.30, ns; 10 µmol/l, 86.8±4.6%, p=0.03; 30 µmol/l, 61.1±3.6%, p<0.001). In state 4, the lowest employed concentration of the steroid hormone was sufficient to trigger significant inhibition (control = 100%; 1 µmol/l progesterone, 92.6±2.6%, p=0.04; 3 µmol/l, 91.4±2.4%, p=0.02; 10 µmol/l, 84.3±5.4%, p=0.03; 30 µmol/l, 69.3±4.1%, p<0.001). In succinate-fed mitochondria, inhibitory action of progesterone was still present but less distinct than in such fed with glutamate and malate (with succinate, state 3: 10 µmol/l progesterone, 96.5±1.4%, p=0.06, ns; 30 µmol/l, 93.1±3.0%, p=0.07, ns; state 4: 10 µmol/l progesterone, 94.5±1.7%, p=0.02; 30 µmol/l, 87.9±2.0%, p=0.002). In mitochondria uncoupled by 100 µmol/l 2,4-dinitrophenol (DNP), inhibitory action of progesterone was also obvious (30 µmol/l progesterone: with glutamate and malate, 66.9±3.3%, p<0.001; with succinate, 94.3±1.0%, p=0.003).
Conclusion: Progesterone can impair respiratory function by direct interaction with isolated mitochondria in vitro. A progesterone concentration that can be reached in plasma of pregnant humans and rats is sufficient to induce such effects on mitochondrial function, which could be the mechanism responsible for impaired cell respiration seen in progesterone-exposed tissue specimens. Apart from possible relevance for the metabolic adaptations to pregnancy, direct modulation of mitochondrial function could be a novel pathway, via which progesterone triggers non-genomic effects.

Short-term changes in serum sex steroid levels affect postprandial triglyceride metabolism in healthy young men
B.M. Lapauw[1], D.M. Ouwens[2], L.M. 't Hart[2], B. Wuyts[3], G.G. T'Sjoen[1], J.-M. Kaufman[1], J.B. Ruige[1];
[1]Department of Endocrinology, Ghent University Hospital, Belgium, [2]Department of Molecular Cell Biology, Leiden University Medical Center, Netherlands, [3]Laboratory for Metabolic Diseases, Ghent University Hospital, Belgium.

Background and aims: Male hypogonadism is associated with obesity and diabetes, which suggests a relation between sex steroid status and glucose and/or lipid metabolism. However, it is not clear if this is due to direct hormonal effects or results from changes in body composition. By this intervention study, we investigated whether short-term changes in sex steroid levels directly affect post-meal lipid-handling in healthy young men.
Materials and methods: In order to obtain two contrasting groups with high estradiol (E2) and low testosterone (T) vs. low E2 and high T levels, healthy young men (aged 20-40 yrs) were randomized to receive either an aromatase inhibitor (letrozole 2.5 mg daily) plus an E2 patch (75µg/day) (group 1; n=10) or letrozole only (group 2; n=10), for a duration of 7 days. All subjects ingested a mixed-meal (1000 KCal - 45% fat, 36% carbohydrates, 19% proteins) and blood samples were taken up to 5 hours post-meal to assess the postprandial triglyceride (TG)-response. Changes in response between both groups were assessed using longitudinal mixed-effects modeling analyses.
Results: In group 1, mean E2 levels rose 43% and T levels decreased 44%, whereas mean T levels rose 114% and E2 levels decreased 56% in group 2. Fasting TG levels did not change in either group (P>0.12). However, postprandial TG-response was differentially affected by treatment in both groups. Following 7 days of treatment, the increment in postprandial TG levels in group 1 was faster as compared to baseline (+0.54 mg/dL/min vs. +0.50 mg/dL/min; P = 0.010), whereas this was slower in group 2 (+0.44 mg/dL/min vs. +0.50 mg/dL/min; P = 0.036), resulting in a significant treatment effect (P = 0.006) (see Figure).
Conclusion: Short-term administration of letrozole plus E2 in healthy young men appeared to have direct elevating effects on the postprandial TG-response. Contrasting effects were observed in men treated with letrozole only, displaying a lower postprandial TG-response. These data suggest that part of the increase in metabolic risk in obesity in males might be explained by adverse affects on lipid-handling by changed sex steroid levels.

Role of sex hormones in insulin resistance - a lesson from the Aromastase Knockout (ArKO) mouse
M.L. Van Sinderen[1,2], J. Chow[1,2], G. Steinberg[3], S.B. Jorgensen[3], J. Honeyman[3], E.R. Simpson[1], M.E.E. Jones[1], W. Boon[4,1];
[1]Prince Henrys Institute of Medical Research, Clayton, [2]Anatomy and Developmental Biology, Monash University, Clayton, [3]St Vincents Institute, Melbourne, [4]Howard Florey Institute, Melbourne, Australia.

Background and aims: Sex hormones such as estrogens and androgens are known to influence development of insulin resistance and adiposity, which

contribute to many disease processes such as type 2 diabetes and the Metabolic Syndrome. Estrogen (E2) and testosterone (T) are known to have bi-phasic effects on insulin resistance in a dose-dependent manner. To research the effects of sex hormones on insulin resistance we studied Aromatase knockout (ArKO) mice which are unable to convert androgens to estrogens.
Materials and methods: Glucose and pyruvate tolerance and insulin sensitivity of 12, 24 and 52 week-old animals were assessed by Glucose Tolerance Test (GTT; ip glucose injection, 1mg/g of body wt), Insulin Tolerance Test (ITT; ip insulin injection, 0·05 or 0.025U/g) and Pyruvate Tolerance Test (PTT; pyruvate injection 1mg/g of body wt) after a 6-8h (GTT and ITT) or overnight fast (PTT). Blood glucose concentrations were measured at 0, 20, 40, 60, 90 and 120 min. Fed, fasted and GTT (20min) blood insulin concentrations were measured.
Results: Sexually dimorphic differences were observed between the male and female ArKO mice. Male ArKO mice by 12 wks of age present with hyperglycemia and significant glucose and pyruvate intolerance and signs of reduced insulin sensitivity. Similar phenotypes are present in 24- and 52-wk-old male ArKO mice. Upon estrogen treatment, these phenotypes were corrected to WT levels. Only ArKO males develop hepatic steatosis which may be a contributing factor in the development of the insulin resistant state. Female ArKO mice by 12 wks of age show signs of hyperglycemia and glucose intolerance with trends continuing at 24wks. They also develop significant pyruvate intolerance and reduced insulin sensitivity. Surprisingly, upon administration of 17β-estradiol (E2, 0.0025mg/day) to 12 and 24wk female ArKO mice, we observed no improvement of the insulin resistance phenotype. Further, upon E2 administration to 12wk WT mice, we saw a similar development of insulin resistance as seen in the plus E2 treated ArKO mice. We hypothesise that high estrogen levels may have a negative effect on insulin sensitivity. An example of a physiological state in which estrogen levels are high is pregnancy. The National Institute of Health (NIH) estimate that 7% of women develop gestational diabetes with 40% increased risk of developing type 2 diabetes later in life. By 52wks no differences were observed between the ArKO and WT females. This maybe attributed to WT females now showing significantly increased basal glucose levels and reduced sensitivity to insulin. WT females at this age have completed natural cycling - a state similar to human 'menopause' with low E2 levels making them more hormonally similar to the ArKO mouse. Upon E2 administration to the 52wk old ArKOs there was an improvement of glucose and pyruvate tolerance and insulin sensitivity. We are currently elucidating the mechanism/s that underpins our observations.
Conclusion: Estrogen may have biphasic effects on insulin sensitivity in female animals.

Estradiol derivative PE0607 decreases visceral obesity and improves insulin sensitivity in ovariectomized rats fed on a high fat diet
N. Gorbenko, K. Taran, A. Borikov, S. Oksenenko, O. Ivanova, A. Stepanova, F. Yaremenko;
Pharmacology, Institute of Endocrine Pathology Problems, Kharkiv, Ukraine.

Background and aims: It is believed that estrogen deficiency contributes importantly to the pathogenesis of menopausal metabolic syndrome and symptoms can be ameliorated with estradiol therapy Estrogens have been found to reduce coronary heart disease and to have favorable effects on glycaemic and lipid profiles. However, the risks of adverse health effects must be balanced against the benefits associated with hormone replacement therapy. The aim of the study was to assess the effects of novel estradiol derivative PE0607 (P) on the visceral fat accumulation and insulin resistance development in ovariectomized (OVX) rats fed on a high-fat diet (HFD).
Materials and methods: Wistar rats were divided into three groups: OVX group fed on a regular diet (OVX, n=8), OVX rats fed on a HFD for 4 months (OVX+HFD, n=8), and OVX rats treated with P (20 μg/kg/day per os) during the last 2 months of HFD feeding (OVX+HFD+P). Bilateral ovariectomy was applied to the animals under anaesthesia. At the end of the study fasted rats were subjected to the glucose tolerance test (GTT, 3 g/kg i.p.). Indexes of insulin resistance (IR) were determined using the homeostasis model assessment methods (HOMA) and quantitative insulin sensitivity check index (QUICKI). Plasma levels of non-esterified fatty acids (NEFA), triglycerides (TG) and alanine aminotransferase (ALT) were assessed as parameters of insulin resistance. Visceral fat weight was calculated as the sum of the retroperitoneal, mesenteric, and epigonadal fat pad weights.
Results: HFD induced obesity (body weight was increased by 52%) and severe insulin resistance in OVX rats, as indicated by higher HOMA-IR index (OVX+HFD: 8.91±0.70 vs OVX: 3.39 ±0.30, $p<0.001$) and lower QUICKI ($p<0.01$) indexes. The combined weight of the abdominal fat depots was threefold greater in the HFD animals compared with OVX rats on a regular diet ($p<0.001$). OVX+HFD group also developed glucose intolerance, hypertriglyceridemia, elevated NEFA levels, and ALT activities ($p<0.01$). Administration of P ameliorated HFD-induced glucose intolerance. Area under curve over the GTT was OVX+HFD+P: 1375±101 mM x hour vs OVX+HFD: 1837±145 $p<0.01$; OVX: 1071±176. The treatment with P decreased insulin resistance (HOMA-IR index OVX+HFD+P: 2.97±0.28, $p<0.01$), triglyceride concentration (OVX+HFD+P: 0.75±0.08 vs OVX+HFD: 1.38±0.27 mmol/l, $p<0.01$), NEFA levels and ALT activity ($p<0.02$).The reduction in body weight gain in OVX rats treated with P was accompanied by a significant reduction in visceral fat (OVX+HFD+P: 16.2±1.6 g vs OVX+HFD: 32.3±4.5 g, $p<0.001$) P. In addition, there were no differences in uterine weights between OVX rats treated with P or vehicle.
Conclusion: These data demonstrate that the novel estradiol derivative PEO607 ameliorate adiposity and insulin resistance in OVX rats fed on a HFD without impact on the uterine weight .We suggest that the use of PE0607 may be beneficial for the treatment of obesity and associated metabolic disturbances in postmenopausal women.

PS 44 Systemic inflammation in obesity and diabetes

617

PKCδ augments IL-6 signalling and proinflammatory response

E. Wallerstedt;
Department of Molecular and Clinical Medicine, Lundberg Laboratory for Diabetes Research, University of Gothenburg, Sweden.

Background and aims: We have previously shown in differentiated 3T3-L1 adipocytes that insulin antagonizes interleukin-6 (IL-6) signaling and exerts anti-inflammatory effects by significantly reducing the Tyr-705 phosphorylation and nuclear translocation of the intracellular signaling molecule STAT3. Both insulin and IL-6 increase the Ser-727 phosphorylation of STAT3 but through two independent pathways. Ser-727 phosphorylation of STAT3 is important for the transcriptional activity of STAT3. The aim with the present study was to examine the importance of PKCδ for STAT3 phosphorylation and activation of proinflammatory genes in response to IL-6.
Materials and methods: Differentiated 3T3-L1 cells were cultured and pre-incubated with or without the PKCδ inhibitor rottlerin (6 μM) for 30 minutes before stimulation with insulin (100 nM) and/or IL-6 (20 ng/ml) for 30 minutes up to 24 hours. Wt MEFs and PKCδ-/- MEFs were incubated with IL-6 (30 ng/ml) and soluble IL-6 receptor (30ng/ml) for 60 minutes and 24 hours. RNA was extracted and the gene expression was analyzed with real-time RT-PCR (TaqMan) while the proteins were analyzed by immunoblotting. Transcriptional activity of STAT3 was analyzed by using a STAT3 transcription factor assay kit.
Results: Inhibition of PKCδ with rottlerin significantly reduced not only the Ser-727 phosphorylation, but also Tyr-705 phosphorylation of STAT3. As a consequence, both nuclear translocation of STAT3 and the IL-6-induced gene transcription of the inflammatory molecules SAA3 and haptoglobin were reduced, as well as the transcription of the negative feed-back inhibitor of IL-6, SOCS3. Similar to STAT3, we found that PKCδ translocated to the nucleus upon IL-6 addition and that rottlerin reduced this translocation. We also examined the importance of PKCδ for IL-6 signaling and action in Mouse Embryonic Fibroblasts (MEFs) lacking PKCδ expression. Similar to rottlerin, PKCδ-/- MEFs displayed a significantly reduced activation of SAA3, haptoglobin and SOCS3 compared to wt MEFs. These results correlated with an impaired nuclear translocation and a reduced Tyr-705 phosphorylation of STAT3.
Conclusion: Our results show that PKCδ plays a critical role for IL-6 signaling and action. PKCδ seems to be an interesting target for the development of anti-inflammatory agents.

The role of macrophage migration inhibitory factor in obesity-associated type 2 diabetes

T. Cvjeticanin[1], S. Stosic-Grujicic[1], S. Sandler[2], I. Stojanovic[1];
[1]Department of Immunology, Institute for Biological Research "Sinisa Stankovic", Belgrade, Serbia, [2]Uppsala Biomedical Centre, Sweden.

Background and aims: Obesity-associated type 2 diabetes (T2D) develops as a consequence of inappropriate insulin action and is a state of persistent low grade inflammation. Both lipids and immune mediators are involved in maintaining this inflammatory process. Recently, elevated expression of pro-inflammatory cytokine macrophage migration inhibitory factor (MIF) has been associated with obesity and glucose intolerance. Our preliminary data indicate that mice with MIF gene knock-out (MIF-KO) kept on standard diet gain more weight then their wild type (wt) counterparts C57BL/6 mice. Introduction of high fat diet (HFD) provoked considerable obesity in C57BL/6 strain, while MIF-KO mice did not significantly increase their body weight. Furthermore, MIF-KO mice on HFD responded normally to glucose overload during intraperitoneal glucose tolerance test and preserved euglycemia compared to wt mice. Our next goal was to further examine involvement of MIF in the course of obesity-associated T2D induced by HFD.
Materials and methods: MIF-KO and C57BL/6 mice were fed a standard diet (10% fat) or HFD (60% fat) for 14 weeks. Pancreatic islets were isolated by collagenase V digestion and hand-picked. MIF mRNA expression in pancreatic islets from C57BL/6 mice was detected by Real-time PCR. Serum MIF and MIF secreted from cultured pancreatic lymph node cells (PLNC) were measured by ELISA. Serum insulin and insulin secreted from islets stimulated by 1.7 mM or 16.7 mM glucose was measured by ELISA, while triglycerides were determined spectrophotometrically after enzymatic digestion and oxidation.
Results: As expected, MIF serum level was elevated in C57BL/6 mice fed a HFD and accompanied with higher MIF expression in the islets and secretion in PLNC compared to mice on standard chow. This indicates a causal relationship between MIF and the development of obesity-associated T2D. Accordingly, MIF-KO mice which are inherently mildly obese did not respond to HFD as wt mice and maintained normal levels of triglycerides and insulin. In addition, when challenged with glucose MIF-KO mice on HFD secreted less insulin compared to C57BL/6 mice. Also, it was evident that pancreatic islets from MIF-KO mice on HFD preserved normal function compared to wt mice as observed by their better response in glucose-stimulated insulin release test.
Conclusion: Our results indicate that MIF is probably required for optimal manifestation of obesity-associated T2D in mice since lack of MIF ensures normal glucose, insulin and triglycerides levels. These data implicate a potential new approach for T2D treatment.

Transgenic mice overexpressing C reactive protein show reduced insulin secretion and impaired glucose homeostasis

M.L. Hribal[1], M.F. Ruffo[1], A. Greco[1], T.V. Fiorentino[1], D. Samols[2], G. Sesti[1];
[1]University of Catanzaro Magna Graecia, Italy, [2]Case Western Reserve University, Cleveland, United States.

Background and aims: Epidemiological studies indicate that increased plasma C reactive protein (CRP) levels are associated with type 2 diabetes and glucose metabolism disorders, and even predict the development of these diseases. We thus wished to investigate if the pro-inflammatory molecule CRP directly affects insulin sensitivity and glucose homeostasis *in vivo*.
Materials and methods: Transgenic mice(tgCRP) used in this study express the rabbit CRP transgene under the control of the PEPCK promoter. ELISA assays were used to evaluate CRP and insulin concentration in plasma obtained from transgenic and wild-type (WT) mice. Fed and fasting insulin and glucose levels have been assessed in 3- and 6-months old mice and the mice have also been subjected to intraperitoneal glucose (IPGTT) and insulin tolerance (ITT) and acute-phase glucose-stimulated insulin secretion (A-GSIS) tests. For high fat diet studies, mice were fed a diet fcontaining 60% kcal as fat or 24 weeks after weaning. Statistical differences were assessed by Student's t or two-ANOVA tests as appropriate
Results: We confirmed that TgCRP had serum CRP concentrations ranging between 10 and 20 μg/mL, comparable to those considered to confer high risk for atherosclerosis, insulin resistance, and type 2 diabetes in humans. We observed then a slight, but significant, increase of fasting glucose levels in 3-months-old TgCRP as compared with WT littermates (98±13 and 119±17 mg/dl for WT and TgCRP respectively, $p<0.05$, n=10-12), however fed glucose levels were unaltered and IPGTTs and ITTs showed that young TgCRP had a normal glucose metabolism. By contrast, 6 months-old transgenic mice had significantly increased fasting (108±14 and 128.9±36 mg/dl for WT and tgCRP respectively, $p<0.05$, n=10-12) and fed (135±30 and 160±29 mg/dl for WT and tgCRP respectively, $p<0.05$, n=10-12) glucose and significantly lower insulin(3.3±2.3 ng/ml and 2.33±1.2 $p<0.02$ for WT and TgCRP respectively, n=8-10). IPGTTs and ITTs revealed that 6 months-old TgCRP have developed glucose intolerance ($p<0.05$) and insulin resistance ($p<0.05$). Interestingly, when we performed A-GSIS tests to further elucidate the defects underlying this phenotype, we found that TgCRP mice release significantly less insulin at every time point examined ($p<0.01$), thus suggesting that the primary defect in TgCRP may be reduced insulin secretion. When we subjected mice to HFD for 24 weeks, TgCRP gained more weight than WT littermates (47.6±7.6 and 51.5±3.69 grams for WT and TgCRP respectively, $p<0.05$, n=6-8), and had significantly higher fed (204±55.32 and 257±50.28 mg/dl for WT and TgCRP respectively $p<0.05$, n=6-8) and fasting (133.6±31.9 and 149±30.38 mg/dl for WT and TgCRP respectively, $p<0.05$, n=6-8) glucose levels and significantly lower fasting insulin levels (2.2±1.3 and 2±1 for WT and TgCRP respectively $p<0.05$, n=6-8); IPGTT tests revealed that TgCRP develop a significantly higher glucose intolerance than their WT littermates ($p<0.05$, n=6-8).

Conclusion: Our data suggest that CRP may directly affect glucose metabolism and, notably, insulin secretion *in vivo*. TgCRP may thus represent a model to study the progression from a chronic low-level, inflammatory state to full-blown type 2 diabetes and to identify potential therapeutical intervention points to stop the progression of the disease.

C-reactive protein mediates the association of liver fat and carotid intima media thickness in men with the metabolic syndrome and/or type 2 diabetes

N.J. Van Der Zijl[1], M.H.A. Muskiet[1], M.E. Tushuizen[1], L.J. Rijzewijk[1], P.J. Pouwels[2], M. Diamant[1];
[1]Department of Endocrinology / Diabetes Centre, [2]Department of Physics & Medical Technology, VU University Medical Centre, Amsterdam, Netherlands.

Background and aims: Liver fat content is closely related with features of the metabolic syndrome (MetS), including central obesity, dyslipidaemia and glucometabolic disorders. Liver fat is also associated with increased risk of cardiovascular disease (CVD). Mechanisms underlying this association are incompletely understood. The liver-derived pro-inflammatory marker C-reactive protein (CRP), has been associated with increased CVD risk. We assessed the inter-relationships of liver fat, subclinical atherosclerosis and CRP in men with uncomplicated type 2 diabetes (T2DM) and/or the MetS and healthy controls.
Materials and methods: Liver fat was quantified by proton magnetic resonance spectroscopy in 16 men with known T2DM (mean±SD age 55.4±4.8 yrs), 36 men with the MetS, according to IDF criteria, (55.5±7.0 yrs) and 21 age-matched healthy men (56.8±7.4 yrs). High liver fat content was defined as liver fat percentage ≥5.56%. Carotid intima media thickness (cIMT) was measured by ultrasound. Relations of liver fat, cIMT and high sensitivity CRP were analyzed by univariate and multivariable regression.
Results: Median (IQR) liver fat percentage was highest in T2DM, as compared to MetS and controls [17.8% (9.4-39.8); 8.2% (4.2-14.2); 5.4% (2.4-8.4), respectively; ANOVA $P<0.001$]. Subjects with high versus low liver fat content had higher cIMT ($P=0.050$) and CRP ($P=0.001$). In all subjects, liver fat content was associated with cIMT (r=0.253; $P=0.039$) and CRP (r=0.425; $P<0.001$). This association between liver fat content and cIMT disappeared after adjustment for CRP. The association of cIMT with CRP (r=0.322; $P=0.011$) remained unchanged after adjustment for age, BMI, waist, blood pressure, HbA1c, fasting plasma glucose, or triglycerides.
Conclusion: Liver fat content is associated with carotid artery subclinical atherosclerosis in men with the MetS and/or uncomplicated T2DM. Since this association disappeared after correction for plasma CRP we suggest that this circulating inflammatory marker mediates the relationship between liver fat and subclinical atherosclerosis in this high risk population.

621

Plasma C-reactive protein, apolipoprotein B and triglycerides/HDL-cholesterol ratio as cardiometabolic risk factors in adolescents with and without metabolic syndrome

C. Musso, M. Graffigna, J. Soutelo, M. Honfi, L. Ledesma, V. Miksztowicz, M. Migliano, L. Litwak, I. Sinay, G. Berg;
Sociedad Argentina de Endocrinologia y Metabolismo, Capital Federal, Argentina.

Background and aims: The prevalence of the metabolic syndrome (MS) has increased worldwide. That imposes a substantial risk for type 2 diabetes and premature cardiovascular disease in adults. However to date no unified criteria exist to assess risk or outcomes in children and adolescents. The objetive was to establish the prevalence of MS and risk factors for cardiovascular disease in adolescents.
Materials and methods: Adolescents from high school were studied (n=943), 429 females and 514 males, ages range from 11 to 14 years old. Weight, height, body mass index (BMI), waist circumference (WC), and blood pressure were determined in all patients. Glycemia, lipid and lipoprotein profile, apolipoprotein B (Apo B) and high sensitivity C-reactive protein (hs-CRP) levels were measured after an overnight fast of 12 hours. Triglycerides/HDL-Cholesterol ratio (TG/HDL) was calculated.. Metabolic syndrome was diagnosed according to the NCEP: ATP III criteria modified by Cook et al. A parent or guardian gave consent for participation. The protocol was approved by the ethics committee.
Results: Prevalence of metabolic syndrome was 5.45% in the male group and 1.63% in the female group. MS group presented higher TG/HDL ratio than those without MS, median (range): 3.58 (0.94-7.4) vs 1.38 (0.63-7.59), p<0.001; no differences in hs-CRP were observed between groups: 1.7 mg/L (0.1-8.3) *vs* 1.20 mg/L (0.1-8), respectively. Apo B (mean±SD) was 74.1 ± 6.3 mg/dl in MS group and 46 ± 15.7 mg/dl in those without MS (p= 0.001). TG/HDL ratio positively correlated with BMI (r=0.18, p <0.001), WC (r=0.24,p<0.001), and Apo B (r=0.24, p<0.001). Although no differences between groups were observed, hs-CRP correlated with WC (r=0.14, p<0.001) and BMI (r=0.17, p< 0.001).
Conclusion: Even when prevalence of MS in our patients was low, in those patiens who had MS atherogenic lipoprotein parameters were higher. However the inflamatory marker was not different between groups. The risk to develop cardiovascular disease was clearly higher in the group with MS than in the group without MS. These findings emphasize the importance to evaluate cardiovascular risk factors in adolescents to assess strategies to prevent future disease.

Metabolic endotoxaemia and saturated fat contributes to circulating NGAL concentrations in subjects with insulin resistance

J.M. Fernandez-Real[1], J. Moreno-Navarrete[1], M. Manco[2], J. Ibáñez[3], E. García-Fuentes[4], F. Ortega[1], M.R. Chacón[5], E. Gorostiaga[3], J. Vendrell[5], M. Izquierdo[3], C. Martínez[3], G. Mingrone[6], F. Tinahones[4], W. Ricart[1];
[1]Hospital of Girona, Spain, [2]Scientific Directorate, Bambino Hospital, Roma, Italy, [3]Studies, Research and Sports Medicine Center, Navarra, Spain, [4]Hospital Virgen de la Victoria de Málaga, Spain, [5]University Hospital of Tarragona, Spain, [6]Catholic University, Rome, Italy.

Background and aims: Lipocalin-2 (NGAL) is an innate immune system protein linked to insulin resistance and obesity, but the mechanisms behind these associations are poorly known. The aims of this study were 1) to evaluate the cross-sectional association among serum NGAL concentration, circulating inflammatory markers and insulin sensitivity; 2) To evaluate the effects of weight loss-induced changes in insulin sensitivity on circulating NGAL concentration and diurnal NGAL rhythm; 3) to test the acute effects of saturated fatty acids on circulating NGAL concentration according to insulin resistance status; and finally, 4) to investigate the effects of LPS on NGAL concentration in adipose tissue explants and whole blood.
Materials and methods: We studied 4 cohorts: 1) a cross-sectional study in 194 subjects (109 with normal glucose tolerance and 85 with type 2 diabetes); 2) the changes in NGAL concentration induced by diet and weight loss in 36 obese women (with circadian rhythm in 8 of them); 3) the effects of acute fat intake on circulating NGAL concentration in 42 morbidly obese subjects; and 4) LPS-induced NGAL secretion e*x vivo* (whole blood and adipose tissue explants).
Results: In NGT subjects, circulating NGAL concentration was significant lower than in T2D subjects (61.1 ± 25.9 vs. 99.04 ± 52.3 ng/ml, p<0.001). Serum NGAL concentration was significantly associated with fasting triglycerides, sTNFR2, and lipopolysaccharide (LPS) binding protein) in patients with type 2 diabetes. In obese subjects, the intake of saturated fatty acids contributed independently to 14 % of NGAL variance. Weight loss changed significantly the circadian rhythm of NGAL. The acute increase in circulating NGAL after fat-overload was significantly associated with fasting insulin (r=0.52, p<0.001), HOMA-IR (r=0.36, p=0.02) and post-load triglyceride concentrations (r=0.38, p=0.018).). In ANOVA analysis, we found a significant association between the changes in circulating NGAL and HOMA-IR status (p=0.03). LPS-induced NGAL secretion from adipose tissue explants did not change significantly but LPS led to a significant increase in NGAL concentration in whole blood from patients with type 2 diabetes (1.86 ± 0.12-fold, p= 0.003).
Conclusion: In summary, metabolic endotoxemia and saturated fat contributes to circulating NGAL concentration in patients with insulin resistance.

Inflammation markers and metabolic characteristics of subjects with 1-hour hyperglycaemia

G. Bardini, I. Dicembrini, C.M. Rotella;
Obesity Agency, Department of Clinical Pathophysiology, University of Florence, Italy.

Background and aims: Chronic subclinical inflammation may be associated to a worsening of glucose metabolism and cardiovascular disease risk factors (CV risks) such as pre-diabetes (pre-DM). Recently, 1-hour hyperglycaemia (1hPG) after an oral glucose load (OGTT) with a cut point of 155 mg/dl, has been indicated as a risk factor to develop type 2 diabetes. Aim of this study is to evaluate the association of 1hPG and inflammation markers in subjects with normal glucose tolerance (NGT) and pre-DM.
Materials and methods: We examined a consecutive series of 1549 subjects aged 44.8±14.2 years with a body mass index (BMI) of 34.8±7.3 kg/m^2 with no history of diabetes or inflammatory diseases and without drugs interfering with glucose or lipid metabolism, seeking treatment for overweight or obesity. Glucose tolerance was determined after overnight fasting by a standard OGTT (75 g) with blood samples at 0', 60', 120' for glucose and insulin; the cut point of 1hPG>155 mg/dl was applied for each subject, subdividing all patients with NGT and pre-diabetes (impaired fasting glucose and impaired glucose tolerance) above or below the cut off of 1hPG: NGT-high, NGT-low, pre-DM-high and pre-DM-low. Insulin resistance were evaluated by HOMA2-IR computer model. A lipid profile for total and HDL cholesterol (HDL-C) and triglycerides was performed. Triglycerides/HDL cholesterol ratio (Tg/HDL-C) >3.5 and total cholesterol/HDL-C ratio (TC/HDL-C) >5 were considered for CVD risk; moreover, uric acid, and inflammatory markers such as fibrinogen and leucocytes count (WBC) were determined.
Results: In the sample studied, according to American Diabetes Association criteria, 46.2% subjects were NGT, 40.5% with pre-diabetes and 13.2% with type 2 diabetes. NGT and pre-DM subjects with 1hPG>155 mg/dl showed a significant increase (p<0.05) of inflammatory markers versus those patients below 1hPG cut point. In age-sex-BMI-adjusted analysis, 1-hour hyperglycaemia is associated with a significant high levels of WBC count and fibrinogen. Tg/HDL ratio was significantly higher in NGT-high vs NGT-low (3.6±2.8 vs 2.8±2.4, p<0.05) such as TC/HDL ratio (4.6±1.5 vs 4.2±1.4, p<0.05). In patients with pre-DM, those with pre-DM-high showed a significant higher levels of Tg/HDL ratio (4.2±3.8 vs 3.5±2.4, p<0.05) and TC/HDL ratio (5.0±1.6 vs 4.5±1.5, p<0.05) than pre-DM-low individuals. The distribution of subjects with high levels of lipid ratios shows a significant increase of prevalence of 1hPG-high versus 1hPG-low groups. In particular, in the category of NGT, subjects with Tg/HDL ratio>3.5 were 38.6% vs 17.7% (1hPG-high vs 1hPG-low) and TC/HDL>5 patients were 34.0% vs 22.3%, respectively. The two categories of 1hPG for the pre-DM group showed 41.3% vs 30.3% of patients with Tg/HDL ratio>3.5 and 43.7% vs 34.0% of subjects with TC/HDL>5. In NGT and pre-DM subjects, no significant difference has been shown for HOMA2-IR levels between 1hPG-high and 1hPG-low groups.
Conclusion: High 1hPG in normal glucose and pre-DM state is associated to an higher levels of inflammatory markers and lipid ratios exposing those subjects to an increase CV risk, despite no significant difference in insulin resistance levels.

624

Increased levels of proinflammatory cytokines are associated with impaired immune activity of natural killer (NK) cells of prediabetic subjects (PS)

A. Czech[1], P. Piatkiewicz[1], M. Nowaczyk[2], J. Marek[1];
[1] Department of Internal Medicine and Diabetology, [2]Department of Clinical Immunology, Warsaw Medical University, Poland.

Background and aims: Inflammatory mechanisms are believed to be involved in the pathogenesis of diabetic complications. Diabetic hyperglycemia may suppress the function of peripheral blood NK cells. Recent experimental studies have shown significant differences in immune activity of NK cells of Type 2 diabetic patients in comparison to healthy subjects. The aim of this study was to asses the relation between the plasma concentration of selected proinflammatory cytokines (interleukin 1; IL-1 and interleukin 6; IL-6) and the number and activity of NK cells obtained from PS.
Materials and methods: The study group included 12 newly-diagnosed (according to WHO definition) PS, naive to any hypoglycaemic drugs and 8 normoglycaemic control subjects (CS) matched for sex, BMI and waist circumference. Peripheral blood mononuclear cells (PBMC) were isolated by Ficoll gradient centrifugation. Immunofluorescent phenotyping of NK (CD16$^+$) cells in PBMC was performed using specific murine anti-human CD16 PE-conjugated monoclonal antibodies. The K562 human erythroleukemia cell line was used as the standard target for human NK cytotoxicity assay. K562 were labelled with DIO(3,3-dioctadecyloxacarbocyanine perchlorate). Target and effector cells were added to reach effector/target rations: 50:1 ,12:1. Dead target cells were stained with PI (propidium iodide). After 4 hours of incubation data were collected for analysis on the Becton-Dickinson FACScalibur flow cytometer. The data was analyzed using Cell Quest software. Concentrations of IL-1 and IL-6 were determined using fluorescent cytometric microbead assay. Plasma aliquots were incubated with color-coded fluorescent microbeads labeled with antibodies against respective cytokines. The fluorescence intensity was determined using dual-laser detector and cytokines concentrations were read from standard curve.
Results: PS exhibited higher insulin resistance reflected by HOMA-IR (3.21±2.32) compared to control group (1.96±1.18, p=0.03). Plasma concentrations of investigated cytokines were significantly higher in the PS compared to CS (IL-1: 1.36±1.27 vs 0.35±0.31 pg/ml, p=0.01; IL-6: 4.09±3.30 vs 2.12±1.13 pg/ml, p=0.03). Correlations between cytokines and HOMA-IR were weak and non-significant (all p>0.05). The PS in comparison to healthy subjects had an increased number (12,45±5,8% vs 9,63±4,7%) but decreased activity (4,4±2,0% vs 9,2±3,7%) of NK cells (p=0.01). Correlations between cytokines and both the number and activity of NK cells were statistically significant (p<0.05).
Conclusion: In the prediabetic state the increased number and decreased activity of peripheral NK cells are associated with high excretion of proinflammatory cytokines (IL-1, IL-6). This supports the hypothesis that inflammation is involved in the pathogenesis of early impairment of NK cell killing function. Inflammation markers are likely to be useful in the screening of metabolically vulnerable individuals.

Matrix metalloproteinases in type 2 diabetes and in non-diabetic controls: effects of short-term and chronic hyperglycaemia

K.C. Lewandowski[1], E. Banach[2], A. Lewinski[1];
[1]Department of Endocrinology & Metabolic Diseases, The Medical University of Lodz, [2]Department of Internal Medicine, St Alexander Hospital, Kielce, Poland.

Background and aims: Matrix metalloproteinases (MMPs) remodel extracellular matrix in various physiological and pathological conditions, including cancer, inflammatory states and cardiovascular disease. The role of MMPs in type 2 diabetes (DM) is not clear as increased activation of MMPs in vasculature contrasts with decreased activity of MMPs in kidneys, thus contributing to the development of diabetic nephropathy. In our study we have aimed to assess the effects of transient *versus* chronic hyperglycaemia on concentrations of MMPs.
Materials and methods: We measured serum MMP-2, MMP-9 in 22 subjects with type 2 DM, age (mean±SD) 56.7±16.8 years, BMI 31.8±4.6 kg/m^2, HbA1c 8.45±1.78% and in 32 Controls, age 39.2±16.0 years, BMI 35.2±8.5 kg/m^2. In 15 subjects with type 2 DM we also measured MMP-2 and -9 at discharge from hospital and after three months (n=8). In a subgroup of Controls MMP-2 and -9 were also measured during 75 gram oral glucose tolerance test (OGTT).
Results: Concentrations of MMP-2 and MMP-9 were lower in subjects with type 2 DM (219±62ng/ml *versus* 305±63ng/ml and 716±469ng/ml *versus* 1285±470ng/ml, for MMP-2 and MMP-9, respectively, p<0.05). Control subjects were younger (p<0.05), however, without statistical difference in BMI between the groups. MMP-9 concentrations fell at 120 minutes of OGTT from 1675±372 ng/ml to 1276±422 ng/ml, p<0.05). In diabetic subjects there was a correlation between MMP-9 and HbA1c (r=0.51, p<0.05). In patients with diabetes there was no difference in MMP-2 at the time of admission *versus* discharge from hospital with a trend towards lower MMP-9 (p=0.08, n=15) at discharge, that became significant at three months post-discharge (p<0.05).
Conclusion: Concentrations of MMP-2 and MMP-9 were lower in subjects with type 2 diabetes than in non-diabetic controls. Regulation of MMPs appears to be, however, complex as hyperglycaemia during OGTT results in a decrease in MMP-9, while chronic hyperglycaemia, reflected by HbA1c, correlates with MMP-9 concentrations in subjects with type 2 diabetes.

Serum IL-18 concentration is increased in obese subjects with impaired glucose tolerance and related to the markers of atherogenesis

I. Kowalska, M. Straczkowski, A. Nikolajuk, A. Adamska, M. Karczewska-Kupczewska, A. Lebkowska, M. Gorska;
Department of Endocrinology, Diabetology and Internal Medicine, Medical Univeristy of Bialystok, Poland.

Background and aims: IL-18 is considered as a proinflammatory and proatherogenic factor. Therefore the aim of the present study was to asses the serum IL-18 concentration in relation to insulin sensitivity and markers of endothelial dysfunction in obese subjects with normal (obese-NGT) and impaired glucose tolerance (obese-IGT).
Materials and methods: The study group consisted of 87 lean subjects with NGT (control group), 120 obese-NGT and 41-obese IGT. In the entire group OGGT, euglycemic hyperinsulinemic clamp and estimation of serum concentration of IL-18, soluble intercellular adhesion molecule 1 (sICAM-1) and soluble E-selectin (sE-selectin) were performed.
Results: Serum IL-18 concentration was the highest in obese-IGT group (327.9±132.8 pg/ml vs 282.9±123.9 pg/ml, p= 0.01 in obese-NGT and 238.3±121.3 pg/ml, p=0.002 in the control group). Obese-IGT subjects had also the lowest insulin sensitivity and the highest concentration of sICAM-1 and sE-selectin (all p<0.05 for comparisons with obese-NGT and control group). In the entire group serum IL-18 was inversely correlated with insulin sensitivity (r=-0.32, p<0.0001), HDL-cholesterol (r=-0.022, p<0.0001) and positively related to systolic (r=0.19, p=0.003) and diastolic blood pressure (r=0.18, p=0.004), fasting glucose (r=0.25, p<0.0001), TG (r=0.39, p<0.0001), sICAM-1 (r=0.41, p<0.0001), sE-selectin (r=0.325, p<0.0001). All these correlation were also present in all subjects with NGT. In the obese-IGT group, serum-IL-18 were related to fasting glucose (r=0.47, p=0.002), insulin (r=0.325, p=0.046), sICAM-1 (r=0.72, <0.0001) and sE-selectin (r=0.33, p=0.037).
Conclusion: Our data indicate that IL-18 might contribute to the proatherogenic state observed in IGT.

Expression of the bone morphogenetic protein receptor 2 (*BMPR2*) mRNA in adipose tissue and *BMPR2* genetic variation are related to human obesity

D. Schleinitz[1], N. Klöting[2], Y. Böttcher[2], S. Wolf[2], K. Ruschke[2], K. Dietrich[1], M. Koriath[2], B. Enigk[1], G.H. Scholz[3], Y.-H. Tseng[4], A. Tönjes[2], M. Stumvoll[2], M. Blüher[2], P. Kovacs[1];
[1]Interdisciplinary Center for Clinical Research, University of Leipzig, Germany, [2]Department of Medicine, University of Leipzig, Germany, [3]St. Elisabeth Hospital, Institute for Preventive Medicine GmbH, Leipzig, Germany, [4]Joslin Diabetes Center, Harvard Medical School, Boston, United States.

Background and aims: The human bone morphogenetic protein receptor 2 (BMPR2), a family member of transmembrane serine/threonine kinases, is one of the specific BMP-receptors essential for BMP signalling during adipogenesis, osteogenesis and myogenesis. We hypothesized that *BMPR2* mRNA expression in adipose tissue and genetic variation could be related to the pathophysiology of human obesity.
Materials and methods: *BMPR2* mRNA expression was measured in 198 human paired samples of visceral and subcutaneous adipose tissue. The mRNA levels were compared between lean and obese subjects. To determine, whether genetic variants within the *BMPR2* are associated with mRNA expression in fat and whether they are related to measures of obesity and fat distribution, we sequenced the *BMPR2* in DNA samples from 48 non-related subjects from Eastern Germany. Ten representative variants including HapMap tagging single nucleotide polymorphisms (SNPs) were genotyped for subsequent association studies on quantitative traits in 1808 subjects from Eastern Germany with a wide range of BMI distribution and glucose tolerance.
Results: Expression of *BMPR2* mRNA was significantly increased both in visceral and subcutaneous fat of 51 overweight (BMI 25 - 30 kg/m^2) and 91 obese (BMI > 30 kg/m^2) subjects compared with 56 lean subjects (BMI < 25 kg/m^2) (P<0.001). In a case control study including 461 lean and 678 obese subjects, two intronic SNPs (rs6717924 and rs13426118) were significantly associated with obesity (P<0.05, adjusted for age and sex). Consistent with this, we found significant associations of *BMPR2* SNPs with BMI, % body fat and circulating serum leptin (adjusted P<0.05) in 896 non-diabetic subjects. Finally, the rs6717924 was significantly associated with *BMPR2* mRNA expression levels in visceral fat (P=0.05, adjusted for age, sex and BMI).
Conclusion: Our data suggest a role of *BMPR2* in the pathophysiology of human obesity. The association of genetic variants with obesity might be mediated via effects on *BMPR2* mRNA expression in fat.

628

Thyroid hormone responsive Spot 14 increases during differentiation of human adipocytes and its expression is down-regulated in obese subjects

F.J. Ortega[1], A. Vazquez-Martin[2], J.M. Moreno-Navarrete[1], J. Bassols[1], J. Rodriguez-Hermosa[3], J. Girones[3], W. Ricart[1], B. Peral[4], F. Tinahones[5], G. Fruhbeck[6], J.A. Menendez[2], J.M. Fernandez-Real[1];
[1]Service of Diabetes, Endocrinology and Nutrition, Institut d'Investigació Biomèdica de Girona (IdIBGi), [2]Catalan Institute of Oncology (ICO), Institut d'Investigació Biomèdica de Girona (IdIBGi), [3]Department of Surgery, Institut d'Investigació Biomèdica de Girona (IdIBGi), [4]Instituto de Investigaciones Biomédicas Alberto Sols (IIB), Girona, [5]Service of Endocrinology and Nutrition, Hospital Clinico Universitario Virgen de Victoria de Malaga, Girona, [6]Department of Endocrinology, Clínica Universitaria de Navarra, Girona, Spain.

Aims: Thyroid hormone responsive spot 14 (THRSP or S14) has been postulated to be involved in lipogenesis but very limited information regarding its role in adipogenesis and human adiposity is available. We aimed to evaluate S14 expression in human adipocytes and in fat samples from a cohort of subjects who varied widely in terms of obesity and body fat distribution.
Materials and methods: We evaluated S14 during differentiation of human pre-adipocytes into mature adipocytes using an automated confocal imaging approach. We also studied the relative levels of S14 mRNA (assessed by RT-PCR) in stromal-vascular cells (SVCs) and mature adipocytes (MAs) isolated from human fat biopsies. In parallel, we performed a cross-sectional study in which S14 gene expression levels were measured in 161 visceral and 87 subcutaneous adipose tissue samples.

Results: We report the occurrence of S14 up-regulation during the early stages of differentiation of human pre-adipocytes accompanied by cytoplasmic accumulation of fatty acid synthase. These observations were most prominent in those individual cells exhibiting the more marked differentiation features. In agreement with these findings, S14 gene expression increased by ~130-fold from pre-adipocytes to mature adipocytes. Interestingly, S14 levels were decreased in visceral adipose tissue from overweight (-42.0%) and obese subjects (-56.5%) compared with lean subjects ($p<0.05$ and $p<0.0001$, respectively). S14 gene expression was inversely associated with obesity measures such as body mass index ($p=0.001$), percent fat-mass ($p=0.001$), waist-to-hip ratio ($p=0.02$) and with systolic blood pressure ($p=0.03$). Otherwise, increased S14 mRNA levels were found in stromal-vascular cells/pre-adipocytes (3.8-fold, $p<0.05$) and in whole adipose tissue samples (1.9-fold, $p<0.0001$) from subcutaneous compared with visceral fat depots.
Conclusion: These results suggest that S14 is involved in human adipogenesis. The inverse association between S14 gene expression levels and obesity measures hints at a negative feed-back among adiposity, adiposity-related disorders and S14 gene expression levels.

Insulin increases natriuretic peptide clearance receptor expression in the subcutaneous fat depot in obese subjects: a clamp study
N.N. Rudovich[1,2], O. Pivovarova[1,2], A. Ernst[3], Ö. Goegebakan[1,2], A. Bergmann[3], A.F.H. Pfeiffer[1,2];
[1]Clinical Nutrition, DIFE Potsdam-Rehbrücke, Nuthetal, [2]Charite, CBF, Berlin, [3]B.R.A.H.M.S AG, Berlin, Germany.

Background and aims: Atrial natriuretic peptide (ANP) is a cardiac hormone that protects cardiovascular integrity through different mechanisms. Moreover ANP has multiple metabolic properties and it was recently discovered to induce lipolysis. Obese subjects have reduced levels of circulating ANP for unknown reasons. An intensive weight reduction enhanced circulating ANP in obesity. Our recent observation suggested that insulin suppresses ANP levels in humans. To investigate a possible regulation of natriuretic peptide receptors (NPRs) expression by insulin, we conducted hyperinsulinemic, eu- and hyperglycemic clamp experiments on obese subjects and determined the concentrations of circulating midregional proANP53-90, a stable prohormone fragment co-released with mature ANP from proANP, and investigated the expression of three types of NPR´s in subcutaneous fat tissue.
Materials and methods: Hyperinsulinemic, euglycemic (EC) (4.4 mmol/l for 240 min, n=10) and hyperinsulinemic, hyperglycemic clamps (7.8 mmol/l for 240 min, n=7) were conducted on healthy obese non diabetic men. Natriuretic peptide receptors A, B and C were determined by QPCR in biopsies of subcutaneous fat tissue (-40 and 240 min of the clamp). Insulin and MR-proANP53-90 levels were assessed at -70, 120 and 210 min of the clamp.
Results: MR-proANP53-90 levels decreased under insulin infusion at 120 and 210 min in both clamps ($p<0.05$ for EC and $p<0.01$ for HC). Natriuretic peptide clearance receptor expression (NPRC) was increased 1.75 fold under insulin infusion in EC ($p=0.04$) and 1.3 fold in HC ($p=0.02$). A trend to an increase of NPRA expression was observed in HC ($p=0.07$) but not in EC ($p=0.5$). NPRB expression did not change in both clamps.
Conclusion: Acute insulin infusion increases expression of NPRC in subcutaneous fat tissue independent of glucose concentration in obese subjects. Insulin thus may increase the elimination of ANP via regulation of NPRC and suppresses the secretion as shown by decreased MR-proANP53-90.

Adipocyte lipid-binding protein (ALBP) in subjects with different categories of glucose intolerance during acute hyperinsulinaemia
E. Krušinová[1], P. Wohl[1], K. Zídková[1], L. Kazdová[1], P. Mlejnek[2], M. Pravenec[2], T. Pelikánová[1];
[1]Diabetes Center, Institute for Clinical and Experimental Medicine, [2]Institute of Physiology, Academy of Sciences of the Czech Republic, Prague, Czech Republic.

Background and aims: Adipocyte lipid-binding protein (ALBP) has been shown to regulate lipid metabolism and to affect thereby insulin sensitivity. However, its regulation in human obesity and different stages of glucose intolerance has not been clarified yet. Our aims were to evaluate plasma concentrations of ALBP and its expressions in subcutaneous adipose tissue (SAT) during acute hyperinsulinaemia in subjects with different categories of glucose intolerance.
Materials and methods: 12 subjects with impaired glucose homeostasis (IGH), 11 patients with type 2 diabetes (D) and 11 age-matched healthy men - controls (C), underwent 2-hour hyperinsulinaemic (1 $mU.kg^{-1}.min^{-1}$) euglycaemic (5 mmol/l) clamp to verify insulin sensitivity. Plasma concentrations of ALBP were measured at 0 and 120 min of the clamp. Needle biopsy of abdominal subcutaneous fat was performed (0 and 30 min of the clamp) to assess the ALBP expression using the real-time PCR method. As a reference gene human cyclophilin was used. For statistical analysis ANOVA with repeated measures was used.
Results: Insulin sensitivity estimated as metabolic clearance rate of glucose (MCR) was significantly higher in C compared to D and IGH, whereas IGH did not differ from D: MCR (IGH: 4.47±0.66 vs. D: 4.88±0.49 vs. C: 9.12±1.0 $ml.kg^{-1}.min^{-1}$; $p<0.001$ vs. C). Other anthropometric and metabolic parameters (fasting serum lipids, waist circumference, BMI) were comparable between IGH and D, and lower in C compared to other groups. Plasma concentrations of ALBP were lowest in C compared to D and IGH ($p<0.001$) at baseline as well as during the clamp, there were no significant differences between D and IGH. Relative expressions of ALBP were highest in D compared to IGH and C ($p<0.001$) both at baseline and during the clamp; the differences between IGH and C were not significant. ALBP plasma concentrations significantly correlate with its expression in SAT ($r=+0.45$; $p<0.05$), BMI ($r=+0.64$; $p<0.001$), waist circumference ($r=+0.70$; $p<0.001$), fasting plasma glucose ($r=+0.49$; $p<0.01$) and fasting insulinaemia ($r=+0.38$; $p<0.05$) and negatively correlate with MCR ($r=-0.42$; $p<0.05$). Significant positive correlations were found between ALBP expression and BMI ($r=+0.46$; $p<0.01$) or fasting plasma glucose ($r=+0.60$; $p<0.001$).
Conclusion: Our results support the hypothesis that ALBP expression and secretion are differentially regulated in different source tissues and depots during the progression of glucose intolerance: while ALBP plasma concentrations were comparable in IGH and D, the ALBP expressions in SAT were higher in D, which suggests the involvement of other important source of circulating ALBP in IGH than SAT. Our results also show the association of plasma ALBP with parameters of obesity, insulin resistance and dysregulation of glucose metabolism.

ALBP plasma concentrations (ng/ml) and relative expression in SAT. Data expressed as mean±SEM.

Group	p-ALBP (ng/ml)		Relative expression (AU) ALBP mRNA/cyclophilin mRNA	
	0 min	120 min	0 min	30 min
IGH	24.14±2.84	25.31±3.50	1062±114.3	734±70.03
D	22.61±2.77	19.68±1.99	2024±194.8	2382±330.3
C	12.92±1.89	13.04±1.76	769.4±77.46	730±86.23

Histone lysine demethylase LSD1 is required for adipogenesis
M. Parrizas, M.M. Musri, R. Gomis;
Laboratory of Diabetes and Obesity, IDIBAPS/CIBERDEM, Barcelona, Spain.

Background and aims: Obesity has reached epidemic proportions worldwide, thus prompting a renovated interest on the mechanisms regulating the differentiation and function of the adipose cells. However, although the hormonal and transcriptional cascades involved in adipogenesis have been thoroughly examined, much less is known about the role of epigenetic phenomenons on the differentiation of adipocytes. We have previously shown that the promoters of key adipogenic genes display significant levels of dimethylation at the Lys 4 of histone H3 (H3K4Me2) in preadipocytes, where those genes are not yet expressed, even though H3K4Me2 is considered to be an activating epigenetic mark. Thus, we were interested in elucidating the role of histone methylation and the enzymes involved in regulating its turnover on adipogenesis.
Materials and methods: We knocked down the expression of different regulators of histone methylation in 3T3-L1 preadipocytes by means of siRNA transfections. We studied the effects of knocking down those regulators upon adipogenesis, as well as upon the expression (measured by real time RT-PCR) and chromatin environment (by chromatin immunoprecipitation assays) of key adipogenic promoters.

Results: We focused on the histone demethylase LSD1, which has been shown to demethylate both the positive signal H3K4Me2 and the repressive mark H3K9Me2, thus acting either as a repressor or an activator, depending on context. Our results show that adipogenesis in the absence of LSD1 is severely impaired, as measured by lipid accumulation and the expression of mature adipocyte-specific genes. This outcome is associated with decreased H3K4Me2 (37%, p<0.0005) and increased H3K9Me2 (235%, p<0.0005) levels at the promoter of the key adipogenic transcription factor *Cebpa*, which is silenced in preadipocytes but whose expression increases exponentially during adipogenesis. Our data suggests that LSD1 acts as a H3K9 demethylase in this promoter, maintaining low levels of this repressive mark and probably counteracting the action of a H3K9 methyltransferase. We tested the possible involvement of the H3K9 methyltransferase SETDB1, since it has previously been shown to block adipogenesis in pluripotent precursor cells. In 3T3-L1 preadipocytes, both LSD1 and SETDB1 are bound to the *Cebpa* promoter, but the recruitment of LSD1 increases after the start of differentiation, whereas the recruitment of SETDB1 decreases. Knocking down SETDB1 increases H3K4Me2 (202%, p<0.0005) and decreases H3K9Me2 (48%, p<0.001) at the *Cebpa* promoter, thus producing the opposite results to LSD1 knock down and suggesting that both factors might be involved in the same regulatory pathway.
Conclusion: Our data suggest that the expression and function of the proteins involved in the regulation of histone methylation play a crucial role in the correct differentiation of adipocytes. Specifically, the histone demethylase LSD1, which is currently being explored as a possible target for cancer treatment and has also been shown to be involved in diabetes and inflammatory pathways, is shown to be crucial for adipogenesis, thus offering new insights into the function of this pleiotropic transcriptional regulator and providing new targets for the treatment of diabetes and obesity.

Orexin regulates glucose and lipid metabolism - *in vitro* study on isolated primary rat adipocytes and 3T3-L1 cells
M. Skrzypski[1], T.T. Le[1], P. Kaczmarek[2], E. Göncz[1], E. Pruszyńska-Oszmałek[2], D. Szczepankiewicz[2], K.W. Nowak[2], B. Wiedenmann[1], M.Z. Strowski[1];
[1]Hepatologie, Gastroenterologie & Interdisziplinäres Stoffwechsel-Centrum/ Endokrinologie und Diabetes, Charité - Universitätsmedizin Berlin, Germany, [2]Department of Animal Physiology and Biochemistry, Poznań University of Life Sciences, Poland.

Background and aims: Orexin regulates energy expenditure, food intake and sleeping behavior. Lack of orexin/orexin receptors is associated with increased body mass index and type 2 diabetes mellitus. Recently, we and others demonstrated that orexin receptors (orexin receptor 1 and 2) are expressed in the endocrine pancreatic islets and in adipose tissue in rodents. It is unknown, whether orexin regulates adipose tissue functions. We therefore studied the role of orexin in regulating the lipid and carbohydrate metabolism in adipocytes.
Materials and methods: We used isolated primary rat adipocytes and 3T3-L1-cells that were differentiated into adipocytes. We studied the short - (8 hours) and long-term (up to 72 hours) effects of orexin A (OXA) on lipogenesis, lipolysis, glycerol secretion, glucose uptake and ATP levels. Furthermore, we characterized the effects of OXA on adiponectin and resistin secretion and expression using RIA and Western blot analysis.
Results: We detected orexin receptor expression in both, differentiated 3T3-L1 cells and primary rat adipocytes, with OX1R, as the predominant receptor subtype. Isolated adipocytes showed higher rate of lipogenesis after 2 hours of exposure to OXA, as compared to non-treated cells. In addition, OXA potentiated the lipogenic effect of insulin. OXA increased intracellular triglyceride content after 24 and 48 hours of incubation and potentiated the effect of insulin. OXA reduced glycerol secretion from adipocytes. OXA time-dependently increased glucose uptake by adipocytes and the intracellular ATP content. In addition, OXA increased the secretion and expression of adiponectin, while the secretion of resistin was attenuated.
Conclusion: We identify orexin A as an anabolic factor which enhances glucose uptake and lipogenesis. In addition, orexin enhances the effects of insulin on lipid and glucose metabolism, suggesting possible insulin sensitizing activity. Furthermore, orexin stimulates adiponectin and inhibits resistin secretion. In summary, the effects of orexin on adipose tissue may represent mechanisms, by which orexin lowers hyperglycemia, an effect previously reported in animal models of type 1 and type 2 diabetes mellitus.

Adiponectin independently improves endothelial dysfunction in obese rats
G. Deng, Y. Yu, M. Li;
Endocrinology and metabolism, West China Hospital of Sichuan University, Chengdu, China.

Background and aims: Hypoadiponectinemia has been proved to be closely related to vascular endothelial dysfunction and is thought to be an independent risk factor for cardiovascular disease. The aim of this study was to determine whether adiponectin might independently improve endothelial dysfunction in aorta isolated from high-fatty diet induced obese rats.
Materials and methods: Two weeks aged male SD rats were assigned to control group (fed with normal chow) and OB group (fed with high-fat food). Aortic rings were extirpated at the end of six weeks and the rings obtained from OB group were sub-divided into three groups and incubated with vehicle (OB-C group), globular adiponectin (OB-gAd group), or adiponectin plus L-NAME, the inhibitor of NO synthase, (OB-gAd-NAME) for 2 hr. The rings were placed into an organ bath and endothelial dependent or independent relaxation was tested with acetylcholine (Ach) or sodium nitroprusside (SNP). Total NO production (NOx) by aortic segments was determined by measuring the concentration of nitrite.
Results: Severe endothelial dysfunction (maximal vasorelaxation in response to ACh: 24.5±6.1 vs. 84.1±3.2% in control, $P< 0.05$) was observed in OB-C group aortic segments, and treatment with gAd significantly improved endothelial function (49.6±7.4%, $P<0.05$). Concentration-dependent vasorelaxation in response to SNP, an endothelium-independent vasodilator, remained unchanged in these vessels. Total NO production was decreased in OB-C group vessels (6.39μmol/mg dw, vs. 13.47μmol/mg dw in control, $P< 0.01$) and treatment with gAd increased total NO production in these vessels (10.53μmol/mg dw, $P< 0.05$). Addition of L-NAME completely blocked vasorelaxation in response to ACh and NOx production in those vessels pretreated with gAd.
Conclusion: Impaired endothelial dependent vasodilatation is one of the hallmarks of vascular injury in patients with metabolic syndrome. The present study demonstrated that adiponectin is a unique cytokine that may directly and independently improves endothelial function by enhancing NO production. Reduced adiponectin production and/or development of adiponectin resistance in patients with metabolic syndrome may play a critical pathogenic role in atherosclerosis.

Background and aims: Inflammation is a response to oxidative stress, endoplasmic reticulum (ER) stress and local hypoxia. These processes are highly integrated and work in vicious cycles. Tumor necrosis factor (TNF)-like weak inducer of apoptosis (TWEAK) is a cytokine that controls many cellular activities and is a new player in the inflammatory processes. TWEAK acts by binding to Fn14, a highly inducible cell-surface receptor that is linked to several intracellular signalling pathways, including NF-κB pathway. Fn14 mRNA has been found to be increased in severely obese type 2 diabetic patients. It has been reported a preponderant role of TWEAK and Fn14 in brain ischemic injuries in human patients. TWEAK can stimulate angiogenesis. We hypothesize that TWEAK and Fn14 could act as pro-inflammatory cytokines in human obesity; been in time with micro-hypoxic events in adipose tissue. We aimed to explore the role of TWEAK mRNA expression in obesity and to investigate its relation to hypoxia and ER stress genes markers.
Research design and methods: *Obese cohort:* 19 lean, 28 overweight, and 15 obese non-diabetic subjects. *Severely obese cohort:* 23 severely obese subjects. *Type 2 diabetes (T2D) cohort:* composed by 11 type 2 diabetic obese subjects. RNA from subcutaneous (SAT) and visceral (VAT) from 96 paired samples were obtained. Gene expression relative and quantification was assayed for: *Fn14*, *TWEAK*, *VISFATIN HYOU1*, *FIAF*, *HIF-1a*, *VEGF*, *GLUT-1*, *GRP78*

and *XBP-1*. Statistical analysis was performed by using the SPSS statistical package.
Results:
TWEAK/Fn14 expression
In obesity: *TWEAK* mRNA levels were significantly high expressed in SAT (p<0.001) whereas *Fn14* was predominantly expressed in VAT samples (p<0.001). *TWEAK* and *Fn14* expression levels both in SAT and VAT depots did not change among obesity groups.
The presence of T2D did not alter the expression of *TWEAK* and *Fn14* in any depot.
In severe obesity: *TWEAK* and *Fn14* mRNA were significantly over-expressed when compared to its control group independently of the adipose depot.
TWEAK /Fn14 expression in relation to hypoxia and ER
In obese and T2D cohorts
Regression analysis showed that SAT *XBP-1* expression levels (B=0.514 p<0.001) predicted the SAT *TWEAK* expression. The presence of T2D did not affect the results of the model. VAT *TWEAK* was predicted by WHR (B=0.007 p=0.006), and SAT *FIAF* (B=0.110 p=0.032).
SAT *Fn14* expression was only predicted by SAT HIF-1α (B=1.3 p<0.001).
VAT *Fn14* expression was predicted by WHR (B=3.7 p=0.003, FIAF (B=-0.42 p=0.02, GRP78 (B=1.6 p=0.041) and XBP-1 (B=3.3 p<0.001).
In severe obese cohort
Regression analysis showed that SAT *Fn*14 expression was predicted by SAT *VISFATIN* (B=2.3 p<0.001), *SAT GLUT*-1 (B=5.8 p=0.001) and SAT *VEGF* (B=-5.5 p=0.015). VAT *Fn14* expression was predicted by VAT *XBP-1* (B=24.4 p<0.001)
Conclusion: Tweak-Fn14 system seems to be closely associated with hypoxia and ER stress gene markers in both adipose tissue depots. Likewise, the presence of visceral adiposity determines in part the TWEAK-Fn14 adipose tissue expression, with independence of the glucose metabolic status.

Control of adipose tissue inflammation in obesity and diabetes through pseudokinases
S. Herzig, A. Ostertag;
Molecular Metabolic Control, German Cancer Research Center, Heidelberg, Germany.

Background and aims: Inflammation of adipose tissue represents a major hallmark of obesity-related type II diabetes and the Metabolic Syndrome. Despite its critical importance for the development of insulin resistance and associated complications, major molecular pathways in adipose tissue inflammation still remain unknown.
Materials and methods: We employed expression profiling studies in cultured and primary white adipocytes and white adipose tissue (WAT) depots of various obesity and type II diabetes mouse models to identify dysregulated marker genes under these conditions. Subsequently, molecular pathways leading to aberrant gene expression under diabetic conditions and functional consequences of genetic dysfunction were investigated by employing genetic and acute gene ablation technology and metabolic monitoring.
Results: Expression profiling in mouse models of systemic inflammation demonstrated the transcriptional induction of the tribbles pseudokinase TRB1 in WAT in response to acute pro-inflammatory stimuli. Furthermore, we found that TRB1 mRNA is also significantly upregulated in WAT of obese db/db and ob/ob animals, suggesting that TRB1 represents a novel marker gene for obesity-related WAT inflammation. Indeed, levels of TRB1 but not of highly-related family members, TRB2 and TRB3, were strongly induced in fully differentiated adipocytes in response to lipopolysaccharide-conditioned macrophage supernatant, thereby demonstrating the cell autonomy of this effect. Intriguingly, the induction of TRB1 through conditioned macrophage supernatant in differentiated adipocytes could be blocked by interference with specific cytokine-dependent signaling pathways, leading to the improvement of cellular inflammation in white adipocytes.
Conclusion: These results indicate that the induction of TRB1 is a novel adipocyte-specific feature of pro-inflammatory conditions as associated with obesity-related type II diabetes, thereby providing a novel molecular checkpoint and potential therapeutic target in adipose tissue dysfunction under these conditions.
