

MULTI-MESSENGER OBSERVATIONS OF A BINARY NEUTRON STAR MERGER

LIGO SCIENTIFIC COLLABORATION, VIRGO COLLABORATION AND PARTNER ASTRONOMY GROUPS

(Dated: October 6, 2017)

ABSTRACT

On August 17, 2017 a binary neutron star coalescence candidate (later designated GW170817) with merger time 12:41:04 UTC was observed through gravitational waves by the Advanced LIGO and Advanced Virgo detectors. The *Fermi* Gamma-ray Burst Monitor independently detected a gamma-ray burst (GRB170817A) with a time-delay of ~ 1.7 s with respect to the merger time. From the gravitational-wave signal, the source was initially localized to a sky region of 31 deg^2 at a luminosity distance of 40_{-8}^{+8} Mpc and with component masses consistent with neutron stars. The component masses were later measured to be in the range 0.86 to $2.26 M_{\odot}$. An extensive observing campaign was launched across the electromagnetic spectrum leading to the discovery of a bright optical transient (SSS17a, now with the IAU identification of AT2017gfo) in NGC 4993 (at ~ 40 Mpc) less than 11 hours after the merger by the One-Meter, Two Hemisphere (1M2H) team using the 1-m Swope Telescope. The optical transient was independently detected by multiple teams within an hour. Subsequent observations targeted the object and its environment. Early ultraviolet observations revealed a blue transient that faded within 48 hours. Optical and infrared observations showed a redward evolution over ~ 10 days. Following early non-detections, X-ray and radio emission were discovered at the transient's position ~ 9 and ~ 16 days, respectively, after the merger. Both the X-ray and radio emission likely arise from a physical process that is distinct from the one that generates the UV/optical/near-infrared emission. No ultra-high-energy gamma rays and no neutrino candidates consistent with the source were found in follow-up searches. These observations support the hypothesis that GW170817 was produced by the merger of two neutron stars in NGC 4993 followed by a short gamma-ray burst (GRB170817A) and a kilonova/macronova powered by the radioactive decay of r-process nuclei synthesized in the ejecta.

1. INTRODUCTION

Over 80 years ago [Baade & Zwicky \(1934\)](#) proposed the idea of neutron stars, and soon after, [Oppenheimer & Volkoff \(1939\)](#) carried out the first calculations of neutron-star models. Neutron stars entered the realm of observational astronomy in the 1960s, by providing a physical interpretation of X-ray emission from Scorpius X-1 ([Giacconi et al. 1962](#); [Shklovsky 1967](#)) and of radio pulsars ([Hewish et al. 1968](#); [Gold 1968, 1969](#)).

The discovery of a radio pulsar in a double neutron-star system by [Hulse & Taylor \(1975\)](#) led to a renewed interest in binary stars and compact-object astrophysics, including the development of a scenario for the formation of double neutron stars and the first population studies ([Flannery & van den Heuvel 1975](#); [Massevitch et al. 1976](#); [Clark 1979](#); [Clark et al. 1979](#); [Lipunov et al. 1987](#); [Dewey & Cordes 1987](#); for reviews see [Kalogera et al. 2007](#); [Postnov & Yungelson 2014](#)). The Hulse-Taylor pulsar provided the first firm evidence ([Taylor & Weisberg 1982](#)) for the existence of gravitational waves ([Einstein 1916, 1918](#)), and sparked a renaissance of observational tests of general relativity ([Damour & Taylor 1991](#); [Taylor et al. 1992](#); [Damour & Taylor 1992](#); [Wex 2014](#)). Merging binary neutron stars were quickly recognized to be promising sources of detectable gravitational waves, making them a primary target for ground-based interferometric detectors (see [Abadie et al. 2010](#), for an overview). This motivated the development of accurate models for the two-body, general-relativistic dynamics ([Blanchet et al. 1995](#); [Buonanno & Damour 1999](#); [Pretorius 2005](#); [Campanelli et al. 2006](#); [Baker et al. 2006](#); [Blanchet 2014](#)) that are critical for detecting and interpreting gravitational waves ([Abbott et al. 2016a,b, 2017a,b,c](#)).

In the mid-1960s gamma-ray bursts (GRBs) were discovered by the Vela satellites, and their cosmic origin was first established by [Klebesadel et al. \(1973\)](#). GRBs are classified as *long* or *short*, based on their duration and spectral hardness ([Dezalay et al. 1992](#); [Kouveliotou et al. 1993](#)). Uncovering the progenitors of GRBs has been one of the key challenges in high-energy astrophysics ever since ([Lee & Ramirez-Ruiz 2007](#)). It has long been suggested that short GRBs might be related to neutron-star mergers ([Paczynski 1986](#); [Goodman 1986](#); [Eichler et al. 1989](#); [Narayan et al. 1992](#)).

In 2005 the field of short gamma-ray burst (sGRB) studies experienced a breakthrough (for reviews see [Nakar 2007](#); [Berger 2014](#)) with the identification of the first host galaxies of sGRBs and multi-wavelength observation (from X-ray to optical and radio) of their afterglows ([Gehrels et al. 2005](#); [Fox et al. 2005a](#); [Villasenor et al. 2005](#); [Hjorth et al. 2005a](#); [Berger et al. 2005](#)). These observations provided strong hints that sGRBs might be associated with mergers of neutron stars with other neutron stars or with black

holes. These hints included: (i) their association with both elliptical and star forming galaxies ([Barthelmy et al. 2005](#); [Prochaska et al. 2006](#); [Berger et al. 2007](#); [Ofek et al. 2007](#); [Troja et al. 2008](#); [D’Avanzo et al. 2009](#); [Fong et al. 2013](#)), due to a very wide range of delay times, as predicted theoretically ([Bagot et al. 1998](#); [Fryer et al. 1999](#); [Belczynski et al. 2002](#)); (ii) a broad distribution of spatial offsets from host-galaxy centers ([Berger 2010](#); [Fong & Berger 2013](#); [Tunnicliffe et al. 2014](#)), which was predicted to arise from supernova kicks ([Narayan et al. 1992](#); [Bloom et al. 1999](#)); and (iii) the absence of associated supernovae ([Fox et al. 2005b](#); [Hjorth et al. 2005b,c](#); [Soderberg et al. 2006](#); [Kocevski et al. 2010](#); [Berger et al. 2013a](#)). Despite these strong hints, proof that sGRBs were powered by neutron-star mergers remained elusive, and interest intensified in following up gravitational-wave detections electromagnetically ([Metzger & Berger 2012](#); [Nissanke et al. 2013](#)).

Evidence of beaming in some sGRBs was initially found by [Soderberg et al. \(2006\)](#); [Burrows et al. \(2006\)](#) and confirmed by subsequent sGRB discoveries (see compilation and analysis by [Fong et al. 2015](#) and also [Troja et al. 2016](#)). Neutron-star binary mergers are also expected, however, to produce isotropic electromagnetic signals, which include: (i) early optical and infrared emission, a so-called kilonova/macronova (hereafter kilonova) ([Li & Paczyński 1998](#); [Kulkarni 2005](#); [Rosswog 2005](#); [Metzger et al. 2010](#); [Roberts et al. 2011](#); [Kasen et al. 2013](#); [Barnes & Kasen 2013](#); [Tanaka & Hotokezaka 2013](#); [Grossman et al. 2014](#); [Barnes et al. 2016](#); [Tanaka 2016](#); [Metzger 2017](#)) due to radioactive decay of rapid neutron-capture process (r-process) nuclei ([Lattimer & Schramm 1974, 1976](#)) synthesized in dynamical and accretion-disk-wind ejecta during the merger; and (ii) delayed radio emission from the interaction of the merger ejecta with the ambient medium ([Nakar & Piran 2011](#); [Piran et al. 2013](#); [Hotokezaka & Piran 2015](#); [Hotokezaka et al. 2016](#)). The late-time infrared excess associated with GRB130603B was interpreted as the signature of r-process nucleosynthesis ([Berger et al. 2013b](#); [Tanvir et al. 2013](#)), and more candidates were identified later (for a compilation see [Jin et al. 2016](#)).

Here we report on the global effort¹ that led to the first joint detection of gravitational and electromagnetic radiation from a single source. A ~ 100 s-long gravitational-wave signal (GW170817) was followed by a sGRB (GRB170817A) and an optical transient (SSS17a/AT2017gfo) found in the host galaxy NGC 4993. The source was detected across the electromagnetic spectrum – in the X-ray, ultraviolet, optical, infrared, and radio bands – over hours, days, and weeks. These

¹ This effort was established in the time between initial and advanced LIGO-Virgo observations. Partners have followed up binary-black-hole detections, starting with GW150914 [Abbott et al. 2016](#), but have discovered no firm electro-magnetic counterparts to those events.

observations support the hypothesis that GW170817 was produced by the merger of two neutron stars in NGC4993, followed by a sGRB and a kilonova powered by the radioactive decay of r-process nuclei synthesized in the ejecta.

2. A MULTI-MESSENGER TRANSIENT

On August 17, 2017 12:41:06 UTC the *Fermi* Gamma-ray Burst Monitor (GBM) (Meegan et al. 2009) on-board flight software triggered on, classified, and localized, a GRB. A Gamma-ray Coordinates Network (GCN) Notice (Fermi-GBM 2017) was issued at 12:41:20 UTC announcing the detection of the GRB, which was later designated GRB170817A (von Kienlin et al. 2017). Approximately 6 minutes later, a gravitational-wave candidate (later designated GW170817) was registered in low latency (Cannon et al. 2012; Messick et al. 2017) based on a single-detector analysis of the Laser Interferometer Gravitational-wave Observatory (LIGO) Hanford data. The signal was consistent with a BNS coalescence with merger time, t_c , 12:41:04 UTC, less than 2 s before GRB170817A. Single-detector gravitational-wave triggers had never been disseminated before in low-latency. Given the temporal coincidence with the *Fermi*-GBM GRB, however, a GCN Circular was issued at 13:21:42 UTC (The LIGO Scientific Collaboration et al. 2017a) reporting that a highly significant candidate event consistent with a BNS coalescence was associated with the time of the GRB². An extensive observing campaign was launched across the electromagnetic spectrum in response to the *Fermi*-GBM and LIGO-Virgo detections, and especially the well-constrained, three-dimensional LIGO-Virgo localization. A bright optical transient (SSS17a, now with the IAU identification of AT2017gfo) was discovered in NGC 4993 (at ~ 40 Mpc) by the One-Meter, Two Hemisphere (1M2H) team (August 18 01:05 UTC; Coulter et al. 2017a) less than 11 hr after the merger.

2.1. Gravitational Wave Observation

GW170817 was first detected online (Cannon et al. 2012; Messick et al. 2017) as a single-detector trigger and disseminated through a GCN Circular at 13:21:42 UTC (The LIGO Scientific Collaboration et al. 2017a). A rapid re-analysis (Nitz et al. 2017a,b) of data from LIGO-Hanford, LIGO-Livingston and Virgo confirmed a highly significant, coincident signal. These data were then combined to produce the first three-instrument sky map (Singer & Price 2016; Singer et al. 2016) at 17:54:51 UTC (The LIGO Scientific Collaboration et al. 2017b), placing the source nearby, at a luminosity distance *initially* estimated to be 40_{-8}^{+8} Mpc, in an elongated region of ≈ 31 deg² (90% credibility), centered

around right ascension $\alpha(\text{J2000.0}) = 12\text{h}57^{\text{m}}$ and declination $\delta(\text{J2000.0}) = -17^{\circ}51'$. Soon after, a coherent analysis (Veitch et al. 2015) of the data from the detector network produced a sky map that was distributed at 23:54:40 UTC (The LIGO Scientific Collaboration et al. 2017c), consistent with the initial one: a $\simeq 34$ deg² sky region at 90% credibility centered around $\alpha(\text{J2000.0}) = 13\text{h}09^{\text{m}}$ and $\delta(\text{J2000.0}) = -25^{\circ}37'$

The offline gravitational-wave analysis of the LIGO-Hanford and LIGO-Livingston data identified GW170817 with a false-alarm-rate of less than one per 8.0×10^4 years (Abbott et al. 2017c). This analysis uses post-Newtonian waveform models (Blanchet et al. 1995, 2004, 2006; Bohé et al. 2013) to construct a matched-filter search (Sathyaprakash & Dhurandhar 1991; Cutler et al. 1993; Allen et al. 2012) for gravitational waves from the coalescence of compact-object binary systems in the (detector frame) total mass range $2 - 500 M_{\odot}$. GW170817 lasted for ~ 100 seconds in the detector sensitivity band. The signal reached Virgo first, then LIGO-Livingston 22 ms later, and after 3 ms more, it arrived at LIGO-Hanford. GW170817 was detected with a combined signal-to-noise ratio across the three-instrument network of 32.4. For comparison, GW150914 was observed with a signal-to-noise ratio of 24 (Abbott et al. 2016a).

The properties of the source that generated GW170817 (see Abbott et al. 2017c for full details; here we report parameter ranges that span the 90% credible interval) were derived by employing a coherent Bayesian analysis (Veitch et al. 2015; Abbott et al. 2016) of the three-instrument data, including marginalisation over calibration uncertainties and assuming that the signal is described by waveform models of a binary system of compact objects in quasi-circular orbits (see Abbott et al. 2017c and references therein). The waveform models include the effects introduced by the objects' intrinsic rotation (spin) and tides. The source is located in a region of 28 deg² at a distance 40_{-14}^{+8} Mpc, see Fig. 1, consistent with the early estimates disseminated through GCN Circulars (The LIGO Scientific Collaboration et al. 2017b,c). The misalignment between the total angular momentum axis and the line of sight is $\leq 56^{\circ}$.

The (source-frame³) masses of the primary and secondary components, m_1 and m_2 , respectively, are in the range $m_1 \in (1.36 - 2.26) M_{\odot}$ and $m_2 \in (0.86 - 1.36) M_{\odot}$. The chirp

³ Any mass parameter $m^{(\text{det})}$ derived from the observed signal is measured in the detector frame. It is related to the mass parameter, m , in the source-frame by $m^{(\text{det})} = (1 + z)m$, where z is the source's redshift. Here we always report source-frame mass parameters, assuming standard cosmology (Ade et al. 2016) and correcting for the motion of the Solar System Barycenter with respect to the Cosmic Microwave Background (Fixsen 2009). From the gravitational-wave luminosity distance measurement, the redshift is determined to be $z = 0.008_{-0.003}^{+0.002}$. For full details see (Abbott et al. 2016, 2017c; The LIGO Scientific Collaboration et al. 2017d).

² The trigger was recorded with LIGO-Virgo ID G298048, to which it is referred throughout the GCN circulars.

mass⁴, \mathcal{M} , is the mass parameter that, at the leading order, drives the frequency evolution of gravitational radiation in the inspiral phase. This dominates the portion of GW170817 in the instruments’ sensitivity band. As a consequence, it is the best measured mass parameter, $\mathcal{M} = 1.188_{-0.002}^{+0.004} M_{\odot}$. The total mass is $2.82_{-0.09}^{+0.47} M_{\odot}$, and the mass ratio m_2/m_1 is bound to the range $0.4 - 1.0$. These results are consistent with a binary whose components are neutron stars. White dwarfs are ruled out since the gravitational-wave signal sweeps through 200 Hz in the instruments’ sensitivity band, implying an orbit of size ~ 100 km, which is smaller than the typical radius of a white dwarf by an order of magnitude (Shapiro & Teukolsky 1983). However, for this event gravitational-wave data *alone* cannot rule out objects more compact than neutron stars such as quark stars or black holes (Abbott et al. 2017c).

2.2. Prompt Gamma-Ray Burst Detection

The first announcement of GRB170817A came from the GCN Notice (Fermi-GBM 2017) automatically-generated by Fermi-GBM at 12:41:20 UTC, just 14 s after the detection of the GRB at $T_0 = 12:41:06$ UTC. GRB170817A was later detected by the International Gamma-Ray Astrophysics Laboratory (INTEGRAL) spacecraft using the anti-coincidence shield (von Kienlin et al. 2003) of the Spectrometer onboard INTEGRAL (SPI), through an offline search initiated by the LIGO-Virgo and Fermi-GBM reports. The final Fermi-GBM localization constrained GRB170817A to a region with highest probability at $\alpha(\text{J2000.0}) = 12\text{h}28^{\text{m}}$ and $\delta(\text{J2000.0}) = -30^\circ$ and 90% probability region covering $\sim 1100 \text{ deg}^2$ (Goldstein et al. 2017). The difference between the binary merger and the GRB is $T_0 - t_c = 1.734 \pm 0.054$ s (LIGO Scientific and Virgo Collaboration et al. 2017). Exploiting the difference in the arrival time of the gamma-ray signals at Fermi-GBM and INTEGRAL SPI-ACS (Svinkin et al. 2017) provides additional significant constraints on the gamma-ray localization area (see Figure 1). The IPN localization capability will be especially important in the case of future gravitational-wave events that might be less-well localized by LIGO-Virgo.

Standard follow-up analyses (Paciesas et al. 2012; Goldstein et al. 2012; Gruber et al. 2014) of the Fermi-GBM trigger determined the burst duration to be $T_{90} = 2.0 \pm 0.5$ s, where T_{90} is defined as the interval over which 90% of the burst fluence is accumulated in the energy range of 50–300 keV. From the Fermi-GBM T_{90} measurement, GRB170817A was classified as a sGRB with 3:1 odds over being a long GRB. The classification of GRB170817A as a sGRB is further supported by incorporating the hardness

ratio of the burst and comparing it to the Fermi-GBM catalog (Goldstein et al. 2017). The SPI-ACS duration for GRB170817A of 100 ms is consistent with a sGRB classification within the instrument’s historic sample (Savchenko et al. 2012).

The GRB had a peak photon flux measured on a 64 ms timescale of $3.7 \pm 0.9 \text{ photons s}^{-1} \text{ cm}^{-2}$ and a fluence over the T_{90} interval of $(2.8 \pm 0.2) \times 10^{-7} \text{ erg cm}^{-2}$ (10–1000 keV) (Goldstein et al. 2017). GRB170817A is the closest sGRB with measured redshift. By usual measures, GRB170817A is sub-luminous, a tantalizing observational result that is explored in LIGO Scientific and Virgo Collaboration et al. (2017); Goldstein et al. (2017).

Detailed analysis of the Fermi-GBM data for GRB170817A revealed two components to the burst: a main pulse encompassing the GRB trigger time from $T_0 - 0.320$ s to $T_0 + 0.256$ s followed by a weak tail starting at $T_0 + 0.832$ s and extending to $T_0 + 1.984$ s. The spectrum of the main pulse of GRB170817A is best-fit with a Comptonized function (a power-law with an exponential cutoff) with a power-law photon index of -0.62 ± 0.40 , peak energy $E_{\text{peak}} = 185 \pm 62$ keV, and time-averaged flux of $(3.1 \pm 0.7) \times 10^{-7} \text{ erg cm}^{-2} \text{ s}^{-1}$. The weak tail that follows the main pulse, when analyzed independently, has a localization consistent with both the main pulse and the gravitational-wave position. The weak tail, at 34% the fluence of the main pulse, extends the T_{90} beyond the main pulse and has a softer, blackbody spectrum with $kT = 10.3 \pm 1.5$ keV (Goldstein et al. 2017).

Using the Fermi-GBM spectral parameters of the main peak and T_{90} interval, the integrated fluence measured by INTEGRAL SPI-ACS is $(1.4 \pm 0.4) \times 10^{-7} \text{ erg cm}^{-2}$ (75–2000 keV), compatible with the Fermi-GBM spectrum. Because SPI-ACS is most sensitive above 100 keV, it detects only the highest-energy part of the main peak near the start of the longer Fermi-GBM signal (The LIGO Scientific Collaboration et al. 2017e).

2.3. Discovery of Optical Counterpart and Host Galaxy

The announcements of the Fermi-GBM and LIGO-Virgo detections, and especially the well-constrained, three-dimensional LIGO-Virgo localization, triggered a broadband observing campaign in search of electromagnetic counterparts. A large number of teams across the world were mobilized using ground- and space-based telescopes that could observe the region identified by the gravitational-wave detection. GW170817 was localized to the southern sky, setting in the early evening for the northern hemisphere telescopes, thus making it inaccessible to the majority of them. The LIGO-Virgo localization region (The LIGO Scientific Collaboration et al. 2017b,c) became observable to telescopes in

⁴ The binary’s chirp mass is defined as $\mathcal{M} = (m_1 m_2)^{3/5} / (m_1 + m_2)^{1/5}$.

Figure 1. Localization of the gravitational-wave, gamma-ray, and optical signals. The left panel shows an orthographic projection of the 90% credible regions from LIGO (190 deg^2 , light green), the initial LIGO-Virgo localization (31 deg^2 , dark green), IPN triangulation from the time delay between *Fermi* and *INTEGRAL* (light blue), and *Fermi* GBM (dark blue). The inset shows the location of the apparent host galaxy NGC 4993 in the Swope optical discovery image at 10.9 hours after the merger (top right) and the DLT40 pre-discovery image from 20.5 days prior to merger (bottom right). The reticle marks the position of the transient in both images.

Chile about 10 hours after the merger with an altitude above the horizon of about 45 degrees.

The One-Meter, Two-Hemisphere (1M2H) team was the first to discover and announce (Aug 18 01:05 UTC; Coulter et al. 2017a) a bright optical transient in an *i*-band image acquired on Aug 17 at 23:33 UTC ($t_c+10.87 \text{ hr}$) with the 1 m Swope telescope at Las Campanas Observatory in Chile. The team used an observing strategy (Gehrels et al. 2016) that targeted known galaxies (from White et al. 2011) in the three-dimensional LIGO-Virgo localization taking into account the galaxy stellar mass and star-formation rate (Coulter et al. 2017). The transient, designated Swope Supernova Survey 2017a (SSS17a), was $i = 17.057 \pm 0.018 \text{ mag}^5$ (Aug 17 23:33 UTC, $t_c+10.87 \text{ hr}$) and did not match any known asteroids or supernovae. SSS17a (now with the IAU designation AT2017gfo) was located at $\alpha(\text{J2000.0}) = 13^{\text{h}}09^{\text{m}}48^{\text{s}}.085 \pm$

0.018 , $\delta(\text{J2000.0}) = -23^{\circ}22'53''.343 \pm 0.218$ at a projected distance of $10.6''$ from the center of NGC 4993, an early-type galaxy in the ESO 508 group at a distance of $\simeq 40 \text{ Mpc}$ (Tully-Fisher distance from Freedman et al. 2001), consistent with the gravitational-wave luminosity distance (The LIGO Scientific Collaboration et al. 2017b).

Five other teams took images of the transient within an hour of the 1M2H image (and before the SSS17a announcement) using different observational strategies to search the LIGO-Virgo sky localization region. They reported their discovery of the same optical transient in a sequence of GCNs: the Dark Energy Camera (01:15 UTC; Allam et al. 2017), the Distance Less Than 40 Mpc survey (01:41 UTC; Yang et al. 2017a), Las Cumbres Observatory (04:07 UTC; Arcavi et al. 2017a), the Visible and Infrared Survey Telescope for Astronomy (05:04 UTC; Tanvir et al. 2017a), and MASTER (05:38 UTC; Lipunov et al. 2017a). Independent searches were also carried out by the Rapid Eye Mount (REM-GRAWITA, optical, 02:00 UTC; Melandri et al. 2017a), Swift UVOT/XRT (ultraviolet, 07:24 UTC;

⁵ All apparent magnitudes are AB and corrected for the Galactic extinction in the direction of SSS17a ($E(B - V) = 0.109 \text{ mag}$; Schlafly & Finkbeiner 2011).

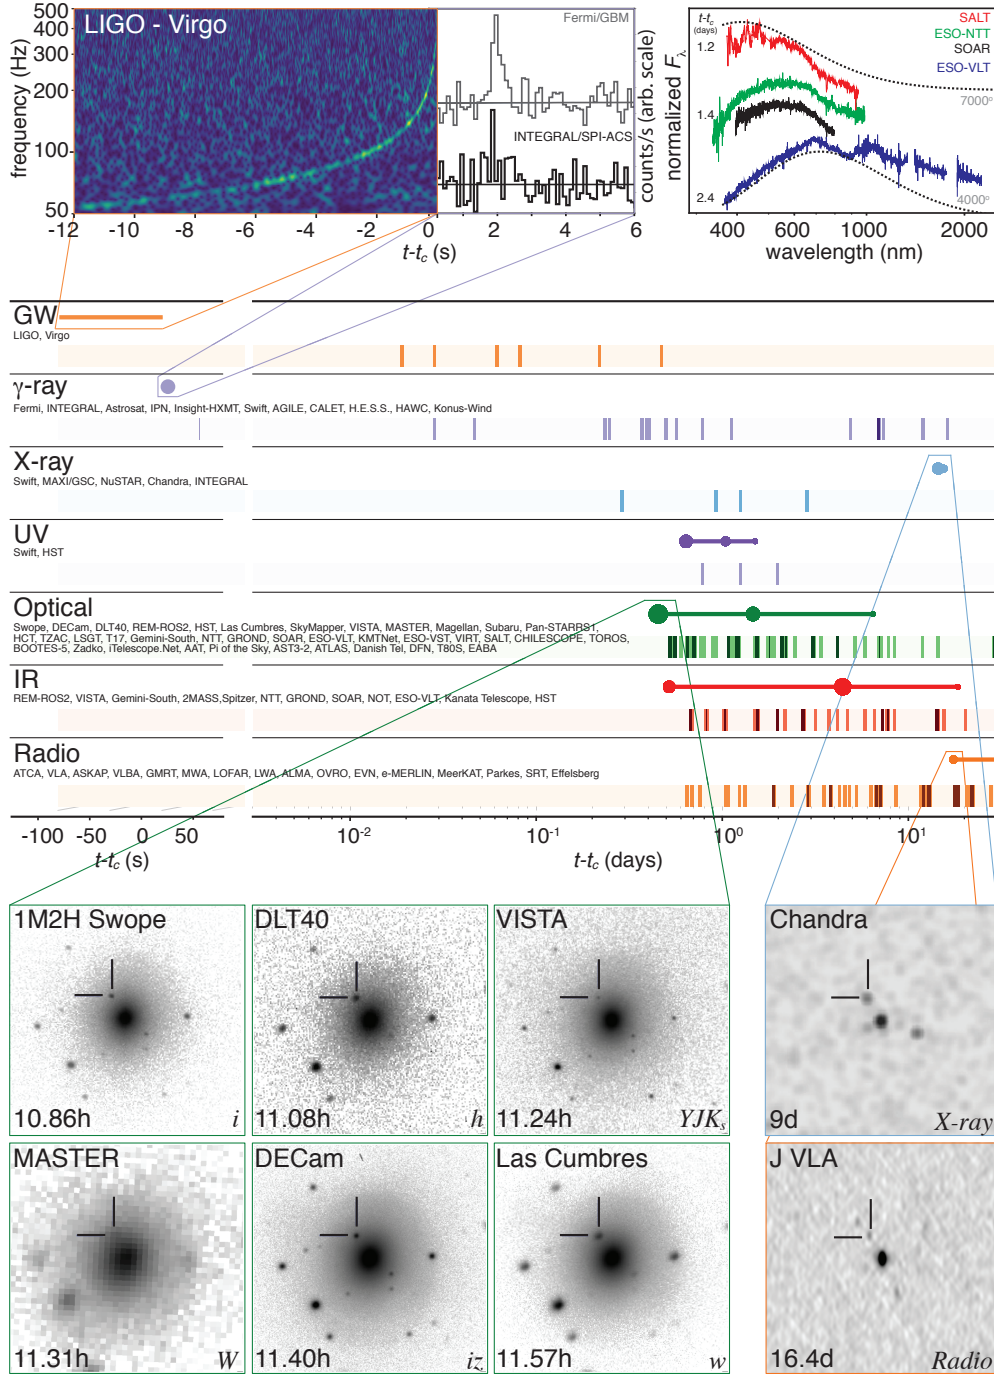

Figure 2. The timeline of the discovery of GW170817, GRB170817A, SSS17a/AT2017gfo and the follow-up observations are shown by messenger and wavelength relative to the time t_c of the gravitational-wave event. Two types of information are shown for each band/messenger. First, the shaded dashes represent the times when information was reported in a GCN Circular. The names of the relevant instruments, facilities or observing teams are collected at the beginning of the row. Second, representative observations (see Table 1) in each band are shown as solid circles with their areas approximately scaled by brightness; the solid lines indicate when the source was detectable by at least one telescope. Magnification insets give a picture of the first detections in the gravitational-wave, gamma-ray, optical, X-ray and radio bands. They are respectively illustrated by the combined spectrogram of the signals received by LIGO-Hanford and LIGO-Livingston (see Sec. 2.1), the *Fermi*-GBM and INTEGRAL/SPI-ACS light-curves matched in time resolution and phase (see Sec. 2.2), $1.5' \times 1.5'$ postage stamps extracted from the initial six observations of SSS17a/AT2017gfo and four early spectra taken with the SALT (at $t_c+1.2$ d McCully et al. 2017; Buckley et al. 2017), ESO-NTT (at $t_c+1.4$ d, Smartt et al. 2017), the SOAR 4-m telescope (at $t_c+1.4$ d, Nicholl et al. 2017), and ESO-VLT-XShooter (at $t_c+2.4$ d, Smartt et al. 2017) as described in Sec. 2.3, the first X-ray and radio detections of the same source by Chandra (see Sec. 3.3) and JVLA (see Sec. 3.4). In order to show representative spectral energy distributions, each spectrum is normalized to its maximum, and shifted arbitrarily along the linear y-axis (no absolute scale). The high background in the SALT spectrum below 4500 Å prevents the identification of spectral features in this band (for details McCully et al. 2017).

Evans et al. 2017), and Gemini-South (infrared, 08:00 UT; Singer et al. 2017a).

The Distance Less Than 40 Mpc survey (DLT40; L. Tartaglia et al. 2017, in prep.) team independently detected SSS17a/AT2017gfo, automatically designated DLT17ck (Yang et al. 2017a) in an image taken on Aug 17 23:50 UTC while carrying out high-priority observations of 51 galaxies (20 within in the LIGO-Virgo localization, and 31 within the wider *Fermi*-GBM localization region) (Valenti et al. 2017, accepted). A confirmation image was taken on Aug 18 00:41 UTC after the observing program had cycled through all of the high-priority targets and found no other transients. The updated magnitudes for these two epochs are $r=17.18\pm 0.03$ and 17.28 ± 0.04 mag, respectively.

SSS17a/AT2017gfo was also observed by the Visible and Infrared Survey Telescope for Astronomy (VISTA) in the second of two 1.5 square-degree fields targeted. The fields were chosen to be within the high-likelihood localization region of GW170817 and to contain a high density of potential host galaxies (32 of the 54 entries in the list of Cook et al. 2017a). Observations began during evening twilight and were repeated twice to give a short temporal baseline over which to search for variability (or proper motion of any candidates). The magnitudes of the transient source in the earliest images taken in the near-infrared, were measured to be $K_s = 18.63\pm 0.05$, $J = 17.88\pm 0.03$ and $Y = 17.51\pm 0.02$ mag.

On Aug 17 23:59 UTC, the MASTER-OAFA robotic telescope (Lipunov et al. 2010), covering the sky location of GW170817, recorded an image that included NGC 4993. The auto-detection software identified MASTER OT J130948.10-232253.3, the bright optical transient with the unfiltered magnitude $W = 17.5 \pm 0.2$ mag, as part of an automated search performed by the MASTER Global Robotic Net (Lipunov et al. 2017; Lipunov et al. 2017a).

The Dark Energy Camera (DECam; Flaugher et al. 2015) Survey team started observations of the GW170817 localization region on Aug 17 23:13 UTC. DECam covered 95% of the probability in the GW170817 localization area with a sensitivity sufficient to detect a source up to 100 times fainter than the observed optical transient. The transient was observed on 2017 August 18 at 00:05 UTC and independently detected at 00:42 UTC (Allam et al. 2017). The measured magnitudes of the transient source in the first images were $i = 17.30 \pm 0.02$, $z = 17.45 \pm 0.03$. A complete analysis of DECam data is presented in Soares-Santos et al. (2017).

Las Cumbres Observatory (LCO Brown et al. 2013) surveys started their observations of individual galaxies with their global network of 1 m and 2 m telescopes upon receipt of the initial *Fermi*-GBM localization. Approximately five hours later, when the LIGO-Virgo localization map was issued, the observations were switched to a prioritized list of

galaxies (from Dalya et al. 2016) ranked by distance and luminosity (Arcavi et al. 2017a). In a 300-second *w*-band exposure beginning on Aug 18 00:15 UTC, a new transient, corresponding to AT2017gfo/SSS17a/DLT17ck, was detected near NGC 4993 (Arcavi et al. 2017a). The transient was determined to have $w = 17.49\pm 0.04$ mag (Arcavi et al. 2017b).

These early photometric measurements, from the optical to near-infrared, gave the first broadband spectral energy distribution of AT2017gfo/SSS17a/DLT17ck. They do not distinguish the transient from a young supernova, but they serve as reference values for subsequent observations which reveal the nature of the optical counterpart as described in section 3.1. Images from the six earliest observations are shown in the inset of Figure 2.

3. BROADBAND FOLLOW-UP

While some of the first observations aimed to tile the error region of the GW170817 and GRB170817A localization areas, including the use of galaxy targeting (Dalya et al. 2016; White et al. 2011; Cook & Kasliwal 2017), most groups focused their effort on the optical transient reported by Coulter et al. (2017) to define its nature and to rule out that it was a chance coincidence of an unrelated transient. The multi-wavelength evolution within the first 12 to 24 hrs, and the subsequent discoveries of the X-ray and radio counterparts proved key to scientific interpretation. This section summarizes the plethora of key observations that occurred in different wavebands, as well as searches for neutrino counterparts.

3.1. Ultraviolet, optical, and infrared

The quick discovery in the first few hours of Chilean darkness, and possibility of fast evolution, prompted the need for the ultraviolet-optical-infrared follow-up community to have access to both space-based and longitudinally-separated ground-based facilities. Over the next two weeks, a network of ground-based telescopes, from 40 cm to 10 m, and space-based observatories spanning the ultraviolet (UV), optical (O) and near-infrared (IR) wavelengths followed up GW170817. These observations revealed an exceptional electromagnetic counterpart through careful monitoring of its spectral energy distribution. Here we first consider photometric and then spectroscopic observations of the source.

Regarding photometric observations, at $t_c+11.6$ hr, the Magellan-Clay and Magellan-Baade telescopes (Drout et al. 2017; Simon et al. 2017) initiated follow-up observations of the transient discovered by the Swope Supernova Survey from the optical (g-band) to NIR (Ks-band). At $t_c+12.7$ hr and $t_c+12.8$ hr, the Rapid Eye Mount (REM)/ROS2 (Melandri et al. 2017b) detected the optical transient and the Gemini-South FLAMINGO2 instrument first detected near-infrared Ks-band emission constraining the early optical to infrared color (Singer et al. 2017a; Kasliwal et al. 2017) respectively. At $t_c+15.3$ hr, the *Swift* satellite (Gehrels 2004)

detected bright, ultraviolet emission, further constraining the effective temperature (Evans et al. 2017; Evans et al. 2017). The ultraviolet evolution continued to be monitored with the *Swift* satellite (Evans et al. 2017) and the *Hubble* space telescope (Adams et al. 2017; Kasliwal et al. 2017; P. Cowperthwaite et al. 2017).

Over the course of the next two days, an extensive photometric campaign showed a rapid dimming of this initial UV-blue emission, and an unusual brightening of the near-infrared emission. After roughly a week, the redder optical and near-infrared bands began to fade as well. Ground-based facilities participating in this photometric monitoring effort include (in alphabetic order): CTIO1.3m, DECam (Nicholl et al. 2017a; P. Cowperthwaite et al. 2017; Nicholl et al. 2017), IRSF, the Gemini-South FLAMINGO2 (Singer et al. 2017a; Troja et al. 2017a; Chornock et al. 2017a; Troja et al. 2017b; Singer et al. 2017b), Gemini-South GMOS (Troja et al. 2017a), GROND (Wiseman et al. 2017; Chen et al. 2017), Hubble Space Telescope (HST Levan et al. 2017a; Tanvir & Levan 2017; Troja et al. 2017; Levan & Tanvir 2017; P. Cowperthwaite et al. 2017), iTelescope.Net telescopes (Im et al. 2017a,b), the Korea Microlensing Telescope Network (KMTNet Im et al. 2017c,d), Las Cumbres Observatory (Arcavi et al. 2017b; Arcavi et al. 2017b,c), the Lee Sang Gak Telescope (LSGT)/SNUCAM-II, the Magellan-Baade and Magellan-Clay 6.5-m telescopes (Simon et al. 2017; Drout et al. 2017), the Nordic Optical Telescope (Malesani et al. 2017a), Pan-STARRS1 (Chambers et al. 2017a,b,c,d), REM/ROS2 and REM/REMIR (Melandri et al. 2017a,c), SkyMapper (Wolf et al. 2017), Subaru Hyper Suprime-Cam (Yoshida et al. 2017a,b,c,d; Tominaga et al. 2017), ESO-VISTA (Tanvir et al. 2017a), ESO-VST/OmegaCAM (Grado et al. 2017a,b), and ESO-VLT/FORS2 (D’Avanzo et al. 2017).

One of the key properties of the transient that alerted the world-wide community to its unusual nature was the rapid luminosity decline. In bluer optical bands (i.e., in the g -band) the transient showed a fast decay between daily photometric measurements (Melandri et al. 2017c; P. Cowperthwaite et al. 2017). Pan-STARRS (Chambers et al. 2017c) reported photometric measurements in the optical/infrared izy -bands with the same cadence, showing fading by 0.6 mag per day, with reliable photometry from difference imaging using already existing sky images (Chambers et al. 2016; P. Cowperthwaite et al. 2017). Observations taken every 8 hours by Las Cumbres Observatory showed an initial rise in the w -band, followed by rapid fading in all optical bands (more than 1 mag per day in the blue), and reddening with time (Arcavi et al. 2017b). Accurate measurements from Subaru (Tominaga et al. 2017), LSGT/SNUCAM-II and KMTNet (Im et al. 2017c), ESO-VLT/FORS2 (D’Avanzo et al. 2017), and DECam (Nicholl et al. 2017b; P. Cowperthwaite

et al. 2017) indicated a similar rate of fading. On the contrary, the near-infrared monitoring reports by GROND and Gemini-South, showed that the source faded more slowly in the infrared (Wiseman et al. 2017; Chornock et al. 2017a) and even showed a late-time plateau in Ks-band (Singer et al. 2017b). This evolution was recognized by the community as quite unprecedented for transients in the nearby (within 100 Mpc) Universe (e.g., Siebert et al. 2017).

Table 1 reports a summary of the imaging observations, which include coverage of the entire gravitational-wave sky localization and follow-up of SSS17a/AT2017gfo. Figure 2 shows these observations in graphical form.

Concerning spectroscopic observations, immediately after discovery of SSS17a/AT2017gfo on the Swope 1 m telescope, the same team obtained the first spectroscopic observations of the optical transient with the LDSS-3 spectrograph on the 6.5m Magellan-Clay telescope and the MagE spectrograph on the 6.5m Magellan-Baade telescope at Las Campanas Observatory. The spectra, just 30 minutes after the first image showed a blue and featureless continuum between 4,000 Å and 10,000 Å, consistent with a power-law (Drout et al. 2017; Shappee et al. 2017). The lack of features and blue continuum during the first few hours implied an unusual, but not unprecedented transient since such characteristics are common in cataclysmic-variable stars and young core-collapse supernovae (see e.g., Li et al. 2011b,a).

The next 24 hours of observation were critical in decreasing the likelihood of a chance coincidence between SSS17a/AT2017gfo, GW170817, and GRB170817A. The SALT-RSS spectrograph in South Africa (Shara et al. 2017; McCully et al. 2017; Buckley et al. 2017), the ePESSTO with the EFOSC2 instrument in spectroscopic mode at the ESO New Technology Telescope (NTT, in La Silla, Chile; Lyman et al. 2017), the X-shooter spectrograph on the ESO Very Large Telescope (Pian et al. 2017) in Paranal, the Goodman Spectrograph on the 4m SOAR telescope (Nicholl et al. 2017c) obtained additional spectra. These groups reported a rapid fall-off in the blue spectrum without any individual features identifiable with line absorption common in supernova-like transients (see e.g., Lyman et al. 2017). This ruled out a young supernova of any type in NGC 4993, showing an exceptionally fast spectral evolution (Drout et al. 2017; Nicholl et al. 2017). Figure 2 shows some representative early spectra (SALT spectrum is from McCully et al. 2017; Buckley et al. 2017, ESO spectra from Smartt et al. 2017 and SOAR spectrum from (Nicholl et al. 2017)). These show rapid cooling, and the lack of commonly observed ions from elements abundant in supernova ejecta, indicating this object was unprecedented in its optical and near-infrared. Combined with the rapid fading, this was broadly indicative of a possible kilonova (e.g., Kasen et al. 2017; Kasliwal et al. 2017; Smartt et al. 2017; McCully et al. 2017; Arcavi et al.

2017b; P. Cowperthwaite et al. 2017; Nicholl et al. 2017). This was confirmed by spectra taken at later times, such as with the Gemini Multi-Object Spectrograph (GMOS; Troja et al. 2017a; Troja et al. 2017; Kasliwal et al. 2017; McCully et al. 2017), the LDSS-3 spectrograph on the 6.5m Magellan-Clay telescope at Las Campanas Observatory (Drout et al. 2017; Shappee et al. 2017), the Las Cumbres Observatory FLOYDS spectrograph at Faulkes Telescope South (McCully et al. 2017; McCully et al. 2017) and the AAOmega spectrograph on the 3.9m Anglo-Australian Telescope (Andreoni et al. 2017), which did not show any significant emission or absorption lines over the red featureless continuum. The optical and near-infrared spectra over these few days provided convincing arguments that this transient was unlike any other discovered in extensive optical wide-field surveys over the last decade (see e.g., Siebert et al. 2017).

The evolution of the spectral energy distribution, rapid fading and emergence of broad spectral features indicated that the source had physical properties similar to models of kilonovae (e.g., Metzger et al. 2010; Kasen et al. 2013; Barnes & Kasen 2013; Tanaka & Hotokezaka 2013; Metzger et al. 2014; Barnes et al. 2016; Tanaka 2016; Metzger 2017; Kasen et al. 2017). These show a very rapid shift of the spectral energy distribution from the optical to the near-infrared. The FLAMINGOS2 near-infrared spectrograph at Gemini-South (Chornock et al. 2017b; Kasliwal et al. 2017) shows the emergence of very broad features in qualitative agreement with kilonova models. The ESO-VLT/X-shooter spectra, which simultaneously cover the wavelength range 3200–24800 Å, were taken over 2 weeks with a close to daily sampling (Pian et al. 2017; Smartt et al. 2017) and revealed signatures of the radioactive decay of r-process nucleosynthesis elements (Pian et al. 2017). Three epochs of infrared grism spectroscopy with the Hubble Space Telescope (Levan et al. 2017a; Tanvir & Levan 2017; Troja et al. 2017; Levan & Tanvir 2017; P. Cowperthwaite et al. 2017)⁶ identified features consistent with the production of lanthanides within the ejecta (Levan & Tanvir 2017; Tanvir & Levan 2017; Troja et al. 2017).

The optical follow-up campaign also includes linear polarimetry measurements of SSS17a/AT2017gfo by ESO-VLT/FORS2, showing no evidence of an asymmetric geometry of the emitting region and lanthanide-rich late kilonova emission (Covino et al. 2017). In addition, the study of the galaxy with the MUSE Integral Field Spectrograph on the ESO-VLT (Levan et al. 2017b) provides simultaneous spectra of the counterpart and the host galaxy, which show broad absorption features in the transient spectrum, combined with

emission lines from the spiral arms of the host galaxy (Levan & Tanvir 2017; Tanvir & Levan 2017).

Table 2 reports the spectroscopic observations, that have led to the conclusion that the source broadly matches kilonovae theoretical predictions.

3.2. Gamma-rays

The fleet of ground- and space-based gamma-ray observatories provided broad temporal and spectral coverage of the source location. Observations spanned ~ 10 orders of magnitude in energy and covered the position of SSS17a/AT2017gfo from a few hundred seconds before the GRB170817A trigger time (T0) to days afterwards. Table 3 lists, in chronological order, the results reporting observation time, flux upper limits, and the energy range of the observations, which are summarized here.

At the time of GRB170817A, three out of six spacecraft of the Inter Planetary Network (Hurley et al. 2013) had a favorable orientation to observe the LIGO-Virgo sky-map. However, based on the *Fermi*-GBM (Goldstein et al. 2017) and INTEGRAL analyses, GRB170817A was too weak to be detected by *Konus-Wind* (Svinkin et al. 2017a). Using the Earth Occultation technique (Wilson-Hodge et al. 2012), *Fermi*-GBM placed limits on persistent emission for the 48-hour period centered at the *Fermi*-GBM trigger time over the 90% credible region of the GW170817 localization. Using the offline targeted search for transient signals (Blackburn et al. 2015), *Fermi*-GBM also set constraining upper limits on precursor and extended emission associated with GRB170817A (Goldstein et al. 2017). INTEGRAL (Winkler et al. 2003) continued uninterrupted observations after GRB170817A for 10 hours. Using the PiCSIT (Labanti et al. 2003) and SPI-ACS detectors, the presence of a steady source ten times weaker than the prompt emission was excluded (Savchenko et al. 2017).

The High Energy telescope on-board *Insight*-HXMT monitored the entire GW170817 sky map from T0−650 s to T0+450 s but, due to the weak and soft nature of GRB170817A, did not detect any significant excess at T0 (Liao et al. 2017). Upper limits from 0.2 – 5 MeV for GRB170817A and other emission episodes are reported in Li et al. (2017).

The Calorimetric Electron Telescope (CALET) Gamma-ray Burst Monitor (CGBM) found no significant excess around T0. Upper limits may be affected due to the location of SSS17a/AT2017gfo being covered by the large structure of the International Space Station at the time of GRB170817A (Nakahira et al. 2017). *AstroSat* CZTI (Singh et al. 2014; Bhalerao et al. 2017) reported upper limits for the 100 s interval centered on T0 (Balasubramanian et al. 2017); the position of SSS17a/AT2017gfo was occulted by the Earth, however, at the time of the trigger.

⁶ HST Program GO 14804 Levan, GO 14771 Tanvir & GO 14850 Troja

For the AstroRivelatore Gamma a Immagini Leggero (AGILE) satellite (Tavani et al. 2009) the first exposure of the GW170817 localization region by the Gamma Ray Imaging Detector (GRID), which was occulted by the Earth at the time of GRB170817A started at $T_0 + 935$ s. The GRID observed the field before and after T_0 , typically with 150 s exposures. No gamma-ray source was detected above 3σ in the energy range 30 MeV–30 GeV (Verrecchia et al. 2017).

At the time of the trigger, *Fermi* was entering the South Atlantic Anomaly (SAA) and the Large Area Telescope (LAT) was not collecting science data (*Fermi*-GBM uses different SAA boundaries and was still observing). *Fermi*-LAT resumed data taking at roughly $T_0 + 1153$ s, when 100% of the low-latency GW170817 sky-map (The LIGO Scientific Collaboration et al. 2017b) was in the field of view for ~ 1000 s. No significant source of high-energy emission was detected. Additional searches over different time scales were performed for the entire time span of LAT data, and no significant excess was detected at the position of SSS17a/AT 2017gfo (Kocevski et al. 2017).

The High Energy Stereoscopic System (H.E.S.S.) array of imaging atmospheric Cherenkov telescopes observed from August 17 18:00 UTC with three pointing positions. The first, at $T_0 + 5.3$ hr, covered SSS17a/AT 2017gfo. Observations repeated the following nights until the location moved outside the visibility window, with the last pointing performed on August 22 18:15 UTC. A preliminary analysis with an energy threshold of ~ 500 GeV revealed no significant gamma-ray emission (de Naurois et al. 2017), confirmed by the final, offline analysis (see Abdalla, H. et al. (H.E.S.S. Collaboration) (2017) for more results).

For the High-Altitude Water Cherenkov (HAWC) Observatory (Abeysekara et al. 2017) the LIGO-Virgo localization region first became visible on August 17 between 19:57 and 23:25 UTC. SSS17a/AT 2017gfo was observed for 2.03 hours starting at 20:53 UTC. Upper limits from HAWC for energies > 40 TeV assuming an $E^{-2.5}$ spectrum are reported in Martinez-Castellanos et al. (2017).

INTEGRAL (3 keV–8 MeV) carried out follow-up observations of the LIGO-Virgo localization region, centered on the optical counterpart, starting 24 hours after the event and spanning 4.7 days. Hard X-ray emission is mostly constrained by IBIS (Ubertini et al. 2003), while above 500 keV SPI (Vedrenne et al. 2003) is more sensitive. Besides the steady flux limits reported in Table 3, these observations exclude delayed bursting activity at the level of giant magnetar flares. No gamma-ray lines from a kilonova or e^+e^- pair plasma annihilation were detected (see Savchenko et al. 2017).

While the UV, optical, and IR observations mapped the emission from the sub-relativistic ejecta, X-ray observations probed a different physical regime. X-ray observations of GRB afterglows are important to constrain the geometry of the outflow, its energy output, and the orientation of the system with respect to the observers' line of sight.

The earliest limits at X-ray wavelengths were provided by the Gas Slit Camera (GSC) of the Monitor of All-Sky X-ray Image (MAXI; Matsuoka et al. 2009). Due to an unfavorable sky position, the location of GW 170817 was not observed by MAXI until August 17 17:21 UTC ($T_0 + 0.19$ d). No X-ray emission was detected at this time to a limiting flux of 8.6×10^{-9} erg cm $^{-2}$ s $^{-1}$ (2–10 keV; Sugita et al. 2017; Sugita et al. in prep.). MAXI obtained three more scans over the location with no detections before the more sensitive pointed observations began.

In addition, the Super-AGILE detector (Feroci et al. 2007) onboard the AGILE mission (Tavani et al. 2009) observed the location of GW170817 starting at August 18 01:16:34.84 UTC ($T_0 + 0.53$ d). No X-ray source was detected at the location of GW170817, with a 3σ upper limit of 3.0×10^{-9} erg cm $^{-2}$ s $^{-1}$ (18 – 60 keV) (Verrecchia et al. 2017).

The first pointed X-ray observations of GW170817 were obtained by the X-Ray Telescope (Burrows et al. 2005) on the *Swift* satellite (Gehrels 2004) and the NUClear Spectroscopic Telescope ARray (*NuSTAR*; Harrison et al. 2013), beginning at $T_0 + 0.62$ d and $T_0 + 0.70$ d, respectively. No X-ray emission was detected at the location of GW170817 to limiting fluxes of 2.7×10^{-13} erg cm $^{-2}$ s $^{-1}$ (0.3 – 10.0 keV; Evans et al. 2017; Evans et al. 2017) and 2.6×10^{-14} erg cm $^{-2}$ s $^{-1}$ (3.0 – 10.0 keV; Evans et al. 2017; Evans et al. 2017). *Swift* continued to monitor the field, and after stacking several epochs of observations, a weak X-ray source was detected near the location of GW170817 at a flux of 2.6×10^{-14} erg cm $^{-2}$ s $^{-1}$ (Evans et al. 2017).

INTEGRAL (see Section 3.2) performed pointed follow-up observations from one to about six days after the trigger. The X-ray monitor JEM-X (Lund et al. 2003) constrained the average X-ray luminosity at the location of the optical transient to be $< 2 \times 10^{-11}$ erg cm $^{-2}$ s $^{-1}$ (3 – 10.0 keV) and $< 7 \times 10^{-12}$ erg cm $^{-2}$ s $^{-1}$ (10 – 25 keV; Savchenko et al. 2017).

Chandra obtained a series of observations of GW170817 beginning at August 19 17:10 UTC ($T_0 + 2.2$ d) and continuing until the emission from NGC 4993 became unobservable because SSS17a/AT 2017gfo's proximity to the Sun (Margutti et al. 2017; Troja et al. 2017a; Fong et al. 2017; Troja et al. 2017b; Haggard et al. 2017b). Two days post-trigger, Margutti et al. (2017) reported an X-ray non-detection for SSS17a/AT 2017gfo in a $\simeq 25$ ks *Chan-*

3.3. Discovery of the X-ray counterpart

dra exposure⁷, along with the detection of an extended X-ray source whose position was consistent with the host NGC 4993 (R. Margutti et al. 2017). Refined astrometry from subsequent Swift observations confirmed that the previously reported candidate was indeed associated with the host nucleus (Evans et al. 2017; Evans et al. 2017).

Nine days post-trigger, Troja et al. (2017a) reported the discovery of the X-ray counterpart with *Chandra*. In a 50 ks exposure observation they detected significant X-ray emission at the same position of the optical/IR counterpart (Troja et al. 2017, top right panel in Figure 2)⁸. Fifteen days post-trigger, two additional 50 ks *Chandra* observations were made, which confirmed the continued presence of X-ray emission. Based on the first of these two observations^{9,10}: Fong et al. (2017) reported the detection of the X-ray counterpart and the presence of an additional X-ray point source in the near vicinity (R. Margutti et al. 2017), and Troja et al. (2017b) reported a flux of 4.5×10^{-15} erg cm⁻² s⁻¹ for the X-ray counterpart. One day later, Haggard et al. (2017b) reported another deep observation showing continued distinct X-ray emission coincident with SSS17a/AT2017gfo, NGC 4993, and the additional point source (Haggard et al. 2017b,a).¹⁰

Neither *Swift* nor *Chandra* can currently observe GW170817 because it is too close to the Sun ($< 47^\circ$ for *Swift*, $< 46^\circ$ for *Chandra*). Hence, until early December 2017, *NuSTAR* is the only sensitive X-ray observatory that can continue to observe the location of GW170817.

All X-ray observations of GW170817 are summarized in Table 4.

3.4. Discovery of the Radio Counterpart

Radio emission traces fast-moving ejecta from a neutron star coalescence, providing information on the energetics of the explosion, the geometry of the ejecta, as well as the environment of the merger. The spectral and temporal evolution of such emission, coupled with X-ray observations, are likely to constrain several proposed models (see e.g., Nakar & Piran 2011; Piran et al. 2013; Hotokezaka & Piran 2015; Hotokezaka et al. 2016; Gottlieb et al. 2017).

Prior to detection of SSS17a/AT2017gfo, a blind radio survey of cataloged galaxies in the gravitational-wave localization volume commenced with the Australian Telescope Compact Array (ATCA, Wilson et al. 2011), and observed the merger events location on August 18, 2017 at 01:46 UTC (Kaplan et al. 2017a). In addition, the Long Wave-

length Array 1 (LWA1, Ellingson et al. 2013) followed up the gravitational-wave localization 6.5 hr after the time of coalescence (Callister et al. 2017a). A preliminary analysis suggested the possible presence of a variable radio source (Callister et al. 2017b). Analysis of follow-up observations, however, proved inconclusive. Further study of the LWA1 data is ongoing, including the exploration of flux density upper limits at 25 and 45 MHz.

The first reported radio observations of the optical transient SSS17a/AT2017gfo's location occurred on Aug 18 at 02:09:00 UTC (T0+13.5 hr) with the Karl G. Jansky Very Large Array (VLA) by Alexander et al. (2017a).¹¹ Initially attributed to the optical transient, this radio source was later established to be an AGN in the nucleus of the host galaxy, NGC 4993 (Alexander et al. 2017b; K. Alexander et al. 2017). Subsequent observations with several radio facilities spanning a wide range of radio and millimeter frequencies continued to detect the AGN, but did not reveal radio emission at the position of the transient (Bannister et al. 2017a; Kaplan et al. 2017a; De et al. 2017a; Alexander et al. 2017c; Corsi et al. 2017a,b; De et al. 2017b; Mooley et al. 2017a; Lynch et al. 2017a; Corsi et al. 2017c; Lynch et al. 2017b,c; Resmi et al. 2017).

The first radio counterpart detection consistent with the HST position (refined by Gaia astrometry) of SSS17a/AT2017gfo (Adams et al. 2017) was obtained with the VLA on September 2 and 3, 2017 at two different frequencies (≈ 3 GHz and ≈ 6 GHz) via two independent observations: the Jansky VLA mapping of Gravitational Wave bursts as Afterglows in Radio (JAGWAR)¹² (Mooley et al. 2017b) and VLA/16A-206¹³ (Corsi et al. 2017d). Marginal evidence for radio excess emission at the location of SSS17a/AT2017gfo was also confirmed in ATCA images taken on September 5 at similar radio frequencies (≈ 7.25 GHz; Murphy et al. 2017). Subsequent repeated detections spanning multiple frequencies have confirmed an evolving transient (Hallinan et al. 2017, Hallinan, Corsi et al. 2017, Corsi et al., 2017, Mooley et al. 2017). Independent observations carried out on September 5, 2017 with the same frequency and exposure time used by Corsi et al. (2017d) did not detect any emission to a $5\text{-}\sigma$ limit¹⁴ (Alexander et al. 2017d), but this group also subsequently detected the radio counterpart on September 25 2017 (Alexander et al. 2017e; K. Alexander et al. 2017).

SSS17a/AT2017gfo, as well as other parts of the initial gravitational-wave localization area, were and are also being continuously monitored at a multitude of different frequencies with the Atacama Large Millimeter Array

(ALMA; Wootten & Thompson 2009; Schulze et al. 2017; Kim et al. 2017; K. Alexander et al. 2017; Williams et al. 2017a), the Australian Square Kilometre Array Pathfinder (ASKAP; Johnston et al. 2007), ASKAP-Fast Radio Burst (Bannister et al. 2017b; Bannister et al. 2017), ATCA, Effelsberg-100 m (Barr et al. 2013), the Giant Metrewave Radio Telescope (GMRT; Swarup et al. 1991), the Low Frequency Array (LOFAR; van Haarlem et al. 2013), the Long Wavelength Array (LWA1), MeerKAT (Goedhart et al. 2017a), the Murchison Widefield Array (MWA; Tingay et al. 2013), Parkes-64 m (SUPERB, Bailes et al. 2017a, Keane et al. 2017), Sardinia Radio Telescope (SRT; Prandoni et al. 2017), VLA, VLA Low Band Ionosphere and Transient Experiment (VLITE; Clarke et al. 2016), and also using the very long baseline interferometry (VLBI) technique with e-MERLIN (Moldon et al. 2017a,b), the European VLBI Network (Paragi et al. 2017a,b), and the Very Long Baseline Array (VLBA; Deller et al. 2017a,b). The latter have the potential to resolve (mildly) relativistic ejecta on a timescale of months.

Table 5 summarizes the radio observations of GW170817.

3.5. Neutrinos

The detection of GW170817 was rapidly followed up by the IceCube (Aartsen et al. 2017) and ANTARES (Ageron et al. 2011) neutrino observatories and the Pierre Auger Observatory (Aab et al. 2015a) to search for coincident, high-energy (GeV-EeV) neutrinos emitted in the relativistic outflow produced by the BNS merger. The results from these observations, described briefly below, can be used to constrain the properties of relativistic outflows driven by the merger (Albert, A., et al. 2017, in prep.).

In a search for muon-neutrino track candidates (Aartsen et al. 2016), and contained neutrino events of any flavor (Aartsen et al. 2015), IceCube identified no neutrinos that were directionally coincident with the final localization of GW170817 at 90% credible level, within ± 500 s of the merger (Bartos et al. 2017a,b). Additionally, no MeV supernova neutrino burst signal was detected coincident with the merger. Following the identification via electromagnetic observations of the host galaxy of the event, IceCube also carried out an extended search in the direction of NGC 4993 for neutrinos within the 14-day period following the merger, but found no significant neutrino emission (Albert, A., et al. 2017, in prep.).

A neutrino search for up-going high-energy muon neutrinos was carried out using the online ANTARES data stream

(Ageron et al. 2017a). No up-going neutrino candidates were found over a $t_c \pm 500$ s time window. The final localization of GW170817 (The LIGO Scientific Collaboration et al. 2017c) was above the ANTARES horizon at the time of the GW event. A search for down-going muon neutrinos was thus performed and no neutrinos were found over $t_c \pm 500$ s (Ageron et al. 2017b). A search for neutrinos originating from below the ANTARES horizon, over an extended period of 14 days after the merger, was also performed, without yielding significant detection (Albert, A., et al. 2017, in prep.).

The Pierre Auger Observatory carried out a search for ultra high-energy (UHE) neutrinos above $\sim 10^{17}$ eV using its Surface Detector (Aab et al. 2015a). UHE neutrino-induced extensive air showers produced either by interactions of downward-going neutrinos in the atmosphere or by decays of tau leptons originating from tau neutrino interactions in the Earth’s crust can be efficiently identified above the background of the more numerous ultra-high energy cosmic rays (Aab et al. 2015b). Remarkably, the position of the transient in NGC 4993 was just between 0.3 and 3.2 degrees below the horizon during $t_c \pm 500$ s. This region corresponds to the most efficient geometry for Earth-skimming tau neutrino detection at 10^{18} eV energies. No neutrino candidates were found in $t_c \pm 500$ s (Alvarez-Muniz et al. 2017) nor in a 14-day period after it (Albert, A., et al. 2017, in prep.).

4. CONCLUSION

For the first time, gravitational and electromagnetic waves from a single source have been observed. The gravitational wave observation of a binary neutron star merger is the first of its kind. The electromagnetic observations further support the interpretation of the nature of the binary, and comprise three components at different wavelengths: (i) a prompt, sGRB which demonstrates that BNS mergers are the central engine of at least a fraction of such bursts; (ii) an ultraviolet, optical and infrared transient (kilonova), which allows for the identification of the host galaxy and is associated with the aftermath of the BNS merger; and (iii) delayed X-ray and radio counterparts which provide information on the environment of the binary. These observations, described in detail in the companion articles cited above, offer a comprehensive, sequential description of the physical processes related to the merger of a binary neutron star. The results of this campaign demonstrate the importance of collaborative gravitational-wave, electromagnetic and neutrino observations, and mark a new era in multi-messenger, time-domain astronomy.

APPENDIX

A. SUPPLEMENTARY INFORMATION

Table 1. A partial summary of photometric observations up to Sep 5 2017 UTC with at most 3 observations per filter per telescope/group, i.e. the earliest, the peak, and the latest in each case. This is a subset of all the observations made in order to give a sense of the substantial coverage of this event.

‡ Deceased, 18 August 2017.

§ Deceased, August 2016.

Acknowledgements: (1M2H) We thank J. McIver for alerting us to the LVC circular. We thank J. Mulchaey (Carnegie Observatories director), L. Infante (Las Campanas Observatory director), and the entire Las Campanas staff for their extreme dedication, professionalism, and excitement, all of which were critical in the discovery of the first gravitational wave optical counterpart and its host galaxy as well as the observations used in this study. We thank I. Thompson and the Carnegie Observatory Time Allocation Committee for approving the Swope Supernova Survey and scheduling our program. We thank the University of Copenhagen, DARK Cosmology Centre, and the Niels Bohr International Academy for hosting D.A.C., R.J.F., A.M.B., E.R., and M.R.S. during the discovery of GW170817/SSS17a. R.J.F., A.M.B., and E.R. were participating in the Kavli Summer Program in Astrophysics, “Astrophysics with gravitational wave detections.” This program was supported by the the Kavli Foundation, Danish National Research Foundation, the Niels Bohr International Academy, and the DARK Cosmology Centre. The UCSC group is supported in part by NSF grant AST-1518052, the Gordon & Betty Moore Foundation, the Heising-Simons Foundation, generous donations from many individuals through a UCSC Giving Day grant, and from fellowships from the Alfred P. Sloan Foundation (R.J.F.), the David and Lucile Packard Foundation (R.J.F. and E.R.) and the Niels Bohr Professorship from the DNRF (E.R.). A.M.B. acknowledges support from a UCMEXUS-CONACYT Doctoral Fellowship. Support for this work was provided by NASA through Hubble Fellowship grants HST-HF-51348.001 (B.J.S.) and HST-HF-51373.001 (M.R.D.) awarded by the Space Telescope Science Institute, which is operated by the Association of Universities for Research in Astronomy, Inc., for NASA, under contract NAS5-26555. This paper includes data gathered with the 1 meter Swope and 6.5 meter Magellan Telescopes located at Las Campanas Observatory, Chile.

(AGILE) The AGILE Team thank the ASI management, the technical staff at the ASI Malindi ground station, the technical support team at the ASI Space Science Data Center, and the Fucino AGILE Mission Operation Center. AGILE is an ASI space mission developed with programmatic support by INAF and INFN. We acknowledge partial support through the ASI grant no. I/028/12/2. We also thank INAF, Italian Institute of Astrophysics, and ASI, Italian Space Agency.

(Antares) The ANTARES Collaboration acknowledges the financial support of: Centre National de la Recherche Scientifique (CNRS), Commissariat à l’énergie atomique et aux énergies alternatives (CEA), Commission Européenne (FEDER fund and Marie Curie Program), Institut Universitaire de France (IUF), IdEx program and UnivEarthS Labex program at Sorbonne Paris Cité (ANR-10-LABX-0023 and ANR-11-IDEX-0005-02), Labex OCEVU (ANR-11-LABX-

0060) and the A*MIDEX project (ANR-11-IDEX-0001-02), Région Île-de-France (DIM-ACAV), Région Alsace (contrat CPER), Région Provence-Alpes-Côte d’Azur, Département du Var and Ville de La Seyne-sur-Mer, France; Bundesministerium für Bildung und Forschung (BMBF), Germany; Istituto Nazionale di Fisica Nucleare (INFN), Italy; Nederlandse organisatie voor Wetenschappelijk Onderzoek (NWO), the Netherlands; Council of the President of the Russian Federation for young scientists and leading scientific schools supporting grants, Russia; National Authority for Scientific Research (ANCS), Romania; Ministerio de Economía y Competitividad (MINECO): Plan Estatal de Investigación (refs. FPA2015-65150-C3-1-P, -2-P and -3-P, (MINECO/FEDER)), Severo Ochoa Centre of Excellence and MultiDark Consolider (MINECO), and Prometeo and Grisolfá programs (Generalitat Valenciana), Spain; Ministry of Higher Education, Scientific Research and Professional Training, Morocco. We also acknowledge the technical support of Ifremer, AIM and Foselev Marine for the sea operation and the CC-IN2P3 for the computing facilities.

(AST3) The AST3 project is supported by the National Basic Research Program (973 Program) of China (Grant Nos. 2013CB834901, 2013CB834900, 2013CB834903), and the Chinese Polar Environment Comprehensive Investigation & Assessment Program (Grand No. CHINARE2016-02-03-05). The construction of the AST3 telescopes has received fundings from Tsinghua University, Nanjing University, Beijing Normal University, University of New South Wales, and Texas A&M University, the Australian Antarctic Division, and the National Collaborative Research Infrastructure Strategy (NCRIS) of Australia. It has also received fundings from Chinese Academy of Sciences through the Center for Astronomical Mega-Science and National Astronomical Observatory of China (NAOC).

(Astrosat) We thank the “Indo-US Science and Technology Forum.” CZTI is built by a TIFR-led consortium of institutes across India, including VSSC, ISAC, IUCAA, SAC and PRL. The Indian Space Research Organisation funded, managed and facilitated the project.

(Auger) The successful installation, commissioning, and operation of the Pierre Auger Observatory would not have been possible without the strong commitment and effort from the technical and administrative staff in Malargüe. We are very grateful to the following agencies and organizations for financial support: Argentina – Comisión Nacional de Energía Atómica; Agencia Nacional de Promoción Científica y Tecnológica (ANPCyT); Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET); Gobierno de la Provincia de Mendoza; Municipalidad de Malargüe; NDM Holdings and Valle Las Leñas; in gratitude for their continuing cooperation over land access; Australia – the Australian Research Council; Brazil – Conselho Nacional de

Desenvolvimento Científico e Tecnológico (CNPq); Financiadora de Estudos e Projetos (FINEP); Fundação de Amparo à Pesquisa do Estado de Rio de Janeiro (FAPERJ); São Paulo Research Foundation (FAPESP) Grants No. 2010/07359-6 and No. 1999/05404-3; Ministério da Ciência, Tecnologia, Inovações e Comunicações (MCTIC); Czech Republic – Grant No. MSMT CR LG15014, LO1305, LM2015038 and CZ.02.1.01/0.0/0.0/16_013/0001402; France – Centre de Calcul IN2P3/CNRS; Centre National de la Recherche Scientifique (CNRS); Conseil Régional Ile-de-France; Département Physique Nucléaire et Corpusculaire (PNC-IN2P3/CNRS); Département Sciences de l’Univers (SDU-INSU/CNRS); Institut Lagrange de Paris (ILP) Grant No. LABEX ANR-10-LABX-63 within the Investissements d’Avenir Programme Grant No. ANR-11-IDEX-0004-02; Germany – Bundesministerium für Bildung und Forschung (BMBF); Deutsche Forschungsgemeinschaft (DFG); Finanzministerium Baden-Württemberg; Helmholtz Alliance for Astroparticle Physics (HAP); Helmholtz-Gemeinschaft Deutscher Forschungszentren (HGF); Ministerium für Innovation, Wissenschaft und Forschung des Landes Nordrhein-Westfalen; Ministerium für Wissenschaft, Forschung und Kunst des Landes Baden-Württemberg; Italy – Istituto Nazionale di Fisica Nucleare (INFN); Istituto Nazionale di Astrofisica (INAF); Ministero dell’Istruzione, dell’Università e della Ricerca (MIUR); CETEMPS Center of Excellence; Ministero degli Affari Esteri (MAE); Mexico – Consejo Nacional de Ciencia y Tecnología (CONACYT) No. 167733; Universidad Nacional Autónoma de México (UNAM); PAPIIT DGAPA-UNAM; The Netherlands – Ministerie van Onderwijs, Cultuur en Wetenschap; Nederlandse Organisatie voor Wetenschappelijk Onderzoek (NWO); Stichting voor Fundamenteel Onderzoek der Materie (FOM); Poland – National Centre for Research and Development, Grants No. ERA-NET-ASPERA/01/11 and No. ERA-NET-ASPERA/02/11; National Science Centre, Grants No. 2013/08/M/ST9/00322, No. 2013/08/M/ST9/00728 and No. HARMONIA 5–2013/10/M/ST9/00062, UMO-2016/22/M/ST9/00198; Portugal – Portuguese national funds and FEDER funds within Programa Operacional Factores de Competitividade through Fundação para a Ciência e a Tecnologia (COMPETE); Romania – Romanian Authority for Scientific Research ANCS; CNDI-UEFISCDI partnership projects Grants No. 20/2012 and No. 194/2012 and PN 16 42 01 02; Slovenia – Slovenian Research Agency; Spain – Comunidad de Madrid; Fondo Europeo de Desarrollo Regional (FEDER) funds; Ministerio de Economía y Competitividad; Xunta de Galicia; European Community 7th Framework Program Grant No. FP7-PEOPLE-2012-IEF-328826; USA – Department of Energy, Contracts No. DE-AC02-07CH11359, No. DE-FR02-04ER41300, No. DE-FG02-99ER41107 and No. DE-SC0011689; National Science

Foundation, Grant No. 0450696; The Grainger Foundation; Marie Curie-IRSES/EPLANET; European Particle Physics Latin American Network; European Union 7th Framework Program, Grant No. PIRSES-2009-GA-246806; European Union’s Horizon 2020 research and innovation programme (Grant No. 646623); and UNESCO.

(Australian Radio) TM acknowledges the support of the Australian Research Council through grant FT150100099. SO acknowledges the Australian Research Council grant Laureate Fellowship FL15010014. DLK and ISB are additionally supported by NSF grant AST-141242. PAB and the DFN team acknowledge the Australian Research Council for support under their Australian Laureate Fellowship scheme. The Australia Telescope Compact Array is part of the Australia Telescope National Facility which is funded by the Australian Government for operation as a National Facility managed by CSIRO. This scientific work makes use of the Murchison Radio-astronomy Observatory, operated by CSIRO. We acknowledge the Wajarri Yamatji people as the traditional owners of the Observatory site. Support for the operation of the MWA is provided by the Australian Government (NCRIS), under a contract to Curtin University administered by Astronomy Australia Limited. We acknowledge the Pawsey Supercomputing Centre which is supported by the Western Australian and Australian Governments. The Australian SKA Pathfinder is part of the Australia Telescope National Facility which is managed by CSIRO. Operation of ASKAP is funded by the Australian Government with support from the National Collaborative Research Infrastructure Strategy. ASKAP uses the resources of the Pawsey Supercomputing Centre. Establishment of ASKAP, the Murchison Radio-astronomy Observatory and the Pawsey Supercomputing Centre are initiatives of the Australian Government, with support from the Government of Western Australia and the Science and Industry Endowment Fund. Parts of this research were conducted by the Australian Research Council Centre of Excellence for All-sky Astrophysics in 3D (ASTRO 3D) through project number CE170100013.

(Berger time-domain group) The Berger Time-Domain Group at Harvard is supported in part by the NSF through grants AST-1411763 and AST-1714498, and by NASA through grants NNX15AE50G and NNX16AC22G.

(Bootes) AJCT acknowledges support from the Spanish Ministry Project AYA 2015-71718-R (including FEDER funds) and Junta de Andalucía Proyecto de Excelencia TIC-2839. IHP acknowledges the support of the National Research Foundation (NRF-2015R1A2A1A01006870). SJ acknowledges the support of Korea Basic Science Research Program (NRF2014R1A6A3A03057484 and NRF-2015R1D1A4A01020961). We are also grateful to the staff of the Observatorio Astronomico Nacional de San Pedro Martir for their support.

(CAASTRO) Parts of this research were conducted by the Australian Research Council Centre of Excellence for All-sky Astrophysics (CAASTRO), through project number CE110001020. The national facility capability for SkyMapper has been funded through ARC LIEF grant LE130100104 from the Australian Research Council, awarded to the University of Sydney, the Australian National University, Swinburne University of Technology, the University of Queensland, the University of Western Australia, the University of Melbourne, Curtin University of Technology, Monash University and the Australian Astronomical Observatory. SkyMapper is owned and operated by The Australian National University's Research School of Astronomy and Astrophysics.

(CALET) The CALET team gratefully acknowledges support from NASA, ASI, JAXA and MEXT KAKENHI Grant Number JP 17H06362, JP26220708 and JP17H02901.

(Chandra/McGill) This work was supported in part by Chandra Award Number GO7-18033X, issued by the Chandra X-ray Observatory Center, which is operated by the Smithsonian Astrophysical Observatory for and on behalf of the National Aeronautics Space Administration (NASA) under contract NAS8-03060. Daryl Haggard, Melania Nynka, and John J. Ruan acknowledge support from a Natural Sciences and Engineering Research Council of Canada (NSERC) Discovery Grant and a Fonds de recherche du Québec–Nature et Technologies (FRQNT) Nouveaux Chercheurs Grant. Phil A. Evans acknowledges UKSA support. Jamie A. Kennea acknowledges the support of NASA grant NAS5-00136. Daryl Haggard also acknowledges support from the Canadian Institute for Advanced Research (CIFAR).

(CZTI) CZTI is built by a TIFR-led consortium of institutes across India, including VSSC, ISAC, IUCAA, SAC and PRL. The Indian Space Research Organisation funded, managed and facilitated the project.

(DLT40) D.J. Sand acknowledges support for the DLT40 program from NSF grant AST-1517649.

(EuroVLBI) The European VLBI Network is a joint facility of independent European, African, Asian, and North American radio astronomy institutes. Scientific results from data presented in this publication are derived from the following EVN project code: RP029. e-MERLIN is a National Facility operated by the University of Manchester at Jodrell Bank Observatory on behalf of STFC. The collaboration between LIGO/Virgo and EVN/e-MERLIN is part of a project that has received funding from the European Unions Horizon 2020 research and innovation programme under grant agreement No 653477.

(ePESSTO) We acknowledge ESO program 199.D-0143 and 099.D-0376. PS1 and ATLAS are supported by NASA Grants NNX08AR22G, NNX12AR65G, NNX14AM74G,

and NNX12AR55G. We acknowledge the Leibniz-Prize to Prof. G. Hasinger (DFG grant HA 1850/28-1). The Pan-STARRS1 Surveys (PS1) were made possible by the IfA, University of Hawaii, the Pan-STARRS Project Office, the Max-Planck Society, MPIA Heidelberg and MPE Garching, Johns Hopkins University, Durham University, University of Edinburgh, Queen's University Belfast, Harvard-Smithsonian Center for Astrophysics, Las Cumbres Observatory Global Telescope Network Incorporated, National Central University of Taiwan, Space Telescope Science Institute, National Science Foundation under Grant No. AST-1238877, University of Maryland, and Eotvos Lorand University (ELTE) and the Los Alamos National Laboratory. EU/FP7-ERC Grants 291222, 615929, 647208, 725161 STFC grants ST/P000312/1 and ERF ST/M005348/1, ST/P000495/1. Marie Skłodowska-Curie grant No 702538. Polish NCN grant OPUS 2015/17/B/ST9/03167, Knut and Alice Wallenberg Foundation. PRIN-INAF 2014. David and Ellen Lee Prize Postdoctoral Fellowship at the California Institute of Technology. Alexander von Humboldt Sofja Kovalevskaja Award. Royal Society - Science Foundation Ireland Vilho, Yrjö and Kalle Väisälä Foundation. FONDECYT grant number 3160504. US NSF Grant AST-1311862. Swedish Research Council and the Swedish Space Board. The Quantum Universe I-Core program, the ISF, BSF and Kimmel award. IRC grant GOIPG/2017/1525. Australian Research Council CAASTRO CE110001020 and grant FT160100028. We acknowledge Millennium Science Initiative grant IC120009.

(FermiGBM) B.C., V.C., A.G., and W.S.P gratefully acknowledge NASA funding through contract NNM13AA43C. M.S.B, R.H., P.J., C.A.M, S.P., R.D.P., M.S., and P.V. gratefully acknowledge NASA funding from co-operative agreement NNM11AA01A. E.B. is supported by an appointment to the NASA Postdoctoral Program at the Goddard Space Flight Center, administered by Universities Space Research Association under contract with NASA. D.K., C.A.W.H., C.M.H., and J.R. gratefully acknowledge NASA funding through the *Fermi* GBM project. Support for the German contribution to GBM was provided by the Bundesministerium für Bildung und Forschung (BMBF) via the Deutsches Zentrum für Luft und Raumfahrt (DLR) under contract number 50 QV 0301. A.v.K. was supported by the Bundesministeriums für Wirtschaft und Technologie (BMWi) through DLR grant 50 OG 1101. S.M.B acknowledges support from Science Foundation Ireland under grant 12/IP/1288.

(FermiLAT) The *Fermi*-LAT Collaboration acknowledges support for LAT development, operation and data analysis from NASA and DOE (United States), CEA/Irfu and IN2P3/CNRS (France), ASI and INFN (Italy), MEXT, KEK, and JAXA (Japan), and the K.A. Wallenberg Foundation, the Swedish Research Council and the National Space Board

(Sweden). Science analysis support in the operations phase from INAF (Italy) and CNES (France) is also gratefully acknowledged. This work performed in part under DOE Contract DE-AC02-76SF00515.

(FRBSG) SLL is supported by NSF grant PHY-1607291 (LIU). Construction of the LWA has been supported by the Office of Naval Research under Contract N00014-07-C-0147. Support for operations and continuing development of the LWA1 is provided by the National Science Foundation under grants AST-1139963 and AST-1139974 of the University Radio Observatory program.

(GRAWITA) We acknowledge INAF for supporting the project “Gravitational Wave Astronomy with the first detections of adLIGO and adVIRGO experiments - GRAWITA” PI: E. Brocato. Observations are made with ESO Telescopes at the Paranal Observatory under programmes ID 099.D-0382 (PI: E.Pian), 099.D-0622 (PI: P. D’Avanzo), 099.D-0191 (PI: A. Grado) and with the REM telescope at the ESO La Silla Observatory under program ID 35020 (PI: S. Campana). We thank the ESO operation staff for excellent support of this program. The Sardinia Radio Telescope (SRT) is funded by the Department of University and Research (MIUR), the Italian Space Agency (ASI), and the Autonomous Region of Sardinia (RAS) and is operated as National Facility by the National Institute for Astrophysics (INAF).

(GROND) Part of the funding for GROND was generously granted from the Leibniz-Prize to Prof. G. Hasinger (DFG grant HA 1850/28-1). We acknowledge the excellent help in obtaining GROND data from Angela Hempel, Markus Rabus and Régis Lachaume on La Silla.”

(GROWTH, JAGWAR, Caltech-NRAO, TTU-NRAO and NuSTAR) This work was supported by the GROWTH (Global Relay of Observatories Watching Transients Happen) project funded by the National Science Foundation under PIRE Grant No 1545949. GROWTH is a collaborative project among California Institute of Technology (USA), University of Maryland College Park (USA), University of Wisconsin Milwaukee (USA), Texas Tech University (USA), San Diego State University (USA), Los Alamos National Laboratory (USA), Tokyo Institute of Technology (Japan), National Central University (Taiwan), Indian Institute of Astrophysics (India), Inter-University Center for Astronomy and Astrophysics (India), Weizmann Institute of Science (Israel), The Oskar Klein Centre at Stockholm University (Sweden), Humboldt University (Germany), Liverpool John Moores University (UK). AH acknowledges support by the I-Core Program of the Planning and Budgeting Committee and the Israel Science Foundation. TM acknowledges the support of the Australian Research Council through grant FT150100099. Parts of this research were conducted by the Australian Research Council Centre of Excellence for

All-sky Astrophysics (CAASTRO), through project number CE110001020. The Australia Telescope Compact Array is part of the Australia Telescope National Facility which is funded by the Australian Government for operation as a National Facility managed by CSIRO. DLK is additionally supported by NSF grant AST-1412421. AAM is funded by the Large Synoptic Survey Telescope Corporation in support of the Data Science Fellowship Program. PCY, CCN and WHI thank the support from grant MOST104-2923-M-008-004-MY5 and MOST106-2112-M-008-007. AC acknowledges support from the National Science Foundation CAREER award 1455090, “CAREER: Radio and gravitational-wave emission from the largest explosions since the Big Bang. TP acknowledges the support of Advanced ERC grant TRex (TP). BEC thanks SMARTS 1.3-m Queue Manager Bryndis Cruz for prompt scheduling of the SMARTS observations. Basic research in radio astronomy at the Naval Research Laboratory (NRL) is funded by 6.1 Base funding. Construction and installation of VLITE was supported by NRL Sustainment Restoration and Maintenance funding. K.P.M’s research is supported by the Oxford Centre for Astrophysical Surveys which is funded through the Hintze Family Charitable Foundation. JS and AG are grateful for support from the Knut and Alice Wallenberg Foundation. GREAT is funded by the Swedish Research Council (VR). E.O.O. is grateful for the support by grants from the Israel Science Foundation, Minerva, Israeli ministry of Science, the US-Israel Binational Science Foundation, and the I-CORE Program of the Planning and Budgeting Committee and The Israel Science Foundation. We thank the staff of the GMRT that made these observations possible. The GMRT is run by the National Centre for Radio Astrophysics of the Tata Institute of Fundamental Research. A.Y.Q.H. was supported by a National Science Foundation Graduate Research Fellowship under Grant No. DGE-1144469. SR has been supported by the Swedish Research Council (VR) under grant number 2016 03657 3 , by the Swedish National Space Board under grant number Dnr. 107/16 and by the research environment grant “Gravitational Radiation and Electromagnetic Astrophysical Transients (GREAT)” funded by the Swedish Research council (VR) under Dnr 2016-06012.

(HAWC) We acknowledge the support from: the US National Science Foundation (NSF); the US Department of Energy Office of High-Energy Physics; the Laboratory Directed Research and Development (LDRD) program of Los Alamos National Laboratory; Consejo Nacional de Ciencia y Tecnología (CONACyT), Mexico (grants 271051, 232656, 167281, 260378, 179588, 239762, 254964, 271737, 258865, 243290); Red HAWC, Mexico; DGAPA-UNAM (grants RG100414, IN111315, IN111716-3, IA102715, 109916); VIEP-BUAP; the University of Wisconsin Alumni Research Foundation; the Institute of Geophysics, Planetary Physics,

and Signatures at Los Alamos National Laboratory; Polish Science Centre grant DEC-2014/13/B/ST9/945.

(H.E.S.S.) The support of the Namibian authorities and of the University of Namibia in facilitating the construction and operation of H.E.S.S. is gratefully acknowledged, as is the support by the German Ministry for Education and Research (BMBF), the Max Planck Society, the German Research Foundation (DFG), the Alexander von Humboldt Foundation, the Deutsche Forschungsgemeinschaft, the French Ministry for Research, the CNRS-IN2P3 and the Astroparticle Interdisciplinary Programme of the CNRS, the U.K. Science and Technology Facilities Council (STFC), the IPNP of the Charles University, the Czech Science Foundation, the Polish National Science Centre, the South African Department of Science and Technology and National Research Foundation, the University of Namibia, the National Commission on Research, Science and Technology of Namibia (NCRST), the Innsbruck University, the Austrian Science Fund (FWF), and the Austrian Federal Ministry for Science, Research and Economy, the University of Adelaide and the Australian Research Council, the Japan Society for the Promotion of Science and by the University of Amsterdam. We appreciate the excellent work of the technical support staff in Berlin, Durham, Hamburg, Heidelberg, Palaiseau, Paris, Saclay, and in Namibia in the construction and operation of the equipment. This work benefited from services provided by the H.E.S.S. Virtual Organisation, supported by the national resource providers of the EGI Federation.

(Insight-HXMT) The *Insight-HXMT* team acknowledges the support from the China National Space Administration (CNSA), the Chinese Academy of Sciences (CAS, Grant No. XDB23040400), and the Ministry of Science and Technology of China (MOST, Grant No. 2016YFA0400800).

(IceCube) We acknowledge the support from the following agencies: U.S. National Science Foundation-Office of Polar Programs, U.S. National Science Foundation-Physics Division, University of Wisconsin Alumni Research Foundation, the Grid Laboratory Of Wisconsin (GLOW) grid infrastructure at the University of Wisconsin - Madison, the Open Science Grid (OSG) grid infrastructure; U.S. Department of Energy, and National Energy Research Scientific Computing Center, the Louisiana Optical Network Initiative (LONI) grid computing resources; Natural Sciences and Engineering Research Council of Canada, WestGrid and Compute/Calcul Canada; Swedish Research Council, Swedish Polar Research Secretariat, Swedish National Infrastructure for Computing (SNIC), and Knut and Alice Wallenberg Foundation, Sweden; German Ministry for Education and Research (BMBF), Deutsche Forschungsgemeinschaft (DFG), Helmholtz Alliance for Astroparticle Physics (HAP), Initiative and Networking Fund of the Helmholtz Association, Germany; Fund for Scientific Research (FNRS-

FWO), FWO Odysseus programme, Flanders Institute to encourage scientific and technological research in industry (IWT), Belgian Federal Science Policy Office (Belspo); Marsden Fund, New Zealand; Australian Research Council; Japan Society for Promotion of Science (JSPS); the Swiss National Science Foundation (SNSF), Switzerland; National Research Foundation of Korea (NRF); Villum Fonden, Danish National Research Foundation (DNRF), Denmark.

(IKI-GW) ASP, AAV, EDM, and PYuM acknowledge the support from the Russian Science Foundation (grant 15-12-30015). VAK, AVK, IVR acknowledge the Science and Education Ministry of Kazakhstan (grant No. 0075/GF4). RI is grateful to the grant RUSTAVELI FR/379/6-300/14 for a partial support. We acknowledge the excellent help in obtaining Chilescope data Sergei Pogrebsskiy and Ivan Rubzov.

(INTEGRAL) This work is based on observations with INTEGRAL, an ESA project with instruments and science data center funded by ESA member states (especially the PI countries: Denmark, France, Germany, Italy, Switzerland, Spain), and with the participation of Russia and the USA. The INTEGRAL SPI project has been completed under the responsibility and leadership of CNES. The SPI-ACS detector system has been provided by MPE Garching/Germany. The SPI team is grateful to ASI, CEA, CNES, DLR, ESA, INTA, NASA and OSTC for their support. The Italian INTEGRAL team acknowledges the support of ASI/INAF agreement n. 2013-025-R.1. RD and AvK acknowledge the German INTEGRAL support through DLR grant 50 OG 1101. AL and RS acknowledge the support from the Russian Science Foundation (grant 14-22-00271). AD is funded by Spanish MINECO/FEDER grant ESP2015-65712-C5-1-R.

(IPN) K. H. is grateful for support under NASA Grant NNX15AE60G. R. L. A. and D. D. F. are grateful for support under RFBR grant 16-29-13009-ofi-m.

(J-GEM) MEXT KAKENHI (JP17H06363, JP15H00788, JP24103003, JP10147214, JP10147207), JSPS KAKENHI (JP16H02183, JP15H02075, JP15H02069, JP26800103, JP25800103), Inter-University Cooperation Program of the MEXT, the NINS program for cross-disciplinary science study, the Toyota Foundation (D11-R-0830), the Mitsubishi Foundation, the Yamada Science Foundation, Inoue Foundation for Science, the National Research Foundation of South Africa.

(KU) The Korea-Uzbekistan Consortium team acknowledges the support from the NRF grant No. 2017R1A3A3001362, and the KASI grant 2017-1-830-03. This research has made use of the KMTNet system operated by KASI.

(Las Cumbres) Support for IA and JB was provided by NASA through the Einstein Fellowship Program, grants PF6-170148 and PF7-180162, respectively. DAH, CM and GH are supported by NSF grant AST-1313484. DP and DM acknowledge support by Israel Science Foundation grant

541/17. This work makes use of observations from the LCO network.

(LIGO and Virgo) The authors gratefully acknowledge the support of the United States National Science Foundation (NSF) for the construction and operation of the LIGO Laboratory and Advanced LIGO as well as the Science and Technology Facilities Council (STFC) of the United Kingdom, the Max-Planck-Society (MPS), and the State of Niedersachsen/Germany for support of the construction of Advanced LIGO and construction and operation of the GEO600 detector. Additional support for Advanced LIGO was provided by the Australian Research Council. The authors gratefully acknowledge the Italian Istituto Nazionale di Fisica Nucleare (INFN), the French Centre National de la Recherche Scientifique (CNRS) and the Foundation for Fundamental Research on Matter supported by the Netherlands Organisation for Scientific Research, for the construction and operation of the Virgo detector and the creation and support of the EGO consortium. The authors also gratefully acknowledge research support from these agencies as well as by the Council of Scientific and Industrial Research of India, the Department of Science and Technology, India, the Science & Engineering Research Board (SERB), India, the Ministry of Human Resource Development, India, the Spanish Agencia Estatal de Investigación, the Vicepresidència i Conselleria d’Innovació, Recerca i Turisme and the Conselleria d’Educació i Universitat del Govern de les Illes Balears, the Conselleria d’Educació, Investigació, Cultura i Esport de la Generalitat Valenciana, the National Science Centre of Poland, the Swiss National Science Foundation (SNSF), the Russian Foundation for Basic Research, the Russian Science Foundation, the European Commission, the European Regional Development Funds (ERDF), the Royal Society, the Scottish Funding Council, the Scottish Universities Physics Alliance, the Hungarian Scientific Research Fund (OTKA), the Lyon Institute of Origins (LIO), the National Research, Development and Innovation Office Hungary (NKFI), the National Research Foundation of Korea, Industry Canada and the Province of Ontario through the Ministry of Economic Development and Innovation, the Natural Science and Engineering Research Council Canada, the Canadian Institute for Advanced Research, the Brazilian Ministry of Science, Technology, Innovations, and Communications, the International Center for Theoretical Physics South American Institute for Fundamental Research (ICTP-SAIFR), the Research Grants Council of Hong Kong, the National Natural Science Foundation of China (NSFC), the China National Space Administration (CNSA) and the Chinese Academy of Sciences (CAS), the Ministry of Science and Technology of China (MOST), the Leverhulme Trust, the Research Corporation, the Ministry of Science and Technology (MOST), Taiwan and the Kavli Foundation. The authors gratefully

acknowledge the support of the NSF, STFC, MPS, INFN, CNRS and the State of Niedersachsen/Germany for provision of computational resources. The MAXI team acknowledges the support by JAXA, RIKEN, and MEXT KAKENHI Grant Number JP 17H06362. The National Radio Astronomy Observatory is a facility of the National Science Foundation operated under cooperative agreement by Associated Universities, Inc. The European VLBI Network is a joint facility of independent European, African, Asian, and North American radio astronomy institutes. Scientific results from data presented in this publication are derived from the following EVN project code: RP029. e-MERLIN is a National Facility operated by the University of Manchester at Jodrell Bank Observatory on behalf of STFC. The collaboration between LIGO/Virgo and EVN/e-MERLIN is part of a project that has received funding from the European Union’s Horizon 2020 research and innovation programme under grant agreement No 653477. We thank Britt Griswold (NASA/GSFC) for graphic arts. PGJ acknowledges ERC–Consolidator grant nr. 647208 We thank the GMRT staff for prompt scheduling of these observations. The GMRT is run by the National Center for Radio Astrophysics of the Tata Institute of Fundamental Research. INAF, Italian Institute of Astrophysics ASI, Italian Space Agency. This work is part of the research program Innovative Research Incentives Scheme (Vernieuwingsimpuls), which is financed by the Netherlands Organization for Scientific Research through the NWO VIDI Grant No. 639.042.612-Nissanke and NWO TOP Grant No. 62002444–Nissanke.

(LOFAR) LOFAR, the Low Frequency Array designed and constructed by ASTRON, has facilities in several countries, that are owned by various parties (each with their own funding sources), and that are collectively operated by the International LOFAR Telescope (ILT) foundation under a joint scientific policy. P.G. Jonker acknowledges support from ERC grant number 647208. R. Fender was partially funded by ERC Advanced Investigator Grant 267607 ‘4 PI SKY.’

(MASTER) Development Programme of Lomonosov Moscow State University, Sergey Bodrov of Moscow Union OPTICA, Russian Scientific Foundation 16-12-00085, National Research Foundation of South Africa, Russian Federation Ministry of Education and Science (14.B25.31.0010, 14.593.21.0005, 3.10131.2017/NM), RFBR 17-52-80133

(MAXI) The MAXI team acknowledges the supports by JAXA, RIKEN, and MEXT KAKENHI Grant Number JP 17H06362.

(Nordic Optical Telescope) JPUF acknowledges the Carlsberg foundation for funding for the NTE project. DX acknowledges the support by the One-Hundred-Talent Program of the Chinese Academy of Sciences (CAS) and by the Strategic Priority Research Program “Multi-wavelength Gravitational Wave Universe” of the CAS (No.

XDB23000000). Based on observations made with the Nordic Optical Telescope (program 55-013), operated by the Nordic Optical Telescope Scientific Association.

(OzGrav) Part of this research was funded by the Australian Research Council Centre of Excellence for Gravitational Wave Discovery (OzGrav), CE170100004 and the Australian Research Council Centre of Excellence for All-sky Astrophysics (CAASTRO), CE110001020. Jeff Cooke acknowledges the Australian Research Council Future Fellowship grant FT130101219. Research support to Igor Andreoni is provided by the Australian Astronomical Observatory (AAO). Adam T. Deller acknowledges the support of an Australian Research Council Future Fellowship (FT150100415). Based in part on data acquired through the Australian Astronomical Observatory. We acknowledge the traditional owners of the land on which the AAT stands, the Gamilaraay people, and pay our respects to elders past and present. The Etelman/VIRT team acknowledge NASA grant NNX13AD28A.

(Pan-STARRS) The Pan-STARRS1 observations were supported in part by the NASA Grant No. NNX14AM74G issued through the SSO Near Earth Object Observations Program and the Queen's University Belfast. The Pan-STARRS1 Surveys were made possible through contributions by the Institute for Astronomy, the University of Hawaii, the Pan-STARRS Project Office, the Max-Planck Society and its participating institutes, the Max Planck Institute for Astronomy, Heidelberg and the Max Planck Institute for Extraterrestrial Physics, Garching, The Johns Hopkins University, Durham University, the University of Edinburgh, the Queen's University Belfast, the Harvard-Smithsonian Center for Astrophysics, the Las Cumbres Observatory Global Telescope Network Incorporated, the National Central University of Taiwan, the Space Telescope Science Institute, and the National Aeronautics and Space Administration under Grant No. NNX08AR22G issued through the Planetary Science Division of the NASA Science Mission Directorate, the National Science Foundation Grant No. AST-1238877, the University of Maryland, Eotvos Lorand University (ELTE), and the Los Alamos National Laboratory. The Pan-STARRS1 Surveys are archived at the Space Telescope Science Institute (STScI) and can be accessed through MAST, the Mikulski Archive for Space Telescopes. Additional support for the Pan-STARRS1 public science archive is provided by the Gordon and Betty Moore Foundation.

(Pi of the sky) The Pi of the Sky team is grateful for the support of the ESA/INTA-CEDEA personnel in Mazagón, Huelva (Spain). Analysis of the Pi of the Sky data was based on the LUIZA software developed within the GLORIA project, funded from the European Union Seventh Framework Programme (FP7/2007-2013) under grant 283783.

(SALT) DB, SMC, ERC, SBP, PV, TW acknowledge support from the South African National Research Foundation. MMS gratefully acknowledges the support of the late Paul Newman and the Newmans Own Foundation.

(SKA) R Fender was partially funded by ERC Advanced Investigator Grant 267607 '4 PI SKY.'

(Swift) Funding for the *Swift* mission in the UK is provided by the UK Space Agency. The *Swift* team at the MOC at Penn State acknowledges support from NASA contract NAS5-00136. The Italian *Swift* team acknowledge support from ASI-INAF grant I/004/11/3.

(TOROS) We thank support from the USA Air Force Office of International Scientific Research (AFOSR/IO), the Dirección de Investigación de la Universidad de La Serena, the Consejo Nacional de Investigaciones Científicas y Técnicas of Argentina, the FAPESP and the Observatorio Nacional-MCT of Brasil.

(TTU group) A. Corsi and N.T. Palliyaguru acknowledge support from the NSF CAREER Award 1455090: "CAREER: Radio and gravitational-wave emission from the largest explosions since the Big Bang. The National Radio Astronomy Observatory is a facility of the National Science Foundation operated under cooperative agreement by Associated Universities, Inc.

(VINROUGE) Based on observations made with ESO telescopes at the La Silla Paranal Observatory under programmes ID 099.D-0668, 099.D-0116, 099.D-0622, 179.A-2010, and 198.D-2010; and with the NASA/ESA Hubble Space Telescope observations under programs GO 14771, GO 14804, GO 14850. The VISTA observations were processed by CGF at the Cambridge Astronomy Survey Unit (CASU), which is funded by the UK Science and Technology Research Council under grant ST/N005805/1. This research used resources provided by the Los Alamos National Laboratory Institutional Computing Program, which is supported by the U.S. Department of Energy National Nuclear Security Administration under Contract No. DE-AC52-06NA25396. We acknowledge support to the following bodies: the ERC (grant #725246); STFC via grant ST/P000495/1; VILLUM FONDEN (investigator grant project number 16599); the Spanish project AYA 2014-58381-P; the Juan de la Cierva Incorporación fellowship IJCI-2014-21669; the Juan de la Cierva Incorporación fellowship IJCI-2015-26153; the NRFK grant No. 2017R1A3A3001362; grants GO718062A and HSTG014850001A; the Swedish Research Council (VR) under grant number 2016-03657-3; the Swedish National Space Board under grant number Dnr. 107/16; the research environment grant "Gravitational Radiation and Electromagnetic Astrophysical Transients (GREAT)" under Dnr 2016-06012; UKSA.

(Zadko) The Zadko Telescope was made possible by a philanthropic donation by James Zadko to the University

of Western Australia (UWA). Zadko Telescope operations are supported by UWA and the Australian Research Council Centre of Excellence OzGrav CE170100004. The TAROT network of telescopes is supported by the French Centre National de la Recherche Scientifique (CNRS), the Observatoire de la Côte d'Azur (OCA), and we thank the expertise and support of the Observatoire des Sciences de l'Univers, Institut Pythéas, Aix-Marseille University. The FIGARONet network is supported under the Agence Nationale de la Recherche (ANR) grant 14-CE33.
