FISHERIES RESEARCH BOARD OF CANADA

Technical Reports

FRB Technical Reports are research documents that are of sufficient importance to be preserved, but which for some reason are not appropriate for scientific publication. No restriction is placed on subject matter and the series should reflect the broad research interests of FRB.

These Reports can be cited in publications, but care should be taken to indicate their manuscript status. Some of the material in these Reports will eventually appear in scientific publication.

Inquiries concerning any particular Report should be directed to the issuing FRB establishment which is indicated on the title page.

INTRODUCTION

Only a very limited amount of "Eulerian" current-velocity data (those effectively from fixed locations) was obtained in the Strait of Georgia in the pre-1967 period. It became apparent that these data were insufficient to permit the ascribing of generally-valid numerical characteristics to the circulation in a body of water possessing the oceanographic complexity of the Strait. To attempt to remedy such lack of information, a program of measurements at fixed locations was undertaken in 1967 by the Fisheries Research Board of Canada, Nanaimo, B. C. The program is slated to continue at least through 1970. It was decided that measurements would, for the first year of the program (1967), be confined to the portion of the Strait between Lat. 49°N and the mouth of Howe Sound (Fig. 1). This is an area strongly influenced by the outflow from the Fraser River. During 1967, anchored or moored ships were utilized as platforms. The present report is to be considered primarily as a record of data obtained from these vessels.

CURRENT MEASUREMENTS PRIOR TO 1967

In this section, a brief summary of the current data obtained at fixed stations in the Strait prior to 1967 is presented. The summary should serve two purposes: firstly, to provide a basic catalogue of these previous efforts, and secondly, to emphasize the paucity of such data.

By far the most significant portion of the pre-1967 data at fixed stations was obtained in 1963 at three locations on a line between Nanaimo, Vancouver Island, and Sechart on the B. C. mainland. The program was carried out by the Canadian Hydrographic Service (Huggett, 1966). Three sampling depths were involved: 5, 100 and 300 metres. Six self-recording BBT (Neyrpic) meters were utilized. Readings of speed and direction were obtained, every 20 minutes, for periods as long as 30 days.

Data obtained prior to 1963 in the "open" Strait include:

- (a) Those obtained hourly with "captive" floats, for periods between 6 and 25 hours, off the mouths of the North and South Arms of the Fraser River. Several depths, surface to 90 metres, were sampled in 1950 (Pacific Oceanographic Group, 1951).
- (b) Those acquired hourly at scattered stations in the Strait - off the Fraser River (South Arm), and in Discovery, Boundary and Stevens Passages, Malaspina Strait, Desolation Sound and Sutil Channel - during 1953. Surface currents were measured with a "drift pole" (having about 4 metres of its length immersed) and a calibrated "log line". Subsurface currents - in some instances to 270 metres - were measured with an Ekman meter (Pacific Oceanographic Group, 1954; Waldichuk, 1957).

- (c) Those involving surface and bottom currents measured at six stations between Point Roberts and Galiano Island in 1954. Surface currents were obtained, by drift pole, hourly for about 25 hours at each station; bottom currents were obtained at half-hourly intervals with an Ekman meter (Pickard, 1956).

OBSERVATIONAL PROCEDURES

A. Stations sampled

The locations and designations of the stations at which current-velocity data were obtained in 1967 are shown in Fig. 1. The majority of the stations involved - 8 of 11 - was situated in the open Strait; the remaining three were located in the various entrances to Howe Sound, i.e. in Queen Charlotte, Collingwood and Shoal Channels. A summary of general information relevant to the measurements is provided in Table I.

The larger group of stations represents a portion of a network established for much of the Strait during the original planning of the program. The "lines" on which the network was based were taken to be effectively parallel to, or perpendicular to, the "longitudinal" axis of the Strait. The direction of this axis is not the same throughout the Strait; however, within the area involved in the 1967 measurements, the "cross-Strait" lines were considered to be parallel to the Steveston Jetty, which has a "seaward" direction of about 240° (Fig. 1). These lines are 5 kilometres apart. For this group, simultaneous measurements at two stations were carried out on two occasions (January 25: F-16 and F-20, and March 20: F-06 and F-11). Some stations, however, were sampled more than once. It is felt that the choice of "open-Strait" stations made should provide some reasonable indication of the areal characteristics of current in the region involved.

On one occasion, it became possible to sample simultaneously within the two major entrances to Howe Sound (Queen Charlotte and Collingwood Channels).

B. Ships used

It is seen from Table I that four vessels were utilized for current-data collection during 1967:

1. CGS DECIBAR (Fisheries Research Board of Canada) - Aluminum Hull
2. CGS EHKOLI (Marine Sciences Branch, DEMR*) - Wooden Hull
3. CGS PARRY (Marine Sciences Branch, DEMR*) - Wooden Hull
4. CNAV LAYMORE (Defence Research Establishment Pacific, DRB**) - Steel Hull

* Department of Energy, Mines and Resources

** Defence Research Board

Initially, none of these craft possessed facilities for anchoring at the depths associated with the stations involved. It was therefore intended to moor the vessels to buoys laid at the stations. Cooperation in the providing of buoy facilities was sought, and received, from the Royal Canadian Navy (RCN) and the Department of Transport (DOT) - Marine Services. In January 1967, the RCN laid three buoys (at Stations F-11, F-16 and F-20), two of which were supplied by the RCN and the third by DOT - Marine Services. Those at F-16 and F-20 were utilized in January and February. Unfortunately, due to circumstances beyond the control of the project, it was necessary to remove the buoys in March and to desist from any further usage for mooring purposes. However, it was found possible quickly to supply all vessels (except the DECIBAR, which was not used subsequent to January) with a single-anchoring capability adequate for the depths involved. However, this was generally ineffective for holding the vessels on station at wind speeds above 15 knots, and as a result observational periods were in general shorter than desired (page 4). All ships were anchored from the stern; any effect of yawing ("figure-8" motion) which the vessels would undergo because of their lying to a single anchor was not taken into account.

C. Measurements

In the majority of cases, current data were obtained with Hydro Products Model 465 meters, which employ a Savonius rotor to measure speed and a magnetic compass to indicate direction. Visual readout of results was provided by a "remote" unit on shipboard. The meters were calibrated for direction either before or after a cruise, and were considered accurate to within $\pm 5^\circ$. However, no facilities were available for speed calibration and therefore the manufacturer's ratings were accepted as correct; the accuracy was considered to be ± 0.05 knot at speeds greater than 0.1 knot.

It was found during the first usage of CNAV LAYMORE (F-11, March 20) that the action of the meter's compass was strongly influenced by the steel hull of this vessel, thus providing - at the shallower depths at least - spurious readings of current direction. Such an effect was recognized many years ago, but few systematic studies of it have been conducted (e.g. Lüders, 1940). In the present case, solution of the problem would have involved the "swinging" of the current-meter compass at each sampling depth. However, due to lack of time, this procedure was carried out only at 10 metres. The effect of LAYMORE'S hull was assumed to be negligible at depths of 30 metres or more. (It has recently been claimed that current-direction values obtained with an Ekman meter were free from ship's magnetic influence only at depths of 50 metres or more (Barber, 1965). The length of the ship involved was about 285 ft - vs. the 180-ft length of LAYMORE.) The directions of near-surface (1- and 2-metre) currents were considered as being those of the ship's head at the relevant time (since the vessel was anchored from the stern).

During subsequent cruises involving LAYMORE, measurements were carried out from one of the ship's fiberglass ("non-magnetic") lifeboats, tethered to the ship and maintained at least 200 ft from it. The effect, on the meter compasses, of each of the three remaining vessels was assumed to be negligible.

On two occasions (F-20, January 25 and February 27), a BBT (Neyrpic) meter was used because of the unavailability of Hydro Products instruments; it was obtained from the Tidal and Current Surveys Division (Victoria, B. C.) of the Marine Sciences Branch of DEMR. In this instrument speed values are measured by propeller; average values over one-minute intervals were considered representative. However, this particular meter possessed no capability for measuring current direction; thus only the surface (1-metre) current velocity was considered to be determinable; the direction again being considered to be that of the ship's head.

Before commencing current measurements at a station, salinity (and temperature) were measured to a depth of about 50 metres by means of an "in-situ" Industrial Instruments Electrodeless Induction Salinometer[®]. With the data thus gathered, the basic vertical density distribution at a station could be quickly established; this knowledge, especially in the summer, often aided in the spacing of sampling depths in the shallower layers. Salinity and temperature data were subsequently obtained hourly, if possible. All such data will be reported elsewhere.

It was originally planned to measure current characteristics at each sampling depth (very nearly) once an hour. In the main, this aim was achieved. Nevertheless, it is to be noted that, in a few instances, a reading could be delayed by as much as half an hour or so because of mechanical or other problems. (However, subsequent to such a reading, an attempt was made to return to the original "schedule".) At each depth, the meter was permitted about half a minute to attain equilibrium with the surroundings. The output indicated that the current at any depth was generally of a fluctuating nature both in speed and in direction; nevertheless, in most cases an acceptable "mean" value could be obtained. However, in a few instances, the fluctuations were so irregular and of such large amplitude that no meaningful value of speed and/or direction could be assigned. In such cases, values were often provided by linear interpolation (page 5).

The number of depths sampled in the shallowest 15 metres was markedly larger than that for deeper water. This scheme was effected to obtain detailed knowledge of the shallower current shears, which were suspected (and often found) to be more marked than those at depth. Because of logistical limitations, the maximum depth sampled at a station was generally 30 to 50 metres (Table I). However, in two instances measurements were carried out to 90 metres (E-11, May 1 and F-11, May 4).

It was planned that the duration of each station should be three lunar days (about 75 hours), but uncontrollable factors - such as instrument malfunctions or the drifting of the (anchored) vessel because of wind action - precluded the attainment of this goal for all but 5 stations (Table I).

PROCESSING OF DATA

The raw data underwent preliminary inspection for removal of "gross" errors such as incorrect dating, misplaced decimal points, etc. The values (of time and of current speed and direction) were then segregated by depth. For each depth, the values were placed in chronological order. The resulting "aggregates" of values were assigned to one of two groups which were arbitrarily defined by the following characteristics:

Group I

- (a) The associated time interval was about 18 hours or more.
- (b) The aggregates were either "complete", i.e. one set of values (approximately) every hour, or possessed at most a "small" number of "gaps" characterized by the lack of a single set of "hourly" values. These gaps were less than about 1-3/4 hours long. (The most extreme case encountered involved three such gaps within about a 17-hour interval in a 57-hour aggregate - Station F-06, March 20, 1967.)

This group included by far the greater portion of the data.

Group II

- (a) The associated time interval was less than 18 hours, and/or
- (b) The aggregate contained a "large" number of gaps, which could be of various lengths.

This group involved portions of the measurements from two stations only (F-11, May 29 and June 20).

Each gap associated with Group I was filled by values obtained by linear interpolations involving the immediately-preceding and -succeeding values of time and current speed and direction. (One exception was made: the interpolation was not performed if a gap occurred between the final two sets of values of an aggregate.) The gaps in Group II were not treated in any manner.

The data were then transferred to IBM punch cards (duplicates of which are available, upon request, from the Pacific Oceanographic Group). A program for treatment of the data was written for the IBM 1130 Computer at the Biological Station, Nanaimo, by J. Wong. The output obtained by use of this program constitutes the bulk of this report.

The section entitled CURRENT-DATA RECORD - 1967 (pages 13 through 237) consists of the output involving the data in Group I (in chrono-

logical order). That from Group II is displayed in DATA RECORD - 1967, APPENDIX I (pages 239 through 245). This latter output is small in amount and/or extremely irregular for any one depth at a station; nevertheless, it should provide at least some indication of current behaviour during the relevant time intervals, and has therefore been added for completeness.

Explanation of the various terms and abbreviations involved in the computer output is provided in the next section.

EXPLANATION OF TERMS IN THE CURRENT-DATA RECORD - 1967 AND CURRENT-DATA RECORD - 1967, APPENDIX I

1. STATION NO: The designation of the station sampled, in alphanumeric code.
 - (a) The alphabetic portion of the "single-letter" designations refers to the "cross-Strait line" on which the station is situated (page 2; Fig. 1). The numerical portion of a designation is based on the characteristics of line F, which extends from the mouth of the South Arm of the Fraser River to the northern end of Galiano Island. For any station on that line, it refers to the distance in kilometers between that station and the eastern shore of Galiano (e.g., Q2 signifies a distance of 2 kilometres). Corresponding station numbers on the remaining lines involved are obtained by use of the longitudinal lines of the network.
 - (b) Each of the three stations at the mouth of Howe Sound is designated by the letters HS and a two-digit number (38, 42 and 47 for Queen Charlotte, Collingwood and Shoal Channels respectively). Each number indicates the approximate distance in kilometres, by sea, of the associated station from the head of Howe Sound. Although the three stations are at effectively the same latitude the three distances are not equal, since the paths involved are affected by the presence of the large islands within the sound.
2. STARTING DATE: Date (day, month, year) on which the station commenced, based on Pacific Standard Time (PST).
3. POSITION: Latitude and longitude, in degrees, and minutes and hundredths of minutes.
4. DEPTH: Depth to the bottom at the station, in metres (M).
5. TIME ZONE: The zone is +8 for the Strait of Georgia. The time of observation in Greenwich Mean Time (GMT) can thus be obtained by adding 8 hours to the time recorded in PST.

6. IDENTIFICATION:

- (a) STN. NO., YR., MO., DY: Station number and starting date (year - YR, month - MO, and day - DY).
- (b) DEPTH: Depth at which current measurement was made.

7. INPUT DATA:

- (a) YR, MO, DY: The year, month and day of the observation.
- (b) HR, MIN: Time of observation (hour and minute), to the nearest minute, based on a "24-hour" clock.
- (c) SPEED: Current speed as indicated by the current meter, in knots.
- (d) DIR: Direction of the current (i.e. that in which the current is flowing) as recorded by the current meter. This direction is actually in degrees Magnetic.
- (e) VAR: The magnetic variation (about 22° easterly at the present time); when this is added to a direction actually recorded, the direction in degrees True is obtained. For the 1967 data, this addition was carried out before the data were processed in the computer, so that the true direction is actually given in column (d) - DIR. The magnetic variation is therefore taken to be 0 throughout.
- (f) DIR: True direction in which the current is flowing. Corresponding values in the two DIR columns are identical for the 1967 data; they would in general differ by the amount of the magnetic variation.

8. OUTPUT DATA:

- (a) TIME: The cumulative time in hours (to three decimal places) between the first measurement (at any one depth) and the reading being considered. The first measurement is considered to commence at time 0.000. It also indicates the total elapsed time associated with the complete series of readings at one depth at a station.
- (b) NSCOMP: The north-south component of current velocity, in knots. A (+) denotes current flow to the north, and a (-), flow to the south.
- (c) CUMNS: "Cumulative" total of the north-south components for the relevant time interval. If it is assumed that each "hourly" measured value for the component can be considered constant, or nearly so, throughout the entire "hour" subsequent to the measurement, the cumulative total will provide an indication of net movement in nautical miles, in the north-south direction, during the interval.

- (d) EWCOMP: The east-west component of current velocity, in knots. A (+) denotes current flow to the east, and a (-), flow to the west.
- (e) CUMEW: The cumulative total of the east-west components for the relevant time interval. Analogous to the case of (d), this can provide an indication of net movement in the east-west direction during the interval.
- (f) SEQ NO: The sequence number, indicating the chronological order of the various measurements at a single depth.
- N.B. 1. An asterisk (*) after a sequence number indicates that the corresponding values of current speed and direction have been obtained by a linear interpolation between the immediately-preceding and -following values (page 5).
2. When a zero current is recorded, the value 999 appears in both DIR (Direction) columns. This is merely an artifact of the computer program as presently constituted.
3. Individual additions associated with the CUMNS and CUMEW columns may differ from the correct value by as much as ± 0.02 knots. Such differences result from "rounding" during calculations by the computer.

ACKNOWLEDGMENTS

The authors are indebted to the Marine Sciences Branch of the Department of Energy, Mines and Resources, to the Defence Research Establishment Pacific of the Defence Research Board, and to the Fisheries Research Board of Canada for making vessels available for this study. The masters and crews of these ships provided invaluable support and assistance. Thanks are also due the Royal Canadian Navy and the Department of Transport (Marine Services) for aid in the procuring and/or the laying of mooring buoys.
