

TECHNICAL NOTE

Transportation Air Quality Technical Support Interagency Contract with Texas Natural Resource Conservation Commission

TO: Mary McGarry-Barber, Project Manager
Texas Natural Resource Conservation Commission

DATE: 25 January 2002

FROM: Dennis G. Perkinson, Ph.D.
Texas Transportation Institute

TTI STUDY NO: 402011-31

SUBJECT: Air Quality Planning and Assessment Research Support (Umbrella Contract
9880077500-10: Task 2 - Quality Assurance Guidance) - **Final**

BACKGROUND

The Texas Natural Resources Conservation Commission (TNRCC) works with local planning districts, the Texas Department of Transportation (TxDOT), and others to provide on-road mobile source inventories of air quality pollutants. TxDOT typically funds transportation conformity determinations required under 40 CFR Part 93, while TNRCC typically funds mobile source inventory work in support of Federal Clean Air Act Amendments for attainment of the National Ambient Air Quality Standards (NAAQS) under 42 USCA 7409. The two tasks described in this Work Plan examine alternative inventory development methods and develops a comprehensive list of on-road inventory quality assurance checks. This technical note addresses the second of these, quality assurance guidance.

The Eastern Research Group (ERG) has been retained by TNRCC to develop a set of comprehensive analysis tools that will support the needs of various emissions inventories end users. Multiple TNRCC Sections are involved, including Area and Mobile Source Emissions Assessment, Air Modeling and Data Analysis, and Mobile Source Programs. It is essential that all mobile source emissions inventories, prepared by TNRCC staff or by other agencies, be subjected to a rigorous quality assurance check prior to being included in TNRCC's inventory file. Texas Transportation Institute (TTI) staff will develop quality assurance guidance for all on-road mobile source emissions inventories to be added to TNRCC's emissions inventory file.

WORK PLAN

Under Task 2, Quality Assurance Guidance, TTI is committed to accomplish the following specific tasks:

1. Work with ERG staff to understand the mobile source emissions inventory components and data elements that will be a part of the inventory file.
2. Conduct a literature search for mobile source quality assurance guidance published by the U.S. Environmental Protection Agency (EPA), the State of California, and other state and local environmental agencies.
3. Prepare an annotated bibliography of all pertinent literature.
4. Develop quality assurance guidance for the vehicle activity data, emissions factor data, and emissions data that will be included in the TNRCC inventory file.
5. Work with ERG staff to implement the quality assurance guidance within the analysis tools being developed by ERG.

Deliverables

Periodic teleconferences or meetings were held to ensure that TNRCC staff assigned to the project were kept informed of project status. Approved drafts of deliverables shall be submitted to the Project Manager before being approved as Final Deliverables. No bills, purchase orders, or payment demands will be made until the Project Manager approves the draft material and the Final Technical Note and supporting data is accepted. The appropriate Article of the Contract regarding the requirement for fixed fee deliverables and payment will be followed. For the purposes of this Work Order, the following terms are defined:

- **Technical Note.** Deliverables are in a Technical Note format (a narrative in memorandum format which explains the task, the approaches used and the findings) provided to the Project Manager in WordPerfect 6/7/8 format, which is supported by electronic document files. The Technical Notes are submitted in accordance with the following section regarding copies.
- **Electronic Data.** All pertinent data and supporting documentation are submitted to the Contracting Party in appropriate electronic format (e.g., CD-ROM).

Copies

TTI is providing five copies of the final report. One of the copies is a loose-bound original suitable for copying. Electronic copies of all text, graphic, spreadsheet files, or models used in the preparation of any documents related to the project report, to document results and conclusions (e.g., data, work files, text files, etc.), or developed as work products under this contract will be supplied at the conclusion of the project or earlier, as requested by TNRCC staff.

The software standards at TNRCC in word processing and spreadsheet software were followed. TTI has also provided immediate access to data via File Transfer Protocol (FTP) or other electronic file transfer medium as requested by TNRCC. No geographic information system (GIS) data application is anticipated as part of this work order. All electronic copies of documentation supplied in these formats were saved in a format that can be imported in such a way that the document or spreadsheet quality does not suffer. TTI understands that conversions from one spreadsheet or one word processing format to another results in changes in the formatting that detract from the presentation quality at minimum or results in significant work in trying to restore the documents or spreadsheets to presentation quality. This type of work will not be deemed acceptable to TNRCC under this contract.

OVERVIEW

ERG Inventory File

ERG has been retained by TNRCC to develop a set of comprehensive analysis tools that will support the needs of various emissions inventories end users. The heart of this effort is a centralized repository of critical mobile source emissions data, including the results of various on-road mobile source emissions inventories, as well as other related parameters and intermediate results. This repository is expected to include standard mobile activity information, MOBILE model input data, region specific, and county or regional demographic data. (ERG 2001: 1-1 & B-1)

It is essential that all mobile source emissions inventories and associated parameters be subjected to rigorous quality assurance checks prior to inclusion in TNRCC's inventory file. This is the focus of the proposed quality assurance guidance presented here, which is designed to be generally applicable to a wide range of on-road mobile source emissions inventory results.

Emissions Inventory Quality Assurance Practice

This section is intentionally very inclusive, beginning with a general introduction to modeling and issues of model performance, followed by an overview of EPA's perspective on modeling and model performance, leading to a discussion of air quality and travel model performance assurance. Lastly, an explicit set of quality assurance procedures specifically for emissions inventories are presented as recommendations.

Models and Modeling in General

The first and most obvious question is what exactly is a model. At its most basic level, a model is an abstraction of reality (conceptual, physical or mathematical) which reproduces some aspect of the real world for analytical purposes.

Why model in the first place? By being representations of reality, models allow for the isolation and examination of certain reality aspects that are not otherwise available (i.e., too costly, too dangerous, too far in the future, whatever).

How are models used? Models are created and used for various purposes. Some of the more common uses include forecasting, evaluation of alternatives, and the analysis of systems (i.e., their interactions, structure, and principles of operation).

What makes a "good" model? The objectives of all model development are utility (adequate for specified purpose, e.g., accuracy, sensitivity, etc.), validity (internally consistent and consistent with system being modeled), and simplicity (no more complex than necessary).

Within these parameters, models should contain minimal errors. There are two types of errors to consider. Both are related to model complexity. Measurement error is error in estimating parameters of independent variables, e.g., sampling error, other data collection error, etc. Model complexity increases measurement error. Measurement error affects model performance in the form of calibration error (i.e., the model will not replicate real data).

The other type of model error is specification error, the error inherent in modeling and the simplification associated with the modeling process (e.g., the minimization of explanatory variables and the inherent impossibility of exhaustively enumerating complex behavior). Model complexity decreases specification error. Thus, the greater the problem of measurement error, the simpler the model needs to be, but a simpler model could increase the specification error. Models containing a minimal amount of total error are a compromise or balance between model complexity (resulting in measurement error) and model simplification (resulting in specification error). Note that sequential chains of sub-models compound the impact of measurement error (e.g., air quality and emissions estimation models).

Calibration and verification helps determine model quality. Calibration is very specific. The model is run against historical data and is expected to replicate reality. Calibration is an integral part of model development, though subsequent comparison with historical results could be incorporated in the Quality Assurance/Quality Control (QA/QC) process. Verification is more general and broad. A range of model results is examined against each other and against theoretical expectations.

Verification includes the comparisons of the model output with observed data and the comparison of model parameters with parameters for similar areas. Verification may include the comparison of rates, comparison output values, test of the logic of the results (e.g., do estimates follow expected patterns over time or in response to changes in vehicle miles traveled [VMT]), etc. These verification checks evaluate models in terms of their performance according to theory and logic expectations and in terms of consistency of results with the assumptions used in generating the results.

These general comments and background discussion apply to all modeling activities, including but not limited to air quality modeling and emissions inventory estimation. EPA has examined the related issues of quality assurance and uncertainty in the specific context of

emissions estimates. Following an overview of the actual emissions inventory procedure as currently used by TTI and applied throughout Texas, this literature will be discussed in detail.

TTI Emissions Estimation Methodology

To develop on-road mobile source ozone season weekday emissions estimates, a link-based, time-of-day directional method is typically used (either 24 one-hour periods or more aggregate time periods), incorporating the effects of time-of-day travel volumes on speeds and emissions. Emissions are calculated at the roadway network link segment level for each time period. Diurnal emissions calculated separately, and then summed to produce 24-hour totals.

EPA's MOBILE emissions factor model is used to develop emissions factors. Travel demand model (TDM) link-based and intrazonal VMT, adjusted to be consistent with HPMS VMT, is the basis of activity. Automatic traffic recorder (ATR) data is used to produce ozone season weekday adjustment factors. Time-of-day VMT fractions and directional split factors are developed and applied to allocate VMT directionally by time-of-day period. Directional speeds are modeled by time-of-day per link. Vehicle classification data are used to estimate VMT mixes used to apportion fleet wide link-VMT to the EPA vehicle types (eight under MOBILE5, up to 28 under MOBILE6). Diurnal emissions allocation factors are developed to place these emissions in the time periods when they occurred. Directional, link-level emissions by vehicle type are calculated by time period, diurnal emissions are computed and added in, and the time-of-day results are summed yielding the seasonal 24-hour totals.

Additional details of the procedures are described in Appendix A. TTI previously developed a series of computer program to automate the procedures, such as those described above, required in the development of detailed on-road mobile source emissions inventories. These computer programs as they currently exist are described in Appendix B. Work is currently underway to adapt these methods, procedures, and protocols to MOBILE6. Additional examples and related supporting material are contained in Appendices C and D.

Annotated Bibliography

The general quality assurance research literature and standard references are of limited value in this specific application (i.e., emissions inventories) precisely because of their generality. Similarly, the vast majority of the existing emissions-related quality assurance literature and research is concerned with assuring the quality and validity of empirical measurements of air quality and field data collection. (See for example California Air Resources Board [CARB] 1999, NARSTO 1998a, and NARSTO 1998b.)

The NARSTO Quality Systems Science Center effort is particularly comprehensive. The NARSTO quality assurance practices are focused primarily with empirical data collection, validation and reliability. A broad range of products and documents are provided, including quality systems management planning guidance (NARSTO 1998a) and a quality-planning handbook (NARSTO 1998b). (A data management handbook is also provided, however this is concerned entirely with the validation, maintenance, and storage of chemical data.)

NARSTO is a public/private partnership including government, utilities, industrial, and academic members from Mexico, Canada and the U.S. (i.e., North America). The mission of NARSTO is to coordinate policy-related research on tropospheric pollution. Data collection and associated quality assurance is the primary objective of NARSTO as part of facilitating the sharing of research data across countries and institutions. (NARSTO 1998a:ix) The result is the array of products mentioned above.

The NARSTO Quality Systems Management Plan (NARSTO 1998a) is a comprehensive guideline for planning, managing and ensuring data product quality, credibility, integrity, accessibility, and delivery. The focus is at the highest level, focusing on the resources and organizational steps necessary to implement and manage the procedures recommended in the two handbooks.

The NARSTO Quality Planning Handbook (NARSTO 1998b) provides guidance for developing project- and program-level quality integrated work plans, data quality objectives, standard operating procedures, and quality assessment reports. The focus is at a relatively high level, including large research projects, as well as multi-project research programs. The objective is to ensure high quality tropospheric data suitable for wide application.

While the quality assurance practices and procedures outlined in the NARSTO documents are very thorough and detailed, they are not directly applicable to emissions inventories. In some areas, they are too broad (e.g., the large system level project / program focus) and in other areas, they are too narrow (e.g., the primary focus on chemical data collection and validation). Fortunately, the emissions inventory specific quality assurance literature and practice is predicated on these general principles and the supporting research, as well as on the underlying principles reflected in field data quality assurance practice.

EPA has documented a broad and comprehensive QA/QC program in Volume VI of the Emission Inventory Improvement Program (EIIP), prepared through the auspices of EPA by the State and Territorial Air Pollution Program Administrators (STAPPA) and the Association of Local Air Pollution Control Officers (ALAPCO). The scope of this effort goes well beyond the needs of this analysis. Consequently, this document will focus on the specific portions that are particularly relevant to the present effort. First, however, an overview is provided of the entire volume for future reference.

Chapter 1 of the document introduces the concepts of QA and QC, along with the programs necessary for their implementation. Chapter 2 (Planning and Documentation) discusses the critical role of planning and developing a formalized strategy for QA/QC. Chapter 3 (General QA/QC Methods) presents an assortment of tools, procedures, and methods suitable for application to emissions inventories. (More detail on selected portions of this chapter is presented later.) Chapter 4 (Evaluating the Uncertainty of Emissions Estimates) provides a very technical analysis of the sources of uncertainty in emissions estimates, along with methods for assessing and communicating the level of uncertainty. Finally, Chapter 5 (Model QA

Plan) provides examples of the application and implementation of the methods and procedures previously discussed. (EPA 1997a 1.3-2)

In Chapter 3, two of the methods presented (General QA/QC Methods) are of particular relevance. These are reality checks and sample calculations. Each will be discussed separately, relying heavily on the source document.

Reality checks (similar to the reasonableness checks described above) assure that a result "makes sense." In other words, they ensure that a result is not grossly unrealistic or unlikely. There is often an explicit or implied range associated with reality checks. Used liberally throughout the emissions estimation process (either during or at the end), reality checks can identify major errors and mistakes. Reality checks are relatively easy to apply. However, results can appear "reasonable" but still contain errors. More importantly, reality checks are insensitive to multiple errors going in opposite directions (i.e., cancelling each other out). This becomes more likely the further along in the process the check is applied. Similarly, identifying a result as "unrealistic" or "unreasonable" provides no information about the source of the error. Finally, the choice of reference value is critical, since the reality check is useful only if the benchmark or reference value is itself accurate or at least reasonable (EPA 1997b 3.2-1). Consequently, reality checks alone are not adequate to ensure the quality of a result.

Ideally, a standard reference value can be used (e.g., county VMT). These standard reference values are more readily available for input data than results, however. Alternately, the input or result can be compared to a similar value from a similar region or to a previous value from the same region. Comparisons of similar values from other parts of the same inventory are also an option. If all else fails, there is always the so-called expert judgment (EPA 1997b 3.2-2 - 3.2-5). Whatever the source or sources of reference values, the procedure is highly iterative, both in terms of analytical level (i.e., location in the emissions estimation process) and in terms of time (i.e., repetition). Similarly, familiarity with the emissions estimation process is invaluable in the application of reality checks. (This is an especially important point, since there is a tendency to relegate the verification and reality checking activities to junior or even clerical staff. The importance of well-trained experienced staff to the QA effort is supported by both EPA and NARSTO.)

Beyond the use of reality checks are actual sample calculations themselves. Sample calculations replicate the emissions estimation process (or critical portions of it) either in detail or (more commonly) at some higher level of aggregation. Sample calculations verify that the selected calculations were completed correctly (or in the case of more aggregate sample calculations, they provide internal reference values that function similar to reality checks).

Some reflection and understanding is required in the sample calculation selection process. The emissions estimation process as used for Texas emissions inventories is highly sophisticated (and substantially more complex than the simple spreadsheet application assumed in the EPA QA/QC document on sample calculations). The combined issues of location in the process and

level of aggregation need to be fully understood and considered in determining exactly what to sample and what result to accept. As was the case with reality checks, familiarity with the emissions estimation process is invaluable in the application of sample calculations as a QA/QC procedure. (As before, this is an especially important point, since there is a tendency to relegate the sample calculation-based verification to junior or even clerical staff. (The importance of well-trained experienced staff to the QA effort is supported by EPA and NARSTO.)

RECOMMENDED EMISSIONS INVENTORY QA PROCEDURE

Based on the preceding, combined with prior practice and experience, an extensive and systematic quality assurance and verification procedure has been developed by TTI for ensuring the accuracy and internal consistency of emissions estimates and inventories. The strategy was developed specifically for link-based (i.e., using travel demand model data) emissions inventories, however it can be applied to non-link based emissions estimates with only slight modification. There are two parts to the procedure, verification of VMT inputs and the verification of MOBILE inputs and results. Each is discussed separately.

Verification of VMT inputs

- verify VMT estimate against independent forecast;
- verify VMT distribution across roadway functional classifications; and
- verify VMT estimate against population (VMT per capita).

Verification of MOBILE inputs and results

- check the MOBILE set up data used as input to the model. Includes MOBILE flags, temperatures, VMT mix assumptions, fleet age assumptions;
- check speed assumptions input into the analysis (link level);
- check output for extreme values;
- compare essential input data (e.g., VMT, VMT mix, etc.) with corresponding output data; and
- validate regional emissions model results against separately prepared regional emissions estimate, as follows:
 - calculate a single aggregate speed for the entire network (i.e., VMT/VHT);

- look up the composite emissions rate for that speed for each of the critical pollutants (e.g., volatile organic compounds [VOC], carbon monoxide [CO], and oxides of nitrogen [NO_x]).
- multiply composite rate by network VMT, creating an estimate of regional emissions; and
- investigate and reconcile cases where the difference between regional emissions estimates and link-based emissions estimates are greater than 10% of the link-based estimate.

Verification of VMT Inputs

VMT is the most critical measure of activity. It is also one of the most difficult parameters to estimate. There are three separate verifications proposed, comparison against an independent forecast, comparison of the distribution of VMT among roadway types with the HPMS distribution, and comparison of per capita VMT.

The first and perhaps most obvious verification of VMT forecasts is comparison with an independent forecast. The objective is to ensure that forecasts are reasonable. However, wide arrays of assumptions can legitimately be invoked in forecasting VMT, leading to a wide range of possible comparison forecasts. A methodological conservative set of annual county VMT forecasts through 2020 is provided in Appendix E. These particular forecasts are produced as a function of historical growth and official population forecasts (as explained in the accompanying text). Other forecasts are possible, however, and the fact that a particular VMT forecast does not match this particular forecast may merely indicate that different assumptions were used. This is especially true where improvements to the roadway network are assumed. Population projections that vary from the official state forecasts will also produce different results. Thus, forecasts of VMT that vary significantly from those provided in Appendix E are not necessarily incorrect. However, they probably should be examined to determine in what way the assumptions differ from those more conservative assumptions used in the comparison forecasts.

Another form of VMT verification involves the distribution of VMT across the various roadway types (roadway functional classifications). Roadway functional classification is important because of the differences in capacity between roadway types, which result in differences in speed, which in turn result in differences in emissions. All for the same total VMT. The comparison data provided in Appendix F are based on TxDOT Highway Performance Monitoring System- [HPMS] related VMT estimates (the so-called RIFCREC reports) for 1990 through 1999. However, in making these comparisons, cautions similar to those for VMT are necessary. Travel demand models may not use the same roadway functional classification typology (i.e., the categories may be different from the seven used here). Travel demand models may also not assign VMT to future networks in the same proportions that VMT has occurred historically (i.e., the VMT on the various roadway categories may not be the same, even if the categories are defined the same way). Consequently, VMT assignment proportions that vary

greatly from those shown in Appendix F should probably be investigated, though they are not necessarily incorrect.

A third VMT forecast comparison involves the VMT per capita (that is, the ratio of VMT to county population). As in all VMT estimates and forecasts, this is not as straight forward as the forecaster would want. VMT per capita appears to be a measure of the average VMT traveled per person. However, not all VMT comes from the residents of a given county. This is especially true of small rural counties adjacent to large urban counties. Consequently, there are multiple patterns of VMT per capita. Large urban counties tend to have relatively modest VMT per capita that is relatively stable over time (e.g., Harris County for 1990 is 24.2 and for 1999 is 26.4). Isolated rural counties with through traffic (e.g., interstates) or with very low residential populations can have very high VMT per capita that may vary over time (e.g., Hudspeth County for 1990 is 247.0 and for 1999 is 319.3). Finally, rural counties adjacent to large urban counties tend to have VMT per capita that is higher than the adjacent urban area and increasing over time (e.g., Waller County for 1990 is 40.3 and for 1999 is 58.4 and Hays County for 1990 is 30.0 and for 1999 is 41.4). Average VMT per capita values are provided in Appendix G for all 254 Texas counties for 1990 through 1999, along with values for individual years. However, future year values are not provided, since they would be the product of the VMT and population forecasts described in Appendix E (i.e., they are a function of the average per capita VMT itself). As with the other VMT comparison measures, values that violate these generalizations are not necessarily incorrect, but should probably be investigated.

Verification of MOBILE Inputs and Results

The verification of the MOBILE inputs and results is more straightforward and more complex than the verification of VMT. More straightforward in that many of the values are directly verifiable. More complex in that the MOBILE emissions estimation process itself has a large number of input parameters is very complex.

The first and most fundamental verification of MOBILE inputs involves verifying that the correct MOBILE set up parameters were used (i.e., MOBILE flags, temperatures, VMT mix, fleet age, time periods, RVP, etc.). MOBILE flag settings control many of the MOBILE functions. Set up verification consists of inspecting each flag to ensure that the appropriate assumption is activated. Appendix C provides an example of MOBILE flag settings in summary table format. This example is for MOBILE5 and will be replaced with a MOBILE6 example when available. In MOBILE6, flags have been replaced with input commands. (EPA 2001:168) The local area parameter record (LAP record) is also part of the MOBILE set up, capturing aspects such as oxygenated fuels and reformulated gasoline programs. These entries must be inspected for accuracy (i.e., ensure that they correctly represent the programs in place in the local area). Appendix C also provides an example in summary table format (again using MOBILE5). The scenario description is also part of the MOBILE set up, capturing such regional and scenario parameters as altitude, year of analysis, ambient temperature, operating mode fractions, and month of evaluation. These values need to be inspected to ensure that they accurately represent the scenario being modeled. Appendix C also provides an example in summary table format.

Temperatures, VMT mix, fleet age, time periods, and RVP must be inspected to ensure their appropriateness and representativeness. Temperature data is usually obtained from TNRCC or directly from official meteorological data. The temperature inputs must be inspected to ensure that they are correctly entered and that they are consistent with empirical data for the region. In the current TTI, VMT mix is based on TxDOT vehicle classification counts (as described in Appendix A and applied as described in Appendix B) and varies by county or region, as well as by time of day. VMT mix is usually reported in the accompanying documentation. It is appropriate to verify that the values shown in the documentation are the same as the values used in the emissions estimates. This can be done from the output listing (an example is provided in Appendix D).

The situation is similar with fleet age. The current TTI procedure uses TxDOT registration data, converted to proportions. These proportions can be verified directly from the TxDOT data (an example is provided in Appendix H) by applying the calculation described in Appendix A. Finally, time periods (24-hour, hourly, or groups of hours such as AM peak, mid-day, PM peak, and overnight) and RVP can be verified directly to ensure that they are as stated in the accompanying documentation (or other source). Note that time period typology varies with purpose of the analysis, while RVP varies with year and emissions programs in place.

Speed is a critical parameter, however, in the current TTI procedure, speed is not input directly. Rather, it is generated at the link level by direction (and by time of day if the analysis is at that level) using a mathematical model of the speed capacity relationship (described in Appendix A). The appropriate verification, therefore, is to compare the speeds shown in the detailed output listing to ensure that they are all reasonable for the particular time-of-day and roadway type. (An example of speed output is shown in Appendix D, however, 24-hour results are not the best level of analysis for this verification. In practice, the time-of-day output listing should be used.)

Upon completing these specific verifications, the results (i.e., entire output listing) should be inspected for extreme values, especially in the speed and VMT mix summary tables. It is also appropriate to compare the critical input data discussed above with the corresponding output listing to ensure that inputs match outputs.

Current TTI procedure for verifying results is to validate regional emissions results against a separately prepared aggregate estimate (based on parameters taken from the output listing). More specifically, the procedure is to calculate a single aggregate speed for the entire network (VMT/Vehicle Hours of Travel [VHT]), look up a composite emissions rate for that speed for each of the critical pollutants (i.e., VOC, CO, NO_x) and calculate the aggregate emissions for each pollutant (VMT * composite rate). Cases where the difference between the aggregate regional emissions estimate and the link-based estimate are greater than 10% should be investigated and the differences reconciled. Note that as is the case in many of the verification procedures, the mere fact of a difference is not in itself sufficient justification for error determination. Various legitimate conditions and circumstances can produce differences of this

magnitude. However, differences of this magnitude are sufficient to warrant their investigation and reconciliation. An example of the application of this portion of the verification procedure is provided in the section on MOBILE inputs and results verification example.

An example of the on-road emissions inventory checklist currently used by TTI is also provided. This checklist serves as both documentation mechanism (i.e., documenting the details of the procedure in greater detail than it is practical to include in published reports) and as verification mechanism (i.e., a "pre release" confirmation of the accuracy and appropriateness of the various MOBILE inputs, analogous to the pre-flight checklist in aviation). As valuable as the former function is, the checklist is included here for its contribution to the latter function. (Revisions to adapt the checklist to MOBILE6 are pending.)

MOBILE INPUTS AND RESULTS VERIFICATION EXAMPLE

28 Oct - Verify MOBILE set ups (Harris, Coastal, Inland) for each of 24 time periods. Flags differ between Harris and Non-Harris (IMFLAG & ATPFLAG). Temperatures change by time period. Vehicle fleet age distribution was found to be the same for Harris and Non-Harris counties. Subsequent discussions with the sponsor resulted in the sponsor providing new set ups with a separate Non-Harris vehicle age distribution (both set ups were changed). Set ups are believed to be either "super SIP" or "I&M SIP" based. New set ups re-verified as described.

Emissions rates were examined for consistency and outliers (i.e., extreme values) for each area (Harris, Coastal, Inland), each day (Monday through Sunday), for selected speeds (3, 30, 45, 55, and 65 mph). Rates were examined for each hour to determine variation with temperature changes, as well as for time periods of multiple hours to verify the reasonableness of the range of variation. CO was found to become constant for a given speed at 75 degrees. Diesel emissions are constant relative to temperature throughout.

Note concern expressed regarding the speed model. Specifically the default adjustment of all volume/capacity (VC) ratios greater than 1.5 to 1.5. Sponsor suggested that this produces minimum speeds of 21 mph, but experience suggests that speeds are sometimes lower than this. In response, note that speed model estimates are usually for time periods of at least one hour and typically several hours. Thus, minimum observed speeds are not likely to be sustained for long periods. The 21 mph minimum is probably not that far off, even in congested situations. Also, the model is designed to represent typical situations, not extremes which are by definition infrequent.

9 Nov - Initial emissions estimate runs showed a region wide 24-hour speed of 14 mph. Interstate speeds were 10 mph. Subsequent investigation revealed that a coding error truncated the capacity values by three digits (effectively dividing capacity by 1,000).

10 Nov - Completed a Monday 2007 (7 Sept) re-run after correcting truncation problem involving the capacities. The results of the analysis of speeds follow:

<u>County</u>	<u>24 Hr Speed</u>	<u>Missing Roadway Classifications</u>	<u>Other Comments</u>
Brazoria	43.4 mph	No urban or rural interstate	Locals @ 35 mph
Chambers	56.0	No urban anything or rural PA	Locals @ 33 & 35 mph
Galveston	38.3	No rural interstate or freeway	
Harris	37.6		
Fort Bend	41.7		
Liberty	49.1	No urban or rural interstate	Locals @ 38 mph
Montgomery	46.3		Locals @ 34 mph
<u>Waller</u>	<u>54.3</u>	No urban interstate, fwy or PA	Urban Collector @ 65 mph
Region	39.1 mph		

We subsequently verified that the excluded roadway functional classifications are correctly excluded (i.e., consistent with the sponsor provided input data). The two counties (Chambers and Waller) with county wide 24-hour speeds in excess of 50 mph seemed suspect but were deemed reasonable (in a meeting with project staff) based on the proportion of VMT attributable to interstates. Similarly, those counties with 24-hour speeds on local streets over 30 mph (i.e., 33 to 38 mph) were deemed reasonable based on the nature of the "local" functional classification. Finally, the urban collector in Waller County with a 24-hour speed of 65 mph has been deemed acceptable based on an analysis of the individual links.

11 Nov - Prepared aggregate estimates of emissions using countywide 24-hour speeds and the associated emissions rates. Verified VMT mix inputs directly. Verified VMT using previously reported 2007 VMT from original report combined with adjustments developed for this effort. Regional and county differences in the range of 1%. Model VMT is calculated directly from the links and speeds so exact input VMT is not defined.

13 Nov 98 - Resolved the aberrant CO verification. The average speed is at the minimum rate on the emissions rate/speed curve. The actual aggregate emissions rate is for about 35 mph rather than the 54 mph, which is the average speed. The difference is fully explained using link speeds and emissions rates.

Unfortunately, in rechecking we discovered that the wrong trip length time period was used on all of the evening hours on all runs (i.e., used pm peak time period designations instead of overnight). Our initial checks understandably focused on the peaks.

16 Nov - Completed re-running all the earlier work using the correct time periods. Will repeat the entire verification procedure on the new runs today. Will proceed on the documentation while verification is underway.

17 Nov - Completed verification of latest efforts. Independent examination of the verification, as well as performing some spot checks underway today.

18 Nov - Verification of verification complete and we are ready to transmit the output to the sponsor. There is some possibility that the output will be "zipped and shipped" by the end of the day. We estimate that the documentation will be "complete" by Monday the 23rd.

APPENDIX A
OVERVIEW OF EMISSIONS ESTIMATION METHODOLOGY

OVERVIEW OF EMISSIONS ESTIMATION METHODOLOGY

To develop on-road mobile source ozone season weekday emissions estimates, a link-based, four time-of-day period directional methodology is used, incorporating the effects of time-of-day travel volumes on speeds and emissions. Emissions are calculated at the roadway link level for each time period and the diurnal, and are summed yielding 24- hour totals.

EPA's MOBILE emissions factor model is used to develop emissions factors. TDM link-based and intrazonal VMT, adjusted to be consistent with HPMS VMT, is the basis of activity. ATR data are used to produce ozone season weekday adjustment factors. Time-of-day VMT fractions and directional split factors are developed and applied to allocate VMT directionally by time-of-day period. Directional speeds are modeled by time-of-day per link. Vehicle classification data are used to estimate VMT mixes used to apportion fleetwide link-VMT to the EPA vehicle types (eight under MOBILE5, up to 28 under MOBILE6). Diurnal emissions allocation factors are developed to place these emissions in the time periods when they occurred. Directional, link-level emissions by vehicle type are calculated by time period, diurnal emissions are computed and added in, and the time-of-day results are summed yielding the seasonal 24-hour totals.

Additional details of the procedures are described in this appendix. TTI previously developed a series of computer program to automate these procedures. These computer programs as they currently exist are described in Appendix B. Work is currently underway to adapt these methods, procedures, and protocols to MOBILE6. Additional examples and related supporting material are contained in Appendices C and D.

ESTIMATION OF VMT

The outputs of the VMT estimation process are estimates of county VMT (and speeds, as discussed below) by time-of-day and direction for each link of the TDM network and for each of the added intrazonal links. For each county, link-based VMT estimates are adjusted to be consistent with HPMS VMT for that county, and for ozone season (or summer) weekday activity. In general, the link-based VMT are processed in three steps. First, the link-based VMT is adjusted to seasonal weekday VMT (consistent with HPMS), then it is allocated by time-of-day, and finally it is split by direction.

Data Sources

The TDM network, trip table, and the nondirectional 24-hour equilibrium traffic assignment developed by TxDOT are used as the bases for developing the link-based VMT. To adjust the TDM VMT and allocate it as needed, several other sources of data are required.

HPMS VMT estimates are based on traffic count data collected according to a statistical sampling procedure specified by the Federal Highway Administration (FHWA) designed to estimate VMT (as well as lane miles and centerline miles). A wide range of traffic data is

collected under the HPMS program. Specifically, the county total HPMS annual average daily traffic (AADT) VMT is used to ensure travel model VMT consistency with HPMS.

ATR vehicle counts are collected by TxDOT at selected locations on a continuous basis throughout Texas. These counts are available by season, month, and weekday, as well as on an annual average daily basis (i.e., AADT). Since they are continuous, they are especially well-suited for making seasonal, day-of-week comparisons (i.e., adjustment factors), even though there may be relatively few ATR data collection locations in any given area. In practice, these data are grouped by TxDOT district, for example, to offset this limitation. These ATR count data are used to produce the seasonal weekday adjustment factor.

Household travel survey data are processed to estimate the time-of-day travel fractions, and directional split factors provided by TxDOT are applied as well. (TxDOT vehicle classification count data are used to develop the VMT mix, or VMT fractions for the eight EPA vehicle types, discussed in a following section.)

Seasonally Adjusted VMT Control Totals

To obtain HPMS consistent travel model link-based VMT for the typical ozone season weekday, VMT control totals are used. An ATR-based ozone season weekday adjustment factor is developed and applied to each county's HPMS AADT VMT estimate. The results of this procedure are the VMT control totals (ozone season weekday HPMS VMT) for each county. The TDM link-VMT for each county are then scaled to these control totals to reflect both ozone season weekday activity and consistency with HPMS VMT.

ATR data are often aggregated from TxDOT District counties with ATR stations, since not all counties have ATR stations (especially rural counties). ATR data from the analysis year are used. The district-level average summer weekday factor is developed by dividing the district average summer weekday traffic count by the district AADT traffic count.

VMT Adjustment Factor

To obtain county-level TDM link VMT consistent with summer weekday HPMS VMT (control total VMT), the sum of the TDM and intrazonal link VMT for each county is made equal to its VMT control total. To achieve this, county-level VMT adjustment factors are produced and applied to scale the county-level link VMT to their corresponding control totals. On a county basis, the VMT adjustment factor is calculated as the ratio of the summer weekday VMT control total to the travel model VMT total.

VMT Time-of-day Factors

Typically the most recent available household travel survey data for the area are used to develop the estimated portions of travel by time-of-day. The method involves defining the morning and afternoon peak travel hours (AM and PM Peak periods) based on the survey-produced 24-hour VMT profile. Consequently, the bounded periods, the Mid-Day and Overnight (or off-peak)

periods, are fixed as well. These ratios are applied to the adjusted 24-hour link VMT to estimate and allocate the VMT by each of the four time periods.

VMT Directional Split Factors

The 24-hour link assignment volumes, adjusted for VMT control total consistency and allocated by time-of-day, are nondirectional volumes (i.e., the sum of the volumes in the two directions on a link). Directional splits are applied to estimate the portion of the travel that occurred in each direction. These directional volume estimates are used to estimate directional speeds. Application of the directional split factors results in two link records for each network link: one record containing the estimated VMT and speed in the peak (or dominant) direction, and the second record containing the estimated VMT and speed in the opposite direction. This allows the application of MOBILE emissions factors directionally by speed. The TDM network links are categorized by functional classifications and area type. The directional travel fractions are estimated by time-of-day period (the Mid-Day and Overnight periods are grouped for this purpose) for each of the functional classification/area type combinations.

ESTIMATION OF LINK SPEEDS

The 24-hour capacity constrained assignments are performed using nondirectional 24-hour capacities. Time-of-day capacity factors are applied to nondirectional capacity (or service volume) for the time period. In computing the directional V/C ratio for estimating the directional speeds, the directional split for capacity is assumed at 50-50. The network is processed to compute the average capacity per lane by roadway functional classification group and area type. Capacity factors are computed as follows:

$$\text{Capacity Factor} = \frac{(\text{Hourly Capacity per Lane})(\text{Length of the Time Period})}{24\text{-hour Capacity per Lane}}$$

The model uses the following volume/delay equation:

$$\text{Delay} = \text{Min} \left[A e^{B \left(\frac{V}{C} \right)}, M \right]$$

Where:

- Delay = congestion delay (in minutes/mile);
- A & B = volume/delay equation coefficients;
- M = maximum minutes of delay per mile; and
- V/C = time-of-day directional V/C ratio.

The delay model parameters (A, B, and M) were developed for the Dallas/Fort Worth area and verified by application in other Texas urban areas. These are shown in the following table.

Volume/Delay Equation Parameters

Facility Category	A	B	M
High Capacity Facilities (> 3,400 vehicles per hour [vph], e.g., Interstates and Freeways)	0.015	3.5	5.0
Low Capacity Facilities (≤ 3,400 vph, e.g., Arterials, Collectors and Locals)	0.050	3.0	10.0

Given the estimated directional delay (in minutes/mile) and the estimated freeflow speed, the directional congested speed is computed as follows:

$$\text{Congested speed} = \frac{60}{\frac{60}{\text{Freeflow speed}} + \text{Delay}}$$

This model is applied at the link level by area type and functional classification combination for each time period and each direction.

ESTIMATION OF VMT MIX

VMT mix is estimated using the most recent available TxDOT weekday vehicle classification data (often for multiple years, e.g., 1997, 1998, 1999 and 2000). As was the case with the seasonal adjustment factor procedure, these data are aggregated by TxDOT District and used for all the counties. TxDOT classification counts classify vehicles into the standard FHWA vehicle classifications shown.

C	motorcycles and passenger vehicles;
P	two-axle, four-tire single-unit trucks;
B	buses;
SU2	six-tire, two-axle single-unit vehicles;
SU3	three-axle single-unit vehicles;
SU4	four or more axle single-unit vehicles;
SE3	three-axle single-trailer vehicle;
SE4	four-axle single-trailer vehicle;
SE5	five-axle single-trailer vehicle;
SE6	six or more axle single-trailer vehicle;
SD5	five or less axle multi-trailer vehicle;
SD6	six-axle multi-trailer vehicle; and
SD7	seven or more axle multi-trailer vehicle.

A summary of the allocation and conversion procedure follows. The eight EPA vehicle categories are:

LDGV	light-duty gasoline vehicles;
LDGT1	light-duty gasoline trucks up to 6,000 pounds gross vehicle weight rating (GVWR);
LDGT2	light-duty gasoline trucks from 6,001 to 8,500 pounds GVWR;
HDGV	heavy-duty gasoline vehicles over 8,500 pounds GVWR;
LDDT	light-duty diesel trucks;
LDDV	light-duty diesel vehicles;
HDDV	heavy-duty diesel vehicles over 8,500 pounds GVWR; and
MC	motorcycles.

Vehicle classification counts are first aggregated into two intermediate groups as follows:

PV	$C + P$
FLT	$C + P + B + SU3 + SU4 + SE3 + SE4 + SE5 + SE6 + SD5 + SD6 + SD7$

This is followed by a second intermediate allocation that separates light-duty vehicles (LDV) into passenger cars and light-duty trucks (LDT) based on county registration data:

LDV	$0.682 * PV$ (statewide 2000 registration data shown); and
LDT	$0.318 * PV$ (statewide 2000 registration data shown).

A third intermediate allocation allocated light-duty trucks into light-duty trucks 1 (LDT1) and LDGT2 based on county registration data. Note that LDT1 is itself intermediate and is further divided into LDGT1 and LDDT.

LDT1	$0.840 * LDT$ (statewide 2000 registration data shown); and
LDGT2	$0.160 * LDT$ (statewide 2000 registration data shown).

Next, the remaining FHWA categories and this intermediate group are disaggregated into the eight EPA vehicle groups, as shown below. Note that TxDOT vehicle classification count procedures do not distinguish between gasoline and diesel light-duty trucks consequently, MOBILE5ah defaults for the year of interest are used. As before, actual Texas county vehicle registration data are used to separate gasoline from diesel heavy-duty trucks. Note that motorcycles are not counted separately and are included as a default (subtracted from LDGV).

LDGV	$0.997 * LDV$ (MOBILE5ah default for 1999 shown);
LDDV	$0.003 * LDV$ (MOBILE5ah default for 1999 shown);
LDGT1	$0.994 * LDT1$ (MOBILE5ah default for 1999 shown);
LDDT	$0.006 * LDT1$ (MOBILE5ah default for 1999 shown);
LDGT2	$0.160 * LDT$ (Statewide 2000 registration data shown, as above);

HDGV	0.412 * HDV (Statewide 2000 registration data shown);
HDDV	0.588 * HDV (Statewide 2000 registration data shown); and
MC	0.001 of total (subtracted from LDGV).

MOBILE6 VEHICLE CLASSIFICATIONS

Previous research by TTI developed two vehicle classification conversion procedures. One converts the FHWA vehicle classification scheme into a 19 MOBILE6 vehicle classification typology, the other into the 28 MOBILE6 categories.

MOBILE6 19-Category Typology

The 19-category typology is a subset of the eight-category typology. Consequently, a combination of national and Texas vehicle registration and sales data are used to expand the EPA eight-category model to the 19-category model. The heavy-duty vehicle categories (HDGV and HDDV) are expanded, including the addition of explicit bus categories (GSB, GTB, DSB, and DTB), and the light-duty diesel truck (LDDT) category is divided into two categories. The procedures employed to expand the EPA eight-category scheme to the 19-category scheme are largely incremental extensions of the eight-category procedure, involving the disaggregation of the HDGV, LDDT, and HDDV categories. Texas data are used where available. National data are used only where Texas data are unavailable or inappropriate.

MOBILE6 28-Category Typology

The 28-category typology is a subset of the 19-category typology, with a couple of exceptions as noted. These relate to the method used to separate heavy-duty vehicles into the various categories and the division of the two light-duty truck categories into four categories, which is based in part on vehicle loading as opposed to GVWR.

For the 28-category EPA scheme, heavy-duty vehicles (HDGV and HDDV) are separated into eight categories each (along with some bus categories). For the 28-category scheme, these 16 categories are separated from total heavy-duty vehicle (HDV) counts directly (unlike in the 19-category scheme where they are first divided into HDGV and HDDV based on county registration data). For this part of the procedure, HDV is divided into sub-categories based on Texas American Automobile Manufacturers Association (AAMA) data, and then into fuel categories based on national AAMA data. This modification is necessary to accommodate the additional level of vehicle category detail in the 16 categories and to be consistent with the available data on heavy-duty vehicles. (Texas and national data are available for heavy-duty vehicles without fuel distinction. Fuel specific heavy-duty vehicle data are available at the national level only. This procedure represents a refinement over the county registration based method used for the 19-category scheme, although statewide data are used. The forcing of further disaggregation on the HDV categories in the 19-category scheme to generate even smaller category percentages is methodologically inadvisable.)

The 28-category EPA scheme further divides the two light-duty truck categories based in part on assumed loading. This is a radical departure from earlier typologies. Very briefly, the previous

LDGT1 and LDGT2 categories (previously defined as $GVWR \leq 6,000$ and $GVWR < 6,000$ to 8,500, respectively) are redefined in terms of loaded vehicle weight and adjusted loaded vehicle weight. Loaded vehicle weight is vehicle curb weight plus 300 pounds. Adjusted loaded vehicle weight is the average of vehicle curb weight and GVWR. There are two new intermediate categories introduced. These are light light-duty trucks (LLDT) and heavy light-duty trucks (HLDT) defined as follows:

- LLDT - Any light-duty truck rated through 6,000 pounds GVWR; and
- HLDT - Any light-duty truck rated greater than 6,000 pounds GVWR.

These two new intermediate categories are then used to define the four light-duty truck categories. The four LDT categories are as follows:

- LDGT1 - Light light-duty trucks through 3,750 pounds loaded vehicle weight;
- LDGT2 - Light light-duty trucks greater than 3,750 pounds loaded vehicle weight;
- LDGT3 - Heavy light-duty trucks through 5,750 pounds adjusted loaded vehicle weight; and
- LDGT4 - Heavy light-duty trucks greater than 5,750 pounds adjusted loaded vehicle weight.

Light-duty trucks (LDT) are defined as less than 8,500 pounds GVWR and less than 6,000 pounds curb weight. Functionally these are 1/4 ton, 1/2 ton, and 3/4 ton pick-up truck type vehicles (including sport utility vehicles [SUVs] and "suburbans"). The division of LDTs into LLDTs and HLDTs approximates the separation of LDTs into each of the common pick-up truck categories. This, unfortunately, is not without substantial overlap and ambiguity, primarily in the LDGT2 category that includes both 1/4 ton and 1/2 ton vehicles. Most SUVs fall into this category as well. The allocation of vehicles to these four categories is based on a combination of Texas registration data, AAMA statistics for Texas, and researcher judgement. While further refinement may be desirable, the basis for any data refinements is unclear.

ESTIMATION OF EMISSIONS RATES

The MOBILE model is used to produce emissions factors by speed for each time-of-day period (excluding diurnals), and one set per county of 24-hour diurnal emissions rates for the hydrocarbon pollutant. The procedure is typically applied to produce emissions factors for the average ozone season day. Under MOBILE5, emissions rates are produced for the eight EPA vehicle types at 63 speeds (i.e., 3 mph through 65 mph). In MOBILE6, rates are produced in speed ranges for up to 28 vehicle types.

EPA Vehicle Category Conversion List

EPA-8	EPA-19	EPA-28
LDGV	LDGV	LDGV
LDGT1	LDGT1	LDGT1a
		LDGT1b
LDGT2	LDGT2	LDGT2a

	HDDV8b	HDDV8b
	DSB	DSB
	DTB	DTB
		DCB
MC	MC	MC

Vehicle Registration Distributions

Vehicle registration distributions are an input to MOBILE. Vehicle registration data for each county are obtained from TxDOT. The registration data are by vehicle type and year for the total automobiles, total motorcycles, LDGT1, LDGT2, heavy-duty gasoline trucks (HDGT), and heavy-duty diesel trucks (HDDT) categories. The vehicle registration data for 1975 and older vehicles are summed and used as the 25th year. The percentage vehicle distributions by model year are then obtained by dividing the vehicle registration for a given year by the total vehicle registrations. The percentage vehicle distribution data are then rounded to four significant digits and summed.

Residual rounding results in the sum of the percentage vehicle distribution being slightly smaller or greater than 1.0. The difference between the sum and 1.0 is added to the largest value to adjust the total percentage vehicle distribution data of the rounded values to 1.0000. The distributions for total automobiles are used for both the LDGV and LDDV vehicle types. The distributions for LDGT1 are also used for the LDDT vehicle type. For motorcycles, the vehicles registered which are older than 12 years are added to the 12-year-old vehicles (MOBILE has zero mileage for motorcycles older than 12 years).

Summary of Control Programs Modeled

The MOBILE setups reflect any control program through user-input control program modeling parameters.

Estimation of Temperatures

There are three temperature inputs to the MOBILE model: minimum, maximum, and ambient. For each county ozone season analysis there are five applications of MOBILE: one for each of the four time periods, and one for the 24 hour diurnal.

Emissions for time-of-day periods are calculated exclusive of diurnal emissions, which are modeled separately, then apportioned to the time-of-day periods. Separating the calculation of diurnal and non-diurnal VOC emissions rates is required because diurnal emissions are a function of the 24-hour temperature profile (i.e., require a temperature range) and are not calculated appropriately by MOBILE for time periods less than 24 hours. To calculate only the non-diurnal emission factors for each time-of-day run, the MOBILE temperature inputs are set equal to the time-of-day period average temperature value (i.e., no temperature range – no diurnal calculated). For the diurnal (24-hour) MOBILE runs, the seasonal 24-hour average minimum, maximum, and ambient temperature values are used.

Estimation of Gasoline Reid Vapor Pressure

TNRCC typically provides the area seasonal gasoline Reid Vapor Pressure (RVP) MOBILE input. TNRCC bases the estimates on the National Institute of Petroleum and Energy Research 1999 Texas city summer gasoline sample survey data.

Other Inputs to MOBILE

Under MOBILE5, the flag settings, local area parameter records, and scenario description inputs are contained in the MOBILE setups and are typically documented as shown in the example below (Appendix C).

EMISSIONS CALCULATIONS

The method used for calculating emissions, in general, is the multiplication of the estimated quantity of source activity (VMT), by the estimated quantity of emissions per unit of source activity (grams/VMT). For each time period, emissions are calculated for each vehicle type by direction on each network link (the VOC diurnal emissions are calculated in this step and applied to the appropriate time periods). The 24-hour ozone season weekday totals are produced by summing their respective time-of-day emissions estimates. Appendix D contains a example of 24-hour total emissions inventory results produced under MOBILE5 for the JOHRTS area.

Time-of-day Period Emissions

For each county, the emissions are calculated by time-of-day period using the following basic inputs:

- VMT and speeds by direction on each link (other required link data are county number, roadway type number, and centerline miles);
- VMT mix (to allocate link VMT by each of the vehicle types);
- emissions factors for the time period (non-diurnal, indexed by speed and vehicle type);
- emissions factors for the 24-hour diurnal (one for each vehicle type for the day);
- temperature rise and VMT totals for each time-of-day period and the 24-hour period (for calculation and application of time period diurnal scaling factors);
- names of the roadway types used in the study (roadway types are used to summarize emissions results; the roadway types for these analyses are the network functional classifications);
- county name; and
- the units for reporting emissions.

For each time period, the non-diurnal emissions estimates are computed by vehicle type for each link. The emissions factors inputs, discussed previously, are tabulated by vehicle type and speed. Using the VMT mix, the directional link-VMT is separated by vehicle type. Emissions factors are matched with link-level VMT based on vehicle class and speed. (For non-integer link speed estimates, the emissions factors are interpolated.) The emissions factors (by pollutant) and VMT are multiplied to produce the link-level emissions estimates. Upon calculation of link-based non-diurnal emissions, the emissions results are accumulated (along with the diurnal VOC emissions estimates) for each county by vehicle type and roadway type.

The 24-hour diurnal (VOC) emissions are calculated and factored to the time periods where diurnal emissions occurred (time periods with temperature rises). The diurnal emissions estimates are computed by vehicle type for each link by multiplying the diurnal scaling factor by the vehicle type-matched diurnal emissions factors and link VMT. (The time periods when

diurnal emissions occurred are identified by comparing the average temperatures between time periods. The diurnal scaling factor equals zero for time periods of no temperature rise, thus zero diurnal emissions are applied to these periods.) The diurnal VOC emissions are summed with the non-diurnal VOC emissions at the link-level. The total VOC results are accumulated for each county by vehicle and roadway type.

The 24-hour temperature rise is the sum of the period temperature rise values, which are calculated by subtracting consecutive time-period average temperature values. The time-of-day period VMT totals are calculated by multiplying the VMT control totals by the time-period travel fractions.

Since the sum of the period temperature rise fractions equals one (i.e., comprises the 24-hour rise), these fractions can be used to allocate total 24-hour diurnal emissions among the periods where temperature rise occurs. Total diurnal emissions are divided between the appropriate time periods using the product of the VMT expansion factor and the temperature rise fraction for each period. (Since the diurnal emissions factors are in units of grams/mile, the VMT accumulated during the periods of no temperature rise [e.g., overnight period] must be accounted for in the diurnal emissions calculations.) The VMT expansion factor increases the link VMT per time period diurnal emissions run proportional to 24-hour VMT. In other words, the VMT expansion factor allocates the VMT accumulated during the periods of no temperature rise to those periods when a temperature rise occurs ensuring the allocation of total diurnal emissions to only those periods where diurnal emissions could actually occur.

Ozone Season Weekday (24-hour) Emissions

The seasonal weekday 24-hour emissions estimates are calculated by summing their corresponding time-of-day emissions estimates. These calculations are performed by pollutant at the vehicle type and travel model functional classification level for each county.

For annual emissions estimates, TTI has developed an annualization procedure which incorporates seasonal differences in VMT and emissions rates, as well as including weekend VMT.

APPENDIX B
TTI EMISSIONS ESTIMATION PROGRAMS

TTI EMISSIONS ESTIMATION PROGRAMS

A series of programs developed by TTI are used to prepare emissions estimates for MOBILE5. Each is described briefly below. Work is currently underway to adapt these programs for use with MOBILE6.

PREPIN

The PREPIN program was developed for use in urban areas that do not have time-of-day assignments and speeds available for air quality analyses. The program reads (inputs) the nondirectional 24-hour assignment data set. The 24-hour nondirectional assignment volumes on each link are initially scaled to the appropriate VMT. The time-of-day factors are applied to the adjusted 24-hour assignment results on each link to estimate the directional time-of-day travel on the link. Speed models, originally developed for the Dallas-Fort Worth area, are used to estimate the operational time-of-day speeds by direction on the links. Special intrazonal links are defined, and the VMT and speeds for intrazonal trips are estimated. These VMT and speeds by link are subsequently input to the IMPSUMA program for the application of MOBILE5ah emissions factors. Using the PREPIN software, the assignments are used to develop seasonally adjusted time-of-day VMT and speed estimates for the four time-of day periods.

POLFC5HB

The POLFC5HB program is used to apply the EPA's MOBILE5ah program to obtain the emissions factors. The MOBILE5ah emissions factors are obtained for each of eight vehicle types and 63 speeds (i.e., 3 mph through 65 mph). There are 504 factors (i.e., $8 \times 63 = 504$) for each pollutant type: VOC, CO, NOx, and VOC subcomponents. These emissions factors are output to an ASCII file for subsequent input to the IMPSUMA program. The POLFC5HB program is applied for each time-of-day period being modeled. These time-of-day emissions factors are applied using the IMPSUMA program to time-of-day VMT estimates by link. The POLFC5HB program was applied to develop emissions factors for each time-of-day period. The temperatures for the time-of-day period are inputs to the POLFC5HB application of the MOBILE5ah model. A separate 24-hour application of POLFC5HB was used to develop the diurnal emissions factors.

VMTSUM

The VMTSUM program sums the VMT by time period and county. These data are converted to data records that are input into IMPSUMA. These data along with the time period temperature increases are used to allocate the diurnal emissions to the time periods.

IMPSUMA

The IMPSUMA program applies the emissions factors obtained from POLFC5HB and VMT mixes to the time-of-day VMT and speed estimates to estimate emissions. The six primary inputs to IMPSUMA are:

- MOBILE5ah emissions factors developed using POLFC5HB including 24-hour diurnal emissions factors;

- abbreviated assignment results by link input for the subject time period developed using the PREPIN program. The PREPIN program allows the user to estimate the VMT and speed on each link by time period. For each link, the following information is input to IMPSUMA: county number, roadway type number, VMT on link, operational speed estimate, and link distance;
- VMT mix by county and roadway type;
- X-Y coordinates (if used);
- temperature increases by time period; and
- total VMT by time period from the VMTSUM program.

Using these input data, the VMT for each link is stratified by the eight vehicle types and the MOBILE5ah emissions factors are applied to estimate the mobile source emissions for that link. The emissions for the county and emissions type are reported by both roadway type and vehicle type (i.e., cross classified by roadway type and vehicle type). A data set is produced for subsequent input to the SUMALLA program. The IMPSUMA program was applied to estimate the emissions for each of the four time-of-day periods. The 24-hour diurnal estimates are computed using the 24-hour diurnal rates.

SUMALLA

The SUMALLA program is used to sum the emissions estimates for the four time periods to develop the ozone season weekday (24-hour) emissions estimates. A second run of the SUMALLA program applies annualization ratios to the 24-hour emissions estimates to produce the annual emissions estimates. The emissions by pollutant type are reported by roadway type and vehicle type.

APPENDIX C
1999 JOHRTS OZONE SEASON WEEKDAY MOBILE5ah SETUPS

**1999 JOHRTS Ozone Season Weekday MOBILE5ah Setups
Flag Settings**

Model Parameter Description	Assigned Value	Methodology Description
PROMPT	1	Standard input when using MOBILE in batch run mode.
PROJID	Modeler's choice	No effect on results.
TAMFLG	1	Use MOBILE default tampering rates.
SPDFLG	1	One speed for all vehicle types.
VMFLAG	1	Use MOBILE default VMT mix. POLFC calculates vehicle type rates, not fleet composites which require a VMT mix. Value has no effect on results.
MYMRFG	3	Use MOBILE default annual mileage accumulation rates (AMAR). There are no county-specific AMARs available. Use county-specific registration distributions.
NEWFLG	1	Tier 1 Federal Motor Vehicle Control Program (FMVCP) is on; use MOBILE default basic emissions rates (BERs).
IMFLAG	1	No I/M program modeled.
ALHFLG	1	No load corrections done in modeling calculations.
ATPFLG	1	No anti-tampering program, and no pressure and purge tests modeled.
RLFLAG	5	No refueling emissions calculated.
LOCFLG	Modeler's discretion	No effect on results.
TEMFLG	1	MOBILE calculates temperature corrections from minimum and maximum temperature.
OUTFMT	Modeler's discretion	No effect on results.
PRTFLG	Modeler's discretion	No effect on results.
IDLFLG	1	No idle emissions calculated.
NMHFLG	3	Hydrocarbon emission factors should be for VOC.
HCFLAG	Modeler's discretion	Diurnal runs will need to have appropriate flag setting. Otherwise use the value appropriate for obtaining output in the format needed for emissions calculation models.

**1999 JOHRTS Ozone Season Weekday MOBILE5ah Setups
Local Area Parameter Record**

General Comments: None.		
Model Parameter Description	Assigned Value	Methodology Description
Scenario name	Modeler's discretion	Does not effect results.
American Society for Testing and Materials (ASTM) Class	A	July volatility class code from the ASTM schedule of seasonal and geographical volatility classes. Value has no effect on results.
Minimum daily temperature	1990 ozone season base-year emissions inventory value.	24-hour and four time period temperatures.
Maximum daily temperature	1990 ozone season base-year emissions inventory value.	24-hour and four time period temperatures.
Period 1 RVP	Use summer 1999 county actual RVP value (7.8 psi) provided by TNRCC.	No effect on results (see below).
Period 2 RVP	Use summer 1999 county actual RVP value (7.8 psi) provided by TNRCC.	Since the analysis is for one calendar year, Period 1 and Period 2 RVP are both set to the analysis year (seasonal) value.
Period 2 start year	99	Set to 1999 since this is the only year of interest, and since both Period 1 and 2 RVP use the actual 1999 value.
Oxygenated fuel flag	1	No oxygenated fuels program.
Diesel sales fraction flag	1	No alternate diesel sales fractions.
Reformulated gasoline (RFG) flag	1	No RFG.

**1999 JOHRTS Ozone Season Weekday MOBILE5ah Setups
Scenario Description**

General Comments: None.		
Model Parameter Description	Assigned Value	Methodology Description
Region	1	Standard input for low altitude areas.
Calendar Year of Evaluation	99	Inventory definition.
Average speed	XXXX	Set to XXXX when creating an emission factor file for POLFC.
Ambient temperature	1990 ozone season base-year emissions inventory value.	24-hour and four time period temperatures.
Operating mode fractions	National default values provided with model.	Beaumont/Port Arthur specific inputs were not available.
Month of evaluation	7	Models the fleet as of July (used for ozone season analyses) for the calendar year of analysis.

Note to Appendix E: VMT Forecast Methodology

The VMT by roadway functional classification contained in Appendix G is based on historical HPMS AADT data (RIFCREC) for 1990 - 1999 and official (i.e., U.S. Census and Texas State Data Center) county population statistics and projections, which are subsequently disaggregated by facility type using the ATR data described

More specifically, there are conceptually two types of VMT, local and through. Local VMT is generated by the residents of the county. Through VMT is generated by persons and vehicles passing through the county. The relative importance of through VMT varies by the proximity of the county to large urban areas, which generate substantial VMT of their own.

Theoretically, local VMT is more closely related to population, while through VMT is more closely related to historical VMT. Though these distinctions are not absolute (i.e., local VMT is not independent of historical patterns and through VMT is not independent of county population), they imply very different strategies for forecasting. Local VMT is more likely to be a function of population, while through VMT is more likely to be a function of historical VMT and change over time (i.e., growth). If used alone, however, each tends to err in a different direction. Population based forecasts (i.e., VMT per capita) tend to under estimate future VMT, especially in small counties adjacent to large urban areas. Conversely, historical (i.e., growth trend) based forecasts tend to over estimate future VMT, especially in areas where there has been recent atypical rapid growth.

Viewed differently, however, these two forecast strategies can be seen as defining the boundaries of the forecast, that is, defining a range within which we can be relatively confident of our result. Consequently, the strategy adopted for the near non-attainment counties was to use the midpoint of the two forecasts. In other words, both methods were used. First, a forecast was developed for each county with a per capita based method using a VMT to population ratio (based on 1990 through 1999 population and VMT) applied to official Texas State Data Center county population projections.

Next, a traditional regression analysis was performed on the historic HPMS VMT data from 1990 to 1999 to develop coefficients which were then used to forecast future VMT for each near non-attainment county. Next, the two forecasts are combined and the midpoint calculated. The midpoint of the two methods is used as the forecast VMT value for each county for each forecast year. Finally, a linear adjustment is made to the forecast VMT to reconcile the forecast stream with the historical data.

APPENDIX F
AVERAGE DISTRIBUTION OF VMT BY ROADWAY FUNCTIONAL
CLASSIFICATION (1990 - 1999)

Average Distribution of VMT by Roadway Functional Classification (1990 - 1999)
