EJE Award 2019 – Biography

Mirjam Christ-Crain is full Professor of Endocrinology, Diabetes and Metabolism at the University of Basel and the University Hospital of Basel, Switzerland. She studied medicine in Basel and Vienna and did her MD in the year 2000 at the University of Basel and completed her PhD degree in 2007 at the University of London followed by her habilitation at the University of Basel in 2007. From 2009 to 2015 she had a research professorship of the Swiss National Science Foundation. Her main research interest is on vasopressin-dependent disorders of fluid homeostasis, i.e. diabetes insipidus and hyponatremia. She authored and co-authored more than 200 publications and received several awards for her research. From 2013, she has been the Deputy Chief at the Clinic for Endocrinology, University Hospital Basel and from 2014 she has been the Head of the Department of Clinical Research at the University of Basel.

The European Journal of Endocrinology Prize Lecture

EJE1

New approaches in the differential diagnosis of Diabetes insipidus

Prof Mirjam Christ-Crain
Switzerland.

The differential diagnosis of hypotonic polyuria is a frequent problem in clinical practice. Three fundamentally different types of defects have to be differentiated: central diabetes insipidus characterized by a lack of the antidiuretic hormone arginine vasopressin; nephrogenic diabetes insipidus characterized by renal insensitivity to arginine vasopressin; and primary polydipsia due to primary excess of fluid intake. The differentiation is crucial as treatment differs substantially and incorrect strategies may lead to severe complications. Since decades the indirect water-deprivation-test is the reference standard for this differentiation. However, it is technically cumbersome and highly vulnerable to false diagnosis. A new test with high diagnostic accuracy is urgently needed. Copeptin is the C-terminal segment of the arginine vasopressin prohormone and is an easy to measure and stable arginine vasopressin surrogate. In patients with hypotonic polyuria, high baseline copeptin levels without prior water deprivation unequivocally identified patients with nephrogenic diabetes insipidus. Conversely, in a large prospective diagnostic study the performance of copeptin after hypertonic saline-infusion was directly compared with that achieved by the water-deprivation-test. Stimulated copeptin levels with a cutoff of 4.9 pmol/L had a high diagnostic accuracy to differentiate between patients with central diabetes insipidus and primary polydipsia, clearly superior to the diagnostic accuracy of the classical water deprivation test. More patients preferred the hypertonic saline plus copeptin test to the water deprivation test, mainly because of its shorter duration. Constant surveillance of plasma sodium levels is important and even simpler test methods should be evaluated. In conclusion, copeptin measured after hypertonic saline infusion has the potential to become the new reference standard in the differential diagnosis of hypotonic polyuria.

ESE Geoffrey Harris Prize 2019 – Biography

Günter K Stalla MD, is Professor of Internal Medicine at the Ludwig-Maximilians University, Munich and medical director of Medicover Neuroendocrinology. For almost 30 years, he has been the head of the Department of Internal Medicine and Clinical Neuroendocrinology in the Max Planck Institute of Psychiatry. He finished his residency at the Medical Clinic IV of the Ludwigs-Maximilians University of Munich. He is auditor for endocrinology, diabetology and andrology at the Bavarian Chamber of Physicians. Günter Stalla has focused his entire career in neuroendocrinology in general and the discovery of pathogenic and therapeutic mechanisms for pituitary diseases in particular. He has more than 400 publications in renowned international journals, including The Lancet, Cell, and Nature Medicine, and supervised clinical trials for the development of new treatment concepts for endocrine diseases. Believing in the importance of education and training, he has been a supervisor and mentor of more than 50 MD and PhD students and early career researchers, several of whom moved on to curve excellent career paths in academia and industry. Prof. Stalla has been founding member and chair of the Neuroendocrinology Section of the German Society of Endocrinology (DGE), former board member and media spokesperson of the DGE and is now the President elect of the DGE. He has served as President and President past of the European NeuroEndocrine Association. He has organized several successful national and international meetings.

The Geoffrey Harris Prize Lecture

GH1

Translational research in pituitary disease

Mr Günter K Stalla
Germany.

The pituitary gland has always held a special allure; so small and yet so complex pathophysiology and clinical presentation. I heard the call of its sirens in the late 70's just after finishing my medical examination and it was the realization of how little we know about pituitary disorders that prompted me to specialize in endocrinology in view of working in neuroendocrinology. In 1990, I got the great fortune to head an endocrine outpatient unit and a research laboratory, which enabled me to embark on a life-long quest on pituitary disorders in general and pituitary tumours in particular, in a truly translational manner. During the years, we identified factors that are deregulated during pituitary tumorigenesis and brought forward novel therapeutics, without forgetting that there is more in our patients than their tumour. Their comorbidities are as complex as the tumour that causes them and cause deep scars that affect their physical wellbeing and quality of life. Almost 30 years later, we undoubtedly know a lot more about the triggering molecular events, but when it comes to patient management, we still rely on improved versions of traditional therapeutics. There is still a long way to go and only with cooperation and rigorous training of the next generation of experts, we can hope one day to defeat this multifaceted devastating disease.

European Hormone Medal 2019 – Biography

Jens Bollerslev is head of the Section of Specialized Endocrinology at Oslo University Hospital, and Professor of Endocrinology at the University of Oslo, Norway. He has been a member of the Executive Board of the European Society of Endocrinology (ESE), former chair of the ESE Education Committee (2014–17), chair of the ESE committee for Post Graduate Courses (2016–19) and is currently chair of the newly established ESE PARAT project. Moreover, he was a member of the ESE Clinical Committee and was involved in the development of ESE Clinical Guidelines. He serves on the Editorial Board of the Journal of Clinical Endocrinology & Metabolism as well as Endocrine. His special interest is within clinical and translational endocrinology, and in particular in classical endocrine diseases, such as Acromegaly and Cushing's, often studying bone as target tissues for clinical activity. A major interest has been devoted to metabolic bone disorders, other than postmenopausal osteoporosis, as illustrated by his work for The Scandinavian Investigation of Primary Hyperparathyroidism. He has a deep interest in the control of bone remodeling as seen in the classical endocrine and inherited metabolic diseases (like Human Osteopetrosis and High Bone Mass Phenotypes), and also in relation to solid organ transplantation. As such, he has published more than 280 papers in international, peer reviewed journals and has been a mentor of more than 20 doctoral thesis projects.

European Hormone Medal Lecture

EHM1

Monogenic Bone Disorders as a Model for Novel Treatment of Osteoporosis

Prof Jens Bollerslev
Norway.

Bone remodeling is a fine tuned process optimizing bone biomechanical properties. Peak bone mass is reached in early adult life, where after bone mass declines in both sexes leading to an increasing risk for low energy fractures. The understanding of bone remodeling has led to pharmacologic treatment of osteoporosis, being different antiresorptive modalities or anabolic treatment with PTH - or analogues. Inherited osteosclerotic bone disorders have been diagnosed since the introduction of radiography. Interestingly, some disorders were prone to pathological fractures, some not. The most severe forms were typically found to be autosomal recessive, whereas mild types were dominantly inherited. Early systematic studies of different osteosclerotic disorders indicated defective bone resorption as a common radiogrammetric and histomorphometric finding, whereas bone formation seemed to be relatively normal. The high bone mass phenotype was described in the Nineties based on family studies of index cases with high BMD. Further genetic studies revealed gain of function mutations in the LRP5 gene in several different family forms, pointing to the *Wnt* signaling pathway as pivotal for bone remodeling. The opposite picture, the Osteoporosis Pseudo-Glioma Syndrome was at the same time found to be caused by a loss of function mutation in *LRP5*. The regulation of the *Wnt* signaling pathway was discovered to be even more complicated by studies of van Buchem's disease and Sclereosteosis in the early Zero'es, discovering Sclerostin produced by the osteocytes as yet another important player in the bone remodeling mosaic. Defective Sclerostin leads to a constitutive activation of *Wnt* with bone formation activation, followed indirectly by inhibition of bone resorption – a new dual concept by Nature. Monoclonal antibodies towards Sclerostin (Romososumab) are by now close to the clinic (approved by FDA) as a new treatment modality for osteoporosis. Fracture prevention seems promising, whereas potential cardiovascular side effects are investigated.

DOI: 10.1530/endoabs.63.EHM1

Clinical Endocrinology Trust Award 2019 – Biography

Susan M. Webb was born and qualified from Medical School in Barcelona, Spain, and completed training at St. Bartholomew's Hospital, London and in San Antonio, Texas. She is a Senior Consultant Endocrinologist at the Hospital Sant Pau, and Professor of Medicine at the Universitat Autònoma de Barcelona. She runs the Neuroendocrine Clinic and the Pituitary Disease network of excellence research group (CIBERER unit 747), interested in the long-term consequences of having suffered pituitary diseases and evaluation of health-related quality of life. She coordinates the European Registry on Cushing's Syndrome (ERCUSYN) initially funded by the EU, has been President of the Spanish Society for Endocrinology and Nutrition, Secretary of ENEA, and until 2018 member of the ESE ExCo; she has served on the editorial boards of JCEM, Pituitary, Endocrine, among others. She has been a member of the European Union Committee of Experts on Rare Diseases (EUCERD), and is currently Scientific Assistant Director of CIBERER (Spanish network of excellence for rare diseases) and President of the Rare Disease Advisory Committee of the Catalan health system Catsalut. She has supervised some 20 PhD theses and has (co)-authored over 350 publications (original papers, invited reviews, and book chapters).

Clinical Endocrinology Trust Lecture

CET1

How can patients' perception of outcome be improved after controlling pituitary disease?

Prof Susan M Webb
Spain.

As endocrinologists, we consider a patient with a pituitary disease is controlled if hormone parameters are normalized and tumour growth is stabilized. However, the patients' perception of health is related to whether they can continue performing their daily life, both personal and professional; this is often not the case due to pain, physical or psychological limitations or social/family issues related to their disease. This is more relevant nowadays that pituitary dysfunction can be controlled in most cases, either after surgery or with medical therapy. In the last 2 decades, the long-term impact of prior exposure to hypercortisolism, excess GH/IGF-I or hypopituitarism on patients' health perceptions have become apparent. More cardiovascular, skeletal and neuropsychological morbidity persist after endocrine 'cure'; the latter include worse memory, cognition, executive function, emotional coping, which often lead to more anxiety, depression and psychological distress, with an important impact on perceived quality of life. Patients' perceptions may be overseen or ignored by health professionals, unless specifically mentioned; in this respect, the personal experiences of 'cured' patients, especially those in some way related to the health system or patient associations are very illustrative. It is recommendable to make patients aware of these problems, by devoted multi-disciplinary teams with an understanding of these persistent issues, so they can adapt to these limitations.This understanding, together with a positive approach to day-to-day life, and comprehension and support from family and friends, contribute to accept this new situation, impacting positively on patients' health perception and long-term prognosis.

Plenary Lectures

Designing Cities and Homes as Exercise Machines: Helping Endocrinologists to Fight Metabolic Disease

PL1

Designing cities and homes as exercise machines: helping endocrinologists to fight metabolic disease

Avi Friedman
Canada.

The obesity epidemic has affected many nations. In Canada, by some estimates, more than 6 million Canadian adults age 20 to 64 are overweight and nearly 3 million are obese. The common tendency is to blame people's dietary choices and sedentary habits. Yet, it can also be argued that poor urban planning practices have largely contributed to a lack of active lifestyles. Low-density suburban sprawl, long commutes, diminishing land for green area and the elimination of sidewalks from local streets are some aspects that have led to reduced physical activity, among residents of all ages. Reversing course and regarding the community and the home as exercise machines need to be a top priority of urban planners and public health officials. Public transit, commercial hubs walking distance away, jogging tracks, bike paths and play spaces should become mandatory features of new residential development. In his presentation, Dr. Avi Friedman, Professor of Architecture at McGill University, recipient of the World Habitat Award and a practicing architect, will illustrate the decline of community planning for healthy living and outline measures that can be reintroduced to foster active lifestyles.

DOI: 10.1530/endoabs.63.PL1

Genetic Epidemiology of Puberty Timing and Reproductive Lifespan (*Endorsed by the European Journal of Endocrinology*)

PL2

Genetic epidemiology of puberty timing and reproductive lifespan

Ken Ong
UK.

Background
The timing of puberty varies widely between individual children. Those in the extreme early or late groups present commonly to endocrine clinics. Furthermore, in population studies the continuum in puberty timing is associated with long-term health outcomes, such as obesity, Type 2 diabetes, sex steroid-sensitive cancers and also with the timing of menopause and reproductive lifespan. This timing is highly heritable. Genome-wide association studies (GWAS), which genotype hundreds of thousands of common genetic variants located across the entire genome, have identified many specific genetic determinants of pubertal timing and these findings have informed the mechanisms that link earlier pubertal timing to increased risks of disease.
Methods & Findings
Through ReproGEN and other large international GWAS consortia, we have identified hundreds of genomic loci with highly robust associations with puberty timing in both sexes, and with menopause timing in women. These studies have shone new light into the biological regulation of the reproductive axis. For puberty timing, many loci implicate genes that regulate the hypothalamo-pituitary-gonadal axis, energy homeostasis and weight gain, and other unanticipated pathways such as genomic imprinting. For menopause timing, DNA damage sensing and repair is the predominant overall mechanism, but there are notable contributions by some hypothalamo-pituitary-gonadal axis genes.
Discussion
This talk will provide an update on GWAS for puberty and menopause timing and will highlight the clinical implications of the findings.

DOI: 10.1530/endoabs.63.PL2

Pancreatic Beta-cell Ageing: Novel Mechanisms and Consequences in the Management of Diabetes

PL3

Pancreatic beta-cell ageing: Novel mechanisms and consequences in the management of diabetes

Susan Bonner-Weir
USA.

Pancreatic beta-cells maintain the body's glucose levels within a very narrow range. In the face of insulin resistance and obesity, most people do not become diabetic due to the ability of the endocrine pancreas to have compensatory growth. Any limitation on replacement or shortening of lifespan could have dire consequences for glucose homeostasis. Type 2 diabetes develops only when b-cells fail to compensate for increased demand from insulin resistance. While Type 2 diabetes (T2D) increases with age with the majority of patients being above the fifth decade of life, the specific contribution of beta cell aging and senescence to diabetes has had limited study. Yet the deficiency in proliferative response to increased demand may arise partly from the accumulation of senescent beta-cells. Cellular senescence is a state in which cells cease to divide but remain metabolically active with an altered phenotype. Cells in general, and presumably beta cells, senesce in response to stressors and aging, resulting in changes in structure and function that may include irreversible growth arrest and alterations in gene expression. With age, an accumulation of dysfunctional senescent beta-cells likely contributes to impaired glucose tolerance and diabetes. From our studies we have shown that there are differently aged beta cells in the adult pancreas. Even in young (3–4 month old) mice, a population of beta-cells express known aging markers (senescence-associated acidic beta-galactosidase activity (b-Gal), *p16Ink4a* and p53BP1) and that this population increased with age. Aged beta-cells had impaired function, characterized by higher basal insulin secretion and a lower recruitment to glucose challenges; senescent beta cell secrete a number of cytokines and chemokines, known as senescence-associated secretory profile (SASP) that have detrimental effects on neighboring cells. Importantly acute insulin resistance, induced by the insulin receptor antagonist S961 or high fat diet, resulted in expression of aging markers suggesting that insulin resistance as a driver of accelerated beta-cell aging. Additionally even mild hyperglycemia induces a markedly changed beta cell phenotype and dysfunction. We will address the relationship between beta-cell aging, the development of diabetes and if there are strategies to decrease the load of aged beta-cells in order to improve cellular identity, function and overall metabolic parameters.

DOI: 10.1530/endoabs.63.PL3

Exercise Training in the Management of Type 2 Diabetes

PL4

Exercise training in the management of type 2 diabetes

Juleen Zierath
Sweden.

Type 2 diabetes mellitus is a life threatening metabolic disease reaching epidemic proportions. Although the molecular basis for this pathology is incompletely understood, genetic and environmental factors, probably in a synergistic manner, contribute to the risk of developing type 2 diabetes. The burden of type 2 diabetes and related co-morbidities on society is enormous, and growing, given that there is no cure in sight. Type 2 diabetes shares many features of 'accelerated aging' including insulin resistance, defective oxidative metabolism/mitochondrial function and loss of muscle mass. Strikingly, long-term participation in vigorous exercise programs mitigates secondary aging and reduces disability and mortality. This association advances the notion that exercise promotes 'healthy aging', reduces the impact of metabolic disease, and improves the quality of life. At the molecular level, exercise results in a rapid, but transient change in the epigenome by modifying DNA methylation of the promoters of key genes regulating mitochondrial function and biogenesis in skeletal muscle. Recent evidence suggests that intimate links between epigenetic regulation and the circadian clock exist that are likely to contribute to the plasticity of insulin sensitive organs to exercise and nutrition. Therefore, we are currently addressing whether synchronizing exercise and nutrient interventions to the molecular circadian clock will maximize the health promoting benefits of exercise to enhance insulin sensitivity and mitochondrial biogenesis. This lecture will present new evidence highlighting exercise-responsive treatment targets and optimal exercise intervention strategies to mitigate secondary aging and prevent metabolic disease.

DOI: 10.1530/endoabs.63.PL4

Paracrine Regulation of the Adrenal Cortex

PL5

Paracrine regulation of the adrenal cortex

Dr Hervé Lefebvre
France.

Numerous *in vitro* studies have shown that the secretory activity of the human adrenal cortex is activated by a wide variety of neuropeptides and conventional neurotransmitters released in the vicinity of adrenocortical cells by chromaffin cells, endothelial cells, adipocytes, cells of the immune system and nerve endings. The role of these paracrine factors in the physiological control of the adrenocortical function remains unclear, especially for cortisol production which is principally dependent on ACTH secretion. However, it appears likely that intraadrenal bioactive signals are involved in the regulation of aldosterone secretion which is partly independent of the renin-angiotensin system. In particular, increasing evidence indicates that aldosterone production is stimulated by neural inputs, leptin and serotonin (5-HT) released by subcapsular mast cells. Interestingly, the occurrence of paracrine regulatory processes has also been reported in adrenocortical hyperplasias and tumors responsible for aldosterone or cortisol excess. These mechanisms roughly involve the same actors as those operating in the normal adrenal but exhibit alterations at various levels which tend to reinforce their potency to increase steroid production. The main defects in the intraadrenal control systems noticed so far include hyperplasia of cells producing the paracrine factors and illicit expression of the latter and their receptors. This new pathophysiological concept is nicely illustrated by mast cell hyperplasia in aldosterone-producing adenomas (APAs) and upregulation of the 5-HT signaling pathway or ectopic synthesis of ACTH in adrenocortical cells in bilateral adrenal hyperplasias responsible for cortisol excess. Upregulated paracrine factors and their receptors are likely to play a significant role in adrenocortical hyperplasia/tumor expansion and associated steroid hypersecretion together with somatic mutations affecting the calcium signaling pathway in APAs or the cAMP/protein kinase A pathway in cortisol-producing adenomas. They also represent new targets for the pharmacological treatment of primary adrenal steroid excess.

DOI: 10.1530/endoabs.63.PL5

Graves Orbitopathy

PL6

Graves Orbitopathy

George Kahaly
Germany.

Graves' orbitopathy (GO) is a rare complex auto-immune disorder which causes substantial morbidity. It can result in orbital disfigurement, double vision and even visual loss. Consequently it has a substantial negative effect on quality of life, mental health and socioeconomic status. The vast majority of patients have Graves' disease (GD), an inflammatory auto-immune condition which is characterized by thyrotropin receptor auto-antibodies (TSHR-Ab). Ocular inflammation at baseline, smoking, TSHR-Ab titre and duration of thyroid dysfunction being the four key risk factors for developing GO in GD. Most of the signs and symptoms of GO can be explained by the expansion of the orbital contents. The orbital fibroblast is the target of a spectrum of autoimmune responses which collectively promote proliferation, excess adipogenesis (formation of new fat cells by differentiation of preadipocytes) and over-production of extra-cellular matrix (ECM). The ECM comprises glycosamino-glycans such as chondroitin sulphate and hyaluronic acid, which is not sulphated but is able to absorb up to 1000 times its weight in water. Steroids are the mainstay of treatment in GO. While this may be a non-specific effect of reducing inflammation and depleting leucocytes, a direct action on the adipocytes including the inhibition of 'browning' processes in orbital fat cells is discussed. Other strategies such as radiotherapy have had their role in combination therapy called into question. Recurrence may occur once steroids are withdrawn. Furthermore, in most cases, normal orbital anatomy is not restored, and skilled rehabilitative surgery is required to reduce disfigurement, double vision and occasionally, to preserve vision. In the last decade, the pathophysiology of GO has also been revised with identification of new potential therapeutic targets. Recent clinical trials have shown that considerable benefit may be derived from the addition of anti-proliferative agents (e.g. mycophenolate sodium) in preventing deterioration after steroid cessation. In addition, targeted biologic therapies have shown promise, including teprotumumab (anti-IGFR) which appears to substantially reduce proptosis, rituximab (anti-CD20) which reduces inflammation and tocilizumab (anti-IL6) which potentially benefits both of these parameters. This review therefore outlines the optimal management of GO and summarises the recent research developments in this area.

Control of Integrative Physiology by the Melanocortin Circuitry

PL7

Control of integrative physiology by the melanocortin circuitry

Jens Claus Brüning
Germany.

Proopiomelanocortin (POMC)- and agouti related peptide (AgRP)-expressing neurons in the arcuate nucleus of the hypothalamus (ARH) are critical regulators of food intake and energy homeostasis. They rapidly integrate the energy state of the organism through sensing fuel availability via hormones, nutrient components and even rapidly upon sensory food perception. Importantly, they not only regulate feeding responses, but numerous autonomic responses including glucose and lipid metabolism, inflammation and blood pressure. More recently, we could demonstrate that sensory food cue-dependent regulation of POMC neurons primes the hepatic endoplasmic reticulum (ER) stress response to prime liver metabolism for the postpramndial state. The presentation will focus on the regulation of these neurons in control of integrative physiology, the identification of distinct neuronal circuitries targeted by these cells and finally on the broad range implications resulting from dysregulation of these circuits as a consequence of altered maternal metabolism.

What is the value of molecular markers in nodules?

Laura Fugazzola
Italy.

Cytological evaluation establishes the diagnosis of a benign or malignant nodule in 70–80% of all cases, but the remaining cases lack the features needed for a definitive diagnosis. Molecular tests have been developed to assist in determining if a nodule with indeterminate cytology is benign or malignant. The first studies focused on the analysis of the most common thyroid cancer (TC) mutation, BRAFV600E. However, since many TCs are driven by other mutations, testing for BRAF alone does not provide sufficiently high negative predictive value (NPV) to avoid surgery for nodules lacking this gene mutation. The sensitivity of molecular testing was improved through the introduction of gene panels, which became available for clinical use in the late 2000s. In addition to BRAF, they tested for several other common genes mutated in TC, and these typically rule-in tests panels detected genetic alterations present in ~70% of cases. The next step in the evolution of molecular testing has involved the use of NGS. The ThyroSeq panels are NGS panels with a high sensitivity and are able to quantitatively assess the proportion of cells carrying a given mutation. In 2012 a 'rule out' test was introduced, namely the Afirma test, which does not rely on detecting gene mutations but is based on the analysis of expression changes in 167 genes. The Afirma test evaluates the gene expression profiles, reports the result as either 'benign' or 'suspicious', and has a high NPV. The main disadvantage of these tests is the high cost, which makes them rarely used in Europe. In order to generate a reliable but cheaper test, we set up a custom Mass Array platform (PTC-MA), which allows the simultaneous detection of the 13 hotspot mutations and seven fusion genes more frequently found in TC, in a time and cost-effective manner.

Iodine refractoriness in thyroid cells

Chris McCabe
UK.

The ability of thyroid cells to specifically uptake radioiodine is frequently compromised in the neoplastic setting, particularly in older patients with poorly differentiated thyroid cancer and larger metastases, resulting in a 10-year survival rate of less than 10%. The mechanisms which govern cellular iodide uptake via the sodium iodide symporter (NIS) have been elucidated with increasing molecular clarity over the past 35 years. NIS is regulated in a tissue-specific manner, and its correct functioning is sensitive to an incredibly wide array of regulatory events, from the genetic to the epigenetic, via miRNAs and lncRNAs, as well as transcription factors, hormones and growth factors, and is particularly at the mercy of activated kinase pathways. New mechanisms regulating NIS activity continue to be identified, shining fresh light on the ways in which thyroid cells become refractory to iodide uptake, particularly in aggressive thyroid cancer. This considerable experimental endeavour is currently driving ongoing clinical trials aimed at overcoming iodine refractoriness, with the consensus view that single agent approaches may not be sufficient to boost NIS function for effective therapy. To this end, new insight into how NIS is intracellularly trafficked and targeted to the plasma membrane is emerging, which may transform our understanding of how to ultimately address iodine refractoriness. Thus combinatorial approaches targeting key components of NIS repression and mislocalisation may finally be able to overcome the iodine refractoriness which is a hallmark of dedifferentiated thyroid cancer, opening the possibility of effective treatment to patients who currently cannot uptake sufficient radioiodine for tumour cell ablation.

Trends in Puberty

S2.1

Exploring the Epigenetic landscape of puberty

Alejandro Lomniczi
USA.

During the infantile-pubertal transition, a diversity of behavioral, physiological, morphological and molecular changes are required in order to attain fertility. An essential step in this process is the reactivation of the pituitary-gonadal axis by increased hypothalamic secretion of Gonadotropin-Releasing Hormone (GnRH). This drives the adenohypophysis to increase the pulsatile release of luteinizing hormone (LH) with diurnal periodicity, the first endocrine sign of pubertal development. The current dogma postulates that diminishing transsynaptic inhibition jointly with increased excitatory inputs is responsible for the reactivation of GnRH release. With the advent of new high throughput genomic technologies today we can interrogate the developing hypothalamus for genome-wide changes in mRNA expression as well as epigenetic modifications associated with gene regulatory/promoter regions. Over the last several years, a plethora of new transcriptional complexes, some of which with epigenetic capabilities have been found to be involved in the hypothalamic control of pubertal development. Here, we will review the contribution of several families of epigenetic writers, readers, and erasers in the shift from a repressive to an activated chromatin state at promoter and enhancer regions of the Kiss1 gene during the infantile-pubertal transition. This relatively new mode of epigenetic regulation opens up to the exciting possibility that the reactivation of the GnRH pulse generator lays in the genetic/epigenetic architecture of the Kiss neuron. In addition, we will discuss the tantalizing possibility that epigenetics serves as a relay of environmental signals known for many years to modulate pubertal development.

Endocrine disrupters in puberty

Anne-Simone Parent
Belgium.

Onset of puberty strongly depends on organizational processes taking place during the fetal and early postnatal life. Therefore, exposure to environmental pollutants such as Endocrine disrupting chemicals during critical periods of development can result in delayed/advanced puberty and long-term reproductive consequences. Human evidence of altered pubertal timing after exposure to endocrine disrupting chemicals is equivocal. However, the age distribution of pubertal signs points to a skewed distribution towards earliness for initial pubertal stages and towards lateness for final pubertal stages. Such distortion of distribution is a recent phenomenon and suggests environmental influences including the possible role of nutrition, stress and endocrine disruptors. Some rodent and ovine studies indicate a possible role of fetal and neonatal exposure to EDCs, along the concept of early origin of health and disease. Such effects involve neuroendocrine mechanisms at the level of the hypothalamus where homeostasis of reproduction is programmed and regulated. We have shown that neonatal exposure to the ubiquitous endocrine disruptor Bisphenol A (BPA) leads to opposing dose-dependent effects on the neuroendocrine control of puberty in the female rat. In particular, a very low and environmentally relevant dose of BPA delayed neuroendocrine reproductive maturation through increased inhibitory GABAergic neurotransmission. More recently, we studied the effect of a mixture of endocrine disrupting chemicals on female sexual development during three generations. Female rats (F0 generation) were orally exposed to a mixture of 14 anti-androgenic and estrogenic EDCs or corn oil for 2 weeks before and throughout gestation and until weaning. While F2 and F3 females showed delayed vaginal opening, decreased percentage of regular estrous cycles and decreased GnRH interpulse interval, no such changes were detected in F1 animals. These reproductive phenotypes were associated with alterations in both transcriptional and histone posttranslational modifications of hypothalamic genes involved in reproductive competence. F1 females that were exposed *in utero* to the EDC mixture, showed a reduction in thyroxin hydroxylase mRNA expression and impaired maternal behavior. Overall, our data shows that gestational and lactational exposure to an environmentally relevant EDC mixture transgenerationally affects sexual development throughout epigenetic reprogramming of the hypothalamus. Such effects could be mediated by alterations of maternal behavior caused by exposure of the first generation to the EDC mixture.

S2.3

The genetic basis of pubertal timing

Sasha Howard
UK.

Whilst the timing of pubertal onset varies within and between different populations, it is a highly heritable trait. The timing of sexual maturation is highly correlated within families and in twin studies, suggesting strong genetic determinants. However, despite this strong heritability, our knowledge of the genetic control of puberty remains limited. Disturbances of puberty (precocious, delayed or arrested) encompass an important group of pathologies. Firstly, they are common, affecting up to 4% of adolescents. In addition, abnormal timing of pubertal development is associated with adverse health and psychosocial outcomes. This has importance both for the individual, but also has a potential major impact on public health, especially in view of the secular trend towards an earlier age of puberty onset. Self-limited delayed puberty (DP) and familial central precocious puberty (CPP) are common inherited conditions defined by disordered pubertal timing, each with an established genetic basis. Self-limited DP, also known as constitutional delay of growth and puberty, is a highly heritable condition, which segregates in an autosomal dominant pattern (with or without complete penetrance) in the majority of families. Like self-limited DP, CPP often has a strong familial basis. Segregation analysis points to an autosomal dominant inheritance pattern with incomplete sex dependent penetrance. Two key imprinted genes have been identified as causal in pedigrees of CPP: *MKRN3*, and *DLK1*. *MKRN3* is thought to contribute to the puberty 'brake' restraining the hypothalamic-pituitary-gonadal axis via inhibition of GnRH release. Recent discoveries have begun to address the question of genetic regulation in self-limited DP. Using next generation sequencing (NGS) to explore a large DP patient cohort, mutations in the *IGSF10* gene were in 10% of probands. Following this discovery, mutations in several further genes involved in the gonadotropin-regulating hormone (GnRH) pathway have been identified in families with self-limited DP: *EAP1*, *HS6ST1* and *LGR4*. These results provide a new mechanism for delayed puberty: through defects in genes controlling the development of the GnRH neuroendocrine network. Importantly, for the majority of DP patients these are not defects in those genes that are known to produce complete GnRH deficiency in conditions such as hypogonadotropic hypogonadism. Moreover, genetic overlap has been identified between regulators of the timing of puberty in the general population identified from genome wide association studies, and both self-limited DP and CPP, including genes involved in energy metabolism.

Circadian Clocks: From Pathophysiology to Chronomedicine

S3.1

Circadian control of glucocorticoid function

David Ray
UK.

The glucocorticoid receptor (GR) is a nuclear receptor, a major drug target, and the end point of the hypothalamic-pituitary-adrenal axis. Glucocorticoids (GC) are essential for life, but in excess cause disordered energy metabolism, including increased weight gain, adiposity and hepatosteatosis; all programmes modulated by the circadian clock. Secretion of GC is regulated by the circadian clock, but could their actions be also? Here, using mouse as a model, we found that while the anti-inflammatory GC actions were maintained irrespective of dosing time, the liver was significantly more GC sensitive during the day. The time of day variation in GC action was underpinned by a physical interaction of GR with circadian transcription factor REVERBa, and co-binding with liver specific HNF transcription factors on chromatin. REVERBa promoted efficient GR recruitment to chromatin during the day, acting in part by maintaining histone acetylation, with REVERBa dependent GC-responses providing segregation of carbohydrate and lipid metabolism. Importantly, deletion of *Reverba* inverted circadian liver GC sensitivity, and protected mice from hepatosteatosis induced by chronic GC administration. Our results reveal a mechanism by which the circadian clock acts through REVERBa in liver on elements bound by HNF4A/HNF6 to direct GR action on energy metabolism.

S3.2

Fixing the broken clock in adrenal disorders

Andrea Isidori
Italy.

Context
Glucocorticoids (GC) mediate some of the adverse health-related consequences of circadian misalignment, such occurs in shift workers who have an increased cardio-metabolic, immune and cancer risk. Investigating the effect of circadian cortisol exposure in patients with GC excess and defect is crucial. In a therapeutic perspective large attention has been given to the total daily GC exposure, much less to the timing-of-the-day relative exposure. Clock genes are essential components of the machinery controlling circadian functions and are synchronized by GCs. Until recently, clock genes have not been investigated in patients with Adrenal Insufficiency (AI) or Cushing's syndrome (CS), despite they represent a disease model of endogenous clock misalignment.
Objective
We evaluated the effect of the timing of GC exposure on circadian gene expression in peripheral blood mononuclear cells (PBMCs) of patients with AI or CS enrolled in the DREAM[1] and TheHOURS (The circadian rhythm in cusHing syndrOme in active phase and dUring RemiSsion) trials.
Results
Compared with healthy controls, we found dysregulated many clock-related genes, with a distinctive profile in the AI and CS groups. Several metabolic and inflammatory signalling pathways were found altered in patients exposed to high evening/night GC levels or multiple peaks and trough during the day. Disease-specific effects were found in the profile of circulating PBMCs. More, PBMCs fluctuations during the day was not entirely abolished, but shifted or altered in patter and intensity. Medical interventions were partially able to restore the expression on clock-related genes, intracellular signalling and profiles of circulating PBMCs.
Conclusions
Pharmacological strategies designed to consider circadian timing of drug/hormone delivery, and circadian regulation of drug metabolism and of target gene/protein expression may be beneficial in the treatment of many chronic HPA-axis disorders.

Understanding the molecular basis of seasonal changes in behavior

Takashi Yoshimura
Japan.

Appropriate timing of various seasonal processes, such as reproduction, migration and hibernation, is crucial to the survival of animals living in temperate regions. Although this phenomenon has been studied for decades, the underlying mechanisms of seasonal changes in behavior are not well understood. Medaka fish (*Oryzias latipes*) are an excellent model for studying seasonal adaptation, as they are active and exhibit clear phototaxis in conditions simulating summer, but are inactive and fail to exhibit phototaxis in conditions simulating winter. Mate preference tests using virtual fish created with computer graphics demonstrate that medaka are more attracted to orange-red-colored model fish in summer than in winter. Transcriptome analysis of the eye reveals dynamic seasonal changes in the expression of genes encoding photopigments and their downstream signaling components, suggesting that plasticity in phototransduction is crucial for seasonal changes in color perception. We have also performed transcriptome analysis using medaka hypothalamus and pituitary gland and found that an uncharacterized long non-coding RNA (lncRNA) is strongly regulated by photoperiod. Since knockout medaka of this lncRNA show different responses to stress, we propose that photoperiodic regulation of this lncRNA modulates seasonal changes in behavior. Although humans are not typically considered seasonal, some evidence suggests that seasonal variation in physiology and behavior do exist. Seasonal affective disorder patients, experiencing recurrent winter episodes of depressed mood, show electroretinogram changes in winter with lower sensitivity compared with healthy subjects. I will discuss how we can better understand seasonal changes in behavior using unique animal models.

Clinical: Immunotherapy and endocrine disease

Maria Stelmachowska-Banaś
Poland.

Immunotherapy with immune checkpoint inhibitors has become an effective treatment of many malignancies resistant to conventional chemotherapies. Immune checkpoints are molecules on the surface of immune cells involved in the regulation of the immune response and immune checkpoint inhibitors are monoclonal antibodies directed against certain immune checkpoints, such as cytotoxic T-lymphocyte-associated protein 4 (CTLA-4) and programmed death 1 (PD-1) and its ligand (PD-L1), resulting in T-cell activation and antitumor activity. However, immune checkpoints also play a crucial role in maintaining immunological self-tolerance and preventing autoimmune disorders. Interfering with this mechanism can cause immune-related adverse events (irAEs) presenting as autoimmune disorders affecting numerous organs in the body. Endocrinopathies are among the most common irAEs associated with immune checkpoint inhibitors and most of them include thyroid dysfunction (typically associated with anti-PD-1 antibodies) and hypophysitis (typically associated with anti-CTLA-4 antibodies probably as a result of ectopic expression of CTLA-4 antigens on the cells of a human hypophysis). Insulin-deficient diabetes mellitus and primary adrenal insufficiency are rare endocrine toxicities associated with immune checkpoint inhibitors, but can be life-threatening if not promptly recognized and treated. Some endocrinopathies as thyrotoxicosis are transient, may resolve spontaneously and require only monitoring or symptom control but others, such as central adrenal insufficiency and primary hypothyroidism, are persistent and require proper life-long hormonal replacement. Combination of anti-CTLA-4 and anti-PD-1 treatment is usually associated with the highest incidence and severity of immune checkpoint inhibitors endocrinopathies. Given the increasing use of immune checkpoint inhibitors, cooperation between oncologists and endocrinologists is crucial in the management of patients with immunotherapy-induced endocrinopathies. Making an appropriate diagnosis and adequate hormonal relacement may improve the prognosis of oncological patients in whom immunotherapy-induced endocrinopathy have occurred.

Human gut microbiome: hopes, threats and promises

Hubert VIDAL
France.

The gut microbiota is now the subject of considerable investigation and our knowledge of its composition and understanding of functions are rapidly growing.Gut microbiota has profound impact on host physiology and it is now well-established that dysbiosis is associated with altered glycemic control and type 2 diabetes development. Targeting microbiota appears therefore as a promising strategy for the treatment of diabetic patients. Using probiotics in order to modulate blood glucose has been considered for a long time. However, the low efficacy of currently available probiotics highlights the lack of well-defined and standardized methodology to identify and select bacterial strains with real anti-diabetic properties. A better understanding of the mechanisms by which gut microbiota impacts host physiology is needed to identify such probiotic strains. In this presentation, we will discuss some innovative strategies to identify bona fide probiotic strains with anti-diabetic potential.

DOI: 10.1530/endoabs.S5.1

S5.2

Fecal transplantation: Myth or reality

Max Nieuwdorp
The Netherlands.

Alterations in (small) intestinal microbiota are associated with aberrant insulin secretion. We previously showed that fecal transplantation (infusing intestinal microbiota from lean donors) in insulin resistant subjects has beneficial effects on the recipients' microbiota composition and glucose metabolism via altering fecal SCFA producers levels (Vrieze, Gastroenterology 2012). Followup studies suggest that this beneficial effect can be divided in responders and non responders based on SCFA producing microbiota engraftment and beneficial metabolites (Kootte, Cell Metabolism 2017). In line, unpublished data from our group suggest that FMT in new onset type 1 diabetes patients also can drive beneficial effects on residual betacell function (de Groot/Roep/Nieuwdorp, manuscript in preparation). To our surprise however, oral butyrate supplementation had no beneficial effect on glucose metabolism in both type 1 and type 2 diabetes subjects (de Groot/Roep/Nieuwdorp, submitted; Bouter/Nieuwdorp, Clin Transl Gastro 2018). Combined our data thus suggest that specific missing intestinal (SCFA producing) strains might be developed as therapeutics for treatment in both type 1 and type 2 diabetes.

A Better Life with Thyroid Hormone (*Endorsed by the European Journal of Endocrinology*)

S6.1

Prediction of the thyroid axis set-point

Marco Medici
The Netherlands.

In the last few years studies have shown that subtle variations in thyroid function, including subclinical thyroid dysfunction, and even variation in thyroid function within the normal range, are associated with morbidity and mortality. It is estimated that 40–65% of the inter-individual variation in serum TSH and FT4 levels is determined by genetic factors. To identify these factors, various linkage and candidate gene studies have been performed in the past, which have identified only a few genes. In the last decade, genome-wide association studies identified >100 genetic variants, while whole exome and whole genome sequencing studies are expected to further clarify the genetic basis of thyroid function in the near future. The identification of these genes has paved the way for various lines of research. Examples of follow-up *in vitro* characterization studies of these genes include the identification of SLC17A4 as a novel thyroid hormone transporter and AADAT as a novel thyroid hormone metabolizing enzyme. Furthermore, mendelian randomization studies are expected to clarify whether the observed associations between minor variations in thyroid function and clinical endpoints are causal or not, which is key when considering treatment for these mild variations in thyroid function. Finally, these genetic markers have been associated with normal range thyroid function as well as thyroid dysfunction, thereby possibly serving as predictive markers for the individual thyroid setpoint and for thyroid disease.

DOI: 10.1530/endoabs.S6.1

S6.2

Subclinical hypothyroidism in children

Mariacarolina Salerno
Italy.

Subclinical hypothyroidism (SH) is a biochemical condition defined by increased TSH serum concentration above the normal range associated with normal concentrations of T4 and Free T4. In children SH is often a benign and remitting condition, for which risk of progression to overt hypothyroidism depends on the underlying cause (i.e. autoimmune SH is associated with an increased risk whereas non–autoimmune with a low risk of progression to overt hypothyroidism). The major concern regarding SH is to establish whether this condition should always be considered an expression of mild thyroid dysfunction. Growth and neurocognitive outcome in children do not appear to be affected by SH, however recent data suggest that mild SH may be associated with subtle pro-atherogenic abnormalities. The benefits of levothyroxine therapy are far from clear, therefore the optimum management of children with SH remains a matter of debate and depends on the etiology and degree of TSH elevation and should be individually tailored.

DOI: 10.1530/endoabs.63.S6.2

S6.3

Subclinical hypothyroidism in the elderly

Salman Razvi
UK.

Background
Both overt hypothyroidism as well as subclinical hypothyroidism is frequently encountered in older individuals. It is increasingly being recognised that treatment of subclinical hypothyroidism may not be beneficial, particularly in an older person. These findings are particularly relevant at a time when treatment with thyroid hormones is increasing and more than 10–15% of people aged over 80 years are prescribed levothyroxine therapy.
Main body
The prevalence of hypothyroidism increases with age. However, the upper limit of the TSH reference range also rises with age. Furthermore, there is evidence to suggest that minor TSH elevations are not associated with important outcomes such as symptoms, impaired quality of life, cognition, cardiovascular events and mortality in older individuals. There is also evidence that treatment of mild subclinical hypothyroidism may not benefit quality of life and/or symptoms in older people. It is unknown whether treatment targets should be reset depending on the age of the patient. It is likely that some older patients with non-specific symptoms and incidental mild subclinical hypothyroidism may be treated with thyroid hormones and could potentially be harmed as a result or, at best, have no beneficial impact.
Conclusions
Evidence suggests that threshold for treating mild subclinical hypothyroidism in older people should be high. In addition, it is reasonable to aim for a higher TSH target in treated older hypothyroid patients, as their thyroid hormone requirements are lower. Therefore, it is important that age-appropriate TSH reference ranges should be considered in the diagnostic pathway of identifying hypothyroidism. Appropriately designed randomised controlled trials are required to confirm risk/benefit and cost-effectiveness of treatment of subclinical hypothyroidism in older people. Until the results of such RCTs are available to guide clinical management international guidelines should be followed that advocate a conservative policy in the management of mild subclinical hypothyroidism in older individuals.

Endocrine Disrupting Chemicals (*Endorsed by Endocrine Connections*)

S7.1

Mixtures measured in human, disrupt thyroid hormone signaling and behavior in Xenopus laevis

Jean-Baptiste Fini
France.

Endocrine disrupting chemicals (EDCs) harm human health both as single molecules and as mixtures. Most research on EDCs is done on individual chemicals whereas we are exposed to mixtures of numerous and possibly interacting molecules. This discrepancy presents a dilemma for risk assessment and legislation. Thyroid hormones are essential for normal brain development where they influence, through specific embryonic and post-natal periods all the steps of brain development. In adults, TH roles are essential to brain function and to general metabolism (thermogenesis, fat burning, etc.). As number of compounds produced by chemical industries increased by 300 fold since the 70's, and many reports in the scientific literature show that many of these chemicals are potential Endocrine disruptors (EDCs) we questioned the thyroid hormone disrupting effect of common chemicals. We hypothesized that this axis could be a key target for disruption and hence alter normal brain development. To test this hypothesis, we used a thyroid disruptor screening assay, the Xenopus Embryonic Thyroid Assay (XETA), RT-qPCR on brain tissue, and behavior analysis. We used to independent strategies with different mixtures from human data. First we recreated m a mixture of 15 compounds commonly found in Human beings and tested them at the concentration meassured in amniotic fluid and study the effects on thyroid hormone signaling and adverse effects on our tadpole model. Second, a novel approach, developed within the European project, EDC-MixRisk, was to classify adverse mixtures of chemicals found in population based on epidemiological studies and test their EDC potential with both *in vivo* and *in vitro* assays. Samples from about 2,000 pregnant women were examined and retrospective analysis on offspring identified a chemical mixture for which embryonic exposure was associated with language delay, an indication for neurodevelopmental delay. Results on the two kind of mixtures show significant modification of TH availability (XETA assay) at the actual mixture concentration found in fluids of pregnant women. Second, mRNA levels of key genes involved the TH-signaling pathway showed significant alteration of TH-dependent genes at the accrual exposure level. Finally, mixtures were found to alter tadpoles'mobility behavior. Taken together, these results show advantages of using different strategies and necessity to take into consideration mixture in both experimental studies and risk assessment.

DOI: 10.1530/endoabs.S7.1

S7.2

Actions of endocrine disrupting chemicals on pancreatic beta cells and risk of diabetes mellitus

Angel Nadal
Spain.

Type 2 diabetes (T2D), results from a deficiency in insulin action on peripheral tissues together with a lack of compensatory insulin production and release by pancreatic beta cells. The etiology of T2D involves both, genetic predisposition and environmental factors. Bisphenol-A (BPA) is a widespread endocrine disrupting chemical that modify pancreatic beta cell function and induce insulin resistance in rodents after treatment during different timing of exposure, including pregnancy. This is a sensitive period of susceptibility for both mothers and offspring. Epidemiological studies associate BPA levels in urine with T2D development in adult humans. Adult male mouse treatment with low doses of BPA induces insulin resistance and hyperinsulinemia. Experiments using isolated beta cells as well as whole islet of Langerhans, suggest that BPA acts directly in beta cells to increase insulin content and release. Insulin content regulation by BPA is an estrogen receptor alpha (ERα) dependent process. In addition, BPA regulates beta cell electrical activity via a pathway which involves estrogen receptors β (ERβ). Electrophysiological measurements showed a decrease in sodium, calcium and total potassium currents in BPA-treated islets which is in line with BPA effects on gene expression. BPA-induced changes were abrogated in beta cells derived from $ER\beta^{-/-}$ mice, suggesting that ERβ mediates BPA effects on ion channel expression and function in pancreatic beta cells.

Prenatal obesogen exposure leads to a transgenerational thrifty phenotype in mice

Bruce Blumberg
USA.

Obesity is commonly ascribed to an imbalance between caloric intake and energy expenditure, but a growing body of evidence underscores the contributions of other factors in the obesity epidemic. We found that exposure of F0 animals to TBT throughout pregnancy and lactation predisposed male F4 descendants of TBT-treated animals to obesity when challenged with a higher fat diet. The TBT group showed impaired ability to mobilize fat during fasting and elevated serum leptin levels. Limited fat mobilization and elevated leptin levels suggest that fat accumulation results, in part, from leptin resistance. Integrated methylome and transcriptome analysis from fat and liver of F4 animals revealed that ancestral TBT exposure led to changes in global DNA methylation consistent with architectural changes in chromatin structure. Our results show that ancestral, in utero exposure to TBT alters chromatin structure to modulate expression of genes important for fat storage and mobilization. We propose that altered chromatin structure is a novel method for transgenerational transmission of the effects of obesogen exposure.

Genderdysphoria – Delayed Puberty

S8.1

Psychoendocrinology of gender dysphoria

Emmanuele A Jannini
Italy.

Usually, gender identity (GI) and biological sex are physiologically consistent, but this is not the case when individuals have a GI disorder/dysforia (GD) and thus require hormonal and/or surgical feminization/masculinization to reduce the discrepancy between the sense of self and sexual characteristics. The role of the Endocrinologist expert in Sexual Medicine and, in particular, in GD is crucial and pivotal. They (the transgenders), in fact, are a heterogeneous population for age of first referral to a specialist, type and amount of adjustment required, and for clinical situations. The GI is the perception that the subject has of his/her belonging to a gender, regardless of biological sex. Hence, the diagnosis of GD can only be self-reported, and 'cross-sex' hormonal treatment (HT) plays a key role in the process of transition: anatomical and psychological changes, when properly prescribed in the above-mentioned cases can significantly improve the psycho-social quality of life and indirectly confirm the diagnosis. HT itself represents, in fact, the confirmation of GI to the subject. Quality of life improvement thanks to HT reduces any psychiatric co-morbidity often associated with GD. By using an open-source morphing program (gtkmorph) based on the X-Morph algorithm we found that Male-to-Female (MtF) GD subjects and heterosexual females showed the same pattern of mating strategies measured as face preferences: a clear preference for less dimorphic (more feminized) faces for both short- and long-term relationships. Conversely, both heterosexual and homosexual men selected significantly much more dimorphic faces, showing a preference for hyperfeminized and hypermasculinized faces, respectively. These data showed that the facial preferences of MtF GD individuals mirror those of the sex congruent with their gender identity, providing a new evidence on the psychoendocrinology of GD.

S8.2

Management of puberty in transgender adolescents

Martine Cools
Belgium.

Context
Childhood gender dysphoria, when not attenuating after the onset of puberty, is very likely to persist. The aim of puberty suppressing therapy in gender dysphoric adolescents is increasingly shifting from 'buying time to reflect on the diagnosis' towards 'avoiding the development of secondary sexual characteristics while awaiting eligibility for cross-sex hormones'. Various treatment regimens are available to suppress or decrease the effects of endogenous gonadal hormones.
Methods
We will review the literature and research data from our group to investigate the effects of various puberty suppressing medications (GnRH analogues, pro- and anti-androgenic progestins) on the developing body. Effects on growth, bone mass development and body composition will be discussed, as well as treatment schedules and effects of cross-sex hormones. Unsolved questions and directions for future research will be indicated.
Results
GnRHa can prevent but not reverse the development of secondary sexual characteristics. Progestins are a cheap alternative and induce discrete body changes towards the desired gender, which may be beneficial especially in adolescents diagnosed at more advanced pubertal stages. Final height is suboptimal for many trans boys and girls. GnRHa should be started as early as possible to prevent the early growth-limiting effects of estrogens in trans boys. Bone health is mainly compromised in trans girls, irrespective of treatment choice, and is at least in part related to other than sex steroid effects.
Conclusion
Puberty suppressing and cross-sex hormone therapies can be safely used in transgender adolescents although very little data exist on the long-term use of GnRHa. The respective place of the various alternative medications for puberty suppression needs to be determined. Modifications to the existing schemes for puberty induction are needed in this specific population to ensure optimal outcomes. Transgender youth represent an excellent model to study the development of sexually dimorphic traits during puberty.

Metanephrines: Plasma or Urine

Graeme Eisenhofer
Germany.

Measurements of plasma or urinary metanephrines are recommended for diagnosis of pheochromocytoma and paraganglioma (PPGL). Differences of opinion exist concerning what test offers optimal diagnostic accuracy and whether supine sampling is required for the plasma test. Whether urinary free metanephrines offer advantages over deconjugated metabolites and the relative utilities of additional measurements of methoxytyramine are also unclear. This presentation covers 25 years of experience with PPGL, including a recent prospective study of 2,056 patients with suspected PPGL, among who 236 had tumors confirmed. Patients at high risk for PPGL were screened due to an incidentaloma, hereditary risk or past history of PPGL, whereas those at low risk were tested because of signs and symptoms of apparent catecholamine excess. With seated sampling the plasma test suffers from compromised specificity rendering diagnostic performance no better than urinary tests. With supine sampling the plasma test offers higher diagnostic sensitivity than urinary free and deconjugated metabolites at identical specificities for plasma and urinary free metabolites, but lower specificities for deconjugated metabolites. Addition of methoxytyramine is useful for the plasma panel, but offers negligible value for urinary panels. Superiority of plasma over urinary tests is most apparent for patients at high risk of PPGL, whereas diagnostic performance differs little for those at low risk. The superior diagnostic performance of the plasma than both urinary panels for patients at high risk of PPGL indicates preference for this test at specialist centers where such patients may be best managed, but only with appropriate pre-analytics. At other centers where it is not possible to sample blood in the supine position or where testing is largely carried out because of signs and symptoms it may be preferable to use urinary measurements. In this case traditional measurements of deconjugated metanephrines should be abandoned in favor of the free metabolites.

The dos and don'ts of genetic testing in phaeochromocytoma

Mercedes Robledo
Spain.

Phaeochromocytomas and paragangliomas (PPGLs) are rare neuroendocrine tumours with marked genetic heterogeneity, being the most inherited human tumour described so far. Around 40% of patients will be a carrier of a germline mutation in any of the know PPGL genes, and thus, for years most of studies have been performed on germline DNA. Findings from genetic testing in tumour DNA has dramatically changed the scenario. Nowadays, it is as relevant to make the screening on the germline DNA as to discard somatic mutations in those negative patients for the former analysis. From a daily basis genetic testing lab, there are important implications of having a genetic diagnosis in every single PPGL patient regardless the age of diagnosis or metastatic status, especially when the results would influence the management of the patient, or relatives at risk of being a mutation carrier. Where Next Generation Sequencing platforms are available, it is not only determinant the source of DNA sample to study, but also the availability of clinical information that will be used in the variant's interpretation step. This is a challenging task not only for laboratories that very often must apply a plethora of functional assays to demonstrate pathogenicity, but also for professionals responsible of genetic counseling and patient management. Another factor that should not be overlooked is the importance of selecting appropriately the tumour material to work with. This critical step should be done by pathologists in order to avoid masked mutations and therefore, false negative results. An increase in the knowledge of the molecular mechanisms involved in PPGL initiation, progression, and metastasis is fundamental for optimizing clinical management of this complex disease. It make sense that genetic information could be useful for selecting therapeutic options, as in the most of PPGLs it is detected a germline or somatic mutation in a gene or molecular pathway that can be therapeutically targeted by at least one antitumor agent clinically available for another disease.

Is there a role for subtotal adrenalectomy

Radu Mihai
UK.

Historically, bilateral subtotal adrenalectomy was first attempted in patients with failed pituitary surgery for Cushing syndrome. Currently the operation is discussed predominantly in the context of familial phaeochromocytomas in an attempt to preserve sufficient cortical function and avoid life-long steroid dependence. The patients have to be informed of the significance of their particular genetic mutation, the impact of the size of tumours on the intraoperative feasibility of cortex-sparring, the risk of ipsilateral recurrence and the (limited) ability to ensure adequate stress-related steroid response. Technically the operation is made possible by the extensive venous drainage of the gland, such that dividing the main adrenal vein does not preclude preservation of viable and functional adrenal remnant. The advantages of the retroperitoneoscopic versus the laparoscopic approach will be discussed. Such patients should be referred to units/surgeons with established experience with adrenal surgery and this can only be achieved through centralization of these rare cases in dedicated medical institutions. Current issues regarding training and delivery of adrenal surgery will be mentioned.

Cancer Drug-induced Osteoporosis (*Endorsed by Endocrine Connections*)

S10.1

Mechanisms of skeletal metastasis

Martina Rauner
Germany.

Skeletal lesions are a frequent complication of breast and prostate cancer. At present, 60–80% of patients with breast or prostate cancer develop bone metastases, which frequently result in skeletal-related events, including pathological fractures, pain, and neurological syndromes that require surgery or radiotherapy, and reduce quality of life. Autocrine and paracrine factors modulate various aspects of bone metastasis, including tumor proliferation, epithelial-to-mesenchymal transition, sensitization of skeletal sites to tumor homing, instruction of the microenvironment to support tumor persistence, and initiation of a vicious cycle that further promotes tumor growth and survival. In the vicious cycle, tumor cells, in particular breast cancer cells, produce osteoclast-stimulating cytokines and growth factors, either directly or by enhancing their production by mesenchymal stromal cells. This process results in excessive bone destruction that is typical of osteolytic bone metastases. However, it also releases large amounts of locally stored growth factors from the bone matrix that serve as survival factors for tumor cells. More recently, osteogenic pathways have been implicated in the development of bone metastasis. Normal bone formation depends on osteogenic differentiation of mesenchymal stromal cells towards osteoblasts and later to osteocytes. Tumors such as breast cancer secrete e.g. the Wnt inhibitor DKK-1, which suppresses osteoblast differentiation and inhibits bone formation and repair. By contrast, prostate cancer cells produce growth factors, which act as local stimulators of osteoblast functions, contribute to the osteomimicry phenotype of prostate cancer, and lead to excessive, but unorganized, newly formed bone, the hallmarks of osteosclerotic bone metastases. Taken together, prostate and breast cancer use specific molecular setups to induce their hallmark-type of bone lesion. Understanding the underlying mechanisms will help develop targeted therapies to treat bone metastasis.

TSH suppressive therapy and bone

Claudio Marcocci
Italy.

Thyroid hormones stimulates bone turnover. Increased blood levels of thyroid hormones are associated with a negative balance at individual bone remodeling unit and bone loss. It is well know that hyperthyroidism is a common cause of secondary osteoporosis and increased risk of fragility fractures. Mild hyperthyroidism (suppressed TSH and normal free thyroid hormones), as observed in autonomous thyroid nodules or following administration of TSH-suppressive doses of thyroid hormones (TSH-ST), may be associated with bone loss and fragility fractures, particularly in postmenopausal women. Low/undetectable TSH may also contribute to the deleterious effects of TSH-ST on bone, as suggested by animal studies showing that TSH inhibits osteoclastogenesis, promotes apoptosis of mature osteoblasts and stimulate osteoblast differentiation and the association of bone mineral density and TSH in postmenopausal women. The guidelines suggest measuring bone mineral density (BMD) in assessing skeletal health women under TSH-ST, but recent data suggest that BMD measured by DXA may not be a reliable marker of bone fragility in this context. In this regard an increased rate of vertebral fractures has been reported in postmenopausal women receiving TSH-ST independently of BMD (normal, osteopenia and osteoporosis), suggesting a potential role of structural abnormalities. As a matter of fact, recent studies in postmenopausal women under long-term TSH-ST have shown a deterioration of trabecular bone score (TBS) in the absence of a decline in vertebral BDM measured by DXA, but a significant association of TBS with volumetric BMD as assessed by central quantitative computed tomography.

Environmental endocrine disruptors and testicular germ cell cancer

Patrick Fénichel
France.

Testicular germ cell cancer is the most frequent cancer of the young men with an increasing incidence all over the world. Pathogenesis and reasons of this increase remain unknown but epidemiological and clinical data have suggested that like genital malformations and sperm impairment, it could include developmental and environmental factors, including fetal exposure to environmental endocrine disruptors (EEDs). Several groups including ours have shown that TGCC is estrogen dependent especially seminoma the most frequent histological type. By studying *in vitro* human seminoma cell lines, it was possible to identify two different kind of effects of estrogens and xenoestrogens through at least two different estrogen receptors. Estradiol (pM and nM) and diethylstilbestrol induced a suppressive genomic effect by binding to ERβ, the only classical nuclear receptor expressed in normal and malignant germ cells. However, estradiol, estradiol linked to bovine serum albumin (E2-BSA) which does not cross the membrane, bisphenol A and atrazine, induced a proliferative effect through the non classical membrane G protein related estrogen receptor GPER/GPR30, by a rapid non genomic activation of transduction pathways including several G protein-dependent kinases. Bisphenol A acted at very low doses (pM and nM) similar to the concentrations which were found in human male cord blood, illustrating a very high affinity for GPR30 explaining the paradoxal inverse U shaped dose response curve. GPR30 was found to be overexpressed in seminomas partly due to the presence of a particular genetic polymorphism and ERβ was decreased when compared with normal testicular tissue possibly linked to epigenetic modifications which can be induced in rodent by fetal exposure to EEDs. Carcinogenetic effect of EEDs by impairing germ stem cells development is supported by TGCC estrogen dependency. However, more longitudinal prospective epidemiological studies and molecular epigenetic screening are necessary to clearly demonstrate this developmental relationship.

Impact of pesticide postnatal exposure on oocyte quality and clinical outcomes of patient undergoing IVf programme

Moncef Benkhalifa[1,2], Rosalie Cabry[1,2], Véronique Bach[2] & Philippe Merviel[3]
[1]Reproductive Medicine, Reproductive Biology & Genetics, University Hospital & School of Medicine, Picardie University Jules Verne, CHU SUD, 80054 Amiens, France; [2]PERITOX–INERIS laboratory, Jules Verne University of Picardy, Amiens, France; [3]Department of Oby/Gyn, Regional University Hospital, Morvan University, 29200 Brest, France.

In reproductive pathology, the impact of endocrine disruptor's on fertility potential declining is well documented; women exposed to pesticides have a risk to affect oocyte maturation and competency because Oocyte quality is a key limiting factor in female fertility which is firstly reflected by morphology feature. Centrally located cytoplasm granulation (CLCG) is one of cytoplasmic dysmoprhisms exhibited by oocytes which could be linked to pesticide exposure with relative risk to decrease ICSI outcomes. During our IVF programme we included 633 women undergoing intracytoplasmic spermatozoa injection (ICSI) program between 2009 and 2011 living in Picardy region-France with pesticide exposure. The whole lot was divided into two groups based on CLCG prevalence of oocytes (LCLCG; $n=83$: Low prevalence of CLCG under 25%; and HCLCG; $n=68$: High prevalence of CLCG over 75%). The embryological and clinical outcomes were analysed for both groups calculating the difference between them. As result, couples with HCLCG compared to LCLCG showed a decrease in embryo cleavage, ongoing pregnancy and live birth rates (82%, 14% and 13% vs 99%, 32% and 30%, respectively) while early miscarriage rate was increased (47% vs 11%) with OR (3.1 [95%CI]). Due to high pesticide exposure (over 3000 g/ha), there is higher risk to engender disturbed oocytes cohort with high prevalence of CLCG over 75%.

Mitigating against endocrine disruption in pregnancy

Katharina M Main
Denmark.

Three decades ago wildlife findings of intersex, malformations and sex ratio changes in marine species, birds and mammals could be associated to environmental pollution. Public concern arose as to whether this was also a threat to humans as many countries experience an increase i.e. in the prevalence of infertility and obesity. Humans are continuously exposed to small doses of hundreds of EDCs throughout life and we know very little about their combined effects. Over the past 10–15 years more and more plausible links are being established between chemical exposures to a large range of new and old, persistent and non-persistent, chemicals and male as well as female reproductive health, i.e. dioxins, PCBs, flame retardants, perfluorinated chemicals, pesticides, phthalates, parabens, phenols and UV filters. Especially foetal exposure during pregnancy has been linked to adverse health effects in the offspring as this period is a vulnerable developmental window. After initial scepticism, many academic societies have endorsed the concept of endocrine disruption through environmental chemicals and modern lifestyle. Their support helps on many fronts: promoting research in the field, raising funds, engaging producers of customer products in better labelling and development of safer alternatives, increasing public awareness as well as prompting governmental agencies into action. Population cohort biomonitoring studies show that regulatory bans of chemicals in consumer products, i.e. certain phthalates, indeed lower individual exposure and thereby the individual 'cocktail load'. In parallel, it is paramount to ensure that any novel chemical is well-tested for endocrine disrupting effects before being approved for unlimited use.

New potential treatment alternatives in patients with papillary craniopharyngioma

Tareq Juratli
USA.

Craniopharyngiomas are surgically challenging brain tumors. Postoperatively, quality of life is often significantly impaired due to neurological and endocrinological complications. Currently, FDA approved systemic treatments are not available for patients in whom craniopharyngiomas recur after surgery and radiation. Papillary craniopharyngiomas are characterized by the presence of $BRAF^{V600E}$ mutations. In this presentation, the authors generate an overview of all currently available information on targeted therapy in patients with $BRAF^{V600E}$ mutant papillary craniopharyngiomas with BRAF and/or MEK inhibitors. To date, all cases showed dramatic responses to targeted treatment with BRAF (and MEK) inhibitors. Although our data are highly informative for guiding patient treatment, uncertainty remains with regards to the optimal timing, the specific agents (single agent or dual therapy) to be used and the duration of treatment. The ongoing multicenter phase II Alliance A071601 trial (NCT03224767) of vemurafenib and cobimetinib for patients with biopsy-proven residual or recurrent papillary craniopharyngiomas should provide additional information to help inform patient management.

How to manage the long-term consequences of hypothalamic damages

Eva Marie Erfurth
Sweden.

When a craniopharyngioma (CP) causes hypothalamus (HT) damage this will result in hypothalamic obesity (HO), cognitive dysfunction and increased stroke mortality. Suggested treatment when the HT is affected by a CP is subtotal resection and in some cases followed by cranial radiotherapy (CRT). In the preoperative phase, a multidisciplinary team may suggest HT sparing surgery with subtotal tumour removal. If in spite of all efforts the HT is damaged, there will be an immediate increase in hunger craving resulting in a devastating weight increase. The strongest increase in weight is within the first 12 mo and the proposal is that neurally mediated high insulin is the primary factor in the development of HO. Within weeks, an MRI gives information of the extent of HT damage and also of the remaining HT volume. The HT volume may give the cardiovascular prognosis. Immediate efforts of dieticians and cardiovascular drugs with GLP-1 agonist, and central stimulating drugs need to be administered. Later in the follow up diffusion tensor imaging (DTI), a noninvasive technique of the white matter of the brain, may predict cognitive dysfunction. White matter lesions (WML), seen on T2 MRI, are pathological changes caused by obstruction of small cerebral vessels resulting in hypo-perfusion and are predictive of stroke. CP patients, who have a reduced HT volume and were treated with CRT have increased WML volume. Assessment of HT volume, DTI, WML should be considered in the postoperative phase and follow up care of patients with CP as this may create an opportunity for early preventive treatment of cognitive dysfunction, CV disease and stroke risk. These different assessments can also be used in a broader perspective for all tumours that involves the HT.

Central Control of Metabolism: Brain Rules All

S13.1

Sensors of survival: Pleiotropic function and the regulation of hunger circuits

J Nicholas Betley
USA.

The brain regulates food intake by processing sensory cues and peripheral physiological signals. Recently, we have gained an increased understanding of the neural networks that regulate food intake. However, understanding how nutrients and post-ingestive signals regulate the activity of hunger-sensitive neurons remains an important question. To understand the neural control of food intake, we monitor the activity of hunger-sensitive neural populations in the awake behaving animal. Our recent work has demonstrated that nutrients, independent of the sensory experience of food, have the ability to change the activity of both hypothalamic and midbrain neurons that influence food intake. Further, vagal gut-brain signaling is necessary to rapidly transmit this information. We have identified satiation hormones that are likely responsible for activating the vagal signaling and have discovered that they work synergistically. Finally, we find coordinated and bidirectional modulation of hypothalamic and midbrain circuits by food rewards. Taken together, these studies begin to unpack how networks of neurons in the brain influence food intake.

Role of mitochondria/cell bioenergetics in CNS regulation of energy balance

Marc Claret
Spain.

Pro-opiomelanocortin (POMC) neurons in the arcuate nucleus (ARC) of the hypothalamus are critical regulators of appetite, energy expenditure and glucose metabolism. POMC neurons are able to sense circulating hormones and nutrients informing about the energy status of the organism. However, the molecular mechanisms underlying nutrient-sensing in POMC neurons remain incompletely understood. Mitochondria are key organelles implicated in cellular nutrient/energy management and are able to bioenergetically adjust to different metabolic situations. A remarkable feature of mitochondria is their capacity to change their morphology through coordinated fusion and fission events, a mechanism that links nutrient availability with bioenergetic adaptations. Mitochondrial fusion is a process that requires the GTPases mitofusin (Mfn) 1, Mfn2 and OPA1. We hypothesized that mitochondrial fusion in hypothalamic POMC neurons may represent primary nutrient/energy-sensing processes implicated in the hypothalamic regulation of energy balance and metabolism. To test this hypothesis, we have generated mice lacking the main fusogenic proteins specifically in POMC neurons and conducted detailed phenotyping and molecular studies. Our data demonstrate divergent metabolic outcomes depending on the deleted fusion protein, which are mediated by different tissues and molecular processes. These results suggest that mitochondrial dynamics in POMC neurons is a critical mechanism implicated in the maintenance of systemic energy balance and glucose homeostasis.

Genetics of appetite regulation: Can an old dog teach us new tricks?

Giles Yeo
UK.

It is clear that the cause of obesity is a result of eating more than you burn. What is more complex to answer is why some people eat more than others? Over the past 20 years, insights from human and mouse genetics have illuminated multiple pathways within the brain that play a key role in the control of food intake. We now know that the brain leptin-melanocortin pathway is central to mammalian food intake control, with genetic disruption resulting in extreme obesity. These, however, remain rare, with the major burden of disease carried by those of us with 'common obesity'. In recent years, genome-wide association studies have revealed more than 100 different candidate genes linked to BMI, with most, including many components of the melanocortin pathway, acting in the CNS and influencing food intake. So while severe disruption of the melanocortin pathway results in severe obesity, subtle variations in these same genes influence where you might sit in the normal distribution of BMI. As we now enter this 'post-genomics' world, can this new information influence our treatment and management of obese patients?

Innovations in NETs

S14.1

Innovative imaging of benign insulinomas – the end of sampling

Emanuel Christ
Switzerland.

Background
Benign insulinomas are the most prevalent cause of endogenous hyperinsulinaemic hypoglycaemia (EHH) in adults and due to their small size difficult to localise. Until now, the most sensitive test to localize the area of the potential insulinoma was the intra-arterial calcium stimulation test, an invasive procedure with its associated risk. In contrast to the other neuroendocrine tumors, benign insulinomas do not exhibit upregulated somatostatin receptors sutype 2 (sst2) but present with an increase in GLP-1 receptors (GLP-1R). GLP-1Rs can be targeted with GLP-1 analogues such as exendin-4. We aimed at prospectively comparing the accuracy of ^{111}In-DOTA-exendin-4 SPECT/CT, ^{68}Ga-DOTA-exendin-4 PET/CT, standardised 3-Tesla contrast-enhanced MRI (ceMRI), and non-standardised baseline imaging (ceCT/ceMRI) in patients with EHH.
Methods
We prospectively enrolled $>$ 80 patients with neuroglycopenic symptoms due to EHH and no evidence for metastatic disease on conventional imaging using ^{111}In-DOTA-exendin-4 SPECT/CT, ^{68}Ga-DOTA-exendin-4 PET/CT and compared the sensitivity of the GLP-1R imaging to conventional imaging procedures (ceMRI and ceCT). The reference standard was surgery with histology and normalisation of blood glucose levels.
Findings
Patients were referred from whole Switzerland, Europa and USA. Baseline not standardised conventional imaging identified suspicious lesions in ca. 40% of the patients. Accuracy for PET/CT, SPECT/CT and standardised MRI, was 93·9%, 67·5% and 67·6%, respectively. GLP-1R imaging was useful in EHH in the context of benign sporadic insulinomas, in adult nesidioblastosis (^{68}Ga-DOTA-exendin-4 PET/CT) and in patients with multiple endocrine neoplasia type 1 with multiple pancreatic lesions on conventional imaging. The size of the detected lesions was 4–25 mm.
Conclusion
GLP-1R PET/CT performed significantly better than SPECT/CT and conventional imaging and should be the diagnostic tool of choice in patients where localization fails with conventional imaging. Intra-arterial calcium stimulation test may only be indicated when GLP-1R PET/CT fails to localize the suspected lesion.

DOI: 10.1530/endoabs.63.S14.1

S14.2

A role for radionuclide therapy for high-grade NETs

Halfdan Sorbye
Norway.

Background
Peptide receptor radionuclide therapy (PRRT) is an established treatment of metastatic low-grade and intermediate-grade neuroendocrine tumors (G1-G2). However, its possible benefit in high-grade gastroenteropancreatic (GEP) neuroendocrine neoplasms (NEN G3: NET G3 and NEC) has been unknown.
Methods
Data from 3 recent retrospective studies (Thang *et al*. 2018, Zhang *et al*. 2018, Carlsen *et al*. 2019) on efficacy and toxicity of PRRT in patients with GEP NEN G3 were assessed. All patients had a high uptake on somatostatin receptor imaging and most had progressive disease.
Results
The 3 studies (one multicenter) included in total 249 patients, mainly pancreatic primaries (60–69%). Treatment was mainly given as 2nd or 3rd line therapy. Response rates were 31–44%. Disease control rate (DCR) was 69–78%. Grade 3-4 hematological or renal toxicity occurred in 1%, 16% and 17% of patients. Progression free survival (PFS) and overall survival (OS) was higher in patients with Ki-67 21–55% vs Ki-67 $>$55%: PFS 11–16 m vs 4–6 months and OS 22–46 m vs 7–9 months. In the multicenter study, patients with well differentiated tumors (NET G3, $n=60$) had a better PFS and OS compared to poorly differentiated carcinomas (NEC, $n=62$): PFS 19 vs 8 months ($P<0.001$) and OS 44 vs 19 months ($P<0.001$).
Conclusion
Three retrospective cohorts of patients with GEP NEN G3 treated with PRRT demonstrates quite similar results with promising response rates, disease control rates, PFS and OS in patients with mainly progressive disease. Based on these results, PRRT may be considered for patients with high-grade GEP NEN G3 (NET G3 and NEC).

Fishing for NETs

Giovanni Vitale
Italy.

Neuroendocrine tumors (NETs) are a class of rare and heterogeneous neoplasms derived from the neuroendocrine system. Animal models are indispensable tools for investigating the pathogenesis, mechanisms for tumour invasion and metastasis and new therapeutic approaches for cancer. Unfortunately, only few models are available for NETs, probably due to the rarity and heterogeneity of this group of neoplasms. The tropical teleost zebrafish (Danio rerio) is a popular vertebrate model system that offers unique advantages for the study of a variety of biological processes. The small size and low cost of maintenance, together with the high prolific nature, the external fertilization and the rapid development of its transparent embryos have led to the first emergence of the zebrafish as reliable and suitable embryological model. Moreover, due to the proved conservation in genetic programs and physiology between fish and mammals, zebrafish has become a powerful model for studying human diseases, including cancer. This presentation provides an overview of the state of the art of zebrafish model in the cancer research with a main focus on NETs, highlighting future developments in this field.

European Young Endocrine Scientists (EYES) – Organ cross-talk in endocrine disease

Peter Aldiss
UK.

'European Young Endocrine Scientists' (EYES), founded in 2011, is a committee under the patronage of the European Society of Endocrinology (ESE). Our primary goal is to increase the mutual exchange of ideas and knowledge between early career researchers (ECR's) across Europe, in both basic and clinical endocrinology. EYES enables ECR's from all ESE member societies to actively contribute to the society's activities and help them fully develop into the next generation of endocrinologists. We provide a platform for ECR's in endocrinology to make them feel welcome at ESE and to familiarize themselves with the society's conferences. This years' session will once again give outstanding ECR's a platform to present their research with a focus on the role

of organ cross-talk in disease. With exciting talks on the role of glucocorticoids in the expansion of bone marrow fat and the winner of best oral communication at the annual EYES meeting this session is not to be missed! We invite all early career basic and clinical endocrinologists to attend and join us here and at the EYES networking event at ECE 2019.

DOI: 10.1530/endoabs.63.S15.1

S15.2

Investigating glucocorticoid excess as mediators of bone marrow adiposity expansion during caloric restriction

Andrea Lovdel
UK.

Background
Bone marrow adipose tissue (BMAT) comprises >10% of total adipose mass in healthy humans and further increases during caloric restriction (CR). However, BMAT function during CR and other conditions remains poorly understood. Circulating glucocorticoids also increase during CR, and glucocorticoid therapy increases BMAT; thus, ***we hypothesise that glucocorticoid excess mediates BMAT expansion during CR***. Many effects of endogenous glucocorticoid excess are mediated by 11β-Hydroxysteroid dehydrogenase type 1 (11β-HSD1), which catalyses intracellular regeneration of active 11-hydroxy glucocorticoid from inert 11-keto forms.
Objectives
Determine 1) if CR increases glucocorticoid activity within adipose tissue and bones; and 2) if ablation of 11β-HSD1 blocks CR-induced BMAT expansion.
Methods
Male and female C57BL/6J mice lacking 11β-HSD1 (KO) or littermate controls were fed *ad libitum* (AL) or 70% of AL intake (CR) from 9–15 weeks of age. Each week, body mass and composition were measured and blood collected. Plasma corticosterone and 11-dehydrocorticosterone were measured by ELISA or liquid chromatography-tandem mass spectrometry. Bone loss and BMAT were measured by micro-computed tomography.
Results
1) In control and KO mice, CR decreased body and lean mass. Body fat decreased in males only. CR increased circulating corticosterone levels in both sexes and genotypes. Circulating 11-dehydrocorticosterone concentration was significantly greater in AL and CR KO mice than in controls. 2) CR increased expression of the glucocorticoid target gene *Fkbp5* in white adipose tissue and bone. CR-induced BMAT expansion occurred in females of both genotypes and in control males, but not in KO male mice. CR induced cortical bone loss in females only and this was unaffected by genotype.
Conclusions
CR increases glucocorticoid action within bones and induces cortical bone loss. Knockout of 11β-HSD1 prevents CR-induced BMAT expansion in male, but not female, mice. These findings highlight glucocorticoids as potential mediators of sexually-dimorphic BMAT formation during CR.

The role and cross-talk between incretin hormones and occurrence of non-alcoholic steatohepatitis

Benjamin Bouillet
France.

Non-alcoholic fatty liver disease (NAFLD) is the most common cause of chronic liver disease and has an estimated prevalence of 25–30% worldwide, rising to 90% in morbidly obese patients and to 60% in patients with type 2 diabetes (T2D). The mortality related to NAFLD, attributed to hepatic and extra-hepatic diseases, continues to increase. Moreover, T2D is an aggravating factor for NAFLD, as it increases the risk of developing non-alcoholic steatohepatitis (NASH), liver fibrosis, cirrhosis and hepatocellular carcinoma. Nevertheless, there is currently no specific pharmacologic treatment for NAFDL and its only validated treatment is weight loss. A number of studies of animal models and human trials have provided evidence of a beneficial effect of glucagon-like peptide-1 receptor agonists (GLP-1RAs) on liver fat content and NASH. These data suggest that this treatment could represent a new alternative for NAFLD management. The studies evaluating the effects of GLP-1RAs on NAFLD will be described and discussed. The mechanisms underlying these effects will be analyzed. Indeed, the effects of GLP-1RAs on weight reduction and lipid metabolism seem to be the two main mechanisms explaining the decrease in liver fat content with this treatment. However, larger studies of longer duration with complete histological outcomes are needed to determine the precise effect of GLP-1RAs in NASH improvement and to assess the efficacy of GLP-1RAs according to the presence or not of type 2 diabetes.

Lysophosphatidic acid in pathogenesis of *HNF1B*-MODY syndrome

Beata Małachowska
Poland.

Background
HNF1B-MODY is a rare autosomal dominant monogenic form of diabetes coexisting with kidney abnormalities.
Objectives
Identification of altered serum metabolites among *HNF1B*-MODY patients and investigating its function in syndrome pathogenesis.
Methods
We recruited patients with *HNF1B*-MODY ($N=10$), *HNF1A*-MODY ($N=10$), polycystic kidney disease: non-dialyzed and dialyzed ($N=8$ and $N=13$ respectively) and healthy controls ($N=12$). Serum samples were fingerprinted by LC/MS. Observed metabolic changes were validated. A HepG2 cell line was used in order to study *in vitro* the cellular effect of selected serum metabolite stimulation.
Results
From serum metabolomics fingerprinting we identified eight metabolites that had convergent fold change for comparison of *HNF1B*-MODY versus all other groups. Three of them were lysophosphatidic acid species (LPAs: 18:1, 18:2, 20:4) that proved to be the best biomarkers for *HNF1B*-MODY (Area under ROC curve 1.00 (95%CI 0.91–1.00); 1.00 (95%CI 0.91–1.00); 0.92 (95%CI 0.80–0.98) respectively). On a second set of samples we confirmed elevated levels of LPA among *HNF1B*-MODY patients ($P=0.0063$). The main enzyme producing serum LPA – autotaxin – was down-regulated in sera of *HNF1A*- vs *HNF1B*-MODY patients ($P=0.0173$) but did not differ between *HNF1B* and other groups (all P values >0.84). Upon LPA stimulation of human hepatocytes with silenced *HNF1B* the downregulation of autotaxin expression was observed. In the absence of functional Hnf1b, the stimulatory effect of LPA on the Wnt pathway was disrupted and reversed, with LPA stimulation leading to a decrease of phospho-GSK-3a/b protein ($P=0.0169$).
Conclusions
An important lipid mediatory compound – LPA was found to be elevated in serum of patients with *HNF1B*-MODY. LPA can be involved with pathogenesis of *HNF1B*-MODY syndrome via the disruption of LPA-mediated regulation of Wnt pathway.
The study was funded by the PRELUDIUM grant (2016/21/N/NZ5/01448) of the National Science Center, Poland and by JDRF-ISPAD Research Fellowship Award 2017.

Thyroid in Pregnancy

S16.1

Thyroid autoimmunity and (in)fertility

David Unuane
Belgium.

Thyroid autoimmunity (TAI) is the most frequent autoimmune disorder in women of childbearing age and increases the risk of thyroid dysfunction. TAI has been shown to be more common in women seeking counselling for infertility. The underlying causal mechanism that may account for any possible detrimental effect of TAI on fertility aspects remains hypothetical. In general, increased levels of anti-thyroid peroxidase abs (TPO-abs) have been defined as the most sensitive marker of TAI and linked to the risk of (sub) clinical hypothyroidism. As a consequence most studies investigating the prevalence of TAI in infertile women or any relation between TAI and pregnancy outcomes are based on the presence of TPO-abs alone and do not take into account thyroglobulin autoantibodies (Tg-abs). Assisted reproductive technology (ART) is often proposed as a treatment option for couples confronted with fertility problems. TAI has been linked to adverse pregnancy outcome with an increased risk of miscarriage and preterm delivery in spontaneous pregnancy as well as in pregnancy after ART. Since the late 1990s several studies have been published on the impact of TAI and pre-conception TSH thresholds on the outcome after ART. The outcome of these studies however are conflicting. Therefore, todays guidelines on the management of TAI in the particular case of ART are based on limited evidence. In the present presentation we will give an overview on the association of TAI and female infertility. We will discuss the possible underlying mechanisms that may connect TAI to fertility issues. Furthermore, the current evidence on the impact of TAI and pre-conception TSH thresholds on outcome after ART will be highlighted. Based on this evidence we will have a critical look at today's guidelines on this issue.

Mild maternal thyroid dysfunction during pregnancy and offspring neurodevelopment

Deborah Levie
The Netherlands.

In humans, brain developmental processes start already around week 5 of gestation and continue throughout pregnancy and postnatal life. The migration, differentiation, proliferation, and myelination of neurons are thyroid hormone dependent processes, as shown in animal studies. The fetal thyroid gland is not functionally mature before week 18–20 of gestation. During this period the fetus acquires thyroid hormone for the most part via placental transfer from the mother. This implies that there is an important time frame during which thyroid hormone dependent processes of brain development are completely dependent on the placental transfer of maternal thyroid hormones. A lack of thyroid hormone exposure to the fetal brain during its developmental stages in utero can lead to severe neurological phenotypes, such as cretinism, which is caused by iodine deficiency. While there is abundant evidence for an association of low maternal FT4 (hypothyroidism and/or hypothyroxinemia) during gestation with poorer fetal neurocognitive outcomes, evidence for an association of maternal subclinical hypothyroidism (elevated TSH but normal FT4) during pregnancy with offspring neurodevelopmental outcomes is scarce. In this talk the latest clinical studies on mild thyroid dysfunction and offspring neurodevelopmental outcomes will be discussed, including studies that have investigated critical time windows for exposure to inadequate thyroid hormone availability. Identifying critical time windows are important for improved understanding of thyroid physiology, translation of animal studies to human physiology, to facilitate the design of future randomized controlled studies on the benefits of treatment (i.e. subclinical hypothyroidism or hypothyroxinema) and aid clinicians in optimizing risk assessment strategies. In this talk I will also go over some of the challenges and next steps in these type of studies.

Where do Pituitary Tumours Come From?

S17.1

Specification of pituitary cell fates

Jacques Drouin
Canada.

The pituitary derives from an invagination of the oral ectoderm, Rathke's pouch, where pituitary progenitors are specified during early development. These progenitors are marked by expression of Sox2 and their entry into differentiation involves a switch from Sox2 to expression of other transcription factors implementing each of the lineage-specific differentiation programs. This switch is also accompanied by a switch in cell cycle control mechanisms that may be disrupted in pituitary tumors. Determination and maintenance of each pituitary lineage is dependent on a small number of the lineage-specific transcription factors. Whereas the mechanism for specification of the pituitary fate compared to oral ectoderm is still unknown, recent work has identified Pax7 as the pioneer transcription factor that specifies the intermediate lobe melanotrope fate. Pax7 achieves this through epigenetic mechanisms that 'open' about 2500 enhancers genom- wide. The interplay between the specification pioneer factor Pax7 and the POMC lineage determination factor Tpit will be discussed. The diversity of pituitary tumors reflect the composition of the normal gland with some tumors presenting with relatively well differentiated features and hormone secretion whereas others, the non-functioning adenomas, may reflect some progenitor or precursor states.

'From Lab to Clinic – Can we translate into effective therapeutics'

Peter Kamenický
France.

The first line treatment of somatotroph adenomas is pituitary surgery, that aims at removing the tumor, but which is frequently incomplete, as invasion into cavernous sinuses often limits the surgical resection. Multimodal medical treatment, which is burdensome, very expensive and has variable therapeutic efficacy, is currently required in more than 60% of the patients. New therapeutic approaches are therefore necessary for controlling hormone secretion, tumor development and (invasive) growth. Besides activating *GNAS* gene mutations, promoting tumor development in ~30% of cases, the molecular pathogenesis of somatotroph adenomas is rather poorly understood. We have recently described a distinct molecular subclass of *GNAS* mutation-negative somatotropinomas, clinically revealed by a paradoxical increase of GH to oral glucose load related

to pituitary glucose-dependent insulinotropic polypeptide receptor (GIPR) expression. This ectopic *GIPR* expression occurred through hypomorphic transcriptional activation and is likely driven by *GIPR* gene micro-amplifications and/or DNA methylation abnormalities. These findings provide useful molecular profiling that refines the somatotroph tumor classification. However, to what extent the ectopic GIPR is functionally involved tumor growth and GH hypersecretion? A hallmark of GIP-dependent Cushing syndrome is the low fasting plasma cortisol concentration that increases following GIP release after meals. In patients with acromegaly with ectopic GIPR in their somatotropinomas, fasting GH concentrations are not suppressed. The impact of prolonged fasting is difficult to address because of ethical issues. Recently, a specific naturally occurring GIP antagonist GIP (3–30) NH2 has been investigated in humans. Targeting the ectopic GIPR by this antagonist could be an interesting novel therapeutic strategy in some acromegalic patients. However, the important intra-tumor heterogeneity of pituitary adenomas with GIPR expressed only in some cell clones challenges the therapeutic efficacy of this approach.

Congenital Hypogonadotropic Hypogonadism: New Insights into GnRH Regulation

S18.1

The transcription factor Gli3 plays a pivotal role in controlling the development of the terminal nerve and GnRH-1 neuronal migration

Paolo E Forni
USA.

Normosmic idiopathic hypogonadotropic hypogonadism (nIHH) and Kallmann syndrome (KS) represent two rare phenotypic presentations of humans with hypogonadotropic hypogonadism secondary to GnRH deficiency. KS/nIHH is genetically heterogeneous and is characterized by incomplete penetrance and variable expressivity. Some genetic variants may play the role of modifier alleles or act as 'second hits', providing an explanation of this phenotypic variability. In addition to the reproductive phenotypes, nIHH and KS subjects also commonly exhibit craniofacial defects. In humans, mutations in *GLI3,* encoding a transcriptional regulator of sonic hedgehog (Shh) signaling, causes a spectrum of craniofacial defects including a short nose with flat nasal bridge and cleft palate. *Gli3 loss-of-function affects the development of the olfactory system*: By examining the development of the vomeronasal sensory neurons, terminal nerve and GnRH-1 neurons, in a Gli3 mouse mutant model [Gli3 extra-toe (Xt)], we found: 1) a large reduction in the number of vomeronasal sensory neurons, 2) defective development and routing of the terminal nerve fibers, and 3) nearly complete absence of GnRH-1 neuronal migration to the brain. Notably, only a delay in GnRH-1 neuronal migration was observed in $Gli3^{Xt/WT}$heterozygous embryos with no obvious differences after birth. Analyzing whole exome data from a large cohort of nIHH/KS probands, we also identified several rare *GLI3* variants in humans. Luciferase assays and subcellular localization confirmed complete loss-of-function for one novel *GLI3* mutation which was seen in an KS individual who also displayed polydactyly. As a some of the patients carrying rare missense *GLI*3 variants also harbored heterozygous mutations in other KS/nIHH candidate genes we propose that human *GLI3* mutations could play an important modifier role and contribute to the oligogenic nature of KS/nIHH.

Flipping the GnRH switch with microRNAs

Andrea Messina
Switzerland.

A sparse population of a few hundred primarily hypothalamic neurons forms the hub of a complex neuroglial network that controls reproduction in mammals by secreting the 'master molecule', gonadotropin-releasing hormone (GnRH). Both the Kisspeptin input on GnRH neurons and timely changes in GnRH expression are necessary for the onset of puberty. However, the exact molecular mechanisms underlying this process remain elusive. Here, we report that a dramatic inversion in microRNA expression profile within postnatal GnRH neurons acts as an epigenetic switch that triggers the prepubertal increase in GnRH expression and controls the ability of GnRH neurons to sense Kisspeptin input, for a correct initiation of puberty. The disabling of this microRNA-mediated switch leads to hypogonadotropic hypogonadism and infertility in mice. The underlying mechanism involves a complex and multilayered network of transcriptional activators and repressors reciprocally controlled by several microRNA species, including miR-200 and miR-155. These microRNAs tune the balance between inductive and repressive signals to trigger a rise in hypothalamic GnRH expression and to control the expression of Kisspeptin receptor. Anomalies in this microRNA-embedded genetic network, which appears essential for the neuroendocrine control of reproduction by controlling both Kisspeptin sensitivity and GnRH production, could thus underlie dysfunctions of human puberty and fertility when a genetic cause is not apparent.

Adrenal Insufficiency

S19.1

New insights into autoimmune adrenal insuffisiency

Esytein Husebye
Norway.

Autoimmune adrenal insufficiency (AAI) is a classic organ-specific autoimmune disease caused by immune-mediated destruction of steroidogenic cells in the adrenal cortex. Autoreactive T cells and autoantibodies targeting the steroidogenic cytochrome P450 enzyme 21-hydroxylase (21OH) are present in the majority of patients. AAI can appear isolated or as part of two forms of autoimmune polyendocrine syndromes, the rare monogeneic autoimmune polyendocrine syndrome type 1 (APS-1) and the common autoimmune polyendocrine syndrome type 2 (APS-2), the latter affecting more than half of the AAI population. A study of the Swedish twin registry has revealed that the probandwise concordance for monozygotic twins was 0.71 (95% CI 0.40-0.90) and the heritability 0.97 (95% CI 0.88-99), which is at least as high as for celiac disease. Several genes are implicated in disease risk, first and foremost the major histocompatibility complex (MHC). Other associated genes include BACH2 (BTB and CNC Homology 1, Basic Leucine Zipper Transcription factor 2) and AIRE (autoimmune regulator). Disease risk is associated with an accumulated number of risk variants in the individual patient. Lymphocytic infiltrations of the adrenal cortex of deceased AAI patients have been described. We now demonstrate the presence of both T- and B cells during active autoimmune adrenalitis. The majority of the T cells are CD8+ cytotoxic T cells, although CD4+T and CD20+B cells as well, particularly in distinct foci of dense lymphocytic infiltrations. T cells with reactivity towards distinct and conserved portions the 21OH protein have been reported in peripheral blood and is probably present in abundance in these foci. Autoimmune adrenalitis is a slowly evolving process in most cases, leading to clinical symptoms and biochemical aberrations only in the latter stages of the disease. Although the majority are thought to loose all adrenocortical function, a subset of patients seem to retain both glucocorticoid and mineralocorticoid function even decades after being diagnosed with AAI. This indicates that there is an opportunity for immunomodulary and regenerative therapy in AAI.

S19.2

Long-term results of modified release glucocorticoids in adrenal insufficiency – are they really better?

Gudmundur Johannsson
Sweden.

Before the availability of glucocorticoids as drugs, the majority of patients with primary adrenal insufficiency (AI) died within 2 years of diagnosis. Today patients with AI receive life-long replacement therapy with glucocorticoids with the assumption that life expectancy is normal. Recent studies have, however, shown excess mortality in patients with both primary and secondary AI mainly due to cardiovascular diseases and infections. Patients with AI also have increased rate of diabetes, hypertension and hospital admission rates due to infections. It is likely that non-physiological exposure of glucocorticoids both in term of dose and time exposure profile contributes to this poor outcome together with inadequate intercurrent illness rescue therapy. Modified release hydrocortisone has been developed to improve outcome among patients with AI, by improving the circadian exposure of hydrocortisone. Prospective trials have shown indications that the metabolic outcome is improved and frequency of infections may be reduced in comparison with the same daily dose of conventional hydrocortisone. Treatment with modified release hydrocortisone may also improve and normalise immune function and peripheral expression of clock genes. Limited data exist on the long-term safety of these new treatments from prospective studies. Available data from a 5 year prospective study suggest a good safety profile, but the question remains whether long-term outcome is improved in comparison with conventional glucocorticoid replacement therapy. New options have emerged for the treatment of glucocorticoid deficiency in AI. Outcome from prospective short-term studies has shown promising results. Limited data on long-term treatment outcome with modified hydrocortisone support their safety.

Optimising care delivery in congenital adrenal hyperplasia

Nils Krone
UK.

Congenital adrenal hyperplasia represents a group of autosomal recessive disorders in steroidogenesis causing deficient cortisol biosynthesis. The incidence of congenital adrenal hyperplasia (CAH) in the general population of Western countries is approximately 1 in 10,000 to 1 in 15,000 life births with about 95% of cases caused by 21-hydroxylase deficiency. After the introduction of replacement therapy with glucocorticoids and mineralocorticoids in the 1950s, congenital adrenal hyperplasia is no longer a life-limiting condition. However, CAH has become a chronic life-long condition, with associated comorbidities and long-term health implications. Long-term consequences of CAH and current treatment regimens include unfavourable outcomes involving all organ systems. Comprehensive long-term data on mortality are not available. An important emerging task for paediatric health care provision in CAH is the prevention of long-term health problems. Pharmacotherapy with current approaches remains challenging, with keeping the balance between glucocorticoid overexposure and androgen excess. Over the life-span type and dose of glucocorticoid can change. The relative mineralocorticoid dose per body surface area declines with increasing age. Replacement doses are monitored by clinical and biochemical parameters, with suppression of steroid hormones commonly indicating overtreatment. Several novel experimental pharmacotherapies with the aim to reduce glucocorticoid exposure and to mimic physiological glucocorticoid secretion are under development. The approach to treatment and monitoring remains highly variable and the effects on long-term outcomes remain elusive. This presentation will provide an update on current developments covering care provision, novel adrenal-specific biomarkers with the potential to improve monitoring and experimental approaches. All of these ongoing approaches have will in theory improve CAH management; however, the evidence for improved long-term outcomes is lacking.

News on Nutrition: When to Eat What

S20.1

Precision nutrition for managing obesity – does it work?

Carlos Celis-Morales
UK.

Background
The epidemic of obesity, together with its associated health burden, continues to spread globally. It is estimated that approximately 2.1 billion adults worldwide are now classified as overweight or obese. Thus, there is an urgent need to develop more effective strategies for preventing and managing obesity. Most population strategies to reduce the rising prevalence of non-communicable diseases (NCDs) have used a 'one size fits all' public health recommendations, e.g. 'eat at least five portions of fruit and vegetables daily'. However, the global burden of NCDs continues to rise, emphasising the need for more effective prevention strategies.
Results
Recent findings from randomised controlled trials have suggested new personalised approaches for the prevention and treatment of obesity, as an alternative to the current strategy of 'one-size-fits-all' approach. Personalised Nutrition (PN), also called Precision Nutrition, has been developed to deliver Personalised interventions designed according to key characteristics of the individual participants (including but not limited to socio-demographics, biomarkers, phenotypic, microbiome and genetic characteristics). The more tailored the intervention, the more sophisticated and potentially expensive it will be to acquire, analyse and act upon those participant characteristics. However, with interventions becoming increasingly plausible on a large scale, thanks to smartphone technology and internet accessibility, some have begun to view PN as a novel way to deliver the right dietary intervention to the wider population. This talk will explore existing evidence, including the Food4Me study, one of the largest personalised trials conducted to date and provide an insight into the real benefits of personalised interventions for obesity management and prevention. Moreover, I will discuss how genetics and novel biomarkers, could be used to improve the design and effectiveness of future personalised interventions and whether existing evidence justifies the use of more sophisticated interventions, to tackle the current obesity epidemic.
Conclusions
Is personalised or Precision Nutrition the way forward?

DOI: 10.1530/endoabs.63.S20.1

S20.2

Is limiting the timing of food intake a viable nutritional approach?

Denise Robertson
UK.

Food restriction and weight-management strategies have been at the forefront of most efficient strategies to prevent and reduce the risk of type 2 diabetes and cardiovascular disease (CVD). However, when people find themselves in an increasingly obesogenic environment it becomes challenging to achieve and maintain successful behavioral changes. Fasting protocols such as intermittent energy restriction (IER) and time-restricted feeding (TRF), or restricting food consumption to specific period during the day or week, have received considerable interest as approaches for weight-management and reducing risk for metabolic diseases. In these strategies, food consumption is altered to produce frequent, repeated periods of short-term fasting, or severe energy restriction. For example, the 5:2 dietary pattern, involving 2 fast days/week (with normal eating on the remaining 5 days) has been shown to be particularly successful. Our previous work in humans has shown significant effects on weight-reduction in addition to lowering blood glucose and lipids, both key risk factors for type diabetes and CVD. TRF is an example of a timed dietary approach, which also falls under the 'intermittent fasting' umbrella, involving limiting intake to a period of several hours (usually ≤ 12 hours), which thereby extends the length of the daily fasting interval. There is some suggestion that the length of fasting duration may exert an additive benefit, presumably by elongating the time spent in a catabolic state. Both IER and TRF appear to demonstrate a metabolic advantage above a simple reduction in energy intake although much of the data is still in rodent models.

PREDIMED Plus trial - energy-restricted Mediterranean diet plus exercise and metabolic health

Emilio Ros
Spain.

The PREDIMED trial showed that long-term adherence to an ad libitum Mediterranean diet (MeDiet) supplemented with extra-virgin olive oil (EVOO) or

mixed nuts reduced incident cardiovascular disease (CVD) in older subjects at high risk. No clinical trials have been conducted to demonstrate whether weight loss sustained over time with an energy-restricted healthy diet plus increased physical activity (PA) reduces CVD risk. We designed the PREDIMED-PLUS study, a 6-year, multicentre, randomized clinical trial for the primary prevention of CVD with an energy-restricted MeDiet plus behavioural support and advice to increase PA, aimed at losing weight in comparison with a control, energy-unrestricted MeDiet without counsel on PA (*www.isrctn.com/ISRCTN89898870*). Participants are 6874 older individuals (aged 55–75 y) with overweight/obesity and the metabolic syndrome and they receive gifts of EVOO and nuts to promote the MeDiet irrespective of group assignment. The final goal regarding adiposity is to obtain a between-group average absolute difference in weight loss and waist circumference reduction $>5\%$. The results of the pilot study concerning the first 610 randomized participants completing intervention for 12 months showed that diet and PA changes were in the expected direction, with significant improvements in the intervention group compared with the control group. After 12 months, participants in the intervention group lost an average of 3.2 kg vs. 0.7 kg in the control group ($P<0.001$). Weight loss $\geq 5\%$ occurred in 33.7% of participants in the intervention group vs. 11.9% in the control group ($P<0.001$). Compared to participants in the control group, those in the intervention group had greater improvements in classical cardiovascular risk factors, except for blood pressure and LDL-cholesterol levels, and greater reductions in insulin resistance, hemoglobin A1c, and circulating levels of leptin, IL-18 and MCP-1 ($P<0.05$, all). In conclusion, among overweight/obese adults with metabolic syndrome, an intervention using energy-restricted MeDiet, PA and behavioral support for 12 months resulted in clinically meaningful weight loss and improvements in intermediate cardiovascular risk factors.

DOI: 10.1530/endoabs.63.S20.3

Rare Bone Disorders

S21.1

Animal models of bone fragility

Antonella Forlino
Italy.

Osteogenesis imperfecta (OI), the most common among the rare hereditary skeletal dysplasias, is a juvenile form of osteoporosis ranging from mild to perinatal lethal forms. Classical OI is a dominant disease affecting the *COL1A1* and *COL1A2* genes encoding for the α chains of type I collagen, the most abundant protein of the bone extracellular matrix (ECM). In the last decade new causative genes associated to dominant, recessive and X-linked transmission of the disease and encoding for proteins involved in type I collagen biosynthesis, processing and secretion as well as in osteoblasts differentiation and activity have been described. How mutations in these genes cause the bone fragility phenotype still require further investigation, but already shed new light on bone biology. The molecular basis of OI was historically attributed to the presence of abnormal collagen in the ECM. Nevertheless, mutant collagen is partially retained in the ER and its misfolding and intracellular accumulation had been observed in OI patients' cells and animal models of classical and new OI forms. A deep understanding of the matrix and intracellular molecular mechanism of the disease as well as the development of new therapeutic approaches for OI and other bone fragility disorders benefit of the use of appropriated animal models. A review of the achievement obtained by the generation and characterization of murine models for dominant and recessive OI forms will be provided. The more recent development and use of teleost models, that provide new tools for osteochondrodysplasia investigation, will be discussed.

The Pituitary as Metabolic Sensor (*Endorsed by Endocrine Connections*)

S22.1

Kiss1 as integrator of endocrine and metabolic function in the hypothalamic-pituitary axis

Victor Navarro
USA.

Reproduction is a very energy costly function for the organism and, therefore, very tightly regulated by central and peripheral cues that ultimately determine the proper pattern of kisspeptin and GnRH release. Among these, metabolic cues play a critical role in the control of reproductive function, through the interplay of satiety and hunger signals. Further, the interaction between reproductive and metabolic functions is bidirectional, as kisspeptin has also emerged as a novel satiety factor. However, despite the critical role of these neuronal networks for the survival of the individual, the precise mechanisms underlying the control of reproduction and food intake remain incompletely understood. Recent studies from our lab have extended the characterization of this bidirectional regulatory process and identified, on one hand, a novel leptin-responsive population of PACAP neurons in the ventral premammillary nucleus that targets Kiss1 neurons to regulate reproduction—as part of the metabolic control of reproduction. On the other hand, we have documented an active role of Kiss1 neurons in the metabolic (anorexigenic) action of melanocortins through MC4R—as part of the reproductive control of metabolism. Overall, understanding the neuronal pathways and mechanisms underlying this bidirectional interaction of metabolism and reproduction is critical for the development of new approaches to treat metabolic and reproductive disorders with a central origin.

DOI: 10.1530/endoabs.63.S22.1

S22.2

How treatments with endocrine & metabolic drugs influence pituitary cell function?

Giovanni Tulipano
Italy.

A variety of endocrine and metabolic signals regulate pituitary cell function acting through the hypothalamus-pituitary neuroendocrine axes or directly at the pituitary level. The underlying intracellular transduction mechanisms in pituitary cells are still debated. AMP-activated protein kinase (AMPK) functions as a cellular sensor of low energy stores in all mammalian cells and promotes adaptive changes in response to calorie restriction. It is also regarded as a target for therapy of proliferative disorders. Various hormones and drugs can promote tissue-specific activation or inhibition of AMPK by enhancing or inhibiting AMPK phosphorylation, respectively. In the last ten years, evidence has accumulated that pituitary AMPK plays a role in the interplay between the activity of neuroendocrine axes and metabolic functions. AMPK was shown to be a potential point of integration of energy homeostasis with reproduction at the level of pituitary [1]. Moreover, AMPK activation contributes to regulate the normal rat somatotroph cell function in-vitro. More recently, the hypoglycaemic agent metformin was shown to negatively modulate the basal hormone release from non-human primate somatotroph-, gonadotroph- and corticotroph cells in-vitro and to affect the expression of key receptors involved in the regulation of the distinct cell subtype function [2]. Metformin targets different sites of cellular bioenergetics and is an indirect activator of AMPK. To this end, metformin enhances AMPK phosphorylation at threonine-172 in rat pituitary tumor cells. As to pituitary proliferative disorders, the direct AMPK activator AICAR reduces the growth of rat pituitary tumor cells. Actually, primary cell cultures from

GH-secreting human pituitary adenomas were less sensitive to AICAR than rat cell lines. Our research group and other groups [3] have also investigated a possible role of metformin in the treatment of GH-secreting and prolactin-secreting tumors. Metformin can affect cell metabolism and cell signalling, and ultimately cell growth and function in-vitro when used at millimolar concentrations. Both AMPK-dependent and independent mechanisms are involved. The in-vitro effects of metformin may also help highlighting differences in metabolic requirements between pituitary adenomatous cells and normal cells.

Bidirectional interrelationship between growth hormone and metabolism

Raul M Luque
Spain.

Growth hormone (GH)-producing pituitary cells (somatotropes) comprise a fundamental regulator for a plethora of relevant physiological functions, including somatic growth and whole-body metabolism, by controlling the function of different endocrine/non-endocrine targets. Synthesis and release of GH has been classically thought to be primarily regulated by central, dual neuroendocrine signals: i.e. GH-releasing hormone and somatostatin. However, it is progressively becoming evident that multiple metabolic factors, from insulin and IGF-I to adipokines, ghrelin, obestatin, melatonin, cortistatin, neuronostatin, kisspeptin, etc., produced by GH-sensitive metabolic tissues (e.g. pancreas, liver, fat, stomach, etc.) can feedback directly to the pituitary to exert capital adjusts on GH synthesis and release. In this manner, somatotrope cells serve as metabolic sensors of the organism to integrate central and peripheral signals in order to fine-tune whole-body homeostasis, although it is clear that pituitary cell regulation is species-, age- and sex-dependent. The purpose of this presentation is to provide a comprehensive, general overview of our current knowledge on: 1) Central and peripheral metabolic regulators that directly control somatotrope cell function, and their associated intracellular mechanisms, as elucidated by using primary pituitary cell cultures from different species as well as *in vivo* mouse model treated with different metabolic factors; and 2) the metabolic consequences of changing circulating GH levels, by using multiple mouse models with elevated or reduced circulating GH levels [i.e. transgenic animal models with extreme altered levels of GH (giants vs. dwarf), as well as models with alterations in GH levels within the physiologic range (Adult-onset, isolated, GH deficient/AOiGHD, somatostatin/cortistatin-deficient, somatotrope specific insulin-R/IFGI-R deficient mice, etc.]. Additionally, it is now also becoming apparent that different agents used to improve altered metabolic conditions (e.g. biguanides and statins in diabetes and obesity) might also target somatotropes to exert, at least part, some of their beneficial metabolic actions. Thus, overall, the data gathered over the last years reinforce the contention that a clear, bidirectional and (patho)physiologically relevant, interrelationship is in place between GH and metabolism under both normal and altered metabolic conditions, where somatotrope cells act as true homeostatic sensors of the organism, controlling whole body homeostasis and metabolism by integrating central and peripheral signals.

PCOS: Can We Personalise Treatment?

S23.1

Gut and brain axis

María Insenser
Spain.

Microbiota plays a major role in health and disease in humans. Sex hormones influence the diversity and composition of the gut microbiota. Polycystic ovary syndrome (PCOS) is the most prevalent endocrine disorder in women of reproductive age (6–20%). PCOS is characterized by the association of androgen excess with oligomenorrhea, anovulatory infertility, and increased metabolic risk factors. The study of the interaction between gut microbiota and sex hormones in PCOS could be key to developing future personalized microbiota-based therapies. The mechanism underlying the association of sexual steroids and gut microbiota composition remains unclear. Very little evidence has been published regarding the implication of microbiota in women with PCOS. However, some studies have found a lower diversity and differential microbiota composition between women with and without PCOS, as well as correlations with clinical parameters of PCOS. Studies of PCOS animal models confirm that hyperandrogenism is capable of modifying the diversity of the gut microbiota community, and this may be a potential mechanism in the pathogenesis of PCOS. The current limitation of our knowledge about molecular mechanisms linking specific bacteria and PCOS highlights the need of interventional studies. Modulation and manipulation of gut microbiome will boost the efficacy of treatments to prevent the deleterious effect of hyperandrogenism on these women and improving their care.

Implicating androgen excess in metabolic disease in PCOS

Michael O'Reilly
UK.

Insulin resistance and androgen excess, alongside anovulatory infertility, are the cardinal clinical and biochemical features of polycystic ovary syndrome (PCOS). Circulating androgen burden and metabolic dysfunction in PCOS are closely correlated, but an independent contribution of androgens *perse*to metabolic and other complications of PCOS remains poorly characterised. My work focuses on delineating the distinct impact of androgens on metabolic function, with a particular focus on adipose tissue and insulin resistance. Adipose tissue is capable of androgen activation, and has a complex network of activating and inactivating enzymes. One of these enzymes, aldoketoreductase type 1 C3 (AKR1C3), activates the androgen precursor androstenedione to more potent testosterone. AKR1C3 expression is upregulated in subcutaneous adipose tissue from women with PCOS compared to BMI-matched controls. Using adipose tissue microdialysis, we have shown that PCOS women have significantly increased adipose concentrations of the active androgens testosterone and dihydrotestosterone compared to controls. Furthermore, using *in vivo* and *in vitro*studies, we have demonstrated direct effects of intra-adipose androgens on adipocyte lipid biology, with increased *de novo* lipogenesis and suppression of lipolysis promoting adipocyte hypertrophy. In other aspects of the presentation, I will discuss the relative contribution of the 11-oxygenated androgen synthesis pathway to circulating androgen burden and metabolic dysfunction in PCOS, which traditionally has been understudied in PCOS and other disorders of androgen excess. Data from a number of population-based studies will also be presented, which we have used to delineate the independent effects of androgen excess on metabolic disorders such as diabetes and non-alcoholic fatty liver disease, as well as on conditions as obstructive sleep apnoea. Lastly, I will present our recent data providing a mechanistic link between androgen excess and idiopathic intracranial hypertension in women, a distinct neuro-metabolic complication.

Treatment options in cardiometabolic pcos phenotype

Mojca Jensterle
Slovenia.

Background
Cardiometabolic polycystic ovary syndrome (PCOS) phenotype is predominantly characterized by obesity. It is clearly associated with impaired metabolic and reproductive health, whereas implications on cardiac health are mostly limited with the exploration of cardiovascular risk factors without actual cardiovascular endpoints. There is a relative lack of systematic prospective studies investigating long-term effects of different treatment options that include phenotype specific outcomes.

Aim
We will cover different treatment interventions available for cardiometabolic PCOS phenotype. The treatment goals will include weight reduction, improvements of metabolic health, decrease of cardiovascular risk and increase in the fertility potential.
Results
Multicomponent lifestyle modification (LSM) is crucial intervention for this phenotype. Metformin in addition to LSM should be considered for managemnent of weight and metabolic outcomes. In clinical practice, LSM and metformin are often insufficient, by means of decreasing weight, preventing conversion rate from normal glucose tolerance to prediabetes and to type 2 diabetes and improving reproductive outcomes. Potential new modifiable risk factors should be addressed in this high-risk population. Some limited data from preclinical and clinical studies support an adjunct management with agents mediating through glucagon-like peptide-1 (GLP-1) axis, including GLP-1 receptor agonists and dipeptidyl peptidase-4 inhibitors. GLP-1 receptor agonists have shown a beneficial effect on weight loss, some cardiometabolic risk factors and some reproductive outcomes. In severly affected individuals, bariatric surgery can be effective in achieving significant weight loss, reduction of cardiovascular risk and might result in a striking PCOS resolution rate.
Conclusions
Management of patients with cardiometabolic PCOS phenotype should aim to reduce weight, improve metabolic derangemnets, decrease risk for cardiovascular diseases and increase fertility potential. There exist some unsolved questions that implicate an exciting new research field with potential wider clinical implications. All this will be put in perspective in this talk.

What's New in the Adrenal Cortex? (*Endorsed by the European Journal of Endocrinology*)

S24.1

Adrenocortical tumors: new genes, new understanding, new therapy

Mr Guillaume Assie
France.

For the last ten years, genomic approaches have led to important discoveries in adrenocortical tumors, unraveling mechanisms of tumorigenesis and autonomous hormone secretion. Autonomous aldosterone secretion in primary aldosteronism is now seen as induced by abnormal intra-cellular calcium signaling in glomerulosa cells, related to somatic mutations. The most common affects KCNJ5, coding for a membrane channel. A clinical trial with macrolides - impacting this channel- is ongoing. These mutations also impact primary aldosteronism nosography. Firstly, many 'aldosterone producing adenomas' correspond to diffuse adrenal diseases rather than focal alterations. Secondly, there seems to be a continuum between adrenal cortex aging and primary aldosteronism. These novelties should impact the screening and therapeutic strategies. Somatic mutations are found in one third of adrenocortical adenomas. Clinical impact is currently limited. Diffuse primitive adrenal cortex alterations are heterogenous. Discovering ectopic adrenal expression of hormone receptors permitted pharmacological treatment of a few patients with macronodular hyperplasia. Germline mutations of *PRKAR1A* and ARMC5, respectively associated to primary pigmented nodular adrenocortical dysplasia and to multinodular primary macronodular hyperplasia, helped to better classify these lesions. These mutations also improved our mechanistic understanding. Clinical impact is major for mutations carriers and their relatives, enabling early and efficient treatment of potentially deadly conditions. In adrenocortical carcinoma, recurrent somatic mutations mostly affect Wnt/beta-catenin (*CTNNB1* and ZNRF3) and cell-cycle (*TP53*). Therapeutic targeting of these mutations is limited. Few cases with high mutation burden or microsatellite instability - potentially related to germline *MUTHY* or Mismatch repair genes mutations respectively-, may orient towards immune checkpoint inhibitors. Finally, genomic screening of these carcinomas identified two main molecular classes, associated with major differences in outcome. Early prognostic stratification may impact the decision of adjuvant therapy after complete surgery. Taken together, genomic accelerated adrenal research pace, with clinical implications now coming to bedside. Clinical evaluation is now needed.

S24.2

Primary hyperaldosteronism: does our treatment work?

Dr Tracy Ann Williams
Germany.

Primary aldosteronism (PA) has a prevalence of 5–15% in the general population with hypertension and patients with PA display an increased frequency of target organ damage and cardiovascular damage than patients with hypertension with matched cardiovascular risk profiles. The unilateral and bilateral forms of PA are treated differently usually surgically (unilateral PA) or by antagonism of the receptor for aldosterone (bilateral PA). Medically-treated patients with PA have an increased risk of cardiovascular events which is likely related to insufficient mineralocorticoid receptor blockade. Surgically treated patients with unilateral PA can be potentially cured but a wide between-centre variability has been demonstrated. An expert-based consensus established standard criteria to assess clinical and biochemical outcomes after unilateral adrenalectomy (the Primary Aldosteronism Surgical Outcome [PASO] consensus). Application of these criteria to an international cohort demonstrated that less than half of patients are clinically cured (37%, range 17–62) and showed that younger and female individuals are more likely to achieve clinical remission. The identification of baseline factors associated with post-surgical outcomes were used to develop an online score employing 6 presurgical variables for the prediction of clinical remission *versus* patients with likely persistant hypertension after surgery (the PASO predictor). Analysis of adrenal specimens from patients with PA showed that adrenals from patients with persistent aldosteronism after surgery more frequently display signs of hyperplasia and no obvious aldosterone-producing adenoma than those from patients surgically cured of aldosteronism. These approaches are relevant to the clinical setting for the differentiation of patients who are likely to be clinically and biochemically cured after surgery from those who will need continuous surveillance after surgery due to persistent hypertension and primary aldosteronism.

S24.3

Autonomous cortisol secretion has cardiovascular consequences

Prof Iacopo Chiodini
Italy.

Background
Patients with adrenal incidentaloma (AI) and autonomous cortisol secretion (ACS) show a high prevalence of cardiovascular risk factors and an increased prevalence and incidence of cardiovascular events. Furthermore, some recent data suggest that in these patients, the cardiovascular mortality is also increased. Unfortunately, to date, the diagnosis of ACS is still a matter of debate, and, therefore, it is still not possible to reliably predict the effect of the recovery from ACS in the individual patient. As a consequence, addressing the treatment of choice (i.e. surgical or conservative) is still a challenge in many AI patients.
Material and Methods
We performed a systematic search of medical databases (PubMed, Cochrane Register and EMBASE) until January 31th 2019 using the following key-words: subclinical hypercortisolism, cardiovascular risk, cardiovascular mortality, adrenal incidentaloma and autonomous cortisol secretiom.
Results
The available data show that in AI patients with ACS the surgical removal of the adrenal mass causing ACS can lead to the improvement of hypertension and diabetes, but in many patients with possible ACS the effect of surgery is still largely unknown. No data are available on the effect of the recovery from ACS on the cardiovascular events. Finally, recent evidence suggest that cortisol secretion, peripheral activation and sensitivity could be associated with the presence of hypertension, diabetes and fragility fractures. Therefore, the development of safe and well-tolerated drugs aimed to control cortisol secretion and/or peripheral activation and to modulate glucocorticoid sensitivity will be among the goals of the future research.
Conclusions
Randomized studies are needed to investigate the possibility of predicting the usefulness of surgery by using the available indexes of cortisol secretion in the individual AI patient. The different sensitivity to glucocorticoids and cortisol peripheral activation capacity might influence the choice of the treatment in the individual subject.

Levothyroxine in preconception women with thyroid peroxidase antibodies

Rima Smith
UK.

Background
Thyroid peroxidase antibodies are associated with increased risk of miscarriage and preterm birth, even when thyroid function is normal. Small trials indicate levothyroxine could reduce such adverse outcomes.
Methods
We conducted a double-blind, placebo-controlled trial to investigate whether levothyroxine treatment would increase live birth rates among euthyroid women with thyroid peroxidase antibodies and a history of miscarriage or infertility. We randomly assigned women to receive 50 mcg daily of levothyroxine or placebo, commenced preconception and continued until the end of pregnancy. The primary outcome was live birth ^{3}34 weeks gestation.
Results
We tested 19,585 women for thyroid peroxidase antibodies and thyroid function across 49 hospitals in the United Kingdom. A total of 952 women were randomly assigned to receive either levothyroxine (476) or placebo (476). The follow-up rate for the primary outcome was 98.7% (940/952). A pregnancy was achieved in 266/470 (56.6%) in the levothyroxine group and 274/470 (58.3%) in the placebo group. The live birth rate in the levothyroxine group was 37.4% (176/470) versus 37.9% (178/470) in the placebo group (relative risk, 0.97; 95% confidence interval [CI], 0.83 to 1.14, $P=0.74$; absolute risk difference, -0.4%; 95% CI, -6.6% to 5.8%). There were no significant differences in other pregnancy outcomes, including the rates of pregnancy loss, preterm birth, or in neonatal outcomes. Serious adverse events occurred in 6% of women in the levothyroxine group and 4% in the placebo group ($P=0.14$).
Conclusion
Treatment with levothyroxine in euthyroid women with thyroid peroxidase antibodies did not increase the rate of live births.

Maternal smoking and high BMI disrupt thyroid gland development

Panagiotis Filis
UK.

Around half of expectant mothers worldwide are overweight or obese and 20% smoke. Exposure to such factors during fetal life is linked to diseases including obesity, cardiovascular disease, and behavioural disorders. Because thyroid hormones control fetal metabolism, cardiac output and brain development, altered fetal thyroid signalling can contribute to future disease. We examined the impact of maternal smoking and overweight/obese (body mass index, BMI, ≥ 25) on the thyroid system in 2nd trimester human fetal tissues from normally progressing, electively-terminated pregnancies. We measured circulating thyroid hormones (THs), thyroid-stimulating hormone (TSH), and thyroid hormone-binding proteins, scored thyroid histology and examined the expression of developmentally-relevant proteins and transcripts in the human fetus and quantified TH transporter and signalling proteins and transcripts in placental plasma membrane preparations and fetal livers extracts. The fetal thyroid system is sexually dimorphic: male thyroids appeared more immature, lacking developmentally increased PAX8. The developmental increase of thyroid sodium-iodide importer NIS and a developmental decrease of the major placental TH transporter LAT1, in male fetuses only, suggest reduced reliance on maternal TH supply and increased fetal TH synthesis. Further, higher circulating triiodothyronine (T3) levels and reduced liver *DIO3* transcript in males indicate decreased peripheral degradation of T3. Maternal smoke exposure increased the developmental trajectory of fetal circulating thyroxine and altered the developmental trajectory of TSH, reversed the negative T4:TSH correlation and decreased PAX8 staining in female fetuses. Fetal thyroids from high BMI mothers were heavier, had reduced PAX8 staining and, in female fetuses, thyroids appeared more immature. Circulating TSH was higher in female fetuses from high BMI mothers. In conclusion, we showed that physiologically the fetal thyroid system is highly sexually dimorphic and responds to maternal smoking and high maternal BMI in a sex-specific manner. Our findings imply that management of the fetal thyroid function in children at risk may minimize predisposition to disease.

Impact of Thyroid Disease on...

S26.1

Role of thyroid hormones in the pathogenesis and treatment of psychiatric disorders

Bernard Lerer
Israel.

A link between thyroid function and psychiatric illness, particularly major depressive disorder (MDD) is well established. Hypothyroidism has been shown to render patients more susceptible to MDD and less responsive to antidepressant drugs. Triiodothyronine (T3) has been shown to enhance antidepressant response in euthyroid patients who have not responded to standard antidepressant treatment. Furthermore, concurrent treatment with T3 may enhance and possibly accelerate treatment response when administered from the onset of treatment concurrently with antidepressant medication. In mouse studies we have shown that antidepressant effects of T3 as a sole treatment are dose dependent and linked to enhanced serotonin release mediated via effects of chronic administration on 5-HT-1A and 1-B autoreceptors. We have further shown that combined treatment with T3 and an antidepressant enhances hippocampal neurogenesis to a greater extent than antidepressant alone. Since long-term administration of T3 to euthyroid patients is not clinically feasible, we have sought avenues to enhance brain T3 levels by alternate routes. One direction we have explored is specific inhibition of deiodinase 3 (DIO3) by means of novel small molecules synthesized by the use of a DIO3 mimic. Preliminary findings in mice suggest that brain T3 levels may be enhanced by these novel compounds and antidepressant effects may be demonstrable on screening tests. Further studies are in progress.

Thyroid hormones in the cardiac physiopathology

Maria Luiza Barreto-Chaves

Our group studies the influence of different endocrine factors on cardiovascular function. Ang II is the main vasopeptide of Renin-Angiotensin System (RAS) and exerts its potent biological effects through AT1 and AT2 receptors. In heart, Ang II induces cardiomyocyte hypertrophy and fibroblast hyperplasia through TGF-β1

recruitment. On the other hand, cardiovascular system is very sensitive to the action of the Thyroid Hormones (THs). One major cardiovascular manifestation of THs excess is cardiac hypertrophy. There is a long time our group contributes with different studies demonstrating the interaction between these endocrine systems (RAS and THs). Then, some manifestations that disrupt this interaction may help to explain the variability of cardiovascular manifestations observed, for example, in hypo and hyperthyroidism. In recent years, cardiac hypertrophy and remodeling have increasingly been documented as a consequence of activation of immunologic machinery, where recurrent or sustained inflammatory response plays a causal role in the development of hypertrophy and its transition to heart failure. We have identified novel pathways regulated by THs, which are related to the immune-inflammatory context and may potentially play important roles in the hyperthyroid heart. In this context and consistent with our findings, crosstalk between THs and the RAS suggests that the RAS may be an important mediator of some cardiovascular manifestations of THs. To address this question we have used *in vivo* and *in vitro* experimental models providing a suitable system to monitor changes in the structure and cardiovascular function induced by endocrine factors. Different methodologies have been employed and morphologic, morphometric, biochemical and functional parameters have been used to study molecular and cellular mechanisms associated to cardiovascular biology and in special to this endocrine interaction (RAS and THs).

What's New in Reproductive Endocrinology?

S27.1

Dissecting androgens in Polycystic Ovary Syndrome (PCOS)

Kirsty Walters
Australia.

Polycystic ovary syndrome (PCOS) is a common hormonal disorder characterised by reproductive hormone dysregulation involving luteinising hormone (LH) hypersecretion and hyperandrogenism, as well as reduced fertility, due to ovulatory disturbance. In addition, women with PCOS are also predisposed to metabolic disturbances such as obesity, insulin resistance, and dyslipidemia, with an increased risk of cardiovascular disease and type 2 diabetes. Currently, as the origins of PCOS remain unknown, mechanism-based treatments are not feasible and management relies on the treatment of symptoms only. However, if the underlying mechanisms involved in the development of PCOS were uncovered then this would pave the way for the development of new interventions for PCOS. Hyperandrogenism is the most consistent PCOS characteristic, and as androgens mediate their actions via the androgen receptor, we have combined a hyperandrogenised PCOS mouse model with global and neuron, granulosa cell or adipose-specific androgen receptor knockout mice to unravel the role of androgens in PCOS. These studies have revealed that androgen actions can mediate the development of PCOS, and have highlighted the importance of non-ovarian (neuroendocrine and adipose) androgen receptor-mediated androgen actions in the origins of PCOS. In particular, we have identified that a specific loss of androgen receptor signalling in the brain protects hyperandrogenised PCOS mice against the development of key reproductive and metabolic PCOS characteristics. These findings support excess androgen receptor-mediated actions in the brain as a key mechanism underpinning the development of PCOS. Hence, our data strongly supports targeting androgen actions in the brain in the development of targeted pharmacological approaches. Collectively these findings provide new insights into how evidence-based interventions may be developed in the future to treat PCOS.

S27.2

Large scale genetic studies in male infertility

Frank Tüttelmann
Germany.

Infertility affects 10–15% of couples. In about half of them, a descriptive cause can be established in the male partner, mostly reduced sperm output, of which azoospermia, the complete lack of spermatozoa in the ejaculate, is the most severe form. Non-obstructive azoospermia (NOA) comprises several subforms of spermatogenic failure, such as meiotic arrest (MeiA) and Sertoli-Cell-Only syndrome (SCOS). Most of these phenotypes are suspected to be of genetic origin. However, aside from chromosomal aberrations and Y-chromosomal AZF deletions, monogenic causes are poorly understood. Still, a number of candidate genes have been proposed to be associated with NOA, but for the majority functional analyses and validation in independent studies are lacking. Like in many other diseases, genome-wide analyses comprising arrays to detect Copy Number Variants (CNVs) and whole-exome sequencing (WES) to detect nucleotide variation are now utilised in several large scale studies to promote validation of proposed candidate genes and identification of novel genes. Candidate genes for NOA and male infertility will be reviewed and put into perspective of novel findings from the recent WES results. The importance of functional assessment especially of missense variants causing amino acid substitutions will be highlighted. Indeed, we could recently increase causal genetic diagnoses in non-obstructive azoospermic men from ~20% to ~30% by WES together with in silico/in vitro analyses. Identifying the causal mutations in an infertile men has direct implications on treatment, especially decisions on performing a testicular biopsy and counselling about risks for offspring.

DOI: 10.1530/endoabs.63.S27.2

S27.3

Menopause and cardiovascular risk

Irene Lambrinoudaki
Greece.

The transition to menopause is characterised by a decrease in circulating estradiol, relative androgen excess and a decrease in sex hormone-binding globulin concentrations. These hormonal changes are frequently accompanied by an increase in body weight, central obesity, dyslipidemia, insulin resistance and an increase in blood pressure. Aging, comorbidities, depression and inactivity further contribute to the increase in cardiovascular risk after the menopause. Beyond traditional cardiovascular risk, female – specific risk factors consist of a history of preeclampsia or gestational diabetes, a history of PCOS and the presence of severe menopausal symptoms. The risk of ischemic heart disease and stroke increases steeply after the menopause, becomes equal to that of men after the age of 60 and is higher than the risk of men after the age of 75. Cardiovascular mortality in Europe is higher in women compared to men, as women are less aware of their risk and less likely to seek medical help. Life style adaptations including healthy eating patterns, physical activity, maintaining a normal body weight and quitting of smoking are the cornerstone of prevention. Menopausal hormone therapy (MHT), if commenced within the first 10 years after menopause, has a favourable effect on the cardiovascular system, as it promotes vascular compliance, prevents central adiposity and restores lipid and glucose metabolism. MHT, if properly customized, is effective and safe for the majority of women. Transdermal estrogens are the best option for women with risk factors for thrombosis, like obesity or a family history of venous thromboembolism. A metabolically neutral progestogen, like micronized progesterone, dydrogesterone or transdermal norethisterone should be chosen for women with dyslipidemia or impaired glucose metabolism.

Abstract Unavailable.

S28.2

Vitamin D and type 1 diabetes

Suvi M Virtanen
Finland.

The rapidly increasing incidence of T1D worldwide and studies among migrants have shown that environmental factors play an important role in the pathogenesis of T1D. Identification of these risk-modulating factors would offer an excellent

opportunity to develop effective strategies for prevention of T1D. Vitamin D is one of the main candidates for protection from type 1 diabetes, although prospective epidemiological studies on the effect of vitamin D exposure during pregnancy, infancy and childhood have given inconsistent results. Vitamin D regulates the immune system and autoimmunity, which could be of relevance in the pathogenesis of type 1 diabetes. According to a prospective Norwegian study, high vitamin D status (25-OH vitamin D concentration) during the last trimester was inversely associated with the risk of type 1 diabetes in the offspring, whereas in a comparable Finnish study, vitamin D status during the first trimester was not associated with the disease risk. Recently, maternal vitamin D receptor (VDR) variants were found to be associated with a child's risk of type 1 diabetes independently of the child's genotype suggesting early programming of type 1 diabetes in the fetus. In north Finland 1965 birth cohort, vitamin D supplementation during infancy were inversely associated with type 1 diabetes development, whereas occurrence of rickets was directly associated with the disease. It is noteworthy that vitamin D supplementation recommendations were high at that time in Finland (50 μg/day). Recently findings from international TEDDY Study showed that childhood vitamin D status was protectively associated with islet autoimmunity and that association was modified by one SNIP of VDR. Interactions between genes and vitamin D intake/status on the development of islet autoimmunity and type 1 diabetes may explain the inconsistent findings. Vitamin D metabolism genes are associated with development of islet autoimmunity and type 1 diabetes as well as with vitamin D status.

S28.3

How and when to measure vitamin D?

Jean Claude Souberbielle
France.

The 25-hydroxyvitamin D (25OHD) serum concentration is the marker of vitamin D status. It is measured by immunoanalysis, mostly on automated platforms, or by separative methods such as HPLC or LC/MS-MS. An important inter-method variability has been evidenced some years ago. This has however improved recently thanks to the availability of an international standard and of a reference method (RM), and to the implementation of the Vitamin D Standardization Program (VDSP). Some problems remain however, specially in conditions where the concentration of the vitamin D-binding protein is greatly modified, such as in late pregnancy, or when the altered composition of the serum induces a «matrix» effect, such as in chronic kidney disease (CKD). The RM is a LC/MS-MS method which uses a complicated sample preparation and an isotope dilution step. It is not designed for use in routine, and a frequent mistake is to consider that LC/MS-MS is (always) the RM. Indeed, while the results of the LC/MS-MS assays are usually better correlated with those of the RM than those of most immunoassays, a significant, and sometimes huge, bias exists between the results of many LC/MS-MS assays and the RM. The VDSP has validated a certification protocol to ascertain that a 25OHD assay is strictly comparable to the RM. An important question is «to which patients should we measure 25OHD ?». Clearly, the answer is to some extent a matter of opinion as evidenced by the very different recommendations published by many groups of experts. My personnal opinion is not to measure 25OHD in the general population but to focus on some patients such as those with (or at high risk of) osteoporosis, those with CKD, those with malabsorption, and in any exploration of calcium/phosphate metabolism when serum PTH is measured.

Endocrine Controversies in Sport

S29.1

Female hyperandrogenism and elite sport

Angelica Lindén Hirschberg
Sweden.

Androgens are considered beneficial for athletic performance by potent anabolic effects on muscle mass and bone tissue. Testosterone also increases circulating hemoglobin, which will enhance oxygen uptake. Furthermore, androgens may exert behavioral and psychological effects of importance for athletic performance including increased mental drive and competitiveness. Studies in men have shown clear relationships with both exogenous and endogenous circulating testosterone to muscle mass, strength and hemoglobin. Corresponding evidence in women is much more limited. However, recent studies have demonstrated associations between circulating testosterone in the normal female range and muscle mass and strength, respectively. Moreover, it has been demonstrated that women with polycystic ovary syndrome (PCOS) are overrepresented in elite athletes. PCOS, which is a mild form of hyperandrogenism, is associated with an anabolic body composition including more muscle mass than in non-PCOS women. There are data to support that PCOS is advantageous for physical performance. This condition could therefore play a role in the recruitment of women to competitive sports. The prevalence of differences of sex development (DSD) is also increased among female athletes. XYDSD may cause a greatly increased production of testosterone in the male range, i.e. 10–20 times higher than in the normal female range. If the individual has normal androgen sensitivity, her muscle mass will develop as in males, along with increasing signs of virilization. Since sports are divided into female and male classification, it could be considered unfair to allow female athletes with endogenous testosterone in the male range to compete against women with normal female androgen levels. This lead the International Association of Athletics Federation and the International Olympic Committee to establish regulations for management of hyperandrogenism in female athletes. However, the regulations are controversial, and have been challenged. Ultimately, it is a question of ensuring fair and meaningful competition in women's sport.

S29.3

Omics to fight doping

Guan Wang
UK.

Erythropoietin, testosterone and growth hormone are drugs of choice for those athletes wishing to gain a competitive advantage as they are most difficult to detect using the current anti-doping methods. The illicit use of such substances violates the spirit of clean sport and fair competition. Since its formation in 1999, the World Anti-Doping Agency (WADA) has been responsible for drug testing. Direct detection of substances complemented by the indirect Athlete Biological Passport (ABP) approach has been developed and implemented by WADA with some success. The similarity between exogenous substances and endogenous products, the limited detection window and the often sophisticated doping strategies challenge the existing anti-doping methods. A paradigm shift is needed that focuses on the identification of biomarkers that are triggered by a doping substance. Recent progress of high-throughput technologies aimed at characterising genetic variation, gene regulation, protein and metabolite, collectively known as an 'omics' profile, is enabling advances of unprecedented speed and efficiency that should encourage a new era not only in medicine but also in the field of anti-doping. New mathematical approaches that are capable of recognising and extracting patterns from the large and complex 'omics' data are in high demand. Notably, deep learning algorithms have great potential to transform a wide range of features (input) to actionable knowledge (output) in data-intensive disciplines albeit challenges remain in interpreting these models and generating testable hypotheses in biology and medicine. In summary, concerted international research efforts across disciplines are required to systematically analyse the multilayered 'omics' data obtained from the high-throughput state-of-art technologies for identifying robust biomolecules indicative of doping, which may be incorporated into the ABP or serve as a stand alone test.

Personalised Medicine in Diabetes and Obesity (*Endorsed by the European Journal of Endocrinology*)

S30.1

Mechanisms for Cardiovascular Complications of Diabetes – Implications for Personalized Therapy

E Dale Abel
USA.

Cardiovascular disease is the major complication of diabetes that drives mortality and morbidity. Individuals with type 2 Diabetes have a 2-fold increased risk of major cardiovascular events (death, myocardial ischemia and stroke). There is also a 2–4-fold increased risk of heart failure, via mechanisms that are partially independent of underlying coronary disease and myocardial ischemia. Diabetes increases cardiovascular disease via multiple mechanisms including accelerated atherosclerosis, dyslipidemia, increased hypertension, increased thrombosis and increased inflammation. In addition, hyperglycemia and hyperinsulinemia may directly accelerate vascular injury. Additional mechanisms that increase the risk of heart failure in diabetes include altered myocardial energy metabolism, mitochondrial dysfunction, gluco-lipotoxicity and oxidative stress. Some landmark cardiovascular outcomes trials failed to demonstrate a relationship between tight glycemic control and reduction in major adverse cardiovascular complications. More recent trials have indicated that some GLP1R agonists and SGLT2 inhibitors might reduce major adverse cardiovascular outcomes. As such, an evaluation of an individual patients risk for macrovascular disease are now being factored into clinical decision making algorithms regarding the choice of glucose lowering therapies. Given the association between diabetes and atherosclerosis updated guidelines for lipid management emphasize specific guidelines and approaches to lipid management in individuals with diabetes and hypercholesterolemia. Finally, SGLT2 inhibitors and metformin have emerged as agents that might reduce the risk of heart failure in individuals with type 2 diabetes, via mechanisms that are incompletely understood. The presentation will discuss mechanisms that are responsible for the increased risk of cardiovascular disease in type 2 diabetes, particularly those that might be independent of glycemia and discuss the opportunity that this knowledge provides in personalizing therapeutic strategies that may reduce the risk of CVD.

DOI: 10.1530/endoabs.63.S30.1

S30.2

New avenues for novel drugs to treat obesity

John Wilding

Obesity is a chronic disease with significant adverse implications for health. Guidelines recommend first line treatment with lifestyle interventions that include restriction of energy intake, increased physical activity and behavioural modification, but these only reduce body weight by 3–5% initial over 12 months, and weight regain is common. Bariatric surgery is effective, but most suitable for people with more severe obesity or with significant complications such as diabetes. Pharmacotherapy is an adjunct to lifestyle intervention and may help bridge the efficacy gap between lifestyle and surgery. The anti-obesity drugs currently available in Europe are the peripherally-acting intestinal lipase inhibitor, orlistat, a combination of the mu opioid antagonist naltrexone with bupropion, and the GLP-1 receptor analogue liraglutide. In the USA phentermine as monotherapy, or in combination with topiramate, and the 5HT2c receptor agonist lorcaserin are also approved. These drugs provide approximately 3–6% greater weight loss than lifestyle intervention alone over 12 months or more treatment duration. Adverse effects depend on the mode of action, and regulators have focussed on cardiac and neuropsychiatric safety given previous problems with older (now withdrawn) medicines for weight loss such as sibutramine and rimonabant. Lorcaserin was recently shown to be safe from a cardiovascular perspective, and data with the lower dose of liraglutide in people with diabetes suggests cardioprotection in those at high risk. The recently reported results of a phase 2 trial with the GLP1 agonist semaglutide are promising and suggest even greater weight loss is possible with potent long-acting GLP-1 analogues with central effects. Future developments will likely target multiple gut hormone pathways such as GLP1 together with glucagon, amylin or PYY in an attempt to optimise efficacy and approach the weight loss seen with surgical approaches. Drugs for specific monogenic forms of obesity such as metreleptin for leptin deficiency and the melanocortin 4 receptor agonist setmelanotide for patients with POMC mutations will also be discussed.

Obesity gives you cancer: the bigger picture!

Jeff Holly
UK.

The global obesity epidemic needs no introduction to endocrinologists, but there has also been a parallel growing epidemic in the common epithelial cancers (breast, colorectum and prostate) that has largely coincided in timing and geography. Obesity has some clear effects that may increase the propensity for the development of specific tumors. There are however broader effects that could impact more generally on the most common epithelial cancers. Epithelial cells form barriers in the body that have to be constantly replenished, requiring rapid cell turnover throughout life with a consequence that naturally occurring mutations accumulate with aging. The explosion of genome sequencing data has confirmed this accumulation and revealed the build up of huge numbers of mutations in normal epithelial tissues with advancing years. These numerous mutations are more than sufficient to initiate carcinogenesis, and as a consequence elderly individuals develop many occult neoplastic lesions in epithelial tissues, as consistently confirmed by autopsy studies. Most of these lesions will however not progress to become life-threatening cancers. Such progression appears to depend on context: the tissue ecosystem within our body. This implies that the initiating mutations are not rate limiting and the transformed 'seeds' can be plentiful but they only 'germinate' into clinical cancers if the 'soil' is right. The incidence of these cancers is much lower in the East, but is increasing with Westernisation, and increases more acutely in migrants to the West. Epidemiology has also indicated that metabolic biomarkers are prospectively associated with the incidence and poor prognosis of exactly the same cancers. A Western lifestyle is strongly associated with perturbed metabolism and obesity: these may then provide a fertile soil within the body that could enable the progression of epithelial cancers. Obesity and the associated metabolic disturbance are characterised by insulin resistance and increased levels of glucose and other metabolites, dyslipidemia and altered levels of adipokines, cytokines and growth factors.The latent neoplastic seeds, which naturally accumulate with age, may then be more likely to germinate and grow in this more fertile soil. Evidence from many different fields is increasingly indicating that for the common epithelial cancers our lifestyles and especially our metabolic health, rather than our genes, may be more important for their progression to life-threatening disease. This raises new opportunities for different strategies for prevention and treatment of these cancers.

SS1.2

Sleep deficiency: A pathway to obesity

Erin Hanlon
USA.

Worldwide, rates of obesity have been steadily increasing, along with disorders commonly associated with obesity, such as cardiovascular disease and type II diabetes. Simultaneously, average sleep times have progressively decreased. Evidence from both laboratory and epidemiologic studies has consistently associated insufficient sleep or short sleep with increased risk of obesity. In the

laboratory, it is now possible to control sleep behavior and study the link between sleep duration and alterations in circulating hormones involved in feeding behavior, hunger, and appetite. Carefully controlled laboratory studies of systematic sleep restriction in healthy adults have reported alterations in peripherally secreted hormones that modulate feeding. In these studies, participants also displayed increased subjective appetite and hunger ratings, greatest for high carbohydrate and high fat foods. Most importantly, recent studies have shown that short sleep duration is associated with increased actual consumption of snacks and high energy foods. These reported increases in hunger and food intake in a state of sleep debt exceed the energy demands of extended wakefulness therefore suggesting the involvement of hedonically driven eating, i.e. eating for pleasure rather than to fulfill a caloric need. We have recently examined the endocannabinoid system, known to facilitate hedonic eating, following normal and restricted sleep. Our studies show that under normal sleep conditions, blood levels of the most abundant endocannabinoid increase from mid-sleep to early afternoon. After sleep restriction, this increase in endocannabinoid concentration is amplified, coinciding with greater desire for palatable food. The identification of the endocannabinoid system as a mediator of increased hunger following sleep curtailment may help develop novel preventive strategies in the treatment of obesity.

New Scientific Approaches

NSA1

Steroidomics

Stefan A Wudy
Germany.

The 'central dogma of biology' - a term coined by Francis Crick in 1957 - describes the flow of sequential information from genome via transcriptome, proteome and metabolome to the phenotype. Associated with each stage is the respective systems biology '-omics tool', e.g. metabolomics. The metabolome represents the complete set of metabolites (low-molecular weight molecules) in a biological sample and metabolomics describes the systematic study of these small molecules present in this biological sample (Daviss and Bennett 2005). A typical workflow of metabolomics studies implies: i) collection of a biological sample (e.g. a biofluid), ii) sample preparation, iii) multicomponent analysis by analytical platform techniques consisting of a powerful separation technique (gas chromatography (GC) or liquid chromatography (LC)) combined with mass spectrometric (MS) or nuclear magnetic resonance (NMR) based detection, iv) data acquisition, v) data analysis by sophisticated bioinformatics tools (e.g. principal component analysis), and vi) interpretation to finally recognize patterns, characterize disease signatures or biomarkers. If all components in a complex mixture are determined in a non-discriminatory (unbiased) way, such an approach is called 'untargeted'. In case only selected components are recorded, this approach is a 'targeted' one. Early attempts in characterizing normal and pathological human steroid metabolomes (steroid metabolomics, steroidomics) started from the 7th decade of the last century onwards. GC and GC-MS were the dominating techniques pioneered by Sjövall (2004) and Shackleton (2006). From the eighties of last century onwards, LC-MS techniques joined and soon ascended impressively (Wudy and Choi 2016). Focusing on the currently prevailing analytical techniques GC-MS and LC-MS (Wudy *et al.* 2018; Shackleton *et al.* 2018), this talk will demonstrate the roles of these techniques in various examples from steroid research and clinical endocrinology with respect to delineation of steroid metabolomes, characterization of disease signatures and new biomarkers.

Single cell spatial reconstruction of endocrine organs

Keren Bahar Halpern
Israel.

Mammalian tissues are composed of heterogeneous populations of cells, interacting in highly structured microenvironments to achieve physiologic goals. Understanding the design principles of endocrine tissues organization requires approaches to analyze spatially-resolved sub-populations of cells within the tissue. The mammalian liver consists of hexagonal-shaped lobules, radially polarized by blood flow and morphogens. Key liver are differentially expressed along the lobule axis, a phenomenon termed zonation. These diverse functions are carried out by hepatocytes that closely interact with supporting cells termed non-parenchymal cells (NPCs). Spatially resolved single-cell RNA sequencing (scRNAseq) is a powerful approach to infer connections between tissue coordinates and molecular identities. We have recently combined two powerful technologies - Single cell RNAsDefault (scRNAseq) and single molecule Fluorescence In-Situ Hybridization (smFISH) to reconstruct the spatial gene expression gradients of both hepatocyte and liver endothelial genes. Using this approach, we obtain the zonation profiles of all liver genes with high spatial resolution. Our work revealed an unexpected breadth of liver spatial heterogeneity, with $\sim$50% of liver genes expressed in spatially non-uniform patterns. The spatial division of labor we uncovered is in line with previous theory suggesting that liver zonation confers optimality for liver function. Pancreatic beta cells are heterogeneous at multiple levels. However, interrogating transcriptional heterogeneity in the intact tissue has been challenging. We used an optimized smFISH protocol to identify a sub-population of 'extreme' beta-cells with elevated mRNA levels of insulin. Extreme beta cells contain higher ribosomal and proinsulin content, but lower levels of insulin protein in a fasted state, suggesting that they may be tuned for basal insulin secretion. In addition, the proportion of extreme cells increases in *db/db* diabetic mice, potentially facilitating the required increase in basal insulin. Our results thus highlight a sub-population of beta-cells that may carry distinct functional roles along physiological and pathological time scales. Understanding the relation between structure of tissues and their single-cell gene expression patterns in healthy states can help up reveal how these interactions are perturbed in disease.

How can AI create value for the endocrinologist? Challenges and opportunities for AI-enabled solutions

Anca Bucur
The Netherlands.

The risk of unsustainability faced by many healthcare systems drives the focus on leveraging technology for effective solutions to key problems. Technologies such as AI, enabling to better leverage the power of data in healthcare, hold the potential to play a transformative role and contribute to improvements in both efficiency and quality. AI-enabled solutions may lead to lower costs, better patient outcomes, increased safety, streamlined information flows, and free healthcare professionals of tedious and frustrating data handling tasks. These solutions must support patient-empowerment as well, turning patients into informed partners in the medical decision making processes and fostering a shift towards preventive care. An important enabler for AI is increasing data quality. Tailored data transformation and information extraction need to be developed to augment data quality at clinical sites and help leverage all relevant information. Techniques for at-integration data extraction and in-flight classification with AI models need to be combined to unlock valuable information. Emerging Open Data initiatives could add significant value by accelerating research and development in AI, reducing innovation cost, and introducing community-wide standards and best practices. The adoption of AI in healthcare relies on the ability to provide proper, privacy-preserving use of data, and to ensure that the outputs are adequately validated, transparent, and explainable. Moreover, the new solutions must seamlessly fit in the clinical workflows, which is a non-trivial challenge, and users need to be appropriately trained to use them and to correctly interpret the outputs. The diversity of business models under which different AI assets are monetized to make the whole ecosystem sustainable, complicates things even further. A healthcare-specific AI platform that helps efficiently address the above challenges is essential to scaling the development and deployment of AI assets. The talk will introduce our ongoing work and discuss new ideas for research and collaboration.

Genome-wide effects of vitamin D on chromatin

Carsten Carlberg
Finland.

Vitamin D_3 can be produced endogenously in UV-B exposed skin, but during winter months it should be supplemented via fortified foods or pills. The main physiological functions of vitamin D are the control of cellular metabolism and immunity via regulating calcium homeostasis and modulating the response of cells of the innate and adaptive immune system, respectively. The vitamin D metabolite 1α,25-dihydroxyvitamin D_3 ($1,25(OH)_2D_3$) directly affects the epigenome and transcriptome of vitamin D receptor (VDR) target tissues and cell types. THP-1 human monocytes represent a model system that has studied most comprehensively for epigenome- and transcriptome-wide effects of $1,25(OH)_2D_3$. These data are the basis of the chromatin model of vitamin D signaling describing how VDR's spatio-temporal binding profile provides key insight into the pleiotropic action of vitamin D. Some 300 primary vitamin D target genes are regulated by VDR in concert with the pioneer transcription factors PU.1 and CEBPA and the chromatin organizer CTCF. Moreover, $1,25(OH)_2D_3$ directly affects histone markers of active promoter and enhancer regions as well as chromatin accessibility. Epigenome- and transcriptome-wide data obtained in context of the short-term vitamin D intervention study VitDbol (NCT02063334), where before and 24 h after a vitamin D_3 bolus chromatin and RNA were prepared from peripheral blood mononuclear cells. Comparable principles of vitamin D signaling were confirmed in this *in vivo* model concerning target gene responses as well as changes in chromatin accessibility. Interestingly, the VitDbol study subjects showed a personalized response to vitamin D and

could be distinguished into high, mid and low responders. In conclusion, short-term vitamin D supplementation studies represent a new type of safe *in vivo* investigations demonstrating that vitamin D and its metabolites have direct effects on the human epigenome and modulate the response of the transcriptome in a personalized fashion.

Diving into the brain: deep brain imaging techniques in conscious animals

Pauline Campos
France.

Survival of most species relies on the fact that small populations of endocrine neurons located in the hypothalamus determine critical functions such as reproduction, growth, and metabolism. These neurons are so finely regulated that their functions have been conserved across evolution; nonetheless, the mechanisms underlying these regulatory features remain hazy. Indeed, research efforts have been hindered by the complexity and inaccessibility of the hypothalamic-pituitary system, and the study of neuroendocrine function has been dominated by techniques that consist of studying *in vitro* or *ex vivo* preparations that lack many of the important regulatory mechanisms functioning *in vivo* at the level of the brain, pituitary and periphery. Nowadays, it is possible to exploit the advantages of neuronal transfection and advanced imaging techniques to study hypothalamic neuron activity *in situ*, in real time, and in conscious animals. Genetically-encoded calcium indicators have now become widely used for calcium imaging in living organisms. Their always-improving characteristics make them not only an excellent proxy for electrical activity, but also a versatile tool that allows diverse imaging techniques. Deep-brain imaging of calcium activity can be performed through gradient-index lenses that are chronically implanted and permit imaging of multiple neurons at single-cell resolution. Depending on the research question and the imaging quality required, visualisation of the neurons can be carried out in head-fixed configuration using bench-top microscopes, or in freely-moving configuration using miniature head-mounted microscopes. Alternatively, population-level neuronal calcium activity can be recorded in freely-moving animals using fibre photometry; here, an optical fibre delivers excitation light and collects the overall fluorescence of neurons expressing a calcium indicator. Importantly, using any of these techniques, it becomes possible to correlate the impact of neuronal activity on other functions, for example, blood sampling can be performed whilst recording neuronal activity in order to provide a link between the activity of specific hypothalamic neuron and the resulting peripheral hormonal release. Overall, the use of deep-brain imaging techniques in conscious rodents has the potential to broaden our understanding of how the brain controls endocrine function. It also gives us the opportunity to study why endocrine functions become disrupted in pathophysiological conditions, and how these changes may lead to the development of pathological consequences.

Debates

Food Addiction in Humans: To Be or Not to Be?

D1.1

PRO: Food addiction in humans: to be or not to be?

Fernando Fernandez-Aranda
Spain.

The **food addiction** (FA) construct has become a topic of great interest in the scientific community; however, its diagnostic, clinical and potential therapeutic implications remain unresolved. Although there is not enough evidence to confirm its diagnostic utility, given that some of the findings obtained in preclinical research associating the addictive capacity of certain palatable foods have not yet been replicated in humans, there are signs of neurobiological vulnerability and greater susceptibility to using food as a means of coping with problems and negative affect. While the first human studies focused on obesity and the general population, later research concentrated on eating disorders (ED), bariatric surgery patients and other psychiatric disorders. FA seems to reflect a transdiagnostic condition that is shown to be more prevalent in subjects with obesity (ranging from 18 to 24%) and even higher in patients with ED, particularly binge eating disorder and bulimia nervosa (ranging from 70% to 95%, respectively), but also in behavioral addictions. Considering the literature, published so far, FA is frequently associated with higher ED severity and more general psychopathology, but also with more dysfunctional personality traits and neuropsychological impairments, associated with decision making and attentional bias to food neural circuitry. The few prospective studies have shown higher food addiction to be negatively associated with treatment outcome, as well in bulimia nervosa, as pre and post-operatively in bariatric surgery. The addictive model has the potential to open new avenues of conceptualization and management in obesity and eating disorders, providing potentially new targets that might be complementary to the complex models of treatment needed in those disorders.

Surgical Treatment of Phaeochromocytoma - Query Pre-treatment?

D2.1

PRO: Surgical treatment of phaeochromocytoma - query pre-treatment?

Henri Timmers
The Netherlands.

Pheochromocytomas/paragangliomas (PPGLs) are catecholamine secreting tumors that, if missed or not properly treated, can be devastating due to potential lethal cardiovascular complications. The 2014 Endocrine Society clinical practice guideline on PPGL includes recommendations regarding optimalperi-operative care [1]. The main goal of preoperative management is to prevent a patient from developing anesthesia- or surgery-induced catecholamine storm. This warrants the involvement of an expert team of endocrinologists, surgeons and anesthesiologists. It is recommended that all patients with a hormonally functional PPGL should undergo preoperative adrenergic blockade, primarily with alpha-adrenergic receptor blockers such as phenoxybenzamine, doxazosin, prazosin or terazosin. During 10–14 days prior to surgery, doses are gradually increased until blood pressure is steadily controlled. Beta-adrenergic blocking agents such as propranolol, atenolol and metoprolol are needed when significant tachycardia or a catecholamine-induced arrhythmia occurs. A beta-blocker should not be used in the absence of an alpha-blocker because this will exacerbate epinephrine-induced vasoconstriction by blocking its vasodilator component. Calcium channel blockers or, in rare cases, the tyrosine hydroxylase inhibitor metyrosine, can be added when maximum doses of alpha- blockers are insufficient to achieve hemodynamic control. Salt and fluid loading are given to expand blood volume to prevent pre-operative orthostatic hypotension and severe post-operative hypotension. Anesthesiological management should be in experienced hands. Despite pre-operative blockade, intra-operative blood pressure may still vary, necessitating the use of short acting drugs such as phentolamine, nicardipine and sodium nitroprusside. Post-operatively the patient is monitored in the ICU for at least 24 hours to manage potential complications such as hypotension and hypoglycaemia.

T4 is Not Enough

D3.1

'Yes, T4 is not enough'

Birte Nygaard
Denmark.

Most L-T4 treated hypothyroid patients return to normal health without complaints. However, persistent symptoms such as tiredness, depression, decreased cognitive function, weight increase and musculoskeletal symptoms are described in 25% of L-T4 treated hypothyroid patients compared to 15–20% in controls. It has been assumed that all the necessary T3 could be derived from peripheral de-iodination of orally administered L-T4. Nevertheless, data has pointed towards a possible need for supplementary T3 in selected patient groups to fully restore the balance between TSH, TRH, thyroid hormones, de-iodinase and metabolism. Data show a 15–20% lower serum FT3/FT4 ratio given a stabile serum TSH after thyroidectomy than before and in thyroidectomized rats it is only possible to restore normal concentrations of FT3 in all tissues by giving a combination of L-T4 as well as L-T3. A meta-analysis in 2006 of data from more than 1200 unselected patients could not confirm an effect of L-T4/L-T3 combination therapy. However, the included studies were heterogeneous, including unselected patients. A minor study in a highly selected patient-group with Hashimoto' disease and overt hypothyroidism as well as persistent symptoms demonstrated significant effects in seven out of eleven quality of life scores and preference for L-T3/L-T4 combination therapy in 49% compared to L-T4 monotherapy in 15% ($P=0.002$). A suggested explanation for a possible need for a T3 substitution as well as T4 has been related to a change in the feedback in the hypothalamic-pituitary-thyroid axis induced by high dose og T4 and a possible relative inactivation of deiodinase 2 and hereby lower values of T3. Another possible suggested explanation is polymorphisms in the deiodinase 2 gene (D2-92 Ala) or to the cellular membrane transporter (MCT10) and by this a potential decrease in the transportation of thyroid hormone from plasma to the intracellular space and a decreased deiodination of T4 to T3. However, extended research is needed to explore the exact effect of these and other polymorphisms.

D3.2

'No, T4 is enough'

James Hennessey
USA.

To date, all major guidelines designate LT4 as the standard. Are symptoms a reliable indicator of the presence of hypothyroidism? Fatigue in primary care, predicts a lifetime diagnosis of depression or anxiety more frequently than other outcomes. Tiredness has been examined in 26 meta-analyses. Only 4.3% of tired subjects have identifiable somatic disease (includes anemia, diabetes and

hypothyroidism). In studies with control groups, the prevalence of somatic diseases was identical, an association that was clearly not causal. Based on symptoms, thyroid function testing occurs frequently but correlation with thyroid function is not significant. Symptoms or mild 'elevations' in TSH result in labeling individuals as hypothyroid and the initiation of LT4. Reports show similar symptoms in euthyroid, subclinically hypothyroid (SCHypo) and overtly hypothyroid (OHypo) patients, overlap between the groups is clear. Others reinforce the non-specificity of symptoms especially among older women. Do circulating T3 levels correlate with symptoms of hypothyroidism or predict response to LT4/LT3? Several studies demonstrate no correlation between serum T3 (on LT4) and QOL and mood. Massolt et al. demonstrated no correlation of QOL with serum T3 levels but recognized positive factors such as the time since the diagnosis of the thyroid cancer and a negative correlation with the number of all drugs ingested by the subjects. Two studies showed that T3 levels measured while on LT4 or after treatment with LT4/LT3 did not predict a positive response to LT4/LT3. Two patient surveys, shed light on patient satisfaction. The most satisfied patients are followed by primary care physicians, ingest thyroid hormone extract (DTE), have lower TSH values and adjust their doses based on symptoms. The second study reported equivalent overall satisfaction on LT4 or LT4/LT3 while DTE was superior. Dissatisfaction with weight, fatigue, mood, and memory were similar in those on LT4 and those on LT4/LT3 while DTE users complained less. Symptoms are imprecise. Utilizing T3 levels to make clinical decisions and/or predict the outcome of LT4/LT3 is not substantiated. Pending further research in new areas like DIO2 SNPs and LT4/LT3 sustained release, I will continue to utilize levothyroxine monotherapy.

Pituitary Pathology: Do We Care?

D4.1

Yes, we care about pituitary pathology!

Olivera Casar-Borota
Sweden.

Complex embryonal development of pituitary gland and sellar region explains a huge diversity of sellar neoplastic lesions. The spectrum ranges from the most frequent pituitary neuroendocrine tumours via craniopharyngiomas and tumours arising from the posterior pituitary, meninges or other mesenchymal tissues to high grade malignant primary or secondary malignancies. Furthermore, benign cysts and an increasing number of inflammatory conditions should be considered in differential diagnosis. As the clinical symptoms and imaging manifestations of different sellar lesions may be overlapping, histopathological examination of the specimen obtained during the surgery is the way to secure a diagnosis. Clinically relevant classification of pituitary neuroendocrine tumours and identification of potentially aggressive tumour types cannot be achieved without histological and immunohistochemical evaluation. Histopathological and immunohistochemical methods are important tools in the assessment of prognostic and predictive biomarkers. Moreover, tissue availability is essential for the identification of molecular therapeutic targets in several types of tumours occurring in the sellar region. A thorough histological characterisation of tissue specimens used in experimental and clinical studies is a prerequisite for high-quality research on pituitary tumours. Well-established histological and tissue-based molecular techniques enable high throughput analyses of the vast number of tumour specimens. In this debate, I will present my arguments in favour of pituitary pathology as an essential part of the clinical management of patients with sellar lesions and a tool to bring pituitary research to its height.

MicroRNAs as hormones?

D5.1

PRO: MicroRNAs and extracellular vesicles as hormones?

Edit Buzás
Hungary.

Abstract Unavailable.

D5.2

CON: MicroRNAs and extracellular vesicles as hormones?

Alberto Davalos
Spain.

The capacity of microRNAs (miRNAs) to simultaneously repress multiple targets provide a mechanism to treat disease by modulating entire biological networks. miRNAs are present in the systemic circulation and other biological fluids associated with extracellular microvesicles, exosomes, Ago2 complex or HDL. Even exogenous miRNAs have been described in our circulation. The active secretion of miRNAs by the cells has been suggested to mediate intercellular communication. The inter-organ and intra-organ cross-talk, traditionally mediated by hormones, was recently evidenced to be also regulated by extracellular vesicles. However, the biological significance, the factors that modulate their extracellular secretion and the mechanisms by which they reach the target tissue still remains elusive. Exosomes are stable nanovesicles that transport bioactive molecules (i.e. miRNAs) to target cells. One of the advantages of exosomes is that they can easily cross the blood-brain barrier without use of an additive vehicle. Recent evidence suggest that breast milk exosomes contain miRNAs that can be transferred from mother to infants, producing a potential inter-individual communication *via* miRNAs. Moreover, increasing evidence suggest that exogenous miRNAs can be transferred from diet (i.e. plants-derived miRNAs) and taken up by mammalian cells where they exert a biological effect. Their transport in extracellular vesicles might avoid their degradation by extracellular/intracellular RNases, being active signaling molecules involved in the intercellular communication. However, their real *in vivo* biological effects are under debate. In addition, how much extracellular miRNAs reach the target cell to exert a hormone-like effects is poorly understood. We here discuss some relevant biological process to understand the potential of extracellular miRNAs as hormones. The many barriers when reaching the circulatory system, the biological barriers before entering any target-cells and bypass the many intracellular barrier to reach the appropriate subcellular localization in order to exert any effects is also point out.

Should We Treat Young Osteoporotic Patients?

D6.1

Yes, we should treat young osteoporotic patients

Serge Ferrari
Switzerland.

Abstract Unavailable.

D6.2

'No, we shouldn't treat young osteoporotic patients'

Barbara Obermayer-Pietsch
Austria.

Low bone mass and a high fracture risk in young individuals has only recently become a focus of interest in bone research and health care as compared to elderly patients. In fact, according to WHO criteria, 'osteoporotic' T-scores in bone mineral density (BMD) below −2.5 can be found in less than 1% of women

before menopause, and 'osteopenia' as defined by T-scores between −2.5 and −1 in only about 10–15% of a healthy population. However, secondary causes of osteoporosis, such as inflammatory bowel disease, rheumatoid arthritis or coeliac disease have a prevalence of low BMD and/or fragility fractures between 15 and 50%. This is also true for patients with anorexia nervosa or patients on insulin therapy due to type 1 diabetes mellitus. Many other endocrine diseases, neuromuscular or metabolic disturbances and even medications with impact on the musculoskeletal system including anticancer therapy and systemic glucocorticoids have been identified to increase fracture risk. In addition, the perception of bone status or fracture risk among young patients regarding the severity of the disease or the adherence to osteoporosis prevention strategies has been reported to be very low. From a medical perspective, low BMD and/or the occurrence of low trauma or multiple fractures should alert doctors in various fields of medicine to start further investigations of their patients' bone status. A diagnostic workup should therefore include clinical exams, imaging including DXA and laboratory analyses including bone biomarkers and a large panel of investigations for secondary underlying disorders and/or medications potentially associated with osteoporosis. Therapeutic implications cover lifestyle-associated factors, physical activity for the preservation of muscle and bone mass and adapted nutritional intake. Indications and contraindications of osteotropic therapeutics will be discussed as well as general guidance for young osteoporosis patients.

The road from flash glucose monitoring to hybrid closed loop systems: keys to success.

Christophe De Block
Belgium.

Living with type 1 diabetes (T1D) is challenging and requires intensive glucose monitoring and titration of insulin in order to obtain near-normal glucose levels to reduce the risk of complications. However, changes in dietary intake and level of activity can cause large glucose excursions. Continuous glucose monitoring systems, either intermittently scanned either real-time, can provide a comprehensive picture of glucose profiles, allowing patients to make therapeutic adjustments to improve metabolic control. The use of CGM systems has proven to positively impact the management of type 1 diabetes with the potential to lower HbA1c, enhance time spent in range, reduce frequency and time spent in hypo- and hyperglycemia, lower glycemic variability, and improve quality of life. Intermittently scanned CGM or flash glucose monitoring (FGM) is beneficial for patients using multiple daily injections (MDI). For patients being treated by continuous subcutaneous insulin infusion (CSII), RT-CGM devices are better suited. Several stand-alone RT-CGM devices exist, but the next step is the combination of both, called sensor-augmented pump (SAP) therapy. Low glucose suspend (LGS = Paradigm Veo pump) and predictive low glucose suspend (PLGS = 640G pump) have shown improvements in HbA1c, hypoglycaemia and quality of life, and are particularly advantageous for people with hypoglycaemia unawareness. However, for brittle type 1 diabetic patients with erratic life style, a hybrid closed-loop system (670G pump) seems the best option so far. In this review we will highlight benefits and limitations of use of FGM/CGM for open-loop control and recent progress in closed-loop control systems. We will also discuss different patient profiles for the different systems, educational aspect which are key to successful use of the systems and touch upon costs.

Risk classification of thyroid nodules by ultrasound and indications for FNA

Laurence Leenhardt
France.

Objectives
Thyroid ultrasound (US) is a key examination for the management of thyroid nodules. Thyroid US is easily accessible, noninvasive, cost-effective and is a mandatory step in the workup of thyroid nodules. Thyroid US assessment of the risk of malignancy is crucial in patients with nodules, in order to select those who should have a fine needle aspiration (FNA) biopsy performed. Specific US features suggestive of malignancy have been recognized and described in literature, namely hypoechogenicity, irregular or blurred margins, microcalcifications, taller than wider shape and vascular signals. These features have been included in different US classifications developed over the years by many scientific societies: the American Thyroid Association (ATA), American Association of Clinical Endocrinologists (AACE), American College of Endocrinology (ACE), Associazione Medici Endocrinologi (AME), Korean Society of Thyroid Radiology, American College of Radiology and European Thyroid Association who built the European Thyroid Imaging and Reporting Data System, called EU-TIRADS. Therefore, these societies set up guidelines about indications for FNA.
Methods
We aimed to estimate and compare the performance and the limits of the different US classifications in discriminating nodules for malignancy. We compared the indications for FNA among the different US scoring systems. The non indication for FNA and the relevance of repeated FNA were also discussed.
Results
Despite some differences between the US scoring systems, we observed that all the US classifications provide an effective malignancy risk stratification for thyroid nodules, demonstrated the ability of these schemes in selecting nodules for FNA. It is time to figure out a unique international TIRADS system that will gather the strengths of the different US scoring systems and refine the indications of FNA in thyroid nodules.

Primary hyperparathyroidism: surgical vs. medical therapy

Tomaz Kocjan
Slovenia.

Primary hyperparathyroidism (PHPT) is a common endocrine disorder that is characterized by hypercalcaemia and elevated or inappropriately normal levels of parathyroid hormone (PTH), which is excessively secreted from one or more parathyroid glands. Classical disease is nowadays only seldom seen due to widespread biochemical screening. Most patients are asymptomatic and have more subtle, but clinically important skeletal and renal involvement. A normocalcaemic variant of the disease with high PTH levels and persistently normal serum calcium values is sometimes diagnosed during the evaluation of osteoporosis. Parathyroidectomy is the only curative option and the procedure of choice for all patients with symptomatic PHPT. Guidelines for surgery in asymptomatic disease include age <50 years, increased serum calcium >0.25 mmol/l (1 mg/dl) above upper limit of normal, reduced bone mineral density (BMD) by DXA to a T-score of <-2.5 S.D. at any site and/or a vertebral fracture by imaging, creatinine clearance <60 ml/min, kidney stone or nephrocalcinosis by imaging, hypercalciuria >400 mg/day accompanied by biochemical stone risk profile placing patient at risk of kidney stones. Patients who do not meet surgical criteria or those who decline surgery should be monitored for signs of disease progression. If surgery is not an option, pharmacological approaches are available and effective. Medical management starts with correction of dietary calcium and vitamin D insufficiency. Cinacalcet is a calcimimetic agent that effectively reduces calcium levels, but does not appear to have any effect on BMD. On the other hand, alendronate improves BMD without any changes in the serum calcium. Less data is available for other bisphosphonates and denosumab. Recently, thiazides have re-emerged as a potentially effective and safe option for controlling hypercalciuria in selected patients with PHPT, but careful monitoring for hypercalcemia is required.

Non functional pituitary tumours - not always easy

Davide Carvalho
Portugal.

Tumours of the pituitary gland and sellar region represent approximately 15% of all brain tumours. The most common tumours are by far pituitary adenomas, confined to the sella. However, several types of tumours may involve the sellar region, reflecting its complex anatomy. The differential diagnosis of nonpituitary sellar masses is broad and includes inflammatory and infectious diseases, cell rest tumours, germ cell tumours, lipomas, gliomas, meningiomas, metastatic tumours, and vascular lesions. Nonadenomatous sellar lesions do not present with any hypersecretory syndrome but rather with neurologic or hypopituitary symptoms as a result of the mass-effect mechanism. Neurologic symptoms include headache, visual disturbance, cranial neuropathy, hydrocephalus, and mental changes. Hypopituitarism most often is characterized by growth hormone deficiency and gonadal dysfunction, followed by secondary hypothyroidism and adrenal insufficiency. Hyperprolactinemia secondary to stalk compression is a common cause of hypogonadism. Diabetes insipidus is highly suggestive of nonadenomatous sellar lesions, especially in sarcoidosis and in metastatic sellar involvement. For most of these tumours, surgery is first choice intervention. Resolution of headaches and amelioration of visual field defects occur shortly after surgery in the majority of patients. The recovery of visual fields is progressive, with an early fast phase of improvement during the first week after surgery, an early slow phase (4–6 months postoperatively) by the end of which most of the eventual recovery takes place and a late phase (up to 3–5 years) in which mild further improvement may still occur. Regarding pituitary function, in most but not all series, normalization of one or more hypothalamo-pituitary-axis function has been reported after surgery, whereas worsening of pituitary function is less common. The degree of improvement is variable. Patients in whom tumour has been completely excised usually are follow-up in an expectant way. In contrast, the best management of patients in whom residual tumour is detected on postoperative MRI is controversial, and may include surgery, radiotherapy, and medical therapy namely the use of dopamine agonists.

Comorbidities in Turner syndrome

Claus H. Gravholt
Denmark.

Treatment with growth hormone (GH) during childhood and adolescence allows a considerable gain in adult height. SHOX deficiency explains some of the phenotypic characteristics in TS, principally short stature. Puberty has to be induced in most cases, and female sex hormone replacement therapy should continue during adult years. These issues are normally dealt with by the paediatrician, but once a TS female enters adulthood it is less clear who should be the primary care giver. The proper dose of hormone replacement therapy (HRT) with female sex steroids has not been established, and, likewise, benefits and/or drawbacks from HRT have not been thoroughly evaluated. In most countries it seems that the transition period from paediatric to adult care is especially vulnerable and the proper framework for transition has not been established. Likewise, no framework is in place for continuous follow-up during adult years in many countries. During the transition period many young females opt out of longitudinal follow-up, probably because they feel well and cannot clearly see the need for continued medical surveillance, which has to be thoroughly and well explained to patients. However, osteoporosis, diabetes, both type 1 and 2, hypothyroidism, obesity and a host of other endocrinological diseases and conditions are seen more frequently in Turner syndrome in the long term. Prevention, intervention and proper treatment is only just being recognized. Hypertension is frequent and can be a forerunner of cardiovascular disease. The description of adult life with Turner syndrome has been broadened and medical, social and psychological aspects are being added at a compelling pace. With the new international guideline for TS a proposed setup for management is presented. In summary, Turner syndrome is a condition associated with a number of diseases and conditions which need the attention of a multi-disciplinary team both during childhood and adulthood.

Co-morbidities in Klinefelter syndrome

Anne Skakkebæk
Denmark.

Klinefelter syndrome (47,XXY; KS) is still a diagnostic challenge. Many patients are misdiagnosed, or remain undiagnosed, and thereby prevention and treatment of associated comorbidities is often delayed. The presence of the additional X chromosome is associated with a number of health problems involving multiple organs and consequently are both morbidity and mortality significantly increased. The increased morbidity seen in KS is due to an increased risk of developing physical diseases such as diabetes, metabolic syndrome, obesity, cardiovascular disease, infections, osteoporosis, as well as psychiatric diseases. However, the degree of co-morbidity seen between KS patients display great heterogeneity. Recent studies in genetics indicate that global DNA methylation and RNA expression changes may play a central role for the phenotype. Recommendations for improving clinical practice, including neonatal KS screening programs, and a multidisciplinary approach to KS treatment will be discussed.

NCAH and female reproduction

Melek Eda Ertorer
Turkey.

Nonclassical Congenital Adrenal Hyperplasia (NCAH) usually due to 21 Hydroxylase deficiency (21OHD) is an autosomal recessive disease, occurring in upto 1/200 of Caucasians and more often in certain ethnic groups. Common CYP21A2 mutations from most severe to mildest are; null, I2 splice, I172N, P30L, and V281L. Mutations leaving 20–70% of enzyme activity is responsible for NCAH, mostly caused by V281L mutation. About 25–50% of patients are homozygous or compound heterozygous for two mild (nonclassical) alleles. Remaining have one severe (classical) and one mild mutation. Carrier frequency for a severe CAH mutation is about 1/60, whereas mild mutations are detected ranging from 1/5 to 1/16 of the population. Thus, preconception counseling is very important for avoiding birth of classical CAH babies to NCAH mothers. Probability of a NCAH mother having an infant affected by classic CAH is about 1/480. Following confirmation with dynamic hormone testing, analysis for 21-hydroxylase gene can determine the underlying mutation and disease risk for the fetus. Male partner of a NCAH female carrying a severe mutation should also be genetically examined. There is an overlap between the stimulated serum 17OHP levels of heterozygotes for 21OHD and unaffected subjects. Although heterozygotes do not need medical treatment, they should have genetic counselling. In adults, first symptoms of NCAH are usually acne, hirsutism, oligo-menorrhea. Symptoms of a NCAH individual with one classic allele is more severe and 17OHP level is more elevated than the one with homozygous mild mutations. Infertility is the presenting symptom in only 13%. Glucocorticoid (GC) therapy is the treatment of choice for hyperandrogenism and infertility. It usually takes about three months for the reversal of complaints. This treatment also seems to shorten the time to conceive and reduce miscarriage rates. Ovulation induction with clomiphene citrate or aromatase inhibitors can be performed for selected NCAH females.

'Shifting treatment paradigms in osteoporosis'

Núria Guañanens
Spain.

In recent years a number of paradigms have changed the way we go about therapy and its monitoring. So, what has changed? Bisphosphonates were until recently the cornerstone of osteoporosis treatment, but in the last few years new drugs and treatment concepts have appeared. Thus, anabolics such as teriparatide are established as the gold standard in patients with high risk of vertebral fractures. In addition, monoclonal antibodies against bone turnover regulators such as denosumab have found their place in the osteoporosis scope. Furthermore, the new drug almost on the market: romosozumab, is another monoclonal antibody, inhibitor of sclerostin, which is proving to be a potent anabolic drug in major trials. New drugs with prolonged anabolic effects are needed. But, from my point of view the main paradigm change is how to figure out all the different kinds of

sequential treatment. We know now that after an anabolic agent a potent antiresorptive treatment must be started and in a concise way; a next immediate medication should be planned after denosumab and romosozumab discontinuation. The last paradigm shift is how bone turnover markers are gaining momentum in monitoring, in addition to bone mineral density and bone fracture outcomes. To conclude, with these new concepts we should be open-minded about both new therapies and monitoring strategies.

Fracture risk prediction in benign and tumoral bone: new insights

Cyrille Confavreux
France.

Among the different functions of bone, the biomechanical one is the most evident. Biomechanical function of bone allows locomotion and protection of essential organs like brain and in a way can be considered as a survival function. Optimal bone strength maintenance through bone remodeling is an active energy consuming process. When a fracture occurs, two sides of the phenomenon should be evaluated: the trauma and the bone resistance including bone mass and bone quality. Bone resistance impairment leads to fragility fractures which is source of pain, local complications, disability, surgery and excess mortality. Performing a diagnostic assessment to understand origin of bone resistance impairment is the first key step for the physician. Etiologies are numerous including osteoporosis, osteomalacia, bone metastases, chronic kidney diseases, genetic disorders, endocrine diseases such as hyperparathyroidism. The second key step is fracture risk evaluation to advise patients on bone targeted treatments and lifestyle. The available tools are not the same in a benign bone fragility context and in bone metastases. In benign bone fragility, physicians will use bone densitometry (DXA), clinical risk factors, FRAX® score tool, TBS, or bone remodeling markers. Some device like HR-pQCT, MRI and qCT may also be useful. For bone metastases, some scores like the Mirels, the SINS, or the Tokuashi's scores, have been developed. These scores have limitations and we will point out the difficulty to assess fracture risk and the need for new tools.

How multidisciplinay care and tailor-made transition save lives of young adults with Prader-Willi syndrome

Laura de Graaff
The Netherlands.

Introduction
Due to improved pediatric care, life expectancy of children with complex genetic syndromes (CGS) is increasing. Many children with CGS now do reach adult age and have to make the transition to adult endocrine healthcare. However, many adult endocrinologists are not yet prepared for the increasing number of adults with CGS. Although patients receive multidisciplinary (MD) care at the pediatric department, MD care is not yet available for most adults with CGS. Also, for most of the CGS, little is known about the manifestations at adult age as patients used to die before reaching adult age. As the number of CGS adults is rapidly increasing, it is important to know which medical problems we can expect and how we should treat them.
Methods
We have launched a MD outpatient clinic (OPC) for adults with rare CGS with (suspected) internal/endocrine problems. We perform thorough medical screening in all patients in order to detect and treat undetected health problems. We routinely collect clinical data to get an overview of the health problems at adult age, which are yet unknown for most CGS.
Results
In the first three years since start of the MD OPC, we have helped over 520 new CGS patients, of which 124 have Prader-Willi syndrome (PWS). We found a striking number of undetected and untreated health problems, like hypogonadism, osteoporosis, diabetes mellitus, hypothyroidism, obesity and cardiovascular disease.
Conclusion
Adults with CGS often have endocrine disorders as part of their syndrome, and therefore adult endocrinologists should know at least the basics of each syndrome. PWS is one of the CGS in which comorbidity often goes undetected due to atypical presentation of health problems. Undetected endocrine and cardiovascular problems can lead to significant morbidity and mortality. Knowledge of PWS can prevent painful and expensive complications.

The metabolic effects of SGLT2 inhibitors – Does the increase in ketone bodies protect the heart?

Esben Søndergaard

Type 2 diabetes causes excess cardiovascular mortality and microvascular disease. Therefore, the results of the EMPA-REG OUTCOME trial were received with great excitement, since this was the first trial with cardiovascular end points to show a benefit for persons suffering from type 2 diabetes. The striking benefit of a 38% reduction in cardiovascular mortality during SGLT2 inhibitor treatment was surprising and exceeded what was expected based on the relatively modest reductions in glycemic levels, blood pressure and body weight observed in the trial. Therefore, alternative explanations for the cardioprotective effects are sought. It has been suggested that the increase in circulating ketone bodies, observed during SGLT2 inhibitor treatment, could mediate these effects by acting as a superfuel for the heart. This remains controversial since experimental evidence regarding the metabolic effects of SGLT2 inhibitor treatment is limited, however, we have recently demonstrated a striking effect with a 50% reduction in glucose uptake during ketone infusion. In our ongoing study, we continue to investigate the hypothesis, that the increase in circulating ketone bodies will reduce oxygen consumption and improve the efficiency of the heart by increasing ketone body oxidation at the expense of FFA and glucose oxidation. We are doing this in a randomized, placebo-controlled crossover study in persons with type 2 diabetes. Using a novel combination of PET tracer techniques, we measure oxygen consumption, energy efficiency, and FFA and glucose oxidation in the heart. Uniquely, this allows previously inaccessible in-vivo measurement of cardiac substrate metabolism. The results of the study will provide new important mechanistic insight into the role of ketone bodies in the cardioprotective effects of SGLT2 inhibitors. A beneficial effect of an increase in ketone bodies could lead to development of targeted treatment to promote ketogenesis in people suffering from type 2 diabetes or ischemic heart disease.

New tracers for PET in humans: Hopes, aims and current evidence

Lars Christian Gormsen
Denmark.

Positron emission tomography (PET) using the glucose analog tracer fluoro-deoxy-glucose (FDG) is today a widely available and highly useful functional imaging modality. Thus, FDG-PET has proved its clinical worth in particularly malignancy detection and treatment monitoring and is now often a first-line choice in the diagnostics of a range of diseases. However, PET is also an excellent tool for non-invasive measurement of metabolic processes, pathophysiology and pharmacokinetics, since virtually any molecule, drug or metabolite can be labeled with a PET-isotope. Simultaneous measurement of tracer input coupled with detection of tracer buildup in various organs or tissues of interests allows for accurate tracer kinetics and therefore also of tracer transfer between tissue compartments. In this talk, I will cover the basic set-up of metabolic PET as it is practiced in a tertiary university unit. Different approaches to basic research questions as well as some basic kinetic models will be presented with examples drawn from our own experience coupled with recent interesting studies from other centres. Finally, the use of PET to image tissue ketone body utilization (by 11C-hydroxybutyrate), peripheral organ damage in early Parkinsons disease (by 11C-Donepezil), drug pharmacokinetics (by 11C-metformin) and cholinergic signaling in inflammation (by 18F-FEOBV) will be presented. Combined, these examples will highlight the use of PET as a tool to image not only whether tissue is metabolically active (traditional FDG PET) but also as a biomarker suited for precision medicine.

Genetically tailored pig models in translational endocrine and metabolic research

Eckhard Wolf
Germany.

The pig is an interesting model species for translational endocrine and metabolic research. Many organ systems relevant for endocrine research, including pancreas and gastrointestinal tract, are more similar to the corresponding human organs than those of other species. The human-like size and weight of pigs allows direct transfer of medical products, surgical techniques and *in vivo* imaging techniques to applications in human patients. Moreover, metabolic tests, such as glucose tolerance tests, can be performed with frequent blood sampling of volumes sufficient for a broad spectrum of clinical-chemical, metabolomic and other analyses. Due to the establishment of efficient and precise techniques for genetic modification of pigs, it is possible to generate tailored pig models, which resemble human disease mechanisms on a molecular and functional level. To mimic the markedly reduced insulinotropic action of glucose-dependent insulinotropic polypeptide (GIP) in type 2 diabetic patients, we generated transgenic pigs expressing a dominant-negative GIP receptor ($GIPR^{dn}$) in the pancreatic islets. $GIPR^{dn}$ transgenic pigs exhibit an impaired incretin effect due to a blunted insulinotropic action of GIP, a progressive deterioration of glucose control due to delayed and – at later stages – quantitatively reduced insulin secretion, and an impairment of physiological age-related expansion of beta-cell volume. $GIPR^{dn}$ transgenic pigs provide a unique opportunity to screen for biomarker candidates during the pre-diabetic period and to test therapeutic strategies targeting the glucagon-like peptide 1 (GLP1) receptor. In addition, we generated transgenic pigs expressing INS^{C94Y} as a model for mutant *INS* gene-induced diabetes of youth (MIDY). MIDY pigs show early-onset clinical diabetes mellitus, markedly reduced body weight gain and beta-cell volume associated with a marked reduction of insulin secretory granules and severe dilation of the endoplasmic reticulum in the beta cells. MIDY pigs can be used for insulin treatment studies or for testing the efficacy of gene or cell therapies as well as islet transplantation. Secondary lesions of diabetes mellitus are another interesting area of research. We thus established the Munich MIDY pig biobank as a unique resource for studying systemic consequences of chronic insulin deficiency and hyperglycaemia. A multi-omics analysis (transcriptome, proteome, metabolome, lipidome) of liver samples revealed increased activity in gluconeogenesis, ketogenesis, amino acid metabolism and oxidation of fatty acids in the MIDY samples, whereas pathways related to extracellular matrix and inflammation/pathogen defence response were less active than in wild-type samples. The multi-omics data set provides a valuable resource for comparisons with other experimental or clinical data sets.

The gravitostat – possible relation to hormones

John-Olov Jansson
Sweden.

There are several regulatory systems the body that keep body functions, like body temperature and blood glucose, constant. In this study we have added and removed weight loads from experimental animals and measured the effects on biological body weight. The results of these experiments indicate that there is a novel regulatory mechanism to keep the body weight constant, mostly by adjusting the body fat mass. The mechanism was dependent on intact bone cells. We hypothesize that there is a sensor for body weight in the long bones of the lower extremities acting as 'body scales'. This is part of regulatory system, a gravitostat, that keeps body weight and body fat mass constant. Later findings demonstrate that the gravitostat regulates fat mass in obese mice while leptin regulates fat mass only in lean mice with low endogenous serum leptin levels. We propose that activation of the gravitostat primarily protects against obesity while low levels of leptin protects against undernutrition.

Immunotherapy-induced Endocrinopathies: Assessment, management and monitoring

Daniel Morganstein
UK.

Checkpoint Inhibitors have emerges as a major breakthrough in cancer therapy. Side effects are largely immune mediated, termed immune related adverse events. Whilst the majority of these respond to immunosuppressive treatment, most frequently glucocorticoids, endocrinopathies are amongst the more frequent adverse events, and usually lead to permanent hormone deficiency, requiring life long hormone replacement. There are differences in the pattern of endocrinopathy between different checkpoint inhibitors. The CTLA-4 inhibitor ipilimumab results in hypophysitis in up to 20% of individuals, usually resulting in multiple anterior pituitary deficiencies, whilst thyroid changes are often mild and sub-clinical. In contrast the PD-1 and PD-L1 inhibitors cause both a destructive thyroiditis with a transient thyrotoxic phase, often progressing to hypothyroidism, or *de novo* hypothyroidism. They are also associated less frequently with isolated ACTH deficiency and insulin requiring diabetes closely resembling type 1 diabetes. The non-specific symptoms of many endocrine disorders, coupled with the frequency of symptoms in patients with advanced cancer and other immune related adverse events means a high index of suspicion for the development of endocrine adverse events is required, aided by an understanding of the pattern of expected adverse events for each agent. Although initial management closely resembles that of more common endocrine dysfunction, the longer term outcomes and likelihood of recovery of hormone function are currently unknown. In addition, around a third of patients receiving checkpoint inhibitors require high dose steroids for management of non-endocrine toxicity, with a significant incidence of steroid induced hyperglycaemia and adrenal suppression, both of which may require the input of the endocrine team.

Nursing approach to the holistic care of patients with intellectual disability

Ruth Northway
UK.

People with intellectual disabilities are known to face many inequalities in healthcare that lead to poor health as well as premature and preventable death. They often experience multiple comorbidities, often at a younger age than the wider population, and often these include endocrine disorders. However, many of the barriers they face to accessing timely and appropriate health care are preventable and/or their impact can be reduced. This presentation aims to highlight both the nature of these barriers and the strategies that nurses can use to overcome them. First the presentation will consider the wide range of ability and disability encompassed in the term 'intellectual disability'. It will draw upon relevant literature to identify the prevalence of common endocrine disorders in people with intellectual disabilities. The barriers that may exist to identification of such disorders will also be explored. Literature, personal experience and personal research will be used to discuss the physical, cognitive, communication, economic, ethical, organisational and intrapersonal barriers that may impact upon access to healthcare for people with intellectual disabilities who have endocrine disorders. Strategies that can be used by nurses to facilitate holistic person centred care will be considered and the concept of reasonable adjustments to care will be introduced. In particular the implications for self-management (or supported self-management) of long term conditions will be explored. It will be concluded that nurses working in partnership with others can do much to promote holistic person centred care for people with intellectual disabilities and hence reduce the health inequalities they so often experience. However, this has implications for the development of nurse education and practice and such developments need to be underpinned by a robust evidence base. Potential future developments will thus be proposed.

Testosterone replacement: 'The best practice'

A Hawkins, E Casey & K Nikookam
Department of Endocrinology, King George Hospital, Barking, Havering & Redbridge University Hospitals NHS Trust, Ilford, Greater London, UK.

Testosterone deficiency syndrome (TDS) may well contribute to a number of co morbidities and multitude of symptoms which may affect one's daily activities adversely. TDS prevalence in UK is 1:500 and certain groups of patient's are at higher risk of TDS, in particular elderly and patients with diabetes mellitus where 42% are known to have TDS. A retrospective audit was carried out to bench mark our practice in line with a publication of a recommended National/European guidelines of 'A practical guide for the management of men with suspected testosterone deficiency'. We obtained and analysed the medical records of 35 patients who attended our endocrine services over a 6 month period. 31 of them had already been started on testosterone from the year before. Seven patients were excluded due to lack of data availability. The age in our cohort ranged from 31 to 72 years with a mean age being 53 years. Initial testosterone and PSA results ranged between 0.4 nmol/l to 9.4 nmol/l (normal 8.4–28.7 nmol/l) with mean of 5.9 nmol/l and 0.1 ug/l to 2.1 ug/l (normal 0–3.0 ug/l) with a mean of 0.7 ug/l respectively. We found, the time lapse between initial blood results and testosterone initiation where from 1 to 18 months, with a mean of 7 months. The guidelines suggests; prior to testosterone initiation PSA and a rectal examination (PR) should be carried out. Within our patient group only 5/28 (18%) had a PR, 21/28 (75%) had PSA,16/28 (57%) had USS of prostate and 16/28 (57%) of our patients have had neither a PR nor an USS. 18/28 (64%)of the patients who had been started on testosterone were on Nebido 1 g injection, 15 of whom had this administered by their GP, the other 3 by the hospital Endocrine Specialist Nurse (ESN). The 3 ESN treated patients had an ultra sound scan (USS) before commencing treatment. Recommended on-going monitoring of 3 to 6 monthly intervals in the first year was achieved on 23/25 (92%) of our patients.

Conclusion

We recommend a dedicated andrology service and a shared care pathway with community colleagues to ensure all patients have received the best possible care by means of investigations, treatment and follow up care in line with National/European guidelines.

NPD2.1

Hypoparathyroidism: Aetiology, diagnosis and challenges in management

Ansgar Heck

Hypoparathyroidism is an endocrine disease resulting in hypocalcemia due to inappropriately low circulating parathyroid hormone levels. It is defined as an orphan disease by the European Commission, and commonly managed by endocrinologists and endocrine units. All healthcare personnel involved in the management of patients with chronic hypoparathyroidism should have knowledge about symptoms, treatment and potential complications.

Causes

In adults, hypoparathyroidism most commonly is an acquired condition due to neck surgery or autoimmunity. Idiopathic or autoimmune hypoparathyroidism can occur isolated or in a setting of other associated autoimmune endocrinopathies. In children, adolescents and young adults, underlying genetic conditions have to be considered.

Symptoms

Acute symptoms of hypoparathyroidism are caused by decreasing and low circulating levels of calcium. Patients with rapidly changing calcium levels have more severe symptoms than patients with gradually decreasing levels. In the latter, symptoms can be surprisingly few and weak despite low calcium levels. Common and early neuromuscular symptoms of hypocalcaemia are numbness, tingling and muscle spasm in hands, feet and face. Many patients report muscle stiffness and cramps, slow thinking, lack of concentration and initiative, often described as 'brain fog'. Severe hypocalcaemia can result in life threatening symptoms as tetany, seizures, larynx spasms and ventricular arrhythmias. In patients with chronic hypoparathyroidism, it is important to have basic knowledge about symptoms and treatment of hypercalcemia as overtreatment frequently occurs. Symptoms of hypercalcemia include: nausea, anorexia, constipation, polyuria, dehydration, bradycardia, muscle weakness, confusion and coma.

Treatment and management

As primary treatment, activated vitamin D analogues (calcitriol and alfacalcidiol) plus calcium supplements in divided doses are recommended. Treatment should aim serum calcium levels in the low normal range and serum phosphate within the normal range. A high intake of Calcium supplements (>1000 mg/day) should be avoided. Sufficient dietary intake or supplement of magnesium and conventional vitamin D (cholecalciferol or ergocalciferol), and a phosphate low diet may result in more stable serum calcium levels and lower risk for long term complications. Recently, a synthetic PTH-analogue has become commercially available. This replacement therapy may improve treatment. But so far, this treatment is costly and there is only limited documentation of improved outcomes. The lecture will focus on a patient orientated, team based approach in the management of chronic endocrine conditions as hypoparathyroidism. Team based endocrine care should include assessment of symptoms, eventually aided by disease specific questionnaires, patient education, nutritional advice and follow up of compliance of pharmacologic treatment.

The microenvironment of pituitary neuroendocrine tumors: focus on folliculostellate cells

Mirela Diana Ilie
France.

The tumor microenvironment can comprise more than 50% of the tumor mass and includes resident and infiltrative non-tumor cells, as well as extracellular matrix proteins, signaling molecules, and blood and lymph vessels (Balkwill et al., 2012). In recent years, the tumor microenvironment has begun to be considered both a prognostic tool and a therapeutic target (Hui and Chen, 2015). While the existence of the tumor microenvironment is well accepted and described in numerous cancers, little is known about the tumor microenvironement of pituitary neuroendocrine tumors. Even less is known about the folliculostellate cells in the context of the microenvironment of pituitary neuroendocrine tumors. Folliculostellate cells are resident cells of the normal anterior pituitary, comprising 5–10% of the normal anterior pituitary. Beside the role folliculostellate cells have in the normal anterior pituitary, their identification in pituitary neuroendocrine tumors suggests they may also have a major implication in these tumors. Therefore, better characterization of pituitary neuroendocrine tumor-associated folliculostellate cells and understanding of their contribution and their functional interactions with tumor cells and tumor-associated stroma may provide important indications regarding the mechanisms that drive tumorigenesis-associated processes such as immune escape, proliferation, local invasion, dedifferentiation, and ultimately tumor aggressiveness. The research project in which I was involved during the fellowship aimed at better characterizing folliculostellate cells within pituitary neuroendocrine tumors, and it involved a combined exploration of their histological characteristics and of their cellular properties.

Genetic testing for hereditary hyperparathyroidism in a large UK cohort

Sashi Mariathasan, Katrina Andrews, Edward Thompson, Ruth Armstrong, Soo-Mi Park & Ruth Casey
Cambridge University Hospital NHS Foundation Trust, Cambridge, UK.

Primary hyperparathyroidism (PHPTH) is a common endocrine disorder and it is estimated that 10% of cases are hereditary, related to syndromes including; multiple endocrine neoplasia (MEN) type 1, MEN type 4, MEN2A and hereditary hyperparathyroidism jaw tumour syndrome. Further hereditary cases can occur in the absence of syndromic features such as familial hypercalcemia hypocalcuria. Identifying cases of hereditary PHPTH enables a personalised medicine approach. Current guidelines recommend that genetic testing is considered for patients i) presenting with PHPTH <40 years of age, ii) with multi-glandular/ recurrent disease, iii) with a personal or family history suggestive of an endocrine neoplasia syndrome or iv) a family history of PHPTH.

Aims and methods

A retrospective review of patients referred for genetic testing for suspected hereditary HPTH over a 4 year period at Cambridge University Hospital NHS Foundation Trust was performed. Genetic analysis was performed by next generation sequencing of a gene panel including; *MEN1*, *RET*, *CDC73*, *CDKN1A*, *CDKN2B*, *CDKN2C*, *CaSR*, *AP2S1*, *GNA11*. Aims of this study were to better define testing criteria for suspected hereditary PHPTH in a UK cohort.

Results

75 patients were included in this study (54 female) with a mean age of 40 (SD 16.4). A pathogenic germline variant was identified in 17.3% ($n=13$) and a variant of uncertain significance was identified in 5 patients (6.7%). A pathogenic variant was identified in *CDC73* in a single patient, *MEN1* in 3, *CaSR* in 8 patients and *AP2S1* in a single paediatric case. Five of the eight patients with a *CaSR* mutation had a calcium creatinine ratio (CaCrR) <0.01 and there was a significant difference in the mean CaCrR in those patients with an identified *CaSR* mutation versus those without ($P=0.0078$). Age at diagnosis, histology showing hyperplasia and gender were not predictive of a pathogenic germline variant ($P=0.28$) ($P=0.57$) and ($P=0.31$) but a positive family history was ($P=6.4e-05$). 20 patients were $>$ 50 years of age and the diagnostic rate of a pathogenic variant was 10% in those patients $>$ 50 years compared to 19% in those $<$ 50 years. Two patients $>$ 50 years were diagnosed with a pathogenic variant in *MEN1* and *CaSR* but both patients had at least one risk factor for genetic testing. Family history was a strong predictor of hereditary PHPTH in this cohort. Pathogenic variants can be identified in older patients particularly those with additional risk factors. Such patients should therefore should be considered for genetic testing.

OC1.2

Urinary magnesium as predictor of nephrolithiasis in patients with asymptomatic primary hyperparathyroidism

Federica Saponaro[1], Filomena Cetani[1], Marina Di Giulio[1], Francesco Di Giulio[1], Laura Mazoni[1], Matteo Apicella[1], Marco Scalese[2], Elena Pardi[1], Simona Borsari[1] & Claudio Marcocci[1]
[1]Endocrinology Unit, University of Pisa, Pisa, Italy; [2]Institute of Clinical Physiology, National Council of Research, Pisa, Pisa, Italy.

The 4th International Workshop for the management of asymptomatic PHPT included the presence of hypercalciuria (dUCa$>$ 400 mg/day) and increased stone risk by biochemical stone risk profile as criteria for surgery. Our aim was to evaluate the complete stone risk profile in 176 consecutive patients with asymptomatic PHPT. We recorded clinical and biochemical data, including 24 hours urinary measurements of the following parameters: volume and pH, creatinine, calcium, magnesium, sodium, potassium, ammonium, uric acid, oxalate, citrate, phosphate, inorganic sulphate and chloride and kidney ultrasound. In our cohort dUCa$>$400 mg/day showed a low sensitivity and positive predictive value (PPV) for nephrolithiasis with high specificity (46.2, 32.7, 73.0% respectively), while hypercalciuria by 4 mg/kg/bw (d-UCa$>$ 4 mg/kg) had a high sensibility, with low PPV and specificity (79.5, 27.7, 40.1%). Daily hypomagnesuria (d-HypoMg), but not any other urinary parameter, was an independent predictor of nephrolithiasis in the univariate (OR 2.97 CI 1.27–7.09 $P=0.014$) and multivariate analyses adjusting for age, sex, BMI, and eGFR (OR 3.13 CI 1.17–8.42 $P=0.02$). In the regression analyses with urinary calcium d-HypoMg was relatively lower in patients with nephrolithiasis compared with those without. The mean ratio between (dUCa) and (dUMg) was higher in patents with nephrolithiasis compared with those without (4.6 ± 2.0 vs 3.3 ± 4.1; $P<0.001$). In the univariate and multivariate analyses the dUCa/dUMg ratio was a significant predictor of nephrolithiasis [OR 4.9 (2.3–10.5); $P<0.001$; OR 5.3 (2.4–11.6), $P<0.001$, respectively]. The AUC using the dUCa/dUMg ratio as variables was 0.69 (CI 0.60–0.79; $P<0.0001$). The best cut-off value, set at the highest Youden index, was equal to 4.0, with a sensitivity of 59.0% and a specificity of 77.4%. In patients with hypercalciuria ($>$400 mg/24-hour) dUMg was positively correlated with dUCa in those without nephrolithiasis ($r=0.50$, $\beta=0.2$, $P=0.002$) but not in those with nephrolithiasis ($r=0.05$, $\beta=0.014$; $P=0.8$). In patients without hypercalciuria we found that hypomagnesuria remained a predictor of nephrolithiasis using either 400 mg/die ($P=0.002$, OR 5.12 (1.84–14.24) or 4 mg/kg bw ($P=0.014$, OR 6.24 (1.45–26.8). Moreover, the OR for nephrolithiasis improved using the combination of d-HypoMg with d-UCa$>$4 mg/kg (OR 8.12, CI 1.92–34.18, $P=0.004$), but not with dUCa$>$ 400 mg/day. The current urinary calcium threshold of $>$400 mg/24-hour has a low sensitivity in detecting nephrolithiasis; our data suggest that sensitivity, specificity and positive predictive value could be improved including dUMg, dUCa/dUMg ratio and the combination of d-HypoMg with d-UCa$>$4 mg/kg in the stone risk evaluation.

Epigenetic deregulation is emerging as a component of the parathyroid tumorigenesis. We identified a long non-coding RNA (LNCRNA) signature clearly distinguishing parathyroid adenomas (PAds) and carcinomas from normal glands. Among the deregulated LncRNAS, *HAR1B* was upregulated in PAds harboring the common chromosome 11q loss of heterozygosity (Chr11q-LOH; $n=10$) compared with PAds harboring normal chromosome 11 haplotype (Chr11q-WT; $n=12$; $P<0.0001$), suggesting its involvement in Chr11q LOH-related parathyroid tumorigenesis. Considering the oncosuppressor *MEN1* mapping on Chr11q, transient silencing of the *MEN1* gene expression in PAds-derived cells ($n=5$) increased *HAR1B* expression levels. We tested the hypothesis that other genes mapping on Chr11q may be involved in *HAR1B* modulation: *EED* and *DPF2* genes, whose proteins are components of the polycomb repressive complex 2 (PRC2) and BAF complex, respectively, map on Chr11q. Interestingly, the *MEN1* product menin is known to cooperate with EZH2, the PRC2-methyltransferase, to repress a number of genes, and the *HAR1B* promoter is predicted to be regulated by EZH2. We investigated the role of EZH2 activity in this context: treatment with Tazemetostat, a selective inhibitor of EZH2 activity, increased the *HAR1B* expression levels in HEK293T cells. Notably, H3K27me3 protein levels, modulated by the EZH2 activity, were lower in Chr11q-LOH compared with Chr11q-WT PAds, and, analyzing the expression levels of the EZH2 target genes AXIN2, *CCND1* and *CDKN1A/p21* in the series of genotyped PAds, all transcripts significantly differed between Chr11q-LOH and Chr11q-WT PAds, suggesting the occurrence of reduced EZH2 activity in Chr11q-LOH PAds. Investigating the *HAR1B* functional role, we detected in HEK293T cells silenced for HAR1B, upregulation of *LEF1* and *WNT1* mRNA levels and a decrease in *CDKN2B*/p15 protein levels, while silencing of the *HAR1B* gene in PAds-derived cells ($n=3$) did not induce significant changes in the expression of the parathyroid specific genes *CASR, VDR* and GCM2, though a trend in *PTH* transcripts increase could be observed. Further experiments to investigate the function of *HAR1B* are ongoing. In conclusions, *HAR1B* emerges as a new candidate gene in Chr11q-LOH-related parathyroid tumorigenesis, likely as consequence of reduced menin and EZH2 repressive activity. Our data suggest a new function of menin as modulator of the LncRNAs expression.

Risk of sepsis, respiratory infections, and kidney or other genitourinary (GU) infections in patients with chronic hypoparathyroidism (HypoPT): a retrospective cohort study

Kristina Chen[1], Gary Curhan[2], Elvira Gosmanova[3], Fan Mu[4], Allison Briggs[4], William Pajerowski[4], Nicole Sherry[1], Markus Ketteler[5] & Lars Rejnmark[6]

[1]Shire Human Genetic Therapies, Inc., a member of the Takeda group of companies, Cambridge, MA, USA; [2]Brigham and Women's Hospital, Boston, MA, USA; [3]Stratton VA Medical Center and Albany Medical College, Albany, NY, USA; [4]Analysis Group Inc., Boston, MA, USA; [5]Klinikum Coburg GmbH, Coburg, Germany; [6]Aarhus University and Aarhus University Hospital, Aarhus, Denmark.

Background

Prior small studies have suggested increased risk of infections in patients with hypoparathyroidism (HypoPT). This study using a large managed care cohort evaluated whether chronic HypoPT is associated with increased risk of sepsis, respiratory infections, and kidney or other genitourinary (GU) infections.

Methods

A retrospective cohort study using a US commercial claims database (Q1 2007–Q2 2017) was conducted to examine the association between chronic HypoPT and the risk of each infection category (sepsis, respiratory, and kidney or other GU; all identified using diagnoses codes). The study cohort included chronic HypoPT patients (identified using diagnosis codes; excluding those receiving parathyroid hormone) and randomly selected non-HypoPT patients during 5 years of follow-up. For HypoPT patients, the first date of follow-up (i.e., index date) was the earliest HypoPT diagnosis date $\geq$6 months after the initial HypoPT diagnosis (to establish chronic HypoPT); for non-HypoPT patients, it was the date of a randomly selected medical claim. Patient characteristics at baseline (the 6 months prior to index date) and risk of each infection category were compared between cohorts. The risk of each infection category was assessed among patients free of the infection category during the baseline period using Kaplan-Meier analysis and Cox proportional hazards models adjusting for baseline demographic characteristics (age, sex, race, region, and index year).

Results

The study included 8097 chronic HypoPT patients and 40,485 non-HypoPT patients. At baseline, HypoPT patients were older than non-HypoPT patients (58.6 years vs. 47.3 years), a higher proportion were female (76.2% vs. 54.4%), and higher proportions had sepsis (1.4% vs. 0.8%), respiratory infections (20.6% vs. 16.6%), and kidney or other GU infections (10.8% vs. 5.9%) (all $P<0.001$). Kaplan-Meier analyses showed HypoPT patients had an increased risk of developing sepsis, respiratory infections, and kidney or other GU infections, as compared with non-HypoPT patients (all $P<0.001$). The adjusted hazard ratios (95% confidence intervals) associated with HypoPT versus non-HypoPT were 1.64 (1.42, 1.90) for sepsis, 1.20 (1.14, 1.25) for respiratory infections, and 1.41 (1.32, 1.50) for kidney or other GU infections (all $P<0.001$).

Conclusions

Chronic HypoPT was associated with increased risk of new occurrence of sepsis, respiratory infections, and kidney or other GU infections. Further research is warranted to understand the potential mechanisms for the relationship of chronic HypoPT and the observed risks of these infections.

OC1.5

Renal function in 711 patients with hypoparathyroidism during more than 4 years of therapy

Heide Siggelkow[1,2], Bettina Stamm[3], Niklas Stamm[4], Martina Blaschke[4,5] & Martin Grußendorf[6]

[1]Clinic for Gastroenterology and Endocrinology, Goettingen, Germany; [2]MVZ Endokrinologikum, Goettingen, Germany; [3]Medicover Saarbrücken MVZ, Saarbrücken, Germany; [4]Clinic of Gastroenterology and Endocrinology, Goettingen, Germany; [5]MVZ Endokrinologikum, Goettingen, Germany; [6]Halblech, Halblech, Germany.

Patients (pts) with hypoparathyroidism (HypoPT) are at risk to develop renal failure possibly caused by hypercalciuria and nephrocalcinosis. We retrospectively evaluated the data of 711 Patients with HypoPT in 3 endocrine centres in Germany.

Methods

Records of 711 pts with HypoPT were reviewed. Patients were predominantly female ($n=592$, male: $n=119$; age 50.9 ± 14.1 years, range 12 – 99 years). The following parameters were documented during treatment and follow-up (MW 52 ± 40.9 months, time range 2–334 months): medication, calcium in serum and urine, phosphate, calcium-phosphate-product (CPP), glomerular filtration rate (GFR) calculated by CKD-EPI formula.

Results

Of these 711 pts. 29 had idiopathic HypoPT, 10 HypoPT after parathyroidectomy, 669 after thyroid operation. At first visit 4.0% of pts <40 years, 11.1% in the age group 40–59, 28.4% in the age group 60–69, and 49.0% in pts >69 years had a GFR $<$ 60 ml/min. At the last visit no worsening of renal function was observed (GFR $<$ 60 ml/min in 5.9% <40 years, 9.8% in the age group 40–59, 17.1% in the age group 60–69, 36.0% >69 years). An elevated CPP $>$ 55 mg^2/dl^2 was found in 25 pts (3.5%). In these pts the proportion of GFR $<$ 60 ml/min was 33.5% compared to 21.1% of those with normal CPP. In comparison of the therapeutic strategies pts treated exclusively with dihydrotachysterol renal function was the lowest ($n=46$; mean GFR 70.2 ± 26.2 ml/min). In pts treated with calcitriol and calcium ($n=226$) mean GFR was better than in all other treatment groups (84.9 ± 20.9).

Conclusion

We saw no worsening of renal function in a large cohort of patients with HypoPT during 4 years of therapy. High CPP was associated with lower GFR. Different treatment strategies of HypoPT seem to affect kidney function.

Diabetes 1

OC2.1

Every fifth patient with type 1 diabetes suffers from an additional endocrinological autoimmune disease – a finnish nationwide study

Sari Mäkimattila[1], Valma Harjutsalo[2,3,4], Carol Forsblom[2,3,4] & Per-Henrik Groop[2,3,4,5]

[1]University of Helsinki and Helsinki University Hospital, Abdominal Center, Endocrinology, Helsinki, Finland; [2]University of Helsinki and Helsinki University Hospital Abdominal Center, Nephrology, Helsinki, Finland; [3]Folkhälsan Research Center, Helsinki, Finland; [4]Research Program for Clinical and Molecular Metabolism, Faculty of Medicine, Helsinki, Finland; [5]Department of Diabetes, Central Clinical School, Monash University, Melbourne, Australia.

Autoimmune diseases tend to coexist in the same subjects and are more often present in women than in men. Finland has the highest incidence of type 1 diabetes (TID). However, the coexistence of autoimmune diseases and excess risk compared to individuals without T1D in unknown. This study compares the proportion of autoimmune hypothyreosis and hyperthyreosis, Addison's disease and celiac disease in adults in Finland with and without T1D. The study included 4,758 patients with T1D from the Finnish Diabetic Nephropathy (FinnDiane) Study. For each patient with T1D, three nondiabetic control individuals, who were matched for sex, age, and place of residence in the year of diagnosis of diabetes in the FinnDiane patient, were selected from the Finnish Public Register Centre, altogether 12,710 controls. The autoimmune diseases were identified by linking the data with Finnish nationwide health registries such as the Finnish Care Register for Health Care (data available for the years 1970–2015), the Finnish National Drug Reimbursement Register (available for years 1965–2015) and the Drug Prescription Register (available for years 1993–2015). The median age of the FinnDiane patients at the end of follow-up in 2015 or at death was 51.4 (IQR 42.6–60.1) years. The most prevalent additional autoimmune disease was hypothyreosis, that was three times more common in patients with T1D compared to controls; 18.1% vs 6.0%. Hyperthyreosis was present in 2.4% of patients compared to 0.8% in controls resulting in a 2.9-times higher risk. Addison's disease was 24 times more common in patients with T1D; 0.38% vs 0.016%. The risk of celiac disease was 4.4 times higher in the patients; 4.4% vs 0.99%. Women had higher risk of all autoimmune diseases than men, i.e. 2.5 times higher risk of hypothyreosis, 2.8 times of hyperthyreosis, 2.2 times of Addison's disease and 1.5 times of celiac disease. 21.6% of patients with T1D had at least one additional autoimmune disease and 2.9% had two additional autoimmune diseases. Of the controls 7.3% had one, and 0.6% had two autoimmune diseases. The median age at diagnosis of hypothyreosis was lower in the patients with T1D, 41.0 (IQR 30.0–51.0) years, than in the controls, 48.0 (38.0–56.0) years ($P<0.0001$). This is the largest study quantifying the risk of coexisting autoimmune disease in adult individuals with T1D in Finland, the country with the highest incidence of T1D. Notably, these results highlight the importance of screening for other autoimmune diagnoses, if the patient presents with new symptoms.

DOI: 10.1530/endoabs.63.OC2.1

OC2.2

Elevated glucose uptake in skeletal muscle with increased sarcolemma translocation of GLUT4 and glycogen synthesis contributes to bariatric surgery mediated diabetes remission

Qiaoran Liu[1], Xin Huang[1], Yugang Cheng[1], Teng Liu[1], Mingwei Zhong[1], Guangyong Zhang[1], Sanyuan Hu[1] & Shaozhuang Liu[1,2]
[1]Department of General Surgery, Qilu Hospital of Shandong University, Jinan, China; [2]State Key Labototary of Diabetes and Obesity Surgery, Qilu Hospital of Shandong University, Jinan, China.

Background
Bariatric surgery can profoundly ameliorate hyperglycemia and improve insulin sensitivity thus contribute to diabetes remission. However the detailed mechanisms underlying this effect is yet to be revealed. The aim of this research is to investigate the metabolic alterations in skeletal muscle after bariatric surgery and explore the possible mechanisms to further explain the diabetes remission effect of bariatric surgery.
Methods
Duodenal-jejunal bypass (DJB) and sleeve gastrectomy (SG) were performed in diabetic rats induced by high fat diet and low dose of streptozotocin. Glucose uptake was evaluated in vivo by positron emission tomography (PET) with fluorine-18 labelled fluorodeoxyglucose. Insulin signaling pathway, glucose transporters GLUT1 and GLUT4, and translocation related molecules such as AS160, TBC1D1, Adenosine 5'-monophosphate (AMP)-activated protein kinase (AMPK) were evaluated in skeletal muscle. PAS stain and western blot of glycogen synthase (GS), phospho-GS, glucose synthase kinase β (GSK3β) and phospho-GSK3β were performed to evaluate the glycogen synthesis activity. We also preformed gas chromatography-mass spectrometry-based metabolomics to identify the altered metabolic pathways in skeletal muscle.
Results
PET scan showed remarkably increased glucose uptake in skeletal muscle in both DJB and SG groups. Though no difference was found in expression of total GLUT1 and GLUT4, the sarcolemma level of GLUT4 significantly increased in both DJB and SG group, combined with up-regulated phosphorylation of AMPK and AS160. PAS positive rate in DJB and SG group is significantly higher than that of SHAM group. Protein level of GS is also increased with a down-regulated phosphorylation of GS, followed with decreased level of glycogen synthase kinaseβ. Pathway analysis of metabolomics revealed alterations in several amino acid metabolism pathways, which are strongly related to enhanced GLUT4 translocation and improved glycogen synthesis.
Conclusion
DJB and SG facilitate glucose uptake in skeletal muscle with improved sarcolemma translocation of GLUT4 and enhanced activity of glycogen synthesis. This effect is probably due to altered amino acid metabolism.

DOI: 10.1530/endoabs.63.OC2.2

OC2.3

Identification of oxygen-18 isotope of breath carbon dioxide as a non-invasive marker to distinguish type 1 and type 2 diabetes

Chiranjit Ghosh & Manik Pradhan
Satyendra Nath Bose National Centre for Basic Sciences, Kolkata, India.

Background
There is a pressing need to develop a new and an effective strategy for early detection of T1D and to precisely distinguish T1D from type 2 diabetes (T2D). The aim of the present study was to find out the potential link between the erythrocytes carbonic anhydrase (CA) activity and ^{18}O-isotopic exchange of breath CO_2 in T1D and T2D.
Methods
Fasting and post-dose breath and blood samples were collected simultaneously after ingestion of 75-gm normal glucose dissolved in 150-ml water. Blood samples were analysed to measure the CA activity. The breath samples were utilised to measure the carbon dioxide isotopes ($^{12}C^{16}O^{16}O$, $^{13}C^{16}O^{16}O$ and $^{12}C^{16}O^{18}O$) by a laser based high-precision carbon dioxide isotope analyzer.
Results
The CA activities are markedly altered during metabolism of T1D and T2D and this facilitates to oxygen-18 (^{18}O) isotopic fractionations of breath CO_2. In our observations, T1D exhibited considerable depletion of ^{18}O-isotopes of CO_2, whereas T2D manifested isotopic enrichments of ^{18}O in breath CO_2, thus unveiling a missing link of breath ^{18}O-isotopic fractionations in T1D and T2D. The optimal diagnostic cut-off points were determined to be $\delta^{18}_{DOB}O‰ = 2.1‰$ and $\Delta CA = 3.15$ U/min/mL for screening T1D and T2D individuals.
Conclusions
Our findings suggest the changes in erythrocytes CA activities may be the initial step of altered metabolism of T1D and T2D, and breath ^{18}O-isotope regulated by the CA activity is a potential diagnostic biomarker that can selectively and precisely distinguish T1D from T2D and thus may open a potential unifying strategy for treating these disease.

Background
Sodium glucose co-transporter 2 inhibitors reduce the incidence of cardiovascular events in patients with type 2 diabetes mellitus based on the results of recent cardiovascular outcome studies. Herein, we investigated the effects of long-term treatment with empagliflozin on biochemical and immunohistochemical markers related to atherosclerosis development in apolipoprotein E knockout [Apo-$E^{(-/-)}$] mice.
Methods
At the age of 5 weeks, mice were switched from normal to high-fat diet. After 5 weeks, Apo-$E^{(-/-)}$ mice were divided into control-group ($n=10$) treated with 0.5% hydroxypropyl methylcellulose and Empa-group ($n=10$) treated with Empagliflozin (10 mg/kg/day) *per os*. After 10 weeks of intervention, animals were culled, and heart and aorta were removed. Sections stained with hematoxylin–eosin (H&E) were used for histomorphometry. Immunohistochemistry was performed to evaluate protein expression of MCP-1, CD68, α-SMA, MMP-2, MMP-9, TIMP-1, ICAM-1 and VCAM-1. mRNA expression of matrix metalloproteinases and their inhibitors, ICAM-1, VCAM-1, IL-6, MCP-1 was measured by q-PCR. Blood pressure, heart rate and biochemical indices were measured at the onset and by the end of the intervention in both groups.
Results
Empa-group mice had lower glucose levels and HDL-cholesterol ($P<0.01$), while totalcholesterol, LDL and triglycerides did not change significantly compared to control group. Diastolic blood pressure and heart rate were significantly lower ($P\leq0.01$ and $P<0.05$ respectively) in Empa-group compared to control-group. Histomorphometry of the aorta root revealed that 6 in 10 Empa-group mice versus 8 in 10 control mice developed atheromatosis. The lumen area was wider (approximately 50%) in Empa-group compared with control-group reaching statistical significance ($P=0.06$). Empagliflozin administration significantly reduced VCAM-1 and MCP-1 mRNA levels ($P<0.05$ and $P\leq0.01$ respectively) while marginally induced TIMP-1 and TIMP-2 mRNA expression ($P\leq0.08$ and $P=0.1$ respectively). There were no significant alterations in IL-6, ICAM-1, MMP-2 and MMP-9 mRNA levels compared to controls; however, TIMP-1/MMP-2 mRNA ratio was significantly higher in Empa-group ($P<0.05$) compared to control-group. Immunohistochemistry staining of aortic root sections revealed that treatment with Empagliflozin led to border line increase in TIMP-1 ($P=0.1$) and marginal reduction in VCAM-1 and MMP-9 ($P=0.1$) without affecting the expression of ICAM-1, MMP-2, TIMP-2, MCP-1, CD68 and α-SMA in atherosclerotic lesions.

Conclusions
Empagliflozin attenuates the progression of atherosclerosis, reducing (1) hyperglycemia, and (2) inflammatory process by lowering the expression of inflammatory molecule VCAM-1. Moreover, it increased TIMP-1/MMP-2 mRNA ratio expression possibly leading to increased plaque stability.

DOI: 10.1530/endoabs.63.OC2.4

5β-reductase (AKR1D1) deletion drives hepatic inflammation, fibrosis and tumour development *in vitro* and *in vivo*

Shelley Harris[1], Nikolaos Nikolaou[1], Anastasia Arvaniti[2], Roger Cox[3], Laura Gathercole[2] & Jeremy Tomlinson[1]
[1]Univrsity of Oxford, Oxford, UK; [2]Oxford Brookes University, Oxford, UK; [3]MRC Harwell Institute, Didcot, UK.

The enzyme 5β-reductase (AKR1D1) catalyses an essential step in bile acid synthesis, but in addition, controls intra-cellular steroid hormone availability by generating 5β-reduced dihydrosteroid metabolites. As disturbances in steroid hormone and bile acid metabolism have potent effects on metabolic health and lipid homeostasis, we hypothesize that AKR1D1 may play a role hepatic lipid accumulation and contribute to the development of metabolic disease. We generated a global AKR1D1 knockout (KO) mouse, which were fed either normal chow (NC) or the American lifestyle induced obesity syndrome diet (ALIOS; 45% fat, 55% fructose: 45% glucose in H_2O), which replicates the clinical features of non-alcoholic fatty liver disease (NAFLD), for 52 weeks. Metabolic phenotyping was undertaken at 37 and 52 weeks. Weight gain was similar in WT and KO normal chow and ALIOS treated animals. However, in WT mice, the ALIOS diet induced liver inflammation and fibrosis in comparison with NC. AKR1D1 KO mice fed the ALIOS diet had increased hepatic steatosis in comparison with WT mice (WT: 16.7±3.3, KO: 21.7±3.6 mg/g, $P<0.005$). In addition, there was evidence of increased hepatic inflammation on H&E stained sections in male AKR1D1 KO mice on a NC, but not ALIOS diet (1.6 vs. 1.1, $P<0.01$). However, at 37 weeks of age, liver biochemistry was significantly elevated in AKR1D1 KO mice fed the ALIOS diet in comparison with WT mice (ALT; WT: 140.7±51.9, KO: 404.7±171.4U/l, $P<0.05$. AST; WT: 136.7±39.0, KO: 360.7±121.7U/l, $P<0.05$). Endorsing observations in our rodent model, AKR1D1 knockdown experiments in human hepatoma cells (Huh7 and HepG2) increased mRNA expression and secretion of the pro-inflammatory cytokines IL1β, IL-6 and IL-8 as well as inducible nitric oxide synthase (iNOS). Hepatic inflammation is a key driver of fibrosis. AKR1D1 KO mice fed the ALIOS diet for 52 weeks had increased hepatic fibrosis as quantified by sirius red staining (WT: 5.4±2.6%, KO: 10.0±4.9%, $P<0.01$). Furthermore, it is well-established that advanced fibrotic metabolic liver disease increases the risk for the development of hepatocellular carcinoma (HCC) and AKR1D1 mice were more prone to tumour development in comparison with WT mice (WT: 11.5%, KO: 42.1%, $P<0.05$). Deletion of AKR1D1 in combination with a dietary stress evokes increased hepatic triacylglycerol content and fibrosis, which could exacerbate the progression of NAFLD to NASH and potentially fuel the development HCC. These data suggest that AKR1D1 may have a pivotal role in the regulation of the NAFLD progression.

Introduction
Osilodrosat is a potent oral 11β-hydroxylase inhibitor. During the 24-week, single-arm, open-label period of the Phase III LINC 3 study (NCT02180217), osilodrostat treatment demonstrated rapid, sustained reduction in mean urinary free cortisol (mUFC) in most Cushing disease (CD) patients. In the subsequent 8-week, double-blind, randomized-withdrawal phase, a significantly higher proportion of patients receiving osilodrostat maintained normal mUFC at week (W)34 without a dose increase versus placebo (86.1% vs 29.4%; OR: 13.7, $P<0.001$ [primary efficacy endpoint]; Pivonello R *et al.* ICE 2018;abstract 1025). The effects of osilodrostat on CD signs/symptoms/biochemistry parameters are reported here for the first time.
Methods
137 adults with CD and mUFC > 1.5xULN (ULN = 138 nmol/24h; baseline median mUFC = 3.5 × ULN) initiated open-label osilodrostat 2mg bid with dose adjustments every 2 weeks (maximum 30 mg bid) until W12 based on mUFC and safety. At W26, 71 eligible patients (mUFC ≤ ULN at W24 without up-titration after W12) were randomized to continue osilodrostat ($n=36$) or matching placebo ($n=35$) in an 8-week double-blind phase (ineligible patients continued open-label osilodrostat; $n=47$), followed by open-label osilodrostat until W48. Cardiovascular-related metabolic parameters and CushingQoL and Beck Depression Inventory (BDI) scores were evaluated at baseline, every 2, 4 or 12 weeks (depending on study phase), and at end of treatment (W48).
Results
By W48, in all patients ($N=137$), mean absolute change ± SD from baseline in signs/symptoms/biochemistry parameters were: weight, −3.8±5.7 kg; BMI, –1.4±2.2 kg/m^2; waist circumference, –4.6±7.8 cm; fasting plasma glucose, –0.5±1.3 mmol/L; HbA_{1c}, –0.4±0.7%; total cholesterol, –0.5±0.9 mmol/L; LDL cholesterol, –0.2±0.8 mmol/L; HDL cholesterol, –0.3±0.3 mmol/L; triglycerides, –0.1±0.9 mmol/L; systolic blood pressure (BP), –9.8±15.5 mmHg; diastolic BP, –6.3±11.1 mmHg. Mean ± SD CushingQoL score (including physical problems and psychological issues subscores) improved by 52.4±107.4% and BDI score by –31.8±65.0%. Osilodrostat was generally well tolerated; most common AEs were nausea (42%), headache (34%), fatigue (29%). Hypocortisolism-related AEs were experienced by 51% of patients, occurring mainly during dose titration (W0–12) as a single episode. Anticipated AEs of interest (based on osilodrostat mechanism of action) were manageable; those leading to discontinuation were adrenal insufficiency ($n=4$ [2.9%]), hypokalaemia, increased diastolic or systolic BP, and electrocardiogram QT prolonged ($n=1$ [0.7%] each).
Conclusion
Reductions in mUFC during 48 weeks of osilodrostat treatment were accompanied by weight, waist circumference, glucose, and systolic/diastolic BP improvements, as well as improved CushingQoL and BDI scores. Osilodrostat was effective and generally well tolerated, showing promise for the treatment of patients with CD.

Nelson's syndrome (NS) is a potentially severe complication following bilateral adrenalectomy for Cushing's disease (CD). Series assessing outcomes of treatments for NS are limited by small sample size, often short follow-up and variability of success criteria. We performed a UK multi-centre study aiming to review outcomes of primary treatment for NS. Clinical, laboratory, imaging data were collected. Kaplan-Meier method, log-rank test, Cox regression analysis were used for statistical analyses. 68 patients from 13 centres were included [58 females, median age at CD diagnosis 30 years (11-69)]. Management of CD included surgery + adrenalectomy ($n=32$, 8 had two and 1 had three operations), surgery + radiotherapy + adrenalectomy ($n=15$, 2 received >1 course of irradiation), radiotherapy + adrenalectomy ($n=1$), adrenalectomy ($n=20$). NS diagnosis relied on i) imaging (adenoma growth or identification of tumour if previous scan negative) combined or not with increasing ACTH levels and/or pigmentation ($n=53$), ii) only increasing ACTH levels and/or pigmentation ($n=14$) (no information for one patient). Diagnosis of NS was between 1969–2018 (in 59/68, after 1990) at median interval 3 years after adrenalectomy (3 months-32 years). Primary management of NS included surgery ($n=10$), radiotherapy ($n=22$), surgery + radiotherapy ($n=18$, one had also carmustine implant), observation ($n=16$), pasireotide ($n=2$). Imaging follow-up data were available for 64 patients; there was no significant difference in probability of tumour progression between the primary management groups (10-years cumulative probability of progression-free survival: total group 76%, surgery 75%, radiotherapy 83%, surgery + radiotherapy 73%, observation 68%). Based on cases with relevant available data, sex, age at CD diagnosis, adenoma size at diagnosis (micro/macro), presence of adenoma on imaging before adrenalectomy, extent of adrenalectomy (complete/or not), interval between adrenalectomy and NS diagnosis (<3 or ≥ 3 years) and diagnostic criteria for NS (positive imaging/or not) were not predictors of tumour progression. However, type of management of CD was predictor ($P<0.05$); thus, in comparison with surgery + adrenalectomy, hazard ratios for surgery + radiotherapy + adrenalectomy were 5.5 (95%CI 1.8–17.1) and for adrenalectomy 0.3 (95%CI 0.7–1.1). This finding persisted even after adjusting for type of primary treatment of NS. Median follow-up between NS diagnosis and last review was 16 years (0–48); 13 patients had died and in three the cause was related with NS. At 10-years follow-up, 24% of the Nelson's tumours will show progress after various management approaches. Complexity of CD treatment, possibly reflecting corticotroph adenoma aggressiveness, is a significant predictor of Nelson's tumour progress.

Monosynaptic inputs to corticotropin-releasing hormone neuron in hypothalamic paraventricular nucleus of mice at the whole brain scale

Yu Wang & Jiang-Ning Zhou
Hefei National Laboratory for Physical Sciences at the Microscale, School of Life Sciences, Chinese Academy of Sciences Key Laboratory of Brain Function and Diseases, University of Science and Technology of China, Hefei, China.

Corticotropin-releasing hormone (CRH), a 41-aminoacid peptide that is mainly produced in the hypothalamic paraventricular nucleus (PVN), plays a crucial role in stress response and is considered to be the central driving force in the activity of hypothalamic–pituitary–adrenal (HPA) axis. Previous studies of neuronal input to the PVN were limited by experimental techniques and could not be restricted by a single neuron type. In the present study, by using a novel deficient rabies virus combined with the CRF-Cre transgenic mouse, which not only limits the start neurons within CRF neuron in PVN, but also restrict the input neurons to monosynaptic scale, we investigated the input projections of CRH neurons in the PVN. We observed the monosynaptic input projections received by CRH neurons in the whole brain and discovered projection neurons in forebrain, midbrain, hindbrain and other brain regions except in olfactory bulb. Basal forebrain, preoptic area, hypothalamus, brainstem reticular nucleus all had a large number of fluorescence-labeled projection neurons. Remarkably, the direct projections from cortex have not been reported before. These neurons distributed in layer 5 and 6 of orbital cortex, motor cortex and piriform cortex, and other sub-regions. Benefit from the good neuronal morphology revealed by virus tracing, we could observe that most of the labeled neurons obviously had the morphological characteristics of pyramidal neurons, such as the apical dendrites and branches, basal dendrites and the axon structures extending downward in cortical surface. Dendritic spines could also be clearly visible. We further obtained the input projection imaging data of CRH neurons with single cell resolution in the whole brain range using fluorescence micro-optical sectioning tomography system (fMOST). After data processing, we obtained the 3D distribution pattern of input projection neurons in the entire brain which demonstrated the detail morphologies of projection neurons inside mPFC, BST, amygdala and PVN, etc. as well as their local connections. We also dissected the entire morphologies of labeled pyramidal neurons within mPFC and traced their axons to the region near the injection site. The above neuronal tracing and reconstruction experiments have demonstrated the CRH-neuron-specific monosynaptic inputs to PVN at the whole brain scale for the first time.

Restoration of basal glucose turnover after disease control in acromegaly depends on treatment modality: a prospective, investigator-initiated trial

Mai C Arlien-Søborg[1], Jakob Dal[2], Michael Madsen[1], Morten Høgild[1], Astrid Hjelholt[1], Niels Jessen[1], Niels Møller[1] & Jens Otto Lunde Jørgensen[1]
[1]Aarhus University Hospital, Aarhus, Denmark; [2]Aalborg University Hospital, Aalborg, Denmark.

Background
Growth Hormone (GH) reversibly suppresses insulin-stimulated glucose uptake in skeletal muscle, but less is known about GH effects on glucose metabolism in the basal state. Somatostatin suppresses GH as well as insulin, and may also exert direct effects in skeletal muscle. This may have therapeutic implications in the treatment of acromegalic patients with a somatostatin analogue (SA).
Aim
To study basal and insulin-stimulated glucose metabolism in patients with acromegaly before and after disease control by either surgery-alone (surgery) or SA treatment.
Patients and methods
21 patients (10 surgery and 11 SA) were studied before and after treatment during a 3 h basal period followed by a 3 h hyperinsulinemic, euglycemic glucose clamp (HEC) combined with glucose tracer infusion, indirect calorimetry, muscle biopsies, and MR spectroscopy to quantify ectopic lipid in liver (IHL) and muscle (IMCL).
Results
IGF-I levels (μg/l) normalised after treatment [696 ± 57 vs. 211 ± 21] with no treatment-specific difference ($P=0.72$). GH-dependent gene expression in muscle (IGF-I and SOCS2) also declined after treatment ($P< 0.05$). The glucose infusion rate (GIR) during the HEC (mg/kg/min) increased after treatment ($P=0.001$) regardless of modality ($P=0.51$) [GIR: 3.3 ± 0.4 (before) vs. 4.7 ± 0.5 (after)]. Basal glucose levels declined after surgery but not after SA, whereas SA significantly suppressed insulin levels compared to surgery ($P<0.000$). Treatment decreased the basal state endogenous glucose production (EGP) [1.96 ± 0.1 vs. 1.47 ± 0.1 ($P=0.007$)], but less so after SA ($P=0.02$). By contrast, basal state glucose disposal (Rd) was lower after SA compared to surgery ($P<0.000$). Moreover, Rd after SA was dominated by non-oxidative glucose disposal, whereas the opposite was true after surgery ($P < 0.01$). Ectopic fat did not predict insulin sensitivity in either group.
Conclusions
1) Stimulated insulin sensitivity (HEC) improves after disease control in acromegaly independent of treatment modality, 2) Basal glucose metabolism also restores after disease control but less so, after SA, 3) The absence of association between insulin sensitivity and body composition including ectopic fat is unique for acromegaly.

T2-signal intensity, SST receptor expression and first-generation somatostatin analogues efficacy predict hormone and tumor responses to pasireotide in acromegaly

Eva C Coopmans[1], Joppe J Schneiders[2], Nour El-Sayed[1], Ammar Muhammad[1], Leo J Hofland[1], Patrick Petrossians[3], Aart. J van der Lely[1] & Sebastian JCMM Neggers[1]
[1]Department of Internal Medicine, Endocrinology section, Pituitary Center Rotterdam, Erasmus University Medical Center, Rotterdam, the Netherlands, Rotterdam, Netherlands; [2]Department of Radiology, Erasmus University Medical Center, Rotterdam, the Netherlands, Rotterdam, Netherlands; [3]Department of Endocrinology, Centre Hospitalier Universitaire de Liège, Domaine Universitaire du Sart Tilman, 4000 Liège, Belgium, Liège, Belgium.

Background
Previous studies indicate that PAS-LAR can achieve control of insulin-like growth factor I (IGF-I) levels and may reduce tumor size, however a subset of acromegaly patients responds poorly. T2-signal intensity, somatostatin receptor (SST) subtype 2 and 5 expression, and the response to first-generation somatostatin receptor ligands (SRLs) are recognized predictors of therapy response. Valid prediction of the response to PAS-LAR can alter treatment stratification.
Aim
To analyze T2-signal intensity and SST receptor expression in relation to the hormone and tumor response during PAS-LAR treatment, and to determine to what extent this equals SRLs responsiveness.
Methods
We included 45 patients initially receiving SRLs, followed by a combination therapy including pegvisomant, and finally treated with PAS-LAR. The hormone response to PAS-LAR was evaluated using IGF-I (x ULN) levels at 24 weeks. T2-weighted MRI signal intensity of the adenoma was visually assessed and quantified by region of interest measurement. A tumor volume change of $\geq$25% from baseline was considered significant. SST receptor expression in adenomas was evaluated in 13 out of 45 patients using a validated immunoreactivity score (IRS). The clinical characteristics and the hormone and tumor response to PAS-LAR were assessed using multivariable regressions.
Results
Patients with the lowest percentage IGF-I (x ULN) reduction during SRLs also showed weak IGF-1 (x ULN) control during PAS-LAR and, however, more significant tumor shrinkage ($r=0.41$, $P=0.006$; $P=0.036$). Lower IGF-I (x ULN) levels during PAS-LAR were associated with higher T2-signal intensity and less significant tumor shrinkage (ß$=-0.29$, $P=0.045$; ß$=0.34$, $P=0.035$). With regards to tumor response, adenoma volume at baseline was associated with higher random GH levels at diagnosis and greater absolute tumor shrinkage during PAS-LAR (ß$=69$, $P=0.0018$; ß$=1.05$, $P=0.020$). Significant tumor shrinkage was associated with female patients, higher IGF-I (x ULN) levels during PAS-LAR and borderline significant with non-hypointense adenomas at baseline (OR$=6.35$, 95% CI$=1.42$–36.4; OR$=13.2$, 95% CI$=2.14$–129.1; OR$=5.97$, 95% CI$=0.91$–65.5 respectively). Lower IGF-I (x ULN) levels after PAS-LAR correlated with higher ($r=-0.68$, $P=0.011$; $r=-0.52$, $P=0.083$), while significant tumor shrinkage correlated with lower SST_2 levels and SST_2/SST_5 ratio ($P=0.040$; $P=0.024$).
Conclusions
Patients not responding to somatostatin analogs with particularly large adenomas, low SST_2 receptor expression and higher T2-signal intensity are more prone to show tumor shrinkage during PAS-LAR than patients with high SST_2 receptor expression and T2-hypointense adenomas. Surprisingly, tumor shrinkage is not accompanied by lower IGF-I (x ULN) levels, which are associated with a high SST_2 receptor expression and a higher T2-signal intensity.

Subclinical hypothyroidism troughout pregnancy in TPOAb positive pregnant women

Marta Baraia-Etxaburu Astigarraga[1], Javier Pi Barrio[2], Simón Gundín Menéndez[1], Ángela Arrabal Alonso[1], Enrique Ruiz Pérez[1], Irene Esparcia Arnedo[1], Jorge Monroy Sánchez[1] & Estefanía Santos Mazo[1]
[1]Burgos University Hospital, Burgos, Spain; [2]Sierra Llana Hospital, Torrelavega, Spain.

Background and objective
According to recent studies, endocrine societies have modified the treatment criteria of subclinical gestational hypothyroidism, increasing TSH upper-limit value commonly set at 2.5 μU/ml to a new threshold set at 4 μU/ml. This change in criteria has responded to numerous studies which seem to indicate that the obstetrical complications do not generally increase despite this variation of the threshold TSH value. A further discussion lays now on whether euthyroid (TSH$<$ 4 μU/ml) pregnant women with autoimmune thyroid disease may still benefit from treatment within this 2.5–4 μU/ml TSH range, as some authors found a higher risk of developing subclinical gestational hypothyroidism in this population. This study aims to evaluate the progression towards subclinical hypothyroidism (TSH$\geq$4 μU/ml) throughout gestation of healthy first-trimester pregnant women with and without positive TPOAb status.
Methods
A prospective observational study was performed, in which TPOAb, TSH and FT4 levels were measured between 8th and 12th weeks of pregnancy from Nov 2017 to Dec 2018 at the screening visit. Later, TSH and FT4 levels were also measured in the third trimester. New hypothyroidism diagnosis in third trimester was recorded, and women were divided in two groups according their TSH value in the first trimester. First group those with TSH$<$2.5 μU/ml and the second group included those with TSH between 2.5 and 4 μU/ml.
Results
From the 1042 pregnant women who participated in the study, 6.24% (65) were positive for TPOAb. 23 of them were treated with levothyroxine: 13 due to a first-trimester TSH $>$ 4 μU/ml and 10 owing to an abnormal thyroid palpation in women within 2.5–3.9 μU/ml TSH range. Regarding the group that did not receive treatment (42), 35 showed a TSH$<$2.5 μU/ml and 7 of them were 2.5–3.9 μU/ml. None (0%) of the pregnant women from this not-treated group developed a subclinical hypothyroidism (TSH$\geq$4 μU/ml) in the third trimester. In the group of negative thyroid autoimmunity (977), the progression towards subclinical hypothyroidism was of 1.53% (15).
Conclusions
- In our population there is no development to hypothyroidism in those women who were not initially treated in the first trimester despite positive TPOAb. The criteria to indicate thyroid hormone was TSH$\geq$4 μU/ml or TSH 2.5–3.9 μU/ml with abnormal thyroid exploration.
- In fact, the incidence of subclinical hypothyroidism in the third trimester was higher in those with negative TPOAb, although it is low (1.53%).
- These results require further studies.

OC4.2

Thyroid dysfunction and mortality in cardiovascular hospitalized patients – a 12 year follow-up observational study

Meir Frankel[1], Feras Bayya[2], Rivka Farkash[2], Michael Glikson[2] & Gabriel Munter[1]
[1]Endocrinology Unit, Shaare Zedek Medical Center, Jerusalem, Israel; [2]Cardiology Department, Shaare Zedek Medical Center, Jerusalem, Israel.

Background
Thyroid dysfunction is associated with increased cardiovascular morbidity and mortality. Early detection may influence the clinical management of the patients. There is insufficient data about the prevalence and clinical significance of thyroid dysfunction in cardiovascular hospitalized patients.
Aims
To study the prevalence of thyroid dysfunction in cardiovascular hospitalized patients, to characterize patients with high prevalence of thyroid dysfunction and to determine the mortality rate of this population.
Methods
A retrospective analysis of a medical records database of all adult patients admitted not-electively to the Cardiology Department at Shaare-Zedek Medical Center, Israel, between 2005–2017. Blood test for Thyroid Stimulating Hormone (TSH) level was performed as a routine test in all patients, and T4 and T3 levels were checked according to TSH result. Statistical analysis was performed on demographic and clinical characteristics, as well as mortality data, of the entire cohort.
Results
During the described period there were 19281 non-elective hospitalizations of 14388 patients. TSH was available for 14384 patients during their first hospitalization. The mean age was 67$\pm$15. Thyroid dysfunction was present in 10% of the patients (2% TSH$>$10 mIU/L; 5% TSH 5–10 mIU/L; 2% TSH 0.1–0.35 mIU/L; 1% TSH $<$0.1 mIU/L). The prevalence of thyroid dysfunction was significantly higher in elderly patients (age$>$70 y; prevalence 12.1%, Odds ratio[OR]$=1.4$) and in patients with atrial flutter/fibrillation (14%, OR$=1.4$), pulmonary hypertension (14%, OR$=1.4$), chronic renal failure (14%, OR$=1.5$), heart failure (15%, OR$=1.5$), hypothyroidism treated with Levothyroxin (28%, OR$=3.3$) and patients treated with Amiodarone (24%, OR$=3$). Adjusted multivariable analysis showed increased mortality during the study period, for TSH$<$0.35 mIU/L, TSH 5-10 mIU/L and TSH$>$10 mIU/L (hazard ratio 1.44, 1.27 and 1.4, respectively).

Conclusion
The prevalence of thyroid dysfunction in cardiac hospitalized patients is 10% and is even higher in specific patient-groups. Thyroid dysfunction is associated with an increased mortality rate. Screening for thyroid function may be considered in cardiology departments, especially for selected high risk groups.

Prognostic impact of microscopic extrathyroidal extension (mETE) on recurrence-free survival in patients with papillary thyroid carcinoma (PTC)

Nadia Bouzehouane[1,2], Pascal Roy[3], Myriam Decaussin-Petrucci[4], Mireille Bertholon-Grégoire[2], Chantal Bully[2,5], Agnès Perrin[1,2], Françoise Borson-Chazot[1] & Claire Bournaud[2]
[1]CHU LYON EST, fédération d'endocrinologie, LYON, France; [2]CHU LYON EST, centre de médecine nucléaire, LYON, France; [3]CHU LYON, service de biostatistiques, LYON, France; [4]CHU LYON SUD, centre d'anatomopathologie, LYON, France; [5]Groupe hospitalier Les Portes du Sud, service d'endocrinologie, Vénissieux, France.

Background/objective
mETE has shown no effect on survival, and the 8th edition of the AJCC classification no longer considers mETE in the pT3 definition. Therefore, tumors with mETE below 40 mm are now staged pT1/pT2. However, controversy remains regarding mETE impact on disease recurrence. This study assessed the risk of recurrence of PTC patients previously classified as pT3 because of mETE, compared to PTC patients staged pT1-pT2.
Methods
Monocentric retrospective analysis of prospective database of patients treated by total thyroidectomy and radioactive iodine (RAI) from 1998 to June 2013. All patients had available data on pathology report, uni or multifocal PTC <40 mm, with or without mETE, with or without lymph node involvement (LNI) and at least 5 years of follow-up. mETE was defined as extra-capsular invasion without skeletal muscle involvement. The primary outcome, recurrence free survival (RFS), was defined as the time between initial surgery and recurrence treatment. Follow-up of recurrence-free patients was censored after 5 years. In univariate analyses, the 5-years RFS (with standard error) curves were estimated using the Kaplan Meier estimator and compared using the Log-rank test. Multivariate modelling was performed fitting the proportional hazard Cox model. The candidate prognostic factors were: mETE (presence/absence), LNI (N0-Nx, N1a, N1b), aggressive pathological type (Yes/No), margin resection involvement (R1/R0), pathological tumor size in mm ($<=10$,]10; 20],]20, 40]) and advanced age (>55 years).
Results
The overall 5-years RFS was 80.2% (2.3%). In univariate analyses, the 5-years RFS was 62.4% (5.0%) for tumors with mETE and 88.1% (2.2%) for tumors without ($P<0.001$). The 5-years RFS were 88.8% (2.1%), 76.6% (6.2%) and 25.0% (7.7%) in N0-Nx, N1a and N1b tumors respectively ($P<0.001$). The 5-years RFS was 37.7% (17.1%) in aggressive pathological types and 81.4% (2.3%) in others ($P<0.001$). It was 60.0% (12.6%) in R1 tumors, and 81.3% (2.3%) in R0 tumors ($P=0.048$). Neither advanced age ($P=0.125$) nor tumor size ($P=0.890$) were significantly associated with prognosis. In multivariate analysis, mETE ($P=0.002$) and LNI ($P<0.001$) were independent prognostic factors, whereas neither aggressive pathological type ($P=0.440$) nor resection completeness (0.776) were significantly associated with prognosis. In this model, mETE was associated with a hazard ratio of 2.55 (95% CI 1.48–4.40), and N1a and N1b tumors with hazard ratios of 1.67 (95% CI 0.81–3.46) and 8.94 (95% CI 4.92–16.26) respectively, without interaction between mETE and LNI ($P=0.205$).
Conclusion
These results suggest that mETE is a pejorative factor in recurrence risk, regardless of LNI.

Introduction
The syndrome of reduced sensitivity to thyroid hormone (SRSTH) due to mutations of thyroid hormone receptor β *(TRB)* consists of an inappropriate secretion of TSH with elevated levels of thyroid hormones. Cardiovascular manifestations are often the ones that affect patients. Our aim was to evaluate the cardiac and vascular characteristics of patients with SRSTH due to *TRB* mutations.
Materials and methods
We analysed clinical, electrocardiogram and cardiac ultrasound data of 287 patients, collected in our Reference Centre of Rare Thyroid Diseases. Data was recorded on diagnosis or during the follow-up of patients. When several sets of the same data existed, the last ones were taken into account. For each variable, 65 to 181 patients could be analysed.
Results
Patients are mainly female (59.6%) with an average age of 28.6 years old at the time of diagnosis. Clinical symptoms were represented by elevated blood pressure (30%), tachycardia (45.7%) and palpitations (45.8%). Electrocardiogram abnormalities were present among 43.3% of patients: 20.2% supraventricular arrythmia (flutter or fibrillation), 15.4% sinusal tachycardia, 3.9% conduction abnormalities and other abnormalities (3.8%). Few patients had ischemic history (4.4%) or cardiac failure. Cardiac ultrasound abnormalities were found in 9.1% of patients including 48% of valvular heart disease and 20% of hyperkinesia. Left ventricular ejection fraction was altered in 3.5% of patients. Many patients used cardiac or blood pressure medications: 18.8% used beta blockers for cardiac indications, 7.30% used an antihypertensive medication, and 4.9% had an anti-coagulant therapy. The study of the genotype-phenotype association is ongoing.
Conclusion
Our study is one of the largest on cardiac and vascular characteristics of patients with *TRB* mutations. We confirm that patients are mainly affected by tachycardia, palpitations and supraventricular arrythmia that require specific treatment. A regular screening of these cardiovascular manifestations is needed.

A comprehensive assessment of the interplay between the thyroid function and the immune system: results from the Human Functional Genomics Project

Yvette Sloot[1], Martin Jaeger[1], Rob Ter Horst[2], Xiaojing Chu[3], Hans Koenen[4], Irma Joosten[4], Simone Moorlag[2], Vera Mourits[2], Charlotte De Bree[2], Valerie Koeken[2], Antonius van Herwaarden[4], Yang Li[5,6], Jan Smit[1], Mihai Netea[2] & Romana Netea-Maier[1]
[1]Department of Internal Medicine, Division of Endocrinology, Radboud University Medical Center, Nijmegen, Netherlands; [2]Department of Internal Medicine, Radboud University Medical Center, Nijmegen, Netherlands; [3]Radboud Institute for Molecular Life Sciences (RIMLS), Radboud University Nijmegen Medical Center, Nijmegen, Netherlands; [4]Department of Laboratory Medicine, Radboud University Medical Center, Nijmegen, Netherlands; [5]Radboud Institute for Molecular Life Sciences (RIMLS), Radboud University Nijmegen Medical Center, Nijmegen, Netherlands; [6]Department of Genetics, University of Groningen, University Medical Center Groningen, Groningen, Netherlands.

Background
Accumulating evidence indicates the presence of bidirectional cross-talks between the endocrine and the immune system. However, no data are available on the influence of either the thyroid hormones or TSH within the normal range on the immune cell function in healthy humans.
Aim
To comprehensively investigate the effects of the hypothalamic-pituitary-thyroid axis on the variation of immune responses in a cohort of healthy volunteers.
Methods
The immune phenotype was characterized at the level of immune cell subpopulations counts, circulatory mediators of inflammation, platelet function, and production of six cytokines after stimulation with 19 microbial and non-microbial stimuli. The study was performed in a cohort of 534 well described healthy individuals (the 500 Human Functional Genomics cohort (500FG)). Results were obtained using systems biology-based approaches and were subsequently validated in an independent cohort of 324 healthy volunteers with comparable demographic characteristics.
Results
T4 and TSH did not affect cytokine production, circulatory mediators of inflammation (except for the TSH association with leptin) and innate immune cell population numbers. In contrast, we found significant and distinct effects of TSH and T4 on lymphocyte populations in the 500FG cohort. TSH was positively associated with 36 of the 73 independent cell types, particularly the total

circulating lymphocyte counts and T-cell populations. Interestingly, T4 correlated positively with 18 of the 73 independent cell types, mainly circulating B-cell populations. These results were validated in the independent cohort of 324 healthy volunteers. Furthermore, we performed a GWAS on a SNP array covering around 8.8 million SNPs. We identified a high degree of overlap, with 35 SNPs being associated with both the TSH (22 SNPs) or T4 (13 SNPs) concentrations and the cell counts. Some SNPs had strong eQTLs influencing the expression of important genes such as a genetic variant within the *PTGER3* gene and a SNP between *ZC3H7A* and *TXNDC11*, the latter being involved in folding of DUOX proteins involved in H_20_2 generating system within the thyroid.

Conclusion

T4 and TSH have a minimal impact on innate immune responses in healthy volunteers. However, there is a strong interaction between TSH and T4 and adaptive immune responses, particularly with the lymphocyte numbers. These findings represent the first step in understanding the biology of these newly identified interactions, and pave the way towards assessing their impact in clinical situations. Furthermore, the novel genetic loci have to be tested in future experiments, to decipher their precise role in thyroid-immune biology.

Context

Paragangliomas and pheochromocytomas (PPGL) are rare neuroendocrine tumors, characterized by a strong genetic component. Indeed, up to 40% of patients carry a germline mutation in a PPGL susceptibility gene. In accordance with the international recommendations, genotyping of PPGL susceptibility genes is therefore proposed to all patients with PPGL, but it has actually never been shown whether the identification of a germline mutation in one PPGL susceptibility gene changes the outcome of mutation-carriers.

Objective

Our objective was to evaluate how a positive genetic test impacts the management and outcome of propositus patients with PPGL carrying a germline mutation in one of the four major PPGL susceptibility genes (*SDHB, SDHD, SDHC* and *VHL*).

Design

We performed a multicentric retrospective study on 221 propositus carrying a *SDHB, SDHD, SDHC* or *VHL* germline mutation and followed in 24 French clinical centers of the Group of Endocrine Tumors and/or the COMETE network. Patients were divided into two groups: *Genetic* patients, who were informed of their genetic status within the year following the first PPGL diagnosis, and *Historic* patients who only benefited from the genetic test several years after initial PPGL diagnosis.

Results

Compared to *Historic* patients, *Genetic* patients had a better follow-up, with a higher number of examinations and a reduced number of patients lost to follow-up (9.6% *versus* 72%). During follow-up, smaller (18.7 mm *versus* 27.6, $P=0.0128$) new PPGL and metastases as well as lower metastatic spread were observed in *Genetic* patients. Importantly, these differences were reversed in the *Historic* cohort after genetic testing. *Genetic* patients who developed metachronous metastases had a better 5-year survival than *Historic* ones ($P=0.0127$).

Conclusion

Altogether our study clearly shows the positive impact of the identification of an *SDHx* or *VHL* mutation in the management, clinical outcome and survival of patients with PPGL. It reveals, for the first time, the clinical benefits of the practice of oncogenetics for patients with a rare cancer and strongly strengthens the recommendations of the Endocrine Society to consider PPGL genetic testing in all patients affected by PPGL.

Pheochromocytoma aggressiveness induced by tumor microenvironment depends on the SDH subunit involved

Serena Martinelli[1], Maria Riverso[1], Tommaso Mello[1], Giuseppina De Filpo[1], Letizia Canu[1], Mario Maggi[1], Massimo Mannelli[1] & Elena Rapizzi[2]

[1]Department of Experimental and Clinical Biomedical Science, University of Florence, Florence, Italy; [2]Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy.

Pheochromocytoma/paraganglioma (Pheo/PGL) are rare neuroendocrine tumors generally benign. About 30–40% of Pheo/PGL are due to germ-line mutations in one of the susceptibility genes, including those encoding the succinate dehydrogenase subunits A-D (*SDHA-D*). Up to 80% of patients affected by *SDHB* mutated Pheo/PGL develop metastatic disease with no successful cure at present. In this study, we evaluated the different effect of tumor microenvironment on tumor cell migration/invasion by co-culturing tumor cell spheroids with primary cancer-activated fibroblasts (CAFs). To this end, we used three dimension (3D) cultures of a mouse pheochromocytoma cell line (MTT) silenced or not (wild type = Wt) for the catalytic SDHB or the anchoring SDHD subunit. We measured matrigel invasion of spheroid cells by the computation of the migratory areas. Intriguingly, we observed that *SDHD* silenced spheroids had an intermediate migration pattern compared to the highest migration capability of *SDHB* and the lowest one of the Wt spheroids. Interestingly, by confocal

microscopy, we found that all the conditioned spheroids (Wt, *SDHB* and *SDHD* silenced ones) developed long filamentous formations, but only *SDHB* silenced cells invaded the surrounding space moving collectively probably using those filamentous as binaries. Wt and *SDHD* silenced spheroids tended to move individually. Ongoing experiments are aimed to understand if these long outgrowths are neuronal structures (dendrites or axon) or not. To characterize the molecules involved in promoting tumor cell migration, conditioned medium of CAFs was divided into two fractions depending on molecular weights of its components by using cut-off filters. The upper fraction contains molecules with a molecular weight higher than 3000 Da, while the lower fraction is constituted by small molecules (MW $<$ 3000 Da). When the spheroids were conditioned with only the upper or only the lower fraction of conditioned medium we did not observe a significant increase in migration compared with unconditioned spheroids, as suggesting a synergistic role of both fractions in inducing cell migration. This synergy is particularly evident in *SDHB* silenced spheroids. These results suggest that the interplay between tumor microenvironment and *SDHB* silenced spheroids is distinctive compare to the ones of Wt or *SDHD* silenced spheroids. The characterization of the specific factors causing migration may open new approaches for medical therapy.

[1]Maimonides Institute for Biomedical Research of Cordoba (IMIBIC), Cordoba, Spain; [2]Department of Cell Biology, Physiology and Immunology, University of Cordoba, Cordoba, Spain; [3]Reina Sofia University Hospital, Cordoba, Spain; [4]CIBER Physiopathology of Obesity and Nutrition (CIBERobn), Cordoba, Spain; [5]Urology Service, Reina Sofia University Hospital, Cordoba, Spain; [6]Endocrinology and Nutrition Service, Reina Sofia University Hospital, Cordoba, Spain; [7]Neuroendocrinology Research Center/Endocrinology Division, Medical School and Hospital Universitário Clementino Fraga Filho, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil; [8]Molecular Genetics Laboratory, Instituto Estadual do Cérebro Paulo Niemeyer, Rio de Janeiro, Brazil; [9]Neuroendocrinology Division, Instituto Estadual do Cérebro Paulo Niemeyer, Rio de Janeiro, Brazil.

The intrinsic heterogeneity of endocrine-related cancers (ERCs) hampers the identification and development of global and effective therapeutic treatments for these pathologies. However, the dysregulation of the splicing process has been postulated as a new common hallmark shared by most cancer types, since it is associated with the appearance of splicing variants with oncogenic potential (e.g. *CD44v6*, *BCL-Xs*, *AR-v7*, *SST5TMD4*, *In1-ghrelin*). Yet, the putative alteration, pathophysiological role and potential therapeutic utility of the elements involved in the control of the splicing process [i.e. spliceosome components (SCs) and splicing factors (SFs)] remain still unknown. For this reason, we have analysed the expression levels of a representative set of SCs ($n=18$) and SFs ($n=27$) in different cohorts of ERCs [i.e. growth hormone secreting pituitary tumors ($n=96$); non-functioning pituitary tumors ($n=23$); pancreatic neuroendocrine tumors ($n=20$); prostate cancer ($n=126$); and in four *in silico* cohorts of liver cancer (HCC; $n=445$, $n=115$, $n=75$, $n=45$)]. Our results showed that the SF3b subunit 1 (*SF3B1*) gene, which encodes a protein necessary for spliceosome assembly, was consistently overexpressed in all the ERCs evaluated in this study. Interestingly, *SF3B1* expression was positively correlated and associated with clinical and molecular aggressiveness features (e.g. histopathological grade, presence of metastasis, expression of oncogenic splicing variants, etc.) in these ERCs. *In vitro* analyses revealed that the specific blockade of SF3B1 activity, using the pladienolide-B compound, exhibited potent and relevant antitumor effects (reducing cell proliferation, migration, tumorospheres and colonies formation, hormone release and inducing apoptosis) in the vast majority of representative models of ERC cells tested herein (primary ERCs cell cultures and cell lines such as BON-1, QGP-1, LNCaP, 22Rv1, PC-3, HepG2, Hep3b or SNU-387). Remarkably, the antitumor effects of pladienolide-B treatment were further validated *in vivo* in that we found a significant reduction of tumor volume after 9-days of local treatment of pladienolide-B in a xenograft model of ERC. Moreover, we found that pladienolide-B treatment modulated an ample repertoire of molecular events, such as inhibition of major oncogenic signalling pathways (e.g. PI3K/AKT and JNK), modulation of the expression of key tumour markers (e.g. *MKI67*/*CDK6*/*CDKN2A*) and oncogenic splicing variants (e.g. *AR-v7*/*In1-ghrelin*), and regulation of the expression pattern of key components of mRNA homeostasis-associated machineries (spliceosome and SURF/EJC). In conclusion, these results indicate that SF3B1 is consistently overexpressed in different ERCs and associated to malignant features and that its pharmacological blockade with pladienolide-B could represent a novel, global and effective therapeutic approach for ERCs.

The splicing factor NOVA1 is overexpressed in pancreatic neuroendocrine tumors and related to increased aggressiveness and malignancy

Sergio Pedraza-Arévalo[1,2,3,4], Emilia Alors-Pérez[1,2,3,4], Aura D. Herrera-Martínez[5], Ricardo Blázquez-Encinas[1,2,3,4], Rafael Sánchez-Sánchez[6], Rosa Ortega-Salas[6], Raquel Serrano-Blanch[7], Manuel D. Gahete[1,2,3,4], Raúl M Luque[1,2,3,4] & Justo P Castaño[1,2,3,4]
[1]Maimonides Institute of Biomedical Research of Cordoba (IMIBIC), Cordoba, Spain; [2]Reina Sofia University Hospital, Cordoba, Spain; [3]Department of Cell Biology, Physiology and Immunology, University of Cordoba, Cordoba, Spain; [4]CIBER Physiopathology of Obesity and Nutrition (CiberObn), Cordoba, Spain; [5]Service of Endocrinology and Nutrition, Reina Sofia University Hospital, Cordoba, Spain; [6]Service of Anatomical Pathology, Reina Sofia University Hospital, Cordoba, Spain; [7]Service of Medical Oncology, Reina Sofia University Hospital, Cordoba, Spain.

There is increasing evidence that alterations in alternative splicing can be linked to key tumor features in cancer. Dysregulations in the splicing machinery constitute the underlying cause in many of these alterations and, consequently, splicing and its control are emerging as a novel and transversal cancer hallmark, due to its association with different dysfunctions of tumor cells. In line with this, we discovered the existence of aberrantly spliced variants of somatostatin receptor 5 (SST_5TMD4) and ghrelin (In1-ghrelin), which are overexpressed and linked to malignancy features in pancreatic neuroendocrine tumors (PNETs). In this study, we aimed at characterizing the pattern of expression of pivotal components of the splicing machinery, its potential dysregulation and its relation with aggressiveness of PNETs, with the ultimate goal of identifying novel, useful biomarkers for diagnostic and treatment of these tumors. To this end, we designed an array that allowed to determine the expression levels of 45 splicing machinery components using a microfluidic-based technology in 20 pancreatic NETs samples and their control-adjacent non-tumoral tissues. This revealed that the expression of several splicing factors and spliceosome components was altered in tumor tissue compared to non-tumoral adjacent tissue, suggesting a profound dysregulation of the splicing machinery in PNETs. Then, we selected one of the most altered components, NOVA1, to explore its properties in two PNETs model cell lines, BON-1 and QGP-1, by measuring signaling pathways and aggressiveness features, including proliferation and growth of xenografted tumors in mice. This showed that levels of NOVA1, a splicing factor highly overexpressed in tumors, correlated with relevant clinical features, including higher Ki-67 index and necrosis. In vitro assays in BON-1 and QGP-1 cell lines demonstrated that NOVA1 overexpression increased cell proliferation; conversely, NOVA1 silencing markedly decreased cell proliferation. Interestingly, overexpression or silencing of NOVA1 led to opposite changes in the activation/inhibition of key signaling pathways and in the expression of key molecular markers. Of note, alteration of NOVA1 in these cells affected their responsiveness to everolimus in terms of proliferation. Finally, NOVA1 overexpression increased the growth of BON-1 xenografted tumors in nude mice. These results demonstrate that splicing is altered in PNETs, and provide compelling evidence for a role of the splicing factor NOVA1 in PNETs oncogenesis and aggressiveness, thus paving the way to explore its possible value as a biomarker and therapeutic target in PNETs.

Impact of adrenal insufficiency on patient-centred health care outcomes in adult medical inpatients

Andrea Widmer[1], Fahim Ebrahimi[1], Ulrich Wagner[2], Beat Mueller[3,4], Philipp Schuetz[3,4], Mirjam Christ-Crain[1] & Alexander Kutz[1,3]
[1]Division of Endocrinology, Diabetes, and Metabolism, University Hospital Basel, Basel, Switzerland; [2]Division of Health and Social Affairs, Section Health, Swiss Federal Office for Statistics, Neuchâtel, Switzerland; [3]Division of General Internal and Emergency Medicine, University Department of Medicine, Kantonsspital Aarau, Aarau, Switzerland; [4]Division of Endocrinology, Diabetes, and Metabolism, University Department of Medicine, Kantonsspital Aarau, Aarau, Switzerland.

Background
Patients with adrenal insufficiency suffer from increased morbidity and mortality. Quantitative evidence on the health-care burden of either primary (PAI) or secondary adrenal insufficiency (SAI) among hospitalized medical patients is scarce.
Methods
In this observational cohort study, we analysed nationwide acute care hospitalizations from patients with PAI or SAI, respectively, between 2011 and 2015 using prospective administrative data. Patients with either PAI or SAI were compared with propensity score-matched (1:1) controls, based on age, gender, citizenship, hospital volume, year of admission, Charlson Comorbidity Index, and relevant medical diagnoses. The primary outcome was in-hospital mortality. Secondary outcomes were intensive care unit (ICU) admission, intubation rate, length of hospital stay, and 30-day-readmission.
Results
We included 594 patients with PAI and 4880 patients with SAI. Compared with matched controls, in-hospital mortality was comparable among patients with PAI (odds ratio (OR) 1.12 (95% CI 0.65 to 1.95)) and SAI (OR 1.14 (95% CI 0.88 to 1.24)), respectively. Patients with adrenal insufficiency were more likely to be admitted to the ICU (PAI: OR 2.56 (95% CI 1.69 to 3.90), and SAI: OR 3.03 (95% CI 2.60 to 3.54)). The risk for intubation was 3-fold higher in SAI patients (OR 3.04 (95% CI 2.40 to 3.84)), whereas there was a trend in PAI patients (OR 1.77 (95% CI 0.93 to 3.37)). The mean length of hospital stay was 1.8 days longer in PAI patients (8.9 vs. 7.1 days; difference 1.83 (95% CI 0.81 to 2.86)) and 4.6 days longer in SAI patients (12.1 vs. 7.5 days; difference 4.62 (95% CI 4.20 to 5.04)). The risk for 30-day hospital readmissions was increased in SAI patients (OR 1.48 (95% CI 1.33 to 1.64)) but not in PAI patients (OR 1.34 (95% CI 0.93 to 1.93)).
Conclusion
Among medical inpatients, adrenal insufficiency was associated with significant health-care burden, leading to higher rates of ICU admission, intubation and prolonged length of hospital stay. Whether these compromised outcomes can be improved by a more comprehensive diagnostic and therapeutic work-up needs to be addressed in clinical Trials.

Impaired glucose homeostasis in leptin-deficient ob/ob mice is corrected by AZP-3404, a 9-amino acid peptide analog derived from insulin-like growth factor-binding protein 2, a key mediator of leptin action

Michael D Culler[1], Thomas Delale[1], Stéphane Milano[1], Aart Jan van der Lely[2], Thierry Abribat[1] & David Clemmons[3]
[1]Alizé Pharma 3, Lyon, France; [2]Erasmus University MC, Rotterdam, Netherlands; [3]New Paradigm Therapeutics, Chapel Hill, North Carolina, USA.

The key metabolic hormone, leptin, acts in part through the liver to regulate glucose homeostasis, as well as the maturation of both adipocytes and osteoblasts. These actions have been demonstrated to be mediated by insulin-like growth factor binding protein 2 (IGFBP-2), independent of its ability to bind IGF1. The effects of IGFBP-2 on adipocyte and osteoblast maturation can be localized to a short peptide sequence within the unique heparin binding domain (HBD-1) of IGFBP-2. AZP-3404 is a 9-amino acid peptide analog derived from the HBD-1 of IGFBP-2 that reproduces the activity of IGFBP-2 on adipocyte and osteoblast maturation. The present study examines whether AZP-3404 can likewise reproduce the ability of leptin/IGFBP-2 to restore glucose homeostasis in the leptin-deficient ob/ob mouse. Carotid artery glucose levels were continuously monitored in unanesthetized, unrestrained, male B6.Cg-Lepob/J mice fitted with wireless HD-XG telemetric devices (Data Sciences International). The mice were randomly assigned to groups ($n=8$) that received either AZP-3404 or vehicle, b.i.d., for four weeks. By day 27 of treatment, AZP-3404, administered at either 1 or 3 mg/kg, reduced the average daily glucose concentration by 64 ± 29 and 100 ± 16 mg/dl, respectively, from the pretreatment mean level of 507 ± 102 mg/dl. Glucose levels in the vehicle-treated mice slightly increased by 14 ± 29 mg/dl. To assess the efficiency of glucose disposal, an intraperitoneal glucose tolerance test (IPGTT: 1 g glucose/kg) was administered on days 7, 14, 21 and 28 of treatment, following a 24-hour fast. After 28 days of treatment with either 1 or 3 mg/kg AZP-3404, fasting glucose was reduced by 8 and 20%, respectively, as compared with fasted levels on day 7. The IPGTTs demonstrated that AZP-3404 progressively and dose-dependently improved glucose disposal in the severely insulin-resistant ob/ob mice, reducing post-challenge glucose levels by 40% after treating with 3 mg/kg AZP-3404 for 4 weeks. In addition, we have demonstrated that AZP-3404, both alone and in an additive manner with insulin, increases glucose uptake by mouse C2C12 differentiated myotubes through activation of AMP-activated protein kinase (AMPK), suggesting that at least a portion of the observed effect of AZP-3404 in the ob/ob mouse may be by promoting glucose uptake by muscle. These results demonstrate that AZP-3404 is able to reproduce the ability of IGFBP-2 to restore glucose homeostasis in the ob/ob mouse and support the development of AZP-3404 as a novel therapy for syndromes of severe insulin resistance.

Deep Transcranial Magnetic Stimulation modulates body temperature in obesity

Anna Ferrulli[1], Stefano Massarini[1], Concetta Macrì[1], Veronica Redaelli[2], Fabio Luzi[2] & Livio Luzi[1]
[1]Area di Endocrinologia e Malattie Metaboliche, IRCCS Policlinico San Donato, San Donato Milanese (MI), Italy; [2]Dipartimento di Medicina Veterinaria, Università degli Studi di Milano, Milano, Italy.

Obesity is known to be associated with increased heat production. To maintain normothermia, heat retention in areas of the body with greater adiposity is counteracted by an augmented heat release from the extremities, as the fingernail-beds of hands. A possible cause of the altered thermoregulation in obesity is a dysfunction of the neuro-endocrine system. Repetitive deep Transcranial Magnetic Stimulation (dTMS) was proved to be an effective tool in inducing long lasting changes in neural excitability and dopamine release, causing satiety and weight loss. Aims of this study were to investigate the acute and chronic effects of dTMS on body temperature measured by Infrared Thermography in obese subjects. Twenty-nine obese subjects (6 M, 23 F; 48.3 ± 11.8 years; BMI: 37.7 ± 4.3 kg/m^2), seeking treatment for weight control, were randomized into 3 groups receiving 15 sessions (3 per week for 5 weeks) of high frequency (18 Hz), low-frequency (1 Hz) or sham stimulation. Under neutral thermal conditions, fingernail-bed of both hands, abdominal and interscapular skin temperature was measured by Infrared Thermography (AVIO TVS700 camera, 320×240 pixel, spatial resolution 1.4 mrad, temperature resolution 0.08°C). After a single session of 18 Hz dTMS, the average fingernail-bed of both hands temperature significantly decreased (right hand: $-4.4\pm0.3\%$, $P<0.05$ vs baseline; left hand: $-2.7\pm0.2\%$, $P<0.05$ vs baseline). Concurrently, was found a significant increase of norepinephrine ($+18.8\pm7.7\%$, $P<0.05$ vs baseline) and of β-endorphin ($+14.3\pm5.4\%$, $P<0.05$ vs Sham). After a single session of both 18 and 1 Hz dTMS, a trend to increase in abdominal skin temperature was observed (18 Hz group: $+0.9\pm0.9\%$, $P<0.01$ vs Sham group; 1 Hz group: $+1.2\pm1.7\%$, $P<0.05$ vs Sham group). In 2 subjects receiving high frequency stimulation, an increase of interscapular temperature was observed ($+6.0\pm1.0\%$), suggesting an activation of brown adipose tissue. After 15 dTMS sessions, analysis revealed a significant decrease of body weight ($-4.1\pm0.6\%$, $P<0.05$ vs baseline, $P<0.05$ vs Sham) and a decrease of abdominal skin temperature ($-2.3\pm2.9\%$, $P<0.05$) in 18 Hz group. Deep TMS revealed to be effective in modulating body temperature in obese subjects, reversing obesity-induced alterations in heat production and dissipation.

Role of hypothalamic bile acid-TGR5 signaling in the regulation of energy balance

Ashley Castellanos[1], Omar Guzmán Quevedo[1], Valérie Fénelon[1], Philippe Zizzari[1], Samantha Clark[1], Nathalie Dupuy[1], Luigi Bellocchio[2], Giovanni Marsicano[2] & Daniela Cota[1]
[1]INSERM, Neurocentre Magendie, Team Energy Balance and Obesity, U1215, University of Bordeaux, Bordeaux, France; [2]INSERM, Neurocentre Magendie, Team Endocannabinoids and Neuroadaptation, U1215, University of Bordeaux, Bordeaux, France.

Bile acids (BA) are cholesterol-derived molecules that are mostly known for their involvement in lipid digestion and absorption. Recent evidence recognizes them as metabolic integrators able to reduce body weight (BW), increase energy expenditure (EE) and improve glycemic control by activating their specific receptor, the Takeda G protein-coupled receptor 5 (TGR5) in peripheral organs. These outcomes have increased importance in the context of diet-induced obesity and associated metabolic alterations, implying a therapeutic role for TGR5. Here we have hypothesized that TGR5 is also present in the hypothalamus, a major brain structure involved in the regulation of energy balance and whole-body metabolic responses, and that modulation of hypothalamic TGR5 activity is relevant for the control of energy balance, particularly under diet-induced obesity. In order to investigate this hypothesis, we used a multidisciplinary approach, spanning from pharmacological activation of TGR5 to genetic strategies for the hypothalamic deletion of TGR5, associated with evaluation of changes in food intake, body weight, adiposity and other metabolic outputs. Our data demonstrate that TGR5 and BA transporters are expressed in the mediobasal hypothalamus and that diet-induced obese mice have significantly decreased circulating and hypothalamic BA levels. Acute intracerebroventricular (icv) administration of BA or synthetic TGR5 agonist significantly decreased food intake and body weight, particularly in diet-induced obese mice. Similar outcomes were observed after acute administration of TGR5 agonist directly in the mediobasal hypothalamus. Four-weeks continuous icv administration of TGR5 agonist in diet-induced obese mice significantly reduced food intake, body weight, fat mass and improved insulin sensitivity. Effects on body weight and adiposity were in large part due to increased energy expenditure, in turn driven by increased sympathetic activity. Accordingly, chemical sympathectomy or thermoneutrality were able to prevent effects of central TGR5 agonism on body weight and adiposity. Conversely, virally-mediated deletion of TGR5 in the mediobasal hypothalamus of $TGR5^{flox/flox}$ mice caused a rapid increase of food intake, body weight, and fat mass, accelerating the development of diet-induced obesity or worsening the phenotype of already obese mice. These changes were associated to blunted sympathetic activity, which favored the appearance of the obese phenotype. Overall, our results prove the existence of a functional BA-TGR5 hypothalamic system. We show for the first time that the activation of TGR5 in the mediobasal hypothalamus mediates a myriad of effects that improve metabolic parameters, which are particularly relevant in the presence of diet-induced obesity.

Fat mass impact of sirolimus after clinical islet transplantation, a case control study

Arnaud Jannin[1], Stéphanie Espiard[1], Hélène Hoth-Guechot[1], Julie Kerr-Conte[2,3], François Pattou[2,3,4] & Marie-Christine Vantyghem[1,2,3]
[1]Endocrinology and Metabolism, Lille University Hospital, Lille, France; [2]INSERM U1190 Translational Research in Diabetes, Lille, France; [3]E.G.I.D - FR3508 European Genomic Institute of Diabetes, Lille, France; [4]Endocrine Surgery, Lille University Hospital, Lille, France.

Introduction
Sirolimus, a mTOR (mechanistic Target of Rapamycin) inhibitor, is well known for its impact on glucides and lipids metabolism. These effects vary according to factors such as dose and treatment duration, species, cell types and environmental factors. *In vitro* and *in vivo*, sirolimus inhibits adipogenesis by decreasing adipocytes number and size, as well as pre-adipocytes differentiation, leading to subcutaneous and visceral fat mass decrease in murine models of obesity. Little is known on the long-term impact of sirolimus in human. We hypothesized that sirolimus could have a specific role on adipose tissue, possibly influencing islet transplantation prognosis. The aim of this study was to compare body composition and metabolic markers in 2 groups of islet–transplanted patients according to the immunosuppressive regimen including or not sirolimus.

Patients and Methods
We compared body composition and fat markers (weight, DEXA-fat and lean mass, and metabolic parameters) in two groups of non–obese islet-transplanted (ITA) patients treated ($n=18$) or not ($n=13$) with sirolimus, before and one year after islet transplantation for type 1 diabetes (T1D). Continuous variables were expressed as median (interquartile range [IQR]). 'Sirolimus' and 'non-sirolimus' groups were compared with a non-parametric Mann-Whitney test.
Results
Before transplantation, metabolic, renal and body composition parameters were similar in the 2 groups. Compared to baseline, we observed a significant decrease of weight (−6.3 kg (−9.67; −3.85), $P=0.0131$), BMI (−2.2 kg/m^2(−3.17; −1.35), $P=0.009$), leptinaemia (−3.25 ng/ml (−7.6; −0.65), $P=0.0103$) and DEXA fat-mass(−5.5% (−10.7; −1.4), $P=0.0384$), after one year of treatment in the sirolimus-group, while there is no significant modificationt in the 'non-sirolimus' group. One-year after transplantation, weight, BMI, % of fat mass, metabolic and renal parameters did not differ between the 2 groups, except for leptinemia decrease of which was significantly higher in the 'sirolimus' *vs.* the 'non-sirolimus' group ($P=0.008$).
Conclusion
In non-obese T1D patients treated with sirolimus, islet-transplantation was associated with a significant fat loss, concomitant to metabolic improvement. Sirolimus exposure was also associated with a significant reduction of leptin as compared to 'non-sirolimus' islet –transplanted patients,. These findings could be related to the quality of adipose tissue, potentially modulating insulin resistance and innate immunity. On a broader scale, mTOR inhibitors, also used in the treatment of neuroendocrine tumors, could participate to crosstalk between cancer and immunity.

Lipolysis defect in white adipose tissue and rapid weight regaining

Michal Kasher Meron, Dou Yeon Youn, Haihong Zong & Jeffery E Pessin
Albert Einstein College of Medicine, New York, New York, USA.

Weight regain after weight loss is a well described-phenomena in both humans and animal models of obesity and thought to be related to reduced energy expenditure and increased food intake. Reduced lipolysis in white adipose tissue has been described in obesity. We hypothesized that lipolytic defect in adipose tissue in the obese state persists after weight loss increasing efficiency of lipid storing and promotes weight regain. We utilized a mouse model of obesity memory (OM): C57BL/6 mice with diet induced obesity were subjected to 60% caloric restriction to achieve lean body weight, followed by a short period of high fat diet (HFD) re-challenge. Age-matched lean mice without OM which were fed HFD for the first time were used as control. Upon re-challenge with HFD, mice with OM had rapid weight gain compared to the control group. Despite comparable body weight and lean body mass, mice with OM showed higher respiratory exchange ratio than control mice, suggesting higher glucose rather than fatty acid oxidation. In *ex vivo* lipolysis assay white adipose tissue explants with OM had comparable lipolytic response after caloric restriction, however reduced functional lipolytic response to norepinephrine was noted as early as 5 days after re-challenge with HFD accompanied by reduction in HSL serine phosphorylation after norepinephrine stimuli. The relative lipolytic defect was associated with increased expression of inflammatory genes, and a decrease in beta adrenergic receptor genes, most notably *adrb3* compared to the control group. Taken together, white adipose tissue of lean mice with OM shows increased sensitization to HFD compared to white adipose tissue with no OM, rendering it relatively resistant to catecholamine induced-lipolysis. This lipolytic defect associated with OM is tissue-autonomous and could play a role in the rapid weight regain observed after weight loss.

Background
Cortisol excess is associated with a higher prevalence of hypertension (Hy), type 2 diabetes (T2D) and fragility fractures (FX). A possible association between T2D and fragility FX with the degree of glucocorticoid (GC) suppression and peripheral activation or sensitivity even in non-hypercortisolemic subjects has been previously suggested.
Aim
To assess if the degree of GC suppression or peripheral sensitivity and activation are associated with Hy and the simultaneous presence of fragility FX, T2D and Hy in eucortisolemic postmenopausal females.
Patients and Methods
We studied 216 non-hypercortisolemic postmenopausal females (age 50–80 years, 99 with T2D, 108 with Hy, 68 with fragility FX). In all subjects, we assessed 24-hour urinary free cortisol (UFF), cortisone (UFE), their ratio (R-UFF/UFE), cortisol after 1mg-overnight-dexamethasone (F-1mgDST) and the presence of the *N363S* single-nucleotide polymorphism (*N363S*-SNP) in GC receptor gene that is thought to increase GC sensitivity.
Results
In Hy patients, the T2D prevalence and F-1mgDST and R-UFF/UFE levels were higher (64.6%, 1.25 ± 0.43 μg/dL, 0.24 ± 0.13, respectively) while UFE levels were lower (86.9 ± 20.1 μg/24 h) than in non-Hy subjects (35.7%, 1.02 ± 0.41 μg/dL, 0.20 ± 0.08, 94.5 ± 21.9 μg/24 h, respectively, $P<0.05$ for all comparisons). Hy was independently associated with F-1mgDST and with R-UFF/UFE (OR, 95% CI: 6.02, 2.01-17.98, $P=0.001$; 63.3, 1.2-3326.6, $P=0.04$) regardless for *N363S*-SNP and age. The simultaneous presence of Hy, T2D and fragility FX was associated with F-1mgDST, R-UFF/UFE and *N363S*-SNP (OR, 95%CI: 6.67, 1.8–25.2, $P=0.005$; 129.1, 1.8–9108, $P=0.025$; 8.8, 1.7–45.9, $P=0.010$, respectively). The progressive increase of the number of the GC-related comorbidities (i.e. Hy, T2D and fragility FX) was significantly associated with F-1mgDST levels, R-UFF/UFE and with the prevalence of *N363S*-SNP. A eu-cortisolemic postmenopausal female with ≥2 out of *N363S*-SNP, F-1mgDST >0.9 μg/dL (24.8 nmol/L) and R-UFF/UFE >0.18 has a 4.5-fold increased risk of having ≥2 out of T2D, Hy and fragility FX (OR 4.55, 95% CI 1.97–10.53, $P<0.0001$) regardless of age.
Conclusions
In postmenopausal eucortisolemic females, Hy is associated with GC suppression and peripheral activation; the combination of Hy, T2D and fragility FX is associated with GC suppression, peripheral activation and sensitivity.

Thyroid hormones are new key regulators of glucocorticoid metabolism

Laura Bessiène[1], Ségolène Hescot[2], Alexandra Bourdin-Pintueles[2], Laurence Dumeige[2], Géraldine Vitellius[2], Julie Perrot[2], Qiong-Yao Xu[2], Thi-An Vu[2], Laurent Sachs[3], Eric Pussard[4], Marc Lombès[2], Say Viengchareun[2] & Laetitia Martinerie[2,5]
[1]Inserm U1185, Paris-Sud Medical School, Paris-Saclay University, Le Kremlin-Bicêtre, France; [2]Inserm U1185, Paris-Sud Medical School, Paris-Saclay University, Le Kremlin- Bicêtre, France; [3]UMR 7221 CNRS - Muséum National d'Histoire NaturelleUMR 7221 CNRS - Muséum National d'Histoire Naturelle, Paris, France; [4]Department of Molecular Genetics, Pharmacogenetics, Hormonology, Paris-Sud University Hopitaux, Le Kremlin- Bicêtre, France; [5]Department of Pediatric Endocrinology, Robert Debré Hospital, Paris, France.

The 11-beta hydroxysteroid dehydrogenase (11βHSD) isozymes are well-known regulators of glucocorticoid hormone metabolism: 11βHSD2, mostly expressed in the distal nephron, converts cortisol [F] into cortisone [E] in humans or corticosterone into 11-dehydrocorticosterone in rodents (11-dehydro derivatives being inactive compounds), and 11βHSD1, ubiquitously expressed but predominantly in the liver, catalyzes the opposite reaction. Under pathophysiological conditions of hypothyroidism in humans, altered glucocorticoid metabolism has been observed, with decreased [F] to [E] conversion (Boonen, NEJM, 2013; Warner, J Endocrinol, 2010). However, direct functional relationship between these two hormonal pathways has never been demonstrated to date. Using bioinformatics analyses, we identified five putative thyroid hormone response elements in the murine promoter region of the *hsd11b2* gene. Therefore, we aimed at investigating whether thyroid hormones (T3) directly regulate expression and/or activity of the 11βHSD2 enzyme. We used three complementary models: human and mouse translational studies and molecular analyses in HEK293T cells and in fully differentiated KC3AC1 cortical collecting duct cells. Children and adults with hypo- or hyperthyroidism were compared either to age- and sex-matched euthyroid controls, or to themselves after reaching an euthyroid status. The urinary [E]/[F] ratio measured by LC-MS/MS method, was used as an index of renal 11βHSD2 activity. Interestingly, a 60% decrease ($P<0.05$) in the [E]/[F] ratio was observed in hypothyroid patients, suggesting a regulation of glucocorticoid metabolism by thyroid hormones. Next, a mouse model of hyperthyroidism, generated by administrating T3 in drinking water, led to a significant 10% increase in renal 11βHSD2 mRNA and protein levels compared to wild type mice ($n=20$, $P<0.05$). We also demonstrated in HEK293T cells that T3 transactivates both the mouse *hsd11b2* and human *HSD11B2* promoter cloned upstream of the luciferase reporter gene *via* the Thyroid Receptor α1 (TRα1) and that transactivations are abolished in the presence of the NH3 antagonist. Finally, we showed that T3 exposure induces a 50% increase in 11βHSD2 mRNA levels in renal KC3AC1 cells, in a dose-dependent and time-dependent manner ($P<0.01$). Actinomycin D also blunted this effect, underlining a direct transcriptional regulatory mechanism. In addition, 11βHSD2 enzymatic activity, quantified by the [F] to [E] conversion ratio measured by LC-MS/MS in cell supernatants, increased significantly by 20% ($P<0.05$) after 24 h exposure to 100 nM T3. ChIP experiments further demonstrated a T3-dependent specific recruitment of TRα1 onto *hsd11b2* promoter region. Altogether, our findings demonstrate that thyroid hormones directly regulate expression and activity of the renal 11βHSD2 enzyme, thereby controlling glucocorticoid metabolism and action.

Background/aim
Burosumab is a monoclonal antibody against anti-FGF23, which has been recently approved for the treatment of X-linked hypophosphatemia (XLH).

Beyond clinical trials, little is known about its efficacy/safety in clinical practice which is the aim of the present study.
Patients/methods
Thirty-nine children with XLH were switched from conventional therapy to burosumab (starting dose 0.4 mg/kg), on the basis of following indications: non-responder to conventional therapy (persistence of leg deformities, elevated levels of alkaline phosphatase, need for orthopaedic surgery, presence of neurological, dental, hearing complications, secondary hyperparathyroidism, height < -2SDS); intolerance to conventional therapy (nephrocalcinosis, hypercalciuria) or late diagnosis (> 8 years). Serum phosphate level (sP) was checked before starting burosumab (M0) and monitored every 2 weeks for dose adjustment (target sP > 1.2 mmol/l). Other parameters (weight, height, ALP, $1,25(OH)_2D$, PTH, TmP/eGFR, CaU/CrU, side effects) were checked at M0, thereafter at 3 and 6 months of treatment (M3-M6).
Results
Twenty-five girls/14 boys (mean age 9.6 ± 3.8 years; 84.6% of subjects ($n = 33$) with complications) were treated with conventional therapy for 7.7 ± 3.8 years before starting burosumab. 26 patients completed 6 months of treatment. Upon burosumab, levels of sP, TmP/eGFR, $1,25(OH)_2D$ increased significantly (sP 0.7 ± 1.1 → 1.2 ± 0.2 → 1.1 ± 0.1 mmol/l; TmP/eGFR 0.6 ± 1.1 → 1.1 ± 0.2 → 1.0 ± 0.2; $1,25(OH)_2D$ 26.0 ± 15.3 → 73.4 ± 24.0 → 88.0 ± 34.4 pg/ml at M0-M3-M6, respectively, p for trend = 0.000) and ALP decreased (413 ± 163 → 333 ± 150 UI/l at M0-M6, respectively, $P = 0.3$). However, PTH level and CaU/CrU ratio were not modified during the treatment. At M6, the average dose of burosumab was 1.3 ± 0.5 mg/kg (45 ± 23 mg); 61.5% ($n = 16$) of patients did not achieve target sP level. At M6, 27% ($n = 7$) of subjects received the maximal dose of burosumab (2.0 mg/kg or 90 mg), yet had low sP level. The number of complications was positively associated with the final dose of burosumab (32 ± 13 vs 31 ± 16 vs 57 ± 24 mg for children with 0, ≤2 and >2 complications, respectively, P for trend = 0.004). We did not observe severe adverse events during the treatment, the most frequent side effect being redness at sites of injection.
Conclusion
Treatment with burosumab restores phosphate reabsorption, increases sP and endogenous $1,25(OH)_2D$ synthesis. The dose of burosumab needs to be increased with the severity of the disease.

Non-invasive detection of GNAS mutations causing McCune-Albright Syndrome with ddPCR on whole blood or circulating DNA

Pauline Romanet[1], Pascal Philibert[2], Frédéric Fina[3], Thomas Cuny[1], Rachel Reynaud[1], Françoise Paris[2] & Anne Barlier[1]
[1]Aix Marseille Univ, Marseille, France; [2]CHU Montpellier, Montpellier, France; [3]APHM, Marseille, France.

Context
Postzygotic activating mutations in *GNAS* are responsive for fibrous dysplasia (FD) and McCune-Albright Syndrome (MAS). MAS is a rare disease associating fibrous dysplasia, to skin pigmentation and endocrine disorders. The classic genetic non-invasive methods are insufficiently sensitive to detect *GNAS* mutation, due to a low level of mosaicism in blood. Early diagnostic should allow a follow-up and a therapeutic choice adapted to the MAS context in order to reduce the complications and optimize the quality of life. The development of a sensitive and non-invasive test represents a significant step forward for an early diagnosis improving further monitoring of the patients.
Patients and Methods
We used an ultrasensitive quantitative PCR using digital droplet PCR (ddPCR) technology for the detection of *GNAS* mutations. First we did a validation study of assays targeting the R201C and R201H mutations on 18 patients previously characterized by nested-PCR method. Then we tested the DNA of naive patients presented FD or MAS, after extraction from whole blood and from plasma, i.e. circulating cell-free DNA (ccfDNA).
Results
Seventeen patients presented 1 to 3 FD/MAS lesions were included. Using ddPCR, we detect *GNAS* mutations in whole blood DNA from 7/12 patients; and the combined analyses on both whole blood DNA and ccfDNA led to a FD/MAS molecular diagnosis in 4/5 patients.
Conclusions
We demonstrated the relevance of using ddPCR to screen for *GNAS* mutations in patients with at least one feature of FD/MAS, with considerable benefits in terms of precision, acceptability and cost-effectiveness.

Background
APECED syndrome is a rare monogenic disease caused by homozygous mutation of AIRE gene. It classically presents with chronic mucocutaneous candidiasis (CMC), hypoparathyroidism (HP), and adrenal insufficiency (AI) with an early onset in childhood. Non-endocrine manifestations as ectodermic dystrophy, asplenism and pneumonitis are also observed but their incidence remains unknown and their mechanisms not well understood. APECED has been poorly reported in France although it is widely described in several European countries. The aim of this study was to report on rare manifestations of APECED syndrome in a French cohort and to determine the mutational spectrum of the AIRE gene at the national level.
Patients and methods
We performed a multicentric prospective observational study in France in order to collect clinical, biological, immunological and genetic data, after written informed consent in the frame of a PHRC (Hospital Project of Clinical Research #1927). Rare manifestations were systematically investigated in addition to the search of antibodies, analysis of AIRE gene, lymphocyte immunophenotyping and HLA genotyping. This evaluation was carried out 3 times in two years.
Results
We enrolled 25 patients (23 families) between 2009 and 2016. Eleven mutations of the AIRE gene were identified, two of which never previously reported: an intronic variation c.653-70G > A (intron 5) in a patient with hypoparathyroidism as unique manifestation, and c.1066del (p.Arg356GlyfsX22) (exon 9) in a patient from Guadeloupe with composite heterozygous mutations (c.967_979del13; exon 8). The most common AIRE mutation was the Finnish mutation R257X. The median number of manifestations was 7. 76% of patients presented the Whitaker triad. The most common disorders were CMC, AI and HP but pulmonary involvement (62%), ectodermal dystrophy (80%) with ocular involvement (33%), malabsorption (32%) and asplenism (26%) were common. There was an NK lymphopenia with a significant increase in T4 and T8 lymphocytes with age-dependent alteration of B lymphocyte homeostasis (inversion of the naive LB/LB memory ratio) ($P < 0.001$). 100% of tested sera were positive for anti-IFNα-antibodies, 15/18 for anti-IL-22, and 13/18 for anti-IL-17F antibodies.
Conclusion
The French population of APECED patients shows a great genotypic and phenotypic variability. We confirm an alteration of B age-dependent lymphocyte homeostasis. Systematic screening of rare manifestations as asplenism and bronchiolitis could be a useful strategy to make an earlier diagnosis, to prevent infections by vaccination and to treat earlier pulmonary involvement. Antibodies against Th17 cytokines appear as good soluble markers for diagnosis of non-classical presentation of the syndrome.

Kiss1 neurons are essential elements in the central pathways controlling the reproductive axis. In rodents, two major hypothalamic populations of Kiss1 neurons exist, in the arcuate nucleus (ARC) and in the rostral periventricular area of the third ventricle (RP3V). The majority of ARC Kiss1 neurons express two others neuropeptides, neurokinin B (NKB; encoded by Tac2) and dynorphin (Dyn); hence, this population has been named KNDy. Yet, NKB-only and Kiss1-only neurons are also found in the ARC, but the relative contribution of the different subsets of Kiss1 populations to the control of reproductive function, and its modulation by metabolic factors, remains unexplored. To define the precise roles of KNDy-born kisspeptin, and hence of KNDy (vs. Kiss1-only) neurons, we report herein the generation and initial characterization of the first mouse line, named TaK-KO, with conditional ablation of Kiss1 in Tac2 expressing-neurons, produced by crossing the JAX Tac2-Cre mouse with our novel Kiss1 loxP mouse. Male and female TaK-KO mice displayed a significant decrease of ARC *Kiss1* mRNA expression at 2-months of age, while Tac2 (NKB) mRNA levels remained unaltered. Despite this drop of ARC *Kiss1* expression, puberty onset (evidenced by vaginal opening and first estrus in females, and preputial separation in males) occurred at normal timing. Further, the absence of Kiss1 in KNDy neurons did not significantly affect basal LH levels, neither did it alter LH responses to Senktide (NKB agonist) or kisspeptin-10. Yet, uterus weights were markedly decreased in 2-mo-old TaK-KO females, suggesting an incipient perturbation of the reproductive axis. This contention is further supported by initial analyses in 6-mo-old TaK-KO female mice, which displayed overt irregularities in estrous cyclicity; characterization of LH pulsatility and ovarian morphology is in progress. In parallel, our initial metabolic analyses suggest that the ablation of Kiss1 in KNDy neurons leads also to significant changes in body composition (increase of fat mass), detectable in 4 mo-old males and females, together with modest changes of glucose and insulin tolerance, mainly noticed in males. In sum, we report herein the first mouse line with conditional ablation of *Kiss1* in KNDy neurons. Our data suggest that KNDy-born kisspeptins are dispensable for puberty onset but required for proper maintenance of reproductive and metabolic homeostasis in adulthood. Ongoing studies, using different metabolic and reproductive challenges, are currently in progress in this novel mouse line to tease apart the specific roles of KNDy-derived kisspeptins in the control of these key bodily functions.

AMH is a predictive factor for successful sperm retrieval in non-mosaic Klinefelter syndrome patients

Lucie Renault[1], Sandrine Giscard d'Estaing[1,2,3], Beatrice Cuzin[4], Medhi Benchaib[1,2,3], Jacqueline Lornage[1,2,3], Gaëlle Soignon[1,3], Frederique Dijoud[3,5], Hervé Lejeune[1,2,3] & Ingrid Plotton[1,2,3,6]
[1]Service de Médecine de la Reproduction, Hôpital Femme Mère Enfant, Hospices Civils de Lyon, Lyon, France; [2]INSERM U 1208, Lyon, France; [3]Université Claude Bernard Lyon 1, Lyon, France; [4]Service d'Urologie et de Transplantatio, Hôpital Edouard Herriot, Hospices Civils de Lyon, Lyon, France; [5]Laboratoire d'Anatomopathologie, Centre de Biologie et de Pathologie Est, Groupement Hospitalier Est, Hospices Civils de Lyon, Lyon, France; [6]Laboratoire d'Hormonologie - Endocrinologie Moléculaire et Maladies Rares, Centre de Biologie et de Pathologie Est, Groupement Hospitalier Est, Hospices civils de Ly, Lyon, France.

Context
Klinefelter Syndrome (KS) patients, defined by a 47 XXY karyotype, were long considered infertile. Testicular sperm extraction (TESE) now allows some of these patients to access fatherhood. The predictive factors for success, however, remain unknown.
Patients and methods
Non-mosaic KS patients with azoospermia or severe cryptozoospermia on two semen analyses without any other spermatogenesis disorder were included. They were sorted into two age groups: youths, between 15 and 22 years of age, and adults over 23. They had two clinical examinations and blood tests before conventional TESE and one after.
Results
One hundred sixty two KS patients were included between April 2010 and May 2018: 63 youths and 57 adults. Thirty-six gave up before biopsy, 72% of whom were youths. Median age at biopsy was 22 years: 18 years for youths and 31 years for adults. Sperm straws were frozen for 50 patients (41.6%): 26 youths (41.3%) and 24 adults (42.1%). Half of the adults who cryopreserved sperm did at least 1 intra-cytoplasmic sperm injection, leading to 6 pregnancies and 7 live births. Clinical features (BMI, age at diagnosis, testosterone treatment, Tanner stage, and testis volume) were similar between patients with and without successful sperm retrieval. FSH, LH, total and bioavailable testosterone, estradiol and inhibin B levels were not predictive of success. Interestingly, median AMH was significantly higher in patients with successful TESE, at 13 pmol/L [4-31] versus 3 pmol/L [0.9–15.3]; $P = 0.0049$.
Conclusion
Clinical and biological features of a very large cohort of 120 KS patients are described. We show for the first time AMH to be a predictive factor of success for sperm retrieval in non-mosaic KS patients.

Endocrine Disruptors transgenerationally alters pubertal timing through epigenetic reprogramming of the hypothalamus

David Lopez Rodriguez[1], Carlos Francisco Aylwin[2], Arlette Gerard[1], Silvia Blacher[3], Ezio Tirelli[4], Jean-Pierre Bourguignon[1], Alejandro Lomniczi[2] & Anne-Simone Parent[1]
[1]GIGA Neurosciences, Neuroendocrinology Unit, University of Liège, Liege, Belgium; [2]Division of Genetics, Oregon National Primate Research Center, OHSU, Portland, Oregon, USA; [3]Tumor and Development Biology, GIGA-Cancer, University of Liège, Liege, Belgium; [4]Department of Psychology: Cognition and Behavior, University of Liège, Liege, Belgium.

Endocrine disruptors are a rising concern for public health due to their ubiquitous presence affecting reproductive development throughout generations. We aim at studying the transgenerational effect of an EDC mixture on female sexual development and reproduction. Female rats (F0 generation) were orally exposed to a mixture of 14 anti-androgenic and estrogenic EDCs or corn oil for 2 weeks before and throughout gestation and until weaning. The mixture was composed of plasticizers (BPA, DBP, DEHP), fungicides/pesticides (Vinclozolin, Procymidon, Prochloraz, Epoxynazole, Linurone, p-p'-DDT), UV filters (4-MBC, OMC), Butylparaben and the analgesic Acetaminophen. Doses were in the human exposure range (µg/kg). Sexual development and reproductive parameters (vaginal opening, GnRH secretion, estrous cyclicity and folliculogenesis) were studied from F1 to F3 generations. Maternal behavior was measured from F0 to F2 generations. At PND21, mediobasal hypothalamus of the F1 and F3 were removed for gene expression analysis (RNAseq, RT-PCR) as well as for Chromatin Immunoprecipitation of histone modifications at regulatory regions of target genes. The results show multiple multi- and transgenerational effects after ancestral EDC exposure. While F2 and F3 females showed delayed vaginal opening, decreased percentage of regular estrous cycles, decreased GnRH interpulse interval and altered folliculogenesis, no such changes were detected in F1 animals. These alterations were accompanied with transcriptional and histone posttranslational modifications of key hypothalamic genes involved in puberty and reproduction. We observed a downregulation of estrogen signaling (Esr1), genes involved in the GnRH network (Kisspeptin, Grin2d, Tac3R), maternal behavior (Th, Oxt, Avp, Drd1, Drd2) and stress responsiveness (Nr3c1). Upregulated gens involved glucocorticoid activity (Crh) and metabolism (Pomc, Cart). Concomitantly with transcriptional levels, while downregulated genes present higher levels of repressive histone marks (H3K9me3, H3K27me3) and decreased levels of activational histone marks (H3K4me3, H3K9ac), upregulated genes present the opposite pattern. Such histone marks related to changes in the polycomb/thritorax group of protein balance, involved in the control of female puberty. F1 and F2 females displayed decreased licking while spending more time resting alone. F1 RNAseq showed a reduction in Th, *Drd1* and *Drd2* mRNA expression. These alterations on maternal behavior are known to cause transgenerational alterations of the development of the corticotropic and gonadotropic axis. In conclusion, exposure to an environmentally relevant EDC mixture transgenerationally affects sexual development and reproduction throughout epigenetic reprogramming of the hypothalamus. While not yet clear, such effects could be mediated by alterations of maternal behavior caused by exposure to the first generation.

Conditional ablation of AMP-Activated Protein Kinase (AMPK) in GnRH neurons reveals specific roles in reproductive and metabolic homeostasis

Juan Roa[1,2], Delphine Franssen[1], Alexia Barroso[1,2], Francisco Ruiz-Pino[1,2], María Jesús Vázquez[1,2], David García-Galiano[1,2], Juan Manuel Castellano[1,2], Francisco Gaytán[1,2], Carlos Diéguez[2,3], Leonor Pinilla[1,2], Miguel López[2,3] & Manuel Tena-Sempere[1,2]
[1]Department of Cell Biology, Physiology and Immunology, University of Córdoba; Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC)/Hospital Universitario Reina Sofía, Córdoba, Spain; [2]CIBER Fisiopatología de la Obesidad y Nutrición, Madrid, Spain; [3]Department of Physiology, University of Santiago de Compostela, Santiago de Compostela, Spain.

Reproduction is tightly coupled to body energy and metabolic status. GnRH neurons, the final output pathway for the brain control of reproduction, directly or indirectly receive and integrate multiple signals, including metabolic cues regulating reproductive function. Yet, the molecular underpinnings of such phenomenon remain largely unfolded. AMP-activated protein kinase (AMPK), a fundamental cellular sensor that becomes activated in conditions of energy deficit, has a key role in the control of whole-body metabolism. Fragmentary evidence suggests that AMPK participates also in the control of key elements of the reproductive axis, as Kiss1 neurons, driving an inhibitory valence in situations of energy depletion. However, the physiological contribution of AMPK signaling in GnRH neurons to the metabolic control of reproduction is unknown. We report herein the characterization of the first mouse line, named GAMKO, with conditional ablation of a1-AMPK in GnRH neurons. In keeping with a putative inhibitory action of AMPK in GnRH neurons, GAMKO females displayed earlier puberty onset and exaggerated LH (as surrogate marker of GnRH) responses to kisspeptin-10 at the prepubertal age. In adulthood, GAMKO females retained increased LH responsiveness to kisspeptin and the neurokinin-B agonist, Senktide, and showed partial resilience to the inhibitory effects of conditions of negative energy balance on the gonadotropic axis. Thus, GAMKO females submitted to chronic subnutrition showed a faster recovery of estrus cyclicity after re-feeding. Furthermore, elimination of AMPK from GnRH neurons prevented the physiological drop of LH level after fasting and changed the pattern of LH pulsatility. The modulatory role of AMPK in GnRH neurons seems to require estradiol, since no changes in basal LH levels or pulsatility were detected in ovariectomized GAMKO mice subjected to fasting or subnutrition. Notably, AMPK ablation on GnRH neurons caused also alterations in body composition, with increased fat mass, and modest changes in insulin and glucose tolerance in GAMKO females. In sum, our data document a physiological role of AMPK signaling in GnRH neurons in the metabolic control of the reproductive axis, as conduit of at least part of the inhibitory actions of energy deficit. In addition, our results disclose a putative function of AMPK specifically in GnRH neurons in the control of body composition and glucose homeostasis, whose relevance warrants further investigation.

The neurokinin 3 receptor antagonist, fezolinetant, is effective in treatment of menopausal vasomotor symptoms: responder analysis results from a randomized, placebo-controlled, double-blind, dose-ranging study

Graeme Fraser[1], Samuel Lederman[2], Arthur Waldbaum[3], James Young[4], Laurence Skillern[5] & Steven Ramael[1]
[1]OGEDA SA, a wholly owned subsidiary of Astellas Pharma, Inc., Gosselies, Belgium; [2]Altus Research, Lake Worth, USA; [3]Downtown Women's Healthcare, Denver, USA; [4]Astellas Pharma, Inc., Northbrook, USA; [5]Astellas Pharma Europe Ltd, Chertsey, UK.

Background
The brain's thermoregulatory center is stimulated by activation of neurokinin 3 receptor (NK3R) and inhibited by estrogen. In menopause, declining estrogen disturbs this balance, producing vasomotor symptoms (VMS). This study assessed response to the NK3R antagonist fezolinetant in women with menopausal VMS.
Methods
This phase 2b, double-blind trial (NCT03192176) randomized menopausal women (age >40−65 y) with moderate/severe VMS (≥50/wk) to fezolinetant 15, 30, 60, or 90 mg BID or 30, 60, or 120 mg QD or placebo for 12 weeks. Response and percentage reduction in frequency of moderate/severe VMS were prespecified secondary endpoints. Response was defined as ≥50%, 70%, 90%, or 100% reduction in moderate/severe VMS; odds ratios for response were analyzed via logistic regression. Kaplan-Meier was used to estimate time to response, which was summarized descriptively. Least squares (LS) mean percent reduction from baseline in daily VMS frequency was determined with a mixed effect model repeated measures approach.
Results
Of 356 women randomized, 352 received ≥1 dose of study drug (safety population; mean [SD] age: 54.6 [4.7] y; 73% white) and 287 (81%) completed the study (placebo: 84%; fezolinetant: 80%). The percentage of patients with 50% reduction in moderate/severe VMS at last on-treatment assessment was significantly higher with fezolinetant 15, 30, 60, and 90 mg BID (83.7%, 81.4%, 88.1%, and 94.7%, respectively) or 30, 60, and 120 mg QD (82.1%, 88.1%, and 84.1%, respectively) than with placebo (58.5%; all $P < .05$ for odds ratio for response vs placebo). Mean time to 50% reduction in moderate/severe VMS ranged from 2.2–8.4 days with fezolinetant depending on dose, and 15.1 days with placebo (Figure 1). LS mean percentage reduction from baseline to week 12 in daily frequency of moderate/severe VMS were 74.3%, 75.8%, 80.2%, and 86.9% for 15, 30, 60, and 90 mg BID and 75.1%, 77.7%, and 76.9% for 30, 60, and 120 mg QD, respectively (common SE: ∼5; all $P < .01$). Most TEAEs were mild/moderate. No deaths or serious treatment-related TEAEs occurred.
Conclusion
A significantly larger percentage of women treated with most doses of fezolinetant achieved treatment response, compared with placebo, and percentage reductions in daily moderate/severe menopausal VMS were significantly larger with fezolinetant. Kaplan-Meier estimates demonstrate a rapid onset, as early as the first few days.

3D mapping and in silico predictions of the DEHAL1 enzyme as a tool to discriminate pathogenic mutations from non-functional variants in hypothyroidism

García-Giménez Jorge[1], González Wong Ángel[2], González-Guerrero Cristian[1], Iglesias Ainhoa[1], Styrers Emily[1], Cocho José[3], Pardo Leonardo[2] & Moreno J Carlos[1,4]
[1]Thyroid Molecular Laboratory. Medical and Molecular Genetics Institute (INGEMM) Universitary Hospital of La Paz, Madrid, Spain; [2]Computational Medicine Laboratory, Barcelona, Spain; [3]Metabolopathies Laboratory of Universitary Clinical Hospital of Santiago de Compostela, Santiago de Compostela, Spain; [4]Autonomous University of Madrid, Madrid, Spain.

Next Generation Sequencing (NGS) is becoming widely used for genetic diagnosis. While its capacity for detection of human genetic variations (GV) is outstanding, drawbacks is the identification of numerous GV of which functional significance cannot be predicted *in silico* by computer programs (variants of uncertain significance, VUS). Currently, only sensitive (but also expensive and time-demanding) *in vitro* cell assays, can trustfully ascertain pathogenicity of VUSs, generally of selected proteins o signalling pathways, seriously hampering efficiency of genetic diagnostic for the clinic.
Objective
To apply 3D mapping and *in silico* predictions as tools to inform pathogenicity of GVs identified in hypothyroid patients with alleged iodotyrosine deiodinase deficiency, as compared with *in vitro* dehalogenation assays.

Methods
Nine missense DEHAL1 variants identified in goitrous hypothyroid patients were subjected to both *in vitro* functional testing and *in silico* 3D modelling and docking with substrates (MIT, DIT) and cofactor (FMN), using available X-Ray crystallographic information of dimeric DEHAL1. Three (K258N, V265M and R279S) were identified in patients with undisputed diagnosis of iodotyrosine deiodinase deficiency through *in vivo* ^{123}I-MITdeiodination test. The rest (N108S, A202T, R246Q, L260P and E271K) are harboured by patients with clinical suspicion of DEHAL1 defect. The functional assay involved mutagenesis of DEHAL1 variants in expression vectors, transfection in HEK293 cells, addition of MIT, FMN and NADPH to culture medium and determination of % MIT decrease by LC/MS-MS.
Results
The functional assay showed significant decrease of deiodination for K258N (60%) and R279S (58%) versus WT. However, V265M did not, suggesting limitations of our assay to detect less severe mutations. The rest of variants showed normal deiodination with the exception of L260P, which behaved as deleterious (10%). Interestingly, *in silico* studies on K258N, R279S, V265M and L260P revealed that the amino acids changes had damaging effects on the structural stability, electrostatic properties or interaction with cofactor and substrates (FMN and MIT) on the DEHAL1, and provide a structural explanation for the iodotyrosine deiodinase deficiency. Besides, the peripheral location of N108S, A202T, R246Q, and E271K variants in *the* model correlates with the benign nature of such changes in the assay.
Conclusions
Structural modelling and molecular dynamics is a valuable tool to discriminate pathogenic vs VUS changes in human *DEHAL1*, showing consistency with the *in vitro* assay and superior sensitivity to detect some pathogenic changes. An additional advantage of this filtering approach is the prediction of the intrinsic molecular mechanism driving the functional damage of mutations.

Direct evidence for disulfides in the mechanism of deiodinase 1

Alfonso Rubén Ruiz Rodriguez, Doreen Braun & Ulrich Schweizer
Rheinische Friedrich Wilhelms Universität Bonn, Bonn, Germany.

The main product of the thyroid gland, T_4, is a prohormone. 5'-deiodination is needed to convert T_4 into the active, nuclear receptor-binding hormone, T_3. Pharmacological modulation of activating 5'-and inactivating 5-deiodination of iodothyronines would be desirable in a number of medical conditions, including hypothyroidism, hyperthyroidism and various cancers. A structural and mechanistic understanding of deiodinase (DIO) catalysis is a prerequisite of successful pharmacological intervention. Structural data on deiodinases are currently limited on the intracellular catalytic domain of murine Dio3 (1). However, deiodinases are membrane anchored proteins and it is known that the membrane anchor contributes to activity of the enzymes. In order to elucidate the mechanism of deiodinases, we have recombinantly expressed full length human DIO1 as a membrane protein in insect cells. Since these cells do not have the capacity to express selenoproteins, selenocysteine (Sec)126 was replaced by cysteine (Cys). The resulting protein was expressed at high levels and catalytically active in the presence of mM concentrations of DTT as reductant. Similar to murine Dio3, human DIO1 was active in the presence of a physiological reducing system comprising of glutaredoxin (1 μM), glutathione (GSH), GSH reductase, and NADPH. We replaced a series of conserved Cys in DIO1 with Ser or Ala and showed that all these mutations reduced the activity of the enzyme. We could assign different functions to these cysteines. DIO1 is known to function as a dimer. A new finding is that according to mass-spec analyses, Cys95 and possibly Cys105 contribute to stabilization of the dimer via inter-subunit disulfides. In addition, mass-spec analysis for the first time directly demonstrated the formation of a disulfide between Cys124 and Cys(Sec)126 during catalysis as suggested before. Data derived from analysis of mutant DIO1 are compatible with a reducing mechanism similar to that in murine Dio3. Taken together we show for the first time the formation of inter-subunit and intra-subunit disulfides within DIO1. Their function is revealed by the use of a physiological reducing system comprised of Grx, GSH, GR, and NADPH instead of the non-physiological provision of the synthetic DTT reductant.

Novel driver mutations in thyroid cancer recurrence

Hannah Nieto, Caitlin Thornton, Alice Fletcher, Albert Nobre de Menezes, Kate Baker, Mohammed Alshahrani, Martin Read, Kristien Boelaert, Vicki Smith, Jean Baptiste Cazier, Hisham Mehanna & Chris McCabe
University of Birmingham, Birmingham, UK.

The incidence of thyroid cancer is rapidly increasing worldwide. Whilst outcome in thyroid cancer is generally good, up to 25% of patients develop recurrence, and have a significantly reduced life expectancy. We hypothesise those thyroid tumours which subsequently recur display a distinct pattern of driver events. Whole exome sequencing data were downloaded from The Cancer Genome Atlas (TCGA). Bioinformatic analysis of data on $N=43$ patients whose tumours recurred was performed, using a Platypus, Annovar and SIFT/PolyPhen2/MutationTaster filtering pipeline. This identified mutations in biologically significant genes, including Inosine-5'-monophosphate dehydrogenase 2 (IMPDH2), 6-Phosphofructo-2-Kinase/Fructose-2,6-Biphosphatase 4 (PFKFB4) and Dicer 1 ribonuclease type III (DICER1). As in-silico analysis suggested these variants to be potentially pathogenic, we recapitulated mutations from TCGA. Subcellular localisation, proliferation, cellular migration and invasion were investigated in cell lines which represent the most common background driver mutations of papillary thyroid cancer (TPC1: RET/PTC; SW1736: BRAF; Cal62: KRas). In TPC1 cells IMPDH2 mutation significantly increased cell migration at 4, 8 and 24 hrs vs. WT ($P=0.0068$, $P=0.0008$, $P=0.0088$ respectively) and DICER1 mutation induced increased cell migration at 24 hours vs. vector-only ($P=0.0094$). Overexpression of IMPDH2 resulted in altered intracellular localisation into intracellular discrete bodies known as cytoophidia. As recurrence may also affect altered gene expression, we analysed the RNA profile of the recurrent patients ($N=43$) compared to the non-recurrent ($N=457$). In particular, genes involved in matrix adhesion and thyroid cancer pathogenesis were most differentially expressed in recurrence patients, including fibronectin 1 (FN1), thyroglobulin (TG), α3 integrin (ITGA3), SPARC-like protein 1 (SPARCL1), Integral Membrane Protein 2A (ITM2A) and the proto-oncogene mesenchymal-epithelial transition factor (MET) ($P=0.00376$, $P=0.00311$, $P=0.00757$, $P=0.01874$, $P=0.00003$, $P=0.00003$ respectively). Overall, we propose that rare somatic mutations on top of established driver events, as well as specifically altered RNA expression levels, may be key to predicting thyroid cancer prognosis.

Resistance to thyroid hormone alpha associated with early-onset severe NASH

Valentina Pautasso[1], Clementine Dumant Forrest[1], Anne-Marie Guerrot[1], François Fraissinet[1], Frédérique Savagner[2] & Mireille Castanet[1]
[1]CHU de Rouen, Rouen, France; [2]CHU de Toulouse, Toulouse, France.

Introduction
Resistance to thyroid hormone alpha (RTHα) is characterised by tissue-specific hypothyroidism associated with barely normal thyroid function tests. Clinical features include dysmorphic facies, skeletal dysplasia, growth retardation, constipation, dyspraxia and intellectual deficit. Hormonal assessment often shows decreased/low-normal free thyroxine (fT4) and increased/high-normal free triiodothyronine (fT3) concentrations, resulting in a low fT4/fT3 ratio, with a non-adapted normal thyroid stimulating hormone (TSH) level. We describe the case of a 14-year-old *THRA* mutant girl who was diagnosed at birth with peripheric congenital hypothyroidism and who developed marked hypercholesterolemia and severe non-alcoholic steatohepatitis (NASH). Phenotypical presentation includes marked abdominal obesity, macrocephaly, macroglossia, short and large nose, micrognathia and low-implanted ears, associated with mild intellectual impairment.
Methods
A panel of genes involved in congenital hypothyroidism was explored by next generation sequencing (NGS) on DNA sample. Pathogenic variant was confirmed by Sanger sequencing of exon 10 of the *THRA* gene for the proband and her mother. Functional analysis was performed on HepG2 cell line using plasmid transfection of wild type (wt) TRα1 and TRβ, mutated TRα1 and reporter plasmids containing

thyroid hormone responsive elements coupled to the luciferase gene. Transcriptional effect has been assessed through luciferase activity.
Results
Next generation sequencing identified a heterozygous single nucleotide c.1207G>A (p.E403K) *THRA* mutation on exon 10 resulting in impaired function of α1 receptor isoform. The patient's mother carried the same *THRA* mutation. Transfection studies on HepG2 cells showed a significant lower transactivation effect of the mutant TRα1 compared to wt TRα and a dominant negative transcriptional effect of mutated TRα1 on both wt TRβ and TRα.
Conclusions
This peculiar case associates classical clinical and biological features of RTHα with a previously unreported first-plan metabolic profile: obesity, hyperlipidaemia and severe NASH. Functional *in vitro* studies suggest a dominant negative effect of mutated TRα1 receptor on wild type TRβ, which is the main isoform expressed in the liver, as well as on wild type TRα, which is mainly represented in adipose tissue. Taken together, these data are in favor of a pathogenic role of $TR\alpha1^{E403K}$ in the development of this unique hepato-metabolic profile. This case further strengthens the wide phenotypical variability of RTHα presentation and the pleiotropic effect of TRs.

Deciphering the origin of the sexually dimorphic thyrotropin secretion in mouse models

Yasmine Kemkem[1,2], Chrystel Lafont[3,4], Anne Guillou[3,5], Lama El Cheikh[3,5], Pierre Fontanaud[3,5] & Patrice Mollard[3,5]
[1]CNRS Institut de Génomique Fonctionnelle, Montpellier, France; [2]Université de Montpellier, Montpellier, France; [3]Institut de Génomique Fonctionnelle, Montpellier, France; [4]INSERM, Montpellier, France; [5]CNRS, Montpellier, France.

Hypothyroidism refers to a thyroid hormone (TH) deficiency which mainly affects women (10/1 ratio). The higher default incidence in women remains unexplained. Diagnosis of hypothyroidism is based on a single thyroid-stimulating-hormone (TSH) measurement albeit TSH secretion displays pulsatile patterns which are under the positive control of hypothalamic thyrotropin-releasing-hormone (TRH) and negative feedback exerted by THs. Pituitary thyrotrophs form the smallest (2-4%) pituitary endocrine population and the processes which govern their TSH secretion *in vivo* remain largely unknown. The aim of this study is to explore whether pituitary thyrotrophs form, *in vivo*, a functionally-organized and sexually dimorphic cell population capable of generating TSH pulses. Circulating mouse TSH levels were measured using an ultra-sensitive in-house mTSH ELISA, uncovering various pulsatile patterns which would differentially stimulate the thyroid gland. In order to identify the origin of TSH secretion, calcium signals were monitored *in vivo* in mouse models, as a surrogate of the stimulus-TSH secretion coupling and cell-cell communication between thyrotrophs. Using thin needles of gradient-index (GRIN) lenses (7.6 mm long, 0.6 mm diameter) implanted at the pituitary level and a 2g head-mounted miniscope, multicellular calcium activities of the thyrotroph population were monitored in freely-moving TSHβ-cre*x*R26*fl*-*fl*GCaMP6f mice. Such signaling events were monitored during longitudinal studies (weeks to months) in which individual animals act as their own controls. We unveiled that the thyrotroph population functions *in vivo* as a robust generator of recurrent, slowly-evolving calcium waves which propagate between neighboring thyrotrophs and lead to the generation of ultradian TSH fluctuations. To further dissect the mechanisms underlying these sequences of calcium events, we conducted experiments on anesthetized animals, in which hypothalamic (i.e. TRH) inputs were blunted. Several injection patterns of hypothalamic TRH or TSH unveiled how TSH pulses were built-up *in vivo*. In male mice, TSH pulsatility resulted from a finely-tuned combination of prolonged TRH inputs together with an ultrashort intra-pituitary feedback loop exerted by TSH itself. In female mice, distinct patterns of calcium signals were observed in both basal and TRH/TSH-stimulated conditions. Moreover, 3D confocal imaging revealed sexually dimorphic, multicellular thyrotroph motifs (clusters in females vs. columns in males) which were spatially organized in fixed 'cleared' pituitaries. Altogether, our data support that a sexually dimorphic thyrotroph organization underlies a sexually dimorphic stimulus-TSH secretion coupling in animal models.

Background
Measurement of steroid metabolite excretion in urine by gas chromatography-mass spectrometry (GC-MS) provides a comprehensive profile of an individual's adrenal and gonadal steroid production. It has long been acknowledged as a useful tool for diagnosis of inborn disorders of steroidogenesis leading to congenital adrenal hyperplasia and disorders of sex development. Ratios of steroid metabolites can be employed as surrogates for enzymatic activities of distinct steroidogenic enzymes and can also be applied to single random urine samples, making this a more feasible approach for use with paediatric patients. However, widespread use in the acute setting for diagnosis of these disorders is hampered by the considerable expertise required for interpretation. Here we developed a novel steroid metabolomics approach for the detection and differential diagnosis of inborn steroidogenic disorders, combining mass spectrometry-based steroid profiling with machine learning-based data analysis, suitable for automation and interpretation without specialist expertise.
Methods
We performed multi-steroid profiling by GC-MS, quantifying 34 steroid metabolites, in urine samples from 829 healthy controls and 178 untreated patients with inborn steroidogenic disorders. This cohort included patients with inborn deficiencies in the following enzymes: CYP21A2 ($n=26$), CYP11B1 ($n=12$), CYP17A1 ($n=30$), POR ($n=37$), HSD3B2 ($n=22$), and SRD5A2 ($n=51$). We assessed the diagnostic performance of conventional biochemical assessment employing 15 steroid precursor-to-product ratios, each historically established as indicative of a distinct steroidogenesis disorder. We compared this to the performance of our novel steroid metabolomics approach, which involved analysis of the GC-MS multi-steroid profiles by a custom-designed approach, Angle Learning Vector Quantization (ALVQ), which classifies samples by comparing similarity of their steroid metabolome to representative steroid metabolome prototypes for each enzyme deficiency.
Results
The conventional biochemical steroid ratio approach demonstrated acceptable sensitivity and specificity. However, the automated steroid metabolomics approach (ALVQ) performed significantly superior to this, particularly with regards to specificity. For differentiating patients from healthy controls, sensitivity and specificity of ALVQ were 97% and 98%, respectively. For differentiation of each pathogenic enzymatic defect, ALVQ performed superiorly, with sensitivity and specificity ranging between 95 and 100%.
Conclusion
We present a novel steroid metabolomics approach, able to automatically detect and differentiate six different inborn disorders of steroidogenesis, with improved performance when compared to reference standard metabolite ratios. Steroid metabolomics can expedite and standardise interpretation of complex urinary steroid metabolome data, making this technique more accessible to clinicians, and has excellent potential for implementation in routine clinical practice.

Glucocorticoid resistance patients exhibit defective cortisol metabolism, responsible for functional hypermineralocorticism

Géraldine Vitellius[1], Brigitte Delemer[2], Olivier Chabre[3], Philippe Caron[4], Eric Pussard[1,5], Jerome Bouligand[1,5], Séverine Trabado[1,5] & Marc Lombès[1]
[1]INSERM UMR_S U1185, Le Kremlin Bicetre, France; [2]Service d'endocrinologie-Diabète-Nutrition, Hôpital Robert Debré, Reims, France; [3]Endocrinologie, pavillon des Écrins, CHU Grenoble, Grenoble, France; [4]Service d'Endocrinologie, Pôle Cardio-Vasculaire et Métabolique, CHU Larrey, Toulouse, France; [5]Service de Génétique Moléculaire, Pharmacogénétique et Hormonologie, Hôpitaux Universitaires Paris Sud, AH-HP, CHU Bicêtre, Le Kremlin Bicetre, France.

Glucocorticoid resistance syndrome, a rare genetic disease, is often associated with glucocorticoid receptor (GR) loss-of-function mutations. Six patients carrying heterozygous mutations of *NR3C1* gene encoding GR, either missense R477S, Q501H, L672P or non-sense R469X, R491X, Y660X mutations were studied. Surprisingly, *NR3C1* mutation carriers presented with low kalemia, low plasma renin and aldosterone levels associated or not with arterial hypertension, consistent with functional hypermineralocorticism. Importantly, circulating corticosterone or 11-deoxycorticosterone levels, when measured in these patients, were in the normal range, excluding the involvement of these mineralocorticoid agonist compounds in the pathogenesis of pseudohypermineralocorticism, as initially suggested. In this context, we hypothesize that the clinical and biological features of glucocorticoid resistant patients might be secondary to a partial impairment of GR regulation of *HSD11B2*, leading to an enzymatic defect of the renal 11β-hydroxysteroid dehydrogenase type 2 (11β-HSD2), considered as a major MR-protecting mechanism, and thus responsible for an illicit cortisol activation of the mineralocorticoid receptor (MR). The 11β-HSD2 catalyzes the conversion of cortisol into cortisone, unable to bind MR. *HSD11B2* promoter presented with putative glucocorticoid response elements. Transient transfections of plasmid expressing the wild-type GR and *HSD11B2* promoter-luciferase construct in HEK293T cells, disclosed a dexamethasone-dependent increase of reporter gene activity that was totally inhibited by cotreatment with the GR antagonist RU486, indicating a GR-mediated transactivation of *HSD11B2* gene. Likewise, a defective GR Q501H mutant fails to stimulate luciferase activity. In the absence of human renal model endogenously expressing 11β-HSD2, we demonstrate a 3-fold increase in DXM-induced *HSD11B2* mRNA levels in human breast cancer MCF7 cells, which was abolished by RU486 or by the transcription inhibitor Actinomycin D, further supporting a GR-dependent transactivation. The 11β-HSD2 activity, evaluated by cortisone/cortisol ratio quantified by LC-MS/MS, was 10-fold higher in the supernatant of DXM-treated cells than controls, strongly suggesting a GR-dependent stimulation of 11β-HSD2 catalytic activity. Collectively, we provide evidence that 11β-HSD2 expression is transcriptionally regulated by GR. In the context of GR haploinsufficiency, these findings bring additional support for a reduced HSD11B2 transcription and 11β-HSD2 activity, driven by GR signaling defect. Thus, patients carrying heterozygous loss-of-function *NR3C1* mutations exhibited an impaired 11β-HSD2 enzymatic activity, leading to a functional pseudohypermineralocorticism. These findings call for a careful monitoring of such patients to prevent or adequately control the hypertension and its associated cardiovascular consequences.

Genetic predisposition to Primary Bilateral Macronodular Adrenal Hyperplasia (PBMAH): next generation sequencing ARMC5, NR3C1 (glucocorticoid receptor) and PDE11A4 (phosphodiesterase 11) in 389 patients

Anna Vaczlavik[1], Patricia Vaduva[1], Lucas Bouys[1], Mario Néou[1], Amandine Septier[1], Victor Heurtier[1], Rossella Libé[2], Matthias Kroiss[3], Françoise Borson-Chazot[4], Philippe Chanson[5], Marie-Christine Vanthyghem[6], Antoine Tabarin[7], Guillaume Assié[1], Constantine Stratakis[8], Maria Fragoso[9], Bruno Ragazzon[1] & Jérôme Bertherat[1]
[1]Cochin Institute, Paris, France; [2]University Hospital Cochin, Paris, France; [3]University Hospital Würzburg, Würzburg, Germany; [4]University Hospital Lyon, Lyon, France; [5]University Paris-Sud, Paris, France; [6]University Hospital Lille, Lille, France; [7]University Hospital Bordeaux, Bordeaux, France; [8]NIH, Bethesda, USA; [9]Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo & ICESP, São Paulo, Brazil.

Introduction
PBMAH is an heterogeneous disease from the clinical, hormonal, and morphological point of view. *ARMC5* inactivating mutations have been reported as a cause of PBMAH. *PDE11A4* variants have been associated with PBMAH and *NR3C1* variants with bilateral adrenal incidentalomas.
Aim
To analyse the frequency of *ARMC5* pathogenic mutations and *PDE11A4* and *NR3C1* variants in PBMAH patients.
Methods
ARMC5, *PDE11A4* and *NR3C1* were sequenced on leucocyte DNA by NGS using Ion Torrent technology in 389 PBMAH index cases. Identified variants were then annotated using Annovar tool. Combined bioinformatic filters (sequence depth more than 5, allelic ratio more than 0,1 and total population frequency according to Exac less than 5%) and visual validation using Integrative Genomics Viewer (IGV) software were used in order to identify and retain the variants.
Results
Pathogenic *ARMC5* mutations are present in 75 patients (20%). *PDE11A4* and *NR3C1*variants were observed respectively in 23.4% and 8.9% of the patients. The overall frequency of PDE11A4 variants was similar in *ARMC5* mutated and wild type (WT) patients (*P*:0.88), while NR3C1 variants were more frequent in the *ARMC5* WT (*P*:0.04). The following *PDE11A* missense variants already known for altering enzymatic activity have been found: p.R804H in 15 patients (13 ARMC5 WT), p.R867G in 14 patients (9 ARMC5 WT), p.M878V (9 ARMC5 WT) and p.D609N (in 1 ARMC5 mutated patient). Interestingly a stop codon mutation initially reported in Micronodular Adrenal Hyperplasia (p.R307X) was identified in 1 ARMC5 mutated and in 3 ARMC5 WT. Five NR3C1 variants have been found: 3 already known as polymorphism: p.R23K, p.F65V, p.N363S. The last one is associated with high glucocorticoid sensitivity and bilateral adrenal incidentalomas (1 in the *ARMC5* mutated, 18 in *ARMC5* WT) whereas the first one is associated with healthier metabolic profile (1 in *ARMC5* MUT, 9 in *ARMC5* WT). Two variants not previously reported have been identified: p.S404P predicted benign in 1 patient; p. N454S predicted pathogenic in 1 patient.
Conclusion
These results show that clear pathogenic mutations of *PDE11A4* and *NR3C1* are probably rare in PBMAH. By contrast variants that might change the activity of the phosphosphodiesterase or the sensitivity to glucocorticoids are present in PBMAH patients regardless of the *ARMC5* status. Genotype/phenotype correlation analysis will help to determine their potential role in the modulation of the disease phenotype, both in term of PBMAH development or complications of cortisol excess.

Cullin 3 is a partner of armadillo repeat containing 5 (ARMC5), the product of the gene responsible for primary bilateral macronodular adrenal hyperplasia

Isadora Cavalcante[1,2], Anna Vaczlavik[3], Ludivine Drougat[3], Claudimara Lotfi[2], Maria Fragoso[4], Eric Clauser[5], Marthe Rizk-Rabin[3], Jérôme Bertherat[3] & Bruno Ragazzon[3]
[1]INSERM U1016 – Institute Cochin, Paris, France; [2]Institute of Biomedical Sciences, Sao Paulo, Brazil; [3]INSERM U1016 – Institute Cochin, Paris, France; [4]Clinicas Hospital – Adrenal Unit, Sao Paulo, Brazil; [5]Inserm U970, Paris Cardiovascular Center, Paris, France.

Background
Germline mutations of *ARMC5* (Armadillo repeat containing 5 gene) were identified as a frequent cause of primary bilateral macronodular adrenal hyperplasia (PBMAH). *ARMC5* is considered as a tumor suppressor gene regulating apoptosis and steroidogenesis by unknown mechanisms. The ARMC5 protein contains a N-terminal domain made of Armadillo (ARM) repeats and a C-terminal 'Bric-a-Brac, Tramtrack, Broad-complex/Pox virus and Zinc finger (BTB/POZ)' domain. Both domains are important for protein-protein interactions, suggesting that the study of ARMC5 partners might help to understand its cellular function. By co-immunoprecipitation coupled with mass spectrometry, we identified a potential interaction between ARMC5 and Cullin3 (CUL3), also suggested in online databases and in a Yeast-2-Hybrid assay. C*UL3* serves as a scaffold protein and assembles a large number of ubiquitin ligase complexes which mediate ubiquitination and degradation of specific substrates. Therefore, our aim was to confirm this interaction and investigate its mechanisms.
Methods
We performed immunoprecipitation experiments, bioluminescence resonance energy transfer (BRET) proximity assays, protein stability experiments and

ubiquitination assays in order to investigate the interaction of ARMC5 with CUL3.
Results
ARMC5 co-immunoprecipitated with CUL3 and a hyperbolic BRET saturation curve was observed with YFP-CUL3 and ARMC5-Luc indicating a specific proximity between these proteins. We also observed that the *ARMC5* missense mutation in the BTB domain (p.L754P) identified in a patient diagnosed with PBMAH disrupts the interaction with CUL3 and increases ARMC5 protein stability. Moreover, CUL3 overexpression increased ubiquitination of ARMC5 while no effect was observed on ARMC5-p.L754P mutant. Finally, inhibition of the ubiquitin-dependent proteasome system with MG132 induced accumulation of endogenous ARMC5 in secondary cell culture of PBMAH (without ARMC5 alteration), while no effect was observed in a secondary PBMAH cell culture carrying a mutation in the BTB domain (p.H808P) of ARMC5.
Conclusion
In this study we demonstrated the interaction between ARMC5 and CUL3. This interaction leads to the ubiquitination of ARMC5, suggesting that ARMC5 is a substrate for a CUL3-based ubiquitin complex. Moreover, missense mutants in the BTB domain of ARMC5, identified in patients diagnosed with PBMAH, alters the interaction with CUL3 and the ubiquitination by CUL3-based ubiquitin/proteasome system. These data show a new mechanism of regulation of the ARMC5 protein and open new perspectives in the understanding of the pathophysiology of PBMAH.

Cyclin dependent kinase 4 as promising drug target in adrenocortical carcinoma

Raimunde Liang[1], Isabel Weigand[1], Silviu Sbiera[1], Stefan Kircher[2], Juliane Lippert[2], Barbara Altieri[1], Sonja Steinhauer[1], Constanze Hantel[3,4], Simone Rost[2], Andreas Rosenwald[2], Matthias Kroiss[1], Martin Fassnacht[1] & Cristina Ronchi[1,5]
[1]University Hospital of Wuerzburg, Wuerzburg, Germany; [2]University of Wuerzburg, Wuerzburg, Germany; [3]University Hospital of Zurich, Zurich, Switzerland; [4]University Hospital Carl Gustav Carus Dresden, Dresden, Germany; [5]University of Birmingham, Birmingham, UK.

Adrenocortical carcinomas (ACC) are associated with heterogeneous prognosis and limited treatment options for advanced stages. Until now no efficient targeted therapies have been identified. This study aims to identify possible new molecular drug targets for a future personalized therapeutic approach. RNA was isolated from 40 formalin-fixed paraffin-embedded tumor samples from ACC patients (26F&14M, median age 46 yrs) with known genetic background (*Lippert et al. JCEM 2018*). Gene expression of 84 known cancer drug targets was evaluated by RT^2 Profiler PCR Array (Qiagen) and fold change (FC) was calculated with the 2^(-ΔΔCT) formula using 5 normal adrenal glands (NAG) as reference. Most frequently overexpressed genes were *TOP2A* (100% of cases, median FC = 16.5), *IGF2* (95%, FC = 52.9), *CDK1* (80%, FC = 6.7), *CDK4* (62%, FC = 2.9), *PLK4* (60%, FC = 2.8) and *PLK1* (52%, FC = 2.3). CDK4 was chosen as the most promising candidate for functional validation as actionable by approved CDK4/6 inhibitors. ACC samples with copy number gains at *CDK4* locus ($n = 24$) presented significantly higher *CDK4* expression levels ($P = 0.0023$). Nuclear CDK4 protein expression was investigated by immunohistochemistry and significantly correlated with mRNA expression ($R = 0.52$, $P < 0.005$). Efficacy of CDK4/6 inhibitor palbociclib (0.5–16 μM) was tested *in vitro* using two adrenocortical carcinoma cell lines (NCI-H295R and MUC1). We found a concentration- and time-dependent reduction of cell viability, which was more pronounced in NCI-H295R in line with higher CDK4 expression at western blot analysis. Furthermore, we tested palbociclib in combination with dual IGFR/IR inhibitor linsitinib (0.125–4 μM) and showed a synergistic effect on inhibiting cell viability. In conclusion, in this proof-of-principle study we confirm that RNA profiling is useful to discover potential drug targets that could be then investigated by immunohistochemistry in the clinical practice. CDK4/6 inhibitors are promising candidates for treatment of a subset of patients with adrenocortical carcinoma.

Hormonal factors and type 2 diabetes risk in women: a 22 year follow-up study on more than 83 000 women from the E3N cohort study

Sopio Tatulashvili[1], Gaelle Gusto[2], Beverley Balkau[3], Emmanuel Cosson[1], Fabrice Bonnet[4], Hélène Bihan[1] & Guy Fagherazzi[2]
[1]Endocrinology, Diabetes and Metabolic Diseases Unit, Avicenne Hospital, APHP, Bobigny, France; [2]Centre for Research in Epidemiology and Population Health (CESP) 'Health across Generations' team, University Paris-Saclay, Villejuif, France; [3]Centre for Research in Epidemiology and Population Health (CESP) 'Health across Generations' team, Université Paris-Saclay, Villejuif, France; [4]Université de Rennes 1, Department of Endocrinology, Diabetology and Nutrition, Rennes, France.

Background
Early screening and the treatment of glucose metabolism disorders could lower the risk of further complications. For this purpose it is important to identify the risk factors of type 2 diabetes mellitus (T2DM). The aim of this study was to determine the association between various hormonal factors and the risk of incident type 2 diabetes in the large prospective female E3N cohort study.
Material and methods
The study included 83,799 French women from the Etude Epidemiologique de Femmes de la Mutuelle Générale de l'Education Nationale (E3N) prospective cohort followed between 1992 and 2014. Cox multivariable models adjusted for the main T2DM risk factors were used to estimate hazard ratios (HR) and 95% confidence intervals (CI) between various hormonal factors and T2DM risk.
Results
We observed that the elevated age at menarche (HR = 0.88 [0.81–0.95]), the younger age at first term pregnancy (HR = 0.90 [0.82–0.98]), breastfeeding (HR = 0.90 [0.85–0.95]), the elevated number of total menstrual cycles (HR = 0.75 [0.68–0.82]), the elevated age at menopause (HR = 0.70 [0.63–0.78]) and the elevated duration of sex hormone exposure (HR = 0.66 [0.61–0.73]) was associated with a lower risk of type 2 diabetes. While, the use of contraceptive pills (HR = 1.33 [1.25–1.42]) and the elevated duration of menstrual cycles (HR = 1.23 [1.07–1.41]) was associated with the elevated risk of type 2 diabetes.
Conclusion
It seems that longer exposure to sex hormones but later in life could reduce diabetes. Risk induced by oral contraceptives could lead to personalized advice for young women at risk.

OC11.2

Molecular mechanisms regulating hepatic sex hormone-binding globulin production: clinical implications in human diseases

David Selva
Vall d'Hebron Research Institute (VHIR), Barcelona, Spain.

Human sex hormone-binding globulin (SHBG) is produced by the liver and secreted it into the circulation where it binds androgens and estrogens with high affinity. Therefore, SHBG acts as a carrier of these sex steroids and regulates their bioavailability. Low plasma SHBG levels are associated with obesity, fatty liver disease, abdominal adiposity and metabolic syndrome, and predict the development of type 2 diabetes. In addition, an inverse relationship between plasma SHBG levels and risk of cardiovascular disease has been reported. The SHBG gene has changed its tissue expression and therefore its function during the evolution. Rodents express the SHBG gene in the Sertoli cells of the testis. While in humans, the SHBG gene is expressed in the liver and in the germ cells of the testis. This change of function and tissue expression can be explained by the appearance during evolution of new footprinted regions in the human promoter and an alternative promoter. The generation of different transgenic mice expressing the human *SHBG* gene has allowed us to study the SHBG expression and regulation *in vivo*. We have used these mice and HepG2 cells to provide evidences that SHBG expression is regulated by thyroid hormone, proinflammatory cytokines (TNFα and IL1β), adiponectin, monosaccharides, olive oil and resveratrol (red wine). We have described the underlying molecular mechanisms by which all these factors regulate *SHBG* gene expression that involve the regulation of several transcription factors, such as HNF4α, PPARγ and CAR. These findings give an explanation of why diseases such as obesity, type 2 diabetes, hyperthyroidism, fatty liver disease and inflammatory disease (rheumatoid arthritis) have altered plasma SHBG levels. Finally, the generation

of these mouse models has allowed us to demonstrate that SHBG overexpression can protect against obesity and fatty liver development point-out SHBG modulation as a novel therapeutic strategy for the treatment of these prevalent diseases.

Implications of circulating Meteorin-like (Metrnl) level in human subjects with type 2 diabetes

Hye Soo Chung[1], Kyung Mook Choi[2], Hye Jin Yoo[2] & Sei Hyun Baik[2]
[1]Hallym University, Seoul, Republic of Korea; [2]Korea university, Seoul, Republic of Korea.

Aims
Meteorin-like (Metrnl) was recently identified as a novel adipomyokine induced by exercise and cold exposure. Metrnl improves glucose tolerance, increases systemic energy expenditure, induces white adipose browning, and promotes anti-inflammatory gene programs in obese/diabetic mice. However, the relationship of Metrnl with diabetes and cardiometabolic risk variables in humans has not been explored.
Methods
In 800 subjects (400 patients with type 2 diabetes and 400 non-diabetes), Metrnl concentration was measured with an enzyme-linked immunosorbent assay, and the correlations of Metrnl level with anthropometric parameters, lifestyle factors, body composition values, and laboratory measurements were assessed.
Results
Metrnl concentration was significantly higher in patients with diabetes than in those without diabetes [median (inter-quartile range); diabetes: 1219.9 (1020.6, 1535.6), non-diabetes: 1131.2 (993.1, 1313.6) pg/ml, $P < 0.001$]. After adjustment for age and sex, Metrnl level was significantly associated with fasting plasma glucose, blood pressure, lipid profile, and eGFR, but not with BMI or percent body fat. Multiple stepwise regression analysis exhibited that Metrnl level was independently associated with diabetes status ($P < .001$), eGFR ($P < .001$), and total cholesterol ($P = .026$) ($R^2 = 0.127$). In multiple logistic regression analysis, the odds ratio for the risk of diabetes was 3.53 (95% confidence interval: 2.04–6.10) in the highest tertile of Metrnl compared to the lowest after adjustment for confounding factors.
Conclusions
This study is the first to demonstrate that Metrnl level is elevated in human subjects with type 2 diabetes and is inversely related to various cardiometabolic risk factors, including renal function.

DOI: 10.1530/endoabs.63.OC11.3

MiR-30e-5p expression is downregulated in plasma and urine of type 1 diabetic patients with diabetic kidney disease

Daisy Crispim[1,2], Taís Assmann[3], Aline Rodrigues[1,2], Luis Henrique Canani[1,2], Bianca de Souza[1,2], Andrea Carla Bauer[1,2] & Cristine Dieter[1,2]
[1]Hospital de Clinicas de Porto Alegre, Porto Alegre, Brazil; [2]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil; [3]Universidad de Navarra, Navarra, Spain.

Background and aims
Diabetic kidney disease (DKD) is a common microvascular complication that affects 40% of patients with diabetes mellitus (DM). Emerging evidence suggests a role for microRNAs (miRNAs) in the development of DKD. In this context, miR-15a-5p and miR-30e-5p have been shown to regulate the expression of the uncoupling protein 2, a mitochondrial protein that decreases reactive oxygen species (ROS) formation by mitochondria. Since ROS overproduction is a key contributor to the pathogenesis of DKD, dysregulation of these miRNAs may be involved in DKD pathogenesis. Thus, the aims of this study were to compare miR-15a-5p and miR-30e-5p expressions in plasma and urine of type 1 DM (T1DM) patients with DKD (cases) or without this complication (controls) and to perform bioinformatics analyses to investigate their putative targets and biological pathways under their regulation.
Methods
MiR-15a-5p and miR-30e-5p expressions were analyzed in plasma and urine of 17 T1DM controls and 23 DKD cases (12 with moderate DKD and 11 with severe DKD) using real-time PCR. DKD was classified following the Kidney Disease Improving Global Outcomes guidelines, using both urinary albumin excretion (UAE) levels and estimated glomerular filtration rate (eGFR). Bioinformatics analyses were performed using the Cytoscape software.
Results
MiR-30e-5p expression was downregulated in plasma of patients with moderate or severe DKD compared to T1DM controls [severe DKD: 0.53 median (0.25–0.84, 25th–75th percentiles), moderate DKD: 0.25 (0.08–0.82), and T1DM controls: 2.42 (0.51–4.33) n fold changes, $P = 0.003$]. In urine samples, miR-30e-5p expression was only downregulated in severe DKD group compared to the other groups [severe DKD: 0.34 (0.05 – 0.85), moderate DKD: 3.92 (0.23 – 9.66), and T1DM controls: 2.96 (0.99 – 5.97), $P = 0.017$]. No difference was found in miR-15a-5p expression among groups. MiR-15a-5p and miR-30e-5p expressions showed significant negative correlations with UAE ($r = -0.459$, $P = 0.016$ and $r = -0.617$, $P = 0.0001$, respectively) and HbA1c levels ($r = -0.432$, $P = 0.009$ and $r = -0.435$, $P = 0.004$, respectively). No correlation was found between these miRNAs and eGFR or creatinine levels. Bioinformatics analyses indicate that 2197 genes are putative targets of miR-15a-5p and 2208 of miR-30e-5p, being 314 of these genes modulated by both miRNAs. Moreover, these genes participate in pathways related to angiogenesis, apoptosis, cell differentiation, oxidative stress, and hypoxia.
Conclusions
MiR-30e-5p seems to be downregulated in plasma and urine of patients with DKD. Bioinformatics analyses suggested that miR-15a-5p and miR-30e-5p regulate genes involved in key mechanisms related to DKD pathogenesis.

Bone metabolism and circulating myeloid calcifying cells in diabetic post menopausal women: a case-control study

Mariasara Persano[1], Giulio Franceschet[1], Valentina Camozzi[2], Roberta Cappellari[1] & Gian Paolo Fadini[1]
[1]Department of Medicine, University of Padua, Padua, Italy; [2]Endocrinology Unit, Department of Medicine, University of Padua, Padua, Italy.

Introduction
Diabetes mellitus (DM) is a chronic disease associated with multi-organ complications, including poor bone quality and high risk of frailty fracture. Bone and vascular complications seemed to be connected, as diabetic patients with atherosclerotic lesions show enhanced extrascheletric calcifications which in turn are associated with increased fracture risk. The aim of this study was to assessed bone mineral density (BMD) and trabecular bone score (TBS) in diabetic post-menopausal women and healthy controls, and correlate them with aortic calcifications, markers of bone turn-over, glucose metabolism and myeloid calcifying cells (MCCs).
Materials and methods
23 diabetic post-menopausal women and 25 healthy female subjects matched by age were recruited; all subjects underwent a blood exam for glucose, lipid and bone metabolism profile. MCCs were measured using flow cytometry based on the expression of osteocalcin (OC) and bone alkaline phosphatase (BAP) on monocytes and circulating CD34+ stem cells. Abdominal aortic calcifications were evaluated using Kauppila score.
Results
Bone turn-over markes (β-cross laps, BAP, OC and procollagen I N-terminal) were lower in diabetic group, and were inversely correlated with glycemia and HbA1c. We found differences in lumbar Z-score, total femur BMD, total femur T-score that were lower in the controls (-0.02 ± 1.2 vs 0.735 ± 1.4, $P = 0.048$; 0.820 ± 0.1 vs $0.902 \pm 0 - 1$, $P = 0.010$ and 1.004 ± 0.9 vs 0.330 ± 0.9, $P = 0.011$). A direct correlation was found between BMI and total BMD ($r = 0.519$, $P < 0.001$) and total T score ($r = 0.523$, $P < 0.001$). On the contrary, BMI was negatively correlated with TBS ($r = -0.495$, $P < 0.001$). TBS was significantly lower in diabetic women (1.18 ± 0.2 vs 1.26 ± 0.1, $P = 0.037$). DM-patients presented lower magnesium levels than controls (0.78 ± 0.1 vs 0.84 ± 0.1, $P = 0.012$) and it was linked with total cholesterol ($r = 0.355$, $P = 0.014$) and HDL ($r = 0.378$, $P = 0.009$). MCCs levels did not differ among the two groups of patients and were related with BAP levels. Kauppila score was higher in the diabetic group (4.2 ± 4.8 vs 2 ± 2.7, $P = 0.052$) and it was directly correlated to glycemia ($r = 0.310$, $P = 0.032$) and HbA1c ($r = 0.315$, P 0.029). This score was directed correlated to the percentage of OC+ BAP+/CD34+ cells ($r = 0.304$, $P = 0.036$).
Conclusion
Our preliminary data confirmed that the function of bone tissue is not limited to body support and organ protection; in fact, it plays a pivotal role in regulating both glucose metabolism and cardiovascular complications development in type 2 DM, being at the same time a cofactor and a target of diabetic complications.

Weekly shifts in light-dark cycle disrupt circadian clock gene expression in bone and reduce bone turnover

Maaike Schilperoort[1,2], Nathalie Bravenboer[1,3], Jan Kroon[1,2], Joann Lim[2], Leo van Ruyven[4], Patrick Rensen[1,2], Sander Kooijman[1,2] & Elizabeth Winter[1,2,3]
[1]Department of Internal Medicine, Division of Endocrinology, Leiden University Medical Center, Leiden, Netherlands; [2]Einthoven Laboratory for Experimental Vascular Medicine, Leiden University Medical Center, Leiden, Netherlands; [3]Department of Internal Medicine, Center for Bone Quality, Leiden University Medical Center, Leiden, Netherlands; [4]Department of Functional Anatomy, Academic Centre for Dentistry, Amsterdam, Netherlands.

The past decade, epidemiological studies have associated disturbances of the biological clock, as occurs in shift work, with low bone mineral density and increased fracture risk. As a large part of the working population participates in shift work (e.g. almost 30% of workers in the U.S.), this demonstrates the need for further research on the risk of skeletal disorders associated with circadian disturbances. In this study, we aimed to investigate to what extent rhythmicity exists in bone, and whether circadian disruption by weekly shifts in light-dark cycle affects bone turnover and structure in mice. To evaluate whether gene expression in bone is rhythmic, tibiae were collected from mice every 6 hours over a 24 hour period ($n=9$/timepoint). In these bones, we found diurnal expression patterns of clock genes (*Rev-erbα*, Bmal1, Per1, Per2, Cry1, *Clock*), as well as genes involved in osteoclastogenesis, osteoclast proliferation and function (*Rankl*, Opg, Ctsk) and osteocyte function (*c-Fos*). To study the importance of this rhythm for bone health, mice were subjected to either normal light-dark cycles or weekly 12 hour shifts in light-dark cycle for 16 weeks ($n=8$/group). Weekly shifts resulted in a disruption of clock gene expression in bone (i.e. reversed rhythm of *Rev-erbα* ($P<0.001$) and *Cry1* ($P<0.01$), and attenuated rhythm of *Bmal1* ($P<0.001$) and *Clock* ($P<0.05$) three days after a shift), and a reduction in plasma levels of procollagen type 1 amino-terminal propeptide (P1NP, -22.4%; $P<0.05$) and tartrate-resistant acidic phosphatase (TRAP; -19.9%; $P<0.01$), suggestive of a reduced bone formation and bone resorption, respectively. Moreover, shifts in light-dark cycle significantly altered trabecular bone structure as determined by micro-CT, and seemed to reduce bone length and weight, consistent with impaired bone growth. Collectively, these results suggest that circadian rhythm is important for bone health, and that circadian disruption negatively affects bone turnover markers and bone structure.

Epigenetic programming of transgenerational hypertension in preterm birth mice

Laurence Dumeige[1], Mélanie Nehlich[1], Say Viengchareun[1], Eric Pussard[1,2], Marc Lombès[1,3] & Laetitia Martinerie[1,4]
[1]INSERM 1185 Unit, Le Kremlin Bicêtre, France; [2]Hormonology Department, University Bicêtre Hospital, Le Kremlin Bicêtre, France; [3]Endocrinology Department, University Bicêtre Hospital, Le Kremlin Bicêtre, France; [4]Pediatric Endocrinology Department, Robert Debré Hospital, Paris, France.

Renal and cardio-vascular complications of prematurity are well established, notably those associated with renal tubular immaturity, responsible for major salt loss at birth, as well as early hypertension in adulthood. However, the molecular underlying mechanisms remain poorly understood. Our objective was to investigate the impact of preterm birth on the ontogenesis of renal corticosteroid pathways, to evaluate its implication on perinatal complications and on the emergence of hypertension in adulthood. Swiss CD1 pregnant mice were injected with O111:B4 lipopolysaccharides (LPS) at 18 days of gestation to induce preterm birth at 18.5 days of gestation. Offspring of injected mice, when LPS did not trigger preterm birth, were used as a control to exclude intrinsic LPS effects. Pups were sacrificed at various developmental stages (D0, D7 and M6). Blood pressure and heart rate were measured in males at M6 and their plasma steroid profiles were measured using LC-MSMS. Renal mRNA and protein expression of major players of corticosteroid signaling pathways were measured using RT-qPCR and western-blot analyses. Second (F2) and third (F3) generations, established by mating prematurely born adult females with wild type males, were also analyzed. We performed Methylation DNA Immunoprecipitation-qPCR to study the methylation status of candidate corticosteroid target genes that were differentially expressed between the two populations. As anticipated, preterm newborn mice presented with maladaptation, high neonatal mortality (35%), and a lower birth weight compared to controls (1.29 ± 0.21 *vs* 1.46 ± 0.15g, $P=0.0027$). Former preterm males developed hypertension at M6 (123.1 ± 1.43 *vs* 114.5 ± 0.79 mmHg, $P<0.0001$). We found a robust activation of renal corticosteroid target gene transcription at birth in preterm mice (*αENaC* ($+45\%$), *Sgk1* ($+132\%$), *Gilz* ($+85\%$)), which was not related to modified expression of the mineralocorticoid receptor (MR) and glucocorticoid receptor (GR). Interestingly, a significant increased blood pressure was found in the F2 and F3 males, descendants of the preterm group, concomitantly with increased renal *Gilz* mRNA expression, despite similar MR or GR expression, and plasma aldosterone or corticosterone levels. *Gilz* promoter methylation was reduced in preterm offspring with a negative correlation between methylation and expression ($P=0.008$), highly suggestive of an epigenetic *Gilz* regulation. Our study demonstrates prematurity-related alterations of renal corticosteroid signaling pathways, with a transgenerational inheritance of blood pressure dysregulation and epigenetic Gilz regulation up to the third generation. This study should allow a better understanding of molecular mechanisms involved in essential hypertension, which could partly be due to perinatal epigenetic programming from previous generations.

Neuronostatin and GPR107 system: a novel therapeutic circuit in prostate cancer

Prudencio Sáez-Martínez[1,2,3,4], Juan M Jiménez-Vacas[1,2,3,4], Vicente Herrero-Aguayo[1,2,3,4], Antonio J León-González[1,2,3,4], Enrique Gómez-Gómez[1,3,5], Antonio J Montero-Hidalgo[1,2,3,4], María J Requena-Tapia[1,3,5], Justo P Castaño[1,2,3,4], Manuel D Gahete[1,2,3,4] & Raúl M Luque[1,2,3,4]
[1]Maimonides Institute of Biomedical Research of Cordoba (IMIBIC), Córdoba, Spain; [2]Department of Cell Biology, Physiology and Immunology, University of Cordoba, Córdoba, Spain; [3]Reina Sofia University Hospital (HURS), Córdoba, Spain; [4]CIBER Physiopathology of Obesity and Nutrition (CIBERobn), Córdoba, Spain; [5]Urology Service, HURS/IMIBIC, Córdoba, Spain.

Somatostatin (SST)-system is a pleiotropic hormonal system composed by several ligands/receptors that is involved in the regulation of multiple pathophysiological functions. Specifically, certain components of the SST-system are dysregulated in several endocrine-related cancer types compared to control tissues, wherein these alterations seem to influence their development/progression. However, the presence and functional role of neuronostatin (NST) and its putative G-protein coupled receptor GPR107, two novel members of the SST-system, have not been fully explored in cancer. Consequently, we aimed to investigate the pathophysiological role of NST and GPR107 in prostate cancer (PC), one of the most diagnosed tumors among men worldwide, whose most aggressive phenotype [Castration-Resistant PC (CRPC)] remains lethal nowadays. Functional parameters (cell proliferation and migration) were analysed in response to NST treatment (10^{-7}M) and GPR107-silencing in different PC derived cell-lines [androgen-dependent (AD) LNCaP and androgen-independent (AI) 22Rv1 and PC-3; which are models of hormone-sensitive and CRPC, respectively)], and in normal prostate (NP) cells (RWPE-1 cell-line and primary cell cultures). Moreover, western-blotting, RT-qPCR and microfluidic-based qPCR-array were implemented to determine the mechanisms of actions associated to NST treatment and GPR107-silencing in PC-cells. NST-treatment significantly inhibited proliferation and migration rate in AI-PC cells, but not in AD-PC or in normal-cells (RWPE-1 or primary cell-cultures). Mechanistically, the antitumor capacity of NST was associated with a reduction in GPR107 expression levels, and a significant down-regulation of the expression of key genes involved in proliferation (*MKI67/CDK6*), migration (*MMP9/PRPF40A*) and PC-aggressiveness (*sst5TMD4/AR-v7/ghrelin/In1-ghrelin/EZH2/MYC*) as well as with the modulation of important oncogenic signalling-pathways (ERK/p-ERK; AKT/p-AKT; JNK/p-JNK). Remarkably, these functional anti-tumor effects exerted by NST on AI-PC cells were blunted after GPR107-silencing, suggesting that the antitumor actions of NST in PC-cells might be mediated via GPR107. Indeed, we found that GPR107 was significantly overexpressed in AI-PC cells compared to RWPE-1 cells, as well as in a cohort of PC samples compared to healthy control adjacent tissues ($n=85$) and in two in silico-independent samples cohorts (Grasso/Varambally). Finally, GPR107-silencing in AI-PC cells induced a significant decrease in proliferation and migration rate and evoked a similar dysregulation in the expression pattern of key

genes previously found in response to NST treatment (i.e. downregulation of *MKI67/MMP9/sst5TMD4/AR-v7/ghrelin/In1-ghrelin*). Altogether, our results demonstrate that NST treatment reduces PC-aggressiveness in CRPC cells via GPR107 and through the alteration of different key molecular signalling pathways, suggesting that NST/GPR107 system might be considered as a novel therapeutic tool for CRPC.

OC12.4

Long-term follow-up of antitumoral immunotherapy- induced hypophysitis in Lille hospital, France

Tiphaine Pinoche[1], Laurent Mortier[2], Arnaud Scherperel[2], Christine Cortet Rudelli[2] & Emilie Merlen[2]
[1]CH, Seclin, France; [2]CHU, Lille, France.

Ojective
We characterized the onset and follow-up of hypophysitis in a cohort of 612 patients treated for a cancer by antitumoral immunotherapy between june 2010 and may 2017 in CHU Lille, France. Design and patients: 612 patients treated by anti-CTLA4 and or antiPD-1 for melanoma ($n=426$), lung cancer ($n=166$), hematological cancer ($n=19$) or maxillary epidermoid cancer ($n=1$).
Methods
Follow-up of patients treated by immunotherapy. Symptoms, pituitary function and pituitary imaging at diagnosis of hypophysitis and during the follow-up were recorded.
Results
Of 612 patients treated with Ipilimumab or Nivolumab or Pembrolizumab alone or in association, 29 patients presented an hypophysitis (4.7%). The follow-up was on average 64 weeks (39–142). The maximal follow-up was 9 years. 7 patients have received cerebral radiotherapy before the diagnosis of hypophysitis and 11 had cerebral metastatis when the cancer was diagnosed. The main initial symptom was asthenia, 38% patients were asymptomatic. All patients had at least one hormonal defect: corticotroph 96.5%, thyréotroph 48%, gonadotroph 19%, somatotroph 31% (on 19 patients evaluated); one had transient diabetes insipidus; 31.5% had an abnormal rate of prolactin. 22% had an evocative pituitary imaging. Among the patients, 9 have received high-dose glucocorticoids (for hypophysitis $n=4$, cerebral metastasis progression $n=2$, other adverse event of immunotherapy $n=3$). At the end of follow-up 10 patients continued immunotherapy, 19 had stopped (12 for progression of disease, 3 for remission, 4 because of other adverse event of immunotherapy). Corticotroph deficiency persist in 87% of patients, thyréotroph deficiency in 20%, somatotroph deficiency in 66% of 6 patients evaluated (and 2 new deficiencies), gonadotroph deficiency in 25% (1 new deficiency). There was no difference between the two groups (persistance of deficiency or not) for age, sex, number of injections, cumulated dose, continuation of treatment at the end of follow-up, cerebral radiotherapy, other previous treatments. On the other hand more patients recovered from their deficit if they had no cerebral metastasis ($P=0.043$), if they have received high-dose of glucocorticoids ($P=0.031$). Use of two or more immunotherapy lines seemed to be an adverse factor for the recovery of deficits.
Conclusion
Immunotherapy-induced hypophysitis is a common side-effect with frequent hormonal deficiencies at diagnosis. Hypophysitis happens more frequently in patients treated for melanoma. No cerebral metastasis, high dose glucorticoids appear to be an adverse factor in hormonal recovery. on the other hand use of two or more immunotherapy lines seem to be an adverse factor.

Sexual desire in transgender persons in relation with gender affirming hormone treatment: Results from ENIGI, a large multicenter prospective cohort study in transgender people

Justine Defreyne[1], Baudewijntje Kreukels[2], Guyt T'Sjoen[1], Martin Den Heijer[2], Gunter Heylens[1] & Els Elaut[1]
[1]Ghent University Hospital, Ghent, Belgium; [2]VU Medical Centre, Amsterdam, Netherlands.

Background
The effect of testosterone on sexual arousal has been described in testosterone withdrawal and re-adminstration studies in birth-assigned males. In birth-assigned females, the relationship between sex steroids and sexual arousal is complex. Several steps in the transitioning process may affect sexual desire: hormone therapy (HT) and gender affirming surgery. HT in transgender men (TM) generally leads to increased sexual desire, masturbation frequency, sexual fantasies and arousal. Studies in transgender women (TW) are often inconclusive.
Methods
This prospective cohort study was part of the European Network for the Investigation of Gender Incongruence (ENIGI). Upon first clinical contact, psychological questionnaires were completed. Sexual desire (the Sexual Desire Inventory), serum levels of sex steroids, relationship status and surgical interventions were prospectively assessed in 766 participants (401 TW, 364 TM) during a three-year follow-up period, starting at the initiation of HT. Data were analyzed cross-sectionally and prospectively.
Results
Baseline SDI scores were comparable in TW and TM ($P=0.342$). In TW, SDI scores decreased from 39.0 [23.0–54.5] (baseline) to 33.0 [16.3–49.8] (12 months) (-4.77, $P<0.001$), returning to scores comparable to baseline after 18 months ($P=0.114$). After 36 months, SDI scores were higher than baseline scores (51.5 [39.5–61.0], $P=0.003$). In TM, total SDI scores increased from 40.0 [17.0–52.0] (baseline) to 55.0 [40.5–67.0] ($+14.61$, $P<0.001$) (12 months), remaining stable over the following year and returning to scores comparable to baseline scores (58.0 [23.0 – 62.0], $P=0.250$) after 36 months. Factors associated with higher SDI-scores included having a partner ($P<0.001$), having lower levels of self-reported gender dysphoria at baseline (Utrecht Gender Dysphoria Scale, UGDS) (TW only: $P=0.002$) and undergoing hystero-oophorectomy (TW only: $P=0.035$). Serum levels of sex steroids, type of HT and undergoing other types of surgery did not influence cross-sectional SDI scores. Factors associated with a higher prospective increase in SDI scores included undergoing gonadectomy (TW: $P=0.041$, TM: $P=0.001$) and having lower levels UGDS scores at baseline ($P<0.001$). Serum levels of sex steroids, type of HT and undergoing other types of surgery did not influence prospective changes in SDI scores.
Conclusions
Overall, sexual desire scores initially increased in TM and decreased in TW, although three-year results show a small increase in TW and status quo in TM, compared to baseline scores. We observed no association between sexual desire and serum levels of sex steroids. Other factors, such as undergoing gonadectomy, relationship status and gender dysphoria may influence sexual desire in transgender people.

Arginine-stimulated copeptin measurements - a new test for diabetes insipidus

Bettina Winzeler[1], Nicole Nigro-Cesana[1], Julie Refardt[1], Deborah R Vogt[2], Cornelia Imber[1], Benedict Morin[1], Milica Popovic[1], Michelle Steinmetz[1], Clara Sailer[1], Gabor Szinnai[3], Irina Chifu[4], Martin Fassnacht[5] & Mirjam Christ-Crain[1]
[1]University Hospital of Basel, Basel, Switzerland; [2]University Hospital of Basel, Department of Clinical Research, Basel, Switzerland; [3]University Children's Hospital Basel, Basel, Switzerland; [4]Department of Internal Medicine, Division of Endocrinology and Diabetes, University Hospital, Würzburg, Germany; [5]Department of Internal Medicine, Division of Endocrinology and Diabetes, University Hospital, Würzburg, Switzerland.

Background
The differential diagnosis of diabetes insipidus is challenging. The most reliable diagnostic approach is hypertonic saline-stimulated copeptin measurements. However, as this test is based on the induction of hypernatremia, it is associated with adverse effects and needs close sodium monitoring. We hypothesized that arginine-stimulated copeptin measurements provide an alternative, simple and safe diagnostic test for diabetes insipidus.
Methods
We recruited a development cohort (cohort 1, $N=52$) and a validation cohort (cohort 2, $N=44$) including patients with central diabetes insipidus (total $N=38$) and with primary polydipsia (total $N=58$). All patients and 92 healthy controls underwent arginine stimulation with 0.5 g L-Arginin-Hydrochlorid/kg body weight, infused over 30 minutes. Copeptin levels were measured at baseline and 30, 45, 60, 90, 120 minutes after arginine infusion. The primary objective in the first cohort was the diagnostic accuracy of copeptin levels at each measurement after stimulation whereas the second cohort should validate these results.
Results
Arginine infusion stimulated median [IQR] copeptin levels in healthy controls and in patients with primary polydipsia (3.6 pM/L [2.4, 5.7] to 7.9 pM/L [5.1, 11.8]), but not in patients with diabetes insipidus (2.1 pM/L [1.9, 2.7] to 2.5 pM/L [1.9, 3.1]). In the first cohort, a cutoff of 3.5 pM/L at 60 minutes provided the highest diagnostic accuracy to discriminate between diabetes insipidus and

primary polydipsia: 0.94 [95% CI] [0.84, 0.98], sensitivity 91%, specificity 97%. The diagnostic accuracy of this cutoff in the second cohort was 0.86 [0.73, 0.94]. By pooling the data of both cohorts an optimal diagnostic accuracy was reached for a cutoff of 3.8 pM/L at 60 minutes: 0.93 [0.86, 0.97], (sensitivity 93%, specificity 92%). The test was safe and well tolerated: the test burden (median value on a visual analogue scale from 0 [no discomfort] to 10 [maximal discomfort]) was rated 3.5 and 3 in patients with diabetes insipidus and primary polydipsia and 1 in healthy controls.

Conclusion

Arginine is a potent stimulus of the neurohypophysis. Arginine-stimulated copeptin measurements are an innovative tool to discriminate between central diabetes insipidus and primary polydipsia with high diagnostic accuracy.

Empagliflozin increases sodium-levels in patients with the syndrome of inappropriate antidiuretic hormone secretion – a randomized, double-blind, placebo-controlled trial

Julie Refardt[1,2], Cornelia Imber[1,2], Clara O Sailer[1,2], Nica Jeanloz[1,2], Laura Potasso[1,2], Alexander Kutz[1,2], Andrea Widmer[1], Sandrine Urwyler[1,2], Fahim Ebrahimi[1,2], Deborah R Vogt[3], Bettina Winzeler[1,2] & Mirjam Christ-Crain[1,2]

[1]Departments of Endocrinology, Diabetology and Metabolism University Hospital Basel, Basel, Switzerland; [2]University of Basel, Basel, Switzerland; [3]Clinical Trial Unit, Department of Clinical Research, University of Basel and University Hospital Basel, Basel, Switzerland.

Introduction

The syndrome of inappropriate antidiuretic hormone secretion (SIADH) is the predominant cause of hyponatremia but the available treatment options are unsatisfying and often of little efficiency. The selective sodium-glucose co-transporter 2 inhibitor empagliflozin promotes osmotic diuresis due to glucosuria and might be a novel treatment option for SIADH.

Material and methods

From September 2016 through December 2018 we randomly assigned 88 hospitalized patients with hyponatremia below 130 mmol/l due to SIADH to receive either 25 mg of empagliflozin or placebo once daily in addition to standard fluid restriction. The primary endpoint was defined as absolute change in plasma sodium concentration after four days of treatment.

Results

In total, 84 patients completed the trial of whom 40 (48%) received treatment with empagliflozin and 44 (52%) were allocated to placebo. There were no significant between-group differences among main baseline characteristics, showing an elderly study population with a median age of 80 years (IQR 65–84) in the empagliflozin and 78 years (IQR 73–85) in the placebo group. Baseline median plasma sodium concentrations were 126 mmol/l (IQR 122–127) and 126 mmol/l (IQR 123–127), respectively. The most common cause of SIADH was drug-induced. Treatment with empagliflozin resulted in a significantly higher increase of median plasma sodium concentration of 10 mmol/l (IQR 5–13) compared to placebo with 7 mmol/l (IQR 3–11), $P=0.039$. Sodium overcorrection, defined as an increase of more than 12 mmol/l per day, occurred in one patient per group.

Conclusion

In patients with SIADH, empagliflozin in addition to fluid restriction leads to a higher increase in plasma sodium levels compared to placebo and therefore is a promising new treatment option.

Pituitary tumour-derived chemokines modulate immune cell infiltrates in the tumour microenvironment leading to aggressive phenotype

Pedro Marques[1], Sayka Barry[1], Eivind Carlsen[2], David Collier[1], Amy Ronaldson[1], Sherine Awad[1], Nigel Mendoza[3], Neil Dorward[4], Joan Grieve[4], Frances Balkwill[5] & Márta Korbonits[1]

[1]Centre for Endocrinology, William Harvey Research Institute, Barts and the London School of Medicine and Dentistry, Queen Mary University of London, London, UK; [2]Department of Pathology, STHF, Skien, Norway; [3]Department of Neurosurgery, Imperial College Healthcare NHS Trust, London, UK; [4]The National Hospital for Neurology and Neurosurgery, UCLH, NHS Trust, London, UK; [5]Barts Cancer Institute, Queen Mary University of London, London, UK.

Introduction

Tumour microenvironment (TME) is determined by non-tumoral cells, including immune, stromal or endothelial cells, and influences tumorigenesis, proliferation, invasiveness and angiogenesis. Little is known about TME in pituitary adenomas (PAs). We aimed to characterise the TME of PAs and its role in their aggressiveness, focusing on PA-infiltrating immune cells and cytokine network.

Methods

Cytokine secretome from 24 human PAs (16NFPAs, 8GHomas) was assessed on primary culture supernatants using a multiplex immunoassay panel with 42 cytokines. These data were compared to immunohistochemical analysis of the same tumours assessing endothelial cells (CD31), macrophages (CD68), 'M2'-macrophages (CD163), 'M1'-macrophages (HLA-DR), cytotoxic T lymphocytes (CD8), T helper lymphocytes (CD4), T regulatory cells (FOXP3), B cells (CD20) and neutrophils (neutrophil elastase), and 5 normal pituitaries were studied for comparison.

Results

The cytokine array identified IL-8, CCL2, CCL3, CCL4, CXCL10, CCL22 and CXCL1 as the main PA-derived cytokines. PAs with increased macrophage and neutrophil content had higher IL-8, CCL2, CCL3, CCL4 and CXCL1 levels, while CD8+T lymphocyte PA-infiltration was associated with higher CCL2, CCL4 and VEGF-A levels. No significant associations between PA-derived cytokines and CD4+T, FOXP3+ and B cells were noted. PA immune cell infiltrates differ from normal pituitary: PAs contained more CD68-macrophages (4.6 ± 0.4 vs $1.2\pm0.2\%$, $P<0.001$), with a 3-fold increased M2:M1 macrophage ratio, more CD4+T cells (1.0 ± 0.1 vs $0.6\pm0.1\%$, $P=0.005$), but fewer neutrophils (0.7 ± 0.2 vs $1.4\pm0.1\%$, $P=0.047$) and a trend for fewer CD8+T cells (1.8 ± 0.2 vs $2.6\pm0.3\%$, $P=0.077$) with a 2-fold decreased CD8:CD4 T cell ratio. NFPAs had significantly more neutrophils than GHomas (0.9 ± 0.1 vs $0.1\pm0.1\%$, $P=0.002$), but there were no differences regarding other immune cell subpopulations. PA-infiltrating immune cells did not correlate with the respective serum immune cell subpopulations, suggesting differential recruitment into the PA rather than altered bone marrow production. PAs with higher Ki67 had a higher amount of FOXP3+T cells, as well as lower CD68:FOXP3, CD8:CD4 and CD8:FOXP3 cell ratios. All PAs with deleterious immune infiltrate phenotype ($CD68^{hi}CD4^{hi}FOXP3^{hi}CD20^{hi}$) had $Ki67\geq3\%$. M2:M1 ratio was positively correlated with microvessel density ($P=0.015$) and area ($P<0.001$).

Conclusions

PAs are primarily infiltrated by macrophages with an increased M2:M1 ratio compared with normal pituitary, but also have reduced CD8:CD4 and CD8:FOXP3 T cell ratios. PA-derived chemokines (IL-8, CCL2, CCL3, CCL4 and CXCL1) facilitate macrophage, neutrophil and T cell recruitment into the tumour, and our data suggest that this modulation of immune cell infiltrates in the TME determines increased aggressiveness.

DOI: 10.1530/endoabs.63.OC13.3

OC13.4

Pharmacokinetics of somapacitan in individuals with hepatic impairment: an open-label, parallel group, phase 1 study

Birgitte Bentz Damholt, Mette Dahl Bendtsen, Christian Hollensen & Michael Højby Rasmussen

Novo Nordisk A/S, Søborg, Denmark.

Background

Somapacitan is a reversible albumin-binding growth hormone (GH) derivative developed for once-weekly administration. Non-covalent binding to endogenous albumin delays somapacitan elimination, prolonging its half-life and duration of action. Somapacitan is not cleared by a specific organ, but impaired hepatic function may affect its pharmacokinetics. We report data from an open-label, parallel group, phase I trial (NCT03212131) investigating the pharmacokinetic and pharmacodynamic properties, and safety of somapacitan in individuals with mild and moderate hepatic impairment, and normal hepatic function.

Methods

Participants were enrolled in a 16:9:9 ratio to normal hepatic function, mild hepatic impairment, and moderate hepatic impairment, respectively. Participants received a total of three somapacitan administrations (0.08 mg/kg), one per week for 3 weeks.

Results

Thirty-four participants were included: normal function, $n=16$; mild impairment, $n=9$; moderate impairment, $n=9$. Somapacitan AUC_{0-168h} was higher in the moderate impairment group (estimated ratio [ER]=4.69; 90% confidence

interval [CI]: 2.92–7.52) and similar in the mild impairment group (ER = 1.08; 90% CI: 0.66–1.75), versus the normal function group. C_{max} had a similar pattern to $AUC_{0\text{-}168h}$. Median t_{max} was longer for the moderate impairment group (15.8 hours), versus the mild impairment (11.8 hours) and normal function groups (11.9 hours). $AUC_{0\text{-}168h}$ of IGF-I and IGFBP-3 were similar in the mild and moderate impairment groups, but lower than the normal function group ($AUC_{IGF\text{-}I,0\text{-}168h}$ ER = 0.85 [90% CI: 0.67–1.08] and 0.75 [90% CI: 0.60–0.95], respectively). Lower levels of IGF-I and IGFBP-3 were noted at baseline in both impairment groups compared with the normal function group. Albumin values were within normal range for all but two moderate impairment group participants. No unexpected safety signals were reported.

Conclusions

Despite greater exposure to somapacitan, individuals with hepatic impairment exhibited a decreased IGF-I and IGFBP-3 response. GH resistance associated with hepatic impairment may potentially explain the lower response. The increased exposure may indicate that liver GH receptors are either reduced in number, creating a saturation effect for elimination, or not fully functioning after GH binding, slowing elimination. Since albumin concentrations were mostly within normal range, and somapacitan occupancy of albumin is very low (< 0.0005%), it is highly unlikely that decreased albumin concentrations caused increased exposure. Despite the higher exposure in individuals with moderate hepatic impairment, adequate treatment response may require higher somapacitan doses owing to the reduced IGF-I response. However, as somapacitan is planned to be individually dose-titrated, no specific adjustments to the dosing recommendations are relevant.

DOI: 10.1530/endoabs.63.OC13.4

OC13.5

Pan-genomic classification of pituitary adenomas

Mario Neou[1], Chiara Villa[1,2,3], Roberta Armignacco[1], Anne Jouinot[1,4], Amandine Septier[1], Marie-Laure Raffin-Sanson[5,6], Karine Perlemoine[1], Michèle Bernier[2], Bertrand Baussart[2], Jérôme Bertherat[1,7], Stéphan Gaillard[2] & Guillaume Assié[1,7]

Pituitary adenomas, now called pituitary neuroendocrine tumors (PitNETs), vary in histological type, secretion, invasion and growth speed. A World Health Organization (WHO) histo-prognostic classification was released in 2017. Pituitary tumorigenesis is largely unexplained. Rare germline mutations (*MENIN, AIP*), and common somatic mutations in somatotroph (*GNAS*) and corticotroph (*USP8*) are reported. Recently, genomic analyses have been reported. Yet, driver genes and pathways remain to be fully identified, as well as a comprehensive view of omics in the different subtypes of PitNETs.

Aim

To provide a genomic unbiased classification of PitNETs.

Methods

A clinical, histological and genomic characterization of 134 PitNETs of all subtypes was performed, combining exome, RNA and miRNA sequencing, SNP array and methylation array. Unsupervised classifications were generated (non-negative matrix factorization and hierarchical clustering).

Results

Median somatic mutation rate was 95, mainly C > T substitutions belonging to 'signature 1' trinucleotide signature. No difference was observed between histotypes. Only GNAS and USP8 presented > 5% mutations. Three chromosome alteration profiles were identified: extended losses, 'quiet' profiles, and extended gains. Gonadotroph and silent corticotroph were mainly 'quiet'. Chromosomal alterations were not related to aggressiveness. Epigenomic classifications (miRnome and methylome) were strongly associated with PitNETs histological type and secretion (χ^2 $P < 10–18$). Especially, PitNETs from POU1F1 (Pit1) lineage (lacto-, thyro- and somatotroph) showed diffuse DNA hypomethylation. Hypomethylation was correlated with genomic instability (correlation coefficient: 0.4). Unsupervised transcriptome classification revealed 6 groups, associated with histotype and secretion (χ^2 $P < 10–59$), with four noticeable discrepancies compared to WHO2017 classification: « null-cells » were not distinct from gonadotroph; silent corticotroph PitNETs fell apart from overt Cushing corticotroph PitNETs; 5/8 sparsely granulated somatotroph PitNETs were grouped with thyrotroph and PIT1 plurihormonal PitNETs; lactotroph PitNETs were distinct from mixed GH-PRL and somatotroph PitNETs. USP8 and GNAS mutations formed specific homogeneous subgroups. Silent corticotroph and gonadotroph shared a common gonadotroph signature.

Conclusion

This genomic study unravels important new aspects of PitNETs biology. Mainly:
- DNA hypomethylation and chromosomal instability of PitNETs of the Pit1 lineage, suggesting that Pit1 differentiation may induce chromatin opening, with subsequent genome instability.
- A specific molecular signature of sparsely granulated somatotroph PitNETs, which may help to better understand and predict resistance to somatostatin analogues. - Silent corticotroph PitNETs combine corticotroph and gonadotroph differentiation signatures.

This genomic classification of PitNETs supports the importance of pituitary lineage in pituitary tumorigenesis, and proposes a first robust and unbiased classification based on tumor biology.

Testosterone replacement therapy is able to reduce prostate inflammation in men with BPH, metabolic syndrome and hypogonadism: preliminary results from a randomized placebo-controlled clinical trial

Giulia Rastrelli, Sarah Cipriani, Francesco Lotti, Ilaria Cellai, Paolo Comeglio, Valentina Boddi, Pierandrea Della Camera, Mauro Gacci, Sergio Serni, Mario Maggi & Linda Vignozzi

University of Florence, Florence, Italy.

Objectives

BPH is characterised by prostate inflammation, which frequently occurs in men with metabolic syndrome (MetS). MetS is often associated with low testosterone (T). Recent evidence shows that low, rather than high, T is associated with BPH/lower urinary tract symptoms (LUTS). To evaluate if T replacement therapy (TRT) for 6 months in BPH men with MetS and low T, is able to improve LUTS and prostate inflammation.

Methods

120 men in waiting list for BPH surgery and diagnosed with MetS were enrolled in the trial. According to total T (TT) and calculated free T (cFT), they were categorized into eugonadal (TT ≥ 12 nmol/L and cFT ≥ 225 pmol/L; $n = 48$) and hypogonadal men (TT < 12 nmol/L and/or cFT < 225 pmol/L; $n = 72$). Hypogonadal men randomly received T gel 2% (5 g/daily) or placebo for 6 months. At baseline and follow-up visit (after 6 months), all men filled-out the IPSS and NIH-CSPI questionnaires and underwent a transrectal prostatic ultrasound. After surgery, prostate tissue was collected for the assessment of gene expression, by RT-PCR, and of the histopathologic inflammatory score.

Results

After adjusting for the baseline value, age, TT and waist circumference, NIH-CSPI total score significantly decreased in both the groups ($P < 0.001$ vs. baseline), whereas IPSS total score did not change in any of the groups. IPSS bother score significantly decreased only in T-treated ($P = 0.042$ vs. baseline). Although a significant increase in total prostate and adenoma volume occurred in T-treated (both $P < 0.05$ vs. baseline), TRT arm was characterised by a significant decrease in ultrasound markers of prostate inflammation, including arterial velocity and acceleration (both $P < 0.01$ vs. baseline value). The assessment of the gene expression showed that several markers of inflammation (COX2, MCP1, RORγt and IP10) and metabolic-induced inflammation (LDLoxR, RAGE and IRS1), were significantly down-regulated in T-treated men as compared with placebo arm (all $P < 0.05$) and, in some cases, TRT was even able to decrease the gene expression below the values of eugonadal men (MCP1, IP10 and IL12) (all $P < 0.05$). In a subset of men (23 eugonadal, 8 placebo-treated and 9 TRT), TRT showed a trend towards a lower histopathological inflammatory score as compared with eugonadal and placebo-treated men (analyses ongoing).

Conclusions

Six-month treatment with T gel 2% in hypogonadal men with BPH and MetS is able to improve several clinical, ultrasound and molecular proxies of prostate inflammation. This results into a moderate improvement in symptoms, particularly bother for LUTS.

OC14.2

The effect of testosterone therapy on serum oestradiol levels in transgender men

Justine Defreyne[1], Xavier-Philippe Aers[1], Alessandra Daphne Fisher[2], Thomas Schreiner[3], Martin Den Heijer[4] & Guy T'Sjoen[1]
[1]Ghent University Hospital, Ghent, Belgium; [2]University of Florence, Florence, Italy; [3]Olso University Hospital, Oslo, Norway; [4]VU medical centre, Amsterdam, Netherlands.

Background
Testosterone therapy in transgender men (TM) is aimed at achieving serum testosterone levels in the male reference range. It remains unknown if serum oestradiol levels in TM should be evaluated and/or adjusted. Although reported serum oestradiol levels in TM are variable in the current literature, these values may be affected through two possible mechanisms: serum oestradiol levels may increase through aromatization of exogenous testosterone, while the effects of exogenous testosterone on endogenous oestradiol and gonadotropins remain unknown.
Methods
This prospective cohort study was part of the European Network for the Investigation of Gender Incongruence (ENIGI). Serum levels of sex steroids, gonadotropins and body composition were prospectively assessed in 746 TM during a three-year follow-up period, starting at the initiation of testosterone. BMI, body fat%, sex steroids, gonadotrophines were measured at each visit. Data were analyzed cross-sectionally and prospectively (Δ).
Results
Testosterone therapy resulted in a decrease in oestradiol levels over thirty-six months (−34.2, 95% CI −41.1 – −27.3, $P<0.001$), and this was already apparent after the first three months (−17.13, 95% CI −23.82 – −10.56, $P<0.001$). Serum LH levels did not change over the course of testosterone therapy ($P=1.000$), although serum FSH levels remained stable over the first nine months ($P=0.997$), with an increase between nine and thirty-six months (+12.1, 95% CI 4.3 – 19.9). Mean BMI values increased during the first year (+0.744, 95% CI 0.1 – 1.3, $P=0.024$), returning to values comparable to baseline at 18 months ($P=0.880$), and remaining stable thereafter ($P=0.557$). Mean total body fat percentage decreased over the first two years (−11.6, 95% CI −14.3 – −8.8, $P<0.001$), remaining stable thereafter ($P=0.618$). Δ (serum oestradiol) was positively correlated to Δ (serum LH) ($\rho=0.107$, $P< 0.001$) and negatively to Δ (serum FSH) ($\rho=-0.167$, $P<0.001$) and Δ (BMI) ($\rho=-0.082$, $P<0.001$) over the entire follow-up period. Δ (serum oestradiol) was not correlated to Δ (serum testosterone) ($P=0.973$) nor to Δ (total body fat percentage) ($P=0.688$).
Conclusions
Testosterone administration in TM is associated with a decrease in serum oestradiol levels, already apparent at three months follow-up. The observed decrease could not be explained by changes in serum gonadotropins nor by changes in body composition. It remains to be determined to which extent the observed decrease is due to suppression of endogenous oestradiol production and/or decreased aromatase activity. As serum oestradiol levels decrease in TM, we do not suggest monitoring and/or adjusting oestradiol levels for clinical practice.

DOI: 10.1530/endoabs.63.OC14.2

OC14.3

First identification of bone morphogenic protein receptor variants as a cause of primary ovarian insufficiency

Isabelle Beau[1], Lucie Renault[1], Liliana Patiño[2], Françoise Magnin[1], Brigitte Delemer[3], Paul Laissue[2], Jacques Young[4] & Nadine Binart[1]
[1]Inserm U1185, Le Kremlin-Bicêtre, France; [2]Universidad del Rosario, Bogotá DC, Colombia; [3]CHU de Reims-Hôpital Robert-Debré, Reims, France; [4]Assistance Publique-Hôpitaux de Paris, Hôpital Bicêtre, Service d'Endocrinologie et des Maladies de la Reproduction, Le Kremlin-Bicêtre, France.

Bone morphogenetic proteins (BMPs) exhibit broad spectrum of biological activities in various tissues, including bone, cartilage, blood vessels, heart, kidney, neurons, liver and lung. BMPs are members of the transforming growth factor-β (TGF-β) family that bind to type II and type I serine-threonine kinase receptors, and transduce signals through Smad and non-Smad signalling pathways. BMPs together with other intraovarian growth factors are intimately involved in regulation of ovarian follicle recruitment, dominant follicle selection, ovulation, and atresia. We conducted a Whole Exome Sequencing on 69 Caucasian women with sporadic primary ovarian insufficiency (POI) and performed a bioinformatics analysis on a specific subset of 420 coherent candidate genes[1]. We found heterozygous variants in genes encoding *BMP* Receptors (*BMPR1A* and BMPR1B) in three POI women. POI is a major cause of infertility and is characterized by amenorrhea with an increase in gonadotropin levels and affects 1% of women before the age of 40. This disease may be the result of a variety of disorders caused by two main mechanisms: abnormal follicular development and follicle depletion due to a defect in their formation or an aberrantly rapid depletion of the stock. Although the majority of cases are idiopathic, POI can be triggered by autoimmune disease, infectious agents, iatrogenic effects, or genetic causes. It may also be part of syndromic diseases such as Turner, Fragile-X or Blepharophimosis Ptosis Epicanthus Inversus syndrome. The identified missense variants were located in the kinase domain of both receptors 1A and 1B and predicted to be deleterious *in silico*. We studied the signaling pathway of these receptors, Smad proteins phosphorylation, transcriptional activity and expression of *Id1* and *Smad7* target genes. We showed that these variants impaired the activity of the proteins. Consisting with these results, *Bmpr1a* −/− and *Bmpr1b* −/− mouse models develop infertility due to a reduced spontaneous ovulation and compromised cumulus expansion respectively. Altogether, our study describes the first BMPR1A and 1B mutations associated with isolated POI and increases the number of genes formally implicated as being responsible for this condition.

Thyroid diseases in danish women with polycystic ovary syndrome

Dorte Glintborg[1], Katrine Hass Rubin[2], Mads Nybo[3], Bo Abrahamsen[2,4] & Marianne Skovsager Andersen[1]
[1]Odense University Hospital, Department of Endocrinology, Odense C, Denmark; [2]OPEN - Odense Patient data Explorative Network, Institute of Clinical Research, University of Southern Denmark, Odense C, Denmark; [3]Department of Clinical Biochemistry and Pharmacology, Odense University Hospital, Odense C, Denmark; [4]Department of Internal Medicine, Holbæk Hospital, Holbæk, Denmark.

Background
Polycystic ovary syndrome (PCOS) could be associated with increased risk of thyroid disorders. Possible associations between TSH and cardio-metabolic risk in PCOS are debated.
Methods
National Register-based study on women with PCOS in Denmark. 18,476 women had a diagnosis of PCOS in the Danish National Patient Register. PCOS Odense University Hospital (OUH, $N=1,146$) was an embedded cohort including premenopausal women with PCOS and clinical and biochemical examination. Three age-matched controls were included per patient in PCOS Denmark ($N=54,757$). The main study outcome was thyroid disease (myxedema, struma, Graves disease, thyroiditis) defined according to nationwide in- and outpatient hospital contact diagnosis codes and/or inferred from filled medicine prescriptions. A possible link between baseline TSH and development of cardio-metabolic disease (ICD10 codes and/or medical treatment for diabetes and cardiovascular disease including hypertension) was examined in PCOS OUH.
Results
The age at inclusion was median (quartiles) 29 (23–35) years and follow up was 11.1 (6.9–16.0) years. The Hazard ratio (95% CI) for development of thyroid disease was 2.5 (2.3; 2.7) ($P<0.001$) and the total event rate of thyroid disease was 6.0 per 1,000 patient years in PCOS Denmark vs. 2.4 per 1,000 patient years in controls ($P<0.001$). Women in PCOS OUH with TSH ≥2.5 mU/L ($n=133$) had higher BMI (median 29 vs. 27 kg/m^2), higher waist, higher triglycerides, and higher free testosterone by the time of PCOS diagnosis compared to women in PCOS OUH with TSH <2.5 mU/L ($n=588$). Baseline TSH did not predict later development of cardio-metabolic diseases in PCOS OUH.
Conclusion
The event rate of thyroid disease was higher in women with PCOS compared to controls. Baseline TSH was associated with PCOS metabolic phenotype, but did not predict development of cardio-metabolic disease.

OC14.5

The pattern of cancer occurrence in Turner syndrome

Mette Viuff[1], Agnethe Berglund[1], Svend Juul[2], Kirstine Stochholm[1] & Claus H Gravholt[1]
[1]Aarhus University Hospital, Aarhus, Denmark; [2]Aarhus University, Aarhus, Denmark.

Background
Studies have shown that the overall risk of cancer is not increased in Turner syndrome (TS). However, the pattern of cancer occurrence may be different than in the background population.
Aim
To describe the cancer morbidity pattern in TS.
Design
Nationwide epidemiological study using Danish registries on morbidity.
Methods
1,156 Females with TS diagnosed during 1960–2014 were identified using The Danish Cytogenetic Central Registry. Subsequently they were linked with personal-level data from the Danish National Patient Registry. Statistics Denmark randomly identified 115,578 controls matched on sex and age. Stratified Cox regression were used to analyze cancer morbidity, computing proportional hazard ratios (HR).
Results
The overall risk of cancer was not elevated with a HR of 1.04 (Table 1). We observed an increased risk of skin cancer, but not melanoma. In addition, we also observed an increased risk benign skin neoplasms. We also observed a decreased risk of breast cancer, while all remaining cancer types occurred with a frequency equal to that observed in the background population.
Conclusion
In this large cohort of females with TS, we confirm that cancer is not seen more frequently, but that the pattern of cancer occurrence is different from what is observed in the general population. The risk of breast cancer is lower than in the general population. Whether this is due to insufficient treatment with female sex hormone replacement therapy or specific characteristics of females with TS remains to be determined.

Table 1

	All karyotypes		
Neoplasm	Cases n (%)	Controls n (%)	HR (95%CI)
All cancers	67	7,876	1.04 (0.80–1.36)
All benign neoplasms	164	16,318	1.09 (0.91–1.30)
Lip, oral cavity and pharynx cancer	3	168	1.69 (0.42–6.84)
Cancer of the digestive tract	13	1,163	1.58 (0.89–2.80)
Cancer of respiratory organs	4	849	0.63 (0.24–1.70)
Bone cancer	0	22	NA

^{68}Ga-exendin-4 PET/CT detects insulinomas in patients with hypoglycemia in multiple endocrine neoplasia type 1

Kwadwo Antwi[1], Guillaume Nicolas[1], Melpomeni Fanis[1], Tobias Heye[1], Francois Pattou[2], Ashley Grossman[3], Philippe Chanson[4], Jean Claude Reubi[5], Aurel Perren[5], Beat Gloor[6], Deborah Vogt[1], Damian Wild[1] & Emanuel Christ[1]
[1]University Hospital Basel, Basel, Switzerland; [2]Lille University Hospital, Lille, France; [3]Royal Free Hospital, London, London, UK; [4]Hôpital Bicêtre, Paris, France; [5]Department of Pathology, University of Bern, Bern, Switzerland; [6]Department of Visceral Surgery, University Hospital, Bern, Switzerland.

Context
Surgical intervention is advised in patients with multiple endocrine neoplasia type-1 (MEN-1) with non-functioning pancreatic neuroendocrine tumors (PanNET) and a size $\geq$20 mm. However, functioning PanNET such as patients with endogenous hyperinsulinemic hypoglycemia (EHH) due to (one or multiple) insulinomas should be treated surgically independent of size. Reliable preoperative localization of insulinomas is critical for surgical strategy.
Objective
To evaluate feasibility and sensitivity of ^{68}Ga-exendin-4 PET/CT in the detection of relevant lesions in *MEN-1* patients with EHH in comparison with magnet resonance imaging (MRI).
Design
Post-hoc subgroup-analysis of a larger prospective imaging study with 52 EHH patients.
Patients
Six of 52 consecutive patients with EHH and genetically proven *MEN-1* mutation were included.
Interventions
All patients received one ^{68}Ga-exendin-4 PET/CT and one MRI scan within 3-4 days. Thereafter, surgery was performed based on all imaging results.
Main Outcome Measures
Lesion-based sensitivity of PET/CT and MRI were calculated. Readers were unaware of other results when reading the scans. Reference standard was surgery with histology and treatment outcome. True positive was defined as PanNET $\geq$20 mm or insulinoma (=relevant lesions).
Results
In six patients, 37 PanNET were confirmed by histopathology. Sensitivity (95% confidence interval) for combined PET/CT + MRI, MRI and PET/CT was 92.3% (64%–99.8%), 38.5% (13.9–68.4%) and 84.6% (54.6–98.1%), respectively (*P*-value = 0.014 for the comparison of PET/CT + MRI versus MRI). After surgery, EHH resolved in all patients.
Conclusion
^{68}Ga-exendin-4 PET/CT is feasible in *MEN-1* patients with EHH. The combination with MRI is superior to MRI alone in the detection of insulinomas and may guide the surgical strategy.

DOI: 10.1530/endoabs.63.GP1

GP2

Lanreotide therapy vs wait-and-see in patients with pancreatic neuroendocrine tumors

Antongiulio Faggiano[1], Roberta Modica[2], Fabio Lo Calzo[2], Luigi Camera[3], Vincenzo Napolitano[4], Barbara Altieri[2], Federica De Cicco[2], Filomena Bottiglieri[2], Franz Sesti[1], Andrea M. Isidori[1] & Annamaria Colao[2]
[1]Department of Experimental Medicine, Sapienza University of Rome, Rome, Italy; [2]Department of Clinical Medicine and Surgery, University of Naples Federico II, Naples, Italy; [3]Department of Advanced Biomedical Sciences, Radiology, Section of Diagnostic Imaging, Federico II University of Naples, Naples, Italy; [4]Endoscopic Surgery, Università degli Studi della Campania Luigi Vanvitelli, Naples, Italy.

Background & Aim
Pancreatic neuroendocrine tumors (pNETs) are detected in >80% of MEN1 patients. MEN1 pNETs are well differentiated G1-G2 NETs. They are usually not surged unless a size >1–2 cm or a growth rate >0.5 cm per year. Somatostatin analogues represent one of the main therapeutic option in patients affected with G1-G2 NETs. However, neither somatostatin analogues nor other therapies have been prospectively evaluated in clinical trials specifically focusing on MEN1-related pNETs. The aim of this study was to prospectively evaluate the effectiveness of lanreotide in patients with MEN1-related pNETs <2 cm.
Patients & Methods
From 1 January 2012 to 30 December 2018, all MEN1 patients admitted to the Federico II NET Unit of Naples who were diagnosed with one or more pNETs <2 cm of maximal diameter, were considered for this study. Study design was prospective observational, with comparison of patients treated with lanreotide autogel 120 mg every 28 days (LAN group) and patients not receiving any therapy (Follow-up group). All PNETs $\geq$10 mm by CT scan or MRI were taken in account as target lesions. Median PFS was evaluated according to Recist 1.1 criteria. All patients were radiologically evaluated every 6 months. A written informed consent was signed from all participants. The study was approved by the local Ethic Committee.
Results
Forty-two patients (19 M and 23 F, mean age 42.7 years, range 20–65 years) were enrolled. LAN group included 23 patients and Follow-up group included 19 patients. Median follow-up was 66.5 months. As a whole, 49 pNETs $\geq$10 mm were identified. In the LAN group, 19 patients had stable disease at the last follow-up, while 4 had tumor progression (size increase in three and increased number of lesions in one). In the Follow-up group, 13 patients had pNET progression (size increase in ten, increased number of lesions in three, both in two), while 6 were stable. The median PFS was significantly longer in LAN group than in Follow-up group (median not reached vs 40 months, $P<0.001$).
Conclusions
This is the first prospective study evaluating the efficacy of somatostatin analogues in MEN1 patients with pNETs. These findings highlight that lanreotide autogel is effective as anti-proliferative therapy in MEN1-related pNETs <2 cm, suggesting the use of these compounds to arrest the development of tumor lesions as well as to delay or avoid pancreatic surgery.

DOI: 10.1530/endoabs.63.GP2

GP3

ProGRP is an effective marker for disease monitoring in lung carcinoids with non-informative chromogranin A: Lessons from clinical practice

Kira Oleinikov[1], Simona Grozinsky-Glasberg[1], David J Gross[1], Hovav Nechushtan[2], Tamar Peretz[2], Ophra Maimon[2] & Beni Nisman[2]
[1]Neuroendocrine Tumor Unit, Hadassah-Hebrew University Medical Center Endocrinology & Metabolism Department, Jerusalem, Israel; [2]Department of Oncology, Hadassah-Hebrew University Medical Center, Jerusalem, Israel.

Introduction
The histologic classification of lung carcinoids (LCs) as typical (TCs) and atypical (ACs) highlights its role as major prognostic factor for these patients. However, in the absence of sensitive biomarkers to effectively predict tumor behavior, long-term imaging surveillance is recommended for disease monitoring. Limited data suggest that progastrin-releasing peptide (ProGRP) may have diagnostic & monitoring utility in LCs.
Aim(s)
To evaluate the possible role of ProGRP, in addition to chromogranin A (CgA), as a biomarker for LCs surveillance.
Materials and methods
Retrospective analysis of consecutive LCs patients treated in an ENETS Center of Excellence with regard to clinico-pathological parameters, treatment outcomes and their correlation with ProGRP and CgA.
Results
Thrity-five patients (pts) were studied (23 women; median age of 62y with a median follow up of 47 m). TCs and ACs were diagnosed in 43 and 57% of pts, respectively. 9 pts (26%) were defined as DIPNECH. The disease was localized in 31% & metastatic in 69% of cases. 71% of pts were already pretreated at the time of the first ProGRP evaluation. Disease status at first ProGRP measurement was: no evidence of disease (NED, 20%), stable disease (SD, 23%), progressive disease (PD, 57%). The NED group had normal ProGRP & CgA. In the SD group, ProGRP was increased in 62% vs 38% increase in CgA, while in the PD group 70% had increased ProGRP vs 35% with elevated CgA. Overall, ProGRP was increased in 50% of pts with evidence of disease, all with normal CgA.
Conclusion
ProGRP seems to be a valuable biomarker for monitoring patients with LCs, mainly when CgA is non-informative. Larger series including prospective long-term follow-up are needed to establish ProGRP's specific role in monitoring disease activity in LCs pts.
Keywords: progrp, lung carcinoids, biomarkers.

Two cases of pseudopheochromocytoma due to Obstructive sleep apnea: which mechanisms?

Héla Marmouch, Haythem Jenzri, Houssem Mrabet, Hamza Fekih & Ines Khochtali
Internal Medicine-Endocrinology Department-University Hospital-Monastir-TUNISIA, Monastir, Tunisia.

Introduction
The obstructive sleep apnea syndrome (OSAS) has a well-documented association with increase cardiovascular morbidity and mortality. The patients with OSAS have a high prevalence of hypertension and the OSAS may present similar to a pseudo-pheochromocytoma (PPH). We report two cases with PPH caused by OSAS; a common medical condition which is less recognized as a cause of raised catecholamines.
Observations
Case 1: 54 year-old man had a history of recent poorly controlled hypertension and obesity. He had a history of fatigue and drowsiness. Laboratory evaluation was elevated 24-h urinary catecholamine levels (UC) (3.2 times the upper normal levels).
Case 2: 52 year-old woman with a history of poorly controlled resistant hypertension was admitted to our hospital with severe hypertension. She had a history of fatigue and intermittent episodes of palpitations. Laboratory evaluation was significant for elevated UC (3.5 times the upper normal levels).
These patients were previously healthy without any medication and denied any alcohol or illicit drug abuse. Other causes of secondary hypertension such as primary hyperaldosteronism, hyperthyroidism, hypercorticism, and endocrine neoplasms were excluded by hormonal explorations. Computed Tomography-scan showed kidneys with normal size, good cortical index, and normal vessels. In addition, MIBG scintigraphy did not detected any catecholamine-producing tumor. The OSAS was established. Following 4 weeks of overnight continuous positive airway pressure (CPAP) therapy, blood pressure were at 130/80 mm of Hg. Three months later, UC were normalized and symptoms were gone.
Discussion
Twenty-four-hour UC were initially found to be increased in patients with untreated OSAS compared with those with narcolepsy. Evidence is accumulating to suggest a role for sympathetic overactivity in the pathophysiology of these observations. OSAS, however, is not the only cause of PPH as they could be showed in other causes, notably physiological stress, antipsychotic drugs, anti-parkinson drugs, etc. None of these conditions were found in our patients. Mechanisms by which chemoreflex dysfunction may contribute to chronically elevated sympathetic tone and hypertension are discussed.
Conclusion
Finally this cases represent two patients with untreated OSAS and difficult to control HTA, with clinical and biochemical evidence of increased sympathetic activity mimicking a pheochromocytoma. Nasal CPAP therapy allows improvement of hypertension with catecholamine hypersecretion and distinction of this condition from pheochromocytoma. We suggest that a diagnosis of OSAS should be considered in patients with clinical and biochemical evidence of catecholamine excess in whom a catecholamine producing tumor cannot be identified.

Pheochromocytomas and paragangliomas (PPGL) are rare neuroendocrine tumors derived from chromaffin cells of the adrenal medulla and paraganglia of the autonomic nervous system, respectively. Despite a common origin, these tumors are quite heterogeneous in terms of driver mutations, copy number alterations and activated downstream-signaling pathways. Genome wide expression analysis has identified at least three main tumor clusters: a pseudo-hypoxic cluster, one with activation of wnt-signaling and one with enhanced kinase-signaling. Further subgrouping has been suggested according to molecular, clinical and pathological phenotypes. Tumors in the pseudo-hypoxic Cluster 1 present a marked increase in cell proliferation and activation of angiogenesis pathways. Several genes predispose to Cluster 1 tumors, including *VHL*, *EPAS1, FH* and *SDHx*, but for some patients the underlying genetic mutation could not be identified. Surprisingly, targeting these genes in mice did not lead to the development of PPGLs. Our unique MENX rat model, carries a germline mutation in *Cdkn1b*, coding for a highly unstable variant of the cell cycle inhibitor p27. MENX rats develop bilateral pheochromocytomas with 100% penetrance: at 8–10 months of age the homozygous mutant; >15 months the heterozygotes. Following genome-wide transcriptomic analyses and candidate gene profiling we observed that the rat tumors display expression signatures characteristic of Cluster 1 human pheochromocytomas. These include increased expression of angiogenesis markers like *VEGF* and *ANGPT2* and pseudohypoxic markers as *HIF2a*. Moreover, lack of PNMT expression and catecholamine secretion in these rats are also in line with a pseudo-hypoxic phenotype. We therefore hypothesize that in MENX rats defective p27 function predisposes to the development of pheochromocytomas resembling human Cluster 1 tumors. Thus, these rats might lead to new insights into the pathomechanism of Cluster 1 tumor formation. Moreover, they offer a unique opportunity to preclinically evaluate drugs for efficacy against this specific subset of PPGLs.

Introduction
The capability of cancer to accommodate to special metabolic circumstances is a hallmark of it's existence. Pheochromocytoma/paragangliomas (Pheo/PGL) are rare neuroendocrine tumors with strong and specific metabolic phenotype due to mutations of genes encoding succinate dehydrogenase (SDH) subunits. In this study our aim was to evaluate the expression of glutaminase-1 in hereditary Pheo/PGL tissues and to inhibit SDH activity via pharmacological treatments and gene silencing in order to identify an *in vitro* model useful for the evaluation of metabolic consequences of SDH inhibition.
Materials and methods
Immunohistochemistry was performed on 15 Pheo/PGL tumor tissue blocks obtained from 9 patients with hereditary Pheo/PGL. *SDHB* silencing was carried out using siRNA on PC12 cells. Itaconic acid (Ita) and atpenin A5 (AA5) were used as pharmacological inhibitors of SDH enzyme on PC12, HeLa and H295R cells. Metabolite profiles were assessed with liquid chromatography-mass spectrometry (LC-MS), data were normalized to DNA concentrations. Cellular viability was assessed with alamarBlue.
Results
The expression of glutaminase-1 (GLS-1) by immunohistochemistry positively correlated with malignancy in Pheo/PGL tumors. All SDH inhibiting treatments significantly increased the succinate/fumarate ratio in all cell lines compared to control. *SDHB* siRNA transfection significantly increased the cell viability of PC12 cells. Itaconate significantly increased the viability of PC12 cells but significantly decreased HeLa and H295R cells' viability. Atpenin significantly decreased viability of H295R cells, and significantly increased HeLa cell line's viability, while no effect in PC12 cells was observed. SDH inhibition had significant effects on the metabolite profiles, depending on the inhibition method and cell type. In PC12 cells glutamate levels showed significant decrease without lactate accumulation after Ita or *SDHB* siRNA treatments. siRNA inhibition resulted in decreased malate and aspartate levels. HeLa and H295R cells showed significantly higher lactate and glutamate and decreased aspartate concentrations upon Ita treatment, while malate concentrations only increased in HeLa cells. AA5 treatment didn't yield cell specific results: all cell lines exhibited significantly increased lactate and decreased glutamate, malate and aspartate levels compared to controls.
Conclusion
Increased GLS-1 expression in malignant samples points to the importance of glutamine/glutamate metabolism in Pheo/PGL. Ita treatment of PC12 cells mimics the phenotype observed in *SDHB* mutated Pheo/PGL tissues. Dissecting

SDH inhibition (Ita) from electron-transport chain blockage (AA5) caused cell type specific effects. Targeting glutamine metabolism might yield a novel therapeutic target for malignant Pheo/PGL.

Parafibromin is regulated by ubiquitin specific protease 37 (USP37) and the c-terminus of USP37 interacts with the beta-catenin binding region of *CDC73* in hyperparathyroidism-jaw tumor syndrome

Su Yeon Kim[1], Ji-young Lee[1], Kwan Hoon Jo[1], Eun Yeong Mo[1], Eun Sook Kim[1], Je Ho Han[1] & Kwang-Hyun Baek[2]
[1]Department of Internal Medicine, Incheon St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea; [2]Department of Biomedical Science, CHA University, Pocheon, Republic of Korea.

CDC73 *(also known as HRPT2*) encodes parafibromin and is known to be the causative gene of hyperparathyroidism-jaw tumor (HPT-JT) syndrome. There is no known ubiquitination of parafibromin, and the deubiquitinating enzyme (DUB) for parafibromin has not been identified to date. Full-length DUB cDNAs encoding 58 family members of ubiquitin specific proteases (USPs) were subcloned. The DUB cDNA was used to identify parafibromin interacting by yeast two-hybrid screening. We investigated biochemical interactions between specific DUBs and parafibromin to confirm their binding and to investigate whether specific DUBs deconjugate ubiquitin from parafibromin by GST pull-down and immunoprecipitation analysis, respectively. And we examined the binding region of USP37 and parafibromin, and vice versa. Parafibromin was polyubiquitinated, especially in mutant forms. In yeast two-hybrid assays, USP37 was found to be a DUB interacting with parafibromin. GST pull-down analysis confirmed that parafibromin binds to USP37. We have shown that parafibromin can bind directly to USP37 and have demonstrated that USP37 specifically controls K48-linked polyubiquitination and stabilizes parafibromin. To determine the correct binding site, full length and deletion constructs were generated for both USP37 and *CDC73*. Simultaneous immunoprecipitation analysis betweenthe USP37 full length and *CDC73* deletion constructs and the *CDC73* full length and USP deletion constructs was performed. The analysis revealed that the c-terminus of USP37 interacted with the beta-catenin binding region of *CDC73*. Our results suggest that USP37 is a novel regulator of parafibromin stability in HPT-JT syndrome.

Pheochromocytoma: Positive predictive values of mildly-elevated urinary fractionated metanephrines in a large cohort of community-dwelling patients

Dania Hirsch[1,2,3], Alon Grossman[2,3,4], Varda Nadler[5], Sandra Alboim[5] & Gloria Tsvetov[1,2,3]
[1]Endocrine Institute, Rabin Medical Center, Petah-Tikva, Israel; [2]Maccabi Health Care Services, Tel Aviv, Israel; [3]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel; [4]Department of Internal Medicine B, Rabin Medical Center, Petah-Tikva, Israel; [5]Maccabi Health Care Services-Central Laboratory, Rehovot, Israel.

Introduction
The importance of highly sensitive screening tests for pheochromocytoma/paragnaglioma (PPGL) is clear. However, a low level of specificity may lead to unnecessary biochemical and imaging investigations and even to needless surgical procedures. Therefore, in patients with elevated values of metanephrines, it is essential to establish a rational threshold for performing prompt thorough diagnostic investigations rather than opting for active surveillance.
Objective
This study sought to investigate the positive predictive value (PPV) of different thresholds of elevated urinary fractionated metanephrines (UFM) and to analyze current features of PPGL in a large cohort of community-dwelling patients.
Methods
The study was conducted at a large publicly-funded health maintenance organization (HMO) in Israel insuring approximately two million residents. We reviewed the computerized files of all patients who performed UFM tests in 2012–2017 and their levels of metanephrines and/or normetanephrines were $\geq$1.5x the upper normal limit (UNL). Clinical, biochemical and imaging data were retrospectively analyzed.
Results
Of the 10164 subjects referred to UFM testing, levels of $>$1.5xUNL and $\geq$2xUNL were found in 264 (2.6%) and 143 (1.4%), respectively. Sixty patients were subsequently diagnosed with PPGL (mean age 51.8$\pm$14.3, 65% females). Of these, 59 (98.3%) had UFM $\geq 2\times$UNL, yielding a positive predictive value (PPV) of 41.3% (59/143) for this threshold. A diagnosis of PPGL was established in only one out of 121 individuals with UFM level of 1.5–2$\times$UNL (PPV$=$0.8%), in 7 out of 45 individuals with UFM level of 2–2.5$\times$UNL (PPV$=$15.6%), and in 7 of 28 with UFM of 2.5–3$\times$UNL (PPV$=$25%). The main reason for UFM screening, in 51.7% (31/60) of PPGL patients, was adrenal incidentaloma. Median metanephrines/normetanephrines levels were 2.9xUNL and 2.5$\times$UNL, respectively (mean: 6.6$\pm$9$\times$UNL and 6.1$\pm$8.9$\times$UNL, respectively). Extra-adrenal tumor was detected in 6 patients (10%); bilateral masses and malignant PPGL in one patient, each. The classical triad of pheochromocytoma (headaches, sweating, tachycardia) was present in only one patient and 34 (56.7%) had none of these symptoms.
Conclusions
Most PPGL patients are currently diagnosed due to the detection of an adrenal incidentaloma. While in patients with UFM $\geq\times$2UNL the PPV for PGGL justifies a thorough diagnostic assessment, in patients with milder elevations the probability of PPGL diagnosis is very low.

Introduction
IGF-1 overexpression has been associated with tumorigenesis. IGF-1Ea, IGF-1Eb and IGF-1Ec isoforms were shown to be regulated differently in cancer. IGF-1Ec and IGF-1Eb overexpression has been positively associated with cell survival and proliferation in various tumors. Elevated IGF1Eb/IGF-1Ea ratio has been suggested as a biomarker of cervical cancer prognosis. Herein, we aimed to examine the expression of IGF-1 isoforms in human adrenocortical carcinomas (ACCs), adrenocortical adenomas (ACAs), pheochromocytomas (Pheo) and compare to normal adrenal gland (NAG). Additionally, we investigated the role of IGF1-Ec and IGF1-Eb peptides in proliferation and migration of adrenal cortex carcinoma cell lines elucidating the underlying mechanism.
Methods
mRNA levels of the isoforms were evaluated by qPCR in fresh frozen tissues (ACA$=$8, ACC$=$6, Pheo$=$11). Immunohistochemical (IHC) analysis (ACA$=$15, ACC$=$13, Pheo$=$8, NAG$=$5) was performed using IGF-1Ec, IGF-1Eb and IGF-1Ea antibodies. SW$-$13 and H295R adrenal cortex carcinoma cells were

incubated with IGF-1Ec and IGF-1Eb peptides at various concentrations alone or in combination with ERK inhibitor. XTT cell proliferation assay and scratching assay were also performed.
Results
IGF-1Ec, IGF-1Eb, IGF-1Ea mRNA levels were increased in adrenal cortex neoplasms (ACC + ACA) compared to medulla (Pheo). Additionally, the mRNA levels of IGF-1Ec and IGF-1Eb were significantly higher in ACCs as compared to ACAs. These findings were confirmed at protein level, since 100% of ACCs (IRS = 6.62) and 73.3% of ACAs (IRS = 3.6) expressed IGF-1Ec, 67% of ACCs (IRS = 5.57) and 25% of ACAs (IRS = 1.25) expressed IGF-1Eb and 58% of ACCs (IRS = 4.5) and 66% of ACAs (IRS = 3.1) expressed IGF-1Ea. More importantly, protein expression of IGF-1Eb (IRS = 6.4) was higher while IGF-Ec expression was attenuated in NAG (IRS = 4.42) compared to ACCs. Interestingly, no expression of any isoform was detected in the Pheo group. A borderline negative correlation between IGF-1Eb ($P = 0.03$) levels as well as IGF-1Eb/IGF-1Ea ratio and Ki-67 ($P = 0.07$) was observed in ACC group. Incubation of SW-13 and H295R cells with IGF-1Ec resulted in significantly increased cell proliferation and migration compared to untreated cells, while ERK inhibitor attenuated this effect, indicating the involvement of ERK1/2 pathway.
Conclusion
Higher expression of IGF-1Ec and IGF-1Eb is linked to increased malignant potential of adrenal neoplasms. IGF-1Ec may play a causative role in ACC tumorigenesis acting -at least in part- through activation of ERK1/2 pathway, while higher expression of IGF-Eb may have a protective effect. Further studies are warranted in order to address the possible prognostic role and/or the use of IGf-1Ec and IGF-1Eb as therapeutic targets.

Brown fat proliferation- A rare complication of Phaeochromocytoma

Sing Yang Sim, Najaf Haider, Darryl Meeking & David Flowers
Portsmouth Hospital NHS Trust, Portsmouth, UK.

Phaeochromocytoma is a catecholamine producing tumour arising from the adrenomedullary chromaffin cells. It produces hormones such as epinephrine, norepinephrine, catecholamine and dopamine. (1) There have been some case reports describing an association between Brown adipose tissue (BAT) accumulation due to catecholamine excess caused by a phaeochromocytoma. We present a similar case in this abstract. A 77 year old lady was referred to the community geriatricians with symptoms of profuse sweating, difficulty walking, increase in abdominal girth, weight loss of 4–5 stones over the previous 4 months, abdominal pain, poor appetite and insomnia. Past medical history included bronchiectasis, Type 2 Diabetes, previous neck of humerus fracture, and pulmonary embolism. A CT chest, abdomen and pelvis showed an ill-defined heterogenous right peri-renal/retroperitoneal mass of fat and soft tissue density, and a 3.2 cm left adrenal enhancing mass. Urine normetadrenaline was raised at 11.21 umol/24hours (Normal Range <3). She was discussed in Urology and adrenal MDTs who felt there was a high likelihood of abdominal malignancy. Subsequently, a core biopsy of the right retroperitoneal mass was carried out to further classify it. She was treated with an alpha-blocker and this dramatically improved her symptoms but the abdominal discomfort remained. She then underwent an ultrasound guided biopsy of this mass. Histology showed adipocytes with multi-vacuolated cytoplasm and central nuclei consistent with brown fat. She subsequently underwent an elective laparoscopic adrenalectomy. A left adrenal mass was localised and removed. Histology of this lesion confirmed a phaeochromocytoma with positive immunohistochemical staining for CD56, chromogranin and synaptophysin with a maximum PASS score of 2. She made an unremarkable recovery post operatively. Her catecholamine levels and her blood pressure normalised post-surgery. A subsequent CT done eight week post-operatively showed a dramatic generalised reduction in the bulk, vascularity and density of the retroperitoneal brown fat with no local recurrence. The patient has reported a dramatic improvement in both her generalised and abdominal symptoms. Her diabetes has also resolved postoperatively. In summary, this case highlights the association between BAT and phaeochromocytoma. It has been hypothesized that catecholamine excess leads to a proliferation of BAT. The presence of clinical symptoms of tachycardia, weight loss, persistent sweats should prompt investigations for an underlying phaeochromocytoma. However, the presence of co-existent abdominal masses on imaging may suggest the possibility of excess BAT accumulation and should not be automatically assumed to be a primary or secondary malignancy.

Corticotropinoma as the underlying cause of intermittent Cushing's syndrome in a patient previously diagnosed with primary pigmented adrenocortical disease (PPNAD) – a case report

Agnieszka Łebek-Szatańska[1], Maria Stelmachowska-Banaś[1], Grzegorz Zieliński[2], Wojciech Zgliczyński[1], Karolina M. Nowak[1], Andrzej Styk[2], Maria Maksymowicz[3], Katarzyna Roszkowska-Purska[4] & Lucyna Papierska[1]
[1]Department of Endocrinology, Centre of Postgraduate Medical Education, Warsaw, Poland; [2]Department of Neurosurgery, Military Institute of Medicine, Warsaw, Poland; [3]Department of Pathology and Laboratory Diagnostics, Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Warsaw, Poland; [4]Department of Pathology, Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Warsaw, Poland.

Background
The diagnostic process to unveil the underlying cause of endogenous Cushing's syndrome (CS) is often challenging. Sometimes, atypical manifestation of the disease or only periodic hypercortisolaemia with spontaneous resolutions are observed and make the diagnosis even more difficult. Although it is common in primary pigmented nodular adrenocortical disease (PPNAD), pituitary corticotroph adenoma can manifest itself as cyclic Cushing's syndrome as well.
Case description
We present the difficulties that came with the patient with previously diagnosed primary pigmented nodular adrenal disease (PPNAD) and conflicting hormonal and radiological findings a few years later. A 33-year-old female with almost 10-year-long history of intermittent Cushing's syndrome and no family history was first admitted for endocrinological evaluation in 2010. As a result, she underwent unilateral adrenalectomy because of an overt, apparently ACTH-independent, Cushing's syndrome with hyperandrogenism and left adrenal hyperplasia. Histological examination revealed the diagnosis of PPNAD. Although being scheduled for right adrenalectomy, she moved on without any additional treatment. Despite repeated search, no other components of Carney's complex had ever been discovered. Since 2015, cushingoid features had been getting more florid. Meanwhile, she gave birth to three healthy children from untreated pregnancies, while single pregnancy ended in miscarriage in 12 Hbd. Finally being able to undergo concluding hormonal evaluation, laboratory and radiological findings were consistent with ACTH-dependent excessive cortisol production this time. Pituitary MRI showed a lesion of <3 mm on the left side of adenohypophysis (suggesting microadenoma) and bilateral inferior petrosal sinus sampling (BIPSS) confirmed this suspicion. The patient underwent effective transsphenoid resection of the tumor and is now eucortisolaemic after one year since the operation. The genetic testing for PRKAR1A mutations was negative and the second histopathological evaluation raised considerable doubts whether the diagnosis of PPNAD was stated correctly.
Conclusions
This case illustrates that careful evaluation of hypercortisolic patients is always crucial before moving on to definite treatment. BIPSS is the procedure of significant value in patients with misleading hormonal tests' results and uncertain source of cortisol. Isolated, non-familiar PPNAD has been very rarely reported. Pituitary lesion as the component of Carney's complex may comprise hormonally active GH/prolactin adenoma or inactive incidentaloma, although single cases of corticotropinoma have also been described. However, genetic testing is helpful to state the diagnosis in many cases.

Functional mixed oncocytic adrenocortical neoplasm presenting as an asymptomatic adrenal mass

Niculina Racolta[1], Sarah Homsi[2], Philippe Keller[3], Felix Lerintiu[4], V Linder[5], Bernard Goichot[6] & Agnès Smagala[1]
[1]Endocrinology and Diabetes Department, Civil Hospital 'Louis Pasteur', Colmar, France; [2]Faculty of Medicine Strasbourg, Strasbourg, France; [3]General Surgery Department, Civil Hospital 'Louis Pasteur', Colmar, France; [4]Pathology Department Civil Hospital 'Louis Pasteur', Colmar, France; [5]Pathology Department 'Hautepierre' University Hospital Strasbourg, Strasbourg, France; [6]Endocrinology Department 'Hautepierre' University Hospital Strasbourg, Strasbourg, France.

Oncocytic adrenocortical neoplasm (OAN) represents a rare variant of adrenocortical carcinoma (ACC) with less than 150 cases reported in the literature. OANs account for 1.8% of adrenal masses, predominantly in adults and usually presenting as large tumors featuring hormonal secretion in 20% of cases. Accurate histological characterization of OANs is crucial as this subtype is believed to be more indolent in clinical behavior. There are 3 categories of OANs: pure oncocytic, mixed oncocytic and ordinary adrenocortical with focal oncocytic changes. The Weiss scoring system used for ACC overestimates malignancy in OANs, therefore alternatives like the Lin-Weiss-Bisceglia (LWB) system need to be used for proper diagnosis and subsequent evaluation of malignant potential. We report the case of a 63-year-old menopaused female with medical history of well controlled type 2 diabetes and hypertension addressed by her GP for exploration of a large adrenal mass neglected by the patient for four years. On interrogation, the patient was completely asymptomatic. Clinical examination revealed a large palpable mass in the left abdomen, normal BMI, no Cushing or virilization syndrome. Hormonal workup showed important elevation of 17OHprogesterone and DHEAS, increased D4Androstendione and total testosterone. The rest of the hormonal workup was in the normal range. Whole body CT scan was consistent with a left heterogeneous adrenal mass of 14×13.6×11 cm, 42HU spontaneous density with calcifications and necrotic areas and no adenopathy or distant metastasis. Open surgery was performed and excised a 15 cm mass weighing 1140 g. Histologic diagnosis was challenging and demanded a second opinion to finally conclude in favor of a mixed OAN with three major criteria and two minor criteria according to the LWB scoring system and a prognosis of malignant evolution. Adjuvant Mitotane treatment was started after discussion in multidisciplinary meeting. Very close clinical, hormonal and imaging follow-up is required for a minimum of 5 years. Although rare entities, OANs should be considered in the differential diagnosis of large adrenal masses. Histological examination by experienced pathologists using the LWB scoring system is of major importance in order to establish the tumor's biologic potential and the patient's prognosis.

KCTD20, a new gene in cortisol-secreting adrenocortical tumors related to inactivating mutations of the Carney Complex gene (PRKAR1A)

Mathilde Brière[1], Bruno Ragazzon[1], Bo Yu[1], Abdelghani Bouchekioua[1], Jérôme Bertherat[1,2] & Marthe Rizk-Rabin[1]

[1]Institut Cochin, U1016 CNRS UMR 8104, Université Paris Descartes, Paris, France; [2]Service d'Endocrinologie, Centre de Référence des Maladies Rares de la Surrénale, Hopital Cochin, Paris, France.

Introduction

Adrenal Cushing due to bilateral multiple adrenal tumors known as Primary Pigmented Nodular Adrenocortical Disease (PPNAD) can be observed in the multiple neoplasia syndrome Carney Complex or as an isolated disease. In both situations germline inactivating mutations of PRKAR1A (regulatory subunit R1A of PKA) can be observed. The loss of *PKA R1A* results in an increased PKA activity. Comparison of the transcriptome of PPNAD and stably transfected H295R adrenal cortical cells with and without inactivation of *PRKAR1A* (H295R/TR/shPRKAR1A) identified a gene whose expression is decreased following the loss of *PRKAR1A* expression: *KCTD20* (potassium channel tetramerization domain containing). This work aims to understand the role of KCTD20 in endocrine hyperactivity and tumor development of PPNADs and Carney Complex.

Methods

H295R, HEK293 cells and PPNAD primary cell culture, were used. The transcriptional regulation of *KCTD20* by PKA R1A (siRNA interference) (RNA, protein) was analysed. The role of *KCTD20* was evaluated through its inactivation by silencing RNA (siKCTD20) and its overexpression (vector-KCTD20) to investigate the effects on PKA R1A alteration concerning cell proliferation/apoptosis (MTT/annexin V, flow cytometer), cell signalling pathways (PKA, AKT, intracellular calcium), and steroidogenesis. KCTD20 intracellular localisation was analysed by immunofluorescence. KCTD20 protein contains a BTB domain. The immunoprecipitation of KCTD20 and mass spectrometry analyses was used to identify the partners of KCTD20 and to precise its role.

Results

In H295R, the decrease in KCTD20 expression after *PRKAR1A* invalidation is independent of PKA activity. Overexpression of KCTD20 increases apoptosis and decreases cell proliferation. Invalidation of *KCTD20* protects against apoptosis ($P<0.01$), increases the activity of the Star-Luc reporter ($P<0.001$), the expression of *Star* ($P=0.01$) and *CYP11B1* genes ($P=0.05$), and cortisol production in H295R cells ($P<0.05$). These effects seem independent of PKA activity. Invalidation of *KCTD20* results in membrane depolarization in response to KCL and increases intracellular calcium ($P<0.001$). Flag-KCTD20 exhibited a cytosolic and spot-like distribution in transiently transfected H295R and Hela cells. Culline 3 was identified as a potential partner of KCTD20. In PPNAD from patients with *PRKAR1A* mutations in primary cell culture, the overexpression of KCTD20 decreases the *CYP11B1* gene (RT/PCR).

Conclusion

PKA R1A acts on KCTD20 via a PKA independent pathway. KCTD20 may play a role in adrenal Cushing by mechanisms independent of PKA activity.

Endoscopic ultrasound guided radiofrequency ablation (EUS-RFA) as a novel therapeutic approach in highly-selected pancreatic functioning and non-functioning neuroendocrine neoplasms (pNENs) patients: Preliminary report

Kira Oleinikov[1], Allain Dancour[2], Julia Epshtein[3], Ariel Benson[3], Haggi Mazeh[4], Ilanit Tal[1], Dan Livovsky[2], Eran Goldin[2], David J Gross[1], Harold Jacob[3] & Simona Grozinsky-Glasberg[1]

[1]Hadassah-Hebrew University Medical Center, Endocrinology & Metabolism Department, Neuroendocrine Tumor Unit, Jerusalem, Israel; [2]Shaare Zedek Medical Center, Department of Gastroenterology, Jerusalem, Israel; [3]Hadassah-Hebrew University Medical Center, Department of Gastroenterology, Jerusalem, Israel; [4]Hadassah-Hebrew University Medical Center, Department of Surgery, Jerusalem, Israel.

Introduction

EUS-RFA is rapidly emerging as a possible treatment alternative for patients with pNENs who are poor surgical candidates.

Aim(s)

To summarize our experience in terms of feasibility, safety and efficacy of EUS-RFA in a cohort of patients with functional and non-functional pNENs.

Materials and methods

Retrospective case series of pNENs patients treated with EUS-RFA at two tertiary referral centers in Israel between March 2017 and October 2018.

Results

Eighteen consecutive pNENs patients that underwent EUS-RFA have been included (11 males, median age of 62.5 (range 28 – 82)). A total of 27 lesions with a median size of 13 mm (range 4.5–29) were treated. The location of the target lesion was: head ($n=10$), body ($n=8$), uncinate process ($n=5$) and tail ($n=2$); in two patients, synchronous liver and lymph node metastasis underwent RFA. Functionally, the tumors were non-functional pNENs and insulinomas in 11 and 7 patients respectively. All tumors were well-differentiated based on Ki-67. Technical success, defined as post RFA changes in tumor vascularity and/or tumor necrosis on surveillance imaging was reported in 26/27 lesions. Normalization of glucose levels was observed in all (7/7) insulinomas within 24 h. There were no major complications 48 h post-RFA. Two patients developed mild pancreatitis post-RFA that resolved within 72 hours. No recurrences were observed during a median follow up of 6 months (range 1–20 m).

Conclusion

EUS-RFA for highly selected pNENs patients who cannot or do not want to undergo surgical resection appears to be safe and feasible. Prospective studies comparing RFA with surgical excision, including larger cohorts of patients and longer follow-up periods, are warranted to establish the role of EUS-RFA in the treatment algorithm for pNENs.

Background
RACE is an open-label study that assessed the long-term safety and efficacy of recombinant human parathyroid hormone 1–84 (rhPTH[1–84]) for the treatment of hypoparathyroidism in adults (ClinicalTrials.gov identifier NCT01297309). Here, we present 6-year safety and efficacy data.
Methods
Patients initially received 25 or 50 μg of rhPTH(1–84) subcutaneously, once daily, with stepwise dose adjustments of 25 μg (up or down) to a maximum of 100 μg/day. rhPTH(1–84) could be titrated and oral calcium (Ca) and calcitriol doses adjusted at any time during the study to maintain albumin-corrected serum Ca levels in the target range (2.0–2.25 mmol/L). A composite efficacy endpoint was the proportion of patients who achieved at least a 50% reduction from baseline (BL) in oral Ca dose (or Ca $\leq$500 mg/day) and at least a 50% reduction from BL in calcitriol dose (or calcitriol $\leq$0.25 μg/day), while normalising or maintaining albumin-corrected serum Ca compared with BL value and not exceeding the upper limit of normal for the central laboratory. Data are summarised with descriptive statistics (mean $\pm$ SD).
Results
The study cohort consisted of 49 patients enrolled at 12 US centres (mean age, 48.1 $\pm$ 9.78 years; 81.6% female); data from 34 patients (69.4%) who completed 72 months (M72) of treatment with rhPTH(1–84) as of July 17, 2018, are presented here. Oral Ca and calcitriol doses were reduced by 40.4% and 72.2% at M72, respectively, and albumin-corrected serum Ca levels were maintained within the target range (BL, 2.1 $\pm$ 0.17 mmol/L; M72, 2.1 $\pm$ 0.17 mmol/L). At M72, 22 of 34 patients (64.7%) achieved the composite efficacy endpoint. Urinary Ca excretion declined from above normal at BL to within the normal range (BL, 8.9 $\pm$ 5.01 mmol/d; M72, 5.3 $\pm$ 3.22 mmol/d). Mean serum creatinine levels remained stable (BL, 84.7 $\pm$ 18.16 μmol/L; M72, 79.7 $\pm$ 18.76 μmol/L), as did estimated glomerular filtration rate (BL, 77.7 $\pm$ 17.67 mL/min/1.73 m^2; M72, 79.4 $\pm$ 18.39 mL/min/1.73 m^2). Serum phosphorus levels declined from above normal at BL to within normal range (BL, 1.6 $\pm$ 0.19 mmol/L; M72, 1.3 $\pm$ 0.20 mmol/L); calcium-phosphorus product levels also declined (BL, 3.4 $\pm$ 0.51 $mmol^2/L^2$; M72, 2.7 $\pm$ 0.40 $mmol^2/L^2$). Treatment-emergent adverse events and treatment-emergent serious adverse events were reported in 98.0% and 26.5% of patients, respectively; no new safety concerns were identified.
Conclusions
Continuous use of rhPTH(1–84) over 6 years resulted in a favourable safety profile, was effective, and improved key measurements of mineral homeostasis, notably normalisation of urinary calcium.

The effect of parathyroidectomy on glucose homeostasis and incretin hormone release in patients with primary hyperparathyroidism: a pilot study

Vasiliki Antonopoulou[1], Maria Grammatiki[1], Theocharis Koufakis[1], Spyridon Karras[1], Maria Yavropoulou[1], Niki Katsiki[1], Spyridon Gerou[2], Elpida Gavana[2], Lemonia Skoura[3], Pantelis Zebekakis[1], Theodosios Papavramidis[4] & Kalliopi Kotsa[1]
[1]Division of Endocrinology and Metabolism, First Department of Internal Medicine, Medical School, Aristotle University of Thessaloniki, Ahepa Hospital, Thessaloniki, Greece; [2]Laboratories 'Analysis', Thessaloniki, Greece; [3]Department of Microbiology, Aristotle University of Thessaloniki, Ahepa Hospital, Thessaloniki, Greece; [4]1st Department of Surgery, Aristotle University of Thessaloniki, Ahepa Hospital, Thessaloniki, Greece.

Background
Primary hyperparathyroidism (PHPT) has been linked to glucose homeostasis disorders, leading to insulin resistance and type 2 diabetes mellitus. Previous small studies evaluating the effect of parathyroidectomy (PTX) on various parameters of glucose metabolism have produced conflicting results. The impact of PTX on incretin hormone levels has not been studied yet. The aim of this pilot study was to investigate the effect of PTX on markers of glucose metabolism and insulin resistance, as well as on incretin hormone levels in patients with PHPT.
Methods
Fourteen non-diabetic patients with PHPT were included in this study. All patients were scheduled for a curative PTX. Preoperatively, fasting plasma glucose(FPG), fasting insulin(I), gastric inhibitory polypeptide(GIP), glucagon-like peptide-1(GLP-1), calcium, phosphorus, parathyroid hormone (PTH) and 25-hydroxyvitamin-D [25(OH)D] were measured. Homeostasis Model Assessment (HOMA2) was used for estimating insulin resistance (HOMA2-IR), β-cell function (HOMA2-B) and insulin sensitivity (HOMA2-S). QUICKI index for insulin sensitivity was also calculated. A 75g oral glucose tolerance test (OGTT) was performed to further evaluate glucose, insulin and incretin response as well as insulin sensitivity using the Matsuda Index. All measurements and calculations were repeated 6 weeks post-PTX.
Results
Patients had a mean age of 52.9 $\pm$ 10 years (female:male ratio = 12:2). Preoperatively, PTH was positively correlated with HOMA2-B (r = 0.74, P = 0.002) and GLP-1 (r = 0.79, P = 0.02). After PTX, calcium and PTH levels were normalized and phosphorus was increased. Body mass index also increased slightly (P = 0.02). A significant increase was observed in GLP-1 response during OGTT after PTX (in 60 min: 55.2 (79.8) vs 91.5 (74.4) pg/ml, P = 0.05 and in 120 minutes: 71.3 (51.3) vs 91.3 (74.0) pg/ml, P = 0.03). GIP response was not significantly altered. Postoperatively, the correlation between HOMA2-B and PTH remained significant (r = 0.55, P = 0.04), whereas PTH was also associated positively with HOMA2-IR (r = 0.56, P = 0.04) and negatively with Matsuda index (r = −0.58, P = 0.03) and QUICKI (r = −0.41, P = 0.04).
Conclusion
To our knowledge, this is the first study investigating the effect of PTX on incretin hormone levels in PHPT patients. The increase of the GLP-1 response observed after curative surgery may potentially reflect the partial recovery of glucose homeostasis. Additional findings of this pilot study indicate a correlation between PTH and indices of β-cell function in PHPT patients. Larger studies are needed to clarify the pathophysiology background behind PHPT and glucose metabolism and to evaluate the impact of PTX on this association.

Introduction
Persistent primary hyperparathyroidism (pHPT) occurs in 2.5 to 15% of cases after parathyroidectomy. Pre-operative localization studies (usually ^{99m}Tc-MIBI and cervical ultrasonography (US)) allow focused surgical approach (unilateral neck exploration or minimally invasive parathyroidectomy). Few studies have evaluated the best pre-reoperative approaches in case of persistent sporadic

pHPT. The aim of our study is to evaluate the value of a second pre-operative ^{99m}Tc-MIBI in persistent sporadic pHPT and the interest of the adjunction of US.
Patients and Methods
Fifty patients operated on between 2006 and 2016 in three French University Hospitals (Nantes, La Pitié Salpêtrière, Paris and Angers) were included in this study. All patients had a persistent sporadic pHPT after a first surgery and have been re-operated on.A ^{99m}Tc-MIBI was performed in each case before the first and the second operation. US was always performed before the first operation and in 43 patients before re-operation. The cure rate (following second ^{99m}Tc-MIBI and second surgery), the number of new pathologic localized glands, and the intrinsic properties of second ^{99m}Tc-MIBI to localize the side of an abnormal parathyroid gland were evaluated. Intrinsic properties of ^{99m}Tc-MIBI and US were also evaluated.
Results
Forty-two patients (84%) were cured after the second surgery. Among these, 31 (62% of the patients) had a gland removed on the area identified by second-MIBI. Twenty-six new pathologic glands (52%) were identified by second-MIBI, including 18 patients (36%) with a multiglandular disease and 8 patients (16%) with a negative first-MIBI. Overall intrinsic properties of the second-MIBI are 67% sensitivity (se), 91% specificity (sp), 82% positive predictive value (PPV) and 81% negative predictive value (NPV). Performing the second-MIBI one year or more after the first -MIBI provided important sp: 97% vs 86% when second-MIBI was performed in the first year, and PPV: 93% vs 77%, but with a decreased sensitivity (59% vs 71%) and NPV (79% vs 82%). Concordant second-MIBI and US (17 patients) had the better se (77%), 85% sp, 77% PPV and 85% NPV.
Conclusion
Performing a second ^{99m}Tc-MIBI leads to find new pathologic glands in more than 50% of the cases in sporadic pHPT, especially in multiglandular disease. The concordant couple ^{99m}Tc-MIBI and US is the most accurate examination to localize the side of an abnormal parathyroid gland before re-operation. When discordant, the ^{99m}Tc-MIBI performed more than one year after the first-MIBI has the best specificity and NPV.

Calcium to Phosphorus (Ca/P) ratio as an accurate index for the diagnosis of primary hyperparathyroidism (PHPT) and hypoparathyroidism (HypoPT)

Sara De Vincentis[1,2], Andrea Repaci[3], Paola Altieri[3], Elda Kara[4], Fabio Vescini[4], Pierluigi Amadori[5], Antonio Balestrieri[6], Vincenzo Rochira[1,2] & Bruno Madeo[2]
[1]Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; [2]Unit of Endocrinology, Department of Medical Specialties, Azienda Ospedaliero-Universitaria of Modena, Modena, Italy; [3]Unit of Endocrinology, Policlinico S. Orsola-Malpighi, DIMEC Alma Mater Studiorum Bologna, Bologna, Italy; [4]Endocrinology and Metabolism Unit, Universitary Hospital S. Maria della Misericordia of Udine, Udine, Italy; [5]Unit of Endocrinology, Azienda Provinciale Servizi Sanitari Trento, Trento, Italy; [6]Unit of Endocrinology and Diabetes, Hospital 'M. Bufalini di Cesena', AUSL of Romagna, Cesena, Italy.

Background
The diagnosis of PHPT and chronic HypoPT is still challenging, mainly due to the wide spectrum of clinical and biochemical presentation and the lack of validated diagnostic index in literature. The serum Ca/P ratio has been proposed as an accurate tool to diagnose PHPT in a small sample of patients, while no data is available about its possible application for HypoPT.
Aim
To validate the serum Ca/P ratio as a diagnostic index for PHPT and to investigate its diagnostic performance in the diagnosis of HypoPT by analyzing a large series of data coming from a multicenter study.
Methods
Multicenter, retrospective, case-control study, including 432 PHPT patients and 217 HypoPT patients, compared with 389 controls. Main outcomes: serum Ca, P, albumin, creatinine, parathyroid hormone (PTH) and 25-OH vitamin D (only for controls and PHPT). *Statistical analysis:* Comparisons among groups were performed by the nonparametric Kruskal-Wallis, followed by the Dunn's post hoc test. The diagnostic accuracy of Ca/P ratio was investigated by receiver operator characteristics (ROC) curves in order to define cut-off points (with the highest sensitivity and specificity).
Results
The Ca/P ratio was significantly different among groups, resulting higher in PHPT and lower in HypoPT patients than controls ($P<0.0001$). At ROC curve analysis, the Ca/P ratio above 3.3 was defined for the diagnosis of PHPT (sensitivity 85.7%, specificity 85.3%), while the Ca/P ratio below 2.3 for the diagnosis of HypoPT (sensitivity 88.2%, specificity 87.9%). Considering the PHPT group, the cut-off of 3.1 for Ca/P was able to specifically identify patients with normocalcemic PHPT (sensitivity 80.3%, specificity 80.2%).
Conclusions
This study further validates the serum Ca/P ratio as a highly accurate diagnostic index for PHPT, defined by Ca/P above 3.3. For the first time, a Ca/P ratio below 2.3 is proposed to identify HypoPT patients. Our findings confirm the reliability of this index to screen and/or rule out disorders of Ca-P metabolism.

18F-Fluorocholine PET/CT in patients with primary Hyperparathyroidism and negative or inconclusive 99mTc-MIBI parathyroid scan: clinico-pathological correlations

Inka Miñambres, Judit Amigó Farran, Diego Alfonso López, Montserrat Estorch, José Ignacio Pérez, Antonio Moral, Montserrat Clos, Eulalia Ballester & Ana Chico
Hospital de la Santa Creu i Sant Pau, Barcelona, Spain.

Introduction
The gold standard for evaluating Occult Parathyroid Adenomas (OPa) in patients with biochemical pattern of primary hyperparathyroidism (PHPT) is the 99mTc-MIBI parathyroid scan. 18F-Fluorocholine (18F-FCH) PET/CT has been proposed as a potential technique for detection and localization of OPa when 99mTc-MIBI scan is negative or inconclusive.
Aims
To evaluate sensitivity and positive predictive value of 18F-Fluorocholine PET/CT in patients with biochemical PHPT with negative or inconclusive 99mTc-MIBI scan. To correlate 18F-FCH PET/CT findings with clinical and surgical characteristics.
Methods
We analyzed all subjects with biochemical PHPT attended in our department (January–December 2018) with a negative/inconclusive 99mTc-MIBI in which 18F-FCH PET/CT was performed. Patient characteristics, time of diagnosis of PHPT, serum calcium and parathyroid hormone (PTH) levels were recorded. In those patients who underwent parathyroidectomy, affected glands, type of surgery, postoperative serum calcium, PTH levels and pathological features were correlated with 18F-FCH PET/CT findings. Differences were considered significant for a*p value* <0.05. SPSS Statistics package was used for statistical analysis (Mann-Whitney, Chi-square and T student tests).
Results
A total of 23 subjects with biochemical PHPT with negative ($n=19$) or inconclusive ($n=4$) 99mTc-MIBI scan were included (74.47% female, 61.4 ± 14.7 years, time since diagnosis 24.7 ± 30 months, 17.4% with previous unsuccessful surgery, calcium 2.69 ± 0.18 mmol/l, PTH 21.75 ± 28 pmol/l, 3 subjects with MEN1 and 1 with familiar PHPT). 18F-FCH PET/CT was positive in 18 patients, negative in 4 and inconclusive in 1. No differences were found between subjects with positive and negative 18F-FCH PET/CT in the analyzed variables (a tendency to higher PTH was observed in subjects with positive 18F-FCH PET/CT ($P=0.057$)). Parathyroidectomy was performed in 12 patients (11 patients are pending of surgery), resulting in 10 cases a solitary OPa by pathology. OPa were located 6 in the left upper gland, 2 in the left lower gland and 2 in the right lower gland. 18F-FCH PET/CT localization was concordant with the excised OPa in all patients except for one case. In one case of failed surgery PET indicated an ectopic gland and in the other case a left low gland. Moreover, elevated preoperative PTH and serum calcium decreased 10 minutes after surgery.
Conclusions
In our series of patients with biochemical PHPT and negative/inconclusive 99mTc-MIBI parathyroid scan, 18F-FCH PET/CT offers greater sensitivity and precision during performance of parathyroidectomy (sensitivity 78.2%, positive predictive value 83.3%). No clinical or biochemical data was associated with PET positivity.

Clinical, biochemical and radiological profile of normocalcaemic hyperparathyroidism: a multicentric cross-sectional evaluation

Anda Mihaela Naciu[1], Gaia Tabacco[1], Stefania Falcone[2], Assunta Santonati[3], Daria Maggi[1], Luca D'Onofrio[1], Silvia Irina Briganti[1], Domenico Castellitto[4], Alessandro Casini[4], Claudio Pedone[5], Andrea Fabbri[2], Nicola Napoli[1], Paolo Pozzilli[1], Silvia Manfrini[1], Roberto Cesareo[4] & Andrea Palermo[1]
[1]Unit of Endocrinology, University Campus Bio-Medico, Rome, Italy; [2]Unit of Endocrinology and Metabolic Diseases, CTO A. Alesini Hospital, University Tor Vergata, Rome, Italy; [3]Department of Endocrinology, San Giovanni Addolorata Hospital, Rome, Italy; [4]Thyroid and Metabolic Bone Diseases Center, Santa Maria Goretti Hospital, Latina, Italy; [5]Unit of Geriatric, University Campus Bio-Medico, Rome, Italy.

Background
The normocalcaemic hyperparathyroidism (NHPT) has been defined as a condition with persistently normal total and ionized calcium levels in the presence of high levels of PTH. The clinical aspects of NHPT have been evaluated in different cohorts but the interpretation of these findings is confounded by differing methods used to rule out secondary hyperparathyroidism and by the small number of NHPT subjects enrolled. Up to now, there is no information available that could determine the optimal management of this condition.
Objective
To evaluate the clinical, biochemical and radiological profile of NHPT in comparison with PHPT and control subjects.
Methods
We designed a multicentric cross-sectional study and we enrolled patients with NHPT and primary hyperparathyroidism (PHPT) diagnosed according to criteria of the 'Fourth International Workshop of Asymptomatic Hyperparathyroidism'. Body mass index (BMI) and age matched control subjects were consecutively recruited from outpatient clinic of endocrinology at Campus Bio-Medico. All patients underwent a biochemical examination including calcium-phosphorus metabolism and bone turnover markers. We evaluated the lumbar spine (L1–L4), total hip, femoral neck, and non-dominant forearm bone mineral density (BMD) and the trabecular bone score (TBS). Morphometric vertebral fracture (VF) were assessed by DXA scan.
Results
From December 2016 to July 2018, we identified 47 patients with NHPT, 41 with PHPT and 39 control subjects. All study groups had no significant differences in terms of age, BMI and kidney function. NHPT and PHPT patients had significantly higher PTH and 25(OH) Vitamin D levels ($P<0.001$) and lower Ca*P ($P<0.001$) compared to controls. NHPT has lower CTX levels compared to PHPT ($P=0.039$) and no differences were recorded compared to controls. In NHPT group, P1NP resulted not different when compared to controls and PHPT subjects. Compared to controls, NHPT ($P=0.035$) and PHPT ($P=0.003$) group have lower total hip BMD; NHPT showed higher non-dominant forearm BMD than PHPT subjects ($P=0.017$), while compared to controls presented similar values. No significant differences in TBS between the three groups have been founded. After adjustment for confounding factors, only PHPT group had an increased risk of VF compared to controls (OR:5.10, 95% CI:1.34 to 21.58). 31% of NHPT and 12% of PHPT patients fulfilled the criteria for asymptomatic hyperparathyroidism.
Conclusion
Up to now, our study described the biochemical and radiological profile of the largest cohort of NHPT subjects. Our findings suggest that the profile of NHPT subjects is closer to control one.

GP21

The long-term outcomes of chronic post-surgical hypoparathyroidism

Natalia Mokrysheva, Anna Eremkina & Elena Kovaleva
Endocrinology Research Centre, Moscow, Russian Federation.

Hypoparathyroidism (HP) is a rare disease characterized by an absence or inappropriately low concentrations of circulating parathyroid hormone, leading to hypocalcaemia, hypophosphatemia and elevated urinary calcium excretion.
Aim
To determine complications in chronic post-surgical HP patients.
Material and methods
We have analyzed the data from 76 patients (71 women and 5 men; median age 51.8 years (range 18–77)) with chronic post-surgical HP reviewed during 2017–2019. We present the main characteristics of patients including a volume of surgery, disease duration, biochemical parameters, treatment modalities and disease-associated complications.
Results
The average HP duration in group was 8.7 years (2–32). In most cases HP developed after total thyroidectomy for nontoxic unilateral/multinodular goiter and well-differentiated thyroid carcinoma (38.2% and 30.3% respectively). Other reasons included diffuse toxic goiter (14.5%), thyroid malignancy with central neck dissection (10.5%) and primary hyperparathyroidism due solitary adenoma (6.6%). 15 patients (19.7%) were diagnosed with HP after the reoperation on neck region. The median levels of serum Ca and albumin-adjusted serum Ca on conditional therapy were 2.03 mmol/l (1.83; 2.24) and 1.97 mmol/l (1.78; 2.15) respectively. Patients required alfacalcidol in medium doses of 1.5 mcg/day (min 0.25; max 6.0) and calcium carbonate in medium doses of 1875 mg/day (min 250; max 4500). 12 patients received thiazide diuretics in doses 25–75 mg/day to control the hypercalciuria. We did not reveal hypomagnesaemia (0.76 mmol/l (0.71; 0.8)) and vitamin D deficiency (32.75 ng/ml (28.1; 42.9)) in study group. The following complications were identified: decrease of estimated glomerular filtration rate (eGFR) of <60 ml/min/1.73 m^2 in 9 patients (11%); nephrocalcinosis and kidney stones in 4 (5%) and 17 (22%) patients respectively. A diagnosis of hypoparathyroid-caused cataract was confirmed in 5 (6.5%). 5 patients suffered from central nervous system calcifications (Fahr's syndrome) detected by CT scan results. An electrocardiogram showed HP-associated cardiac arrhythmias and prolongation of the corrected QT interval in 5 patients (6.5%). Symptoms of myopathy with increased serum levels of creatine phosphokinase and ossification of longitudinal spine ligament were identified in 8 (10%) and 4 (5%) respectively.
Conclusion
Chronic HP and its treatment may lead to long-term complications affecting various organ systems and consequently the quality of life thus active screening of these patients is strongly recommended. The longitudinal studies and further research are required to develop the new effective strategies in prevention of long-term HP complications.

OFELIA – Prevalence of osteoporosis in fragility fracture patients

Randi Tei[1], Oleguer Plana-Ripoll[2], Ole Brink[1] & Bente Langdahl[1]
[1]Aarhus University Hospital, Aarhus, Denmark; [2]Aarhus University, Aarhus, Denmark.

Worldwide, a care gap has been recognized between presenting with a fragility fracture and prevention of the next fracture. Fracture Liaison Service is the most cost-effective method to close this gap, but its implementation is sparse in many countries. To assess the need for a subsequent fracture prevention program in Denmark, we conducted a cross-sectional study – named OFELIA - aiming to estimate the prevalence of osteoporosis in a Danish cohort of fragility fracture patients aged 18+ years. Over at 12 month period, patients were consecutively identified when treated for fragility fractures at Aarhus University Hospital. Patients were informed about bone health and asked to participate in the study meaning accepting a DXA and answering questions about risk factors. Of 1164 identified patients, 832 were included and 794 (70% women, 66% aged $\geq$50 years) patients completed the investigation. The overall prevalence of osteoporosis in this cohort according to WHO's criteria of a T-score at hip or spine below -2.5 was 14.9% (118 patients, of these 20 patients knew their diagnose on forehand), increasing to 20.3% in patients $\geq$50 years (22.9% in women, 9.6% in men). In addition to age above 50 years, female sex, low BMI, and early menopause were significantly associated with osteoporosis. At 3-years follow-up we performed interviews in 93 out of 98 patients diagnosed with osteoporosis according to OFELIA. Of these, a total of 75 patients (81%) received anti-osteoporosis treatment initiated by their GP as a result of the DXA result and 71 (95%) were still – after three years - adherent to treatment. In the group of 93 interviewed patients ten had experienced a subsequent (minor) fracture and 84 patients supplied their daily intake of calcium and D-vitamin. Control DXA after 2–3 years performed in 56 patients showed increasing bone mineral density in 49 (87.5%) patients. Given that osteoporosis was demonstrated in one of five patients aged 50 years or older treated for a fracture at AUH, OFELIA stresses the need for implementation of a program aiming to secure appropriate investigation and treatment in patients presenting a fragility fracture. A suggested high adherence to initiated treatment in patients diagnosed with osteoporosis after a fracture indicates a beneficial outcome of FLS.

Study of hsa-miR-30e miRNA as a biomarker in identifying multiple gland disease in sporadic primary hyperparathyroidism: Is it time for individualized molecular-based surgery?

Maria Mizamtsidi[1], Konstantinos Nastos[1], Fausto Palazzo[2], Vasilis Constantinides[2], Roberto Dina[3], Megan Farenden[4], Ioannis Vassiliou[1] & Maria Gazouli[4]
[1]Endocrine Surgery Unit, Second Department of Surgery, Aretaieion University Hospital, National and Kapodistrian University of Athens, Athens, Greece; [2]Department of Thyroid and Endocrine Surgery, Hammersmith Hospital, Faculty of Medicine, Imperial College London, London, UK; [3]Department of Pathology, Hammersmith Hospital, Imperial College Healthcare NHS Trust, London, UK; [4]Laboratory of Biology, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece.

Introduction
Sporadic primary hyperparathyroidism (sporadic PHPT) is a common endocrine disorder, usually caused by a single parathyroid adenoma. However, up to 15% of patients present with multiple gland disease (MGD), which cannot be always diagnosed preoperatively, raising serious management problems. No predictive genetic screening tests are currently available to distinguishing adenomas from MGD in sporadic PHPT. MiRNAs are widely established as genetic molecules that have unique features suitable for biomarker use, as they display an exceptional stability against degradation and are easily extracted from various specimens including peripheral blood. The aim of this study was to investigate differential expression of hsa-miR-30e miRNA in patients with adenomas or MGD, as well as the association between the single nucleotide polymorphisms (SNP-ss178077483 and rs7556088) found in hsa-miR-30e and their possible role in sporadic PHPT tumorigenesis.
Methods
120 patients with sporadic PHPT were genotyped, 77 presenting with a single adenoma and 43 with MGD. 54 healthy adults served as controls. Patients with secondary hyperparathyroidism or patients with genetic syndromes involving PHPT, familiar hereditary disease or history of other malignancies were excluded. Patients with single adenomas were included only if they were followed-up for at least 2 years and confirmed to be disease free. The control group was tested and found to be negative for PHPT. Clinical data was collected from both Institutions' databases. Polymorphisms were identified using allele specific polymerase chain reaction technique. Hsa-miR-30e expression in samples was detected by real-time quantitative reverse transcriptase PCR.
Results
When comparing patients with adenomas and MGD, there was no significant difference in clinical and biochemical parameters. There was also no difference between weight and size of the resected glands in these two groups. Hsa-miR-30e expression was found to be significantly higher in patients with MGD compared to patients with single adenomas ($P=0.0019$). The genotype frequencies for ss178077483 and rs7556088 were found to differ significantly between patients with sporadic PHPT and healthy controls, but not between patients with adenomas and MGD. Furthermore, no significant differences were found in hsa-miR-30e expression levels regarding to specific genotype carriers.
Conclusions
Although SNPs do not seem to serve as possible genetic biomarkers for the preoperative differential diagnosis of MGD, hsa-miR-30e expression could potentially serve as a marker for this purpose.

GP24

The impact of impaired calcium-phosphorus metabolism on the renin-angiotensin-aldosterone system in patients with primary hyperparathyroidism

Natalia Mokrysheva, Ekaterina Dobreva, Ekaterina Bibik & Anna Eremkina
Endocrinology Research Centre, Moscow, Russian Federation.

Objective
Primary hyperparathyroidism (PHPT) is associated with increased cardiovascular morbidity including hypertension with a prevalence ranging from 40 to 65%. The renin-angiotensin-aldosterone system (RAAS) is a key system in the regulation of sodium/potassium balance, volume homeostasis as well as blood pressure. There is increasing evidence of interactions between calcium and calcium-regulatory hormones with the RAAS. The aim of this study was to investigate the association between impaired calcium-phosphorus metabolism and the RAAS in PHPT patients.
Material and methods
We examined 57 patients with confirmed PHPT (48 women, 9 men, median age 49 years (Q1 = 39; Q3 = 56)). All patients underwent biochemical evaluation with monitoring blood pressure. Standardized blood sampling was performed before and in 3 days after surgical treatment for PHPT. The exclusion criteria were the glomerular filtration rate <75 ml/min/1.73 m^2, severe cardiovascular pathology, obesity, diabetes mellitus and treatment with drugs affected calcium balance.
Results
All cases presented symptomatic PHPT (median serum calcium level 2.73 mmol/l (Q1 = 2.61; Q3 = 2.98), PTH 122.7 pg/ml (Q1 = 94.0; Q3 = 203.0)). 38.6% of patients had mild and moderate hypertension that was corrected with antihypertensive therapy. Median levels of the RAAS components before and after surgery were: plasma renin activity (PRA) 0.42 (Q1 = 0.20; Q3 = 1.47) and 0.29 (Q1 = 0.08; Q3 = 1.16) ng/ml*h, aldosterone 108.2 (Q1 = 88.8; Q3 = 131.7) and 97.9 (Q1 = 77.7; Q3 = 126.8) pg/ml, angiotensin II 19.2 (Q1 = 16.3; Q3 = 21.1) and 20.2 (Q1 = 16.9; Q3 = 22.8) pg/ml respectively. No patients had deviations of serum aldosterone and angiotensin II levels, but slightly elevated PRA levels were defined in 10.5% of them. At the 3-rd day after surgery the biochemical evaluation revealed a significant decrease in PRA ($P=0.019$) and serum aldosterone levels ($P=0.005$). We found a significant positive correlation between intact PTH and PRA ($P=0.009$) as well as serum calcium and PRA levels ($P=0.001$) before parathyroidectomy. Serum calcium was also positively correlated with aldosterone ($P=0.018$) before surgery. In the early postoperative period PTH correlated only with angiotensin II level ($P=0.012$).
Conclusion
The study showed the significant changes of the RAAS activity after parathyroidectomy even in the early postoperative period. Further investigation with a long observation period is required to clarify these findings.

Impact of chronic hypoparathyroidism on health-related quality of life, symptoms, employment, and relationships: findings from a 13-country patient survey

Jens Bollerslev[1], Nawal Bent-Ennakhil[2], Kristina Chen[3], Bart L Clarke[4], Helen Dahl-Hansen[5], John Germak[6], Katie Gibson[2], Elizabeth Glenister[7], Davneet Judge[2], Claudio Marelli[6] & Heide Siggelkow[8]
[1]Section of Specialized Endocrinology, Oslo University Hospital, Oslo, Norway; [2]Adelphi Real-World, Bollington, UK; [3]Shire Human Genetic Therapies, Inc., a member of the Takeda group of companies, Cambridge, MA, USA; [4]Mayo Clinic Division of Endocrinology, Diabetes, Metabolism, and Nutrition, Rochester, MN, USA; [5]hypoPARA NORGE, Oslo, Norway; [6]Shire International GmbH, a member of the Takeda group of companies, Zug, Switzerland; [7]Hypopara UK, East Grinstead, UK; [8]Clinic of Gastroenterology and Endocrinology, University of Göttingen, Göttingen, Germany.

Significant knowledge gaps exist regarding the humanistic effects of hypoparathyroidism, a rare, debilitating disorder. We report results from a global survey to characterise the burden of hypoparathyroidism from the patient perspective. An anonymous survey was conducted in patients with uncontrolled chronic hypoparathyroidism (as determined by patients' report of persistent symptoms and/or poorly controlled calcium levels as told by their physician) despite receiving conventional therapy. Patients currently or previously treated with parathyroid hormone were excluded. Health-related quality of life (HRQoL) and health status were evaluated using 2 validated instruments, SF-36 and EQ-5D-5L. Hypoparathyroidism-associated symptoms were assessed through the disease-specific Hypoparathyroidism Symptom Diary (7 days recall). Levels of work productivity and impairment were evaluated using the WPAI tool. All analyses were descriptive. The survey was conducted October 2017–March 2018 in 398 patients. Patients were asked to rate their self-perceived overall symptom severity level given the scale of no symptoms (3%), mild (32%), moderate (53%), or severe (12%). Mean SF-36 summary scores (0–100) were 45.4/44.6/37.1/28.7 (physical component summary) and 53.2/44.9/35.2/31.6 (mental health component summary) for patients reporting no/mild/moderate/severe hypoparathyroidism symptoms, respectively. Mean EQ-5D-5L utility scores (0–1) were 0.9/0.8/0.7/0.4 and EQ-5D-5L visual analogue scale scores (0–100) were 86.9/72.5/57.7/41.1 for patients reporting no/mild/moderate/severe hypoparathyroidism symptoms, respectively. Per the Hypoparathyroidism Symptom Diary, patients reported moderate/severe/very severe physical symptoms of physical fatigue (39%/25%/9%), muscle cramps (38%/12%/4%), and heaviness

in limbs (37%/14%/4%). Moderate/severe/very severe cognitive symptoms (slow/confused thinking) were reported by 28%/13%/6% of patients. Moderate/severe/very severe mood symptoms of anxiety and sadness/depression were reported by 29%/14%/3% and 28%/10%/4% of patients, respectively. The percentages of patients reporting an impact on family relationships, work, sleep, and ability to exercise were 63%, 75%, 78%, and 84%, respectively. 50% of patients were currently employed. WPAI scores showed patients working at 59% of their full capacity. Overall work impairment increased with self-perceived symptom severity: 18%/28%/49%/68% for patients reporting no/mild/moderate/severe hypoparathyroidism symptoms, respectively. Change of employment resulting from hypoparathyroidism was reported by 0%/29%/67%/83% of patients reporting no/mild/moderate/severe symptoms, respectively. The percentages of patients reporting 'a major impact' on relationships also rose with symptom severity: spouse/partner (0%/14%/33%/55%), family (0%/13%/34%/61%), and friends (0%/16%/45%/65%), for patients reporting no/mild/moderate/severe symptoms, respectively. Findings from this global survey demonstrated substantial burdens associated with uncontrolled chronic hypoparathyroidism with respect to HRQoL, disease-related symptoms, employment status, productivity, and relationships. The degree of burden corresponds with the severity of hypoparathyroidism-related symptoms reported by patients.

Association of MR-proANP with cardiovascular risk factors in middle aged patients with diabetes mellitus type 2 and non-diabetic controls

Simona Chisaliita[1], Magnus Wijkman[2], Fredrik Nyström[3] & Carl Johan Östgren[4]
[1]Department of Endocrinology and Department of Medical and Health Sciences, Linköping University, Linköping, Sweden; [2]Department of Internal Medicine and Department of Medical and Health Sciences, Linköping University, Norrköping, Sweden; [3]Department of Medical and Health Sciences, Faculty of Medicine and Health Sciences, Linköping University, Linköping, Sweden; [4]Department of Medical and Health Sciences, Primary care, Linköping University, Linköping, Sweden.

Aim
To explore if MR-proANP is associated with cardio-metabolic risk factors in patients with med type 2 diabetes mellitus (T2D) and non-diabetic controls.
Methods
MR-proANP was analyzed in 761 middle-aged (54–66years) patients with type 2 diabetes and 184 non-diabetic controls and related cardio-metabolic conventional risk factors as age, sex, previous cardiovascular diseases (atrial fibrillation, myocardial infraction), glucose, LDL cholesterol, mean systolic blood pressure, active smoking, BMI, left ventricular mass index (LVMI), toe pressure index (TBI).
Results
Lower levels of MR-proANP were found in patients with T2D compared to non-diabetic controls (73 ± 38.5 vs. 80.3 ± 31.2 pmol/l, $P=0.03$). In T2D and non-diabetes group MR-proANP was positively correlated to age ($r=0.2$, $P<0.001$ and $r=0.4$, $P<0.001$, respectively) and LVMI ($r=0.1$, $P=0.003$ and $r=0.2$, $P=0.03$, respectively) and negatively to blood glucose ($r=-0.7$, $P=0.05$ and $r=-0.1$, $P=0.03$, respectively) and LDL-cholesterol ($r=-0.01$, $P=0.6$ and $r=-0.1$, $P=0.02$ respectively). For T2D patients linear regression analysis adjusted model for cardio-metabolic risk factors MR-proANP showed an significant association to gender (B = 0.04, 95% CI 0.02–0.06, $P<0.001$), age (B = 0.009, 95% CI 0.005–0.01, $P<0.001$), previous atrial fibrillation (B = 0.09, 95% CI 0.009–0.1, $P=0.03$), BMI (B = 0.005, 95% CI 0.001–0.009, $P=0.03$), systolic blood pressure (B = 0.001, 95% CI 0.001–0.001, $P=0.02$), active smoking (B = 0.04, 95% CI 0.01–0.07, $P=0.001$) and abdominal circumference (B = 0.002, 95% CI 0.001–0.004, $P=0.005$). For non-diabetic controls MR-proANP was associated to gender (B = 0.06, 95% CI 0.01–0.1, $P=0.1$), age (B = 0.004, 95% CI 0.001–0.008, $P=0.03$) and abdominal circumference (B = 0.005, 95% CI 0.001–0.01, $P=0.03$).
Conclusion
Lower levels of MR-proANP in T2D compared to non-diabetic controls showed significant association with cardio-metabolic risk factors. Our results suggest that ANP could have metabolic actions and may be implication in the pathophysiology of T2D.

Serum insulin levels are associated with vulnerable plaque components in the carotid artery

Blerim Mujaj[1], Daniel Bos[1], Maryam Kavousi[1], Jan A Staessen[2], Oscar H Franco[3] & Meike Vernooij[1]
[1]Erasmus MC, Rotterdam, Netherlands; [2]KULeuven, Leuven, Belgium; [3]Institute of Social and Preventive Medicine, Bern, Switzerland.

Background
Impaired insulin and glucose levels are implicated in the etiology of cardiovascular disease, however, their influence on the formation and composition of atherosclerotic plaque remains unclear.
Purpose
To investigate the association between fasting serum insulin and glucose levels with atherosclerotic plaque composition in the carotid artery.
Methods
In 1740 participants (mean age 72.9 years, 46% women, 14.4% diabetes mellitus) from the population-based Rotterdam Study, we performed carotid MRI to evaluate the presence of calcification, lipid core, and intraplaque hemorrhage in carotid atherosclerosis. All participants also underwent blood sampling to obtain information on serum insulin and glucose levels. Using logistic regression models, we assessed the association of serum insulin and glucose levels (per standard deviation (SD) and in tertiles) with the different plaque components, while adjusting for sex, age, intima-media thickness, and cardiovascular risk factors.
Results
High serum insulin levels were associated with the presence of intraplaque hemorrhage [adjusted odds ratio (OR) per 1-SD increase: 1.32 (95% confidence interval (CI) 1.01–1.75)] and with a lower frequency of lipid core [adjusted OR: 0.61 (95% CI: 0.54–0.88)]. We found no association with the presence of calcification. Sensitivity analyses restricted to individuals without diabetes mellitus yielded similar results. No associations were found between serum glucose levels and any of the plaque components.
Conclusions
Higher serum insulin levels are associated with the presence of intraplaque hemorrhage, and with a lower frequency of lipid core in carotid atherosclerosis. These findings suggest a complex role for serum insulin in the pathophysiology of carotid plaque vulnerability.

GP28

The synergistic impact of apolipoprotein B/ A-1 and lipoprotein (a) on coronary artery calcification

Chul Woo Ahn[1], Arim Choi[1], Jung Hye Kim[1], Kahui Park[1], Sang Bae Lee[1], Yusik Kim[2], Ji Sun Nam[1], Shinae Kang[1] & Jong Suk Park[1]
[1]Division of Endocrinology, Department of Internal Medicine, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea; [2]Severance Institute for Vascular and Metabolic Research, Yonsei University College of Medicine, Seoul, Republic of Korea.

Objective
Apolipoprotein B/Apolipoprotein A-1 ratio (Apo B/Apo A-1) and lipoprotein (a) (Lp(a)) are known to be associated with atherosclerotic vascular disease. We investigated the influence of Apo B/Apo A-1 and Lp(a) on coronary artery calcification (CAC) among healthy Korean adults.
Methods
A total of 1081 participants underwent cardiac computed tomography in health promotion center were enrolled. Anthropometric profiles and multiple cardiovascular risk factors, including Apo B, Apo A-1, and Lp(a) were measured were measured. Multi-detector CT was used to measure coronary artery calcium score (CACS) and CACS > 0 was defined as the presence of CAC. Adjusted Odds ratios for the presence of CAC according to Lp(a) and Apo B/Apo A-1 tertiles were estimated using logistic regression.
Results
Subjects were grouped according to Lp(a) and Apo B/Apo A-1 levels. There were significant differences in cardiovascular parameters among the groups and the prevalence of CAC significantly increased with Lp(a) and Apo B/Apo A-1 levels. In the logistic regression analysis adjusted for multiple risk factors, odds ratio (95% CI) for the prevalence of CAC comparing the lowest Lp(a) and Apo B/Apo A-1 group to the highest group was 2.554 (1.256–5.201) ($P<0.05$).
Conclusion
These results show that Apo B/Apo A-1 and Lp(a) have a synergistic impact on prevalence of CAC, which suggests that individuals with elevated Lp(a) and Apo

B/Apo A-1, should be more closely monitored to allow a better risk assessment for subclinical atherosclerosis.

Systematic screening of masked hypertension in normotensive type 2 diabetic patients

Dorra Ghorbel[1], Faten Hadjkacem[1], Faten Triki[2], Mouna Mnif[1], Nadia Charfi[1], Nabila Rekik[1], Samir Kammoun[2] & Mohamed Abid[1]
[1]Endocrinology-Diabetology Department, CHU Hédi Chaker, Sfax, Tunisia; [2]Cardiology Department, CHU Hédi Chaker, Sfax, Tunisia.

Introduction
Masked hypertension (MH) is a relatively recent description leading to a similar cardiovascular risk as permanent hypertension. Masked hypertension is more common among diabetic patients.
Methods
This was a case-control study. We performed 24-hour ambulatory BP in 53 type 2 diabetic patients normotensive in clinical measurement. We compared both Masked Hypertension and Normotensive groups according to clinical/laboratory parameters and target organ damage, and identify MH predictor risk factors among diabetic population.
Results
We recruited 53 patients whose mean age was 55.3 ± 8.4 years (range 35–72 years) with a sex ratio (H/F) equal to 0.89. The mean age of diabetes was 8.7 ± 3.9 years with extremes between 2 and 17 years old. The mean BMI of our patients was 28.2 ± 5.3 kg/m^2. Overweight was found in almost half of our patients (47.2%). Obesity was found in 32.1% of cases. Metabolic syndrome was found in 64.2% of patients. In our study, the prevalence of HTAM in type 2 diabetics was 64%. Our study also found that this HTAM was more often nocturnal (58.5%), occurred in predominantly non-dippers. Left ventricular hypertrophy, micro-albuminuria and documented arterial stiffness by pulsed pressure greater than 60mm Hg in were more common in the group of HTAM. For the predictive factors of HTAM, we were able to collect in univariate analysis the factors age of diabetes, fasting blood glucose, body weight and microalbuminuria. In multi-variate analysis, the predictive factors that emerged in our study are: the bad glycemic control (HbA1c $\geq$7%), elevated BMI and duration of diabetes.
Conclusion
The masked hypertension should be evaluated in diabetic patients because it helps to better assess cardiovascular risk in particular by identifying affected target organs.

DOI: 10.1530/endoabs.63.GP29

Cardiovascular risk factors in patients with type 2 diabetes and non-alcoholic fat liver disease

Rodionova Svetlana[1], Birukova Elena[1,2] & Zvenigorodskaya Larisa[1]
[1]Moscow Clinical Scientific Center named after A.S. Loginov, Moscow, Russian Federation; [2]University of Medicine and Dentist named after A.I. Evdokimov, Moscow, Russian Federation.

Background and aims
To investigate the level of lipoprotein associated phospholipase A2 (LpPLA2), nitrogen oxide (NO) in patients with type 2 diabetes (DM2) and nonalcoholic fatty liver disease (NAFLD) against a variety of hypoglycemic therapies (HT).
Materials and methods
A one-stage examination of 90 patients with DM 2 and NAFLD was carried out. Men ratio 37.8%, women ratio 62.2%, mean age 57.3 ± 11.6 years. Mean HbAlc 7.4 ± 1.82%. According to the HT conducted, the patients were divided into groups: 1) monotherapy with metformin (MF); 2) sulfonylurea preparations (SU) + MF; 3) insulin therapy IT + MF; 4) IT + (SU). The cytolysis parameters (ALT, AST), systemic inflammations (LpPLA2, NO) were evaluated. All the patients underwent liver elastography.
Results
The group average BMI 33.7 ± 3.48 kg^2, waist circumference 118.6 ± 38.4 cm. The highest ALT level (56.35 ± 38.6 u/l), AST (38.6 ± 14.4 u/l) was noted in the group of patients receiving MF. In the group of patients receiving SU, both in combination with MF and with insulin, the concentration of LpPLA2 was significantly higher than in the other groups (562.6 ± 97.8 ng/ml and 672.7 ± 173.08 ng/ml, respectively). The NO level was elevated in all groups, an average of 85.08 ± 40.58 μmol/l. The highest level of NO was recorded in the group of patients receiving insulin. In patients with DM 2 and NAFLD, the most common change in the liver according to elastometry is steatosis (77%). In 33% of the patients fibrosis (F) was detected. The highest F rates were noted in the group of patients on IT (11.8 ± 9.38 kr), with this group having a longer duration of the disease (9.7 ± 4.59 years).
Conclusion
It was found that the patients with DM2 and NAFLD have an increased level of LpPLA2, with its highest rate in patients receiving SU, both in combination with MF and with continuous-acting insulin, that may indicate a higher cardiometabolic risk in this group of patients. Regardless of the variant of hypoglycemic therapy, all the patients had an increase in NO level. The most common change in the liver in combination with NAFLD and DM 2 is steatosis (77%), one in three patients showed signs of liver fibrosis.

Breastfeeding is inversely associated with subclinical atherosclerosis in postmenopausal women

George Kaparos[1], Michael Apostolakis[2], Eleni Armeni[2], Areti Augoulea[2], Stavroula A Paschou[2], Konstantinos Panoulis[2], Panagiotis Bakas[2], Georgios Georgiopoulos[3], Dimitrios Delialis[3], Efthymios Deligeoroglou[2], Kimon Stamatelopoulos[3] & Irene Lambrinoudaki[2]
[1]Biochemical Laboratory, Aretaieio Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece; [2]Second Department of Obstetrics and Gynecology, Aretaieio Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece; [3]Vascular Laboratory, Department of Clinical Therapeutics, Alexandra Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece.

Introduction
The aim of this study was to evaluate the association between a personal history of lactation and indices of subclinical atherosclerosis and arterial stiffness in postmenopausal women.
Patients and methods
This cross-sectional study included 283 postmenopausal women. Sonographically assessed indices of vascular function [pulse wave velocity (PWV)] and vascular structure [intima-media thickness (IMT), atherosclerotic plaque presence] were tested for possible association with the history of lactation.
Results
The duration of lactation ranged between 1 and 80 months. PWV was negatively associated with the duration of lactation (b-coefficient = −0.127, P value = 0.038), independently of age, BMI, LDL-cholesterol levels, smoking and arterial pressure. Subclinical atherosclerosis was associated with lactation (OR = 0.958, P value = 0.042), age, BMI and arterial pressure. Women who had lactated for more than 6 months presented significantly decreased mean common carotid IMT compared with women who had lactated for 1 to 6 months (0.72 + 0.13 mm vs 0.68 + 0.13 mm, F = 4.267, P value = 0.041), independently of other traditional cardiovascular risk factors.
Conclusions
Postmenopausal women with a personal history of breastfeeding present decreased arterial stiffness and atherosclerosis, even after adjustment for traditional cardiovascular risk factors. If causality is confirmed, these findings may indicate a protective effect of lactation against subclinical atherosclerosis in later life.

Application of 3D skin culture model as a tool to study the role of immune mechanisms in chronic diabetic foot ulcers pathogenesis

Maryia Mashkova[1], Vitaly Goranov[1], Tatiana Mokhort[1], Alena Shyshko[1] & Marina Mantachik[2]
[1]Belarusian State Medical University, Minsk, Belarus; [2]10th City Clinical Hospital, Minsk, Belarus.

The aim
To test cytotoxic effects of immune factors of patients with chronic diabetic foot ulcers on keratinocytes and fibroblasts in a 3D skin culture system.
Materials and methods
In this study a multilayer 3D human skin model comprising of keratinocytes, fibroblasts and dendritic cells in an agarose-fibronectin gel was used. 20% serum of 13 patients with chronic noninfected diabetic foot ulcers, 13 diabetic type 2 patients and 13 healthy people and lymphocyte/monocyte mixture of the same groups of patients were added to the culture model. The system was also tested with standard irritants – dimethyl sulfoxide, Lipopolysaccharide. Cell viability and growth of fibroblasts and keratinocytes was measured using the resazurin reduction assay.
Results
Decreased fibroblasts viability was seen in the presence of blood components of patients with chronic diabetic foot ulcers (blood serum and lymphocyte/monocyte mixture). At the same time, the cytoinhibitory effect was observed mainly in the presence of lymphocyte/monocyte mixture of these patients (Table 1).

Table 1 Results of 3D culture model testing.

	Control (standard irritants only, no serum + lymph/monocyte)		Healthy people (20% serum + lymph/monocyte)	
Irritant	Keratinocytes (%)	Fibroblasts (%)	Keratinocytes (% to control)	Fibroblasts (% to control)
Control	100	100	-	-
DMSO, (100 mM)	101.1 [98.7;103.5]	104.8 [101.1;108.2]	103.0 [98.7;107.1]	99.8 [98.3;101.1]
SCS, (5 μg/ml)	94.4 [90.1;99.2]	97.1 [93.6;100.3]	103.8 [102.9;104.2]	99.8 [99.1;103.1]

Stroke in diabetic patients and cardiovascular risk factors control

Soraya León Idougourram, Ana Barrera Martín, Ángel Rebollo Román, Paloma Moreno Moreno, María Alcántara Laguna, Rafael Palomares Ortega & María Ángeles Gálvez Moreno
Reina Sofía Hospital. Endocrinology and Nutrition Service, Córdoba, Spain.

Introduction
Strokes are common diabetes macrovascular complications. A good control of cardiovascular risk factors such as glycemic control has been proven to reduce the risk of its appearance. *Aim:* Describe diabetes prevalence in patients admitted to hospital because of a stroke, as well as their treatment and metabolic control.
Patients and methods
Observational retrospective study of patients admitted to the Neurology section because of a stroke between 2016 and 2017. Statistical analysis performed with SPSS (22th version).
Results
611 patients recruited. Age: 65.13 ± 12.72 years. 32.7% women. Mean of HbA1c 6.75 ± 1.54%. 28 patients died during their hospital stay, 35.7% of which had a previous diabetes story. ($P=0.55$). Prior DM history in 187 patients (30.6%): 0.5% LADA, 1.1% DM1 and 97.9% DM2. 55.9% were treated with antidiabetic drugs, 18.4% with insulin, 12.8% with both and in 12.8% the treatment was unknown. HbA1c was requested in 72.2% of people with diabetes with a HbA1c of 7.71 ± 1.72%. 51.9% of them met their glycemic target. In 53.2% non-diabetic people HbA1c was requested: 20 patients (4.1%) were diagnosed with diabetes (Mean HbA1c 7.06 ± 0.72%) and 85 with prediabetes (34.7%, Mean HbA1c 5.94 ± 0.20%). 23 patients with diabetes (12.3%) and 3 (15%) newly diagnosed were evaluated by an endocrinologist. Treatment at discharge was modified in 22.5% of patients with prior DM history (42.9% by endocrinologists and 57.1% by neurologists) and in 25% of newly diagnosed diabetic patients (40% by endocrinologists and 60% by neurologists). Most patients (68.1%) improved their ambulatory glycemic control with a mean HbA1c reduction of 0.75 ± 1.61% (in 5.48 ± 2.68 months). 19 patients had a worse ambulatory glycemic control and only 2 of these had been evaluated by endocrinologists.
Conclusions
1) Diabetes prevalence in patients with stroke is high in our series, in spite of which HbA1c is not routinely evaluated.
2) Almost a half of diabetic patients (48.1%) do not meet their glycemic goal at admission. However only a small percentage (12.3%) of them are evaluated by an endocrinologist and after this evaluation most of them improve their glycemic target.

Cardiovascular biomarkers and calculated risks - an association study

Alexandra Markova[1,2], Mihail Boyanov[1,2], Deniz Bakalov[1,2] & Adelina Tsakova[3,4]
[1]Clinic of Endocrinology and Metabolism, University Hospital Alexandrovska, Sofia, Bulgaria; [2]Department Internal Medicine, Medical University Sofia, Sofia, Bulgaria; [3]Central Clinical Laboratory, University Hospital Alexandrovska, Sofia, Bulgaria; [4]Department Clinical Laboratory and Clinical Immunology, Medical University Sofia, Sofia, Bulgaria.

The identification of type 2 diabetes patients at particularly high risk for cardiovascular events might be facilitated by the use of specific risk calculators or by measurements of serum biomarkers.
Objectives
To correlate the levels of cardiovascular biomarkers – assymetric dymethylarginine (ADMA), endothelin 1 (ET-1), N-terminal brain natriuretic pro-peptide (NT-proBNP) and placental growth factor (PIGF-1), with calculated cardiovascular risks using three different risk engines.
Material and methods
102 women and 67 men with type 2 diabetes on oral antidiabetic drugs agreed to participate in this cross-sectional study (mean age – 60.3 ± 9.6 years; mean diabetes duration – 7.6 years). Fasting morning blood and urine samples were collected and the glycemic and metabolic parameters were assessed by routine laboratory (glycated hemoglobin A1c, lipid profiles, creatinine, microalbuminuria etc.). Serum levels of NT-proBNP and PIGF-1 were measured by electro-hemiluminescence (Elecsys 2010, Roche Diagnostics) while enzymatic immunoassays were used for ADMA (BioVendor) and ET-1 (IBL International GMBH). Cardiovascular risks were calculated using the Framingham Risk Score (FRS), the UKPDS version 2.0 and the ADVANCE risk engines. Correlation and regression analysis were performed on an IBM SPSS 19.0 for Windows platform (SPSS Corp., Chicago, IL).
Results
ADMA levels were above the upper normal limit in 11.0% of the participants, ET-1 levels - in 20.4%, and NT-proBNP - in 33.5%. Based on the ADVANCE risk calculator 10.8% of the participants had a 4-yr risk for CV events ≥ 8.0%. The FRS based 10-yr risk was very high (> 20%) in 8.0% of the participants, and moderate (15 – 30%) – in 12.1%. The UKPDS-based risk was very high (>30%) in less than 20% of the participants. Levels of PIGF-1 showed no correlation with the calculated CV risks, the same was true for levels of ADMA, except for UKPDS-based 10-yr risk for stroke. Plasma levels of endothelin-1 were correlated only with the UKPDS-based 10-yr risk for stroke and fatal stroke, while NT-proBNP levels were highly and significantly correlated with all possible CV risk calculations. The curve estimations within the regression analyses produced similar results.

Conclusion
Serum levels of ADMA and PIGF-1 do not seem related to calculated cardiovascular risks. ET-1 is linked to risk for stroke, while NT-proBNP - to both cardio- and cerebrovascular risk estimations.

Family education, quality of life and glycosylated haemoglobin control among Nigerian diabetics: a quasi-experimental study

Lucia Y Ojewale & Abimbola Oluwatosin
Department of Nursing, University of Ibadan, Ibadan, Nigeria.

Glycaemic control remains poor among individuals with diabetes mellitus (DM) in Nigeria and is linked to a non-supportive family environment. Family-Integrated Diabetes Education (FIDE) has been shown to improve glycaemic control in studies among Hispanics and Caucasians. However, there is dearth of literature on its effectiveness among Africans; despite the close-knit nature of many African families. The study aimed at determining the effects of FIDE on glycosylated haemoglobin (HbA1c) and Quality of Life (QoL) of type 2 diabetes patients in Nigeria; with the overarching goal of improving diabetes-education policy/operating procedure in Nigerian hospitals. Quasi-experimental design involving two teaching hospitals was utilized. There were 88 patients in Control-Group (CG) and 82 in Intervention-Group (IG), with a corresponding number of family members. Patients' diabetes knowledge, QoL and HbA1c were determined. Family members completed a questionnaire on diabetes-knowledge. IG received FIDE and patients and family were assessed for immediate post-intervention knowledge. HbA1c, and QoL were reassessed at three and six-month post-intervention. Data was analyzed using independent t-test, paired t-test and repeated-measures ANOVA, at $P < 0.05$. One hundred and fifty-two (152) patients completed the study – 78 in CG and 74 in IG. 55.3% being $\geq$60 years. Duration of DM was $<$ 20 years in 88.3%. Family members were mostly female (62.9%) with 52.8% aged $\leq$ 40 years. Knowledge of family members in IG was significantly higher than that of CG post-intervention ($8.6 \pm 3.0/5.8 \pm 2.2$, $P < 0.01$). HbA1c reduced significantly in IG by third month (8.9%/7.8%; $P < 0.01$), but did not in CG. QoL of IG improved significantly between third and sixth month ($51.4 \pm 8.8/56.2 \pm 11.9$; $P = 0.001$). Family Integrated Diabetes Education (FIDE) improved glycaemic control and quality of life of diabetes patients. It is recommended that family members be formally included in diabetes-education in all Nigerian hospitals. It is hoped that results of this study will drive policy change in Nigerian hospitals in the near future towards improving diabetes care.

Beta cell senescence: effect of glucotoxicity and glucolipotoxicity

Mi-kyung Kim[1,2], Hye Sook Jung[2], Jeong Eun Jang[1], Tae Nyun Kim[1], Min Jeong Kwon[1], Soon Hee Lee[1], Byung Doo Rhee[1] & Jeong Hyun Park[1,2]
[1]Division of Endocrinology and Metabolism, Department of Internal Medicine, College of Medicine, Inje University, Busan, Republic of Korea; [2]Paik Institute for Clinical Research, Molecular Therapy Lab, Inje University, Busan, Republic of Korea.

Pancreatic beta cell senescence is one of the recent explanations for theincreased prevalence of type 2 diabetes in the elderly. Aging may exert a distinct influence on pancreatic β cell turnover, regeneration capacity and function. Oxidative stresses induced by metabolic stresses reduce pancreatic beta cell mass and secretion. We investigated how metabolic stresses effect on pancreatic beta cell senescence. INS-1 cells were exposed to 33mM glucose (glucotoxicity: high glucose (HG)) or 33 mM glucose with palmitate 200 uM (glucolipotoxicity: HG + palmitate (HGP)). Cell viability and apoptosis were assessed by MTT assay and Annexin V staining. We compared senescence β-Galactosidase (SA-β-Gal) staining and p16INK4aimmunostaining between high glucose (HG) and HG + palmitate (HGP). We assessed phospho-p38 MAPK, Sirt1 and p16 protein expression with metabolic stresses. CDK4 protein and antioxidant enzyme were assessed in both conditions. INS-1 cell viability was decreased and apoptosis was increased in both HG and HGP. SA-β-Gal and p16INK4a immunostaining were significantly increased in both stresses compared to control. HG and HGP decreased phospho-p38 MAPK and increased p16INK4aprotein expression. HG and HGP decreased CDK4 and catalase expression. In conclusion, we found metabolic stresses like glucotoxicity and glucolipotoxicity increased beta cell senescence. Beta cell aging induced metabolic stress may related to phospho-p38 MAPK and p16INK4apathway, beta cell cycle and anti-oxidant system.

Generalized lipodystrophy associated with delayed neuro-somatic development and multiple dysmorphisms in a neonate with a compound heterozygous missense mutation in the SYNE2 gene

Caterina Pelosini[1,2], Giovanni Ceccarini[2], Paolo Aretini[3], Francesca Lorenzoni[4], Silvia Magno[2], Maria Adelaide Caligo[5], Maria Rita Sessa[1], Federica Ferrari[2], Paolo Ghirri[4] & Ferruccio Santini[6]
[1]Chemistry and Endocrinology Laboratory – University Hospital of Pisa, Pisa, Italy; [2]Obesity and Lipodystrophy Center – University Hospital of Pisa, Pisa, Italy; [3]Fondazione Pisana per la Scienza ONLUS, Pisa, Italy; [4]Neonatology Unit – University Hospital of Pisa, Pisa, Italy; [5]Molecular Genetics Laboratory, Santa Chiara University Hospital, Pisa, Italy; [6]Obesity and Lipodystrophy Center – University Hospital of Pisa, Pisa, Italy.

Generalized lipodystrophies are extremely rare diseases. Despite remarkable progress in identifying genes responsible for the most common forms of genetic lipodystrophies, the molecular basis of disease in some patients with distinctive phenotypes remains unclear. We herein describe the case of a male patient born from non-consanguineous parent affected by a syndrome characterized by generalized lipodystrophy, psycho-somatic growth retardation, cleft palate, macroglossia, right cryptorchidism, fingers with extended base and short femurs. In the third month of life, an abnormally increased appetite, the lack of weight growth and the dystrophic appearance became very evident. Moreover the ultrasound analysis revealed hepatic steatosis and blood test howed high triglyceride values (up to 1577 mg/dl), low serum leptin levels (0.1 ng/ml). Based on patient's clinical features, instrumental and laboratory results, Berardinelli-Seip syndrome was initially hypothesized. The entire coding region of candidate genes involved in congenital generalized lipodystrophy (BSCL1, AGPAT2, CAV1, PTRF) and other forms of lipodystrophy (LMNA) were sequenced by Sanger method but no mutations were found. To have a better insight on the possible genetic alterations causing the disease, we performed exome sequencing using Illumina NextSeq500. After data filtering and segregation analysis, we identified compound heterozygous missense variants in the spectrin repeat containing nuclear envelope protein 2 gene (SYNE2):c.18632C$>$ T (p.T89M) and c.20410G$>$ A (p.D326N). The first genetic variant is shared with the father, the second one with the mother. The mutation p.T89M is classified as patogenetic for Emery-Dreyfuss muscular dystrophy (EDMD) in ClinVar Database, and it was previously reported in two families with EDMD. In conclusion we describe a likely novel syndrome characterized by generalized lipodystrophy, severe delayed psycho somatic development and multiple dysmorphisms, possibly related to a compound heterozygous missense mutation in the SYNE2 gene.

Long-term administration of Empagliflozin may promote hepatic and renal lipid accumulation, and inflammation in the APOE knockout model

Anna Tsara[1], Narjes Nasiri-Ansari[1], Georgios K Dimitriadis[2], Stamatis Theocharis[3], Angeliki Karapanagioti1, Eougken Danas[3], Athanasios G Papavassiliou[1], Harpal S Randeva[2,4,5] & Eva Kassi[1,6]
[1]Department of Biological Chemistry, Medical School, National and Kapodistrian University of Athens, Athens, Greece; [2]Division of Translational and Experimental Medicine-Metabolic and Vascular Health, Warwick Medical School, University of Warwick, Coventry, UK; [3]Laboratory of Pathological Anatomy, Medical School, National and Kapodistrian University of Athens, Athens, Greece; [4]Human Metabolism Research Unit, WISDEM Centre, University Hospitals Coventry and Warwickshire NHS Trust, Coventry, UK; [5]Division of Life and Health Sciences, Aston University, Birmingham, UK; [6]1st Department of Internal Medicine, Laiko University Hospital, National and Kapodistrian University of Athens Medical School, Athens, Greece.

Introduction
Metabolic disorders characterized by insulin resistance/hyperinsulinemia, such as metabolic syndrome and T2DM, are associated with Non-Alcoholic Fatty Liver Disease (NAFLD). SGLT-2i reduce reabsorption of glucose from the kidneys thereby promoting glucosuria, while their beneficial effects on insulin resistance have been recently recognized. In this study, we aimed to investigate the effect of Empagliflozin, in *de novo* triglyceride synthesis and beta-oxidation as well as high-fat diet (HFD)-induced inflammation in the liver and kidneys of ApoE (−/−) male mice.
Methods
At the age of 5 weeks, mice were switched from normal to HFD. After 5 weeks, they were divided into Control-group (9 mice) and Empa-group (9 mice: empagliflozin 10 mg/kg per day). After 10 weeks, animals were culled and liver and kidneys were harvested. Biochemical markers were measured at the onset and at the end of the intervention. The mRNA levels of enzymes contributing in *de novo* triglyceride synthesis including GPAT1, GPAT3, GPAT4, AGPAT2, DGAT1, DGAT2 and beta oxidation (AMPKa 1 and 2) were measured by qPCR. Liver and kidney sections were stained with H&E and histomorphometric analysis was performed. Immunohistochemical staining with anti-MCP-1 and anti-CD-68 was also conducted to assess inflammation.
Results
Empa-group mice had lower glucose and HDL-cholesterol levels ($P \leq 0.01$), while total-cholesterol, LDL and triglycerides did not change significantly compared to control group. Histomorphometry indicated that Empagliflozin significantly induced lipid accumulation and infammation in both liver and kidney, compared to Control-group. Immunohistochemistry staining revealed an increase in CD68 and MCP-1 expression in the Empa-group compared to Control-group in both kidney and liver. GPAT3, AGPAT2 mRNA levels were increased in Empa-group compared to Control-group in both kidney and liver ($P < 0.05$). Empagliflozin also increased GPAT4, DGAT1 and DGAT2 mRNA levels in both kidney and liver approaching statistical significance ($P \leq 0.09$). AMPKa2 expression was up-regulated in the kidney of the Empa-group compared to the Control-group ($P \leq 0.01$) while no significant difference was observed in AMPKa 1 and 2 expression in the liver.
Conclusions
Our study revealed that long-term administration of Empagliflozin in ApoE (−/−) atherosclerosis mouse model, promotes NAFLD and induces lipid accumulation and inflammation in the kidney, at least partially via inducing the expression of enzymes involved in *de novo* synthesis of triglycerides and inflammatory process.

Applying the Bradford Hill criteria to evaluate the association between hypoglycaemia and cardiovascular events/mortality (CVEM) [Data from meta-analysis (MA), Randomized Controlled Trials (RCTs), and observational outcome studies (OBS)]

Pendar Farahani
McMaster University, Hamilton, Canada.

Background
The association between hypoglycaemia and CVEM is controversial. It is not ethical or practical to design RCTs to study this association as the primary clinical outcome measure. Therefore, utilization of epidemiological principles to study this association is essential.
Objective
To systematically explore the data from MA, RCTs and OBS on hypoglycaemia and CVEM applying Bradford Hill criteria [strength, consistency, dose response or biological gradient, specificity, temporality, biological plausibility, coherence, experimental evidence, and analogy].
Methods
A systematic literature search was performed using PubMed database, with several combinations of MeSH terms. Bibliography mining was also done on relevant articles to be as inclusive as possible.
Results
Strength: Three MAs demonstrated significant increase in CVEM; data driven from RCTs and OBS illustrated Hazard Ratio (HR) of 2.0 and 4.0, respectively. Consistency: Four RCTs and two OBS with entirely different populations illustrated increase in CVEM related to hypoglycaemia. Dose response or biological gradient: One MA demonstrated HR of 1.6 for mild hypoglycaemia versus 2.3 for severe hypoglycaemia. Specificity, temporality, biological plausibility and coherence: Not possible to assess directly through studies with CVEM measures; these criteria can be fulfilled by biological and physiological studies; hypoglycemia leads to abnormalities in myocardial perfusion, thrombotic process, cardiac repolarization; these abnormalities could potentially lead to increased risk of CVEM. Temporality has been shown with studies that utilized continuous glucose monitoring and ECG, simultaneously. Experimental evidence: Evidence exists from both interventional and observational studies with hard and surrogate outcomes. Analogy: Collectively the data from biological, physiological and outcome studies for heart disease such as heart failure illustrated increase in CVEM in population without and with diabetes through same pathways that have been observed for hypoglycaemia.
Conclusion
Available data from literature collectively illustrates that the association between hypoglycaemia and cardiovascular events fulfil Bradford Hill criteria for association.

Magnitude of effects of testosterone replacement therapy on testosterone normalization, parameters of metabolic syndrome and vascular function and morphology in obese hypogonadal patients with type 2 diabetes – the SETH2 study

Kristina Groti Antonic
University Medical Centre, Ljubljana, Slovenia.

Background
The association between testosterone deficiency, metabolic syndrome (MetS) and type 2 diabetes (T2DM) is well established. Male hypogonadism is related to an increase in glycometabolic and cardiometabolic complications.
Objective
To evaluate magnitude of effects of testosterone replacement therapy (TRT) on testosterone normalization, parameters of the MetS and vascular function and morphology in obese hypogonadal male patients with T2DM.
Study design
SETH2 was a randomized, double blind, placebo-controlled clinical study of 55 obese diabetic males not treated with insulin, with confirmed late-onset hypogonadism. Two study groups were formed. Group T patients ($n = 28$) were treated with testosterone undecanoate (1000 mg depot injection administered i.m. at first visit, with second injection following six weeks later and the remaining ones every 10 weeks following the previous) while group P patients ($n = 27$) received placebo.
Methods
Ultrasound assessment of endothelial function – flow mediated dilatation (FMD) of brachial artery and vascular morphology of carotid artery (intima media thickness - IMT), biochemical and hormonal blood sample analyses were performed at baseline and after one year. Effect size was assessed using Cohen's d (with 95% confidence interval for Cohen's d).
Results
TRT resulted in a statistically significant decrease of fasting plasma glucose (1.23 ± 1.25 mmol/l, $P < 0.001$; d = 1.07, 95% CI: 0.51 – 1.64), HbA1c (0.94 ± 0.88% points, $P < 0.001$; d = 1.03, 95% CI: 0.47 – 1.59), HOMA-IR (4.64 ± 4.25, $P < 0.001$; d = 1.23, 95% CI: 0.66 – 1.81) and an increase in total (9.80 ± 3.59 nmol/l, $P < 0.001$; d = 2.78, 95% CI: −3.62 – −2.12), calculated bioavailable (5.76 ± 2.16 nmol/l, $P < 0.001$; d = 2.79, 95% CI: −3.53 – −2.05) and calculated free testosterone (248.29 ± 99.45 pmol/l, $P < 0.001$; d = 2.61, 95% CI: −3.33 – −1.89) and FMD (2.40 ± 4.16% points, $P = 0.005$; d = 0.66, 95% CI: −1.20 – −0.12). IMT has decreased in both groups; by 0.10 ± 0.06 mm ($P < 0.001$) in group T and by 0.05 ± 0.09 mm ($P = 0.006$) in group P; d = 0.66, 95% CI: 0.11 – 1.20. No statistically significant effects were observed on other parameters of MetS.

Conclusion
TRT exerted very large effects on levels of testosterone (d ranging from 2.61 to 2.78) and on some parameters of MetS (d ranging from 1.03 to 1.25) with moderate effect on vascular function (d = 0.65) and morphology (d = 0.66).

DOI: 10.1530/endoabs.63.GP42

GP43

The elevated chemerin plasma concentrations in men diagnosed with metabolic syndrome are correlated with markers of low-grade state inflammation but not with SHBG serum levels and accompanying hypoandrogenemia.

Waldemar Herman[1], Piotr Jarecki[2], Barbara Kołodziejczak[3], Marlena Wójcicka[4], Jacek Losy[4,5] & Katarzyna Łęcka[6]
[1]Outpatients Unit of Endocrine Diseases, Wschowa, Poznan, Poland; [2]University of Medical Sciences, Student Scientific Club, Poznan, Poland; [3]University of Medical Sciences, Department of Computer Science and Statistics, Poznan, Poland; [4]University of Medical Sciences, Department of Clinical Neuroimmunology, Poznan, Poland; [5]Mossakowski Medical Research Centre-Neuroimmunological Unit, Polish Academy of Sciences, Poznan, Poland; [6]University of Medical Science Department of Endocrinology, Metabolism and Internal Medicine, Poznan, Poland.

Background
Chemerin (CHEM) is a newly-discovered adipokine involved in the immune, metabolic and reproductive processes. Low-grade state inflammation (LGSI) is a key element in the pathogenesis of metabolic syndrome (MS).
Objectives
The aim of the study was to assess the effect of age on MS prevalence, androgenic status as well as on selected inflammatory indices and CHEM plasma concentrations. Additionally we investigated correlations between CHEM and age-dependent serum androgen changes in addition to LGSI parameters in males diagnosed with MS compared to healthy subjects.
Materials and methods
For the study 149 men aged 40 to 70 years were enrolled. They were divided into four equal numbers groups. Measurement of anthropometric indices, blood pressure and laboratory tests included fasting plasma glucose, lipids, CHEM, selected androgens, IL–18, hs-CRP and SHBG were carried out.
Results
The criteria for diagnosis of MS were fulfilled a total of 67 men (45%). The incidence on MS did not increase with age ($P = 0.533$). Both adrenal androgens decreased with age (DHEA: $P = 0.0042$; DHEAS: $P < 0.0001$), as opposed to total ($P = 0.955$) and free testosterone ($P = 0.526$) as well as SHBG ($P = 0.074$). CHEM concentrations increased with age ($P = 0.0089$) and were higher in men diagnosed with MS compared to healthy subjects: 90.18 (53.7–190.61) vs. 73.64 (15.58–236.55) ng/mL; $P = 0.0002$. Men diagnosed with MS revealed a significantly lower total testosterone serum level: 5.3 (2.0–15.2) vs. 6.3 (2.3–34.2) ng/mL; $P = 0.0004$ and SHBG: 45.62 (17.17–120.31) vs. 71.97 (24.83–193.31) nM/L; $P < 0.000001$. Furthermore, elevated LGSI indices have been demonstrated in men suffering from MS, as opposed to healthy ones [IL-18: 530.64 (261.46–944.97) vs. 418.85 (200.54–791.08) pg/mL; $P = 0.000045$ and hs-CRP: 2.03 (0.31–38.0) vs.0.97 (0.08–90.3) ng/mL; $P = 0.0016$)]. CHEM plasma concentrations were correlated with some components of MS (systolic blood pressure, HDL-cholesterol, triglycerides and waist circumference). Additionally, CHEM serum levels were clearly correlated with LGSI indices: hs-CRP ($R = 0.265$; $P = 0.001$) and IL-18 ($R = 0.375$; $P = 0.000009$)- regardless of age, smoking, metabolic status and androgenemia. In contrast, CHEM plasma levels revealed no statistically significant relationships with androgenemia and SHBG plasma levels.
Conclusions
The elevated CHEM plasma concentrations detected in obese men diagnosed with MS are closely related to accompanying LGSI than to androgen deficiency.

Effects of anti-inflammatory treatment on fibroblast growth factor-21 in obesity and metabolic syndrome

Fahim Ebrahimi[1], Sandrine Urwyler[1], Matthias Betz[1], Emanuel Christ[1], Philipp Schuetz[2], Beat Mueller[2], Marc Donath[2] & Christ-Crain Mirjam[1]
[1]University of Basel Hospital, Basel, Switzerland; [2]University Department of Medicine Kantonsspital Aarau, Aarau, Switzerland.

Background
Fibroblast growth factor-21 (FGF21), which has recently been identified as a central regulator of metabolism, is known to be increased in conditions of obesity, insulin resistance, and fatty liver. Likewise, there is evidence that FGF21 increases with systemic inflammation. The aim of this study was to evaluate whether chronic low-grade inflammation might be the underlying mechanism and whether an anti-inflammatory treatment decreases FGF21 levels in metabolic disorders.
Methods
This is a secondary analysis of two interventional studies of treatment with an Interleukin-1 (IL-1)-receptor antagonist anakinra (Kineret®) in patients with obesity and features of the metabolic syndrome. The CortIL trial was a prospective interventional trial ($n = 61$) investigating short-term effects of anakinra and dexamethasone in metabolic syndrome. The TestIL trial was a placebo controlled, double-blinded interventional trial ($n = 67$) investigating longer-term effects of anakinra in metabolic syndrome versus placebo. FGF21 was measured at baseline, at day 2 and at 4 weeks of treatment with anakinra. Furthermore, FGF21 levels were measured after dexamethasone suppression test.
Results
Mean age of all includes patients ($n = 140$) was 54 years (SD 12.1), 26% were female and the mean body mass index (BMI) was 37 kg/m2 (SD 4.8). Almost half of the patients were diabetic (45%) and had slightly increased c-reactive protein levels of 4.7 mg/L (SD 5.4), mirroring a state of chronic low-grade inflammation. FGF21 levels highly positively correlated with fasting glucose levels, HOMA-index, c-peptide levels, HbA1c and BMI. Treatment with anakinra led to a short-term reduction of FGF21 levels by 49.0 pg/mL (95% CI, (−205.9) – 107.9); $P = 0.064$; however, this effect was no longer visible at 4 weeks (between-group difference: −8.8 pg/mL (95% CI, (−130.9) – 113.3); $P = 0.89$. Short-term treatment with dexamethasone was associated with profound reduction of FGF21 by 174.5 pg/mL (95% CI, (−235.8) – (−113.2)); $P < 0.001$.
Conclusions
Anti-inflammatory treatment led to a reduction of FGF21 levels in individuals with obesity and features of the metabolic syndrome. Chronic low-grade inflammation may be one of the key mediators for increased FGF21 in metabolic disorders.

Hypoglycemia and dementia risk in older patients with type 2 diabetes: a propensity-score matched analysis of a population-based cohort study

Seung Jin Han[1], Young-Gun Kim[2] & So Young Moon[1]
[1]Ajou University School of Medicine, Suwon, Republic of Korea; [2]Ajou University Graduate School, Suwon, Republic of Korea.

Background
Type 2 diabetes mellitus (T2DM) is associated with an increased risk for dementia. The effects of hypoglycemia on dementia are controversial. Thus, we evaluated whether hypoglycemia increases the risk for dementia in senior patients with T2DM.
Methods
We used the Korean National Health Insurance Service Senior cohort, which includes >10% of the entire senior population of South Korea. In total, 7,752 patients who had ever experienced hypoglycemia were matched with those who had not, using propensity score matching. Forty-eight confounding variables, including age, socioeconomic status, medication use, and underlying diseases, which may affect dementia, were corrected for propensity score matching. The risk of dementia was assessed through a survival analysis of matched pairs.
Results
Patients with underlying hypoglycemic events had an increased risk for all-cause dementia, Alzheimer's dementia (AD), and vascular dementia (VaD) compared with those who had not experienced a hypoglycemic event (hazard ratio [HR] 1.254, 95% confidence interval [CI] 1.166–1.349, $P < 0.001$ for all-cause dementia; HR 1.264, 95% CI 1.162–1.375, $P < 0.001$ for AD; HR 1.286, 95% CI 1.110–1.490, $P < 0.001$ for VaD). In the subgroup analysis, hypoglycemia was associated with an increased risk for dementia in both sexes with or without T2DM microvascular or macrovascular complications.
Conclusions
Our findings suggest that patients with a history of hypoglycemia have a higher risk for dementia. This trend was similar for AD and VaD, the two most important subtypes of dementia.

Characteristics and management of Type 1 diabetes mellitus patients with diabetic ketoacidosis

Yan Ling Ong[1] & Cherng Jye Seow[2]
[1]Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore; [2]Tan Tock Seng Hospital, Singapore, Singapore.

Background & Objectives
Type 1 diabetes mellitus (T1DM) is a complex disease with both genetic and environmental factors in its pathophysiology. Higher risks of diabetic emergencies such as diabetic ketoacidosis (DKA) confers a greater difficulty in its management than Type 2 diabetes. This study aims to describe and compare the characteristics, management and outcomes of T1DM patients with and without complication of DKA.
Methods
A total of 333 T1DM patients who visited a tertiary hospital for clinic follow-up of T1DM in Singapore from May 2017 to October 2017 was studied. Patients were then stratified based on presence or absence of DKA after the initial diagnosis. Relevant demographics, pharmacological and non-pharmacological management and outcomes were analysed.
Results
Amongst the T1DM patients, 133 (39.9%) had at least one subsequent DKA episode while 200 patients (60.1%) did not. Greater proportion of patients with subsequent DKA episodes first presented with DKA before diagnosis of T1DM (DKA 62.7% vs No DKA 34.2%, $P<0.01$). Average HbA1c over the last 1-year was higher in patients with DKA than those without DKA (DKA 9.52 ± 1.85% vs. No DKA 8.55 ± 1.72%, $P<0.01$). Incidence of microvascular complications were higher in patients with DKA (50.0% vs 33.5%, $P<0.01$) while incidence of macrovascular complications was similar in both groups (12.9% vs 14.5%, $P=0.70$). Furthermore, hypoglycemic admissions were more common in patients with DKA (24.8% vs 10.0%, $P<0.01$). In terms of non-pharmacological management, compliance to self-blood glucose monitoring (59.4% vs 73.9%, $P<0.01$) and DM education class uptake (7.5% vs 22.6%, $P<0.01$) was poorer in patients with DKA than those without DKA. However, there was no significant difference seen in use of continuous glucose monitoring (DKA: 15.8% vs no DKA: 22.6%, $P=0.13$) or use of insulin pumps (4.0% vs 2.3%, $P=0.54$).
Conclusion
This study highlights the differences in characteristics, complications and management of T1DM with and without subsequent DKA episodes. It suggests that increased emphasis on educating management of hypoglycaemia and DM education classes would be beneficial for the control of T1DM. Moreover, importance of compliance to self-blood glucose monitoring should also be reinforced. Further studies will be required to optimise management of T1DM patients and to prevent future diabetic emergencies in these patients.

Awareness, treatment rates and compliance to treatment in patients with serum LDL cholesterol higher than 250 mg/dL, and possible, probable and definite familial hypercholesterolemia

Samet Yaman[1], Didem Ozdemir[2], Busra Tugce Akman[1], Bekir Cakir[2] & Osman Ersoy[3]
[1]Ankara Yildirim Beyazit University, Ataturk Education and Research Hospital, Department of Internal Medicine, Ankara, Turkey; [2]Ankara Yildirim Beyazit University, Ataturk Education and Research Hospital, Department of Endocrinology and Metabolism Diseases, Ankara, Turkey; [3]Ankara Yildirim Beyazit University, Ataturk Education and Research Hospital, Department of Gastroenterology, Ankara, Turkey.

Aim
Familial hypercholesterolemia (FH) is an autosomal dominant genetic disease characterized by increased levels of low density lipoprotein cholesterol (LDL-chol). Despite relatively high prevalance and significant association with increased mortality, the awareness of physicians and patients is low and it is an underdiagnosed and undertreated disease. We aimed to detect patients with FH and determine treatment status and compliance.
Materials and methods
Patients >18 years old and have a serum LDL-chol $\geq$250 mg/dL between January 2010-December 2016 were identified from the database of our hospital. A survey was performed by reaching patients via phone. Demographic features, smoking status, use of alcohol, exercise, presence of cardiovascular disease (CVD), use of medication for dyslipidemia, CVD and high cholesterol levels in the family were questioned. Patients with a serum thyrotrophin $\geq$10 mIU/mL, patients with glomerulonephritis and nephrotic syndrome, patients with high liver enzymes and patients with serum triglyceride >400 mg/dL were excluded. DUTCH lipid diagnostic criteria was used to classify patients.
Results
LDL-chol was $\geq$250 mg/dL in 1918 measurements. When repeated measurements were excluded, 1365 patients were identified. Patients that could not be reached by phone and who refused to interview were excluded and data of 367 patients were analyzed. There were 248 (67.6%) female and 119 (32.4%) male patients and mean age was 50.5 ± 11.66. LDL-chol was $\geq$330 mg/dL in 50 (13.6%) and 250–329 mg/dL in 317 (86.4%) patients. Mean DUTCH score was 6.36 ± 1.63. 40 (10.9%) patients were classified as definite, 181 (49.3%) as probable and 146 (39.8%) as possible FH. Among patients with definite or probable FH, 84 (38.0%) had CVD. DUTCH scores were 8.09 ± 1.54 and 6.74 ± 1.31 in patients with and without CVD, respectively. Considering all patients, 42% were taking medication for dyslipidemia. Among 213 patients that were not on antilipidemic treatment, 162 (76.1%) stated that medication was never recommended previously, 30 (14.1%) had stopped medication him/herself and 21 (9.8%) had stopped medication with the advice of the physician. 49 (58.3%) definite or probable FH patients with CVD was taking antilipidemic treatment.
Conclusion
A significant proportion of patients with LDL-chol $\geq$250 mg/dL were not taking antilipidemic drugs and other cardiovascular risk factors were not under control. Similar with many other countries, diagnosis and treatment rates of FH patients were very low in our country. Further national studies are required to increase awareness of the disease in both physicians and patients.

Prolonged diagnostic delay in acromegaly is associated with long-term morbidity and excess mortality: data from a nationwide study

Daniela Esposito, Oskar Ragnarsson, Gudmundur Johannsson & Daniel S Olsson
Department of Endocrinology, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg and Sahlgrenska University Hospital, Gothenburg, Sweden.

Background
Clinical features of acromegaly develop insidiously and the diagnosis is often delayed. However, diagnostic delay (DD) in acromegaly has not been systematically investigated. Our primary aim was to investigate DD in a nationwide cohort of patients with acromegaly. Secondary aim was to study the impact of DD on morbidity and mortality.
Methods
Adult patients diagnosed with acromegaly between 2001 and 2013 were identified in the Swedish National Patient Registry. Forty-four diagnostic codes for predefined comorbidities associated with acromegaly, registered from 1987 to 2013, were recorded. The DD was calculated as the time between the first registered comorbidity and the diagnosis of acromegaly.
Results
A total of 603 patients with acromegaly (mean age at diagnosis: 51.8 ± 15.3 years) were included (280 men, 323 women). The mean DD was 5.5 ± 6.2 years (median 3.3; range 0.0–9.4), with a tendency towards a longer DD in women than in men [median 4.1 (0.1–10.6) *vs* 2.7 (0.0–8.0); $P=0.055$]. DD was 1–<5 years in 23% patients; 5–<10 years in 17%; and $\geq$10 years in 24%. Patients without comorbidities and those with comorbidities identified within a year before the acromegaly diagnosis, or later, were analysed as a single group, named *patients without DD* (36%). Of 603 patients, 579 (96%) had comorbidities at any time during the study period. The median number of comorbidities was 4.0 (2.0–5.0), and was significantly higher in patients with longer DD ($P<0.0001$). The most frequent comorbidities were neoplasms, excluding pituitary tumours (61%), cardiovascular (57%), and musculoskeletal (51%) diseases, with a higher frequency in patients with longer DD ($P<0.0001$). The longest DD was found for neurological-psychiatric symptoms (4.6 ± 6.3 years) and the shortest for local effects; *e.g.* symptoms due to tumor compression of surrounding structures (1.7 ± 3.4 years). DD for cardiovascular, musculoskeletal disorders, and neoplasms was 2.6 ± 4.5, 3.4 ± 4.9, and 3.7 ± 5.4 years, respectively. The observed number of deaths was 61, and expected number 42.2, resulting in a standardized mortality ratio of 1.45, 95% CI 1.11–1.86. Excess mortality was only found in patients with *DD* $\geq$*10 years* (1.76, 95% CI 1.12–2.65) whereas mortality was similar to the general population in the groups with shorter DD [*1–<5 years*, 1.32 (95% CI 0.68–2.31); *5–<10 years* 1.54 (95% CI 0.74–2.83)] as well as in patients *without DD* (1.18; 95% CI 0.68–1.92).

Conclusions
Our findings suggest that diagnosis of acromegaly is delayed in a substantial number of patients. The delay of the acromegaly diagnosis is associated with excess morbidity and mortality.

Pharmacokinetics of somapacitan in individuals with renal impairment: an open-label, parallel group, phase 1 study

Birgitte Bentz Damholt, Charlotte Bisgaard, Sarah Louise Dombernowsky & Michael Højby Rasmussen
Novo Nordisk A/S, Søborg, Denmark.

Background
Somapacitan is a reversible albumin-binding growth hormone (GH) derivative developed for once-weekly administration that acts directly or indirectly via insulin-like growth factor I (IGF-I). As renal impairment may affect drug metabolism and excretion, we report data from an open-label, parallel group, phase I trial (NCT03186495) investigating the pharmacokinetic and pharmacodynamic properties, and safety of somapacitan in individuals with varying degrees of impaired renal function or normal renal function classified by glomerular filtration rate (GFR).
Methods
Participants were enrolled in five renal function groups in a planned ratio of 16:8:8:8:8 corresponding to normal renal function, mild renal impairment, moderate renal impairment, severe renal impairment, and requiring haemodialysis treatment, respectively. Participants received a total of three somapacitan administrations (0.08 mg/kg), one per week for 3 weeks.
Results
Forty-four participants were included: normal function, $n=15$; mild impairment, $n=8$; moderate impairment, $n=8$; severe impairment, $n=5$; requiring haemodialysis, $n=8$. Reported data are estimated ratios [90% CI]. Compared with the normal function group, steady-state exposure ($AUC_{0–168h}$) was higher for the severe renal impairment (1.75 [1.00;3.06]) and requiring haemodialysis (1.63 [1.01;2.61]) groups, and similar for the mild (1.25 [0.74;2.11]) and moderate renal impairment (1.27 [0.77;2.07]) groups. C_{max} was similar for all groups (mild impairment, 1.31 [0.71;2.39]; moderate impairment, 1.40 [0.79;2.47]; severe impairment, 1.47 [0.77;2.81]; requiring haemodialysis, 1.34 [0.77;2.32]) compared to the normal renal function group. $AUC_{IGF\text{-}I,0–168h}$ was increased in the moderate (1.35 [1.09;1.66]) and severe renal impairment (1.40 [1.10;1.78]), and requiring haemodialysis groups (1.24 [1.01;1.52]), versus the normal function group. $AUC_{IGFBP\text{-}3,0–168h}$ increased in all renal impairment groups (mild 1.12 [0.99;1.27]; moderate 1.18 [1.06;1.32]; severe 1.36 [1.20;1.55]; requiring haemodialysis 1.53 [1.37;1.70]) versus the normal function group. No unexpected safety signals were reported.
Conclusions
Degree of renal impairment affected steady-state exposure; individuals with severe renal impairment or requiring haemodialysis had significantly higher somapacitan exposure. Increased exposure was likely related to a decreased GFR, indicating that somapacitan, at least in part, is cleared through the kidneys. Increased levels of IGF-I (in the moderate and severe renal impairment, and requiring haemodialysis groups) and IGFBP-3 (in all renal impairment groups) were likely due to increased somapacitan exposure. Patients with severe renal disease or requiring haemodialysis may require lower doses of somapacitan compared to patients with normal renal function, owing to the increased somapacitan exposure. However, as somapacitan is planned to be individually dose-titrated, no specific adjustments to the dosing recommendations are relevant.

Sleep disorders and cognitive dysfunction in acromegaly

Francesca Dassie[1], Alexandra Wennberg[2], Riccardina Lorusso[1], Matteo Parolin[1], Lucia Russo[1], Sara Mazzocut[1], Silvia Benavides-Varela[3], Eugenio De Carlo[1], Chiara Martini[1], Roberto Vettor[1], Carlo Semenza[2] & Pietro Maffei[1]
[1]DIMED, University of Padua, Padua, Italy; [2]DNS, University of Padua, Padua, Italy; [3]DPSS, University of Padua, Padua, Italy.

Background
In the general population, sleep disorders are associated with an increased risk of cognitive impairment; moreover, people with dementia often have sleep disturbances. The prevalence of sleep disorders, such as sleep apnea, in acromegalic patients is higher than in the general population, and they may have a higher risk of cognitive impairment due to acromegaly treatment (i.e. Radiotherapy) or cardiovascular comorbidities. In the literature, data about the relationship between sleep disorders and cognitive dysfunction in acromegaly are scant.
Aim
We aim to study the relationship between sleep disturbances and cognitive dysfunction in a group of acromegalic patients.
Methods
We studied 67 consecutive acromegalic patients at different stages of the disease. We performed a neurocognitive assessment with the following tests: Babcock Story Recall Test, Digit Span Test forward and backward, Corsi Block-Tapping test forwards and backwards, Complex Figure Test, Stroop Color and Word Test, Frontal Assessment Battery, Trail Making Test, phonemic and semantic fluency. Patients also completed the Acromegaly Quality of Life Questionnaire (AcroQoL), Epworth Sleepiness Scale, and Pittsburgh Sleep Quality Index. We also collected clinical, endocrinological, and metabolic data.
Results
Of the 67 acromegaly patients in the study, 38.8% were male, median age of diagnosis was 45 years (interquartile range IQR 35, 53), median age at the neurological examination was 56 (IQR 48, 65) and mean IGF-1 was 441.88 ug/L (3 patients were first diagnosis, 4 patients had a cured disease). Most participants performed within the normal range of cognitive tests, however, approximately 6-10% were impaired, depending on the test. In linear regression models adjusted for age, sex, BMI, disease duration, and disease activity, poorer sleep quality was associated with lower global cognitive z-score ($B=-0.03$, 95% CI -0.06, -0.002). Daytime somnolence was associated with poorer physical QoL subscore ($B=-0.04$, 95% CI -0.08, -0.002). Sleep quality was associated with poorer overall QoL ($B=-0.03$, 95% CI -0.05, -0.006), physical QoL ($B=-0.04$, 95% CI -0.07, -0.005), psychological QoL ($B=-0.02$, 95% CI -0.04, -0.001), and social QoL ($B=-0.02$, 95% CI -0.04, -0.0009).
Conclusions
In acromegaly, we found that poor sleep quality is associated with lower QoL, and some evidence that is associated with lower cognitive function.

Prognostic value of short-acting pasireotide test for response prediction to pasireotide LAR in patients with acromegaly resistant to first-generation analogs. Can a short-acting pasireotide test predict the response of long-acting pasireotide treatment in patients with acromegaly resistant to first generation somatostatin analogs?

Agnieszka Majos[1], Maria Stelmachowska-Banaś[1], Izabella Czajka-Oraniec[1], Jakub Gęsior[2,3] & Wojciech Zgliczyński[1]
[1]Endocrinology Department, Centre of Postgraduate Medical Education, Warsaw, Poland; [2]Faculty of Health Sciences and Physical Education, Kazimierz Pulaski University of Technology and Humanities, Radom, Poland; [3]Clinical Department of Cardiology of Institute of Cardiology, Bielanski Hospital, Warsaw, Poland.

Introduction
The treatment of choice in acromegaly is a transsphenoidal surgery of a growth hormone (GH) - producing pituitary adenoma. In patients with persistent acromegaly after surgery medical treatment is recommended. First generation somatostatin analogs: lanreotide autogel and octreotide LAR are effective in 25% to 45% of patients depending on population and study protocol. Second-generation somatostatin analog – pasireotide LAR seems to be more effective. The possibility to indicate clinical predictive factors of pasireotide LAR response could help in selecting patients who would benefit the most from the treatment.
Aim
The aim of the study was to check if the response to short-acting pasireotide can predict the efficacy of treatment with pasireotide LAR in patients with active acromegaly resistant to first-generation somatostatin analogs.
Patients and methods
Twenty four patients with active acromegaly after surgical debulking treated with first-generation somatostatin analogs were enrolled in the prospective study. After two-month wash-out period all patients had a test with short-acting pasireotide performed (GH measurements 0, 60, 120 and 180 minutes after s.c. administration of 600 μg of short-acting pasireotide) and were then switched to pasireotide LAR 60 mg administered i.m. every 28 days for 3 months. The effects of pasireotide LAR on GH, IGF-1, insulin, glucose and HgbA1c concentrations and the predictive value of the test were analysed after 3-month treatment.

Results
After 3 months of treatment with pasireotide LAR eight patients (33%) reached GH < 1 μg/l, fifteen patients (62.5%) reached GH < 2.5 μg/l. Four patients (16.7%) reached IGF-1 < 1 × upper limits of normal (ULN), eleven patients (45.8%) IGF-1 < 1.5 × ULN. There was a significant decrease in median GH and the mean IGF-1 after pasireotide LAR treatment vs first-generation somatostatin analogs: 1.66 μg/l (IQR:0.24–12.1) vs 2.88 μg/l (IQR:0.75–9.3), $P < 0.001$ and 1.49 ± 0.582 × ULN vs 2.31 ± 0.696 × ULN, $P < 0.001$, respectively. Pasireotide LAR was well tolerated, but hyperglycemia was the most frequent adverse event. Insulin decreased: 10 (IQR:2.4–46.8) vs 7.1 μIU/ml (IQR:1.3–25) $P = 0.001$ and fasting glucose increased: 104 (IQR:84–191) vs 119 (IQR:96–453) mg/dl, $P < 0.001$) within 3 months of pasireotide treatment. We found a statistical significant correlation between a maximal GH decrease during the short-acting pasireotide test and GH and IGF-1 after 3-month treatment ($R = 0.57$, $P < 005$ and $R = 0.56$, $P < 0,05$ respectively).
Conclusions
Pasireotide LAR is more effective in decreasing GH and IGF-1 levels than first-generation somatostatin analogs in acromegalic patients after surgical debulking. Better efficacy of pasireotide LAR is correlated with higher GH decrease after administration of 600 ug short-acting pasireotide.

Final height in childhood onset hypopituitarism

Andrea Esposito[1], Nicola Improda[1], Cristina Moracas[1], Flavia Barbieri[1], Sara Alfano[1], Donatella Capalbo[2] & Mariacarolina Salerno[1]
[1]Pediatric Endocrine Unit, Department of Translational Medical Sciences, University of Naples Federico II, Naples, Italy; [2]Department of Pediatrics, University of Naples Federico II, Naples, Italy.

Background
Growth hormone (GH) deficiency(GHD) in childhood is associated with impairment in linear growth. GH therapy enables the achievement of normal adult height in most cases. The response is variable and factors influencing height outcome are still not clearly defined.
Objective
To evaluate near adult height (NAH) in a single center cohort of childhood onset GHD patients treated with GH and investigate main predictors of final height (FH) .
Patients and methods
80 GHD-patients (41M-39F) followed from the diagnosis to the achievement of NAH were enrolled. Mean age at diagnosis was 9.9 ± 4.0 years. 79% of patients (63/80) had isolated GHD (IGHD), 21% (17/80) had multiple pituitary hormone deficiency(MPHD) and received hormone replacement as necessary. Structural abnormalities of the pituitary gland were detected in 40 patients. Height, Height velocity (HV) and IGF-1 were evaluated at diagnosis, at the end of the first year of treatment, at onset of puberty and at the attainment of NAH and were expressed as standard deviation score (SDS) according to reference standards. Change in HSDS (Δ) from baseline to the different end points was calculated.Multiple regression analysis was used to evaluate predictor of FH.
Results
At diagnosis HSDS (−2.53 ± 0.94), HVSDS (−2.47 ± 1.69) and IGF1SDS (−1.23 ± 1.24) were below normal ranges. After 1 year of GH, HSDS (−1.86 ± 0.84, $P < 0.0001$), HVSDS (3.03 ± 2.79, $P < 0.0001$) and IGFISDS (0.34 ± 1.24, $P < 0.0001$) significantly improved. At puberty onset, mean age of patients was 12.52 ± 1.67 years. ΔHSDS from baseline to pubertal onset was significantly higher in MPHD vs IGHD (3.03 ± 1.66 vs 0.6 ± 0.68, $P < 0.0001$) while was comparable between males and females. NAHSDS (−0.87 ± 0.98), achieved at a mean age of 16.94 ± 1.51 years, was significantly higher compared to baseline ($P < 0.0001$), and was higher in patients with MPHD vs patients with IGHD (−0.47 ± 1.15 vs −0.98 ± 0.91, $P < 0.05$). Although NAHSDS was higher in males vs females (−0.65 ± 0.9 vs −1.11 ± 1.02, $P < 0.05$), the total gain in HSDS was comparable between the two sexes (1.66 ± 0.91 vs 1.64 ± 1.09, P = ns). Multiple regression analysis showed that NAH correlated with sex ($P < 0.05$), severity of GHD ($P < 0.05$), diagnosis ($P < 0.0001$), age at diagnosis ($P < 0.0001$), HV in the 1° year of treatment ($P < 0.0001$), H at onset of puberty ($P < 0.0001$), prepubertal ΔHSDS ($P < 0.0001$) and duration of treatment ($P < 0.0001$).
Conclusion
GH treatment enables the achievement of normal NAH.Early treatment and optimization of prepubertal growth are important to obtain a better growth response. Patients with severeGHD and MPHD have a greater gain in height and NAH than patients with mildGHD and IGHD.

Efficacy and safety of once-weekly somapacitan in adult growth hormone deficiency (AGHD) confirmed in a 53-week REAL-1 trial extension

Gudmundur Johannsson[1], Murray Gordon[2], Michael Højby Rasmussen[3], Ida Holme Håkonsson[3], Claus Sværke[3], Shigeyuki Tahara[4], Koji Takano[5] & Beverly MK Biller[6]
[1]Sahlgrenska University Hospital, Göteborg, Sweden; [2]Allegheny Neuroendocrinology Center, Allegheny General Hospital, Pittsburgh, Pennsylvania, USA; [3]Novo Nordisk A/S, Søborg, Denmark; [4]Nippon Medical School, Tokyo, Japan; [5]Kitasato University, Tokyo, Japan; [6]Neuroendocrine Unit, Massachusetts General Hospital, Boston, Massachusetts, USA.

Background
Following the 34-week, double-blind, placebo-controlled main phase of REAL-1 (NCT02229851), this open-label trial extension evaluated efficacy and safety of somapacitan in patients aged 23–79 years with AGHD, for an additional 52 weeks (8 weeks' dose titration followed by 44 weeks' fixed dose treatment; 86 weeks' treatment in total).
Methods
Patients completing the main trial entered the extension: 1) somapacitan-treated patients continued on that treatment; 2) daily growth hormone (GH)-treated patients were re-randomised 1:1 to somapacitan or daily GH; 3) patients receiving placebo were switched to somapacitan. Starting doses were age- and gender-dependent and titrated towards a target insulin-like growth factor-I standard deviation score (IGF-I SDS) −0.5 to +1.75. Changes from the original baseline to end of extension period in body composition were evaluated by dual-energy X-ray absorptiometry (truncal fat %, truncal fat mass, visceral adipose tissue %, visceral adipose tissue, total fat mass, android fat mass, gynoid fat mass, truncal lean body mass, appendicular skeletal muscle mass, and lean body mass). IGF-I SDS and lipid profiles were also compared. Exploratory analyses on changes from baseline were based on mixed models of repeated measures, comparing somapacitan/somapacitan and daily GH/daily GH arms. 300 patients were treated in the main phase and 272 (91%) in the extension.
Results
Mean patient age was 45.1 years; 51.7% were female. Mean exposure (during the extension alone) was 355 (somapacitan/somapacitan) and 349 days (daily GH/daily GH), respectively. After 86 weeks' treatment, target IGF-I SDS were achieved in all treatment arms (mean values [SD], somapacitan/somapacitan: from −2.54 [1.26] to −0.22 [1.27]; placebo/somapacitan: −2.64 [1.28] to −0.31 [1.08]; daily GH/daily GH: −2.33 [1.28] to −0.24 [1.32]; daily GH/somapacitan: −2.75 [1.20] to −0.39 [1.12]). The beneficial effects of somapacitan on body composition observed in the main phase were maintained and did not differ statistically significantly between the somapacitan/somapacitan and daily GH/daily GH arms ($P > 0.05$). There were no statistically significant differences in IGF-I SDS or lipid parameters between the somapacitan/somapacitan and daily GH/daily GH arms. Incidence, severity and type of adverse events were similar for somapacitan and daily GH treatment. Few injection site reactions were reported and all were mild to moderate in severity. No anti-somapacitan antibodies were detected.
Conclusions
Body composition changes and IGF-I SDS observed in the main phase of REAL-1 were maintained in the trial extension. No new safety signals/tolerability issues were identified for somapacitan.

GP54

Pharmacokinetics in patients with prolactinomas

Natalia Fedorova, Larisa Dzeranova, Ekaterina Pigarova & Svetlana Vorotnikova
Endocrinology Research Centre, Moscow, Russian Federation.

Introduction
Prolactinoma is the most commonly occurring hormonally active pituitary tumor. In most cases, dopamine receptor agonists (DA) as a monotherapy are effective. However, approximately 10% of patients with prolactinomas fail to achieve normalization of serum prolactin levels during treatment with DA, which indicates resistance to this group of drugs.
Aims
The goal was to study the pharmacokinetics of cabergoline in patients harboring prolactinomas sensitive and resistant to cabergoline.
Materials and methods
We evaluated the levels of cabergoline in blood plasma by tandem mass spectrometry. A single determination of the level of cabergoline in plasma during

long-term treatment was performed in 18 patients with prolactinomas, of which six were sensitive to dopamine agonist therapy, 12 were resistant. 10 patients (2 - sensitive and 8 resistant) underwent also measurement of cabergoline levels during the pharmacokinetic test (0, 30, 60, 120, 240 min after patient took 1 tablet of cabergoline (0.5 mg) orally). The test was performed 7 days after the last dose of cabergoline. To determine cabergoline in blood plasma, at 9:00 am a blood sample was taken (0 minute), then blood was taken 30, 120 and 240 minutes after taking the drug.
Results
The concentration of cabergoline in the blood plasma at the 0 minute of the test was not different in patients sensitive and resistant to DA (Mann – Whitney U-test $P=0.147$). In the group of sensitive patients a correlation was found between the level of cabergoline at 0 minute and the dose of cabergoline that the patient constantly takes for a long time ($r=0.89$, $P=0.019$). Among resistant patients this correlation was not found ($r=0.39$, $P=0.238$). The pharmacokinetic test in sensitive patients did not reveal any significant changes in the level of cabergoline during the test ($P=0.392$). In resistant patients there were significant differences in the level of cabergoline ($P=0.0119$). A comparative analysis of the data showed that the concentration of cabergoline in the blood of patients who are resistant to treatment with DA increases sharply by 120 minutes of the sample. A statistically significant difference was found comparing levels at 0 and 120 minutes by the Wilcoxon criterion, $P=0.012$.
Conclusion
Thus, the pharmacokinetics of cabergoline differ in patients sensitive and resistant to treatment with DA, thereby may contribute to the low effectiveness of treatment in patients with prolactinomas resistant to treatment with DA, and predetermine the lack of effect of dose escalation of the drug.

Acromegaly do not increase the risk of vertebral fractures: a retrospective and prospective study on 50 patients

Clarisse Hochman[1], Charlotte Plard[2], Maëlle Le Bras[1], Benoît Le Goff[2], Yves Maugars[2], Pascale Guillot[2], Bertrand Cariou[1] & Delphine Drui[1]
[1]L'institut du thorax, Department of Endocrinology, CHU de Nantes, Nantes, France; [2]Rheumatology Department, CHU de Nantes, Nantes, France.

Context
Previous studies suggest that patients with acromegaly were at higher risk of vertebral fractures (VFs) despite normal bone mineral density (BMD). However, these patients could have several associated endocrine deficits known to increase the fracture risk, such as hypogonadism. In addition, patients with acromegaly have radiological deformations of the spine, called Erdheim's syndrome, which can overestimate the radiological VFs.
Objective
Investigate the prevalence of VFs in a cohort of patients with acromegaly.
Methods
It was a monocentric, retrospective and prospective study. Patients with acromegaly under 80 years of age and followed at the Nantes University hospital in January 2018 were included. Patients were excluded if they had a rheumatologic or endocrine disease interfering with the results. The rheumatologic evaluation was less than 3 years for all patients. The prevalence of radiological VFs was evaluated on conventional lombar and thoracic spine radiographs using Genant's semi quantitative assessment. We studied qualitative abnormalities of the spine using three criteria: osteophytes, disc space narrowing and cuneiform aspect of vertebrae. The X-rays were read by two rheumatologists independently. We analyzed BMD at lumbar spine and total hip, endocrine status and quality of life was investigated by three questionnaires (AcroQol, specific of acromegaly; Oswestry evaluating the functional impact of pain; HAQ evaluating the functional capacity).
Results
Fifty patients (19 females, 31 males) with a median age of 53 (range 28–79) were included. The average of time between the diagnosis of acromegaly and the last rheumatologic evaluation was 9.1 years. Three patients (6.1%) had a VF: 1 grade 1 and 2 grade 2 of Genant's assessment. 28% patients were osteopenic and 12% were osteoporotic. 26% were hypogonadal (100% substituted), 16% had central adrenal insufficiency (100% substituted). 14 women were menopaused (74% of women). Thoracic spine was deformed in 31 patients (61%) and lombar spine in 21 patients (43%). Patients with spine deformation were older ($P=0.043$), with higher BMI ($P=0.004$) and had a trend to be more hypogonadal ($P=0.06$). Concerning quality of life, AcroQoL's average was 70.9% (score 0 to 100, maximal quality of life =100, range 32–98), HAQ's average was 0.18 (score 0 to 3, maximal quality of life 0, range 0–1.38) and Oswestry's average was 9.8 (score 0 to 100, maximal quality of life 0, range 0–44).
Conclusions
Acromegaly patients are not at an increased risk of vertebral fractures, but they have vertebral deformations.

Sclerostin and fracture risk assessment in acromegaly

Jowita Halupczok-Żyła, Aleksandra Jawiarczyk-Przybyłowska, Agnieszka Zembska & Marek Bolanowski
Department and Clinic of Endocrinology, Diabetes and Isotope Therapy, Wroclaw Medical University, Wroclaw, Poland.

Introduction
Sclerostin is well-known as an inhibitor of bone formation but also promotes bone resorption. Acromegaly is a disease characterized by increased bone turnover and higher vertebral fracture risk.
Purpose
The aim of the study was to determine sclerostin levels in acromegaly patients with regard to the disease activity. We also evaluated the associations between sclerostin and random growth hormone (GH), insulin-like growth factor 1 (IGF-I), lumbar spine (LS) bone mineral density (BMD), femoral neck (FN) BMD and fracture risk.
Material and methods
A study group consisted of 72 patients with acromegaly, and was divided into three subgroups: active acromegaly (AA), controlled acromegaly (CTA) and cured acromegaly (CA). Fifty-four age- and sex-matched subjects were enrolled to the control group (CG). Blood samples were obtained from all participants to assess sclerostin, GH, IGF-I. The patients were questioned about clinical risk factors of fracture. Dual-energy x-ray absorptiometry was performed at two sites: LS and hip. Further, we estimated the ten-year probability (10yp) of major osteoporotic and hip fractures using FRAX calculator online.
Results
The patients with acromegaly had significantly lower sclerostin levels than CG, despite of subject classification (AA vs CG; CTA vs CG; CA vs CG; AA+CTA+CA vs CG; CTA+CA vs CG; $P<0.05$). Significantly higher probability of major osteoporotic and hip fractures was observed in the following groups: AA+CTA+CA, CTA+CA, CTA compared with CG. There were no significant differences in sclerostin levels among the subgroups of patients with acromegaly. Sclerostin correlated positively with the 10yp of major osteoporotic fracture in the groups: AA+CTA+CA ($P=0.003$), CTA+CA ($P=0.013$) and with the 10 yp of hip fracture in the groups AA+CTA+CA ($P=0.001$), CTA+CA ($P=0.001$) and CTA ($P=0.007$). No significant correlations were found between sclerostin levels and GH, IGF-I, LS BMD and FN BMD.
Conclusion
Acromegaly is associated with higher fracture risk. Lower sclerostin levels in patients with acromegaly may reflect a compensatory mechanism to increased bone turnover.

Biochemical control was sustained with long-acting pasireotide in patients with uncontrolled acromegaly over continued treatment with first-generation somatostatin analogues (SSAs): Results from the extension of phase 3b, open-label study

Mônica Gadelha[1], Annamaria Colao[2], Marie Bex[3], Rishay Mukherjee[4], Catherine Bourad[5], Ricardo Maamari[6] & Gérald Raverot[7]
[1]Hospital Universitário Clementino Fraga Filho, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil; [2]Università Federico II di Napoli, Naples, Italy; [3]Department of Endocrinology, University Hospitals Leuven, Leuven, Belgium; [4]Novartis Healthcare Pvt Ltd, Hyderabad, India; [5]Novartis Pharma S.A.S, 2 & 4 rue Lionel Terray, F-92500, Rueil-Malmaison, France; [6]Novartis Pharmaceuticals Corporation, East Hanover, New Jersey, USA; [7]Groupement Hospitalier Est, Hospices Civils de Lyon, Lyon, France.

Background
In a phase 3b, open-label study (NCT02354508) assessing efficacy and safety of long-acting pasireotide in patients with uncontrolled acromegaly after ≥ 3 months of treatment with first-generation SSAs, 18/123 (15%) patients achieved the primary endpoint of mean growth hormone (mGH) <1.0 µg/l and insulin-like

growth factor-1 (IGF-1) <ULN (upper limit of normal) at week 36. Here, we present the results from the extension phase of this study.
Methods
Controlled or uncontrolled patients who completed the 36-week core phase were eligible to enter the extension phase (week 36–72). Patients continued on the same pasireotide dose as in the core phase, but uncontrolled patients were allowed additional medication for acromegaly at investigator's judgement. The primary endpoint was evaluated in the core phase. In the extension phase, the secondary endpoints were the proportion of patients who achieved biochemical control: GH<1 μg/l and IGF-1<ULN, GH<1 μg/l, and IGF-1<ULN (by previous treatment, type of therapy and overall) at weeks 48, 60 and 72, toxicity, laboratory assessments and patient-reported outcomes.
Results
Eighty-eight patients (mean (s.d.) age, 43.7 (11.53) years, mean (s.d.) GH, 11.4 μg/l (25.81), and mean (s.d.) IGF-1, 666.7 μg/l (294.43)) entered the extension phase. Of them, 75 patients (85.2%) completed the additional 36 weeks; 6 patients each discontinued due to unsatisfactory therapeutic effect and physician's decision, 1 patient withdrew consent. At weeks 36, 48, 60 and 72, 14.8%, 12.5%, 14.8% and 11.4% of patients, respectively, achieved biochemical control. 21.6, 23.9, 21.6 and 20.5% had GH<1 μg/l and 34.1, 33.0, 37.5 and 33.0% had IGF-1<ULN, respectively. Suppressed levels of median GH and mean standardized IGF-1 at extension baseline (2.3 μg/l, 1.6) were maintained at week 48 (1.9, 1.6), week 60 (1.9, 1.5), and week 72 (1.7, 1.5). A higher proportion of patients with lower screening mGH levels (1.0–2.5 μg/l [$n=20$] vs >2.5 μg/l [$n=68$]) achieved biochemical control at all 4 time points 55%–65% vs 10.3%–11.8%. During overall study period ($N=123$), most frequent adverse events suspected to be drug related were hyperglycaemia (41.5%), diabetes mellitus (23.6%) and diarrhoea (11.4%).
Conclusions
In some patients with uncontrolled acromegaly, switching to long-acting pasireotide after ≥3 months of treatment with first-generation SSAs provided biochemical control, which was sustained over continued therapy until 72 weeks. Lower GH screening levels had a favourable impact on the achievement of biochemical control. The long-term safety and tolerability of pasireotide 40 and 60 mg over 72 weeks was consistent with that observed in the first 36 weeks during the core phase.

ACROSTUDY – safety and efficacy in a cohort of 110 Naïve patients with acromegaly treated with pegvisomant

Michael Wajnrajch[1,2], Roy Gomez[3], Judith Hey-Hadavi[1], Nikoletta Kelepouris[4], Joli van der Lans[5], Jane Loftus[6], Cecilia Camacho-Hubner[1], Maria Fleseriu[7], Roberto Salvatori[8], Jose Cara[1] & Andrew Palladino[4]
[1]Pfizer Inc, New York, New York, USA; [2]NYU School of Medicine, New York, New York, USA; [3]Pfizer, Brussels, Belgium; [4]Pfizer Inc, Collegeville, Pennsylvania, USA; [5]Pfizer, Amsterdam, Netherlands; [6]Pfizer Ltd, Sandwhich, UK; [7]Oregon Health Sciences University, Portland, Oregon, USA; [8]Johns Hopkins Medical Institute, Baltimore, Maryland, USA.

Background
ACROSTUDY is an open-label, non-interventional post-authorization safety study that began in 2004 to evaluate safety in at least 1000 acromegaly patients treated with the GH receptor antagonist pegvisomant (PEGV). This commitment was fulfilled in Jan 2013. ACROSTUDY was later amended to enroll an additional 110 patients that were naïve/semi-naive to PEGV treatment. Semi-naïve patients are defined as not having received PEGV therapy for at least 6 months prior to enrollment.
Objectives
The primary objectives were to: i) assess the long-term safety of PEGV in real world practice; ii) assess the effect of IGF-I normalization on treatment outcomes, including safety, glucose control and patient-reported outcomes (PROs).
Patients & Methods
110 patients with Acromegaly 53.6% male, 81.8% Caucasian, median age 42.4 years at diagnosis; median age 48.9 years at PEGV start. Patients were considered 'IGF-I Controlled' if the most temporally-related IGF-I measurement was normal for that laboratory. Safety data including adverse events and liver tests were collected. IGF-I and HbA_1c were measured; PROs were evaluated using the Acromegaly Quality of Life Questionnaire (AcroQoL) and Patient-Assessed Acromegaly Symptom Questionnaire (PAQ19), stratified by IGF-I control.
Results
No new safety signals were identified in this sub-study. IGF-I SDS >2 decreased from 87% of patients at baseline to 31% at year 2 at a mean dose (±s.d.) of 10.4 (±7.45) mg/day; patients with IGF-I SDS <2 had a mean dose of 14.8(±6.7). Among IGF-I controlled patients, median (range) HbA_1c levels were 5.8% (5.4–6.1) at baseline and 5.6% (4.5–7.2) at year 2; in IGF-I uncontrolled patients, HbA_1c was 6.1% (4.9–6.6) at baseline and 6.3% (2.9–10.6) at year 2. Among IGF-I controlled patients, median (range) global AcroQoL scores were 54.6 (24–73) at baseline and 61.4 (13–86) at year 2; while in IGF-I uncontrolled patients, median global AcroQoL score was 59.7 (8–92) at baseline and 63.6 (25–76) at year 2. Among IGF-I controlled patients, median (range) total PAQ19 score was 20 (3–38) at baseline and 17.5 (1–40) at year 2; in IGF-I uncontrolled patients, median total PAQ19 score was 17 (0–44) at baseline and 14 (3–39) at year 2.
Summary
In this real-life world international study, overall biochemical control (*i.e.* normal IGF-I) was achieved with pegvisomant in 64.3% patients by year 2. Improved IGF-I control was associated with improved HbA_1c, QoL and symptoms of acromegaly. One limitation of the study was that the PEGV dose may not have been sufficiently titrated to achieve IGF-I normalization.

Effects of pegvisomant and pasireotide LAR on incidence of vertebral fractures in patients with acromegaly resistant to treatment with first-line somatostatin analogs

Sabrina Chiloiro[1], Antonella Giampietro[1], Antonio Bianchi[1], Chiara Bima[1], Stefano Frara[2], Federica Mirra[1], Federico Donfrancesco[1], Cara Maria Fleseriu[3,4], Maria Fleseriu[4], Andrea Giustina[2], De Marinis Laura[1] & Alfredo Pontecorvi[1]
[1]OUS di Patologia Ipofisaria, UOC di Endocrinologia e Diabetologia, Fondazione Policlinico Universitario A. Gemelli, IRCCS. Istituto di Patologia Speciale Medica, Università Cattolica del Sacro Cuore, Rome, Italy; [2]Università Vita Salute San Raffaele, Milan, Italy; [3]University of Pittsburgh, Pittsburgh, Pennsylvania, USA; [4]Oregon Health and Science UniversityOregon Health and Science University, Portland, Oregon, USA.

Purpose
Osteopathy is an emerging complication of acromegaly characterized by increased bone turnover, deterioration in bone microarchitecture and high risk of vertebral fractures (VFs). In somatostatin analog (SSA)-resistant patients (pts), Pegvisomant (PegV) and Pasireotide LAR (Pasi) are used for acromegaly treatment, but their effect on skeletal health is still not defined.
Methods
In a longitudinal international multicenter study, we evaluated incidence of radiological VFs in 55 pts (29F/26M), mean age 44.1 years (s.d.: 17) with acromegaly resistant to first line SSA.
Results
At the study entry, prevalent VFs (lumbar, thoracic) were identified in 23 pts (41.8%). Mean spine *Z*-score was −0.4 (−0.6 in PegV, −0.2 in Pasi group, respectively; $P=0.49$). Biochemical acromegaly control was reached in 22/31 pts on Peg-V (71%) and in 16/24 pts on Pasi (66.7%). During follow-up (mean 89.9 months for PegV group and 50.5 months for Pasi group), incident VFs (iVFs) were detected in 16 pts (29.1%). Occurrence of iVFs was associated with the presence of pre-existing VFs ($P=0.009$), persistence of active acromegaly ($P=0.009$) and higher median value of serum IGF-I during follow-up ($P=0.04$). There were no significant differences in age, gender, initial treatment choice and changes in lumbar spine BMD. iVFs occurred in 7/9 pts uncontrolled on Peg-V and 2/8 pts uncontrolled on Pasi. Among pts with active disease at last visit, iVFs occurred less frequently in pts on treatment with Pasi (25%) compared to Peg-V (77.8%), $P=0.03$, independently of the IGF-I values ($P=0.9$). In pts who reached acromegaly biochemical control, 5/17 (22.7%) on Peg-V and 2/14 (12.5%) pts on Pasi had iVFs, $P=0.4$. In pts on Peg-V, factors associated with iVFs during follow-up were persistence of active acromegaly and higher IGF-I values (median IGFxULN: 0.5 IQR:1.8 vs 2.6 IQR: 2.2 $P=0.02$). In pts treated with Pasi, we did not find any factors associated with iVFs. Furthermore, in pts with biochemically controlled acromegaly, no factor was associated with iVFs which occurred less frequently in pts treated with Pasi.
Conclusion
Our data confirm that active acromegaly is the main determinant of VFs and show for the first time that pts with biochemically active disease treated with Pasi had lower risk of incident VFs vs those treated with Peg-V. Conversely, no significant drug-related differences in iVFs in pts with controlled acromegaly were observed. Additional studies on larger populations and with longer follow-up are needed to confirm our data and disclose the mechanisms underlying our findings.

Metabolic outcome in adolescents with growth hormone deficiency during transition phase

Nicola Improda[1], Federica Anselmi[1], Sara Alfano[1], Ida D'Acunzo[1], Lorenzo Bufalo[1], Donatella Capalbo[2] & Mariacarolina Salerno[1]
[1]Pediatric Endocrine Unit, Department of Translational Medical Sciences, University of Naples Federico II, Naples, Italy; [2]Department of Pediatrics, University of Naples Federico II, Naples, Italy.

Background
There is concern that adolescents with childhood-onset GHD (COGHD) and persistent GH deficiency may be exposed to multiple metabolic risks after GH treatment withdrawal at the attainment of final height (FH).
Aim
Aim of our study is to retrospectively compare growth response and metabolic profile in isolated idiopathic COGHD adolescents with permanent GH deficiency in comparison to GHD subjects who normalized their GH response at transition phase.
Patients and methods
20 subjects (12M-8F) (age 17.0±1.4 years) with persistent GHD at retesting and 20 adolescents (12M-8F) (age 16.8±1.0 years) with sufficient response to the test (GHS) were enrolled. In all patients the following parameters were evaluated at diagnosis of GHD during childhood and before and after 6 months of GH withdrawal at the attainment of FH: height, weight, body mass index (BMI), waist circumference (WC), hip circumference (HC), waist/hip circumference (WHR), waist/height ratio (WHtR), IGF-1, blood glucose, insulin, HOMA, QUICKI index, total-, HDL- and LDL-cholesterol, triglycerides, atherogenic index (AI), fibrinogen and homocysteine. Height, weight and BMI were expressed in standard deviation score (SDS) according to reference standards.
Results
At diagnosis during childhood, young adults with GHD were younger than GHS subjects (7.0±4.4 vs 10.6±2.9 years) and had lower HSDS (−3.0±1.1 vs −2.2±0.8, $P=0.03$), HVSDS (−3.6±1.1 vs −2.2±1.5, $P=0.007$), HDL-C (47.6±12.6 vs 60.1±15.6 mg/dl, $P<0.03$) and higher levels of AI (3.6±1.1 vs 2.6±0.9, $P<0.02$), fibrinogen (300.7±46.6 vs 266.3±44.9 mg/dl, $P<0.05$) and homocysteine (11.8±3.9 vs 8.8±3.4 µmol/l, $P<0.04$). The groups became comparable for all these parameters during GH treatment. At the attainment of FH the total gain in HSDS was higher in GHD in comparison to GHS young adults (2.2±1.6 vs 1.2±0.4, $P<0.03$) while all other anthropometric and metabolic parameters were comparable between the two groups. (When subjects were evaluated) After 6 months of GH withdrawal, GHD patients showed higher BMISDS (0.30±1.15 vs −0.67±1.0, $P<0.05$), WHtR (0.50±0.06 vs 0.45±0.03, $P<0.008$), total cholesterol (157.7±22.3 vs 141±22.1, $P<0.05$), AI (3.4±0.5 vs 2.6±0.7, $P<0.002$), fibrinogen (307±45.7 vs 272.3±46.1 mg/dl, $P<0.05$) and homocysteine (12.1±4.6 vs 9.2±2.9 µmol/l, $P<0.05$) and lower levels of HDL cholesterol (47.8±8.8 vs 55.8±10.3 mg/dl, $P<0.03$) than subjects with sufficient GH secretion.
Conclusions
Discontinuation of GH therapy at attainment of FH in subjects with severe COGHD is associated to the development of metabolic abnormalities which are already evident 6 months after withdrawal thus underling the importance to limit the period of treatment discontinuation during transition phase.

Novel phenotype of isolated diminished ovarian reserve and new CSB-PGBD3 (ERCC6) mutations revealed by targeted next generation sequencing in a cohort of caucasian infertile women

Abdelkader Heddar[1], Linda Akloul[2], Yann Lurton[2], Mathilde Domin Bernhard[2], Sylvie Odent[2] & Michleine Misrahi[1]
[1]Hopital de Bicetre, Le Kremllin Bicetre, France; [2]CHU de Rennes, Rennes, France.

Primary Ovarian Insufficiency (POI) affects ∼1% of women under forty leading most often to definitive infertility. About 25% of cases seem to be of genetic origin. The recent leap due to whole exome sequencing has led to the identification of new genes involved. Up to now more than sixty genes have been implicated in POI. Diminished Ovarian Reserve (DOR) also leads to female infertility. DOR is defined by a decreased quantity or quality of follicles based on antral follicle count (AFC < 5) and anti-müllerian hormone plasma levels (AMH < 0.5–1ng/mL). However the etiologies involved remain largely unknown. Here, we studied 66 Caucasian patients with DOR or POI using targeted next generation sequencing comprising 60 genes involved in POI. We identified 3 novel heterozygous missense mutations in CSB-PGBD3. The first mutation, located in exon 5 (c.1339C>T; p.(Arg447Trp)) was identified in a 16 years old patient with DOR (FSH =8.5UI/L, E2=37pg/mL, AFC=6 and AMH=0.6 ng/ml) and irregular menses. Her dizygotic twin sister has regular menses and normal hormonal blood assays up to now (18 years old). Two other novel mutations in *CSB-PGDB3* were found in two patients with POI and secondary amenorrhea (17 and 30 years) (2/65=3%). The mutations are located in exons 2 of CSB-PGDB3 c.364C>T; p.(Arg122Cys) and exon 5: c.1389G>t; p.(Gln463His). All three mutations are predicted to be pathogenic by *in silico* predictive softwares. They involve residues highly conserved during the evolution. CSB-PGBD3, also named ERCC6, encodes a DNA-binding protein involved in repairing DNA damage. Biallelic Mutations of this gene are associated with Cockayne syndrome type B and cerebro-oculo-facio-skeletal syndrome. Heterozygous mutations with a dominant negative effect were found in a single report with a very low incidence (0.7%) in Chinese patients with POI. Our work shows for the first time the implication of a DNA repair gene defect in DOR and reveals that mutations of *CSB-PGBD3* have a high prevalence in POI in Europe (3%). It supports the study of *CSB-PGBD3* in unexplained DOR and isolated POI. An appropriate genetic counseling and management should be performed in the siblings. Fertility preservation should be performed in heterozygous carriers of mutations, since accumulation of oocyte damage will lead to complete loss of the ovarian reserve in the future. We are presently screening a large cohort of DOR to evaluate the frequency of *CSB-PGBD3* mutations.

Hypothalamic miR-30 regulates puberty onset via repression of the puberty-suppressing factor, Mkrn3

Juan M Castellano[1], Violeta Heras[1], Susana Sangiao-Alvarellos[2], Maria Manfredi-Lozano[1], María J Sánchez-Tapia[1], Francisco Ruiz-Pino[1], Juan Roa[1], Maribel Lara-Chica[1], Rosario Morrugares-Carmona[1], Ana P Abreu[3], Denise Belsham[4], María J Vázquez[1], Marco A Calzado[1], Leonor Pinilla[1], Francisco Gaytán[1], Ana C Latronico[5], Ursula B Kaiser[3] & Manuel Tena-Sempere[1]
[1]Department of Cell Biology, Physiology and Immunology, University of Córdoba & Instituto Maimonides de Investigación Biomédica de Córdoba (IMIBIC)/Hospital Universitario Reina Sofia, Córdoba, Spain; [2]Department of Medicine, Faculty of Health Sciences, University of A Coruña, Instituto de Investigación Biomédica (INIBIC), University Hospital A Coruña, A Coruña, Spain; [3]Division of Endocrinology, Diabetes and Hypertension, Brigham and Women's Hospital and Harvard Medical School, Boston, USA; [4]Department of Physiology, Medical Sciences Building, University of Toronto, Toronto, Canada; [5]Unidade de Endocrinologia do Desenvolvimento, Laboratório de Hormônios e Genética Molecular, LIM 42, Hospital das Clínicas, Disciplina de Endocrinologia, Faculdade de Medicina da Universidade de São Paulo, Sao Paulo, Brazil.

Mkrn3, the maternally imprinted gene encoding the makorin RING-finger protein-3, has recently emerged as putative pubertal repressor, as evidenced by central precocity caused by MKRN3 mutations in humans; yet, the molecular underpinnings of this key regulatory action remain largely unexplored. We report herein that the microRNA, miR-30, with three binding sites in a highly conserved region of its 3'-untranslated region (UTR), operates as repressor of Mkrn3 to control pubertal onset. Hypothalamic miR-30b expression increased, while Mkrn3 mRNA and protein content decreased, during rat postnatal maturation. Neonatal estrogen exposure, causing pubertal alterations, enhanced hypothalamic Mkrn3 and suppressed miR-30b expression in female rats. Functional *in vitro* analyses demonstrated a strong repressive action of miR-30b on Mkrn3 3'-UTR. Moreover, central infusion during the juvenile period of target site blockers, tailored to prevent miR-30 binding to Mkrn3 3'-UTR, reversed the prepubertal down-regulation of hypothalamic Mkrn3 protein and delayed female puberty. Collectively, our data unveil a novel hypothalamic miRNA pathway, involving miR-30, with a prominent role in the control of puberty via Mkrn3 repression. These findings expand our current understanding of the molecular basis of puberty and its disease states.

A *KISS1R* gene variant in a pedigree with maternally inherited precocious puberty

Magdalena Avbelj Stefanija[1], Jernej Kovač[2], Galia Yablonski[3,4,5], Alma Toromanović[6], Moshe Phillip[5,7], Tadej Battelino[1,8] & Liat de Vries[5,7]
[1]University Medical Centre Ljubljana, University Children's Hospital, Department for Pediatric Endocrinology, diabetes and metabolism, Ljubljana, Slovenia; [2]University Medical Centre Ljubljana, University Children's Hospital, Unit for special laboratory diagnostics, Ljubljana, Slovenia; [3]Felsentein Medical Research Center, Petah Tikva, Israel; [4]The Jesse Z and Sara Lea Shafer Institute for Endocrinology and Diabetes, Schneider Children's Medical Center of Israel, Petah Tikva, Slovenia; [5]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel; [6]University Clinical Centre Tuzla, Tuzla, Bosnia and Herzegovina; [7]The Jesse Z and Sara Lea Shafer Institute for Endocrinology and Diabetes, Schneider Children's Medical Center of Israel, Petah Tikva, Israel; [8]Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia.

Background
The genetic causes of central precocious puberty (CPP) of clinical value identified to date are the paternally inherited Makorin RING-finger protein 3 (MKRN3) and Delta-like homolog 1 (DLK1) deficiencies. Given that CPP is typically maternally inherited, however, the molecular genetic background in the majority of CPP cases remains unknown. Using candidate gene approach focused on genes regulating GnRH secretion and action so far exceedingly rare patients with CPP were shown to carry mutations in kisspeptin system. KISS1 receptor gene (*KISS1R)* autosomal dominant heterozygous activating mutation p.(Arg386Pro) was reported previously in a girl with CPP by Teles MG *et al*.
Objectives
To identify genetic causes of maternally inherited CPP.
Population and methods
Whole genome sequencing of 9 family trios affected with CPP, demonstrating maternal inheritance pattern, was performed. A family trio analysis approach was utilized as a first tier analysis to generate a set of potential causative genetic variants inherited in the autosomal dominant pattern. The minor allele frequency (MAF) threshold for known variants was set at 0.2%, all variants exceeding this value were excluded from further analysis. Genetic variants with coverage $> 10\times$ were retained and analyzed with Variant Studio 3.0 software. Identified candidate variant and its family segregation were verified by Sanger sequencing. By targeted approach, coding and regulatory regions and copy number variants (CNV) of 398 genes reported to be associated with age at menarche by genome-wide association studies were analyzed for rare variants (MAF $<0.2\%$).
Results
The average coverage of each genome was $38\times$ and around 3.8M SNVs and InDels, 5k SVs and 600 CNVs were detected on average per single sample. In a single pedigree a heterozygous premature termination codon in *KISS1R* NP_115940.2:p.(Cys389Ter), segregating with CPP, was identified. The variant, with CADD score 28.7, was previously reported in a female with hypogonadotropic hypogonadism and has a frequency of 0.04% in GnomAD. The female proband had first signs of puberty at the age of 7.5 years and menarche at 9 years, marginaly advanced bone age, growth spurt at 7–8 years and increased basal and peak luteinizing hormone (LH). Her mother had menarche at 9 years.
Conclusions
To our knowledge this is the second CPP pedigree carrying a *KISS1R* gene variant. Although trunkating, this variant is considered to be of unknown significance. Functional study would be necessary to determine the implication of identified variant on KISS1R function and reproductive phenotype.

Untargeted lipidomics profiling by high-performance liquid chromatography/time-of-flight mass spectrometry in polycystic ovary syndrome: candidate biomarkers and association to disease traits

Carmen Emanuela Georgescu[1], Camelia Vonica[2], Ioana Rada Ilie[1], Corina Moraru[3], Dana Pop[4], Georgeta Hazi[5], Oana Pinzariu[1] & Carmen Socaciu[3,6]
[1]Department of Endocrinology, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania; [2]Department of Diabetes, Nutrition and Metabolic Diseases, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania; [3]BIODIATECH Center, Cluj-Napoca, Romania Department; [4]Department of Cardiology, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania; [5]Central Laboratory, Cluj County Emergency Hospital, Romania; [6]Department of Biochemistry, University of Agricultural Sciences and Veterinary Medicine, Cluj-Napoca, Romania.

Background
Metabolomics profiling of bio-fluids suggests altered signatures in patients with the polycystic ovary syndrome (PCOS).
Subjects and methods
A high-performance liquid chromatography/time-of-flight mass spectrometry (HPLC/TOF-MS)-based metabolomics approach was developed to characterize the untargeted lipidomics signature associated with PCOS status in a discovery cohort of 30 plasma samples (15 PCOS, 15 controls, age-matched), followed in a second step by evaluation of another cohort of 46 samples (27 PCOS, 19 controls, age-matched). Rotterdam criteria were applied to confirm the subjects' eligibility. Of note, all patients with PCOS presented hyperandrogenic phenotypes. Blood samples were processed for extraction of lipids with Bligh & Dyer method, and subjected to HPLC-ESI(+)TOF-MS measurements. To analyze matrix data, Profile Analysis 2.0 (Bruker) and Metabolyst 4.0 bioinformatics tools were used. All participants were referred to body composition assessment by dual X-ray absorptiometry (DXA); in addition to vascular evaluation, including flow-mediated vasodilation (FMD) and arterial stiffness indices in a subset.
Results
Separation of more than 150 low-molecular-weight metabolites between groups resulted by untargeted lipidomics approach, with very good data clustering confirmed in multivariate analysis (PCA, PLS-DA, Cluster Analysis). ROC curves (AUC between 0.834–1) showed that a group of 18 lipid metabolites efficiently discriminated between controls and PCOS, among them, carnitines (decanoylcarnitine, L-octanoylcarnitine, heptadecanoylcarnitine) that presented highly significant elevated levels ($P<0.0001$), in addition to monoacylglycerols (MG20:3/0:0, MG0:0/18:0/0:0), with up to more than 5-fold higher levels ($P<0.0001$). On the contrary, lysophosphocholines were markedly decreased in women with PCOS vs. controls ($P<0.0001$). Tetranor-12R-HETE, released by endothelial cells upon stimulation and directly linked to inflammation, increased more than 3-fold in PCOS ($P<0.0001$). Furthermore, correlations were described. Decanoylcarnitine (C10:1), a fatty ester lipid molecule was strongly associated to a high number of metabolites, including monoacylglycerols and other acylcarnitines, tetranor-12R-HETE, lipoxin B4 and leukotriene. Within the PCOS group, acylcarnitines species correlated with body fat and the lipid profile ($P\leq0.01$). Moreover, an inverse association between carnitines and FMD was revealed ($P<0.05$).
Conclusion
Metabolomics is useful in identifying novel potential biomarkers of PCOS. Alterations in fatty acid metabolism, with decreased fatty acid oxidation may contribute to the cardio metabolic profile in PCOS. Candidate biomarkers are involved in specific metabolomic networks affected by pathological processes and may discriminate between healthy women and PCOS.

Background
In patients with Klinefelter syndrome (KS) morbidity and mortality seem to be higher than general population, this depending on a wide number of possible comorbidities. Impaired metabolic profile, increased risk of venous thrombosis and the consequent increase of cardiovascular diseases might play a key role in this condition as well as reduced bone mineral density and higher fracture risk.

Nowadays testosterone replacement therapy (TRT) is the first-choice treatment for this condition, but no evidence so far has been able to define its positive role in this population related to metabolic, cardiovascular and bone-related outcomes.
Objective
The aim of this study is to meta-analyze currently available data reporting about metabolic, cardiovascular and bone metabolism parameters before and after TRT in KS subjects.
Methods
An extensive Medline search was performed, including the following words: 'klinefelter' [All Fields] AND 'testosterone' [All Fields]. The search was restricted to English-language articles and studies including humans published up to December 31th, 2017. All trials reporting TRT metabolic outcomes in hypogonadal KS in comparison to healthy controls or untreated hypogonadal KS without any arbitrary restriction were included.
Results
Out of 525, 20 trials were included, enrolling 1060 KS patients and 806 age-matched controls with a mean age of 30.8 ± 4.9 years. Among the studies included, 15 reported information on body composition and/or on metabolic profile whereas only 4 and 2, included outcomes on bone and cardiovascular parameters, respectively. Meta-analysis of the data showed a significant increase of body-mass index (BMI) (mean difference 1.17 kg/m^2), body fat mass (mean difference 1.27 SD), waist circumference (mean difference 11.61 cm) and plasma fasting glucose (mean difference 0.26 mmol/L), total cholesterol (mean difference 0.22 mmol/L) and LDL cholesterol (mean difference 0.59 mmol/L) in untreated KS patients compared to age-matched controls ($P <$ 0.01, CI 95%). A significant improvement was observed for body fat mass ($P < 0.01$, CI 95%), LDL cholesterol ($P = 0.02$) and waist circumference ($P = 0.03$) but not for plasma fasting glucose ($P = 0.09$), comparing treated vs untreated KS patients. Finally, comparison of treated KS to age-matched control showed an improvement of BMI, total cholesterol and LDL cholesterol, but persistence of significant difference between two groups ($P < 0.05$). Similar results were observed when bone and cardiovascular outcomes were considered.
Conclusions
Our preliminary results suggest that TRT can only partially improve metabolic profile as well as body composition. Reduction of CV risk in treated KS patients should be confirmed through specific RCT.

Diet patterns in patients with PCOS

Lina Zabuliene[1,2], Mykolas Urbonas[3] & Edita Saukaityte Butvile[2]
[1]Institute of Clinical Medicine, Faculty of Medicine, Vilnius University, Vilnius, Lithuania; [2]Karoliniskiu Out Patient Clinic, Vilnius, Lithuania; [3]Faculty of Medicine, Vilnius University, Vilnius, Lithuania.

The study aimed to investigate diet patterns and its association with metabolic features in patients with PCOS.
Material and methods
116 women with PCOS (according to Rotterdam criteria) were investigated in Vilnius city (Lithuania) in 2009–2011. Information about nutrition habits was collected utilizing qualitative food frequency questionnaire. Participants were tested for total testosterone, sex hormone-binding globulin, fasting glucose, insulin and lipid profile. 2-hours oral glucose tolerance test was performed. Insulin resistance HOMA-IR index were calculated. Body weight and height were measured.
Results
Mean patients' age was 27.16 ± 3.87 years. 57.0% of women had enough knowledge about healthy diet. Mean number of daily meals was 3.31 ± 0.88. 42.2% of women declared that always have breakfast, 67.2% always have lunch and 41.4% dinner. BMI (25.88 ± 6.15 vs. 28.64 ± 7.42 kg/m^2, $P = 0.04$), insulin (9.95 ± 6.13 vs. 14.49 ± 12.18 μU/ml, $P = 0.01$), HOMA-IR (2.29 ± 1.63 vs. 3.52 ± 3.30, $P = 0.01$), triglycerides (1.00 ± 0.44 vs. 1.26 ± 0.73 mmol/l, $P = 0.02$) were lower and HDL-cholesterol (1.61 ± 0.36 vs. 1.43 ± 0.41 mmol/l, $P = 0.02$) was higher in women who always have had breakfast comparing to those who ate breakfast irregularly or never. Obese PCOS women more frequently had dinner comparing with normal weight PCOS. 30.8% of PCOS women ate whole grain bread every day. They had lower glucose after 75 g glucose load by 0.76 mmol/l (5.10 ± 1.52 vs. 5.86 ± 1.61 mmol/l, $P = 0.03$) and higher HDL-cholesterol by 0.17 mmol/l (1.63 ± 0.42 vs. 1.46 ± 0.39 mmol/l, $P = 0.04$) comparing to those who ate whole grain bread occasionally. 41.4% of women ate meat daily, their triglycerides were higher by 0.38 mmol/l (1.37 ± 0.79 vs. 0.99 ± 0.47 mmol/l, $P = 0.002$) comparing to those who did not eat meat every day.
Conclusion
Having regular breakfast, eating whole grain bread, limiting frequency of having meat are associated with better metabolic profile in patients with PCOS.

MRI-based proton-density fat fraction measurements reveal alterations of abdominal fat, bone and muscle composition in lean women with PCOS

Seda H. Oguz[1], İlkay S. Idilman[2], Nafiye Helvaci[1], Musturay Karcaaltincaba[2] & Bulent Okan Yildiz[1]
[1]Hacettepe University School of Medicine, Department of Internal Medicine, Division of Endocrinology and Metabolism, Ankara, Turkey; [2]Hacettepe University School of Medicine, Department of Radiology, Ankara, Turkey.

Background
Proton-density fat fraction (PDFF), derived from chemical shift encoding-based water-fat magnetic resonance imaging, has emerged as an important surrogate method for calculation of fat composition in a number of tissues including liver, vertebrae and muscles. This study aims to determine whether fat composition of these tissues, as well as visceral and subcutaneous adiposity differ between women with PCOS and healthy controls.
Methods
17 lean women with PCOS (age: 21.4 ± 3.1 years, BMI: 22.1 ± 1.9 kg/m^2) and 16 healthy women who were matched for age, BMI and waist circumference ($P =$ 0.56, 0.12 and 0.11 respectively) were included. The diagnosis of PCOS was based on Rotterdam criteria. Hormonal and biochemical evaluations and MRI-based PDFF measurements were performed in all participants. Radiologists reporting MRI examinations were blinded to clinical data and patient control status.
Results
PDFF% values of liver were higher (median 4.5% vs. 3.6%, $P = 0.02$) whereas PDFF% values of both vertebrae and paraspinal muscles were lower (32.8% vs. 41.6%; and 12.8% vs 15.1%, $P < 0.05$ for both) in PCOS patients than controls. Also, subcutaneous and visceral adipose tissue areas were increased in PCOS patients compared to healthy women (median 32.8 cm^2 vs. 18.5 cm^2, and 112.9 cm^2 vs. 83.1 cm^2, $P < 0.05$ for both). Pancreas PDFF% values were similar between the groups. Visceral and subcutaneous fat area measurements were positively correlated with FAI ($r = 0.71$, $P < 0.01$ and $r = 0.49$, $P < 0.05$ respectively). Subcutaneous fat area was also positively correlated with fasting insulin ($r = 0.54$, $P < 0.05$) and 2 h insulin during OGTT ($r = 0.78$, $P < 0.01$). PDFF% of liver in PCOS did not show a correlation with insulin resistance or lipid parameters but there was a trend for positive correlation with free androgen index (FAI) ($r = 0.37$, $P = 0.08$).
Conclusions
Fat composition of liver calculated by PDFF with MRI, subcutaneous and visceral adipose areas are higher in lean PCOS patients than age, BMI and WC-matched healthy women. Biochemical androgen excess and insulin resistance are among the factors modulating intraabdominal adiposity in lean PCOS. Whether decreased PDFF measurements of vertebra and paraspinal muscles in the syndrome are related to muscle or bone strength remains to be determined.

DHT, rather than free testosterone, influences symptoms of aging in eugonadal men

Andrea Sansone[1,2], Sabine Kliesch[2], Frank Tüttelmann[3], Martin Dugas[4], Andrea M. Isidori[1], Stefan Schlatt[2] & Michael Zitzmann[2]
[1]Department of Experimental Medicine, Section of Medical Pathophysiology, Food Science and Endocrinology, Sapienza University of Rome, Rome, Italy; [2]Center of Reproductive Medicine and Andrology, Institute of Reproductive and Regenerative Biology, University of Münster, Münster, Germany; [3]Institute of Human Genetics, University of Münster, Münster, Germany; [4]Institute of Medical Informatics, University of Münster, Münster, Germany.

Aim
To assess the relation between questionnaires of androgenic function (AMS and IIEF-EF scores) and sex hormones (DHT, estradiol and total and free testosterone) in men attending an outpatient clinic for endocrine and reproductive disorders.

Methods
We retrospectively reviewed all data entered in the electronic database of the Münster Center of Reproductive Medicine and Andrology (CeRA) Androbase from patients visited between January 2015 and October 2018. Multinomial ordinal logistic regression models were used to test for independent predictors of the questionnaires score in men naïve of possibly interfering treatments (androgens, aromatase inhibitors or PDE5 inhibitors).
Results
Among 4895 (mean age: 37 ± 12.7 years) subjects with a serum measurement of DHT and total and free testosterone during their first visit to the center, the AMS and IIEF (EF domain) questionnaires were completed by 635 and 574 men free of interfering medications and were included in analysis. Total and free testosterone and DHT were all found associated with IIEF and AMS in the whole group. When considering separately hypogonadal ($n = 219$) and eugonadal ($n = 416$) men, only DHT turned to be a significant predictor of AMS score with an increase of 1 ng/ml in serum DHT associated with a 46.7% decrease in the odds of having worse symptoms ($P = 0.011$) in subjects with normal T, but not in hypogonadal men. No significant effects were observed for free testosterone, BMI or age. No significant effects were observed for both free testosterone and DHT in regards to the EF domain of the IIEF questionnaire.
Discussion
Despite being of little value in hypogonadal men, DHT is significantly associated with aging male symptoms in subjects with normal serum testosterone. In the multivariate analysis, neither DHT nor free or total testosterone show significant association with impairment of erectile function as assessed via the IIEF questionnaire.
Conclusions
The present study is the first to demonstrate that, although DHT can be associated with male aging symptoms, it is of little value in hypogonadal men. DHT measurement might become an useful addition to the diagnostic workflow of symptoms of male aging in subjects with normal T, but should not be routinely included in the diagnostic process.

Male patients with hypogonadism have an impaired lipoprotein function

Biagio Cangiano[1,2], Maria Pia Adorni[3], Francesca Zimetti[3], Valeria Vezzoli[2], Franco Bernini[3], Donatella Caruso[4], Alberto Corsini[4,5], Cesare R. Sirtori[6], Anna Cariboni[4], Massimiliano Ruscica[4] & Marco Bonomi[1,2]
[1]Department of Clinical Sciences and Community Health, Università degli Studi di Milano, Milan, Italy; [2]IRCCS Istituto Auxologico Italiano, Division of Endocrine and Metabolic Diseases & Lab. of Endocrine and Metabolic Research, Milan, Italy; [3]Department of Food and Drug, University of Parma, Parma, Italy; [4]Department of Pharmacological and Biomolecular Sciences, Università degli Studi di Milano, Milan, Italy; [5]Multimedica IRCCS, Milan, Italy; [6]Centro Dislipidemie, A.S.S.T. Grande Ospedale Metropolitano Niguarda, Milan, Italy.

Background
Male hypogonadism is known to be associated with an increased incidence of cardiovascular (CV) events, although the underlying biochemical mechanisms are so far not fully understood. The clinical condition characterized by low levels of testosterone offers a unique model to unravel the possible role of lipoprotein-associated abnormalities in CV risk. In particular, the assessment of the functional capacities of high-density lipoproteins (HDL) may provide novel insights besides traditional risk factors.
Aim of the study
Aim of our study was to determine whether male hypogonadal patients have an impaired function of serum lipoproteins and if testosterone levels correlate with this function.
Methods
We evaluated HDL cholesterol efflux capacity (CEC, both ATP-binding cassette transporter and aqueous diffusion-mediated) and serum cholesterol loading capacity (CLC) in a series of 20 hypogonadal patients and in 17 age and body mass index (BMI) matched healthy control subjects.
Results
Hypogonadism significantly reduced the HDL ATP-binding cassette transporter A1 (ABCA1)-, ATP binding cassette transporter G1 (ABCG1) - and aqueous diffusion-mediated CEC (−19.6%, −40.9% and −12.9%, respectively), with a 16.2% decrement of total CEC. In the entire cohort, positive correlations between testosterone levels and both total HDL CEC ($r^2 = 0.359$, $P = 0.0001$) and ABCG1 HDL CEC ($r^2 = 0.367$, $P = 0.0002$) were observed. On the contrary, serum CLC, significantly raised (+43%) in hypogonadal patients, was inversely correlated with testosterone levels ($r^2 = 0.270$, $P = 0.00014$). HDL-C concentrations did not correlate with either testosterone levels, HDL CECs or serum CLC.
Conclusions
Our results show that in hypogonadal patients pro-atherogenic lipoprotein-associated changes lead to reduced cholesterol efflux and increased influx, thus suggesting a potential explanation for the increased CV risk in hypogonadal patients and a possible objective functional parameter of hormonal dysfunction.

Serum levels of the soluble receptor for advanced glycation end products (AGEs) are reduced and AGEs increased in hashimoto's thyroiditis (HT)

Rosaria Maddalena Ruggeri[1,2], Teresa Manuela Vicchio[2], Maria Teresa Cristani[3], Salvatore Giovinazzo[2], Alfredo Campennì[4,5], Salvatore Cannavò[2,6] & Francesco Trimarchi[7]
[1]Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy; [2]Endocrine Unit at University Hospital of Messina, Messina, Italy; [3]Department of Pharmaceutical Sciences and Health Products, University of Messina, Messina, Italy; [4]Department of Biomedical Sciences and Morphological and Functional Images, University of Messina, Messina, Italy; [5]Nuclear Medicine Unit at University Hospital of Messina, Messina, Italy; [6]Department of Human Pathology of Adulthood and Childhood 'G.Barresi', University of Messina, Messina, Italy; [7]Accademia Peloritana dei Pericolanti at the University of Messina, Messina, Italy.

Objective
AGEs, compounds formed by the transformation of proteins, are increased in conditions of oxidative stress and promote inflammation by interacting with their receptor (RAGE) on cell membrane. By contrast, the soluble receptor for AGE (sRAGE), that is proteolytically cleaved from cell surface receptor via matrix metalloproteinases, sequester RAGE ligands and act as a cytoprotective and anti-inflammatory agent. AGEs/sRAGE interaction play a role in the pathogenesis of several diseases related to oxidative stress. Recently, increased levels of AGEs, as specific markers of oxidative stress, have been reported in HT, but no data are available on sRAGE levels in these patients.
Materials And Methods
We enrolled 50 euthyroid HT patients (5 M e 45 F, mean age 38.5 ± 12 yr) and 50 age- and sex-matched healthy controls. All subjects were eythyroid at time of recruitment (mean TSH value 1.98 ± 1.10 uIU/ml in HT *vs* 1.40 ± 0.73 mIU/ml in controls; $P = 0.689$) and none was on LT-4 therapy. Smokers, subjects with kidney failure, history of cancer or autoimmune, inflammatory and infection comorbidities were excluded. Patients did not differ significantly from controls with regard to the main metabolic and anthropometric parameters. In sera from each subject, sRAGE levels were measured by ELISA (kit sRAGE Elisa, R&D System, Minneapolis, USA; minimum detectable dose 3 pg/ml); AGEs were determined on spectrophotometric method.
Results
sRAGE levels were significantly lower in HT patients (median 424 pg/ml, *range 307–1070*) compared to controls (738 pg/ml, *365–1205*; $P = 0.001$), while AGEs levels were significantly higher in TH than in controls (median: 205 AU/g prot, range 38–463 *vs* 114 AU/g prot, range 30–325; $P = 0.0001$) and the two parameters were inversely correlated ($r = -0.377$; $P = 0.016$). The correlation analysis also showed a positive correlation between BMI and serum AGEs levels. On the contrary, the sRAGE levels showed significantly inverse correlations with BMI and anti-thyroid antibodies positivity ($r = -0.27$, $P = 0.001$). In regression analysis models, adjusted for BMI, serum Ab-TPO were the main predictors for both AGEs ($P = 0.014$) and sRAGEs ($P = 0.027$), irrespective of TSH and/or FT4 values.
Conclusion
sRAGE levels were decreased and AGEs increased in HT patients. Autoimmunity *per se* seems to play a role in AGEs/sRAGE imbalance, irrespective of thyroid function impairement. Given the protective effects of sRAGE, HT subjects may exhibit increased susceptibility to oxidative damage, even when in euthyroid status.

The randomised probiotic trial of indigo study (investigation of novel biomarkers and definition of role of the microbiome in Graves' orbitopathy)

Mario Salvi[1], Giuseppe Colucci[1], Giulia Masetti[2], Danila Covelli[1], Ilaria Muller[1,2], Hedda Koehling[3], Iveta Garaiova[4], Daryn Michael[4], Lei Zhang[2], Marian Ludgate[2], Julian Marchesi[2] & Filippo Biscarini[5]
[1]Graves' Orbitopathy Centre, Fondazione IRCCS Cà Granda and University of Milan, Milan, Italy; [2]School of Medicine, Cardiff University, Cardiff, UK; [3]Department of Ophthalmology, University Hospital Essen/University of Duisburg-Essen, Essen, Germany; [4]Cultech Ltd, Port Talbot, Cardiff, UK; [5]CNR, Milan, Italy.

Background
Changes of the gut microbiota may impact on the mechanisms of immune tolerance in Graves' disease (GD) and Graves' orbitopathy (GO). Probiotics, which contain live micro-organisms, can modify the composition of the gut microbiota.
Aims
We tested in a double-blind randomized placebo controlled trial whether the administration of a well-characterized, commercially available, probiotic would 1) modify the microbiota composition in GD/GO patients, 2) change the natural course of GD and/or GO progression, and 3) affect the systemic immunological status.
Methods
The probiotic compound LAB4 comprises 25 billion colony-forming-units/capsule of two *Lactobacillus acidophilus* strains plus *Bidifobacterium bifidum* and *Bidifobacterium animalis var.lactis*. Thirty GD patients untreated or within 4 weeks of anti-thyroid therapy (ATD) were randomized to receive LAB4 ($n=14$, 11 women and 3 men) or placebo ($n=16$, 14 women and 2 men) for 6 months orally while treated with ATD. Ten patients in each arm had mild to moderate GO. Serum concentrations of IgA, IgG, TSH, FT4, FT3, autoantibodies to the thyrotropin receptor (TRAb) and gene sequencing for 16S rRNA on fecal samples were assessed at baseline, at euthyroidism (EU) and at the end of 6 months follow-up (EFU).
Results
At EU we observed a significant reduction in counts of the Firmicutes phylum in the probiotics group compared to placebo ($P=0.033$). At EFU, 6 and 5 patients on placebo were hyperthyroid and euthyroid, respectively, compared to 3 and 8 on probiotics ($P=$NS). At EFU GD patients treated with placebo had higher FT3 concentrations than those receiving probiotics ($P<0.05$). Severity or progression of GO were not different between patients in the placebo or probiotic group. IgA and IgG levels were transiently lower (at EU) in patients treated with probiotics ($P<0.01$ and $P=0.02$, respectively), and returned to baseline levels after probiotic withdrawal. The probiotic administration did not affect TRAb levels.
Conclusions
Although these results have to be confirmed in a larger clinical trial, we suggest that probiotics are effective in modifying the microbiota composition in GD patients. GD patients on probiotics seem to relapse less at 6 months after ATD therapy, compared with those on placebo. Probiotics induce a transient, but significant decrease of both circulating IgA and IgG, suggesting a systemic effect of the treatment.

Microarray profile of CD19+B cells from Graves' disease patients reveals potential molecular mechanisms associated with the proliferation of B cell signaling

Xuechao Jiang[1,2], Yonghui Wang[3], Qian Yang[3], Leqi He[4], Xiaoying Li[3], Wei Wang[3], Jun Liu[3] & Bingbing Zha[3]
[1]Scientifc Research Center, Xinhua Hospital, affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China; [2]Department of Pediatric Cardiology, Xinhua Hospital, Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China; [3]Department of Endocrinology, Fifth People's Hospital of Shanghai Fudan University, Shanghai, China; [4]Department of Clinical Laboratory Medicine, Fifth People's Hospital of Shanghai Fudan University, Shanghai, China.

Background
Graves' disease (GD) is a common autoimmune disorder characterized by the production of autoantibodies targeting the thyroid, leading to hypothyroidism. It is widely accepted that B lymphocytes play a significant role in GD as they are the source of autoantibodies (TRAb) against the thyroid-stimulating hormone receptor (TSHR). Previously, we reported that B cells infiltrate the thyroid tissue of GD patients, and in this study we observed that the percentage of peripheral blood B cells of GD patients was significantly higher than that in healthy controls. However, few studies have sought to understand the role of thyroid antigen-reactive B cells during disease development.
Methods
LncRNA and mRNA microarray expression profiling were performed to identify the differentially expressed genes in purified $CD19^+B$ cells. Go and Pathway analysis showed the potential function and pathway involved in the target genes. Two independent algorithms were used to predict the lncRNAs that regulate target gene. The Protein-protein interaction (PPI) network present the underlying interaction of these differential genes.
Results
410 differentially expressed mRNAs between GD patients and controls, with 79 mRNAs being upregulated and 331 being downregulated in the B lymphocytes of GD patients as compared with controls. Quantitative real-time polymerase chain reaction (qRT-PCR) validated T-cell leukemia/lymphoma-1A (*TCL1A*) and SH2 domain containing 1A (*SH2D1A*), were upregulated and downregulated, respectively, in GD patients as compared to controls. GO and Pathway analyses revealed that *TCL1A* and *SH2D1A* genes are highly involved in B cell proliferation and survival. lncRNAs TC14001829.hg.1 and TC14002143.hg.1 are predicted to regulate *TCL1A* and lncRNA TC0X002222.hg.1 to regulate *SH2D1A*. qRT-PCR validated the upregulation of the lncRNAs TC14001829.hg.1 and TC14002143.hg.1, and the downregulation of the lncRNA TC0X002222.hg.1 in GD patients.
Conclusion
In conclusion, our study determined the expression profiles of mRNA and lncRNA in B cells of GD patients, and highlighted the changes in *TCL1A*, *SH2D1A*, and the related lncRNAs TC14002143.hg.1, TC14001829.hg.1, and TC0X00222.hg.1, which may participate in GD development by modulating B cell proliferation and survival. These genes and lncRNA could represent novel biomarkers and therapeutic targets for GD.

Clinical experiences in autoimmune polyglandular diseases

Gréta Pham-Dobor[1,2], László Bajnok[1,2], Beáta Bódis[1], Marin Gergics[1,2], Orsolya Nemes[1], Károly Rucz[1] & Emese Mezősi[1,2]
[1]Ist Department of Internal Medicine, Division of Endocrinology and Metabolism, University Medical School of Pécs, Pécs, Hungary; [2]Szentágothai Research Centre, University Medical School of Pécs, Pécs, Hungary.

Introduction
The autoimmune polyglandular syndrome is a complex, heterogeneous disease in which autoimmune diseases of endocrine and non-endocrine organs can occur. There are 4 subgroups: the early-onset APS I develops due to the mutation of the gene AIRE and characterized by the presence of Addison's disease (AD), mucocutan candidiasis and hypoparathyroidism; the APS II is defined by the appearance of AD and autoimmune thyroid diseases (AITDs) and/or diabetes mellitus; in APS III the patients have AITDs and any other kind of autoimmune manifestations except AD, while APS IV consists of patients who could not be included in the previous 3 groups. The aim of this research was to characterize APS patients treated in our Department.
Patients and method
During the searching, 132 APS cases were identified in our database of 1762 patients (7.5% of this population) with autoimmune diseases.
Results
Of the affected individuals, 15 and 117 were male and female patient, respectively. Only 1 patient belonged to the APS I, while 25 to the APS II, 91 to the APS III and 15 to the APS IV subgroups. The average age at the diagnosis was 36.8 year in APS II, 32.9 year in APS III, and 37.9 year in APS IV. Seven different autoimmune manifestations affected endocrine organs; furthermore, 10 non-endocrine organ specific autoimmune disorders and six systemic autoimmune diseases were detected. APS was most common in the group of patients with Addison's disease (29%). AITDs were combined with other autoimmune manifestations in 10%. The first diagnosed autoimmune diseases were AITDs in 28%, AD in 14% and diabetes mellitus in 14%. Ninety-six cases with two, 28 with three, 7 with four and 1 with five autoimmune manifestations were found.
Conclusions
APS is not uncommon in patients with various forms of autoimmune diseases and may occur in one-third of patients with AD. The development of relevant diagnostic and screening protocols to identify these patients timely is warranted.
Keywords: autoimmune polyglandular syndrome, APS, Addison's disease, autoimmune thyroid disease, type I. diabetes mellitus

The change of pulmonary artery pressure and serum vascular endothelial growth factor in Graves' disease before and after treatment

Doo-Man Kim
Hallym University College of Medicine, Seoul, Republic of Korea.

Exertional symptoms, dyspnea, and impaired effort tolerance are common in patients with Graves' disease. Proposed explanations include high-output left heart failure, ineffective oxygen utilization, and respiratory muscle weakness. In addition, cases of pulmonary arterial hypertension (PAH) in patients with Graves' disease have been reported. Vascular endothelial growth factor (VEGF) is produced by thyroid follicular epithelial cells in response to stimulation of the TSH receptor. Secreted VEGF can lead to endothelial cell proliferation and a significant increase in serum VEGF levels in Graves' disease patients has been observed and the role of VEGF in PAH suggested. To evaluate the change of pulmonary artery pressure (PAP) and VEGF in Graves' disease, we performed two-dimensional and Doppler echocardiography and serum VEGF using ELISA (R&D systems) in 28 untreated Graves' disease patients before and after treatment (25 patients on propylthiouracil and 3 with RAI) and 10 normal controls. Pulmonary artery (PA) pressure was increased in patients with Graves' disease compared to normal controls (mean 23.5 vs 29.3 mmHg, $P<0.05$). 44% of Graves' disease (12 patients) showed PAH (PA > 30 mmHg) and serum TBII level was higher in Graves' disease with pulmonary arterial hypertension than normal PA ($P<0.05$). After treatment, PA was normalized and serum VEGF was decreased (from 314.8 ± 81.29 to 267.8 ± 69.15 pg/ml, $P<0.05$). In conclusion, 44% of untreated Graves' disease showed PAH and PAP was decreased after treatment. The pathogenesis of PAH in Graves' disease needs further studies.

Grave's orbitopathy: clinical, paraclinical and therapeutic features

Zineb Boulbaroud, Siham El Aziz, Amal Mjaber, Salma Bensbaa & Asma Chadli
Endocrinology, Diabetology and Metabolic Diseases Department Ibn Rochd University Hospital of Casablanca, Neurosciences and Mental Health Laboratory Faculty of Medicine and Pharmacy-University Hassan II, Casablanca, Morocco.

Introduction
Grave's orbitopathy (GO) is the main extra-thyroid manifestation of Graves' disease (GD) and the leading cause of exophthalmia in adults. Its clinical presentation is extremely heterogeneous, ranging from mild ocular discomfort to sight-threatening disease. The aim of our study was to specify the clinical and paraclinical characteristics, as well as the therapeutic modalities of GO.
Patients and methods
Descriptive retrospective study in the period between September 2008-December 2018, including 45 patients followed for GO in Endocrinology-Diabetology department of the University Hospital of Casablanca.
Results
The average age was 45 years (19–70 years) with male predominance. The average duration of GD was 4.7 years (1 month–14 years). The GO appeared at the same time as the GD in 9 cases, before the GD in 2 cases, and after that in the rest of our patients. The time between GD and diagnosis of GO varied between 0 and 6 years. The GO was unilateral in 4 cases. GO was inactive in 33% of cases. Strabismus was noted in 6 patients, and associated with diplopia in 5 cases. Three of our patients had a complicated GO with a corneal abscess. According to the NOSPECS classification: the GO was classified as stage 1 in 27%, stage II in 25%, and stage III in 48% of cases. An orbital CT-scan was performed in 30 patients, and an MRI in 2 patients, who objected a GO grade I in 9 cases, grade II in 11 cases, and Grade III in 11 cases. The management of the GO was surgical in 3 cases, intravenous glucocorticoids in 32 cases. Selenium supplementation and general measures were the only treatment recommended in 10 patients.
Conclusion
Grave's orbitopathy is more common in the male patient. The clinical expression is variable. The evaluation of the gravity and the activity of the GO as well as the radiological exploration allow a better management. Being considered an autoimmune disorder, corticosteroid therapy is widely used in severe and malignant forms.

Cardiovascular risk factors, autoimmunity and insulin resistance in Graves disease

Cátia Tomás Ferreira[1], Celestino Neves[1,2,3], João Sérgio Neves[1,2], Sofia Castro Oliveira[1,2], Oksana Sokhatska[1,4], Miguel Pereira[2], Ana Oliveira[2], José Luís Medina[1], Luís Delgado[1,4] & Davide Carvalho[1,2,3]
[1]Faculty of Medicine, University of Porto, Porto, Portugal; [2]Department of Endocrinology, Diabetes and Metabolism, Centro Hospitalar Universitário de São João, Porto, Portugal; [3]Institute for Research and Innovation in Health Sciences, University of Porto, Porto, Portugal; [4]Service and Laboratory of Immunology, Centro Hospitalar Universitário de São João, Porto, Portugal.

Introduction
Graves' disease is an autoimmune disease accounting for the majority of hyperthyroidism cases.
Aim
We aimed to assess the interrelationships between cardiovascular risk factors, autoimmunity, insulin resistance and treatment in Graves' disease.
Material and methods
We measured free T3 (FT3), free T4 (FT4), TSH, thyrotropin receptor antibodies (*TRAb*), anti-thyroglobulin and anti-TPO antibodies, thyroid volume (each lobe' volumes sum, given by the formula $0.479 \times depth \times$ wide $\times$ length), BMI, glucose, HbA1c, Homeostatic Model Assessment for Insulin Resistance (HOMA-IR), levels of total cholesterol (TC), HDL, LDL-cholesterol, triglycerides (TG), apolipoprotein B (ApoB), apoA1, lipoprotein(a) (Lp[a]), homocysteine, CRP (C-reactive protein), folic acid, B12 Vitamin in 85 patients with Graves' disease (89.4% female, 52.8 ± 13.4 years). Patients were divided in subgroups according to autoimmunity profile (positive TRAb (9.4%) or negative TRAb (81.2%)] and treatment [previously treated (80%) or in treatment with anti-thyroid drugs (20%)). Then, we divided the previously treated subgroup according to performed treatment [thyroidectomy (33.8%), I^{131} (13.2%) or anti-thyroid drugs (53%)]. *Pearson* correlation, t-test and Mann-Whitney test were performed for statistical analysis.
Results
Regarding TRAbs subgroups there was a positive correlation between Lp(a) and thyroid volume ($r=0.4726$, $P=0.0228$) in positive TRAb subgroup. A negative correlation between thyroid volume and FT3 ($r=-0.4710$, $P=0.0065$) was found in negative TRAb subgroup. Comparing with the previously treated subgroup, significantly higher thyroid volume (20.685 ± 9.86 ml vs 15.43 ± 1.398 ml, $P=0.0480$) and thyroglobulin (74.22 ± 35.29 ng/ml vs 16.47 ± 6.47 ng/ml, $P=0.0315$) and significantly lower TSH (0.85 ± 0.15 UI/ml, vs 2.3 ± 0.41 UI/ml, $P=0.0139$) were found in patients currently treated with antithyroid drugs. There was a positive correlation between HbA1c and thyroid volume ($r=0.4290$, $P=0.0255$), and between CRP and TC ($r=0.4362$, $P=0.0375$) in the previously treated subgroup. Regarding evaluation by performed treatment, significantly lower FT3 (2.395 ± 0.37 pg/ml, IC95 (2.231–2.560), $P=0.0319$ vs 3.02 ± 0.177 pg/ml, IC95 (2.67-3.38), $P=0.032$) was found in patients who performed thyroidectomy. In the thyroidectomy subgroup there was a positive correlation between FT3 and HOMA-IR ($r=0.5734$, $P=0.0103$). In patients without previous surgery or I^{131} treatment there was a positive correlation between age and thyroid volume ($r=0.2972$, $P=0.0425$), homocysteine and TRAb ($r=0.7911$, $P=0.0341$) and a negative correlation between thyroid volume and TRAb ($r=-0.5275$, $P=0.0358$).
Conclusion
In patients with Graves' disease, we found significant interrelationships between thyroid volume and function, autoimmunity, lipid and glycaemic profiles. These associations may contribute to the cardiovascular risk in Graves' disease.

Lipid profile, insulin resistance and cytokines evaluation in autoimmune thyroiditis patients

Juliana Gonçalves[1], Celestino Neves[1,2,3], Francisco Pêgo[1], João Sérgio Neves[1,2], Sofia Castro Oliveira[1,2], Oksana Sokhatska[1,4], Miguel Pereira[2], Ana Oliveira[2], José Luís Medina[1], Luís Delgado[1,4] & Davide Carvalho[1,2,3]
[1]Faculty of Medicine, University of Porto, Porto, Portugal; [2]Department of Endocrinology, Diabetes and Metabolism, Centro Hospitalar Universitário de São João, Porto, Portugal; [3]Institute for Research and Innovation in Health Sciences, University of Porto, Porto, Portugal; [4]Service and Laboratory of Immunology, Centro Hospitalar Universitário de São João, Porto, Portugal.

Introduction
Thyroid dysfunction has been associated with cardiovascular events since it worsens atherogenesis, insulin resistance and dyslipidemia. Thyroid hormones

and adipokines interact with each other to regulate metabolism. The impact of thyroid dysfunction on adipokines serum levels remains controversial.
Objective
To evaluate the interrelations between thyroid function and cardiovascular risk factors as insulin resistance, lipid profile, inflammatory markers and adipokines, in autoimmune thyroiditis patients.
Methods
60 patients with autoimmune thyroiditis were evaluated and tree groups were defined based on TSH level: TSH between 0.4 and 4.0 μUI/ml (50 individuals), TSH between 0.4 and 2.5 μUI/ml (29 individuals) and TSH higher than 4.0 μUI/ml and normal levels of free T4 (FT4) and free T3 (FT3) (10 individuals). We measured thyroid function and autoimmunity, lipid profile, serum homocysteine, vitamin B12, folic acid, high-sensitivity C-reactive protein, adiponectin, resistin, PAI-1 (plasminogen activator inhibitor-1), VCAM-1 (vascular cell adhesion molecule 1), ICAM-1(intercellular adhesion molecule 1), and insulin resistance markers comprising the HOMA-IR and WBISI (Whole-Body Insulin Sensitivity Index). A 75-g OGTT was performed in the morning (before 11 AM), and blood samples were obtained every 30 min for 120 min for measurements of plasma glucose, insulin, and C-peptide. Fisher's exact test, Kruskal-Wallis test, One-way ANOVA test and Pearson's correlations were performed for statistical analysis.
Results
In our sample, median age was 51.0 (32.3–59.8) years. There were no significant differences regarding median age or median BMI between groups. Patients with TSH >4.0 presented higher HOMA-IR when compared to those with patients with TSH 0.4–4.0 (2.1 (1.4–3.0) vs 1.02 (0.41–2.45), $P=0.042$) and lower WBISI (46.4 (27.7–72.7) vs 60.6 (42.8–124.3), $P=0.042$). In all sample, TSH was positively correlated with HOMA-IR ($r=0.317$, $P=0.014$) and negatively with WBISI ($r=-0.311$, $P=0.027$). We observed positive correlation with resistin and fasting C-peptid ($r=0.440$, $P=0.001$). FT3 was negatively correlated with PAI-1 ($r=-0.328$, $P=0.011$). In TSH 0.4–4.0 group, we found positive correlations between TSH and both HOMA-IR ($r=0.404$, $P=0.004$) and resistin ($r=0.420$, $P=0.002$). FT3 was negatively correlated with PAI-1 ($r=-0.311$, $P=0.030$). In TSH 0.4–2.5 group, FT3 was positively correlated with homocysteine ($r=0.441$, $P=0.021$) and negatively correlated with PAI-1 ($r=-0.440$, $P=0.019$). In TSH >0.4 group, we observed positive correlation between FT4 and HDL ($r=0.768$, $P=0.009$).
Conclusions
Autoimmune thyroiditis is associated with an increased cardiovascular risk. This association is complex and involves multiple factors. We found significant interrelationships between thyroid function, lipid profile, insulin resistance, homocysteine, resistin and PAI-1.

Autoimmune thyroiditis, Graves' disease and adiponectin, resistin and plasminogen activator inhibitor-1 levels

Celestino Neves[1,2,3], João Sérgio Neves[1,2], Sofia Castro Oliveira[1,2], Oksana Sokhatska[2,4], Miguel Pereira[1], Ana Oliveira[1], José Luís Medina[2], Luís Delgado[2,4] & Davide Carvalho[1,2,3]
[1]Department of Endocrinology, Diabetes and Metabolism, Centro Hospitalar Universitário de São João, Porto, Portugal; [2]Faculty of Medicine, University of Porto, Porto, Portugal; [3]Institute for Research and Innovation in Health Sciences, University of Porto, Porto, Portugal; [4]Service and Laboratory of Immunology, Centro Hospitalar Universitário de São João, Porto, Portugal.

Introduction
The interrelationship between autoimmune thyroiditis, Graves' disease and plasma adipokines levels remains elusive.
Aims
We aimed to compare the levels of adiponectin, resistin and PAI-1 levels in patients with autoimmune thyroiditis and Graves' disease.
Subjects and methods
We recorded thyroid function tests, BMI, the levels of total cholesterol (TC), HDL, LDL-cholesterol, triglycerides (TG), apolipoprotein B (ApoB), ApoA1, lipoprotein(a) (Lp[a]), homocysteine, CRP (C-reactive protein), folic acid, vitamin B12, adiponectin, resistin and plasminogen activator inhibitor-1 (PAI-1) in 98 patients with autoimmune thyroid disease (75.9% woman, with a mean age of 46.7 ± 15.3 years). We considered three groups of patients based on their thyroid function: euthyroidism ($n=30$), hypothyroidism ($n=35$) or hyperthyroidism ($n=33$). Statistical analysis was performed with Mann-Whitney test and spearman correlations. The results are expressed as mean$\pm$S.D. A two-tailed $P\leq0.05$ was considered significant.
Results
BMI values were significant higher in hypothyroidism compared to hyperthyroid subjects (30.3 ± 9.3vs 25.3 ± 4.7 kg/m^2, $P=0.03$). Serum levels of CRP were significantly elevated in hyperthyroid compared to euthyroid subjects (0.56 ± 0.55 vs 0.30 ± 0.24 mg/dl, $P<0.001$). The levels of Lp(a) were significantly elevated in hypothyroid compared to hyperthyroid subjects (24.6 ± 30.1 vs 18.6 ± 17.8 mg/dl, $P<0.001$). When compared to hyperthyroid subjects, those with hypothyroidism showed higher levels of resistin (20.7 ± 22.6 vs 12.7 ± 10.9 ng/ml, $P<0.01$) and PAI-1 (27.3 ± 25.1 vs 19.9 ± 17.4 ng/ml, $P<0.01$), and lower levels of adiponectin ($21.0\pm13.$vs28.3 ± 14.7 μg/ml, $P<0.01$). In both hypothyroid and hyperthyroid states the levels adiponectin, resistin and PAI-1 were not correlated with BMI. Adiponectin levels were negatively correlated with free T3 in hyperthyroid subjects ($r=-0.35$, $P<0.05$) and with TSH in euthyroid group ($r=-0.61$, $P<0.001$). Resistin levels were not correlated with TSH, free T3 or free T4. PAI-1 levels were negatively correlated with free T3 in both hypothyroid ($r=-0.42$, $P<0.05$) and hyperthyroid subjects ($r=-0.36$, $P<0.05$).
Conclusions
Patients with hypothyroidism due to autoimmune thyroiditis present higher levels of resistin and PAI-1 and lower levels of adiponectin comparing with patients with hyperthyroidism due to Graves' disease. The interrelations between thyroid function and adiponectin, resistin and PAI-1 may be associated with the pathogenesis of autoimmune thyroid disease and may contribute to the increased cardiovascular risk observed in these patients.

The neutrophil-to-lymphocyte ratio as a novel marker in patients with thyroid-associated orbitopathy – a preliminary study

Joanna Szydełko[1], Beata Rodzik[2], Jerzy Tarach[1] & Beata Matyjaszek-Matuszek[1]
[1]Medical University of Lublin, Department of Endocrinology, Lublin, Poland; [2]Maria Curie-Skłodowska University, Institute of Mathematics, Department of Mathematical Statistics, Lublin, Poland.

Introduction
Graves' orbitopathy (GO) is a rare autoimmune inflammatory disease occurring in 25–50% cases of Graves' disease (GD). It is associated with poor clinical outcomes, impaired quality of life and socio-economic status. Genetic, environmental and immunological factors are considered to play a role in the pathogenesis of GO, but the effects of neutrophil, lymphocyte counts as well as neutrophil-to-lymphocyte ratio on the pathophysiology of GO are still unknown.
Aim of the study
The aim of this retrospective study, which based on our knowledge is the first in Poland, was to explore the connection between white blood cell, neutrophil, lymphocyte counts, neutrophil-to-lymphocyte ratio (NLR) and the severity of GO compared with patients without thyroid-associated orbitopathy.
Subjects and methods
110 patients (91 female and 19 male; 82.7% vs 17.3%), mean age 49 ± 28.5 years diagnosed with GO hospitalized in the Department of Endocrinology (Lublin, Poland) in seven-year period was retrospectively analyzed. Among them 92 patients had active and 18 inactive thyroid associated-opthalmopathy. 50 patients with GD with no signs of opthalmopathy were also enrolled. The control group consisted of 50 healthy volunteers (24 female and 26 male: 48% vs 52%, aged 45 ± 27.0 years). All patients with GO were assessed for activity of the disease using clinical activity score (CAS). Active GO was defined as CAS ≥3/7. The correlation between neutrophil/lymphocyte ratio and clinical activity of GO (spontaneous retrobulbular pain, ocular pain with eye movement, redness of the eyelids, swelling of the eyelids, redness of conjunctiva, chemosis of the conjunctiva, swelling of the caruncule) were evaluated.
Results
It has been observed that the NLR values were statistically higher in patients with or without GO ($P=0.0001$ vs 0.0026) compared to controls. Moreover, the NLR, WBC and neutrophil counts were higher and the lymphocyte count was lower in patients with GO than in GD patients without thyroid orbitopathy ($P<0.1$). There was no statistically difference ($P=0.085$) between NLR and the activity of GO in the clinical scale, only one of the symptoms from CAS – redness of conjunctiva was positively correlated ($P=0.023$).
Conclusions
The results suggest that neutrophil/lymphocyte ratio may predict inflammatory process in GD patients with and without GO better than white blood cell, lymphocyte and neutrophil counts separately. However, analyzed group of patients is too small, therefore further research is needed to confirm these findings.

Effect of nine months of vitamin D supplementation on muscle performance in Graves' disease: a double-blinded, randomized clinical trial

Diana Grove-Laugesen[1], Sofie Malmstrom[1], Eva Ebbehoj[1], Anne Lene Riis[2], Torquil Watt[3], Klavs Würgler Hansen[4] & Lars Rejnmark[1]
[1]Aarhus University Hospital, Aarhus, Denmark; [2]Regional Hospital Horsens, Horsens, Denmark; [3]Gentofte Hospital, Gentofte, Denmark; [4]Regional Hospital Silkeborg, Silkeborg, Denmark.

Background
Vitamin D deficiency has been proposed to play a role in development and course of Graves' disease (GD). Muscle weakness and fatigue are shared features of GD and vitamin D deficiency. We aimed to investigate whether vitamin D supplementation would improve restoration of muscle performance and thyroid-related quality of life (QoL) in GD.
Methods
In a double-blinded clinical trial, hyperthyroid patients with a first time diagnosis of GD were randomized to vitamin D 70 mcg/day or matching placebo as add-on to standard antithyroid medication (ATD). At baseline and after three and nine months of intervention, we assessed isometric muscle strength, muscle function tests, postural stability, body composition, and self-reported ThyPRO Tiredness and Impaired Daily Life (0–100, higher score worse). Differences in change between groups were analyzed using linear mixed modelling. (The DAGMAR study clinicaltrials.gov ID NCT02384668).
Results
Nine months of vitamin D supplementation caused a reduced muscle strength increase at all muscle groups investigated, although only significant at knee extension 60° with a 7% (95% CI:0.3;13) lower increase in muscle strength compared with placebo. Vitamin D supplementation showed a trend towards reduced gain of lean body mass (−3.1% (95% CI: −6.5;0.4)). There was no significant difference in Tiredness or Impaired Daily Life, but improvement of Impaired Daily Life tended to be lower in the vitamin D group (10 points (95% CI: −2;22)). In the entire group of patients, all measures improved significantly in response to nine months of ATD with an improvement of 21–37% in muscle strength at the different muscle groups ($P_{all}<0.001$) and of 11% (95% CI:9;13) in lean body mass. Furthermore, performance of the repeated chair stand test and the time-up-and-go test improved by 15% (95% CI:12;18) and 2% (95% CI:0.4;5). Postural stability improved by 26–54% $P_{all}<0.001$. Large changes was observed in Tiredness and Impaired Daily Life with improvements of 22 (95% CI:19;26) and 36 (95% CI:28;45) points. In general, improvements were most marked during the first three months of ATD, but the recovery continued from three to nine months.
Conclusion
Nine months of vitamin D supplementation 70 mcg/day caused unfavorable effects on restoration of muscle performance. In contrast, ATD treatment was associated with marked improvement in all measures of muscle performance and thyroid-related QoL. In patients with newly diagnosed GD, high dose vitamin D supplementation should not be recommended to improve muscle function, but ATD therapy seems to be of major importance to alleviate muscle impairment.

Retrospective analysis of the efficacy of three different dose regimens of rituximab in patients with active moderate-severe graves' orbitopathy

Elisa Lazzaroni[1], Danila Covelli[1], Irene Campi[2], Guia Vannucchi[2], Nicola Currò[3], Giacinta Pirola[4], Claudio Guastella[5], Alessia Dolci[1], Maura Arosio[6] & Mario Salvi[1]
[1]Graves' Orbitopathy Center, Endocrinology, Fondazione IRCCS CàGranda, University of Milan, Milan, Italy; [2]Istituto Auxologico Italiano, IRCCS, Milan, Italy; [3]Opthalmology, Fondazione IRCCS CàGranda, University of Milan, Milan, Italy; [4]Opthalmology, Fondazione IRCCS Cà Granda, University of Milan, Milan, Italy; [5]Otolaryngology, Fondazione IRCCS Cà Granda, University of Milan, Milan, Italy; [6]Endocrinology, Fondazione IRCCS Cà Granda, University of Milan, Milan, Italy.

Aim
The aim of this retrospective study was to assess the efficacy of different doses of rituximab (RTX) in patients with active moderate-severe Graves' Orbitopathy (GO).
Methods
Overall 40 patients, 5 M/35 F; mean age (± S.D.) 58±11 years were treated with RTX; 21 were smokers. The patients received the following treatment: 14 patients (group 1) a single 100 mg dose; 15 patients (group 2) a single 500 mg dose and 11 Patients (Group 3) 2 doses of 1000 mg.
Results (1)

Table 1

	Nr	GO duration (months)	Patients' age (years)	Nr. of pat. with previous steroid therapy	Baseline CAS*	12 weeks CAS*	24 weeks CAS*
Group 1	14	20	56	7/14	4.5±1	2.1±1.6	*1.1±-0.8*
Group 2	15	18	57	2/15	4.3±1	1.3±1.5	*0.1±1.1*
Group 3	11	18	63	2/11	4.4±1	1.8±1.3	*0.8±1.1*
ANOVA		n.s.	n.s.	n.s.	n.s.	n.s.	***0.04***

*values are expressed as mean ±S.D.

Results (2)
- Serum TRAb levels were significantly reduced in the in the three groups at 24 weeks (*P*-value Group 1 0.002, *P*-value Group 2 0.001, *P*-value Group 3 0.05). At 12 weeks serum TRAb levels decreased significantly only in group 2 (*P*-value 0.002)
- 13/40 patients at baseline and 14/40 at 24 weeks were persistently hyperthyroid, despite the change in serum TRAb title throughout RTX therapy.
- 2 patients of group 1 (100 mg dose) developed optic neuropathy.
- 3 patients presented major adverse reaction after only 25–75 mg of RTX: acute cytokine release syndrome, clinically manifesting with marked soft tissue edema associated with pain and transient decrease of vision.
Conclusions
1. RTX induced persistent GO inactivation in all the patients, regardless of the doses used. The higher CAS value at 24 weeks in patients treated with 100 mg compared to those treated with higher doses may be due to a lesser degree of orbital lymphocytic depletion.
2. The analysis of the quality of life questionnaire shows only a minimal improvement of the appearance but not of ocular function score.
3. The decrease of serum TRAb at 24 weeks was observed in all three groups of patients and might be due to the ongoing anti-thyroid therapy rather than to an effect of RTX.
4. Finally, the use of low dose RTX does not seem to prevent the development of adverse effects. We suggest that RTX should not be used in patients with subclinical optic neuropathy.

Coexistence of the BRAF V600E and TERT promoter mutations and their impact on response to therapy and final outcome of papillary thyroid cancer

Tomasz Trybek[1], Agnieszka Walczyk[1], Danuta Gęsior-Perczak[1], Iwona Pałyga[1], Estera Mikina[1], Artur Kowalik[2], Janusz Kopczyński[3], Magdalena Chrapek[4], Stanisław Góźdź[5,6] & Aldona Kowalska[1,6]
[1]Endocrinology Clinic, Holycross Cancer Center, Kielce, Poland; [2]Department of Molecular Diagnostics, Holycross Cancer Center, Kielce, Poland; [3]Department of Surgical Pathology, Holycross Cancer Center, Kielce, Poland; [4]Department of Probability Theory and Statistics Institute of Mathematics, Faculty of Mathematics and Natural Sciences, Jan Kochanowski University, Kielce, Poland; [5]Oncology Clinic, Holycross Cancer Center, Kielce, Poland; [6]The Faculty of Health Sciences, Jan Kochanowski University, Kielce, Poland.

Introduction
Coexistence of the *BRAF* V600E and *TERT* promoter mutations may correlate with more aggressive histopathological features and worse course of the disease. According to the American Thyroid Association (ATA) dynamic risk stratification with modified initial estimated risk based on response- to-therapy and disease course allows individual risk assessment and support clinicians in the appropriate management approach to differentiated thyroid cancer (DTC).
Aim
The aim of this study was to examine the relation between the coexistence of the *BRAF* V600E and *TERT* promoter mutations in the papillary thyroid cancer (PTC) and response to therapy according to the ATA guidelines.

Participants
Unselected 568 PTC cases with known *BRAF* and *TERT* status diagnosed from 2000–2012 and actively monitored at one institution were reviewed retrospectively.
Main outcome measures
The association between the *BRAF* V600E and *TERT* promoter mutation and clinicopathological features, TNM stages, initial risk, response-to-therapy categories, follow-up, and the final outcome of the disease according to the revised 2015 ATA criteria and the 8th edition of the American Joint Committee on Cancer/Tumor-Node-Metastasis (AJCC/TNM) staging system.
Results
Any *TERT* promoter (*TERT*p) mutations were detected in 13.5% (77/568) of PTC cases with known *BRAF* status. The C228T and C250T mutations were 54 (9.5%) and 23 (4%) patients, respectively. Twenty-two additional other *TERT* alterations were found. Coexistence *BRAF* V600E and *TERT* hotspot C228T or C250T promoter mutation was found in 9.5% (54/568). Concurrent *BRAF* and *TERT*p positive status correlated significantly with older patient's age ($P=0.001$), gross extrathyroidal extension ($P=0.003$), pT3–4 tumor stage ($P=0.005$), stage II-IV according to the AJCC/TNM ($P=0.019$), and ATA intermediate or high risk according to the 2015 ATA initial risk stratification ($P=0.003$), as well as with the worse than excellent category of response to primary therapy ($P=0.045$), recurrence ($P=0.015$) and no remission in the final outcome ($P=0.014$). During a median follow-up of 120 months (10 years), 16 (29.6%) patients *BRAF* (+) and *TERT* (+) did not achieve excellent response to primary therapy, three (5.6%) were recurrent after a disease-free period and eight (14.8%) presented no remission at the end of follow-up.
Conclusions
The positive *BRAF* V600E and *TERT* mutation in patients with PTC correlate with poor prognostic initial factors and clinical course. Coexistence the *BRAF* and *TERT* status seems to be suitable for predicting a worse response-to-therapy, recurrence, and poor outcome.

Prognostic significance of TERT promoter and BRAF mutations in cytologically suspicious or malignant thyroid nodules: a monocentric case series at a tertiary-level endocrinology unit

Simona Censi[1], Susi Barollo[1], Elisabetta Grespan[1], Sara Watutantrige-Fernando[1], Elisabetta Cavedon[1], Jacopo Manso[1], Maurizio Iacobone[2], Eric Casal Ide[2], Francesca Galuppini[3], Ambrogio Fassina[3], Gianmaria Pennelli[3], Federica Vianello[4], Loris Bertazza[1] & Caterina Mian[1]
[1]Department of Medicine (DIMED), Endocrinology Unit; University of Padova, Padova, Italy; [2]Endocrine Surgery Unit, Department of Surgical, Oncological and Gastroenterological Sciences (DiSCOG), University of Padova, Padova, Italy; [3]Surgical Pathology and Cytopathology Unit, Pathology Unit, Department of Medicine (DIMED), University of Padova, Padova, Italy; [4]Department of Radiotherapy, Istituto Oncologico Veneto-IRCCS, Padova, Italy.

Background
Follicular-derived thyroid cancers (FDTC) generally have a good prognosis. Nonetheless, a minority of them have an aggressive behavior and develop distant metastases, with increased mortality rates. Pre-surgically available prognostic markers, able to identify this group of patients are still lacking.
Materials and methods
The study involved 436 FNA samples with a malignant/suspicious cytology obtained from thyroid nodules in 436 consecutive patients referred for surgical excision from April 2007 to January 2017. Molecular analysis for somatic mutations of *TERT* promoter was retrospectively performed in all patients. 434 patients also underwent *BRAF* analysis. ^{131}I remnant ablation was performed in 387 patients (median dose: 100 mCi; range: 30–200 mCi). Follow-up was available for 384 patients (median: 59 months, range: 7-293 months).
Results
TERT promoter mutations and *BRAF* mutations were detected in 20/436 (4.6%) and in 257/434 thyroid nodules (59.2%), respectively. At the end of the follow-up, 319/384 patients (83%) had an excellent outcome, 37/384 (9.7%) had an indeterminate response and 28/384 (7.3%) had biochemical or structural persistent disease or died because of disease progression. Tumor size ($P=0.002$), presence of extrathyroidal extension ($P=0.0015$), vascular invasion ($P=0.0024$), lymph node involvement ($P=0.0001$), mostly N1b spread ($P<0.0001$), distant metastasis (DM) ($P<0.0001$), advanced stage at diagnosis ($P<0.0001$) and *TERT* promoter mutation ($P=0.0002$) were all significantly correlated with the risk of persistent/recurrent disease or disease-related death. At multivariate analysis, only cancer size (OR 1.06, 95% CI 1.01 to 1.09), the presence of N1b lymph-node metastases (OR 8.09, 95% CI 2.62 to 25.04) and DM (OR 7.32, 95% CI 1.17 to 45.81) predicted persistence disease or cancer-related death. *TERT* promoter mutations were related with older age ($P<0.0001$), largest tumor size ($P=0.0002$), higher tumor stages ($P<0.0001$), and DM ($P<0.0001$). DM was correlated with older age ($P=0.0487$), larger tumor size ($P=0.0015$), extra-thyroidal extension ($P=0.0120$), presence of N1b ($P=0.0001$) and *TERT* promoter mutation ($P<0.0001$). Presence of *BRAF* mutation was less frequent in patients with DM ($P=0.0201$). *TERT* promoter mutations (OR 40.58; 95% CI 3.06 to 539.04) and N1b (OR 40.16, 95% CI 3.48 to 463.04) were independent predictors of DM at multivariate analysis.
Conclusions
TERT promoter mutation was an independent predictor for DM, giving the clinician the possibility to individuate, already in the pre-surgical setting, many of the patients who deserve a more aggressive initial treatment and a closer follow-up.

Polygenic susceptibility to papillary thyroid cancer: detection of the main genetic signature in Italian patients

Giulia Brigante[1], Clara Lazzaretti[1], Elia Paradiso[1], Asta Foersti[2], Kari Hemminki[2], Rossella Elisei[3], Cristina Romei[3], Manuela Simoni[1], Stefano Landi[4] & Livio Casarini[1]
[1]Department Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; [2]Division of Molecular Genetic Epidemiology C050, German Cancer Research Center (DKFZ), Heidelberg, Germany; [3]Department of Endocrinology, University Hospital, Pisa, Italy. [4]Dept. Of Biology, University of Pisa, Pisa, Italy.

Introduction and aim
Thyroid cancer is the most common endocrine neoplasia affecting 0.2–1.5% of the individuals worldwide and its incidence is increasing [1]. Papillary thyroid carcinoma (PTC) is the main histotype (80–90%). PTC susceptibility is the result of genetic predisposition, environmental factors and lifestyle. We hypothesized that genetic predisposition to PTC is poligenic and characterized by a genetic signature involving combinations of genes previously found to be associated to PTC.
Methods and results
We considered all the genetic variants (SNPs) significantly associated with PTC on the PubMed literature database. 184 informative SNPs were selected after data refining considering linkage disequilibrium. Then, SNPs data were extracted from the 1,000 Genomes database (www.1000genomes.org), comprising genome of 2504 unselected individuals, collected worldwide. The combination of 184 SNPs associated with PTC was used to group individuals in different risk-clusters according to their genetic structure, calculated by Bayesian statistics, as previously successfully performed for polycystic ovary syndrome [2]. Individuals resulted to be distributed among seven groups worldwide, indicating different degree of genetic predisposition to PTC. Then, we repeated the same analyzes considering genetic data from about 1200 individuals (697 PTC *versus* 497 healthy controls) of Central/South Italian origin registered in a GWAS, specific for PTC, by the German Cancer Research Center (DKFZ) of Heidelberg [3]. This first analysis was refined using the 33 SNPs with highest odds ratio, therefore, reasonably most causative of genetic clustering. We clearly demonstrated that PTC and healthy control groups are genetically different, revealing diverse predisposition to develop cancer. Then, the genetic structure of each subject was indicated as a percentage of affinity to each risk-cluster and re-analyzed together with other risk factors: sex, BMI, area of origin and familiarity (quantified in a growing score as the degree of kinship increases). These data were analyzed together by principal component analysis (PCA) and clustering of the two groups was even more pronounced. The most contributive factors to the diversity between PTC and healthy controls were genetics and familiarity, while sex, body-mass index and area of origin were less relevant.
Conclusion
We demonstrated that PTC risk may be predicted using SNPs and risk factors data. Validation of the model in independent groups of PTC patients ($n=200$) and healthy controls ($n=130$) genotyped by iPlex assay is ongoing.

Follistain-like 1 (Fstl1) may reduce metastastic activity of anaplastic thyroid cancer by increasging thyroid transcription factor 1 (TTF1) and epithelial gene markers

Jong Suk Park[1], Arim Choi[1], Jung Hye Kim[1], Kahui Park[1], Sang Bae Lee[1], YuSik Kim[2], Ji Sun Nam[1], Shinae Kang[1] & Chul Woo Ahn[1]
[1]Division of Endocrinology, Department of Internal Medicine, Gangnam Severance Hospital, Yonsei University College of Medcine, Seoul, Republic of Korea; [2]Severance Institute for Vascular and Metabolic Research, Yonsei University College of Medicine, Seoul, Republic of Korea.

Background
Although anaplastic thyroid cancer (ATC) is found in less than 2% of patients with thyroid cancer, it is the most advanced, aggressive and lethal. ATC is known to develop from well-differentiated thyroid cancers, such as follicular thyroid cancer, and it is undifferentiated itself. Among the thyroid-specific transcription factors that are critical for the function of thyroid, the expression of thyroid transcription factor 1 (TTF1), or NKX2.1, has been reported to correlate with the degree of differentiation, thus, its level is the lowest in ATC among thyroid cancers. TTF1 was reported to reduce invasion and metastasis in lung cancer; however, its regulatory effects on metastasis in ATC in unknown. The metastasis suppression effect of follistatin-like 1 (Fstl1) has been recently reported; however, the results are inconsistent. Herein, we investigated the effects of Fstl1 on metastasis of ATC cell line.
Methods
8505C cell line was maintained in EMEM containing 2 mM glutamine, 1% non-essential amino acids and 10% FBS. Human Fstl1 was treated at 200 ng/m for 24 hr, 48 hr, and 72 hr. Cell viability was measured by MTT assay. Expression of epithelial gene markers including claudin 1, claudin 4, claudin 7, and occludin and mesenchymal gene markers including vimentin and N-cadherin were confirmed by real-time quantitative PCR (qPCR). In addition, gene expression of TTF1 was also measured by qPCR. Protein expression of each marker was examined by western blot.
Results
Fstl1 did not affect cell viability. Gene expressions of claudin 1, 4 and 7 significantly increased after 24 hours compared to control while that of TTF1 significantly increased after 72 hours. However, there was no significant change in protein expression of each marker. None of mesenchymal markers were changed in response to Fstl1.
Conclusion
We demonstrated that Fstl1 increased epithelial gene markers and TTF1 in 8505C cell line. These suggest that Fstl1 can suppress metastastic activity of anaplastic thyroid cancer.

Benefits and limitations of TKIs in patients with medullary thyroid cancer: a systematic review and meta-analysis

Zoe Efstathiadou[1], Charalambos Tsentidis[2], Alexandra Bargiota[3], Vasiliki Daraki[4], Kalliopi Kotsa[5], Georgia Ntali[6], Lamprini Papanastasiou[7], Stylianos Tigas[8], Konstantinos Toulis[9], Kalliopi Pazaitou-Panayiotou[10] & Maria Alevizaki[11]
[1]'Hippokration' General Hospital of Thessaloniki, Thessaloniki, Greece; [2]General Hospital of Nikaia 'Agios Panteleimon', Piraeus, Greece; [3]Department of Endocrinology, University of Thessaly, Larisa, Greece; [4]Department of Endocrinology, University Hospital of Crete, Heraklion, Greece; [5]Department of Endocrinology, 'Ahepa' Hospital, Thessaloniki, Greece; [6]Department of Endocrinology, 'Evangelismos' Hospital Athens, Athens, Greece; [7]Department of Endocrinology and Diabetes Center, Athens General Hospital 'G. Gennimatas', Athens, Greece; [8]Department of Endocrinology, University of Ioannina, Ioannina, Greece; [9]Department of Endocrinology, 424 General Military General Hospital of Thessaloniki, Thessaloniki, Greece; [10]Department of Endocrinology-Endocrine Oncology, Theagenion Cancer Hospital, Thessaloniki, Greece; [11]Endocrine Unit, Department of Medical Therapeutics, Athens, Greece.

Tyrosine Kinase Inhibitors (TKIs) have been used in patients with advanced Medullary Thyroid Carcinoma (MTC). However, for some compounds, data on effectiveness and safety are limited. The aim of this systematic review and meta-analysis was to document clinical response and toxicities of TKIs in advanced MTC.
Methods
A literature search in MEDLINE, EMBASE and Cochrane until May 2018 was performed for articles or abstracts on TKI use in MTC. Studies were included in the meta-analysis if they presented results on tumor response to TKIs and/or adverse events of TKI therapy in 5 or more patients with MTC. The primary endpoint was objective response rate; disease stability, median progression free survival (PFS), drug discontinuation due to adverse events and Grade ≥ 3 adverse events (G3AEs) were secondary endpoints. Pooled percentages were calculated using meta-analysis of binomial data. Direct comparisons between specific drugs were not feasible and drug-specific effect estimates are provided descriptively.
Results
Thirty-three publications met the inclusion criteria for analysis: 1 phase IV trial, 2 phase III trials evaluating vandetanib and cabozatinib respectively, 20 phase I or II studies, with the remaining 10 studies of retrospective/observational nature. In total, data on 1274 patients were evaluated, 81 in phase IV trial, 561 in phase III trials, 441 in phase I–II trials and 191 in retrospective studies. Significant heterogeneity was detected for all effect estimates. Overall, objective response (CR & PR) was documented in 23% (95% CI 17–28; $I^2=79.2\%$) of the patients, with higher rate observed with sunitinib [38% (95% CI 20–59)]. Stable disease was reported in 44% (95% CI 38–51; $I^2=71.1\%$) of patients, with higher rate observed with axitinib [58% (95% CI 38–78)]. Overall disease progression was reported in 19% (95% CI 14–25; $I^2=80.1\%$) of patients, with the lowest proportion reported in the motesanib [8% (95% CI 3–15)] patients. Overall, 33% (95% CI 23–42; $I^2=90.7\%$) of patients discontinued the drug due to toxicity or disease progression with the lowest proportion reported in the cabozantinib group 14% (95% CI 11–18). G3AEs were reported in 50% (95% CI 47.1–52.9) of patients, with the lowest proportion reported in pazopanib treated group [14.2% (95% CI 2.7–25.8)].
Conclusion
TKI treatment in MTC exhibited a significant benefit in terms of reducing progression of the disease, however, careful monitoring of patients on these drugs is important to manage AEs efficiently and proactively, and determine if the drug is no longer effective.

Intronic RAS and PI3KCA mutations identified by Next Generation Sequencing in thyroid nodules with indeterminate cytology may associate with follicular thyroid cancer

Patricia Borges de Souza[1], Lucrezia Rossi[1], Anna Crociara[2], Roberta Rossi[2], Maria Rosaria Ambrosio[1], Martina Rossi[2], Marta Bondanelli[1], Giovanni Lanza[3] & Maria Chiara Zatelli[1]
[1]Section of Endocrinology and Internal Medicine, Department of Medical Sciences, University of Ferrara, Ferrara, Italy; [2]Unit of Endocrinology, University Hospital of Ferrara, Ferrara, Italy; [3]Section of Pathology, Department of Medical Sciences, University of Ferrara, Ferrara, Italy.

Introduction
Accurately discern malignant from benign nodules sometimes represents a real challenge. Fine needle aspiration (FNA) biopsy, ultrasound and The Bethesda System for Reporting Thyroid Cytopathology (BSRTC) allow for accurate diagnosis in 60–80% of all nodules. However, 10–20% of thyroid FNAs yield an indeterminate cytology (BSRTC III and IV categories). The real malignancy rate of BSRTC III category is difficult to ascertain because histopathological analysis of the lesion is not always available. Molecular testing may assist clinical practice in the management of controversial FNAs since 67% of thyroid cancers bear at least one genetic alteration. Next-generation sequencing (NGS) provides parallel high-throughput alternative to assess multiple targets of the genome and, in recent years, several mutational panels that include genetic alterations identified in thyroid cancer have been developed and tested for performance.
Aim
In view of the above, the aim of this study was to investigate the presence of not yet described genetic alterations occurring in FNA samples with indeterminate cytology, by using a custom multi-gene NGS panel, in order to better characterize indeterminate cytology nodules.
Materials and methods
The study includes 56 random FNA samples yielding Bethesda III or IV cytological analysis that underwent surgery, therefore histopathological diagnosis is available: 32 are benign nodules, 22 are papillary thyroid carcinomas (PTCs) and 11 are follicular thyroid carcinomas (FTCs). NGS was performed by using a custom library on Ion PGM™ sequencer. Reporter variant caller pipeline was used for data analysis and R and PLINK software were used to compute logistic regression and principal component (PCA) analyses.
Results
PCA analysis did not show any significant variation between PTC, FTC and benign nodules, indicating the heterogeneous nature of thyroid nodules. However, we did find genetic alterations in intronic regions of PI3KCA and HRAS genes that were significantly associated with our population of FTCs, showing an odds ratio >15 and $P>0.001$.

Conclusions
Our results indicate that FNA samples with Bethesda III or IV cytological analysis show genetic alterations in intronic regions of PI3KCA and HRAS genes in 16% of the samples and associate with a final histology consistent with FTCs. Several groups have developed Genetic Classifiers for thyroid cancer in order to increase sensitivity and specificity of molecular testing. However, unknown and/or intronic genetic alterations are usually discarded. We found an intronic HRAS point mutation that was strongly and positively associated with FTC phenotype that should be investigated for its' potential predictive value.

An analysis of false-positive uptake on radioiodine whole-body scintigraphy

Ozlem Turhan Iyidir[1], Pırıl Büyükaşık[2], Adam Rajab Mwinyi[2], Ayse Aktas[3], Arzu Gencoglu[3] & Neslihan Bascil Tutuncu[1]
Baskent University, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Baskent University, Department of Internal Medicine, Ankara, Turkey; [3]Baskent University, Department of Nuclear Medicine, Ankara, Turkey.

Introduction
Radioiodine can be used for the ablation/treatment and imaging of thyroid cancer. However, radioiodine uptake is not specific for thyroid tissue. Iodine-131 can show physiologic accumulation in several organs as breast, thymus, liver and gastrointestinal tract, or in benign conditions, such as cysts and inflammation, or in a variety of benign and malignant non-thyroidal tumors, which could be mistaken for thyroid cancer or cancer metastasis. Here we aimed to evaluate extrathyroidal uptakes in radioiodine scan of our patients with differantiated thyroid cancer.
Patients and methods
We reviewed the data of 701 planar ^{131}I whole-body imaging findings of consecutive 585 patients with differantiated thyroid cancer. The patients were referred either for initial post-surgical ^{131}I ablation, for subsequent ^{131}I therapy of residual, recurrent or metastatic disease or for diagnostic ^{131}I whole-body imaging after initial treatment. We evaluated the false-positive uptake of radioiodine in the whole body and noted the confirmed diagnosis of the incidental finding with further imaging modalities.
Results
Of the 585 patients, 214 (36.6%) had diagnostic whole body scan during their follow up for thyroid cancer, 255 (43.6%) had scans after radioiodine remnant ablation or adjuvant therapy, 116 (%19.8) had both diagnostic and posttreatment scans. The extrathryoidal uptakes are listed in Table 1. Of the 701 planar ^{131}I whole-body imaging, 365 (62.4%) showed no incidental findings. The most commonly reported incidental finding was dental pathology ($n=82$; 14%).

Extrathyroidal uptake	N; %
None	365; 62.4%
Dental pathology	82; 14%
Sialoadenitis	50; 8.6%
Nasal inflammation	62; 10.6%
Bronchopulmonary infection-Bronchiectasis	17; 2.9%
Esophageal retention-Gastroeosophagial reflux disease	11; 1.9%
Arthritis	5; 0.9%
Liver	5; 0.9%
Non lactating breast (fibroadenoma; breast cancer)	4; 0.7%
Thymus	4; 0.7%
Trauma	3; 0.5%
Inguinal hernia	3; 0.5%
Thryoglossal duct	2; 0.3%
Ovarian cyst	1; 0.2%

Discussion
In our study we detailed the extrathyroidal uptake of diagnostic or posttherapy whole body scan of our patients with differentiated thyroid cancer which majority of them considered to be physiologic. Most commonly encountered uptake appeared in the oral cavity and was thought to be due to dental pathology. Further imaging was necessary in only a minority of patients. The awareness of these findings will lead us to be in contact with imaging physcians for characterizing the increased uptakes with additional imaging tehcniques and we can be more confident in establishing proper management for patients with differantiated thyroid cancer.

Prospective sonographic assessment of 214 consecutive nodules as per the ATA 2015 guidelines. Real world data

Angelos Kyriacou[1,2,3] & Giorgos Zavros[1]
[1]Evangelismos Hospital, Limassol, Cyprus; [2]Cyprus International Institute for Environmental and Public Health, Limassol, Cyprus; [3]Salford Royal NHS Foundation Trust, Greater Manchester, UK.

Introduction
Most studies which scrutinized the ATA 2015 thyroid nodule guidelines were performed retrospectively, in tertiary centers of excellence and in Western populations. We sought to prospectively apply these guidelines, under 'real world' conditions and in an eastern Mediterranean population.
Methods
Thyroid nodules were prospectively and independently assessed by two experienced sonographers and classified as per the guidelines. Only nodules that underwent USS-guided FNA were included for this study. Descriptive statistics are provided. Statistical analysis was performed using the chi-square test.
Results
214 nodules in 175 consecutively assessed patients were included (mean age 54.3 years; females 84.6%). They were sonographically classified as per the ATA guidelines as very low, low, intermediate and high risk in 7 (3.3%), 110 (51.4%), 65 (30.4%) and 32 (15%) nodules, respectively. Their cytological classification was Thy1, Thy2, Thy3a, Thy3f, Thy4 and Thy5 in 10 (4.7%), 169 (79%), 15 (7%), 9 (4.2%), 5 (2.3%) and 6 (2.8%). The correlation between the sonographic and cytological classification of nodules was excellent ($P<0.0001$); for example, Thy2 appearances were observed in 7/7 (100%), 100/110 (90.9%), 52/65 (80%) and 10/32 (31.2%) of nodules sonographically classified as very low, low, intermediate or high risk, respectively. Histology was available for 47 nodules; 16/47 (34%) were malignant. The risk of malignancy was 1/1 (100%), 2/17 (11.8%), 2/12 (16.7%) and 11/17 (64.7%) with very low, low, intermediate and high risk USS appearances, respectively ($P=0.002$). The two patients with low risk USS features who were diagnosed with malignancy included one patient with a nodule at 5 cm and another with incidental mPTC not in the nodule which was aspirated. The risk of malignancy was 0/1, 3/18 (16.7%), 1/10 (10%), 2/7 (28.6%), 4/5 (80%) and 6/6 (100%) with Thy1, Thy2, Thy3a, Thy3f, Thy4 and Thy5 cytological appearances, respectively ($P=0.001$). The three patients with Thy2 cytology with malignancy on histology included a 49-year-old lady with a positive family history and a large cystic nodule with very dark/viscous material aspirated, a 25 year-old with intermediate risk nodule but rapid growth associated with discomfort and a 66-year-old lady with a low risk nodule with a diameter up to 3.7 cm.
Discussion
Apart from the relatively higher rate of malignancy observed in Thy2 cytology results, our prospective data are similar to those provided at the guidelines, indicating the utility of the guidelines in routine secondary care practice and in different populations. Notwithstanding, clinical acumen remains of paramount importance when applying the guidelines.

Treatment modalities in DTC patients with neck disease persistence. Second surgical intervention is more beneficial than only radioiodine (RAI) treatment

Katerina Saltiki, George Simeakis, Panagiota Konstantakatou, Spyros Sapounas & Maria Alevizaki
Endocrine Unit, Department Clinical Therapeutics, Medical School National Kapodistrian University, Athens, Greece.

Objectives
DTC has a favorable clinical course. A small percentage of patients undergoing surgery and RAI ablation may have local disease persistence and further therapeutic interventions may be needed such as further RAI administration following or not a second surgery. We investigated whether additional therapeutic interventions may be beneficial for the clinical course in DTC patients with disease persistence.
Methods
812 DTC patients (men 25.7%, age at diagnosis 42.4 ± 15.5 yrs) who received RAI ablation were followed-up in our department for 1–44 yrs (median 3 yrs). 206 of them received further RAI treatment with or without additional cervical surgery. They were classified in 3 groups according to the treatment modality that was followed: RAI-only ($n=47$, 22.8%), RAI+Surgery ($n=86$, 41.7%) multiple-interventions group ($n=73$, 35.4%). Clinical and histological characteristics were compared between groups.

Results
One year after diagnosis and before further intervention, stimulated thyroglobulin levels (sTG, median (IQR)) were in the groups RAI-only 4.9(23) vs RAI+ surgery 6.7(47) vs multiple-interventions 62(179) ng/mL ($P=0.01$). After the additional interventions sTG changed to 5.3(26), 2.4(21), 33(143) respectively in the 3 groups ($P<0.001$). Patients in the RAI-only group showed less frequently disease remission compared to RAI+Surgery group (24.4% vs 43.5%, $P<0.001$). The occurence of distant metastases during follow up was higher in RAI-only group (33.3% vs 16.0%, $P=0.002$). Age at diagnosis, histology type, tumour size, multifocality, presence of lymph node infiltration, capsular invasion, soft tissue invasion, did not differ significantly between groups. The 10-year probability of lack of progression of disease was: RAI-only 67.4% vs RAI+ Surgery 89.5% ($x^2=18.06$, $P<0.001$). Disease progression, RAI refractory DTC and distant metastases were more prevalent in the group of multiple interventions ($P<0.001$).
Conclusions
In DTC patients with disease persistence a second RAI administration without prior surgical intervention may not be beneficial in the majority of cases. Surgical removal of the metastatic disease prior to RAI administration could be a better therapeutic option for these patients.

Detection of *EIF1AX*, *CHEK2* and *PPM1D* gene variants in thyroid carcinomas

Sarka Dvorakova[1], Barbora Pekova[1], Vlasta Sykorova[1], Gabriela Vacinova[1], Eliska Vaclavikova[1], Jitka Moravcova[1], Rami Katra[2], Petr Vlcek[3], Pavla Sykorova[3], Jan Plzak[4], Petr Bavor[5], Daniela Kodetova[6], Martin Chovanec[7], Josef Vcelak[1] & Bela Bendlova[1]
[1]Department of Molecular Endocrinology, Institute of Endocrinology, Prague, Czech Republic; [2]Department of ETN, Motol University Hospital, Prague, Czech Republic; [3]Department of Nuclear Medicine and Endocrinology, Motol University Hospital, Prague, Czech Republic; [4]Department of Otorhinolaryngology and Head and Neck Surgery, Motol University Hospital, Prague, Czech Republic; [5]Department of Surgery, Motol University Hospital, Prague, Czech Republic; [6]Department of Pathology and Molecular Medicine, Motol University Hospital, Prague, Czech Republic; [7]Department of Otorhinolaryngology and Head and Neck Surgery, Royal Vinohrady Teaching Hospital, Prague, Czech Republic.

Objectives
The identification of novel causing genes in thyroid carcinoma is very important in diagnosis and prognosis of the disease. Recently, The Cancer Genome Atlas (TCGA) study found *EIF1AX, CHEK2* and *PPM1D* genes as new minor causing genes in the papillary thyroid cancer (PTC) development. The goal of this study was to detect variants in these genes in PTC, follicular thyroid carcinoma (FTC) and anaplastic thyroid carcinoma (ATC) cohorts.
Methods
DNAs were isolated from 324 fresh-frozen thyroid tissues of the patients – 316 with PTC, 2 with FTC and 6 with ATC. Exons 1, 2, 5 and 6 of the *EIF1AX* gene, exons 3, 4, 7, 11, 13 of the *CHEK2* gene and exons 1, 4, 5 and 6 of the *PPM1D* gene were analyzed by next generation sequencing (NGS) using Nextera XT kit for the preparation of library and sequenced on MisDefault (Illumina). These exons were selected based on the TCGA study results.
Results
In summary, 5 variants in the *EIF1AX* gene were detected - 2 in PTC (0.6%), 1 in FTC (50%) and 2 in ATC (33.3%). A113_splice variant in the exon 6 with *TERT* C250T and *TP53* P153Afs*28 mutations in the first ATC tissue and G9V variant in the exon 2 with *TERT* C228T and *TP53* S215G mutations in the second ATC were detected. c.429+1 G>A splice variant affecting donor site with *HRAS* Q61K mutation in FTC was found. K3N variant in the exon 1 with *BRAF* V600E and *TERT* C250T mutations in one PTC and P2L variant in the exon 1 with *KRAS* Q61R mutation in the other PTC were detected. Only germline variants in *CHEK2* and *PPM1D* genes in 21 PTC (6.6%) and 10 PTC (3.2%) were revealed, respectively. Eight different variants with main I157T variant in the *CHEK2* gene and seven different variants with the most frequent A152A variant in the *PPM1D* gene were recognized.
Conclusions
Totally, five different somatic variants in the *EIF1AX* gene in 5 cases (in ATC, FTC and PTC) were identified. All these variants co-occurred with other known mutations and contribute to cancer behaviour. Only germline variants in the other two genes were detected. Thus, *EIF1AX* gene is verified as a minor causing gene, but *CHEK2* and *PPM1D* genes have predisposition function. However, it is necessary to enlarge the studied cohorts, because the detection rates of variations are low. This work was supported by AZV 16-32665A and MZ ČR-RVO (EÚ, 00023761) grants.

GP92

Diagnostic performance evaluation of a computer-assisted imaging analysis system for ultrasound risk stratification of thyroid nodules

Jordi L Reverter, Carlos Puig-Jové, Federico Vazquez & Manel Puig-Domingo
Endocrinology and Nutrition Service, Germans Trias i Pujol Hospital and Research Institute, Autonomous University of Barcelona, Badalona, Spain.

Aim
To evaluate the diagnostic effectiveness of the first commercially available computer-aided diagnostic (CAD) imaging analysis system.
Methods
Ultrasound images of 300 thyroid nodules (135 malignant) acquired prior to surgical treatment were retrospectively reviewed by a thyroid expert, and then the classification of each image was compared to the classification rendered by an image analysis program (AmCAD-UT®). The American Thyroid Association (ATA), the European Thyroid Imaging Reporting and Data System (EU-TIRADS), and the American Association of Clinical Endocrinologists (AACE/ACE/AME) classification systems were used for risk stratification.
Results
Diagnostic performance of the thyroid expert using the ATA system was: 87.0% sensitivity, 91.2% specificity, 90.5% positive predictive value (PPV) and 90.9% negative predictive value (NPV). Compared to the clinical expert, sensitivity of the CAD program based on the three reporting systems was similar, whereas specificity and PPV were lower. Regarding NPV, results for the clinician did not differ from the CAD program when it applied the ATA classification system (90.9% vs. 86.3%, $P=0.07$), but when it applied the EU-TIRADS and AACE/ACE/AME classifications it performed less well (82.6% and 80.8%, respectively; $P=0.01$ in both cases). The area under the receiver operating characteristic curve (AUC) was 0.88 for the expert clinician and 0.72 for the CAD based on ATA reporting system.
Conclusions
The CAD ultrasound image analysis program evaluated in this study is a useful tool for risk stratification of thyroid nodules, but does not perform better than a clinical expert.

Tirads classification and final diagnosis of thyroid nodules classified as bethesda-3 after fine-needle aspiration

María Rosa Alhambra Expósito[1], Ana Barrera Martín[1], Pedro Seguí Azpilcueta[2] & María Ángeles Gálvez Moreno[1]
[1]Reina Sofia Hospital. Endocrinology and Nutrition Service, Córdoba, Spain; [2]Reina Sofia Hospital. Radiology Service, Córdoba, Spain.

Introduction
Ultrasound is the main diagnostic tool for imaging pathology of the thyroid gland. The TI-RADS classification allows the evaluation of a risk of malignancy in the case of thyroid nodules, indicating the need to perform a puncture for a histological study. Bethesda system classifies them according to the cytological malignancy risk. Bethesda category 3 (B3) comprises 'follicular lesion of undetermined significance' or 'atypia of undetermined significance'.
Aim
Determine final diagnosis of B3 nodules and study associations between malignancy and other variables, as ACR TIRADS classification.
Methods
Retrospective study of thyroid nodules classified as B3 after FNA referred to our hospital between 2012 and 2018. Statistical analysis: SPSS v.22.0 (Student's t-test to compare means and Chi-square/Fisher's test for proportions).
Results
Two hundred two patients (80.7% female); mead (SD) age, 53.5 (13.7) years. Sonographic features of included nodules are shown in table 1. Of the nodules, 7.9% were TIRADS 2 (maximum mean diameter (DMM) 39.86 mm), 14.7% TIRADS 3 (DMM 34.32 mm), 56.5% TIRADS 4 (DMM 29.24 mm), 20.9% TIRADS 5 (DMM 25.66 mm). Eigteen (8.9%) lesions met the reference-standard criteria for malignancy: 13 papillary thyroid cancers, 4 follicular thyroid cancer, 1 thyroid metastases from other malignancies. Application of the ACR TIRADS

system's FNA criteria would have reduced the number of biopsies performed by 19.2%. Of the nodules without indication of FNA, only one was malignant; of those who had an indication for FNA, 16.5% were malignant. In our cohort, the sensitivity of this system was 94.4% and the specificity was 19.6%. The positive predictive value (PPV) of the test was 94% and the negative predictive value (NPV) 19.6%. A false negative rate of 5.6%. The area under the ROC curve was 0.735 (0.588–0.881, *P* 0.001).

Table 1 Sonographic features of included nodules.

Structure/composition		*Echogenicity*		*Shape*	
	%		%		%
Cystic or almost completely cystic	**1.7%**	Anechoic	**0%**	Wider tan tall	**87.6%**
Spongiform	**0.6%**	Hyperechoic o isoechoic	**27.2%**	Taller tan wide	**12.4%**
Mixed	**9%**	Hypoechoic	**56.4%**		
Solid	**88.7%**	Very hypoechoic	**4%**		

Table 1 Continued.

Margin		*Echogenic foci*	
	%		%
Smooth or defined	**64.9%**	None or large comet-tal artifacts	**77.4%**
Lobulated or irregular	**21.8%**	Macrocalcifications.	**12.4%**
Extra-thyroidal extension	**1%**	Periferical calcifications	**2.5%**
		Punctate echogenic foci	**6.4%**

Conclusions
Internationally-endorsed sonographic risk stratification systems vary widely in their ability to reduce the number of unnecessary thyroid nodule FNAs. The ACR TIRADS outperformed the others, classifying over half the biopsies as unnecessary with a FNR of 5.6%.

Somatic transmembrane domain mutations of a cell adhesion molecule, CADM1, cause primary aldosteronism by preventing gap junction communication between adrenocortical cells

Xilin Wu[1], Sumedha Garg[2], Claudia Cabrera[1], Elena Azizan[3], Chaz Mein[1], Yutaka Takaoka[4], Eva Wozniak[1], Wanfeng Zhao[5], Alison Marker[5], Folma Buss[2], Masanori Murakami[6], Felix Beuschlein[7], Martin Reincke[6], Akihiko Ito[8] & Morris Brown[1]
[1]Queen Mary University of London, London, UK; [2]University of Cambridge, Cambridge, UK; [3]The National University of Malaysia, Kuala Lumpur, Malaysia; [4]Kobe University, Kobe, Japan; [5]Cambridge University Hospitals NHS Foundation Trust, Cambridge, UK; [6]Ludwig-Maximilian University of Munich, Munich, Germany; [7]University Hospital Zurich, Zurich, Switzerland; [8]Kindai University, Osaka, Japan.

Background
PA is the commonest curable cause of hypertension. Whole exome sequencing (WES) in 2011 and 2013 identified common somatic mutations in genes regulating membrane polarisation in 60-80% of aldosterone-producing adenomas (APA). In search of the missing variants, we undertook further WES. One APA from a 46-year-old gentleman revealed a novel somatic mutation (Val380Asp); which introduced a charged amino-acid into the single transmembrane domain of Cell Adhesion Molecule 1 (CADM1). The search for similar mutations led to a Gly379Asp mutation from a PA patient in Munich.
Method
Wild-type (WT) and mutant *CADM1* genes were cloned into lentivirus vectors and transduced into adrenocortical (H295R) cells to assess its effect on aldosterone secretion. Previous studies suggest CADM1 contributes to gap junction (GJ) communication between cells. This was assessed using dye transfer assays. Single H295R cells transfected with WT or mutant *CADM1* were microinjected with a calcein dye permeable through GJs, and the effects observed using fluorescent microscopy. H295R cells were also treated with peptide gap27, a specific inhibitor of the adrenocortical GJ protein CX-43. Finally WT or mutant H295R cells were co-transfected with CX-43 tagged by mApple or Venus fluorophores and mixed, allowing confocal visualisation of GJ formation between adjacent cells.
Results
Cells transduced with mutant *CADM1* showed 3-6-fold increase in aldosterone secretion ($P<0.05$) and 10-20-fold increase in CYP11B2 expression ($P<0.05$) compared to WT. RNA sequencing showed *CYP11B2* to be the most upregulated gene (30×) in mutant cells. Dye transfer assays showed paucity of dye transfer between neighbouring mutant *CADM1* cells, while calcein passed easily through GJs in WT cells. Inhibition of CX-43 caused 2-fold increase in aldosterone secretion, and 3 to 8-fold (<0.05) increase in CYP11B2 expression in non- and angiotensin-II stimulated cells respectively. Protein modelling suggested that mutations increased the angle of ectodomains to cell membrane, from 49° in WT cells, to 62° and 90° in Gly379Asp and Val380Asp respectively; increasing inter-cell distance from 21.2 nm to 24.7 and 27.9 nm. A key role of CADM1 may be to bring opposing CX-43 hemichannels close enough to form GJ channels. Mixing of Venus and mApple-tagged CX-43 transfected cells showed fewer intact GJ channels in *CADM1*-mutant cells.
Conclusion
Discovery of the *CADM1* mutation has again demonstrated the importance of membrane proteins in aldosterone regulation, although *CADM1's* impact on cation traffic is indirect. The unsuspected role of cell-adhesion in regulating GJs suggests a role for these in the regulation of aldosterone by oscillating Ca^{2+} currents.

The role of filamin A (FLNA) in the regulation of IGF2/IGF1R pathway in adrenocortical carcinomas

Erika Peverelli[1], Rosa Catalano[1,2], Elena Giardino[1], Federica Mangili[1], Donatella Treppiedi[1], Valentina Morelli[1], Massimo Mannelli[3], Anna Spada[1], Maura Arosio[1] & Giovanna Mantovani[1]
[1]Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico; Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy; [2]PhD Program in Endocrinological Science, Sapienza University of Rome, Rome, Italy; [3]Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy.

Adrenocortical carcinomas (ACCs) are rare endocrine tumors with poor prognosis. The insulin-like growth factor 2 (IGF2) is overexpressed in the great majority of ACC, and IGF2/IGF1R pathway acts as a proliferative autocrine loop, but to date IGF1R-targeted therapies have demonstrated a limited efficacy and the molecular mechanisms regulating this pathway are still unknown. The cytoskeleton acting-binding protein filamin A (FLNA), determinant in cancer progression and metastasis in different tumors, affects the intracellular trafficking and signalling of many receptors, including growth factor receptors such as EGFR, but a possible role of FLNA in regulating IGF1R has never been investigated. The aims of this study are: 1) to test FLNA involvement in modulating IGF1R signaling in human ACC cell lines H295R and SW13; 2) to evaluate FLNA expression in ACCs and a possible correlation with IGF1R pathway activation. By immunoprecipitation we found that IGF1R interacted with FLNA in basal condition, with an increased recruitment of FLNA after IGF2 stimulation, in both cell lines. As expected, IGF2 promoted H295R and SW13 cell proliferation and migration and accordingly increased ERK and cofilin activation. Interestingly, all these tumorigenic actions of IGF2 were potentiated in the absence of FLNA. Indeed, in cell silenced for FLNA, IGF2 induced a further increase of proliferation ($+69\pm40\%$ in SW13 and $+11\pm1.3\%$ in H295R, $P<0.05$), migration ($+10\pm7\%$ in SW13 and $+17\pm8\%$ in H295R, $P<0.05$), p-ERK/tot-ERK ratio ($+1.14\pm0.2$ fold in SW13, $P<0.05$) and a decrease of p-cofilin/tot-cofilin ratio (-0.20 ± 0.02 fold in SW13, $P<0.05$) vs IGF2-stimulated control cells. Furthermore, FLNA silencing in SW13 cells was associated to an increase of IGF1R expression after IGF2 stimulation ($+1.60\pm0.7$ fold vs IGF2-stimulated control cells, $P<0.05$), suggesting that FLNA is involved in receptor downregulation. Finally, western blot analysis showed significantly lower FLNA expression in ACCs ($n=5$) than in adrenocortical adenomas ($n=19$) (FLNA/GAPDH ratio 0.98 ± 1.4 and 4.37 ± 2.5, respectively, $P<0.01$). Moreover, FLNA expression levels in ACC samples were negatively correlated with ERK phosphorylation status. In conclusion, we demonstrated that low levels of FLNA enhance IGF2/IGF1R pathway activation in adrenocortical tumor cells, suggesting FLNA as a new factor possibly influencing the response to the therapy with IGF1R-target drugs.

An unusual association of P450 oxidoreductase Deficiency and Argininosuccinatelyase Deficiency

Federica Anselmi[1], Sara Alfano[1], Nicola Improda[1], Raffaella Di Mase[2], Stefan Alexander Wudy[3], Giancarlo Parenti[1], Lilia Baldazzi[4], Soara Menabò[4], Donatella Capalbo[2] & Mariacarolina Salerno[1]
[1]Pediatric Endocrine Unit, Department of Translational Medical Sciences, University of Naples Federico II, Naples, Italy; [2]Department of Pediatrics, University of Naples Federico II, Naples, Italy; [3]Steroid Research and Mass Spectrometry Laboratory, Division of Pediatric Endocrinology and Diabetology, Center of Child and Adolescent Medicine, Justus Liebig University, Giessen, Germany; [4]Program of Endocrinology, Pediatric Unit, Department of Medical and Surgical Sciences, S. Orsola Malpighi University Hospital, Bologna, Italy.

Background
P450 Oxidoreductase (POR) Deficiency(PORD) represents the most complex form of congenital adrenal hyperplasia. It usuallycauses genital ambiguity in both sexes, and eventually peculiar skeletal malformations resembling Antley-Bixler syndrome. Co-occurrence of POR deficiency and Argininosuccinatelyase Deficiency (ALD)in the samepatient born to non-consanguineous parents has never been reported.
Case report
A male patient was born at term to non-consanguineous parents, with a weight of 3.35 kg. He was diagnosed with ALD (genotype: homozygous p.V178M mutation) at the age of 3 years, following diagnosis in his older brother. Despite good compliance to diet, during follow-up the child developed epilepsy (7 years of age), keratoconus (7.5 years of age), optic and auditory nerve atrophy (8 and 11 years, respectively), the latter being not typical of ALD.He came to our attention at the age of 17.4 years because of short stature (Height -2.02 SDS; target height 0.46 SDS), delayed puberty (pubic hair stage 2, testicular volume 10 ml bilaterally; normal penile length) and bone age of13 years. No skeletal malformations were detected.Laboratory work-up revealed: LH(14.3 mU/ml), FSH (16.1 mU/ml), testsosterone (100 ng/dl), DHEA-S 41 ug/dl (80–560), androstenedione $<$0.3 ng/ml (1.1–3.5), ACTH (222 pg/ml), 17-OHP (28.75 ng/ml), progesterone (21.1 ng/ml), normal electrolytes, renin 36.4 pg/ml (0.9–20). Synacthen test showed suboptimal cortisol response (peak Cortisol 69 ng/ml), so that the patient was started on hydrocortisone. Urinary steroid profile was suggestive ofcombined signs of 21-hydroxylase and 17-hydroxylase deficiency, typical of POR deficiency. Genetic analysis of the POR gene showed homozygous p.N82I mutation, identified in heterozygosis in both parents. Given the lack of progression into puberty, the boy has been started on testosterone.
Conclusions
This is the first description of POR deficiency in a patient with Argininosuccinatelyase Deficiency. Our patient presented with a mild phenotype mainly characterized by delayed puberty underlying the phenotypc heterogeneity of POR gene mutations.

GP97

Structural changes in the zona glomerulosa of normal aging adrenals

Lieke van Bonzel, Elle van de Wiel, Jaap Deinum, Benno Küsters & Johan Langenhuijsen
Radboudumc, Nijmegen, Netherlands.

Background and study aims
Increased aldosterone production in the adrenal gland plays a role in many hypertensive patients. Structural changes of the zona glomerulosa with age in normotensive patients have been described in literature but the influence of aging on aldosterone secretion and physiology is unclear. The aim of this study is to investigate changes in the ZG in order to gain insight in the origin, development and definition of aldosterone producing cell clusters (APCCs) in the normal aging adrenal in patients aged 0 to 40 years old.
Material and methods
We studied one or both adrenal glands collected at autopsies of normotensive patients aged 0 to 40 years who died of non-adrenal disease. We divided patients in age groups 0–5 years, 6–10 years, 11–18 years, 19–30 years and 31–40 years. We related aldosterone synthase (CYP11B2) expression, assessed by immunohistochemistry, with age.
Results
Eighty seven adrenal glands from 58 normotensive patients were collected and classified according to age group. All adrenal glands of patients aged 0 to 10 years show a continuous pattern of aldosterone producing cells without clustering in the outer layer of the adrenal cortex (zona glomerulosa), see Figure 1. In adolescence

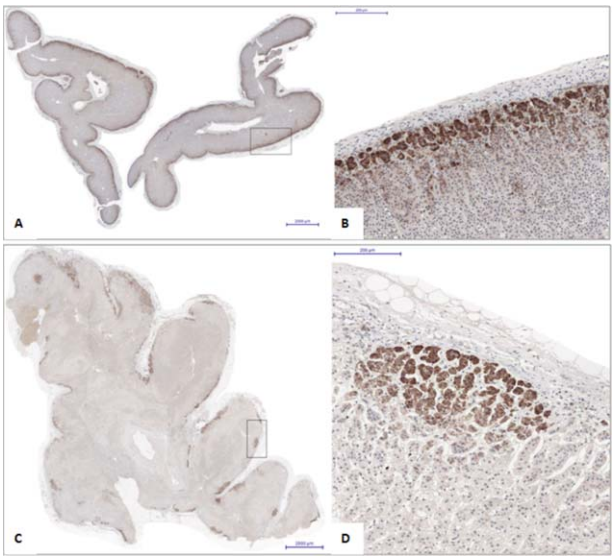

Figure 1 Relationship between CYP11B2 expression patterns and age in normal adrenals. Findings of CYP11B2 immunohistochemistry. CYP11B2-expression is brown. Scale bars in **A**+**C** are 2000 μm and scale bars in **B**+**D** are 200 μm. **A** adrenal gland of a 6-year-old boy showing continous CYP11B2 expression with no clustering. **B** magnification of the boxed area in **A**. **C**. adrenal gland of a 39-year-old women showing a discontinuous CYP11B2 expression with a lot of cell clusters. **D** magnification of the boxed area in **C**.

a discontinuous pattern arises and aldosterone-producing cells start to form clusters (APCCs). With increasing age the number of APCCs then increases. In cases where both adrenal glands of an individual were available ($n=29$) the CYP11B2 expression was symmetric.
Conclusion and discussion
The pattern of CYP11B2 expression in the adrenal cortex evolves over time, and this change can be described as an increase in APCC number with disruption of the continuity of the zona glomerulosa. However, we encountered the problem that a clear definition of APCCs is lacking, rendering quantification of volume and number of APCCs difficult. We nevertheless hypothesize that changes in aldosterone production patterns, exemplified by emergence of APCCs and rarefaction of the zona glomerulosa, may play a causative role in the development of both resistant hypertension and primary aldosteronism.

Methylation status and gene expression of steroidogenic enzymes in benign adrenocortical tumors

Guido Di Dalmazi[1], Luca Morandi[2], Beatrice Rubin[3], Catia Pilon[3], Sofia Asioli[2], Valeria Maffeis[3], Valentina Vicennati[1], Uberto Pagotto[1] & Francesco Fallo[3]
[1]Endocrinology Unit - Department of Medical and Surgical Sciences, Bologna, Italy; [2]Research Laboratory, Department of Biomedical and Neuromotor Sciences, Bologna, Italy; [3]Department of Medicine, University of Padova, Padova, Italy.

Background
DNA methylation has been recognized as a putative regulatory mechanism for *CYP11B2* in primary hyperaldosteronism. We aimed to investigate the DNA methylation and the expression of a panel of genes encoding several enzymes involved in steroidogenesis in adrenocortical benign tumors.
Methods
We collected a total of 60 adrenocortical tissues, including 9 non-functioning adrenal adenomas, 9 adenomas associated with autonomous cortisol secretion, 17 adenomas associated with Cushing's syndrome, 13 Conn's adenomas and 12 tissues derived from adrenal gland adjacent to the Conn's adenomas. Non-functioning tumors and autonomous cortisol secretion were defined according to

cortisol levels after 1 mg dexamethasone suppression test ≤ or > 50 nmol/L, respectively. The DNA methylation level of *CYP11A1*, *CYP11B1*, *CYP11B2*, *CYP17A1*, *CYP21A2*, *DHCR24*, *HSD3B1*, *HSD3B2*, *NR5A1*, *STAR*, and *TSPO* was evaluated by quantitative Bisulfite Next Generation Sequencing (bisulfite-NGS). Bioinformatic analysis was performed in a GalaxyProject environment and processed by BSPAT (Bisulfite Sequencing Pattern Analysis Tool). Spearman correlation coefficients were calculated using IBM SPSS 21 (IBM). *CYP11B1*, *CYP11B2*, *CYP17*, *CYP21*, *STAR* and β-actin gene expressions were examined by quantitative Real-Time PCR using a Sybr Green Assay kit (Thermo Fisher Scientific). The Default $2-\Delta\Delta Ct$ was used to calculate the fold changes in gene expression between the categories of samples.

Results

When compared to other adrenal tissues ($P<0.001$), *CYP11B2* was significantly hypomethylated in Conn's adenoma. No difference in methylation status was found among groups for the remaining genes. *CYP11B2* mRNA levels were significantly higher in Conn's adenoma than in the remaining adrenal tissues ($P=0.001$). *CYP21* mRNA was significantly higher in all but Conn's adenomas, when compared to normal adrenal tissues ($P<0.001$). Overall, we found a negative correlation between *CYP11B2* expression and DNA methylation (rho = −0.379; $P=0.003$).

Conclusion

DNA methylation seems to be a pivotal regulatory mechanism for *CYP11B2* expression. It is feasible that epigenetic mechanisms may be responsible for aldosterone hypersecretion in Conn's adenoma.

DOI: 10.1530/endoabs.63.GP98

Implementation of two preclinical ACC models for a comparative drug screen and initial mechanistic investigations

Ashish Sharma[1], Igor Shapiro[1], Pal Perge[2], Peter Igaz[2] & Constanze Hantel[1,3]
[1]Department of Endocrinology, Diabetes, and Clinical Nutrition, University Hospital Zürich, Zürich, Switzerland; [2]2nd Department of Medicine, Semmelweis University, Budapest, Hungary; [3]Medizinische Klinik und Poliklinik III, University Hospital Carl Gustav Carus Dresden, Dresden, Germany.

Current systemic treatments are not satisfying for the treatment of adrenocortical carcinoma (ACC). However, translation of preclinically promising approaches were often disappointing indicating that existing tumor models might have inadequately predicted clinical applicability. Thus, our workgroup initiated a comparative drug screen of relevant chemotherapies and therapies targeting IGFR, EGFR, VEGFR/PDGFR and Wnt signalling pathway in the classical NCI-H295R and recently developed MUC-1 tumor model. BrdU-assay based investigation of cell-proliferation demonstrated significant anti-proliferative activity for almost all tested single agents and combinatory approaches (n = 20) with more pronounced effects for classical chemotherapies. Subsequent analysis by MTT-assays revealed e.g. for Etoposide (E) and Cisplatin (P) the inhibition of cell viability of NCI-H295R cells in a highly significant (E 180 uM: 2.5%; *P* 160 uM: 17%) and dose-dependent manner, while even at extraordinary high drug concentrations cell viability remained high for MUC-1 (E 180 uM: 67%; *P* 160 uM: 70%, both $P<0.001$ vs NCI-H295R). Moreover, for single treatments with Doxorubicin (D), 9-cis-Retinoic acid (RA), Erlotinib (Erl), XAV-939 (X) and Isoquercitrin (I) we detected comparably low or even a complete lack of toxicity in either MUC-1 alone (for D and Erl) or both tumor models (for I). Of-note, Mitotane (M), Paclitaxel (PTX), Linsitinib (L), Sunitinib (S) and Sorafenib (SF) displayed overall improved toxicities. Interestingly, among combinatory approaches tested so far (such as EDP-M, S + M, S + PTX, S + P, PTX + SF, P + RA, PTX + G, G + P and P + PTX), additive reduction of cellular viability and diminished clonogenicity was observed with treatment of G + P in both tumor models ($P<0.001$). Additionally, P + PTX displayed most promising anti-tumoral efficacy and reduced clonogenicity in both tumor models among all tested drug combinations ($P<0.001$). Mechanistically, G alone induced a dose-dependent increase in expression of, both RRM1 and RRM2, genes that are involved in the development of clinically relevant G-resistance. Interestingly, in combination with either P or PTX these effects were significantly reversed down to basal levels or even below (NCI-H295R RRM1, G: 791% $P<0.001$; G + P: 188%; RRM2, G: 336% $P<0.001$; G + P: 60% and in MUC-1 RRM1, G: 275% $P<0.01$; G + P: 97%; RRM2, G: 474% $P<0.01$; G + P: 175%; vs. 100% controls). Of note, also siRNA-mediated RRM2 silencing alone led to a significant decrease of cell count in both tumor models ($P<0.001$). In summary, our findings indicate that a combination of both tumor models might help to identify potentially new drug combinations for the treatment of ACC.

Characterization of cell death induced by mitotane in adrenocortical carcinoma cells

Isabel Weigand[1], Jochen Schreiner[1], Florian Röhrig[2], Katja Kiseljak-Vassiliades[3], Kerstin Höfner[1], Sabine Kendl[1], Martin Fassnacht[1], Silviu Sbiera[1] & Matthias Kroiss[1]
[1]Department of Medicine I, Division of Endocrinology and Diabetes, University Hospital, University of Wuerzburg, Wuerzburg, Germany; [2]Department of Biochemistry and Molecular Biology, Theodor-Boveri-Institute, University of Wuerzburg, Wuerzburg, Germany; [3]Division of Endocrinology, Metabolism and Diabetes, University of Colorado School of Medicine, Aurora, Colorado, USA.

Background

Mitotane is the only drug approved for treatment of adrenocortical carcinoma (ACC). We have found that mitotane leads to endoplasmic reticulum stress and decreased viability in ACC cells. It is not known by which downstream mechanisms cell death is induced by mitotane.

Aim

To characterize the mechanisms underlying cell death resulting from mitotane treatment in ACC cells.

Methods

Lipid peroxidation in the ACC cell line NCI-H295R was measured with BODIPY 581/591 C11 and cell viability quantified by CellTiter Glo assay. Combination treatment with pan caspase inhibitor zvad-fmk, inhibitors of necroptosis (necrostatin-1) and ferroptosis (liproxstatin, deferoxamine) and ferroptosis activator RSL3 in three ACC cell lines was applied. Marker protein expression was assessed by immunoblotting.

Results

Mitotane induced caspase3 cleavage but caspase inhibition was unable to rescue ACC cells from mitotane-induced cell death. Necroptosis markers were unchanged after mitotane treatment, while lipid peroxides accumulated after mitotane treatment in a concentration dependent manner. Deferoxamine prevented mitotane induced cell death by up to 40%. In line with this finding, synergism of mitotane and RSL3 was observed. RSL3 showed cytotoxicity at nanomolar concentrations in ACC cells (EC_{50}: NCI-H295R: 240 nM, CU-ACC1: 814 nM, CU-ACC2: 14.5 nM) but not in cells of non-adrenal origin.

Conclusion

Mitotane-induced cell death involves caspase action. Iron-dependent accumulation of lipid peroxides are hallmarks of ferroptosis. In addition, synergism of mitotane and RSL3 suggests relevance of this novel pathway but detailed mechanisms require further Investigation.

Introduction

Pituitary Neuroendocrine tumours (PitNETs) present heterogenic characteristics based on their hormonal expression and secretion. While most PitNETs have a slow progression rate, a subset of them exhibit an aggressive behaviour with recurrence properties despite current surgery, radio- and chemotherapy. To explore new clinical strategies based on immunotherapy we initiated a systemic cartography of the pituitary tumour immune microenvironment (PiTME).

Methods

Flow cytometry (FACS) and immunohistochemical (IHC) analysis were performed on a cohort of 43 freshly resected human PiNETs (18 Somatotroph and 25 Gonadotroph tumours). Patient derived xenografts (PDXs) were also performed using Rag2KO mice to further explore the interaction between pituitary tumour cells and mouse macrophages.

Results
Identification of various content of infiltrating T, B, NK and macrophage immune population was confirmed by FACS in all PitNETs. Interestingly, we found Gonadotroph and Somatotroph tumours to show a respective and specific immune signature. While Gonadotroph tumours were presenting a significant increase of $CD68^+$ macrophage infiltration, Somatotroph tumours were showing a larger number of infiltrating T cells. Those observations were subsequently validated by IHC on FFPE tumour-sections, confirming the increased number of CD68+/$CD163^+$ macrophages found within Gonadotroph lesions. Analysis of clinical data demonstrated that macrophage infiltration was correlated with local invasion of Gonadotroph-tumours. Interestingly, we also found those invasive lesions to have a significant histological reduction of collagen deposition, pointing a possible mechanism that could link invasion to a collagen-matrix remodelling by infiltrating macrophages in Gonadotroph tumours. Finally, through the use of a Rag2KO-PDX-model of PitNETs, we found mouse macrophages capable of an increase infiltration potential in grafted Gonadotroph tumours compared to Somatotroph grafted lesions, a result we further found associated with a reduced collagen deposition in Gonadotroph grafted tumours.
Conclusion
Our work underlines the specific immune landscape that respectively exist in Somatotroph and Gonadotroph tumours. It further pinpoints the potent role of CD68+/CD163+ macrophages in Gonadotroph tumour invasion through a collagen-matrix remodelling. Future experiments are needed to explore whether macrophages ablation or re-education could represent beneficial immune therapies for PitNET patients.

Development of a simple experiment to distinguish ARMC5 missense mutants from rare ARMC5 polymorphisms in PBMAH patients using a quantitative western blot approach

Anna Vaczlavik[1], Stéphanie Espiard[2], Christopher Ribes[1], Marie-Odile North[3], Ludivine Drougat[4], Bruno Ragazzon[1], Marthe Rizk-Rabin[1] & Jérôme Bertherat[1]
[1]Cochin Institute, Paris, France; [2]University Hospital Lille, Lille, France; [3]University Hospital Cochin, Paris, France; [4]NIH, Bethesda, Maryland, USA.

Introduction
Germline inactivating *ARMC5* (Armadillo repeat containing 5) mutations are responsible for Primary Bilateral Macronodular Adrenal Hyperplasia (PBMAH). *ARMC5* presents the characteristics of a tumor suppressor gene. Mutations are observed in more than 85% of patients with a clear familial presentation and 20 to 25% of apparently sporadic cases. Genetic alterations are spread all over *ARMC5* coding sequence and more than two-third of them are missense variants. In this case the pathogenicity prediction is mostly based on bioinformatics *in silico* analysis. We have previously developed an apoptosis assay using immunochemistry caspase staining on cells lines overexpressing transiently *ARMC5* wild type (wt) or its missense variants to demonstrate the deleterious effects of newly identified missense variants. However this approach is time consuming and therefore difficult to transfer for routine use in the oncogenetic laboratory of our hospital. We have previously observed that the stability of the ARMC5 mutant is altered.
Aim
To develop a simple functional test to confirm bioinformatic predictions of pathogenicity of newly identified *ARMC5* variants.
Method
HeLa cells are transiently transfected with vectors expressing Flag-tagged *ARMC5* wt or *ARMC5* missenses. Cell lysates are prepared after 14 and 24 hours of transfection and proteins are resolved by SDS-PAGE. Flag-ARMC5 protein levels are analyzed by Western blot experiment using an antibody against the Flag tag (Sigma®).
Results
Similar protein levels were observed for *ARMC5* wt and all its variants tested at 14 hours of overexpression, demonstrating similar expression of all the vectors. By contrast, at 24h of overexpression we observed a marked protein level decrease for ARMC5 wt and for two benign polymorphisms (p.F14Y and p.507L) compared to all other mutants tested (p.R898W, p.L548F, C657R, I664S p,.F700del, p.Y736P, p.L754P, p.L778P, p.C139R, p. R315W, p.L331P, p.R362L, p.R454W).
Conclusion and perspectives
Using a simple ARMC5 protein expression assay, we managed to distinguish pathogenic missense mutants from benign polymorphisms. ARMC5 non-pathogenic polymorphisms have the same protein expression profile than ARMC5 wt. This study shows the potency of this simple assay to confirm in routine practice the pathogenicity of new *ARMC5* variants identified in PBMAH patients. The mechanisms of this observation – stability or apoptosis- is an interesting research question that might help to progress in the understanding of PBMAH pathophysiology.

Identification of genes mediating dysregulated cell growth in aldosterone-producing adenomas

Yuhong Yang[1], Martina Tetti[2], Diana Jaquin[1], Paolo Mulatero[2], Holger Schneider[1], Felix Beuschlein[1,3], Martin Reincke[1] & Tracy Ann Williams[1,2]
[1]Medizinische Klinik und Poliklinik IV, Klinikum der Universität München, Ludwig-Maximilians-Universität München, Munich, Germany; [2]Division of Internal Medicine and Hypertension, Department of Medical Sciences, University of Turin, Turin, Italy; [3]Klinik für Endokrinologie, Diabetologie und Klinische Ernährung, Universitätsspital Zürich, Zürich, Switzerland.

Background
Aldosterone-producing adenomas (APA) are a major cause of primary aldosteronism. Somatic mutations explain the excess aldosterone production in the majority of patients with APA with mutations in the potassium channel *KCNJ5* the most prevalent. In contrast, mechanisms driving cell proliferation are largely unresolved.
Objective
To identify genes that modulate cell growth in APAs.
Methods
Quantitative transcriptome analysis using RNA-seq was used to identify differentially expressed genes between macro-APAs ($n=9$, diameter ≥ 30 mm) and micro-APAs ($n=12$, diameter <10 mm). Validation of RNA-seq by TaqMan real-time PCR was performed for 15 genes in a broader cohort of APAs (wild type, $n=28$; *KCNJ5*-mutated, $n=43$).
Findings
Hierarchical cluster analysis of the top 500 differentially expressed genes indicated sample clustering based on genotype (*KCNJ5* or wild type) and APA diameter. Differential expression of 155 and 348 genes was found between micro- and macro-APA with *KCNJ5* mutations and wild type, respectively. Several genes were identified with a known function related to cell growth. Expression of *BEX1* (a reported tumour suppressor) was 2.8-fold down regulated in macro-APAs relative to micro-APAs ($P=0.001$), and a linear negative correlation of *BEX1* expression with APA diameter was observed in wild type APA ($r=-0.501$, $P=0.007$). Genes involved in β-catenin signalling, *SFRP2*, *DKK1* and *TSPAN12* were 5.9-fold ($P=0.001$), 1.8-fold ($P=0.038$) and 8.3-fold ($P<0.0001$) down regulated in macro-APAs compared with micro-APAs, respectively.
Interpretation
APA display distinct transcriptome profiles according to adenoma diameter which may help identify genes involved in the dysregulated cell growth associated with these tumours.

Reappraisal of the human adrenal cortex and fate

Paméla Camponova[1], Céline Duparc[1], Malanie Roy[1], Hervé Lefebvre[2] & Michaël Thomas[1]
[1]Inserm U1239, Rouen University, Rouen, France; [2]Department of Endocrinology, University Hospital of Rouen, Rouen, France.

The zonation of the human adrenal cortex has long been established morphologically and histologically as three distinct layers of cells. The outer zona glomerulosa (ZG) comprises densely packed cells arranged in clusters that produce aldosterone; the zona fasciculata (ZF) is composed of cells with large cytoplasm, containing lipid droplets arranged in radial columns that synthetize cortisol; and the zona reticularis is composed of compact and pigmented cells producing androgens. The main purpose of this work was to study the expression of aldosterone synthase (CYP11B2 which catalyzes the last steps of aldosterone synthesis) and 11β-hydroxylase (CYP11B1 which catalyzes the last step of cortisol synthesis) in normal adrenal glands to address issues regarding the zonation and the fate of the cells constitutive of each zone through the expression of Ki-67 and cleaved Caspase-3. Thirty eight normal human adrenals (16 females, 22 males, ranging in age from 22 to 81 years old with a median age of 52 years old) were obtained from brain-dead organ donors (kindly provided by the Organ Transplant Clinics, University Hospital of Rouen). As early as 22 years old, we found that the histological ZG (h-ZG) does not correspond to the functional ZG (f-ZG) expressing CYP11B2. Moreover, the h-ZG CYP11B2- cells were CYP11B1+ showing that these cells ascribed to the h-ZG are in fact cortisol producing cells. The progressive replacement of CYP11B2+ cells by CYP11B1+ cells in the h-ZG might demonstrate the role of the extracellular matrix in the morphological maintenance of the adrenal cortex. Our analysis also showed that steroidogenic cells were either CYP11B1 or CYP11B2 positive. By immunofluorescence, we observed in many cases isolated or clusters of CYP11B2+ cells located deeply in the h-ZF and sometimes in the vicinity of the central vein. We were able to show that those cells were probably issued from CYP11B2+ cell clusters located in h-ZG which migrated centripetally. Ki-67 immunoreactivity was highly variable and observed throughout the entire cortex. We also found a positive correlation between the steroidogenic and endothelial cells proliferation. It is interesting to note that some Ki-67+ cells located in the h-ZG were CYP11B1+. Cortical cells positive for cleaved Caspase-3 were extremely rare but detected in all zones when present. These findings challenge the classic view of lineage conversion of differentiated ZG cells and show a new pathway where the CYP11B2+ cells migrate without changing their phenotype.

Gene expression changes in visceral adipose tissue of Cushing syndrome.

Guillermo Garcia-Eguren[1], Mar Gonzalez[2], Enrique Blanco[2], Oriol Giro[1], Oscar Vidal[3], Francesc Carmona[3], Gregori Casals[3], Mireia Mora[3], Irene Halperin[3], Luciano diCroce[2] & Felicia A Hanzu[3]
[1]IDIBAPS, Barcelona, Spain; [2]CRG, Barcelona, Spain; [3]HCB, Barcelona, Spain.

Introduction
Visceral adipose tissue (VAT) is the key target tissue of glucocorticoids (GC) during active Cushing Syndrome (CS) and a metabolic tissue associated to insulin-resistance and an increased cardiometabolic risk. Till date there are no data regarding gene expression in VAT in CS and only few data about the mRNA in subcutaneous one. The aim of this study was to study the visceral VAT tissue transcriptional changes in ACTH-independent CS.
Methods
7 ACTH-independent CS patients due to adrenal cortical adenomas diagnosed in our hospital during the last 3 years and 14 sex (3m/4w), age (32–60y), BMI (29.1 ± 0.5 kg/m^2), cardiovascular and metabolic comorbidities matched controls (CTR) were included in the study. Clinical and analytical phenotype data were obtained prior to surgery. VAT (omentum) was collected after overnight fasting during the laparoscopic abdominal, programmed surgery. VAT plasticity (histology, immunochemistry) and function (RNAseq, rt-PCR) were analyzed. Differentially (up and down, $P^* < 0.05$) expressed genes in CS and CTR were compared and genes identified. RT-PCR was performed to validate the results and pathway analysis is ongoing.
Results
VAT of patients with active CS presented increased hypertrophic adipocytes and macrophage infiltration independent of the associated comorbidities. Heat map, PCA and t-SNE analysis and RT-PCR validation showed 10 up and 18 down regulated genes involved in macrophage activation, adipogenesis, insulin-signaling and lipid metabolism. Analysis of the overall gene changes network and relationship with the CS hormonal and phenotype characteristics are in process.
Conclusion
This is the first study providing insights to tissue transcriptomic changes in VAT of CS that may be have a causative effect on the comorbidities associated with the chronic hypercortisolism.

Exploring the mechanism of TGF-β1 signaling in counteracting BMP activities during the osteogenesis of mesenchymal stem cells

Ying-Wen Wang & Ching-Wei Luo
National Yang-Ming University, Taipei, Taiwan.

Bone is not only a skeletal scaffold but also an endocrine organ. Its formation and remodeling initiate from the recruitment and subsequent differentiation of m*esenchymal stem cells* (*MSCs*), in which the signals are known to be dominated by SMAD2/3 signaling driven by TGF-βs and SMAD1/5/8 signaling driven by BMPs, respectively. Of interest, distinct from the above concepts, we found that TGF-β1 induces not only SMAD2/3 phosphorylation but also SMAD1/5/8 phosphorylation in either primary MSCs or C3H10T1/2 MSC line. To further investigate the underlying mechanism, individual *Smad* knockdown, receptor profiling and signaling inhibitors were applied. Our results indicated that TGF-β1 mainly induces SMAD1 phosphorylation via ALK5-containing receptor complexes in MSCs. In terms of functional characterization, we demonstrated that TGF-β1-induced phosphorylated SMAD1 complexes can be translocated into the nucleus; this then increases the transcription of BMP-responsive genes, such as *Id1* and *Timp3*. However, in contrast to SMAD2/3 activation, we found that SMAD1/5/8 phosphorylation driven by TGF-β1 retained transiently and this may in turn dampen the BMP4-mediated activities in C3H10T1/2 MSC line. Indeed, TGF-β1 co-treatment significantly inhibited BMP4-activated reporter activity as well as expression of osteogenesis-related genes, such as *Runx2*. Using co-immunoprecipitation assay, we proposed that the aforementioned inhibitory effect may involve the formation of SMAD1/5-SMAD2/3 mix complex, which then recruits yet unknown co-repressors in MSCs. Taken together, our findings unveil a previously uncharacterized TGF-β-stimulated SMAD mechanism in MSCs and would further draw interests in exploring whether this signaling participates in balancing the BMP activity during MSC specification.

Sex steroids as determinants of Wnt-Signalling markers in men

Thiberiu Banica, Charlotte Verroken, Hans-Georg Zmierczak, Stefan Goemaere, Justine Defreyne, Guy T'Sjoen, Jean-Marc Kaufman & Bruno Lapauw
Unit for Osteoporosis and Metabolic Bone Diseases, Department of Endocrinology, Ghent University Hospital, Ghent, Belgium.

Background
Canonical Wnt-signalling is important for bone by regulating osteoblastogenesis and osteoblast function. Bone metabolism is also partly determined by sex steroid exposure and sex differences in serum sclerostin levels have been reported. However, it is unclear whether serum sclerostin and other circulating Wnt-signalling components are sex steroid dependent within healthy men.
Objective
To determine whether serum sclerostin, osteoprotegerin (OPG) and Dickkopf-1 (DKK-1) levels associate with sex steroid exposure in men.
Methods
Cross-sectional data comprised 108 healthy males (34 ± 5 years) from the SIBLOS-cohort, and from the ENIGI-cohort 50 transgender women (TW) (35 ± 15 years) and 50 transgender men (TM) (23 ± 6 years) were evaluated before and 1 year after gender-affirming hormone treatment (cyproterone + estrogen and testosterone treatment, respectively). Sclerostin, OPG and DKK-1 were measured using a quantitative sandwich ELISA (Biomedica). Testosterone (T), estradiol (E2) were measured using LC-MS/MS, free fractions calculated.
Results
In SIBLOS, OPG was weakly inversely associated with E2 ($r = -2.8$; $P = 0.017$) and free T levels ($r = -2.4$, $P = 0.043$) and sclerostin with T ($r = -.237$; $P = 0.045$), whereas no significant associations were found in the transgender groups. Sclerostin levels were non-significantly lower in TM than TW (29.67 pmol/l, 35.56 pmol/l, respectively; $P = 0.135$), but otherwise there were no between-group differences in Wnt-signalling markers. After hormonal treatment, sclerostin, OPG and DKK-1 levels were unchanged in TM (30.97 pmol/l). In TW, however, sclerostin levels decreased (28.04pmol/l; $P < 0.001$), this difference being associated with changes in E2 levels ($r = -3.21$; $P = 0.025$).
Conclusion
Although circulating levels of Wnt-signalling components appear not strongly related to native sex steroid exposure in men, combined anti-androgen and estrogen treatment in TW reduced sclerostin levels. Contrastingly, no changes in sclerostin, OPG or DKK-1 were seen in TM receiving T treatment, suggesting that sclerostin production and secretion is regulated by estrogen but not androgen exposure.

Denosumab in post-liver transplantation osteoporosis: preliminary data on the effects on bone mineral density and turnover markers

Guido Zavatta[1], Giulia Vandi[1], Guido Di Dalmazi[1], Andrea Repaci[1], Matteo Ravaioli[2], Matteo Cescon[2], Maria Cristina Morelli[2], Uberto Pagotto[1] & Paola Altieri[1]
[1]Endocrinology Unit, Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy; [2]Department of General Surgery and Transplantation, University of Bologna, Bologna, Italy.

Introduction
Several risk factors are involved in post-liver transplantation osteoporosis. Immunosuppressive agents, glucocorticoids, decreased renal function associated with secondary hyperparathyroidism and immobilization are the main determinants of fragility fractures in this population. Denosumab is highly effective in increasing bone mineral density (BMD) and preventing fragility fractures. However, the efficacy of denosumab in liver transplantation osteoporosis has never been described. The aim of this study was to evaluate bone turnover markers and BMD following denosumab administration in post-liver transplantation osteoporosis.
Subjects and methods
Twenty-nine patients seen at the Endocrinology Unit of Policlinico di Sant'Orsola, Bologna (7 post-menopausal females and 22 males, mean age 64 ± 8 years) who underwent liver transplantation between 1990 and 2018 were retrospectively evaluated. All patients had multiple fragility fractures, namely, vertebral fractures (with a mean of 3 fractures for each patient), diagnosed both clinically and with morphometry. All started denosumab 60 mg every 6 months between July 2014 up to May 2018 (96 ± 70 months after transplantation). Twenty-eight patients were on calcineurin inhibitors and 6 patients were on 5 mg to 10 mg/day prednisone regimen. All patients were receiving cholecalciferol (mean dose of 1860 IU/day). Four patients had recently terminated teriparatide and ten patients were switched to denosumab from oral bisphosphonates. BMD by dual-energy X-ray absorptiometry (DXA) was measured at baseline and every 18-24 months. Baseline and 6-month bone turnover markers were assessed. All patients had a minimum follow-up period of 6 months.
Results
Denosumab was effective in reducing total ($P = 0.010$) and bone-specific ($P = 0.007$) alkaline phosphatase as well as ß-CTX ($P = 0.002$) at six months after the first administration, regardless of prior bisphosphonate or teriparatide treatment. During follow-up, no significant change in BMD at femoral neck (+0.031 g/cm^2; %change 3.4 ± 11.2; $P = 0.290$) or spine (+0.017 g/cm^2; %change 5.6 ± 11.5; $P = 0.355$) was observed in a mean follow-up period of 27 ± 10 (range 13-44) months. We found a slight but significant increase of total hip BMD (+0.033 g/cm^2; %change 6.1 ± 7.0; $P = 0.045$). One atraumatic compound diaphyseal femoral fracture was observed in a diabetic male patient naïve to any osteoporotic treatments, 14 months after starting denosumab. No further clinical fractures were reported in our study population.
Conclusion
Denosumab is highly effective in reducing bone turnover markers in post-liver transplantation osteoporosis. Only mild total hip BMD gain was observed during the period of observation. A longer follow-up is needed to confirm this apparently blunted response.

DOI: 10.1530/endoabs.63.GP110

GP111

Hip structure analyses in acromegaly: Decrease of cortical bone thickness after treatment

Kristin Godang[1], Tove Lekva[1], Kjersti R Normann[1,2], Nicoleta Cristina Olarescu[1], Kristin AB Øystese[1], Anders Kolnes[1], Thor Ueland[1,2,3], Jens Bollerslev[1,2] & Ansgar Heck[1,2]
[1]Oslo University Hospital, Oslo, Norway; [2]Faculty of Medicine, University of Oslo, Oslo, Norway; [3]KG Jebsen TREC, University of Tromsø, Tromsø, Norway.

Background
Long standing growth hormone (GH) excess causes the skeletal clinical signs of acromegaly with typical changes in bone geometry including increased cortical bone thickness (CBT). However, a high prevalence and incidence of vertebral fractures has been reported. The aim of this study was to assess the course of cortical bone dimensions in the hip by comparing patients with acromegaly and clinically non-functioning pituitary adenomas (NFPA) at baseline and one year after pituitary surgery (1 year PO).
Patients and methods
Dual energy absorptiometry (DXA) was performed in patients with acromegaly ($n = 56$) and NFPA ($n = 47$). CBT in the femoral neck (CBTneck), calcar (CBTcalcar) and shaft (CBTshaft) were determined by Hip Structural Analysis (HSA). CBT at baseline and the change to 1 year PO were compared. Test results were adjusted for differences in gender distribution, age and gonadal status.
Results
Cortical thickness analyses showed higher values [mm] at baseline in patients with acromegaly compared to NFPA: CBTneck median [25th; 75th] 6.2 [4.7; 8.0] *vs.* 5.1 [4.1; 6.4] ($P = 0.006$), CBTcalcar 4.8 [4.2, 5.7] *vs.* 4.0 [3.2, 4.5] ($P < 0.001$), CBTshaft 6.2 [5.1, 7.2] *vs.* 5.2 [4.6; 6.0], ($P = 0.003$). In acromegaly, GH was correlated with CBTneck ($r = 0.31$, $P = 0.020$), whereas IGF-1 was correlated with CBTcalcar ($r = 0.39$, $P = 0.003$) at baseline. In acromegaly, CBTneck decreased with 11.2%, $P = 0.002$ during follow-up. Finally, the decrease in CBTneck and CBTcalcar in acromegaly was significant compared to NFPA ($P = 0.023$ and $P = 0.017$, respectively).
Conclusions
Previous observations of increased CBT in acromegaly were confirmed with DXA-derived HSA in a large, well defined cohort. The decline in CBT in acromegaly could contribute to the increased fracture risk in acromegaly despite increased bone dimensions and disease control.

Body composition determines muscle strength in osteoporotic patients with vertebral fractures

Ekaterina Makarova, Larisa Marchenkova, Michail Eryomushkin, Lilia Shakurova & Valeria Vasileva
National Medical Research Center of Rehabillitation and balneology, Moscow, Russian Federation.

The aim of the study was to evaluate the degree of muscle dysfunction and relationship of trunk muscle strength and body composition in patients with

osteoporotic vertebral fractures (VFs). Methods. Study comprised 90 men and woman 40-80 years old with primary osteoporosis. Study group (n = 60) included patients with at least 1 VF (confirmed by X-rays), control group ($n = 30$) consisted of osteoporotic patients of the same age, BMI and BMD without any fracture. Trunk muscles strength was measured with tenzodynamometry at Back-Check Dr. Wolff diagnostic unit. Body composition was evaluated by DXA Total Body. Muscle function was evaluated with Up-and-go test, 10-meters-walk test, testa for static and dynamic of back and abdomen muscles. Results. Patients with VFs had a significant muscle strength deficiency in trunk flexors (TF) −40.9% and extensors (TE) −18.1% with an adequate function of the left (LLF) and right lateral flexors (RLF). Patients in study group had lower muscle strength vs controls in TF (15.6 ± 9.8 vs 27.7 ± 9.9 kg, $P < 0.001$), TE (14.6 ± 8.9 vs 21.3 ± 8.4 kg, $P < 0.001$), LLF (13.1 ± 7.2 vs 24.1 ± 8.9 kg, $P < 0.001$) and RLF (13.4 ± 7.4 vs 24.3 ± 7.7 kg, $P < 0.0001$). No significant difference in functional tests results were registered ($P > 0.05$). Body composition analyses showed differences between study and control groups in relative skeletal muscle index (RSMI, 6.5 ± 1.2 vs 7.5 ± 2.1 kg/m^2, $P = 0.02$) and fat mass (29717 ± 8367.4 vs 35464 ± 9127.4 g, $P = 0.01$). There was no significant difference in soft tissue mass and lean (muscle) mass between groups. Strength of all studied trunk muscles strongly negatively correlated with the number of VFs ($P < 0.001$) and positively correlated with femoral neck BMD (g/m^2), fat mass, soft tissue mass and lean mass ($P < 0.001$), but not with age and RSMI ($P > 0.05$). Conclusions. Patients with VFs have a decrease in trunk muscles strength and lower RSMI, mass and % of body fat in compared with patients without fractures. Number of VFs, low BMD, fat mass, soft tissue mass and lean mass are the main factors of trunk muscle dysfunction in osteoporotic patients. Functional tests showed less specificity for estimation of muscle function than tenzodynamometry.

Vertebral fracture in outpatients with type 2 diabetes mellitus

Tatiana Yalochkina[1], Natalia Tarbaeya[2], Liudmila Rozhinskaya[2], Larisa Nikankina[2] & Zhanna Belaya[2]
[1]City polyclinic No 219 Moscow City Health Department, Moscow, Russian Federation; [2]The National Medical Research Centre for Endocrinology, Moscow, Russian Federation.

According to numerous studies, type 2 diabetes mellitus (T2DM) is associated with an increased risk of low traumatic non-vertebral fracture. There are a limited number of studies which evaluate lateral vertebral X-Rays in order to diagnose vertebral fractures in patients with T2DM. The goal of our study was to investigate the difference in vertebral fracture rate registered on lateral X-Ray between subjects with T2DM and a control group being under observation in the same outpatient clinic.

Materials and Methods

We enrolled 501 subjects from a single outpatient clinic in Moscow. All T2DM patients ($n = 251$) and non-DM controls ($n = 250$) had lateral spine X-Rays at the Th4-L5. All available vertebrae were graded by an experienced radiologist, vertebral fracture was confirmed if visual inspection perceived at least a 20% reduction in vertebral height (anterior, posterior or middle), as described by Genant et al.

Results

Among enrolled subjects 92 (18.4%) were male and 409 (81.6%) were female; the mean age was 64 (95% CI 47–91) years. Vertebral fractures were found in 78 subjects (15.5%) and 108 individuals (21.5%) reported low-traumatic non-vertebral fractures, in total low traumatic fracture was registered in 165 (32.9%) cases out of 501 enrolled. In total among subjects with T2DM ($n = 251$) vertebral fracture was present in 36 cases, in subjects without T2DM ($n = 250$) in 42 cases ($P = 0.408$). There was no statistically significant difference in the number of non-vertebral fractures (62 with T2DM and 42 in the control group) ($P = 0.062$). It seems that among women with T2DM non-vertebral fractures occurred slightly more commonly ($n = 52$) vs the group without T2DM ($n = 42$) $P = 0.031$. Subjects with T2DM (65 male and 186 female) had BMI – 30.5 (27.1–34.6) kg/m^2. The mean duration of T2DM was 8 (4–13) years. They suffered from macrovascular complications in 54.8% of cases; polyneuropathy −54.8%; retinopathy −25.6%; nephropathy −15.2%. Treatment with insulin was prescribed in 82 cases (32.8%). The glucose control was acceptable with HbA1c – 7.4% (6.6%–8.3%) in this group of outpatients with T2DM

Conclusion

Outpatients with T2DM with well-compensated diabetes do not demonstrate an increased risk of vertebral fracture as assessed by lateral X-Ray.

Qualitative and quantitative parameters of diabetic osteopathy in type 1 diabetes mellitus

Yuliya Dydyshka[1], Nadezhda Karytska[2], Alla Shepelkevich[1], Natalia Vasilieva[3] & Volga Zhukouskaya[4]
[1]Belarusian State Medical University, Minsk, Belarus; [2]10th city clinical hospital, Minsk, Belarus; [3]Republic Center of Endocrinology and Medical Rehabilitation, Minsk, Belarus; [4]Department of Clinical Medicine and Surgery, Division of Endocrinology, University of Naples Federico II, Naples, Italy.

Background and aims

Diabetic osteopathy in patients with type 1 diabetes (T1DM) is obvious. However, approaches to its diagnosis are still ambiguous. Thus, the aim was to study the features of serum osteo-specific parameters and dual energy X–ray absorptiometry (DXA) data in T1DM patients.

Materials and methods

157 patients with T1DM (105 women, 52 males) (mean age: 32.5 (25.5–41.6) yrs, duration of DM: 13 (7–20) yrs, age of manifestation: 19 (14–23) yrs, BMI: 23.43 (21.55–25,70) kg/m^2; HbA1c: 8.2 (7.6–8.9) %) and 98 (67 women, 31 men) controls, comparable in sex, age and anthropometric data. The research involved general clinic examination, serum bone-specific parameters, DXA (bone mineral density (BMD) and trabecular bone score (TBS) of lumbar spine). Z–score of –2.0 or less was regarded as «low bone mineral density».

Results

There were no significant differences in L1-L4 BMD and TBS in women compared with men: 1.16 (1.08–1.26 vs. 1.16 (1.08–1.28) g/sm^2; (U = 5506; $P = 0.694$) and 1.40 (1.35–1.46) vs. 1.44 (1.37–1.49) (U = 3230; $P = 0.097$). Similar results were obtained in subgroups of T1DM patients and controls. There was a definite link between BMD (L1–L4) and TBS (L1–L4) – $r^2 = 0.33$, $P < 0.001$. Low BMD was detected in 14.6% (23) of the surveyed patients with T1DM and 4.1% (4) of controls. T1DM patients compared to controls had lower BMD and TBS: BMD 1.14 (1.04–1.22) vs 1.23 (1.13–1.33) g/cm^2; U = 3606; $P < 0.001$; TBS 1.39 (1.33–1.46) vs 1.45 (1.39–1.48); U = 2775; $P < 0.001$), T-score TBS −0.30 (−1.90–0.30) vs 0.10 (−1.025–0.90); U = 248.5; $P = 0.018$; Z-score TBS −0.30 (0.00–0.50) vs. 0.15 (−0.50–1.00), U = 617; $P = 0.092$. In T1DM patients was established decreased alkaline phosphatase (77.98 (67.78–85.18) vs 93.4 (75.58–110.8) U/l; U = 698; $P < 0.001$) and osteocalcin (10.58 (8.08–15.70) vs 19.73 (15.16–26.30) ng/ml; U = 545; $P < 0.001$) compared with the control group. There were an increased osteoprotegerin levels (4.44 (3.38–5.77) vs 2.74 (2.15–3.54) pmol/l; U = 94; $P < 0.001$) and a decreased the RANKL/osteoprotegerin ratio (0.03 (0.02–0.06) vs 0.05 (0.04–0.07), U = 155; $P = 0.017$).

Conclusions

T1DM patients have decreased bone formation markers (alkaline phosphatase, osteocalcin) and elevated resorption markers (osteoprotegerin), which can lead to impaired mineralization (low BMD) and microstructure (low TBS).

Different impact of marrow and visceral adipose tissue on bone phenotype

Francisco de Paula, Iana de Araújo, Adriana Carvalho, Jorge Elias & Carlos Salmon
Ribeirao Preto Medical School, Ribeirão Preto, Brazil.

Introduction

Central obesity and the consequent metabolic syndrome have global devastating effect on the health system due to their strong association with type 2 diabetes

mellitus and cardiovascular disorder. There are contradictory results about the influence of insulin resistance and visceral adipose tissue on bone phenotype. The study was designed to evaluate the association between bone quality and bone mineral density (BMD) with bone marrow adipose tissue (MAT) as well as with insulin resistance-related parameters (i.e. HOMA-IR, visceral adipose tissue (VAT), subcutaneous adipose tissue (SAT) and intrahepatic lipids (IHL).
Material and Methods
The study comprised 56 subjects (36F/20M), which were submitted to biochemical exams of (glucose, HbA1C, calcium, phosphorus, alkaline phosphatase, insulin, PTH, 25-OHD, osteocalcin, telopeptide carboxiterminal of collagen type 1), dual X-ray absorptiometry for the assessment of BMD [lumbar spine, femoral neck, and total hip BMD, as well as lumbar spine trabecular bone score (TBS)]. In addition, all subjects underwent to Magnetic resonance exams for the evaluation of MAT (^{1}H spectroscopy), SAT, VAT and IHL.
Results
No subject had diabetes mellitus based on fasting glucose and HbA1c determinations. The group showed: age $=47\pm14$ years, weight $=67.8\pm10.9$ Kg, height $=1.65\pm0.10$ m; and BMI $=24.8\pm3.9$ Kg/m^2 (17.5–33.6 Kg/m^2). The mean of L3 TBS was 1.4 ± 0.1 (1.17–1.77) and MAT was $32\pm11\%$ (10.6–69.1). There was a negative association between VAT, SAT, IHL with TBS ($R^2=0.29$; $P<0.0001$ and $R^2=0.23$; $P<0.005$; $R^2=0.14$; $P<0.05$, respectively). In addition, there was a negative association between TBS with MAT and HOMA-IR, respectively, $R^2=0.16$; $P=0.001$ and $R^2=0.23$, $P=0.0002$, which was maintained after adjustment age and BMI. There was no association between BMD with SAT, VAT, IHL and HOMA-IR.
Conclusion
The present study shows for the first time that MAT affects bone quantity and quality, while insulin resistance parameters (VAT, IHL and HOMA-IR) are only associated with bone quality (TBS). The present results encourage further studies to verify if TBS may serve as tool for BMD-independent fracture risk assessment in metabolic syndrome.

FGF-23 beyond the kidney: a new bone mass regulator in the general population

Stefana Catalina Bilha[1], Maria-Christina Ungureanu[1], Alina Andreea Gatu[1], Anca Matei[1], Alexandru Florescu[1], Adrian Aancute[2], Valentin Zaharia[2], Cristina Preda[1], Adrian Covic[1] & Dumitru Branisteanu[1]
[1]'Grigore T. Popa' University of Medicine and Pharmacy Iasi, Iasi, Romania; [2]'St. Spiridon' Emergency Hospital, Iasi, Romania.

Aim
Fibroblast growth factor-23 (FGF-23) has been proposed as a predictor of bone abnormalities in chronic kidney disease patients (CKD), with recent data showing that it may also predict bone mass in the general population. We aimed at investigating the relationship between FGF-23 and bone mass parameters in apparently healthy individuals, according to sex, menopausal and nutritional status.
Materials and methods
Bone mass (bone mineral density-BMD, bone mineral content-BMC; assessed by Dual X-Ray Absorptiometry-DXA), body composition (DXA evaluation), and also the serum levels of FGF-23, parathormone (PTH), 25(OH)D_3, bone resorption marker C-terminal telopeptide of type I collagen (CTx) and leptin were determined from 123 apparently healthy volunteers (38 premenopausal women, 55 postmenopausal women and 30 young and middle-aged men). Primary osteoporosis under treatment and secondary osteoporosis (including CKD) were excluded.
Results
FGF-23 was negatively and independently associated with BMD and/or BMC in all groups, explaining up to 10% ($P<0.05$) of femoral neck BMD variance in postmenopausal women, and up to 20% ($P<0.01$) and 32% ($P=0.001$) of 1/3 radius BMC variance in premenopausal women and men, respectively. FGF-23 was increased in postmenopausal women with osteopenia/osteoporosis, but was not an accurate discriminator of normal versus low bone mass (AUC $=0.622\pm0.076$) according to ROC analysis. FGF-23 did not correlate with vitamin D, CTx, body weight, body composition parameters or leptin. FGF-23 was independently associated with PTH in premenopausal women and men only.
Conclusions
FGF-23 was negatively associated with bone mass parameters in both sexes, but was not a discriminator of high accuracy between normal bone mass and osteopenia/osteoporosis in postmenopausal women. The mechanism through which FGF-23 acts upon bone seems not to be mediated by leptin and, thus, requires further investigation. FGF-23 may find its place as a new marker for fine tuning the evaluation of primary osteoporosis and its associated fracture risk.

Bone health and final height in craniopharyngioma patients.

Selveta S. van Santen[1,2], Casper Hammarstrand[3], Daniel S. Olsson[3], Mark Wijnen[1], Gudmundur Johannsson[3], Aart J van der Lelij[1], Marry M. van den Heuvel-Eibrink[2] & Sebastian JCMM Neggers[1,2]
[1]Erasmus MC, Rotterdam, Netherlands; [2]Princess Maxima Center for Pediatric Oncology, Utrecht, Netherlands; [3]Sahlgrenska University Hospital, Gothenborg, Sweden.

Introduction
Craniopharyngioma (CP) is a benign tumor of the sellar/hypothalamic region. It is associated with excess mortality, obesity and endocrinopathies. These endocrinopathies may influence bone health, and increase the risk of fractures.
Methods
In this retrospective study, Dutch/Swedish patients with CP were included if data was available on final height (at age >18 years) or DXA-scan results. Information from the first and last DXA-scans were gathered (i.e. bone mineral density (BMD), T- and Z-scores). Data is presented as mean $\pm$ standard deviation. Z-scores of final height were calculated (based on sex + country of origin).
Results
The cohort included 177 patients, of which 84 (47%) were females. Data was available on final height in 173 patients (98%) and of DXA-scan results in 117 patients (66%). At last follow-up (FU) (mean age 47 ± 18 years), 149 patients had growth hormone deficiency (85%), 155 hypogonadotropic hypogonadism (88%), 146 ACTH insufficiency (83%), 162 TSH insufficiency (92%), and 113 diabetes insipidus (64%). TSH deficiency was significantly more common in male than in female patients (39% vs. 25%, $P=0.042$). At last FU, 69% used growth hormone replacement therapy and the mean daily hydrocortisone dose was 21 ± 6 mg. BMD improving treatment was given to 33 patients (19%), which was higher in females (26% vs. 13%, $P=0.03$). Fractures in the total group occurred in 32 patients (19%). Fractures occurred more frequent in males than in females (29% vs. 10%, $P=0.002$) and more frequent in non-irradiated patients (13% vs. 26%, $P=0.028$). Mean time between DXA-scans was 10 ± 7 years and mean difference in height was 3.0 ± 10 cm. At first DXA-scan, mean T-score and Z-score for the BMD of total body, femur neck and L2–L4 were -0.1 ± 1.5 and -0.5 ± 1.4, -0.6 ± 1.5 and -0.6 ± 1.3, -0.7 ± 1.6 and $\pm-0.7\pm1.6$, respectively (no differences between sexes). Improvement in BMD occurred, expressed by mean change in T and Z-score of the total body (0.7 ± 1.1, 0.7 ± 1.0, $P<0.001$), Z-score of femur neck (0.6 ± 1.9, $P=0.03$) and T- and Z-score of L2–L4 (0.9 ± 1.6, 0.7 ± 1.8, $P<0.01$). Mean final height for male and female subjects was 178.1 ± 7.9 and 165.6 ± 8.0 cm (Z-score Swedish subjects -1.0 ± 4.3 and -0.1 ± 1.2 ($n=69$)).
Conclusion
Fracture rate is high in patients with CP. BMD improves during the FU period. Males had more fractures than females without difference in BMD; they might be undertreated with bone health improving medication.

Gene variants of osteoprotegerin, estrogen-, calcitonin- and vitamin D-receptor genes and serum markers of bone metabolism in patients with Gaucher disease type 1

Anca Zimmermann[1], Radu Popp[2], Heidi Rossmann[3], Simona Bucerzan[4], Ioana Nascu[4], Daniel Leucuta[5], Matthias Weber[1] & Paula Grigorescu-Sido[4]
[1]University Medical Center Mainz, 1. Med. Clinic, Department of Endocrinology and Metabolic Diseases, Mainz, Germany; [2]University of Medicine and Pharmacy Iuliu Hatieganu, Department of Medical Genetics, Cluj, Romania; [3]University Medical Center Mainz, Institute for Clinical Chemistry and Laboratory Medicine, Mainz, Germany; [4]University of Medicine and Pharmacy Iuliu Hatieganu, Center of Genetic Diseases, 1st Pediatric Clinic, Cluj, Romania; [5]University of Medicine and Pharmacy Iuliu Hatieganu, Department of Medical Informatics and Biostatistics, Cluj, Romania.

Purpose
Osteopathy/osteoporosis in Gaucher disease type 1 (GD1) shows variable responses to enzyme replacement therapy (ERT); the pathogenesis is incompletely understood. We aimed to investigate the effect of several gene variants on bone mineral density (BMD) and serum markers of bone metabolism in GD1.
Patients/methods
50 adult Caucasian patients with GD1/117 controls were genotyped for gene variants in the osteoprotegerin (TNFRSF11B; OPG), estrogen receptor alpha (ESR1), calcitonin receptor (CALCR), vitamin D receptor (VDR) genes. In patients and 50 matched healthy controls, we assessed: clinical data, serum markers of bone metabolism, subclinical inflammation. BMD was measured for the first time before/during ERT (median 6.7 years).
Results
42% of patients were splenectomized. ERT led to variable improvements in BMD. Distribution of gene variants was comparable between patients/controls. The AA genotype (c.1024 + 283G > A gene variant; VDR gene) was associated with lower Z scores before ERT vs. GA ($P = 0.033$), was encountered in 82.3% of patients with osteoporosis and was more frequent in patients with pathological fractures. Z score increases during ERT were higher in patients with the CC genotype (c.9C > G variant, TNFRSF11B; OPG gene) compared to GC ($P = 0.003$). The CC genotype (c.1340T > C variant, CALCR gene) was associated with higher Z scores before ERT than the TT genotype ($P = 0.041$) and was absent in osteoporosis. Osteocalcin and osteoprotegerin were lower in patients vs. controls; beta crosslaps, interleukin-6, ferritin were higher.
Conclusions
We suggest for the first time a protective role against osteoporosis in GD1 patients for the CC genotype of the c.9C > G gene variant in the TNFRSFB11 (OPG) gene and for the CC genotype of the c. 1340T > C gene variant (CALCR gene), while the AA genotype of the c.1024 + 283G > A gene variant in the VDR gene appears as a risk factor for lower BMDs. Serum markers suggest decreased osteosynthesis, reduced inhibition of osteoclast activation, increased bone resorption and subclinical inflammation during ERT.

Glycemic variability and mortality in patients hospitalized to general surgery wards

Alexander Gorshtein[1,2], Tzipora Shochat[3], Idit Dotan[4], Talia Diker-Cohen[1,2], Ilan Shimon[1,2] & Amit Akirov[1,2,5]
[1]Institute of Endocrinoligy, Rabin Medical Center, Beilinson Hospital, Petach Tikva, Israel; [2]Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel; [3]Statistical Consulting Unit, Rabin Medical Center, Beilinson Hospital, Petach Tikva, Israel; [4]Toronto General Hospital Research Institute, University Health Network, Toronto, Ontario, Canada; [5]Department of Endocrine Oncology, Princess Margaret Cancer Centre, Toronto, Ontario, Canada.

Background
Glucose variability (GV) is common among hospitalized patients but the prognostic implications among patients hospitalized to surgical wards are unknown.
Objective
Investigate the association between GV, length of stay (LOS) and mortality.
Methods
Historical prospectively collected data of patients ≥18 years, hospitalized to general surgery wards between January 2011–December 2017. GV was assessed by coefficient of variance (CV) and standard deviation (SD) of glucose values during hospitalization. The main outcomes were LOS, 30-day and end-of-follow-up mortality.
Results
Cohort included 8,894 patients (mean age 63 ± 19 years, 48% male, mean follow-up 3.0 ± 1.8 years); 2,012 (23%) patients with diabetes mellitus (DM). Mean LOS was longer with higher CV or SD in patients without and with DM. 30-day mortality was 6%, associated with higher vs. lower CV (9% vs. 3%) and SD (9% vs. 3%) in patients without DM and with DM (9% vs. 5%; 8% vs. 5%, respectively). Mortality at the end-of-follow-up was increased in patients without DM with higher CV (27% vs. 18%) and SD (29% vs. 17%) and in patients with DM (33% vs. 24% and 32% vs. 21%, respectively). Multivariate analysis indicated increased risk for 30-day and end-of-follow-up mortality, in both groups. Adjustment for glucocorticoid treatment or hypoglycemia did not affect the results. In patients with high or low CV, mortality was higher with median glucose levels during hospitalization ≥180 mg/dl, compared with <180 mg/dl.
Conclusions
In patients with and without DM hospitalized to general surgery wards, increased GV is associated with longer hospitalization and increased short- and long-term mortality.

High prolactin levels within the normal range are associated with improved metabolic profile and lower carotid intima media thickness in premenopausal women

Areti Augoulea[1], Stefanos Stergiotis[1], Eleni Armeni[1], Stavroula A. Paschou[1], Panagiota Chatzivasiliou[1], Dimitrios Rizos[2], George Kaparos[2], Konstantinos Panoulis[1], George Georgiopoulos[3], Kimon Stamatelopoulos[3] & Irene Lambrinoudaki[1]
[1]Second Department of Obstetrics and Gynecology, Aretaieio Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece; [2]Biochemical Laboratory, Aretaieio Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece; [3]Vascular Laboratory, Department of Clinical Therapeutics, Alexandra Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece.

Introduction
A growing body of evidence is supporting a beneficial impact of breastfeeding on maternal metabolism and overall cardiovascular risk. The aim of this study was to evaluate the association between prolactin levels and metabolic parameters as well as indices of subclinical atherosclerosis, in a sample of premenopausal women with normal levels of prolactin.
Patients and Methods
This cross-sectional study included a total of 64 non-lactating premenopausal women. We evaluated anthropometric parameters and obtained blood samples for hormonal and biochemical assessments. Sonographical evaluation included indices of structural vascular disease (carotid intima media thickness, IMT) as well as pulse wave velocity (PWV).
Results
Lower levels of IMT were observed in cases with higher levels of prolactin (carotid IMT 5.87 ± 0.78 mm vs 6.47 ± 1.24 mm, P-value = 0.023), an association that remained significant even after adjusting for age and BMI. Measures of PWV did not exhibit a significant difference between high vs low levels of prolactin; instead, we confirmed a direct linear independent association (PWV, b-coefficient = 0.370, P-value = 0.013) in a model adjusted for age, BMI, pulse pressure, HOMA-IR and lipids. Higher levels of prolactin were associated with lower levels of glucose (78.9 ± 6.2 mg/dl vs 85.2 ± 9.5 mg/dl, P-value = 0.025), almost significantly lower values of HOMA-IR (1.17 ± 0.29 vs 1.56 ± 0.70, P-value = 0.058). Women with prolactin levels in the 4th quartile vs 1st quartile presented with higher levels of HDL-cholesterol (69.0 ± 11.8 mg/dl vs 60.13 ± 9.80 mg/dL, P-value = 0.027) and almost significantly lower levels of LDL-cholesterol (93.2 ± 25.3 mg/dL vs 113.8 ± 32.8 mg/dL, P-value = 0.056).
Conclusions
High levels of prolactin within the normal range in non-lactating pre-menopausal women are associated with a beneficial impact on carotid IMT and an adverse effect on arterial stiffness. Moreover, higher levels of prolactin are also associated with improved levels of insulin resistance and blood lipids.

The A allele of the rs4636297 (G/A) polymorphism in the microRNA-126 is associated with protection for diabetic retinopathy

Daisy Crispim[1,2], Eloisa Massignam[1,2], Felipe Mateus Pellenz[1,2] & Cristine Dieter[1,2]
[1]Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil; [2]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil.

Background and aims
Diabetic retinopathy (DR) is an important chronic complication of diabetes mellitus (DM), and is the leading cause of new cases of blindness in adults. Although several single nucleotide polymorphisms (SNPs) have been associated with DR, more information is needed to unravel the genetics of this complex disease. MicroRNAs (miRNAs) are a class of small noncoding RNAs that regulate expression of at least 60% of all protein-coding genes. A number of miRNAs have been described as having abnormal expressions in patients with DR, including miRNA-126, which regulates endothelial cell response to VEGF, an important pro-angiogenic growth factor involved in DR pathogenesis. Polymorphisms in genes codifying miRNAs (miRSNPs) may alter the expression of the corresponding miRNA and, thus, confer susceptibility for DR. Therefore, miRSNPs in miR-126 gene could be associated with DR susceptibility. Therefore, the aim of this study was to investigate the association between the rs4636297 (G/A) miRSNP in miRNA-126 gene and DR.
Methods
This case-control study comprised 196 type 1 DM (T1DM) patients with DR (cases) and 219 T1DM patients without this complication and with ≥ 10 years of DM (controls). The rs4636297 miRSNP was genotyped by allele discrimination – real-time PCR technique, using TaqMan MGB probes (Thermo Fisher Scientific).
Results
Genotype distributions of the rs4636297 miRSNP were in Hardy-Weinberg equilibrium in controls. The A allele frequency was 40.0% in cases and 46.0% in controls, and this allele was associated with protection for DR under recessive (OR $=0.294$, $P=0.032$), additive (OR $=0.087$, $P=0.001$), and dominant (OR $=0.348$, $P<0.001$) inheritance models, adjusting for age, presence of hypertension, diabetic renal disease, and cholesterol levels.
Conclusion
Our results suggest for the first time in a Brazilian population, an association between the A of rs4636297 miRSNP in the miR-126 gene and protection for DR.

Vitamin D supplementation and dynamics of LDF skin microcirculation in patients with diabetes mellitus and diabetic polyneuropathy

Anna Stepanova[1], Tatiana Karonova[1,2], Mikhail Galagoudza[1,2] & Edvard Jude[3]
[1]First Pavlov State Medical University, Saint-Petersburg, Russian Federation; [2]Almazov National Medical Research Center, Saint-Petersburg, Russian Federation; [3]Manchester Metropolitan University, Manchester, UK.

Hypothesis
High doses of vitamin D (VitD) improves dermal microcirculation (MC) in diabetic patients with type 2 diabetes mellitus (T2DM) and diabetic neuropathy (DN).
Purpose
To study the effect of different VD doses on skin MC values in T2DM patients and DN.
Materials and methods
Sixty-two non-smoking T2DM patients with DN were randomized into two groups: Group 1 received 5000 IU (G1) and Group 2 received 40000 IU (G2) of cholecalciferol per week. Inclusion criteria included HbA1c up to 9.0%, neuropathy disability score (NDS) of 4 and higher. MC parameters (value of perfusion – M, standard deviation of blood flow – σ and Kv - coefficient of microcirculation, %) were assessed by Laser Doppler Fluorometry (LDF) (LAKK-M, Russia); two functional tests: postural (blood flow reduction rate was calculated - BFR) and occlusion (capillary blood reserve index was calculated - CBR), 25(OH)D were studied at baseline and after 24 weeks. The MC values of control healthy subjects (Group 3; G3) were used for comparison.
Results
The clinical characteristics of patients werecomparable (G1: $n=31$; age 52.4 ± 5.7, BMI 30.2 ± 4.3; serum 25(OH)D $28.0\pm16,9$ (units); HbA1c $7.6\pm0.8\%$ and G2: $n=31$; age 51.4 ± 6.1; BMI 31.1 ± 4.5; serum 25(OH)D 23.9 ± 7.9; HbA1c $7.7\pm0.9\%$; ($P>0.05$). G3 ($n=16$; age 51.8 ± 3.7; BMI 30.1 ± 2.7, 25(OH)D 29.11 ± 13.6) only difference was HbA1c level ($4.8\pm0.5\%$; $P=0.001$). The MC parameters in T2DM pts were significantly lower than in G3 ($M_{G1+2}=7.2\pm0.8$, & $M_{G3}=10.4\pm5$ ($P=0.007$); $\sigma_{G1+2}=3.1\pm0.4$ & $\sigma_{G3}=4.2\pm0.6$ ($P=0.013$); Kv_{G1+2} 35.2 ± 15.1 & $Kv_{G3}=40.3\pm14.5$ ($P=0.003$) respectively. No changes of MC were seen in G1 after treatment ($M=6.9\pm0.5$ & $M=7.3\pm0.4$; $\sigma=3.5\pm0.6$ & $\sigma=4.4\pm0.8$; Kv 34.7 ± 13.2 & $Kv=35.2\pm14.1$ ($P>0.05$). In G2 HbA1c decreased, 25(OH)D increased, all parameters of MC improved ($M=7.3\pm0.6$, & $M=8.7\pm0.9$ ($P=0.003$); $\sigma=3.4\pm0.3$ & $\sigma=5.3\pm0.7$ ($P=0.005$), $Kv=36.8\pm11.7$ and $Kv=38.1\pm12.1$ ($P=0.008$). The postural test was more informative due to good portability and ease of implementation and revealed lower baseline BFR in pts compared to G3 ($P=0.027$). Positive correlation between BFR, CBR and 25(OH)D after treatment was find only in G2 ($r=0.72$, $P=0.03$ & $r=0.85$, $P=0.02$, respectively).
Conclusions
High dose of VitD supplementation (40,000 IU/week) for 6 months in T2DM patients with DN was associated with HbA1c decrease and improvement in microcirculation parameters.

DOI: 10.1530/endoabs.63.GP122

GP123

Four out of five patients with type 2 diabetes mellitus have hearing loss

Abin Abraham[1], Ashish Verghese[2] & Jubbin Jacob[3]
[1]Department of Medicine, Christian Medical College and Hospital, Ludhiana, Ludhiana, India; [2]Department of ENT, Christian Medical College and Hospital, Ludhiana, India; [3]Endocrine Unit, Department of Medicine, Christian Medical College and Hospital, Ludhiana, Ludhiana, India.

Objectives
This study was undertaken to ascertain the prevalence of hearing loss (HL) in patients with Type 2 Diabetes (T2DM) and to understand its relationship with diabetic neuropathy.
Materials and Methods
Patients between the ages of 30 to 60 years (both ages inclusive) with T2DM were recruited and divided in two groups. Group 1 with moderate to severe distal sensory-motor neuropathy (Michigan Diabetic Neuropathy Score >12) or Group 2 were those with no neuropathy (MDNS score <6). Patients with mild neuropathy (MDNS score 6–12), history of intake of ototoxic drugs, ear surgery or infections, neurological disorders, Meniere's disease, head injuries, renal failure and with occupational exposure to loud noises were excluded. After informed consent HL was assessed with pure tone audiometry (PTA) for various frequencies (250Hz to 8000Hz).
Results
Of the 200 patients recruited (151 with neuropathy and 49 without) the prevalence of any hearing loss (AHL) was overall 81% with 85.5% prevalence among those with neuropathy and 66.6% among those without neuropathy ($P-0.004$). The prevalence of clinical significant hearing loss (CSHL) (moderate and above) was 28.5% (overall), 30.5% (with neuropathy) and 22.8% (without neuropathy ($P-0.28$). On univariate logistic regression with AHL in any ear as outcome, age, gender, taking regular ACE inhibitors, MDNS score, MDNS grade and presence of neuropathy was found to have significant correlation.On multivariate binary logistic regression with AHL in any one ear as outcome, age, gender, taking regular ACE inhibitors and MDNS score was found to have significant correlation.
Conclusions
Four out of five adult patients (30–60 years) with T2DM had some degree of HL on PTA. Of these one in three had CSHL. In addition to age and gender there was some association of HL with the degree of diabetic neuropathy.

Unrecognized high risk for diabetic foot ulcer among hospitalized patients

Shlomit Koren[1], Moriah Sharabi[2], Tamar Moriel Levy[2], Daniel Fux[3], Ronit Koren[4] & Micha J Rapoport[2]
[1]Diabetes Unit, Assaf Harofeh Medical Center, Be'er Ya'akov, Israel; [2]Internal medicine C, Assaf Harofeh Medical Center, Be'er Ya'akov, Israel; [3]Internal medicine B, Assaf Harofeh Medical Center, Be'er Ya'akov, Israel; [4]Internal medicine A, Assaf Harofeh Medical Center, Be'er Ya'akov, Israel.

Aim
Loss of protective sensation (LOPS) commonly precede Diabetic foot ulcer (DFU) which is one of the most fearsome/serious diabetic complications and the

leading cause of foot amputation in T2D patients. However, the prevalence of this high risk state is unknown.
Methods
To estimate the presence of LOPS among hospitalized diabetes patients in internal wards, vibration perception and 10-g monofilament tests were done. Patients with foot ulcer or status post amputation were excluded.
Results
A total of 305 patients were tested. 165(54.1%) males and 140(45.9%) females. mean age was 70.3 ± 12.2 years old. The mean duration of diabetes was 12 years (IQR 6–20). Mean HBA1C was 6.8 (IQR 6.15–7.98). 79(25.9%) patients had known retinopathy and 68(22.3%) had known nephropathy. 150(49.1%) had LOPS (either abnormal monofilament test or vibration test or both). Patients with LOPS tend to be older 72.1 ± 11.8 vs 68.6 ± 12.6 years old, $P = 0.005$ (95% CI 0.53–0.657), had higher creatinine, 1.45 ± 1.1 vs. 1.38 ± 1.4, $P = 0.02$ (95% CI 0.513–0.641), lower albumin, 35.3 ± 5.1 vs. 36.9 ± 4.7, $P = 0.014$ (95% CI 0.518–0.647), lower hemoglobin, 11.5 ± 2.3 vs 12.3 ± 2.3, $P = 0.006$ (95% CI 0.527–0.655) and compelling significant higher RDW, 16.2 ± 2.1 vs 15.3 ± 2.2, $0 < 0.001$ (95% CI 0.583–0.708). Moreover, patients with LOPS tend to have abnormal feet pulses, $P = 0.001$ (95% CI 0.552–0.706). No significant correlation was found between LOPS and disease duration, insulin-treatment, background-diseases or hospitalization cause.
Conclusions
Half of the diabetic patients in internal wards have unrecognized LOPS, the leading cause for DFU. Some simple clinical measures are correlated with LOPS. This window of opportunity should be used to recognize these patients and take measures for DFU prevention.

Vitamin D3 deficiency is associated with more severe insulin resistance and metabolic profile in patients with type 2 diabetes

Udwan Mahmoud, Nazarii Kobyliak & Iuliia Komisarenko
Bogomolets National Medical University, Kyiv, Ukraine.

Introduction
Recently, vitamin D3 (cholecalciferol) deficiency has been considered as one of the factors for the development of type 2 diabetes mellitus (T2D) and metabolic syndrome (MS), which contributes to increased insulin resistance (IR) and reduced insulin secretion. The most pronounced vitamin D deficiency is observed in persons suffering from morbid obesity. The aim of this study was to assess IR, b-cell functional activity and metabolic profile parameters according to the 25 (OH) vitamin D3 (vitD3) status in patients with T2D.
Materials and methods
The study included 109 patients with T2D. All patients were divided according to the Endocrine Society clinical practice guideline for vitD3 status on 3 groups as follows: group 1 ($n = 11$) – no deficiency, with optimal level vitD3 (> 40 ng/ml); group 2 ($n = 38$) – vitD3 insufficiency (21–29 ng/ml); and group 3 ($n = 60$) – vitD3 which was determined as less than 20 ng/ml. The IR, b-cell functional activity were assessed as change C-peptide and HOMA-β (homeostasis model assessment-estimated β-cell function) which calculated using HOMA2 calculator (Diabetes Trials Unit, University of Oxford). Continuous variables were analyzed using one-way ANOVA with Tuckey Post Hoc test. Data with non-parametric distribution was analyzed using Kruskall-Wallis test. The significance level was considered significant at $P < 0.05$. Association between vitD3 amount and metabolic changes was assessed with univariate Pearson's correlation analysis.
Results
In patients with vitD3 deficiency we observed significantly higher C-peptide as compared to both other groups. The HOMA2 (3.29 ± 1.89 vs. 2.12 ± 0.71; $P = 0.049$) and HbA1c (9.11 ± 1.63 vs. 7.75 ± 1.06; $P = 0.016$) levels changes significantly only in vitD3 deficiency group as compared to patient with optimal vitD3 (group 1). Furthermore, in univariate Pearson's correlation analysis, only in vitD3 deficiency group we observed significant association between vitD3 amount and C-peptide ($r = -0.461$, $P < 0.001$), insulin sensitivity ($r = 0.370$, $P = 0.004$), HOMA2 ($r = -0.292$, $P = 0.023$), triglyceride-glucose index ($r = -0.318$, $P = 0.013$), HbA1c ($r = -0.317$, $P = 0.014$) and BMI ($r = -0.285$, $P = 0.027$) respectively. B-cell functional activity changes insignificantly and we did not found significant associations between vitD3 amount and metabolic parameters across all groups.
Conclusions
Our study demonstrated that vitD3 deficiency in patients with T2D associated with more severe IR, obesity and poor glycemic control as compared to optimal value or vitD3 insufficiency. From the other hand, we did not found significant relationships between vitD3 status and β-cell functional activity.

Depression and associated risk factors in older adults with diabetes: the 2010–2011 Korean national health and nutrition examination survey

Sangyong Kim & Jinhwa Kim
Chosun University, Gwangju, Republic of Korea.

Aims
Diabetes is an important health condition in the aging population. The risk of depression is increased in older adults and should therefore be screened and managed. Especially, it is important to early detect and improvement of depression in older adults with diabetes because it is associated with glucose control and development of diabetic complication. We evaluated the prevalence of depression in diabetic older adults and identified associated independent risk factors using data of the Korea National Health and Nutrition Examination Survey (KNHANES) 2010–2011.
Methods
This study was based on data from the Korea National Health and Nutrition Examination Survey, which was conducted by the Korean Ministry of Health and Welfare in 2010–2011. The research selected 2,843 older adults whose data of health condition and mental health exist and ages are older than 65, from the KNHANES 2010–2011. The variables included general characteristics, disease-related characteristics, anthropometric measurements and blood tests, and mental health results. Multiple logistic regression analyses was performed to examinate independent risk factors associated with depression in subjects.
Results
The prevalence of diabetes were 18.2% (518/2,843) in older adults. The prevalence of depression in older adults with diabetes was significantly higher (21.0%) than older adults without diabetes (14.7%), respectively ($P = 0.045$). There was no significant differences in sucidal idea, neuropsychiatry visiting experience during one year, and stress status. Independent risk factors associated with depression in older adults with diabetes were older age group (75–79 years; odds ratio (95% CI), 2.10 (2.01–3.24), ≥ 80 years; 2.14 (1.02–3.24)), diabetes duration ≥10 years (1.34 (1.31–3.62)), and increasing number of comorbid diseases (1; 1.13 (1.01–2.34), ≥2; (2.213 (1.03–3.01)).
Conclusions
The prevalence of depression in diabetic older adults was significantly higher compared to the older adults who do not have diabetes in Korea. Older age, longer diabetic duration, and increasing comorbid diseases were independent risk factors associated with depression. In the management of older adults with diabetes, an individualized approach is required that focus on early diagnose and improving of the depression.

Genetic polymorphisms in patients with type 2 diabetes mellitus and coronary heart disease

Volha Shyshko[1], Tatjana Mokhort[1], Natalia Tsataeva[1], Elena Konstantinova[2] & Alexander Gonchar[3]
[1]Belarusian State Medical University, Minsk, Belarus; [2]Republican Scientific and Practical Center 'Cardiology', Minsk, Belarus; [3]Institute of Genetics and Cytology of the National Academy of Sciences, Minsk, Belarus.

It is known that presence of certain genetic polymorphism plays important role in development of chronic complications in patients with type 2 diabetes (T2D).
Aim
To analyze distribution of VEGF G/C polymorphisms and PAI-1 4G/5G polymorphisms in patients with T2D and IHD.
Materials and methods
The following groups of studies were formed: 1 – 24 almost healthy people; 2 – 28 patients with prediabetes; 3 – 37 patients with T2D; 4 – 35 patients with T2D and IHD. Genetic study included qualitative *in vitro* detection of two alleles of VEGF (G/C) and PAI-1 (4G/5G) genes by polymerase chain reaction.
Results
Genotype G/C of the VEGF gene was associated with IHD in patients with T2D and was revealed in 26 out of 35 patients in group 4, which was 74.3%, compared to group of patients with T2D without accompanying IHD, where the heterozygous variant was registered in 4 out of 37 patients (10.8%) ($F = 0.1$, $P = 0.001$). C/C genotype was not registered in patients with IHD (0%), and was found in 15 patients without IHD (16.9%). When studying the genotype

distribution of the PAI-1 gene, taking into account the presence or absence of IHD, it was found that the presence of the 5G/5G genotype of the PAI-1 gene is the most typical for patients with type 2 diabetes in combination with IHD. This genotype was registered in 16 out of 35 patients with IHD, which was 46.7%, and in 5 out of 37 patients with DM2 without IHD (11.1%) ($\chi^2=9.1$, $P=0.003$). Based on the genotyping results, it was determined that the allele 4 is associated with the absence of IHD ($\chi^2=11.0$, $P=0.001$). This allele was registered in 48 cases in the absence of IHD and in 26 cases in the presence of IHD, allele 5 was registered in 26 cases in the absence of IHD and in 44 cases in the presence of disease.

Conclusion

Genotype G/G of VEGF gene is associated with reduced risk of IHD development ($P=0.024$) and absence of progression of renal dysfunction in case of type 2 diabetes ($P=0.002$). The 5G/5G genotype of the PAI-1 gene is associated with the development of IHD in patients with type 2 diabetes ($P=0.003$). The 4G allele is associated with the absence of IHD ($P=0.001$).

Clinical and metabolic characteristics of a population of diabetic patients previously educated having fasted all month of Ramadan

Chaima Jemai, Faika Ben Mami, Oueld Ali Rim, Ben Amara Sarra, Ben Amor Nadia, Sellami Senda, Chelbi Safa, Temessek Arwa, Tertek Hajer & Zarrouk Mariem

Institut national de nutrition de Tunis (Service C), Tunis, Tunisia.

Introduction

The purpose of this study was to describe the clinical and metabolic characteristics of a population of diabetic patients previously educated and having fasted all month of Ramadan.

Methods

This is a prospective study that involved 140 patients who wish to fast the month of Ramadan (2016).They presented themselves at consultations dedicated to preparing diabetic patients wishing to fast, organized at the National Institute of Nutrition of Tunis (departement C). These patients were given an interview, a thorough clinical examination and a biological assessment and were well informed about the risks they face. They had the appropriate therapeutic adaptation (ADA recommandations of 2010), as well as an adequate hygiene and dietary education. We have totally banned fasting for unbalanced patients.

Results

Of the 140 patients, 102, all diabetics type 2,fasted all month of Ramadan. The average age was 56.83 ± 10.77 years. The sex ratio was 0.8.The average weight was 79.21 ± 14.08 kg. Diabetes was evolving since $8,4\pm6.8$ years on average. 20.4% of cases were insulin-dependent. 69% were unbalanced and fasted against medical advice. 26.5% were hypertensive and 27.46% were dyslipidemic. Mean systolic and diastolic arterial blood pressure was 12.71 ± 1.48 and 7.35 ± 0.78 mmHg, respectively. Fasting glucose averages and HbA1C were respectively 9.37 ± 3.68 mmol/l and 8.1 ± 1.58%. According to the glycemic equilibrium before fasting.Fasting blood glucose was respectively 7.82 ± 3.52 mmol/l in well-balanced patients and 10.09 ± 3.55 mmol/l in unbalanced ones. HbA1C was respectively 6.37 ± 0.45 mmol/l in well-balanced patients and 8.89 ± 1.26 mmol/l in unbalanced ones. The mean clearance of creatinine was 98.17 ± 21.37 ml/min. 4 cases of moderate hypoglycemia and 11 cases of hyperglycemia greater than 3 g/l were reported, but patients continued to fast. No other metabolic complication had occurred. After fasting, the average weight was 79.01 ± 14.19 kg. The systolic and diastolic arterial blood pressure averages were 12.74 ± 1.18 and 7.5 ± 0.7 mmHg, respectively. Fasting blood glucose and HbA1C were 8.99 ± 3.15 mmol/l and 8.1 ± 1.57%, respectively. Fasting glucose was 7.8 ± 2.22 mmol/l in balanced patients and 9.54 ± 3.36 mmol/l in unbalanced one. HbA1C values were 6.47 ± 1.01 mmol/l for balanced patients and 8.47 ± 1.37 mmol/l in unbalanced one. Mean creatinine clearance was 98.04 ± 21.88 ml/min.

Conclusion

In our population, the fasting of the whole month of Ramadan had been well tolerated with an improvement in the poorly balanced glycemic patients.Studies with larger numbers are needed to better characterize the effect of fasting on clinical and metabolic parameters.

Efficiency of application of silicate sorbents in surgical treatment of patients with neuro-ischemic form of diabetic foot ulcer

Maksym Prystupiuk[1], Iuliia Onofriichuk[2], Lev Prystupiuk[3], Ludmila Naumova[3] & Marianna Naumova[4]

[1]Bogomolets National Medical University, Kyiv, Ukraine; [2]Kyiv Clinical Hospital #4, Kyiv, Ukraine; [3]Bogomolets National Medical University, Kyiv, Ukraine; [4]Shupyk National Medical Academy of Postgraduate Education, Kyiv, Ukraine.

Aim

To investigate the clinical efficacy of the treatment of patients with neuro-ishemic diabetic foot ulcers (DF) by using sorption-antimicrobial nanocomposition based on silica sorbents.

Methods

Hydrophobic-hydrophilic sorption-antibacterial nanocomposition, offered for the treatment of ulcers and wounds, contains sorbents (nano-disperse silicon dioxide, polymethylsiloxane) and antibacterial components (decamethoxin, metronidazole). In this study 78 patients with a neuroishemic form of DF and purulent complications on the foot were treated. The control group consisted (CG) of 34 patients, and study group (SG)-44 patients. Groups were comparable. Patients in both groups received standard treatment. The criteria for treatment effectiveness were the presence of epithelization and the dynamics of microbial contamination of the wound.

Results

At the 3rd day of treatment no signs of epithelization were detected in any patient of both groups. At the 7th day of treatment, signs of epithelization appeared in both groups, with the frequency of detecting signs of wound healing in SG with 57.83% higher than in CG ($P<0.001$). The number of patients with signs of marginal epithelization in CG significantly (by 58.90%) increased by the 10th day of treatment. But in EG at the 10th day of treatment, the relative number of patients with signs of marginal epithelization exaggerated such in CG at 31.32% Although healing of wounds depends not only on the degree of regional epithelization, but also on microbial contamination, compensation of diabetes and the course of its complications, the use of sorbent stimulates the development of wound epithelization, which eventually improves ultimate healing ($P=0.0021$) wounds compared with this process in patients with CG.

Conclusions

The analysis of the dependence of the rate of development of boundary epithelization on the level of microbial contamination has been carried out. The negative correlation between the rate of edge epithelization of the wound against the level of microbial contamination, in other words, the direct linear dependence of the development of boundary epithelization on the "purity" of the wound. The use of sorbents leads to a rapid wound cleansing, which is determined by the likely reduction in the number of microbial contamination. Such cleaning contributes to a significant acceleration of the appearance of epithelization, which is a guarantee of healing of ulcers against the background of diabetes.

Glucagon activity in human adipose precursors

Martina Trabucco, Giulia Cantini, Edoardo Mannucci & Michaela Luconi

Endocrinology Unit, Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy.

Obesity is associated with increased and dysfunctional white adipose mass. In the past, pharmacological approaches have not yielded significant results in terms of stable weight loss. Glucagon-like peptide 1 receptor (GLP-1R) agonists (GLP-1RA) used for the treatment of type 2 diabetes have more recently been proposed as anti-obesity drugs due to their relevant effects on weight loss. Furthermore, dual agonists engaging both GLP-1R and glucagon receptor (GCGR) are under investigation for their marked effects on weight loss. However, the mechanisms underlying such effects still need to be clarified. Our group has recently demonstrated that liraglutide and GLP-1 interfere with the proliferative and differentiation ability of human adipose precursors, supporting a peripheral action of GLP-1RA on weight loss. In the present study, we investigated glucagon activity in an *in vitro* model of primary human adipose-derived stem cells (ASCs). Glucagon significantly inhibited ASC proliferation, in a dose and time-dependent manner, with a maximal effect at 3 days of culture (14.0%, 25.2% and 37.1% for 1-10-100 nM glucagon, respectively, $P<0.005$ ANOVA, $n=5$). When added during *in vitro*-induced adipogenesis, glucagon (1-10-100 nM) significantly

reduced intracellular lipid accumulation evaluated by specific intracellular lipid staining (−20%, −31%, −27%, $P<0.001$, ANOVA, $n=5$) and expression of mature adipocyte markers FABP4 (−49%, 73%, 62%, $P<0.001$ ANOVA, $n=5$) and HSL (46%, 54%, 37%, $P<0.001$ ANOVA, $n=5$), respectively. Notably, the inhibitory effect of glucagon on both cell proliferation and adipogenesis was reverted by specific GLP-1R (exendin-9) and GCGR (des-His1-Glu9-glucagon (1–29)) antagonists. In conclusion, we demonstrated a direct inhibitory action of glucagon on the proliferation and differentiation ability of human adipose precursors, which seems to involve both GLP-1R and GCGR present on ASCs. In addition to the previously demonstrated lypolitic activity of glucagon on the mature adipocyte, our data suggest that the adipose stem compartment also is a target of glucagon, possibly contributing to the weight loss obtained with the dual activity molecules.

A Study of the Effect of Laparoscopic Mini Gastric Bypass Versus Sleeve Gastrectomy On Obese Type 2 Diabetic Patients

Maram M Aboromia, Mahmoud Farahat, Ahmed Mortada, Haitham Elmaleh, Alyaa Elsherbiny & Ahmed Bahaa Eldin
Ain Shams University, Cairo, Egypt.

Recent guidelines on diabetes treatment provide that bariatric surgery should be the most logical & cost-effective means of controlling Type 2 diabetes.

Objectives

To compare laparoscopic mini-gastric bypass vs laparoscopic sleeve gastrectomy regarding the efficacy of control of D.M in obese patients.

Summary

A randomized controlled study conducted on 60 obese patients with type 2 D.M divided into, group (1): 30 patients treated by laparoscopic Sleeve gastrectomy (SG), group 2: 30 patients treated by laparoscopic Mini-Gastric Bypass (MGB). They were Type 2 Diabetic patients, above 18 years, (BMI) ≥ 30 kg/m^2, willing to sign an informed consent & comply with the follow up schedule. All patients were subjected to History taking, physical examination, laboratory & imaging investigation. The study was approved by the ethical committee of the faculty of medicine.

Key messages

The MGB group had greater FBG reduction (37.80 ± 6.41 mg/dl) vs (29.93 ± 12.84 mg/dl) in SG group and this was statistically significant (P value <0.004). The mean HBA1c drop after one year in MGB ($2.33 \pm 0.48\%$) vs ($2.01 \pm 0.59\%$) in SG group which was statistically significant ($P<0.024$). In the MGB group, diabetes resolution at 6 months was 46.7% vs 20% in the SG.

Conclusion

MGB has better& earlier effect than SG in diabetes remission. OHG, C peptide >3 ng/ml and diabetes duration <5 years are considered independent significant predictors for diabetes resolution.

Variants in genes of the leptin / melanocortin pathway are involved in 3% of cases of early-onset severe obesity

Johanne Le Beyec-Le Bihan[1], Christine Poitou-Bernert[2,3], Alexandra Karsenty[4], Véronique Pelloux[5], Jean Marc Lacorte[6], Patrick Tounian[3,7], Jean Michel Oppert[2,3], Karine Clement[2,3] & Beatrice Dubern[3,9]
[1]UF génétique obésité et Dyslipidémies, Biochimie Endocrinienne et Oncologique, Pitié-Salpetriére, Paris, France; [2]Nutrition, Pitié Salpétrière, Paris, France; [3]CRMR Syndrome de Prader-Willi et syndromes avec troubles du comportement alimentaire, APHP, Paris Sorbonne Université/ Inserm, Nutriomics, Paris, France; [4]Nutrition et gastroentérologie pédiatrique, Hopital Trousseau, Paris, France; [5]Paris Sorbonne Université/ Inserm, Nutriomics, Paris, France; [6]UF génétique obésité et Dyslipidémies, Biochimie Endocrinienne et Oncologique, Pitié-Salpêtrière, Paris, France; [7]utrition et gastroentérologie pédiatrique, Hopital Trousseau, Paris, France; [8]CRMR Syndrome de Prader-Willi et syndromes avec troubles du comportement alimentaire, APHP, Paris Sorbonne Université/ Inserm, Nutriomics, Paris, France; [9]Nutrition et gastroentérologie pédiatrique, Hopital Trousseau,, Paris, France.

The leptin/melanocortin pathway plays a critical role in hypothalamic control of food intake. Variants in the genes involved in this pathway, such as leptin (LEP), its receptor (LEPR), proopiomelanocortin (POMC) or proconvertase 1 (PCSK1) are associated with early-onset severe obesity and endocrine abnormalities especially in case of homozygosity. Heterozygous variants in the melanocortin-4 receptor (MC4R) gene are associated with an increased risk of severe obesity. The aim is to describe the frequency of variants in the genes of the leptin/melanocortin pathway in obese children and adults consulting in a reference center. The coding eons of the LEP, LEPR, POMC, PCSK1 et MC4R genes were sequenced by Sanger. The 6100 patients included had severe obesity (BMI >35 kg/m^2 for adults and BMI Zscore $>+2.5$ s.d. for children). MC4R was sequenced in 5815 subjects, LEPR in 1180 patients, LEP in 800 patients, POMC in 556 patients and PCSK1 in 288 patients. The frequency of homozygous variants was $\leq 1\%$ with 13 (1.02%) variants in *LEPR* (p.C604G, p.L786P, p.H800_N831del, p.Y422H p.T711N, p.535-1G>A, p.P166CfsX7, p.Met1X), 3 (0.4%) variants in *LEP* (p.Q55X, p.R105W, p.V94M), 1 variant in *PCSK1* (0.4%) (c.286-2A>G), 3 variants in *POMC* (0.6%) (p.R75Profs*44; p.E214G; p.D53G) et 7 variants in *MC4R* (0.12%) (p.R165Q, p.S127L, p.C277X, p.V166I, p.C271R, p.I170V). Homozygous patients developed severe early-onset obesity (before the age of 3y) with major hyperplasia and associated endocrine phenotypes. The frequency of heterozygous variants was 2–3% for POMC, *MC4R* and *LEPR* whereas it was less than 2% for *PCSK1* (1.4%) and *LEP* (0.5%). The presence of one heterozygous variant with functional consequence in these genes was always associated with early-onset obesity (before the age of 10y) without endocrine abnormalities. Four patients had heterozygous combined variants on two genes in the pathway suggesting a cumulative effect. Our work confirms the implication of variants in genes of the leptin/melanocortin pathway in early-onset severe obesity (2-3% of patients with severe obesity) and is currently expanded to other genes modulating this pathway. This screening is critical because now effective therapeutic options by MC4R agonist (setmelanotide) exist and can restore the melanocortin signal despite its interruption in case of variants. Development of clinical tools helping for diagnosis and NGS molecular tests extended to other genes involved in the pathway will help to diagnose patients candidates for this novel therapeutic.

Effect of IL1-receptor antagonist on renin-angiotensin-aldosterone system and hemodynamics in obese individuals

Sandrine Urwyler[1], Fahim Ebrahimi[1], Thilo Burkard[1], Philipp Schuetz[2], Marko Poglitsch[3], Mueller Beat[2], Marc Y Donath[1] & Mirjam Christ-Crain[1]
[1]University Hospital Basel, Basel, Switzerland; [2]Kantonsspital Aarau, Aarau, Switzerland; [3]Attoquant Diagnostics GmbH, Vienna, Austria.

Background

Interleukin (IL)-1 antagonism decreases systolic blood pressure in obese individuals. However, the underlying mechanism is unknown. Based on experimental data in animals we hypothesised a blood-pressure lowering effect of IL-1-antagonism via modulation of the renin-angiotensin-aldosterone system (RAAS).

Methods

In this post-hoc explorative study, we examined short- (2 days) and long-term effects (4 weeks) of IL-1 antagonism (anakinra/Kineret®) on RAAS-peptide-profiles and on hemodynamic parameters assessed by a non-invasive measurement using HOTMAN® system. In total, 128 obese (BMI $>$ 30kg/m^2) individuals with at least one feature of the metabolic syndrome from two previous interventional trials (CortIL trial a prospective interventional trial ($n=61$) and TestIL trial, a placebo controlled-double blinded interventional trial ($n=67$)) were evaluated.

Results

Upon IL-1 antagonism circulating levels of angiotensin II, angiotensin I, aldosterone and renin remained unchanged after short- and long-term treatment, respectively. In contrast, the vasodilatory angiotensin (1–7) peptide significantly increased after 4 weeks compared to placebo (in between group difference 16.35 pmol/L [1.22 to 30.17], $P=0.03$), without short-term effect on day 2. Concurrently, angiotensin (1–7) /angiotensin II-ratio significantly increased after 4 weeks in the anakinra-group compared to placebo (in between group difference 0.42 pmol/L [0.17 to 0.67], $P=0.02$). Non-invasive hemodynamic measurement revealed a decrease in the stroke systemic vascular resistance index (SSVRI) with an in between group difference of -62.65 dyn.sec.cm-5.m^2 [95% CI -116.94 to -18.36], $P=0.008$ (consistent with a 25%-decrease) after 4 weeks of treatment compared to baseline.

Conclusion

IL-1 antagonism increased the vasodilatory angiotensin (1–7) peptide after 4 weeks of treatment in obese individuals with features of the metabolic syndrome. This was consistent with a decrease in peripheral vascular resistance, reflected by the SSVRI. Thus, these findings point to a possible IL-1 mediated blood pressure lowering mechanism via modulation of the RAAS-System.

Higher habitual intakes of dietary carbohydrates are associated with leptin gene expression in visceral and subcutaneous adipose tissues among non-diabetic people

Emad Yuzbashian[1], Maryam Zarkesh[2], Golaleh Asghari[1], Mehdi Hedayati[2], Parvin Mirmiran[1] & Alireza Khalaj[3]
[1]Nutrition and Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Republic of Islamic Iran; [2]Cellular and Molecular Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Republic of Islamic Iran; [3]Obesity Treatment Center, Department of Surgery, Shahed University, Tehran, Islamic Republic of Iran.

Introduction
Leptin is a well-known adipokine which has a critical role in the regulation of body weight, body fat mass, appetite, and food intakes. Energy-supplying nutrients such as carbohydrates is a dietary-related factor which has potential effects on plasma leptin levels. The effect of habitual carbohydrates intake on leptin gene expression was limited only in animal studies. The current study aimed to investigate the association of habitual carbohydrate intake with leptin gene expression in visceral and subcutaneous adipose tissue of non-diabetic adults.
Methods
In this cross-sectional study, visceral and subcutaneous adipose tissues were gathered from 102 participants aged ≥ 20, who had undergone elective abdominal surgery with minimal impact on dietary intake. All of the subjects were free of diabetes and cancers and without using anti-lipid medication. Habitual dietary intake of participants was collected before surgery using a reliable validated semi-quantitative food frequency questionnaire, and daily intake of carbohydrates including total carbohydrates, fiber, glucose, fructose, and total sugar were calculated. To adjust energy intake for dietary exposures, the residual method was used. The mRNA expressions of leptin gene in visceral and subcutaneous adipose tissues were measured by real-time quantitative PCR. Linear regression models were used to estimate dietary carbohydrate intake and leptin gene expression after adjustment for potential confounding variables.
Results
The mean age and body mass index (BMI) of participants was 41.7 years and 25.6 kg/m^2, respectively. Leptin mRNA expression in visceral was higher than subcutaneous adipose tissue (0.375 vs. -1.210, $P=0.891$). After adjusting for age, BMI, and insulin level, total carbohydrate intake was positively associated with leptin gene expression in visceral and subcutaneous adipose tissue ($\beta=0.484$ and 0.522, respectively). Usual intake of sugar ($\beta=0.425$, $P<0.001$), glucose ($\beta=0.323$, $P=0.004$), and fructose ($\beta=0.336$, $P=0.003$) was directly associated with leptin gene expression in subcutaneous fat depots, additionally, we found significant positive association between leptin expression in visceral adipose tissue and sugar ($\beta=0.377$, $P=0.001$), fructose ($\beta=0.263$, $P=0.018$), and glucose ($\beta=0.242$, $P=0.034$). However, dietary intake fiber was negatively associated with leptin mRNA expression in both subcutaneous ($\beta=-0.391$, $P=0.001$) and visceral ($\beta=$-0.330, $P=0.007$) adipose tissues.
Conclusions
There was the significant positive association of total carbohydrate, sugar, fructose, and glucose and inverse association of fiber on leptin gene expression in subcutaneous and visceral fat mass, independent of BMI, age and insulin level. This might provide an initial step towards understanding nutrient effects on energy homeostatic pathways to consider future clinical approaches to dietary weight loss interventions.

GP135

Obesity is associated with a downregulation of UCP2 and miR-133a-3p but not NLRP3 in subcutaneous adipose tissue

Bianca de Souza[1,2], Mayara de Oliveira[1,2], Jakeline Rheinheimer[1,2], Milene Moehlecke[3], Michelle Rodrigues[2], Cristiane Leitão[1,2] & Daisy Crispim[1,2]
[1]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil; [2]Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil; [3]Universidade Luterana do Brasil, Canoas, Brazil.

Background and aims
Obesity is a chronic multifactorial disease characterized by an excessive accumulation of body fat resulting from an imbalance between energy intake and caloric expenditure. Uncoupling protein 2 (UCP2) is located in the inner mitochondrial membrane and plays an important role in the regulation of energy expenditure. NLR family, pyrin domain-containing 3 (NLRP3) inflammasome seems to have a key role in obesity-induced inflammation through production of the pro-inflammatory cytokines IL-1β and IL-18. Accordingly, a number of studies have suggested that *UCP2* and *NLRP3* have important roles in obesity. In addition, the microRNA (miR)-133a-3p regulates *UCP2* expression and appears to be involved in the activation of NLRP3 inflammasome through *UCP2* blockade. However, to date, no study has evaluated the combined association of *UCP2*, *NLRP3* and miR-133a-3p expressions with obesity. Thus, we compared *UCP2*, *NLRP3* and miR-133a-3p expressions in subcutaneous adipose tissue (SAT) of patients with obesity and eutrophic individuals. We also evaluated if these genes correlate with body composition parameters, insulin resistance, and glycemic and lipid profiles.
Methods
SAT biopsies were obtained from 61 individuals who underwent bariatric surgery or elective abdominal surgery. Patients were divided into three groups according to body mass index (BMI): Group 1 (BMI $\leq$ 25 kg/m^2, $n=8$); Group 2 (BMI: 30.0 – 39.9 kg/m^2, $n=24$); and Group 3 (BMI $\geq$ 40 kg/m^2; $n=29$). All subjects underwent physical and laboratory evaluations. *UCP2*, *NLRP3* and miR-133a expressions were quantified using real-time qPCR.
Results
UCP2 expression was decreased in SAT from patients with obesity (Groups 2 + 3) compared to Group 1 [Group 3: median 1.1 (0.9 – 1.6, 25th – 75th percentiles) and Group 2: 1.2 (0.9 – 1.5) *vs*. Group 1: 2.2 (1.6 – 2.5) n-fold changes; $P=0.031$]. MiR-133a-3p expression was also downregulated in patients with obesity [Group 3: 1.6 (0.9 – 2.5) and Group 2: 0.9 (0.5 – 8.5) *vs*. Group 1: 13.5 (3.5 – 33.2); $P=0.029$]. *NLRP3* expression did not differ between groups ($P=0.238$); however, it was positively correlated with waist circumference and weight excess. *NLRP3* expression was also positively correlated with miR-133a-3p expression and negatively correlated with *UCP2* expression.
Conclusion
UCP2 and miR-133a-3p expressions are downregulated in patients with obesity. Although *NRLP3* expression did not differ between groups, it was positively correlated with waist circumference and weigh excess values.

Administration of a growth hormone bolus down-regulates gene-expression of the g0/g1 switch gene 2 (g0s2) in subcutaneous adipose tissue in healthy, obese men: a randomized, placebo-controlled, cross-over study

Astrid Hjelholt[1,2], Niels Jessen[1,3], Mai Christiansen Arlien-Søborg[1,2], Steen Bønløkke Pedersen[1,2] & Jenso Otto Lunde Jørgensen[1,2]
[1]Department of Clinical Medicine, Faculty of Health, Aarhus University, Aarhus, Denmark; [2]Department of Endocrinology and Internal Medicine, Aarhus University Hospital, Aarhus, Denmark; [3]Department of Clinical Pharmacology, Aarhus University Hospital, Aarhus, Denmark.

Background
Growth hormone (GH) potently stimulates lipolysis, and after GH exposure, levels of serum free fatty acids (FFAs) increase in a distinct temporal pattern characterized by a 1-hour lag phase and a peak after 3 hours followed by a gradual return to baseline. This effect predominantly operates during fasting and promotes utilization of lipids from adipose tissue (AT) at the expense of glucose and protein. Prolonged fasting also downregulates the expression of the G0/G1 switch gene 2 (G0S2), which is a suppressor of the adipose triglyceride lipase (ATGL). The molecular mechanisms underlying the lipolytic effect of GH, including putative effects on G0S2, remain elusive.
Aim
To study expression of the lipolytic regulators in consecutive human AT biopsies after a GH bolus.
Methods
In a randomized, placebo-controlled, cross-over study nine healthy, obese men were examined on two occasions: 1) after an IV GH bolus [GH], and 2) after injection of a GH receptor antagonist [control]. Serum FFAs were measured. Biopsies from subcutaneous AT were obtained at $t=0$, $t=60$, $t=180$, and $t=300$ min, and gene and protein expression of putative lipolytic regulators were studied by RT-qPCR and western blotting.
Results
Serum FFAs increased 1 hour after GH exposure and peaked after 3 hours. In AT, we recorded phosphorylation of signal transducer and activator of transcription 5 (STAT5) after 1 hour and increased genexpression of cytokine-inducible SH2-containing protein (CISH) and insulin-like growth factor-1 (IGF-1) after 3 hours, indicative of GH signaling. Furthermore, GH exposure suppressed gene expression of the ATGL inhibitory protein G0S2 in addition to upregulation of PTEN, a known suppressor of insulin-stimulated anti-lipolysis.

Conclusions
1) An intravenous GH bolus acutely induces GH receptor signaling in human AT in vivo. 2) This was associated with a significant increase in serum FFA levels after 1-3 hours and the underlying mechanisms involves suppression of anti-lipolytic signaling in AT. 3) Characterization of the targets for GH-induced lipolysis may have physiological and therapeutic implications.

Empagliflozin as well as Anakinra reduce symptomatic hypoglycemia in patients after Roux-Y-gastric bypass by lowered insulin secretion

Matthias Hepprich[1], Sophia Wiedemann[1], Benjamin Schelker[1], Alessandra Stärkle[2], Beckey Trinh[1], Marianne Böni-Schnetzler[1], Gottfried Rudofsky[3] & Marc Donath[1]
[1]Department of Endocrinology, Diabetology and Metabolism, University Hospital Basel, Basel, Switzerland; [2]Swiss Federal Institute of Technology Zurich, Department of Health Sciences and Technology, Zurich, Switzerland; [3]Endocrinology and Metabolic Diseases, Cantonal Hospital Olten, Olten, Switzerland.

Background
Postprandial hypoglycemia is an increasingly recognized complication after bariatric surgery. Its hallmark is a pronounced glycemic rise after carbohydrate ingestion followed by an exaggerated hyperinsulinemic response. Recent studies have shown that IL-1β contributes to postprandial stimulation of insulin. Furthermore, inhibition of SGLT2 reduces excessive plasma glucose increase. Therefore, we investigated whether inhibition of IL-1β with the IL-1 receptor antagonist anakinra or inhibition of SGLT2 with empagliflozin may reduce postprandial hypoglycemia.
Methods
We performed a placebo controlled, double-blind, randomized, cross-over proof-of-concept study with 12 subjects with confirmed postprandial hypoglycemia after gastric bypass. Subjects received on each of the 3 study days either empagliflozin p. o. or anakinra s. c. along with the respective placebos followed by a standardized liquid mixed-meal-test over three hours with regular clinical assessments and measurement for glucose, insulin, c-peptide, GLP1, glucagon and inflammatory parameters.
Results
Compared to placebo, empagliflozin reduced peak glycaemia at 30 (11.2 vs. 10.1 mmol/l), 60 (9.1 vs. 6.9 mmol/l) and 90 (4.5 vs. 3.5 mmol/l) minutes after ingestion of the mixed meal and was followed by a significant reduction of glucose-requiring hypoglycemic events ($n=2$, 16.6% vs. $n=8$, 61.5%, p-value 0.041). Similarly, treatment with anakinra also reduced the rate of glucose-requiring hypoglycemic events ($n=2$, 16.6%) compared to placebo ($n=8$, 61.5%). Anakinra (AUC 63,458) and empagliflozin (AUC 55,116,) significantly lowered insulin secretion compared to placebo (AUC 80,029). Glucagon and GLP1 levels remained unchanged.
Conclusion
Empagliflozin and anakinra prevented glucose-requiring hypoglycemic episodes in patients after Roux-Y-gastric bypass by decreased insulin secretion via two different mechanisms. Empagliflozin by preventing an excessive postprandial rise in glycemic rise and anakinra may exert direct inhibitory effects on insulin secretion.

Androgen metabolism during weight loss in men with obesity

Frederique Van de Velde[1], Koen Deventer[2], Wim Van Gansbeke[2], Peter Van Eenoo[2], Pieter Van Renterghem[2], Tom Fiers[3], Jean-Marc Kaufman[1], Yves Van Nieuwenhove[4] & Bruno Lapauw[1]
[1]Ghent University Hospital – Endocrinology, Ghent, Belgium; [2]Ghent University – Doping Control Laboratory, Zwijnaarde, Belgium; [3]Ghent University Hospital – Clinical Biology, Ghent, Belgium; [4]Ghent University Hospital - Gastrointestinal Surgery, Ghent, Belgium.

Background
Men with obesity often have low total and, with increasing adiposity, also free testosterone (T) levels, which can partially restore when they lose weight. Although this is in part explained by lower sex-hormone binding globulin (SHBG) production and hypothalamic-pituitary downregulation, it is still not fully unraveled whether changes in androgen metabolization contribute to this phenomenon.
Aim
Investigating metabolisation of sex steroids during weight loss in men with obesity.
SUBJECTS AND METHODS
Eleven obese men (age 49 ± 10 years, BMI 44.9 ± 5.0 kg/m^2) were recruited prior to adhering dedicated lifestyle changes ($n=1$) or undergoing gastric bypass surgery ($n=10$). Before start of weight loss and 3 weeks, 6 weeks, 6 months and 1 year thereafter, 24h urine collections and fasting serum samples were collected. Serum T and estradiol (E_2) levels were analyzed using LC-MS/MS and serum SHBG concentrations using immunoassays. Urinary T, 3α-androstanediol, androsterone, 3α-etiocholanediol, etiocholanolone, estrone, E_2 and estriol levels were analyzed using gas chromatography coupled to mass spectroscopy. Statistical analyses were performed using linear mixed modelling.
Results
Obese men significantly reduced their BMI through this one-year follow-up study with a mean BMI of 30.3 kg/m^2 after one year ($F(4, 9.173)=139.105$, $P<0.001$). Serum T and SHBG concentrations increased by 102% and 87%, respectively (both $P<0.001$), while serum E_2 levels decreased non-significantly ($P=0.129$). A significant increase of total urinary T concentration was observed during follow-up ($F(4, 29.112)=4.529$, $P=0.006$), with a total increase of 101% one year after start of weight loss ($P=0.001$), while the ratios E_2/T and estriol/T decreased ($P=0.001$ and $P=0.010$; respectively) suggesting lower relative aromatization. In addition, T metabolisation by 5α-reductase and 3α-hydroxysteroid dehydrogenase (HSD) reflected by 3α-androstanediol/T- and androsterone/T-ratio, decreased during follow-up ($P=0.006$ and $P=0.002$; respectively) whereas 3α-etiocholanediol/T-ratio and etiocholanolone/T-ratio, reflecting T metabolisation from the 5β-reductase and 3α-HSD pathway, showed a non-significant decrease ($P=0.065$ and $P=0.070$; respectively).
Conclusion
Restoration of T levels into the eugonadal range during weight loss in men with obesity is not only brought about by normalization of circulating SHBG levels but also by increased T production *per se* as reflected by increased urinary secretion of T. In addition, changes in these men's urinary steroid profile, suggest that alterations in T metabolization also contribute to this. More specifically, besides relatively higher aromatization, higher 5α-reductase and 3α-HSD activity might also play a role in the phenomenon of low T levels in men with obesity.

Prediction of clinically significant weight loss with Gelesis100 in the GLOW study as early as 8 weeks post-treatment

Livio Luzi[1], Anne Raben[2], Arne Astrup[2], Erika Matejkova[3], Stepan Svacina[4], Lucio Gnessi[5], Santiago Navas-Carretero[6], J Alfredo Martinez[7], Frank Greenway[8], Louis Aronne[9], Caroline Apovian[10], Lee Kaplan[11], James Hill[12], Ken Fujioka[13], Christopher Still[14], Alessandro Sannino[15], Cosimo Saponaro[15], Henry Calderon[15], Lorien Urban[15], Elaine Chiquette[15], Harry Leider[15], Eyal Ron[15], Yishai Zohar[15] & Hassan Heshmati[15]
[1]University of Milan, Milan, Italy; [2]University of Copenhagen, Frederiksberg C, Denmark; [3]Health & Care, sro, Prague, Czech Republic; [4]General Hospital in Prague, Prague, Czech Republic; [5]Sapienza University of Rome, Rome, Italy; [6]University of Navarra, Pamplona, Spain; [7]CIBERobn and IMDEA Food Institute, Madrid, Spain; [8]Pennington Biomedical Research Center, Baton Rouge, USA; [9]Weill Cornell Medicine, New York, USA; [10]Boston University, Boston, USA; [11]Massachusetts General Hospital, Boston, USA; [12]University of Alabama at Birmingham, Birmingham, USA; [13]Scripps Clinic, San Diego, USA; [14]Geisinger Obesity Institute, Danville, USA; [15]Gelesis, Inc., Boston, USA.

Introduction
Identification of early responders is widely used in pharmacotherapy for weight loss to minimize unnecessary exposure to risks and unnecessary expenses. Gelesis Loss Of Weight (GLOW; NCT02307279), a multicenter, double-blind, placebo-controlled pivotal study, demonstrated that Gelesis100 offers a compelling new potential approach in the management of overweight and obesity.
Objective
A post-hoc area under the curve (AUC) for the receiver operating characteristic (ROC) analysis was conducted on data from the GLOW study to identify the optimal timepoint for predicting body weight responders ($\geq 5\%$ body weight loss at Week 24).
Material and methods
An AUC of the ROC was completed as a post-hoc analysis to model the predictive power of early weight loss for responder status in 322 subjects who were

treatment completers. The AUC ROC analysis optimized the balance between the positive predictive value (PPV) or percent of subjects with early weight loss response who were body weight responders and the negative predictive value (NPV) or percent of subjects with early weight loss response who were not body weight responders. The cutoff for PPV and NPV was set at 80%.
Results
AUC ROC analysis showed that an early response to Gelesis100 treatment ($\geq$ 3% weight loss from baseline at Week 8) successfully predicted clinically meaningful weight loss ($\geq$ 5%) at Week 24. More than 85% of subjects who achieved $\geq$ 5% weight loss at Week 24 had lost $\geq$ 3% of body weight at Week 8. Notably, early responders ($n=93$) achieved a mean weight loss of 9.9% vs. 2.1% in non-early responders ($n=77$) at Week 24. The placebo arm did not reach the required threshold for sensitivity and specificity until near the end of treatment. Safety and tolerability of Gelesis100 in the early responders were similar to the non-early responders, except for the incidence of abdominal pain that was higher in the early responders ($P=0.0415$) but of mild intensity in the majority of cases, and demonstrated no increased risk compared to placebo. No serious adverse events were observed.
Conclusion
The results of AUC ROC analysis suggest that a weight loss of $\geq$ 3% as early as 8 weeks after treatment with Gelesis100 is predictive of clinically meaningful weight loss ($\geq$ 5%) after 24 weeks. Although there are no overall increased safety risks with Gelesis100 treatment, predicting successful treatment early allows efficient use of resources and provides a key milestone to motivate subjects with overweight or obesity for personalized care.

GP140

The efficacy of complex kinesiotherapy in weight loss and muscle function improving in obesity patients

Valeriia Vasileva[1], Larisa Marchenkova[2], Mikchail Eryomushkin[1] & Daria Razvalyaeva[1]
[1]National Medical Research Center for Rehabilitation and Balneology of the Ministry of Health of Russia, Moscow, Russian Federation; [2] National Medical Research Center for Rehabilitation and Balneology of the Ministry of Health of Russia, Moscow, Russian Federation.

Aim of the study was to estimate the effect of complex 3-week treatment with 4 kinesiotherapy methods on body weight loss and muscle function in patients with obesity.
Material and methods
80 men and women aged 21-69 years old with alimentary obesity were enrolled in the study (mean age 52.4$\pm$11 years, weight 111.3$\pm$24.5 kg, BMI 40.3$\pm$8.1 kg/m^2, waist circumstance WC 113.4$\pm$16 cm, hip circumstance HC 124.2$\pm$16 cm). The complex kinesiotherapy administered daily for 3 week and included interactive sensorimotor trainings on double unstable platform, kinesiohydrotherapy in a pool, special complex of physical exercises in a gym and ergocycle trainings. Weight, WC, HC, fall number for last 3 weeks were measured at baseline and after the treatment was completed. Muscle strength and walking speed functional tests results assessment (10-meters-walk test, Up-and-go test, 4 special tests for back and abdomen muscle endurance to static and dynamic loading) were performed at baseline and in 3 weeks.
Results
There was a significant reduction in body weight (111.3$\pm$24.4 kg at baseline vs 107.9$\pm$23.1 kg in 3 weeks; $P=0.000$), in BMI (40.3$\pm$8.1 vs 39.1$\pm$7.7 kg/m^2; $P=0.000$), in WC (113.4$\pm$15.9 vs 109.2$\pm$15.1 cm; $P=0.000$) and in HC (124.1$\pm$15.5 vs 119.7$\pm$14.1 cm; $P=0.000$) in treated obese patients. 10-meters-walk speed increased from 0.84$\pm$0.15 m/sec at baseline to 0.88$\pm$0.17 m/sec in 3 weeks ($P=0.000$). Up-and-go test results improved from 8.4$\pm$2.1 to 7.9$\pm$2.09 sec ($P=0.000$). We registered statistically significant elevation of the endurance to static loading in abdomen muscles from 13.1$\pm$9.7 to 16.49$\pm$12.8 sec ($P=0.000$) and in back muscles from 14.8$\pm$11.9 sec to 18.6$\pm$14.9 sec ($P=0.000$). The endurance to dynamic loading increased in abdomen muscles from 29.9$\pm$11.2 to 34.84$\pm$11.93 times ($P=0.000$) and also in back muscles from 9.1$\pm$7.4 to 12.2$\pm$9.2 times ($P=0.000$). Fall number markably decreased from 0.14$\pm$0.34 at baseline to 0.0 (95%CI: 0.02; 0.25) aftercompletionof treatment.
Conclusions
Investigated complex treatment with 4 kinesiotherapy methods promotesbody weight loss, WC and HC reduction in obesity. 3-week special training of obese patients is associated with increasing in gate speed and lower extremities muscle strength, and it also causes improvement in static and dynamic loading endurance of back and abdomen muscles. Those changes may probably improve balance function and decrease risk of falling in obese patients.

Dietary inflammatory index is differently associated with ectopic fat depots in overweight and obese adults

Eleonora Poggiogalle[1], Carla Lubrano[1], Federica Luisi[1], James R Hebert[2], Nitin Shivappa[2], Michele Di Martino[1], Lucio Gnessi[1], Stefania Mariani[1], Andrea Lenzi[1] & Lorenzo M. Donini[1]
[1]Sapienza University, Rome, Italy; [2]University of South Carolina, Columbia, USA.

Introduction
In overweight and obesity energy unbalance is responsible for the accumulation of ectopic fat. Excess energy and metabolic alterations, namely insulin resistance, may favor ectopic fat depositions. However, the role played by dietary factors, especially the pro-inflammatory properties of dietary patterns, in ectopic fat storage is not thoroughly understood. The aim of our study was to investigate the association between the Dietary Inflammatory Index (DII) and different ectopic fat depots.
Methods
Participants were recruited among subjects admitted to the High Specialization Centre for the Care of Obesity (CASCO), at the Sapienza University, Rome, Italy. Inclusion criteria were: age 18-75 years, body mass index (BMI) $\geq$ 25 kg/m^2. The intrahepatic lipid content (IHL) and the intramyocellular lipid content (IMCL) were assessed through magnetic resonance spectroscopy, whereas intermuscular adipose tissue (IMAT, as adipose tissue between skeletal muscle bundles and beneath the muscle fascia), visceral and subcutaneous adipose tissue (VAT and SAT) were evaluated by magnetic resonance imaging. 3-day dietary records were administered and analyzed by a registered dietician. The DII score (adjusted for energy density) and the HOMA-IR were calculated. High-sensitivity C-reactive protein (hs-CRP) was measured.
Results
77 subjects (males: 18%) were included (age: 47.7$\pm$13.5 years, BMI: 37.1$\pm$5.7 kg/m^2). The DII score was positively associated to IHL (beta: 0.221, SE: 0.101, $P=0.03$) and IMAT (beta: 0.140, SE: 0.066, $P=0.04$) after adjustment for age, sex, hs-CRP levels, HOMA-IR, and VAT. No associations emerged between DII score and IMCL or VAT, or SAT.
Conclusion
A more pro-inflammatory dietary pattern is associated with fatty liver, and intermuscular adipose tissue, but it does not seem to affect intramyocellular lipid storage.

Impact of age and metabolic profile on the definition of 12 circulating steroid reference intervals measured by LC-MS/MS in an Italian healthy adult male cohort

Marco Mezzullo, Guido Di Dalmazi, Alessia Fazzini, Daniela Ibarra Gasparini, Carlotta Pelusi, Uberto Pagotto & Flaminia Fanelli
Endocrinology Unit, Department of Medical and Surgical Sciences, Centre for Applied Biomedical Research (C.R.B.A.), S. Orsola-Malpighi Hospital, Alma Mater University of Bologna, Bologna, Italy.

Background
Steroid profiling by LC-MS/MS is increasingly used in endocrine research, and is being introduced in the clinical practice. Due to the large disagreement with previous immunoassays, and to the enlarged panel of measurable steroids, novel and robust reference intervals (RIs) need to be established. Steroid circulating levels are known to be influenced by several physio-pathological factors, such as age, gender, stress and metabolic status. Therefore, generating unbiased reference cohorts is a non-trivial task.
Objective. Aiming at estimating robust and age-specific RIs for a broad steroid panel, our study evaluated the impact of aging and of the metabolic status on steroid levels in a cohort of disease-free adult men.
Methods. After excluding previous or current diseases, 318 drug-free men aged 18-90y were selected from the Italian general population. Blood was withdrawn in fasting conditions at 8-10am after 10min saline infusion. Cortisol (F) 11-deoxycortisol (11S), 17-hydroxyprogesterone (17OHP4), 17-hydroxypregnenolone (17OHP5), testosterone (T), androstenedione (A4), dheidroepiandrosterone (DHEA), dihydrotestosterone (DHT), progesterone (P4), corticosterone (B), estrone (E1) and estradiol (E2),were measured by two validated in-house LC-MS/MS assays. Anthropometric and metabolic parameters were analyzed by multiple stepwise-regression to estimate their independent impact of on each steroid. For steroids varying with ageing, decade-specific 2.5-97.5 centile RIs were calculated by fractional polynomial regression. For steroids influenced by

metabolic parameters, we excluded subjects displaying BMI $\geq$ 25.0kg/m^2, waist circumference $>$ 88 cm, systolic/diastolic blood pressure $\geq$ 90/140mmHg, HOMA-IR $>$ 2.5 or total-cholesterol/HDL-cholesterol $>$ 5.
Results. Aging negatively impacted 17OHP4, 17OHP5, A4, DHEA, P4 and B (all $P<0.001$), F ($P=0.015$) and 11S ($P=0.006$), while not influencing T, DHT, E1 and E2 levels. BMI positively influenced E2 ($P=0.031$), while negatively associating with 17OHP4 ($P=0.002$), T ($P=0.045$), DHT ($P=0.003$) and P4 ($P=0.023$). Waist circumference directly associated with E1 ($P=0.012$), while inversely associated with F ($P=0.004$). HOMA-IR negatively associated with T ($P=0.002$). Blood pressure positively associated with E1 ($P=0.034$). Finally, total-cholesterol/HDL-cholesterol ratio negatively associated with B ($P=0.001$) and 17OHP5 ($P=0.024$). According to regression results, age-specific RIs were generated on the whole cohort for 11S, A4 and DHEA, and after excluding subjects displaying metabolic abnormalities for F, B, 17OHP4, 17OHP5 and P4. At variance, age-independent RIs were estimated for T, DHT, E1 and E2 in the sub-cohort with no metabolic abnormalities. This study provided LC-MS/MS-based, age and metabolism-adjusted male RIs for a panel of circulating steroids, allowing the effective application of this technique in clinical investigations and in the diagnostic workup of diseases related to steroidogenesis imbalances.

GP143

Impact of age, menstrual phase, menopausal status and metabolic profile on the definition of 12 circulating steroid reference intervals measured by LC-MS/MS in an Italian healthy adult female cohort

Marco Mezzullo, Guido Di Dalmazi, Alessia Fazzini, Daniela Ibarra Gasparini, Alessandra Gambineri, Uberto Pagotto & Flaminia Fanelli
Endocrinology Unit, Department of Medical and Surgical Sciences, Centre for Applied Biomedical Research (C.R.B.A.), S. Orsola-Malpighi Hospital, Alma Mater University of Bologna, Bologna, Italy.

Endocrine clinical practice strongly relies on normative data for the assessment of hormonal imbalance. However, the generation of robust steroids reference intervals (RIs) remains a challenge. As the steroids circulating levels are influenced by many procedural aspects related to blood collection (time, fasting state) and physio-pathological factors, such as age, sex, stress and metabolic status, the need for partitioning RIs is mandatory. Furthermore, unbiased healthy, drug-free cohorts for RI generation are scarce. After clinical examination we selected 333 drug and disease-free female volunteers aged 18-90y, with no signs of hyperandrogenism. Pre-menopausal women displayed regular menses. Blood withdrawal was standardized early in the morning, in fasting conditions and by 10min saline infusion. The steroid profile including cortisol (F) 11-deoxycortisol (11S), 17-hydroxyprogesterone (17OHP4), 17-hydroxypregnenolone (17OHP5), testosterone (T), androstenedione (A4), dheidroepiandrosterone (DHEA), dihydrotestosterone (DHT), progesterone (P4), corticosterone (B), estrone (E1) and estradiol (E2), was determined by two in-house LC-MS/MS methods previously validated by Certified Reference Materials and ring trials. We evaluated the impact of anthropometric and metabolic parameters over each steroid level by multiple stepwise regression. Then, we computed age-specific RIs for steroids impacted by age by fractional polynomial regression. To further refine RIs for steroid affected by metabolic parameters, we excluded subjects displaying abnormalities among BMI $\geq$ 25.0kg/m^2 and waist circumference $>$ 88 cm, systolic blood pressure $\geq$ 140mmHg and/or diastolic blood pressure $\geq$ 90mmHg, HOMA-IR $>$ 2.5, total-cholesterol/HDL-cholesterol $>$ 5 and triglycerides $>$ 150mg/dL. With the exception of F, 11S and B, aging was found in negative relationship with 17OHP4, 17HOP5, T, A4, DHEA, DHT, P4, E1 and E2 (all $P<0.0001$). BMI positively associated with E1 ($P=0.002$) while negatively associated with DHT ($P=0.048$). Waist circumference negatively associated with F, 11S and B (all $P<0.0001$). Triglycerides positively associated with F ($P=0.001$), 11S ($P=0.007$) and B ($P=0.004$), while negatively associated with E1 ($P=0.019$) and E2 ($P=0.036$). Finally, hypertension positively associated with 11S ($P=0.032$). According to regression results, we generated age-specific RIs on the entire cohort for A4, DHEA, T and 17OHP5. Age-independent RIs for F, 11S and B were computed by excluding subjects displaying metabolic abnormalities. Moreover, we applied additional partitioning considering the menstrual phase and menopausal status for 17OHP4, E1, E2, T and DHT. We provided LC-MS/MS-based, age, menstrual phase and metabolism-adjusted RIs fit for each steroid in a broad panel. The generated RIs represent a valuable tool in diagnostic work-up of steroidogenesis imbalances for women throughout the adult life, also providing insights into neglected steroid precursors and intermediates.

Bilateral femoral head necrosis with low dose oral corticosteroid therapy for pan-hypopituitarism

Renata Velloso, Monica Aquino & André Souza
Federal University of Rio Grande do Norte, Natal, Brazi.

Introduction
Femoral head avascular necrosis is a dangerous complication that can occur during glucocorticoid therapy, its frequency having been counted up to 40% of patients using corticoids. Even though the complete mechanism involved in this steroid-induced injury is not completely elucidated, studies have shown there's some relation to bone remodelling, bone vasculature disfunction and apoptosis. We report here a case of femoral osteonecrosis associated to a very low dose corticosteroid therapy, which could not be withdrawn. A 48-year-old man presented four years ago with non functioning pituitary adenoma of 4.3 cm removed surgically. In the follow up with endocrinologist he began hormonal reposition with levothyroxine 25 mcg and prednisone 5 mg. Three years after the surgery he started feeling pain in the hips which worsened and lead to difficulties walking. The MRI showed acute/subacute osteonecrosis of right femoral head and osteonecrosis residue on the left femoral head. He, then, proceeded to surgery with no complications, during and after which he took a reposition dose of corticosteroid. When trying to suspend the corticoid he presented with malaise and episodes of hypotension as well as hyporexia, all of which improved after reintroducing 5 mg of prednisone.
Commentaries
Great part of the researches and case reports point out to a dose related occurrence, being a high dose use of corticoid the most frequent cause of non traumatic femoral damage. To be more specific, the studies show that the dose tends to be higher than 20 mg/day of prednisone in a prolonged period to cause such injuries. The occurrence of osteonecrosis with such a low dose of corticosteroid in a short period was surprising. Other reports show the occurrence of necrosis after a period of 10 years and use of intra-articular and intravenous injections over a shorter period of time. Similar to our case only 2 other reports have shown the appearance of femoral head necrosis after 2 years and 7 months of corticoid therapy. As our patient these cases couldn't stop steroid completely because of adrenal failure due to hypopituitarism. In such circumstance is critical to continue therapy in the lowest dose possible and preferably in a more physiological preparation such as hydrocortisone. It's important to bear in mind while consulting any patient with hip pain and in corticoid therapy to look for AVN since early recognition and treatment is crucial to prevent further deterioration of hip articulation and other dangerous complications.

Final (FH) and target height (TH) in male and female patients with congenital hypogonadotropic hypogonadism (CHH)/Kallmann syndrome (KS): a monocentric study of 216 patients

Luigi Maione[1], Giovanna Pala[2], Séverine Trabado[3], Georgios Papadakis[1], Mohamad Maghnie[2], Claire Bouvattier[4] & Jacques Young[1]
[1]Department of Reproductive Endocrinology, Bicêtre Hospital, Univ. Paris Saclay, Le Kremlin-Bicêtre, France; [2]Department of Pediatric Endocrinology, IRCSS Gaslini Institute, Genoa, Italy; [3]Department of Hormonology, Bicêtre Hospital, Univ. Paris Saclay, Le Kremlin-Bicêtre, France; [4]Department of Pediatric Endocrinology, Bicêtre Hospital, Univ. Paris Saclay, Le Kremlin-Bicêtre, France.

Context
CHH/KS is a major cause of pubertal and bone maturation delay due to sex steroids deficiency. FH and TH have not been evaluated in large series of CHH/KS patients. Analysis of auxometric measures in patients' siblings has never been performed.
Patients and methods
We selected 216 (164/52 men/women; 112/104 KS/normosmic CHH) with available auxometric measures. Sibling stature was available in a subgroup of 162 patients. Difference between the FH and the TH (Delta Height) was calculated. Relation between FH and age at diagnosis was evaluated. In a subgroup of 121 patients, therapeutically-induced growth gain was calculated.
Results
FHs in CHH/KS men and women were higher than in the sex-matched general population. FH was higher than TH (calculated from parents' heights): respectively 179 $\pm$ 8 vs 175 $\pm$ 6 cm in men and 166 $\pm$ 7 vs 162 $\pm$ 5 cm in

women ($P<0.001$ for both). Delta Height was positively correlated with age at diagnosis and age at beginning of hormonal treatment ($P=0.01$). FH and Delta Height were higher in patients than in their siblings ($P<0.01$), excluding a merely 'generational' effect. No difference in Delta Height was found between normosmic CHH and KS. The therapeutically-induced growth gain was inversely correlated with the age at initiation of hormonal treatment.
Conclusions
FH in CHH/KS is higher to either the general population, TH and even to their sex-matched siblings. Our findings show that CHH/KS does not negatively impact adulthood height, and there is no risk of short stature under therapy. Furthermore, the growth gain in CH/KS is disease-related and independent on a generational effect.

Turner syndrome: mental health and social skills from childhood to emerging adulthood

Jeanne Wolstencroft[1], William Mandy[2] & David Skuse[1]
[1]UCL GOS Institute of Child Health, London, UK; [2]UCL Psychology and Language Sciences, London, UK.

Background
The psychopathology of children and young people with Turner Syndrome (45,X; TS) has been well-documented. But these studies have never assessed neurodevelopmental disorders (NDD; autistic/attention-hyperactivity) alongside emotional and conduct disorders. The last extensive study of mental health assessed a narrow range of psychopathologies and excluded under 16s. This study aims to comprehensively examine mental health, NDD and social skills in TS from childhood to emerging adulthood.
Methods
Participants aged 4 to 25 were recruited through the UK Turner Syndrome Support Society and NHS clinics. Standardised assessments were administered to caregivers. (1) The Development and Wellbeing Assessment (DAWBA; $n=100$) is rated by clinicians to generate DSM-V diagnoses. It assesses anxiety, depression, conduct, autism spectrum disorders (ASD), attention deficit hyperactivity disorders (ADHD) and tic disorders, as well as eating, sleeping and feeding difficulties. It has been used in the English national surveys of child and adolescents mental health conducted in 1999, 2004 and 2017. (2) The Strengths and Difficulties Questionnaire (SDQ; $n=124$) measures emotional dysregulation, hyperactivity/inattention, conduct, peer relationship problems and prosocial ability. (3) The Social Responsiveness Scale-2 (SRS-2; $n=117$) measures autistic symptomatology. All assessments are widely used and well-validated.
Results
DAWBA analysis showed elevated rates of mental health disorder compared to female norms. Notably, 33% met criteria for at least one mental health diagnosis. 23% met criteria for ASD, 11% for anxiety disorders and 12% for ADHD. Mean SDQ total scores were raised compared to female norms ($t_{(123)}=12.89$, $P<0.0001$). Emotional dysregulation was positively correlated with age ($r=0.23$, $P=0.01$), whereas hyperactivity problems ($r=-0.47$, $P<0.0001$) and conduct problems ($r=-0.2$, $P=0.025$) were negatively correlated with age. Peer interaction problems were high compared to population norms ($t_{(123)}=12.22$, $P<0.0001$) and prosocial ability was slightly lower than females population norms ($t_{(123)}=-6.56$, $P<0.0001$). Mean total SRS-2 scores were in the moderately impaired range ($M=65.5$, $SD=14.9$). Autistic symptomatology was rated as severe in 27.4% of cases. Participants have 45.67 times the risk of having severe autistic symptomatology compared to female norms.
Conclusion
Girls with TS have higher rates of mental health disorders, NDD and social difficulties than general population females. 18% met criteria for a diagnosis of ASD and 27.4% had severe autistic symptomatology. Difficulties with hyperactivity/inattention and conduct resolve developmentally, however emotional problems increase. Implementing social skills training in adolescence and providing additional support at school to help with concentration/over-activity is recommended.

Risk of nephrolithiasis and nephrocalcinosis in patients with chronic hypoparathyroidism (HypoPT): a retrospective cohort study

Kristina Chen[1], Gary Curhan[2], Elvira O. Gosmanova[3], Lars Rejnmark[4], Elyse Swallow[5], Monica Macheca[5], Allison Briggs[5], Nicole Sherry[1] & Markus Ketteler[6]
[1]Shire Human Genetic Therapies, Inc., a member of the Takeda group of companies, Cambridge, MA, USA; [2]Brigham and Women's Hospital, Boston, MA, USA; [3]Stratton VA Medical Center and Albany Medical College, Albany, NY, USA; [4]Aarhus University and Aarhus University Hospital, Aarhus, Denmark; [5]Analysis Group Inc., Boston, MA, USA; [6]Klinikum Coburg GmbH, Coburg, Germany.

Background
Little is known about the risk of developing nephrolithiasis and nephrocalcinosis in patients with chronic HypoPT treated with conventional therapy (ie, oral calcium and active vitamin D). This study evaluated whether HypoPT is associated with increased risk of these conditions.
Methods
This retrospective cohort study, based on a large US commercial claims database (Q1 2007–Q2 2017), was conducted to compare the risk of nephrolithiasis and nephrocalcinosis between chronic HypoPT patients (excluding those receiving parathyroid hormone) and randomly selected non-HypoPT patients over 5 years of follow-up. For HypoPT patients, the first date of follow-up (ie, index date) was the earliest HypoPT diagnosis date ≥ 6 months after the initial HypoPT diagnosis; for non-HypoPT patients, it was the date of a randomly selected medical claim. Patient characteristics at baseline (the 6 months before index date) and risk of nephrolithiasis (identified by diagnosis and procedure codes) were compared between cohorts, the latter using Kaplan-Meier analysis and Cox proportional hazards models adjusting for baseline demographic (age, sex, race, region, and index year) and clinical (nephrolithiasis, gout, hypercalciuria, hypertension, diabetes, and thiazide diuretic use) characteristics. Similar analyses, adjusting for demographics and hypercalciuria, were conducted on the risk of nephrocalcinosis (based on diagnosis codes) among those without the condition at baseline. A sensitivity analysis for nephrocalcinosis was conducted among those with study period kidney imaging.
Results
The study included 8097 chronic HypoPT patients and 40,485 non-HypoPT patients. At baseline, HypoPT patients were older than non-HypoPT patients (58.6 years vs 47.3 years), a higher proportion were female (76.2% vs 54.4%), and higher proportions had nephrolithiasis (3.3% vs 1.3%), nephrocalcinosis (0.6% vs $<0.1\%$), gout (3.0% vs 1.2%), hypercalciuria (23.8% vs 0.5%), type 2 diabetes (20.6% vs 10.8%), and hypertension (43.7% vs 25.2%) (all $P<0.001$). Over 5 years of follow-up, HypoPT patients had an increased risk of nephrolithiasis and nephrocalcinosis compared with non-HypoPT patients ($P<0.001$ based on Kaplan-Meier analyses). The adjusted hazard ratios (95% CIs) associated with HypoPT vs non-HypoPT were 1.81 (1.60–2.04) for nephrolithiasis and 6.94 (4.41–10.92) for nephrocalcinosis (both $P<0.001$). In the sensitivity analysis, 2.6% of HypoPT and 0.5% of non-HypoPT patients ($P<0.001$) had nephrocalcinosis during the study.
Conclusions
Chronic HypoPT was associated with increased risks of nephrolithiasis and nephrocalcinosis. Further research is warranted to understand the potential mechanisms for the relationship of chronic HypoPT and its management with the observed risk of these conditions.

DOI: 10.1530/endoabs.63.GP147

Risk of myocardial infarction (MI), stroke, and other cardiovascular (CV) conditions in patients with chronic hypoparathyroidism (HypoPT): a retrospective cohort study

Kristina Chen[1], Sanjiv Kaul[2], Gary Curhan[3], Elvira O. Gosmanova[4], Fan Mu[5], Elyse Swallow[5], Allison Briggs[5], Nicole Sherry[6], Markus Ketteler[7] & Lars Rejnmark[8]
[1]Shire Human Genetic Therapies, Inc., a member of the Takeda group of companies, Cambridge, MA, USA; [2]Knight Cardiovascular Institute, Oregon Health & Science University, Portland, OR, USA; [3]Brigham and Women's Hospital, Boston, MA, USA; [4]Stratton VA Medical Center and Albany Medical College, Albany, NY, USA; [5]Analysis Group Inc., Boston, MA, USA; [6]Shire Human Genetic Therapies, Inc., a member of the Takeda group of companies, Cambridge, MA, USA; [7]Klinikum Coburg GmbH, Coburg, Germany; [8]Aarhus University and Aarhus University Hospital, Aarhus, Denmark.

Background
Prior small studies have suggested increased risk of cardiovascular (CV) conditions in patients with hypoparathyroidism (HypoPT). We evaluated whether chronic HypoPT is associated with increased risk of select CV hard endpoints (i.e., myocardial infarction (MI), stroke, and a composite CV endpoint) in a large contemporary cohort.
Methods
A retrospective cohort study, based on a US commercial claims database (Q1 2007 - Q2 2017), was conducted to investigate the risk of select CV conditions associated with chronic HypoPT. The study cohort included chronic HypoPT patients (identified using diagnosis codes; excluding those receiving parathyroid hormone) and randomly selected non-HypoPT patients during 5 years of follow-up. CV outcomes (identified using diagnosis and procedure codes) included MI, stroke, and a composite CV endpoint consisting of cerebrovascular disease, coronary artery disease, heart failure, and peripheral vascular disease. For HypoPT patients, the first date of follow-up (i.e., index date) was the earliest HypoPT diagnosis date $\geq$6 months after the initial HypoPT diagnosis (to establish chronic HypoPT); for non-HypoPT patients, it was the date of a randomly selected medical claim. Patient characteristics at baseline (the 6 months prior to index date) were compared. The risk of each CV endpoint was compared between cohorts among patients free of the corresponding condition at baseline using Kaplan-Meier analysis and Cox proportional hazards models adjusting for demographic (age, sex, race, region, and index year) and clinical (chronic kidney disease, hypertension, and diabetes for all endpoints, and select CV comorbidities for MI and stroke) characteristics at baseline.
Results
The study included 8,097 chronic HypoPT and 40,485 non-HypoPT patients. At baseline, HypoPT patients were older than non-HypoPT patients (58.6 years vs. 47.3 years), a higher proportion were female (76.2% vs. 54.4%), and higher proportions had baseline MI (1.9% vs. 1.3%), stroke (4.6% vs. 2.4%), and any composite CV endpoint condition (19.4% vs. 9.5%) (all $P<0.001$). HypoPT patients had increased risk of MI, stroke, and the composite CV endpoint compared with non-HypoPT patients (all $P<0.001$). The adjusted hazard ratios (95% confidence interval; *P*-value) associated with HypoPT versus non-HypoPT were 1.19 (1.02, 1.39; $P=0.029$) for MI, 1.44 (1.30, 1.61; $P<0.001$) for stroke, and 1.64 (1.53, 1.76; $P<0.001$) for the composite CV endpoint.
Conclusions
Chronic HypoPT was associated with increased risk of incident MI, stroke, and the composite CV endpoint. Further research is warranted to understand the potential mechanisms for the relationship of chronic HypoPT and its management with the observed risk of CV conditions.

Risk of chronic kidney disease (CKD) and CKD progression in patients with chronic hypoparathyroidism (HypoPT): a retrospective cohort study

Kristina Chen[1], Elvira O. Gosmanova[2], Gary Curhan[3], Lars Rejnmark[4], Fan Mu[5], Elyse Swallow[5], Nicole Sherry[1], Monica Macheca[5] & Markus Ketteler[6]
[1]Shire Human Genetic Therapies, Inc., a member of the Takeda group of companies, Cambridge, MA, USA; [2]Stratton VA Medical Center and Albany Medical College, Albany, NY, USA; [3]Brigham and Women's Hospital, Boston, MA, USA; [4]Aarhus University and Aarhus University Hospital, Aarhus, Denmark; [5]Analysis Group Inc., Boston, MA, USA; [6]Klinikum Coburg GmbH, Coburg, Germany.

Background
Previous studies of smaller size signaled heightened risk of CKD in patients with chronic HypoPT treated with conventional therapy (ie, oral calcium and active vitamin D). However, little is known about CKD progression, including progression to end-stage kidney disease (ESKD), in HypoPT patients.
Methods
A retrospective cohort study, using a large US commercial claims database (Q1 2007–Q2 2017), was conducted to compare the risk of CKD between chronic HypoPT patients (excluding those receiving parathyroid hormone) and randomly selected non-HypoPT patients over 5 years of follow-up. For HypoPT patients, the first date of follow-up (ie, index date) was the earliest HypoPT diagnosis date $\geq$6 months after initial HypoPT diagnosis; for non-HypoPT patients, it was the date of a randomly selected medical claim. Diagnosis codes, estimated glomerular filtration rate (based on CKD-EPI formula), and dialysis procedure codes were used to identify CKD stages. Patient characteristics at baseline (the 6 months before index date) and risk of incident CKD stage $\geq$3 were compared between cohorts, the latter using Kaplan-Meier analysis and Cox proportional hazards models adjusting for baseline demographic (age, sex, race, region, and index year) and clinical (heart failure, hypertension, diabetes, and medication use) characteristics. CKD progression to a higher CKD stage and to ESKD was similarly analysed among patients with baseline CKD stages 3 or 4.
Results
The study included 8097 chronic HypoPT patients and 40,485 non-HypoPT patients. At baseline, HypoPT patients were older than non-HypoPT patients (58.6 vs 47.3 years), a higher proportion were female (76.2% vs 54.4%), and higher proportions had CKD stages 3-5 (16.4% vs 3.0%) and stages 3-4 (13.6% vs 2.6%). Among those with baseline CKD stages 3-4, HypoPT patients were younger than non-HypoPT patients (70.6 vs 72.1 years), and a higher proportion were female (67.1% vs 54.8%). HypoPT patients had increased risk of CKD stage $\geq$3, CKD progression, and progression to ESKD compared with non-HypoPT patients (all $P<0.001$ based on Kaplan-Meier analyses). Adjusted hazard ratios (95% CI) associated with HypoPT vs non-HypoPT were 2.57 (2.35, 2.82) for CKD stage $\geq$3, 1.62 (1.29, 2.03) for CKD progression, and 1.95 (1.41, 2.70) for progression to ESKD (all $P<0.001$).
Conclusions
Chronic HypoPT was associated with significantly increased risk of CKD stage $\geq$3, CKD progression, and progression to ESKD. Further research is warranted to understand the potential mechanisms for the relationship of chronic HypoPT and its management with these observed risks.

Background/aim
X-linked hypophosphatemia (XLH) is a rare disease characterized by low phosphate level. Scientific evidence points to link between hypophosphatemia and obesity in general population. The aim of our longitudinal observational study was to investigate the prevalence of obesity and associated factors in a large cohort of children with XLH.
Patients/methods
We selected 172 XLH-children of 5-20 years (113 girls/59 boys). Anthropometric parameters (weight, height, BMI) were collected at birth and during follow-up at mean age of 5.3-8.2-11.3-15.9 years (group 1-2-3-4, respectively). In each group, subjects were classified based on International Obesity Taskforce (IOTF) cut off values of BMI for age and sex as overweight or obese (IOTF 25-30 or $\geq$30 kg/m^2, respectively).
Results
In each age-group, almost 1/3 of XLH-patients were classified as overweight/-obese (29.4% vs 28.7% vs 27.5% vs 36.7% for group 1-2-3-4, respectively). Children without XLH-family history had significantly higher BMI-IOTF at every point of follow-up ($P=0.015$), compared to those with positive XLH-family history. Similarly, higher BMI-IOTF is significantly associated with treatment duration (23.3 ± 4.4 vs 23.8 ± 3.8 vs 25.2 ± 4.5 kg/m^2, for subjects with treatment duration of <5, 5–10 and >10 years, respectively, p for trend $=0.025$). Multiple regression analysis confirmed that treatment length and lack of XLH-family history are positively associated with higher BMI-IOTF.
Conclusion
1/3 of XLH-children have phenotypically unfavourable metabolic profile expressed as increased prevalence of overweight/obesity in comparison to general population. Lack of XLH family history and length of treatment increase

the risk of higher BMI-IOTF. BMI should be carefully followed in children, and later adults, with XLH.

DOI: 10.1530/endoabs.63.GP150

GP151

MEN4: is there a link with autoimmunity?

Benjamin Chevalier[1], Marie-Françoise Odou[2], Jordane Demonchy[3], Catherine Cardot-Bauters[1] & Marie-Christine Vantyghem[1]
[1]Endocrinology and Metabolism Department, Lille University Hospital, Lille, France; [2]Biochemistry and Molecular Biology Department, Lille University Hospital, Lille, France; [3]Hematology Department, Lille University Hospital, Lille, France.

MEN4 is a rare disease characterized by the development of multiple endocrine tumors caused by mutations in the *CDKN1b* gene encoding the cyclin dependent kinase inhibitor $P27^{Kip1}$. Here we report two new cases and address the potential link of MEN4 with autoimmunity. The 1st patient, a 66-year old woman, presented at 35 years high prolactin levels without evidence of pituitary adenoma, treated medically. At 51 years, she was diagnosed with mild primary hyperparathyroidism associated to osteoporosis without any parathyroid lesion initially identified. Thirteen years later a retro-esophageal parathyroid adenoma was revealed and removed with normalization of blood calcium level. The patient also had breast cancer at 37, papillary ovarian serous cystadenoma at 50 and multifocal micropapillary thyroid carcinoma at 55 years. Heterozygous mutation of *CDKN1b* gene was found: c.281C>T, p.Pro941Leu in exon 1, not previously reported. Surprisingly the patient also had a remarkable history of autoimmune diseases, with myasthenia gravis at 12 justifying thymectomy for hyperplasia, Sjögren syndrome, type III cryoglobulinemia and asthma. Her father suffered from diabetes and Grave's disease, her paternal grand-mother from thyroiditis and breast cancer. The 2nd patient, a 70-year old lady was fortuitously diagnosed with a 27×30 mm non-functioning pituitary adenoma at 66 years during a stroke work-up. The volume progression and campimetric involvement led to surgery. Primary hyperparathyroidism was simultaneously discovered, attributed to a unique parathyroid lesion, not removed because of the absence of any complication (Calcium levels ∼2.6 mmol/l, PTH 118 ng/ml (N:15–68)). A mild autonomous cortisol secretion linked to a centimetric adrenal nodule was also confirmed. She also had a history of Crohn's disease treated with azathioprine then steroids and autoimmune thyroiditis. The familial history was difficult to assess because of cognitive impairment. A new heterozygous mutation in exon 1 of *CDKN1b* gene (c.206C>T, p.Pro69Leu) was identified. These two cases with proved germinal *CDKN1b* mutations are consistent with literature regarding MEN4, namely MEN1-like phenotype with late occurrence mostly focused on pituitary and parathyroid tumors. Interestingly, both cases were associated with multiple autoimmune disorders, including systemic and organ-related diseases. A previous meta-analysis has shown that *CDKN1B* was potentially involved in the pathophysiology of systemic lupus erythematosus, with a role in the induction of T-cell tolerance and B-cell lymphopoiesis. Future research about this rare condition will have to investigate this potential association, which confirms the link between neoplasia and immunity.

UMD-MEN1 database: analysis of clinical and genetic data from 1,676 patients by the TENGEN network

Pauline Romanet[1], Sophie Giraud[2], Marie-françoise Odou[3], Marie-Odile North[4], Amira Mohamed[5], Lucie Coppin[3], Alain Calender[6], Françoise Borson-Chazot[6], Christophe Béroud[1], Pierre Goudet[7] & Anne Barlier[1]
[1]Aix Marseille Univ, Marseille, France; [2]HCL, Lyon, France; [3]CHU de Lille, Lille, France; [4]APHP, Paris, France; [5]APHM, Marseille, France; [6]HCL-UCBL, Lyon, France; [7]CHU de Dijon, Dijon, France.

Context
Multiple Endocrine Neoplasia type 1 (MEN1) is an autosomal dominant disease caused by mutations in the *MEN1* gene. MEN1 is characterized by a broad spectrum of clinical manifestations, of which the most frequent are primary hyperparathyroidism, pituitary adenomas, and neuroendocrine tumors. *MEN1* presents a broad spectrum of variants, including large deletions, and truncating, missense, or splicing point mutations. The genotype-phenotype relationship remains under debate. The age-dependent penetrance and the variability of intra- and inter-familial expression of the disease increase the difficulty of interpretation of non-truncating variants in the *MEN1* gene, particularly regarding sporadic patients with incomplete diagnosis criteria.
Patients and Methods
The TENGEN network (French oncogenetics network of neuroendocrine tumors) has interpreted and collected all allelic variants and clinical characteristics of the *MEN1*-positive patients, identified through genetic testing performed in France from 1997 to 2015. We analyzed the clinical and genetic characteristics of patients from the UMD-MEN1 database cohort.
Results
370 distinct variants reported in 1,676 patients have currently been registered. This database analysis pointed out the low frequency of benign or likely benign missense variants in *MEN1* (only 6.6%). Eight families (1.9%) presented a familial isolated hyperparathyroidism and harbored the same mutation found in authentic MEN1-families. An association exists between large rearrangements and an earlier onset of the disease, whereas no difference was observed between truncating and non-truncating variants.
Conclusion
All variants were registered in a locus-specific database called the UMD-MEN1 database (www.umd.be/MEN1/), which provides an exhaustive overview of the *MEN1* variants present in the French population. For each variant, a classification based on the clinical data collection from patients and a standardized analysis is publicly available. Clinical data collections allow the determination of genotype-phenotype correlation and age-related penetrance of lesions in the cohort.

Amsterdam UMC, Amsterdam, Netherlands.

Introduction
In patients with ACTH-dependent hypercortisolism, the corticotropin-releasing-hormone (CRH) test and the high dose dexamethasone suppression test (HDDST) can be used to differentiate between pituitary ACTH production (Cushing's disease) and ectopic ACTH production. The rationale is that a pituitary adenoma will show some response to CRH and ACTH whereas an ectopic source is less responsive to ACTH and CRH. However, there is discussion about the clinical utility of the CRH-test and the HDDST. Many endocrinologists consider bilateral inferior petrosal sinus sampling a superior test. However, inferior petrosal sinus sampling is not ubiquitously available, has a risk of cerebrovascular complications, and can give false positive results. In this study, we aimed to determine sensitivity and specificity of the CRH-test and HDDST.
Methods
We analyzed all CRH-tests and HDDSTs performed in the period 1993–2018 at the Amsterdam UMC (location AMC) in patients with biochemically confirmed endogenous hypercortisolism. For the CRH-test (100 ug intravenously), we used a 20% plasma cortisol increase and/or a 50% plasma ACTH increase from baseline as a cutoff. For the HDDST we used a 190 nmol/l decrease of plasma cortisol from baseline to the average of 6:45–7:15 h after infusion of 8.75 mg dexamethasone as a cutoff. In 2018 we reviewed all patient records, and we determined the final diagnosis by clinical follow-up.
Results
For 52 patients with hypercortisolism (out of 68 patients) who underwent the CRH-test and/or HDDST, a final diagnosis could be determined: Cushing's disease ($n=35$), ectopic ACTH production ($n=3$) and adrenal cortisol production ($n=14$). To diagnose Cushing's disease (versus ectopic ACTH production) using our pre-determined cutoff values, CRH-test derived cortisol values yield a sensitivity of 71% and a specificity of 100%, CRH-test derived ACTH values yield a sensitivity of 74% and a specificity of 100%, and the HDDST has a sensitivity of 97% and a specificity of 100%.
Conclusion
In patients with ACTH-dependent hypercortisolism, the HDDST excellently differentiates between Cushing's disease and ectopic ACTH production, and may reduce the need for inferior petrosal sinus sampling.

Pathway enrichment analysis in functioning and silent corticotroph pituitary adenomas reveals mechanisms to explain their distinct clinical behaviour

Nicoleta Cristina Olarescu[1,2], Kjersti Ringvoll Normann[1,2,3], Arvind YM Sundaram[4], Kristin Astrid Berland Øystese[1], Alexander Eieland[1,2], Tove Lekva[2] & Jens Bollerslev[1,3]
[1]Section of Specialized Endocrinology, Department of Endocrinology, Oslo University Hospital, Oslo, Norway; [2]Research Institute for Internal Medicine, Oslo University Hospital, Oslo, Norway; [3]Faculty of Medicine, University of Oslo, Oslo, Norway; [4]Department of Medical Genetics, Oslo University Hospital, Oslo, Norway.

Background
Functioning (FCA) and silent corticotroph (SCA) pituitary adenomas act differently from a clinical perspective, despite both subtypes showing positive ACTH staining by immunohistochemistry. They are challenging to treat, the former due to functional ACTH production and consequently hypercortisolemia leading to Cushing disease, whereas the latter due to invasive and recurrent behaviour. Moreover, the molecular mechanisms behind their distinct behaviour are not clear.
Aim
To investigate global transcriptome changes and identify signalling pathways that can explain FCA and SCA differences (*e.g.* hormone production *vs.* aggressive growth).
Material and methods
RNA sequencing was performed using Illumina HiSeq in 6 FCA (three women, five microadenomas) and 6 SCA (two women, all macroadenomas). Data was analysed using the tophat2- cufflinks-CummeRbund pipeline and the pathway enrichment analysis was performed using Pathview (https://pathview.uncc.edu). The candidate genes were evaluated by RT-qPCR in a larger cohort of adenomas (26 FCA and 10 SCA).
Results
By assessing the 631 differentially expressed genes (fold change (FC) >1.9, $q<0.05$), we identified eight signalling pathways to be enriched. Firstly, protein processing in endoplasmic reticulum (ER) (hsa04141) pathway was differentially regulated. Accordingly, FCA showed up-regulation of genes involved in ribosome anchor (RRBP1), glycosylation and folding process (RPN1, CALR, PDIA3, and UGGT2), protein recognition by luminal chaperones (HSPA5), and ER-associated degradation (HSPH1 and CRYAB), whereas the only gene to be up-regulated in SCA was EIF2AK2, a protein known to attenuate protein synthesis if activated. Secondly, five signalling pathways involved in cell adhesion (hsa04514, hsa04080, hsa04512, hsa04060, and hsa04510) were also differentially regulated. Of notice, the adenoma subtypes showed a distinct extracellular matrix profile with genes that were up-regulated in FCA (COL1A1, COL4A3, COL4A4, LAMA4 and NRCAM) and in SCA (COL2A1, CADM1, CNTN1, LAMC2, FN1, ITGB2, NECTIN3, NLGN1, PTPRC, SDC2, SPP1, SV2C and VTN). Lastly, two classical proliferation, growth, and survival pathways (MAPK – hsa04010, and PI3K-Akt – hsa04151) were differentially regulated, SCA showing, among other genes, higher levels of MAPK1 and SGK1 and lower DUSP4 gene expression.
Conclusion
Distinct clinical aspects of FCA and SCA may be explained by their different repertoires of activated signalling pathways, namely promoting growth in SCA and protein processing in FCA and their specific patterns of cell adhesion molecules. Further *in vitro* functional studies will be performed, in order to identify possible medical targets and to properly understand the involved mechanisms.

Endocrine immune-related adverse events following immune check-point inhibitors in patients with advanced melanoma: single-center retrospective analysis

Eva Kassi, Anna Angelousi, Nikos Asonitis, Foteini Petychaki, Panayiotis Diamantopoulos, Amalia Anastasopoulou, Olga Benopoulou & Helen Gogas
1st Department of Internal Medicine, Laiko University Hospital, National and Kapodistrian University of Athens Medical School, Athens, Greece.

Introduction
Immune-check point inhibitors (ICPis) has been shown to significantly improve survival in patients with advanced melanoma. Immune-related endocrinopathies (irEs) and in particular hypophysitis and thyroid dysfunction have been well described with an incidence varying from 9–17% and 3.8–13.2% respectively.
Methods
This is a retrospective analysis of irEs in 325 (190 men) patients with melanoma receiving ICPis (PD-1/PDL-1 or CTLA-4 as monotherapy, combined or sequential therapy) in a single center, between 2014 and 2018. Clinical data were reviewed in order to characterize cases of hypophysitis, thyroid dysfunction and other possible endocrinopathies. All patients had hormonal functional tests at screening (before the initiation of ICPis) and during the follow up, while in cases of relevant symptoms imaging with MRI was also performed.
Results
In our cohort, the total incidence of irEs was 12.3% and in particular, 9% for patients treated with anti-CTLA-4 ($n=120$) compared to 17.7% for patients treated with anti-PD-1/PDL-1 ($n=118$). Combination therapy increased the incidence of irEs to 34.7%. Hypophysitis was developed in 8.9% of ICPis-treated patients. A higher incidence (5%) of hypophysitis among patients treated with PD1/PDL-1, in contrast to 4.2% of those treated with ipilimumab was found. From patients who received sequential therapy, 18.7% developed hypophysitis during the second line treatment; the increased incidence was regardless of the class of ICPis given as first-line treatment. MRI abnormal findings were observed in 45% of patients with hypophysitis. Corticotroph axis was the most frequent pituitary failure which was not recovered during the follow up (mean: 19 ± 12.8months). Thyroid dysfunction was developed in 5.8% of total patients treated with ICPis. Thyroid disease was developed in 6.7% of those treated with anti-PD-1/PDL-1 with hypothyroidism being more frequent (79%), while only 4 patients developed transient hyperthyroidism. No patient treated with ipilimumab as monotherapy developed thyroid dysfunction, while combination and sequential therapy increased the incidence compared to PD-1/PDL-1 monotherapy. The most common symptom experienced by patients was fatigue. No severe (>Grade 3) endocrine toxicity was observed and no one patient discontinuated permanently the immunotherapy. Interestingly, one patient developed hypophysitis and three patients hypothyroidism, 26 months and 22–24 months post initiation treatment with ICPis, respectively.
Conclusions
Clinicians should be aware of the risk of irEs endocrine adverse events during treatment with ICPis and there is a necessity of long-term clinical and biochemical follow up. Sequential therapy with ICPis increased significantly the risk of developing endocrine adverse events and in particular hypophysitis.

Correlation between responsiveness to CRH stimulation test in Cushing's disease patients and USP8 mutational status

Adriana Albani[1], Luis Pérez-Rivas[1], Michael Buchfelder[2], Jürgen Honegger [3], Günter Stalla[1], Stefanie Zopp[1], Martin Reincke[1] & Marily Theodoropoulou[1]
[1]Medizinische Klinik und Poliklinik IV, Ludwig-Maximilians-Universität München (LMU Munich), Munich, Germany; [2]Neurochirurgische Klinik, Klinikum der Universitä t Erlangen, Erlangen, Germany; [3]Department of Neurosurgery, Eberhard Karls University Tubingen, Tubingen, Germany.

Corticotrophin-releasing hormone (CRH) stimulation test is used in the differential diagnosis of Cushing's syndrome. Cushing's disease tumours carry somatic driver activating mutations in the ubiquitin-specific-protease 8 (*USP8*) gene in almost half of the cases. The aim of the present study was to examine whether the *USP8* mutational status in Cushing's disease tumours influences the response to the CRH stimulation test. We did a monocentric, retrospective study on 46 (27 female) Cushing's disease patients with complete data after dynamic stimulation test with 100 μg i.v. CRH (basal serum cortisol and/or ACTH levels and their respective peak and percentage increase). The USP8 mutational status was determined by Sanger sequencing on DNA extracted from fresh frozen and formalin fixed paraffin embedded tumour tissues. *USP8* mutations were detected in 22 out of 46 tumours (15/27 female and 7/19 male, chi-square test $P=0.245$). Mean basal serum cortisol and ACTH levels were similar in patients with *USP8* mutant and wild type tumours (μg/dl 24.2 ± 9.5 vs 26.5 ± 11.2, *t*-test $P=0.47$ and pg/ml 70.49 ± 53.36 vs 89.46 ± 62.08, $P=0.97$). Similarly, no significant differences were observed in the cortisol and ACTH peaks after CRH injection between *USP8* mutant vs wild type (cortisol μg/dl 38.13 ± 14.02 vs 36.81 ± 16.08, *t*-test $P=0.78$ and ACTH pg/ml 164.90 ± 118 vs 179.41 ± 162.2, $P=0.73$). The percentage increase in cortisol and ACTH levels were higher in patients with *USP8* mutant tumours (% cortisol 65.82 ± 48.46 vs 41.57 ± 29.46 and ACTH 201.10 ± 259.74 vs 98.59 ± 86.97) even if they did not reach statistical

significance (*t*-test $P=0.053$ and $P=0.097$ respectively). Multivariant analysis showed that patient gender does not influence the response to the CRH stimulation test ($P=0.336$ and $P=0.546$ for cortisol and ACTH variation respectively). These data suggest that *USP8* mutant tumours may be more sensitive to the CRH stimulation test. This observation together with previously published reports of smaller tumour size and better response to high dose (8 mg) dexamethasone stimulation test (1) highlights the role of USP8 in corticotroph cell physiology.

DNA Methylation and fMRI responses in patients with Cushing's syndrome in remission – suggestions of a functional link between hypercortisolism and neurocognitive dysfunction

Camilla Glad[1,2], Johanna Andersson-Assarsson[3], Andreas Stomby[4,5], Per Dahlqvist[4], Lars Nyberg[6,7], Ragnhildur Bergthorsdottir[1,2], Gudmundur Johannsson[1,2] & Oskar Ragnarsson[1,2]
[1]Department of Internal Medicine and Clinical Nutrition, Institute of Medicine at the Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; [2]Department of Endocrinology, Diabetes and Metabolism, Sahlgrenska University Hospital, Gothenburg, Sweden; [3]Department of Molecular and Clinical Medicine, Institute of Medicine at the Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; [4]Department of Public Health and Clinical Medicine, Umeå University, Umeå, Sweden; [5]Region Jönköping County, Jönköping, Sweden; [6]Diagnostic Radiology, Department of Radiation Sciences, Umeå University, Umeå, Sweden; [7]Umeå Center for Functional Brain Imaging, Umeå University, Umeå, Sweden.

Introduction
Compared with healthy controls, women with Cushing's syndrome (CS) in long-term remission have reduced functional brain responses during episodic and working memory testing and decreased overall levels of DNA methylation in blood cells. Here, we sought to test the hypothesis that functional brain responses in the prefrontal cortex and hippocampus are related to epigenetic changes in subjects with CS in long-term remission.
Methods
In this pilot study, 10 women with CS in remission were included. The mean (SD) age was 40 ± 11 yrs and the median (IQR) duration of remission was 9.6 (5–15) yrs. Six patients had Cushing's disease and 4 had a cortisol-producing adrenal adenoma. Functional brain responses were studied with functional magnetic resonance imaging (fMRI) during episodic- and working-memory tasks. DNA was isolated from whole blood and DNA methylation was analysed using the Illumina Infinium HumanMethylation450K BeadChip. In a previous analysis, 461 differentially methylated regions, containing 3,903 probes, were identified in patients with CS in remission compared to healthy controls. Correlations between individual probes and fMRI data were analysed in R, and a false discovery rate (FDR) adjusted *P* (q-value) < 0.2 was considered significant.
Results
Using the predetermined q-value cut off, significant correlations were found between probes and functional brain responses in both right and left hippocampi ($n=592$ and 967 unique probes, respectively). Correlations were also found for right posterior ($n=1145$ unique probes), left anterior ($n=900$ probes) and left posterior ($n=1.198$ probes) hippocampi. Gene ontology analyses revealed that probes correlating to fMRI responses mapped to genes associated with long-term memory function and regulation of synaptic plasticity, to mention some. Three probes in *COL11A2*, *DAGLB* and *TFDP1* genes, previously associated with psychopathology in CS, were also strongly correlated with functional brain responses. Furthermore, one gene with several significantly correlated probes was *RNF39*, a gene previously suggested to be a mediator of the effect of stress on central fear and stress circuitries in the brain.
Conclusions
In women with CS in long-term remission, DNA methylation is correlated with functional brain responses during memory encoding. Some differently methylated genes associated with functional brain response have previously been associated with psychopathology in CS and one, *RNF39*, is suggested to be a susceptibility locus for post-traumatic stress disorder.

Cortisol and cortisone assays in hair by mass spectrometry for the diagnosis of Cushing's syndrome

Julie Brossaud, Delia De Angeli, Jean-Benoît Corcuff, Léa Charret & Antoine Tabarin
University Hospital of Bordeaux, Bordeaux, France.

Background
According to the Endocrine Society's guidelines, the screening and diagnosis of Cushing's syndrome (CS) are based on the results of the overnight dexamethasone suppression test (DST), midnight salivary cortisol and 24-hour urinary free cortisol (UFC) measurements. These 3 tests reflect cortisol levels at the time of sampling without providing retrospective information. Hair cortisol concentration is a non-invasive way to measure cortisol exposure over longer periods of time (weeks and months) but only few studies report its usefulness for the diagnosis of CS. Most of studies were performed with cortisol immunoassays.
Aim
To assess the diagnostic power of the measurements of cortisol and cortisone in hair using liquid chromatography/mass spectrometry method. We provide reference and pathologic values in several populations: no-obese healthy subjects (H-group) and patients with Cs (Cs-Group).
Methods
After a 2-step extraction (incubation in a dithiothreitol solution followed by a dichloromethane extraction), concentrations of cortisol (HairF) and cortisone (HairE) were measured in the proximal 3 cm of scalp hair by using a home-developed multiplex mass spectrometry assay. Hairs were cut from the posterior vertex of 112 volunteers admitted in the Endocrinology Department of the University Hospital of Bordeaux: 76 (62F/14M, 38 [21–83] yrs, median [min-max]) in H-group (44 in a $H_{<50}$ subgroup were <50 year, 32 in a $H_{>50}$ subgroup were >50yr), 36 (29F/7M, 53 [19–78] year) in the Cs group. Based on clinical signs and biological markers (UFC, DST, serum or salivary cortisol at midnight), we included in the Cs-group patients either with mild and patent Cs.
Results
HairF and HairE reference values were similar in $H_{<50}$ and $H_{>50}$ subgroups. As a whole, the H-group reference values were 9.6 [45.0] (median [95th percentile]) and 14.5 [27.64] pg/mg hair, HairF and HairE respectively. In the Cs-group, both HairF and HairE were increased compared to the H-group: 24.9 [2.0 – 738.8] (median [min - max]) and 37.5 [7.0 – 192.4] pg/mg hair ($P<0.001$ for HairF and HairE). HairE ROC curve was significantly larger than HairF curve (areas 0.871 vs 0.733) to distinguish H-group from Cs-group ($P<0.001$).
Conclusion
HairF and HairE assays are useful for the diagnosis of Cs. Importantly, HairE seems to be a better reflect the excess of a long-term cortisol exposure than HairF. The determination of HairF and HairE using mass spectrometry assay may improve the diagnostic accuracy of this specific investigation.

Skeletal muscle fatty infiltration in the thigh, as assessed by MRI T2-weighted and 3-point Dixon sequences, is associated with poor performance on muscle function testing in patients with Cushing's syndrome in remission

Luciana Martel[1], Alicia Alonso[2], Helena Bascuñana[3], Jordi Diaz Manera[2], Jaume Llauger[4], Claudia Nuñez-Peralta[4], Betina Biagetti[5], Paula Montesinos[6], Susan Webb[1] & Elena Valassi[1]
[1]IIB-Sant Pau and Department of Endocrinology/Medicine, Hospital Sant Pau, UAB, and Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBER-ER, Unidad 747), ISCIII, Barcelona, Spain; [2]Neuromuscular Disorders Unit, Neurology Department, Hospital Sant Pau, Barcelona, Spain; [3]Rehabilitation Unit, Hospital Sant Pau, Barcelona, Spain; [4]Radiology Department, Hospital Sant Pau, Barcelona, Spain; [5]Endocrinology Department, Hospital Vall d'Hebron, Barcelona, Spain; [6]Philips Healthcare Iberi, Madrid, Spain.

Background
Muscle weakness may persist in patients with Cushing's syndrome (CS) long-term after resolution of hypercortisolism, but mechanisms determining this sustained impairment are not known. We hypothesized that alteration of muscle structure, due to fatty infiltration, is associated with muscle dysfunctions in these patients.
Patients & methods
Twenty-six CS women [mean(±s.d.) age 49 ± 12 years; mean(±s.d.) BMI 27 ± 4 Kg/m^2; mean(±s.d.) duration of remission, 132 ± 87 months], and 24 age- and BMI-matched controls were studied. The degree of fatty infiltration of the thigh

muscles was measured using magnetic resonance imaging (MRI), ultrashort multiecho T2-weighted and 3-point Dixon sequences in the anterior, posterior, and anterior + posterior compartments. T2 signal intensity was classified as 'high' (corresponding to fat), 'medium' (muscle), 'low' (macromolecules-muscle). The following muscle function tests were also performed: gait speed velocity (GS), timed up and go (TUG), 30-second chair stand and hand grip strength in both hands.

Results

Mean muscle fat fraction (%) in the posterior compartment, as determined by 3-point Dixon, was increased in patients as compared with control group (22.8 ± 6.4% vs 18.7 ± 3.4%; $P = 0.025$), indicating greater muscle fatty infiltration in the former. There was a tendency towards higher mean muscle fat fraction in anterior + posterior compartments of the tight in patients as compared with controls (21.8 ± 6.1% vs 18.2 ± 4.5%; $P = 0.052$). Greater mean muscle fat fraction in the posterior compartment was associated with slower GS ($r = -0.43$, $P = 0.025$), and poorer performance on both TUG ($r = 0.63$, $P < 0.001$) and 30-second chair stand ($r = -0.57$, $P = 0.002$) in patients only. An increase in the percent of high-T2 signal in overall tight muscles, suggesting increased intramuscular fat tissue, was associated with slower GS ($\rho = -0.049$, $P = 0.025$) and worse performance on TUG ($\rho = 0.58$, $P = 0.007$) in patients only. In a multiple linear regression model, mean muscle fat fraction in the posterior compartment predicted TUG in patients, after adjusting for age and BMI (ß 0.64, $P < 0.001$).

Conclusion

Rate of fatty infiltration in thigh muscles is increased in patients with CS in remission and is related to impaired muscle function. Muscle MRI could be a reliable biomarker to follow up treated CS patients who are at risk of developing muscle dysfunction. Future studies are needed to elucidate the mechanisms underlying the relationship between altered muscle structure and function after correction of hypercortisolism.

Brain 18F-fluorodeoxyglucose PET/CT in localization of MRI-negative ACTH-producing pituitary adenomas

Uliana Tsoy, Daria Ryzhkova, Vladislav Cherebillo, Anton Ryzhkov, Natalia Kuritsyna, Lidia Belousova, Anna Dalmatova & Elena Grineva
Almazov National Medical Reseach Centre, St-Petersburg, Russian Federation.

Background

Detection of MRI-negative ACTH-producing pituitary adenomas is a challenge in the management of patients with Cushing's disease. There are some data on the possibility of pituitary adenomas to accumulate 18F-fluorodeoxyglucose (18F-FDG) during the 18F-FDG positron emission tomography and computer tomography (18F-FDG PET/CT).

Aim

To study the potential of brain 18F-fluorodeoxyglucose PET/CT for localization of MRI-negative ACTH-producing pituitary adenomas.

Materials and methods

Twenty one patients were enrolled. 16 patients had Cushing's disease (three men and thirteen women), among them seven had newly diagnosed disease and nine had persistence or recurrence of hypercortisolism after the previous transsphenoidal adenomectomy (TSS). MRI scans were negative in patients with newly diagnosed disease and uncertain (postoperative changes-8 patients; secondary 'empty sella'-1 patient) in patients after TSS. In all patients pituitary source of ACTH hyperproduction was confirmed by bilateral cavernous and inferior petrosal sinuses sampling. Five patients had neuroendocrine tumors (NETs) with ACTH-ectopic production (pheochromocytoma-1; thymus NET -1; lung NET – 3: among them two patients previously had underwent bilateral adrenalectomy due to severe hypercortisolism and failure to find the source of ACTH-ectopy). Brain 18F-fluorodeoxyglucose PET/CT was performed in all patients (in patients with suspected NET it was a part of total body 18F-FDG PET/CT).

Results

Among sixteen Cushing's disease patients fifteen had had focal increased 18F-FDG uptake on pituitary PET/CT scans. All this patients had undergone TSS. In eleven cases diagnosis of ACTH-producing pituitary adenoma was confirmed by pathology examination, among them in seven cases the remission of hypercortisolism was achieved. In four patients the result of pathology examination was negative, but all of them developed remission of hypercortisolism after the TSS. One patient had had negative18F-FDG uptake on PET/CT scans, he was re-examined and the remission of hypercortisolism was diagnosed. All patients with NETs, including those who had previously undergone bilateral adrenalectomy showed negative 18F-FDG uptake on pituitary PET/CT scans.

Conclusion

According to our study brain 18F-fluorodeoxyglucose PET/CT may be useful for localization of MRI-negative ACTH-producing pituitary adenomas, but further research is necessary for the confirmation of these data.

Ubiquitin-specific protease 8 (USP8) potentiates glucocorticoid receptor activity in corticotroph tumour cells

Luis Perez-Rivas, Denis Ciato, Paula Colón-Bolea, Martin Reincke & Marily Theodoropoulou
Medizinische Klinik und Poliklinik IV, Ludwig-Maximilians-Universität München, Munich, Germany.

Cushing's disease tumours bear activating mutations in the ubiquitin-specific-protease 8 gene (*USP8*) gene in 40-60% of cases. We have previously observed that patients with USP8 mutant tumours have smaller tumour size and show a better response to high dose (8mg) dexamethasone stimulation test compared to those with wild type USP8 (1). The aim of this study was to define the role of USP8 on glucocorticoid receptor (GR) in corticotroph tumour cells. We did experiments in immortalized AtT-20 corticotroph tumour overexpressing USP8 wild type or mutants (Pro720Arg, Ser718Pro, Ser718del). Cells overexpressing the USP8 mutants showed better GR transcriptional response to dexamethasone treatment (determined by MMTV luciferase assay) compared to those transfected with wild type USP8. Furthermore, GR nuclear translocation determined as GR content in the nuclear fraction after dexamethasone treatment (10nM, 2 hours) was more prominent in cells overexpressing USP8 mutants than wild type. In addition, although GR protein levels were decreased after long-term exposure to dexamethasone (12 hours) in wild type cells, cells overexpressing USP8 mutants retained GR showing protection from treatment-induced degradation. USP8 knockdown increased GR ubiquitination and coimmunoprecipitation experiments showed that all USP8 forms physically interact with GR, indicating a direct effect of USP8 on GR. Introducing a mutation in the putative ubiquitination site lysine 419 halved the fraction of ubiquitinated GR and potentiated GR activity on POMC promoter and MMTV. These data show that USP8 deubiquitinates and rescues GR activity. USP8 is mainly a cytoplasmatic protein, but its mutants are also localized in the nucleus. Therefore, an intriguing hypothesis is that their closer topological association with GR may render USP8 mutant corticotroph cells more sensitive to the physiological negative glucocorticoid feedback. Resistance to the glucocorticoid negative feedback is a hallmark in Cushing's disease. Our data of a regulatory role of USP8 mutants on GR may explain the smaller size and increased glucocorticoid sensitivity of the USP8 mutant tumours and reveals a novel action of USP8 in corticotroph tumour pathophysiology.

Pharmacokinetics of osilodrostat following single and multiple doses of osilodrostat in healthy subjects and patients with Cushing's disease

Kevin Han[1], Libuse Tauchmanova[2], Susan Atkinson[2], Christelle Darstein[2], Xinrui Zhang[1], François Pierre Combes[1] & Alberto M Pedroncelli[2]
[1]Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA;
[2]Novartis Pharma AG, Basel, Switzerland.

Introduction

Osilodrostat is a potent oral 11β-hydroxylase inhibitor currently in Phase III clinical development for the treatment of Cushing's syndrome (CS). The key pharmacokinetic (PK) properties, drug–drug interactions (DDIs), and population PK findings for osilodrostat in humans are summarized.

Methods
Osilodrostat PK has been characterized in nine Phase I studies (healthy subjects and subjects with hepatic or renal impairment), two Phase II studies (patients with Cushing's [CD] disease or CS), and a Phase III study (patients with CD). Pooled population PK analyses were performed for healthy subjects and patients with CD.
Results
Osilodrostat was rapidly absorbed (tmax: ~1 h) and demonstrated a half-life of ~4 h across all examined doses (range: 0.5–200 mg after single and multiple doses). Median apparent volume of distribution (Vd) for osilodrostat was 101 L following a single oral dose (50 mg) in healthy volunteers. Osilodrostat is extensively metabolized by multiple enzymes, and no single enzyme contributed to >25% of total clearance of osilodrostat, thus it is unlikely to be a victim for DDIs. The total contributions of cytochrome P450 (CYP) and UDP-glucuronosyltransferase (UGT) enzymes to osilodrostat clearance were estimated at 26% and 19%, respectively; non-CYP-, non-UGT-mediated metabolism contributed to ~50% of total clearance. The main metabolite in plasma was LXB168, which is not pharmacologically active. Most osilodrostat-related material was eliminated in urine (~90.6% of administered dose), with only 5.2% as unchanged osilodrostat. Osilodrostat is a moderate inhibitor of CYP1A2, a weak-to-moderate inhibitor of CYP2C19, and a weak inhibitor of CYP2D6 and CYP3A4/5 (50 mg single dose). No clinically significant DDI was observed when osilodrostat was co-administered with oral contraceptives (OCs) in healthy females receiving hydrocortisone. A trend of increasing AUCinf (area under the concentration–time curve from zero to infinity) for osilodrostat was observed in subjects with moderate-to-severe hepatic impairment (geometric mean ratios: 1.44 and 2.66, respectively) compared with healthy subjects. Osilodrostat exposure was similar across three renal function cohorts (normal, severe, and end-stage renal disease), indicating that renal function has no impact on osilodrostat exposure.
Conclusion
The PK properties of osilodrostat in humans are favourable and allow twice-daily dosing. No dose adjustment is required for patients with renal impairment, although patients with moderate or severe hepatic impairment should undergo dose adjustment. Osilodrostat is unlikely to be a victim for DDIs but does produce modest inhibition of CYP enzymes (as perpetrator). OCs can be co-administered with osilodrostat without dose modification.

Effects of a single dose of pasireotide on glucose metabolism in patients with Cushing's disease and predictors of diabetes mellitus developement during treatment

Mattia Barbot, Daniela Regazzo, Marialuisa Zilio, Alessandro Mondin, Laura Lizzul, Silvia Pinelli & Carla Scaroni
Endocrinology Unit, Department of Medicine-DIMED, University of Padova, Padova, Italy.

Introduction
Pasireotide (PAS) is an effective treatment for Cushing's disease (CD) but its use is burdened by the high incidence of diabetes mellitus (DM). We aimed to evaluate the effect of a single subcutaneous injection of PAS on glucose metabolism in CD patients, to identify factors predicting rapid deterioration of glycaemic control.
Methods
14 patients [(f/m = 12/2, mean age 43 ± 11.3 years, follow-up 17 months (2-63)] with CD treated with PAS (600 µg b.i.d.) were studied; before treatment initiation, all patients were submitted to an acute PAS test (600 mcg s.c.) with measurements of ACTH, cortisol, glucose, insulin, c-peptide, insulin, GIP, glucagon, GLP-1, ACTH and cortisol at time 0' and then every 30' minutes for 2 hours to predict the development of DM.
Results
There was a significant reduction in urinary free cortisol (UFC, 582 ± 456 vs 254 ± 356 nmol/24h, $P = 0.001$) and late night salivary cortisol (LNSC, 12.2 ± 11.6 vs 3.8 ± 1.7 nmol/L, $P = 0.003$) in all cohort with concomitant improvement of weight ($P = 0.01$) and waist circumference ($P = 0.02$). Overall 10/14 patients reached UFC normalization whereas LNSC was within normal range only in 4 cases. A single PAS dose produced a significant decrease of all hormonal parameters assessed ($P < 0.0001$), except for glycaemia which reached the highest value 120' after the injection (baseline 4.65 ± 0.52 vs peak 8.91 ± 3.63 mmol/L, $P < 0.0001$). Overall 7/14 patients developed DM within the first 2 months of therapy. Among baseline characteristics, non-DM patients did not differ in age, weight, visceral adiposity, HOMA-index, fasting glucose and severity of CD from those who did not have glucose metabolism alterations; however, compared to non-DM patients, DM patients displayed higher baseline fasting c-peptide (respectively 694.4 ± 109.6 vs 947.4 ± 318.4 pmol/L, $P = 0.05$) and HbA1c levels (30 ± 3.0 vs 37.1 ± 1.8 mmol/mol, $P = 0.001$), with the latter being normal in all cases. Finally, glucose peak tent to be higher in DM-patients than in those who did not develop hyperglycaemia (7.2 ± 2.2 vs 10.6 ± 4.1mmol/L, $P = 0.06$).
Conclusions
PAS confirmed to be a valuable tool for the treatment of CD. It was able to rapidly suppress insulin secretion and the incretin system with a subsequent increase in glucose levels into the diabetic range producing also a concomitant decrease in glucagon values. Patients at higher risk of DM during PAS therapy were those with higher fasting c-peptide at elevated serum glucose peak during the acute test. Interestingly baseline HbA1c, seems to predict the risk of PAS-induced DM.

Assessment of bone marrow fat by single-voxel vertebral magnetic resonance spectroscopy in cushing's syndrome with or without vertebral fractures

Francesco Ferraù[1], Salvatore Giovinazzo[2], Agostino Tessitore[3], Erika Messina[2], Sergio Vinci[3,4], Gherardo Mazziotti[5,6], Andrea Lania[5,6], Marcello Longo[3,4], Francesca Granata[3,4] & Salvatore Cannavò[1,2]
[1]Department of Human Pathology 'G. Barresi', University of Messina, Messina, Italy; [2]Endocrine Unit, University Hospital AOU Policlinico G. Martino, Messina, Italy; [3]Neuroradiological Unit, University Hospital AOU Policlinico G. Martino, Messina, Italy; [4]Department of Biomorphology, University of Messina, Messina, Italy; [5]Endocrine Unit, Humanitas Research Hospital, Humanitas University, Milano, Milano, Italy; [6]Department of Biomedical Sciences, Humanitas University, Milano, Milano, Italy.

Chronic hypercortisolism is associated with dramatic increase in fragility fractures. The evaluation of skeletal fragility in Cushing's syndrome (CS) is a clinical challenge, since fractures may occur even in presence of normal bone mineral density (BMD). Recently, measurement of bone marrow fat (BMF) by vertebral magnetic resonance spectroscopy (MRS) was proposed as alternative tool for evaluating skeletal fragility in primary and secondary osteoporosis. Noteworthy, recent evidence shows that cortisol excess may cause BMF increase but it is still unknown whether it may be a biomarker of fracture risk in CS patients. In this cross-sectional study, we evaluated association between BMF and vertebral fractures (VFs) in 20 patients (5 M, age 44 ± 13 years) with active CS (16 cases with ACTH-dependent and 4 with ACTH-independent CS). Fifteen healthy volunteers (4 M, age 43 ± 12 years) acted as control group (CG) for BMF evaluation. BMF was measured by a single-voxel MRS (1,5 Tesla) on lumbar vertebral bodies, whereas VFs were assessed by a radiological and morphometric approach on thoracic and lumbar spine X-ray images. CS patients were also evaluated for lumbar spine BMD by dual-energy X-ray absorptiometry (DXA). Fractured vertebrae were excluded from BMF and BMD evaluations. Baseline parameters of pituitary-adrenal function and bone metabolism were also measured in CS patients. Overall, vertebral BMF was higher in CS patients than in CG (51.1 + 22.6% *vs.* 28.4 + 17.0%, $P = 0.003$), and directly correlated with patients' age at CS diagnosis (rho: 0.48; $P = 0.03$), 24-hrs urine cortisol values (rho: 0.476; $P = 0.03$), midnight serum cortisol values (rho 0.50; $P = 0.02$), serum CTX (rho: 0.54; $P = 0.01$), serum alkaline phosphatase (rho: 0.57; $P = 0.009$) and urinary phosphate values (rho: 0.51; $P = 0.01$). VFs were found in 13 CS patients (65%; 3 with normal BMD, 4 with osteopenia and 6 with either osteoporosis or low BMD for age, according to WHO criteria). Patients with VFs showed higher BMF than patients without (59.4 *vs* 35.8%, $P = 0.03$). Fractured patients with either normal BMD or osteopenia showed comparable BMF to fractured patients with either osteoporosis or low BMD for age (60.8 + 18.0 *vs* 57.7 + 21.5%; $P = 0.71$). When the analysis was restricted to patients with normal BMD or osteopenia, VFs were still associated with higher BMF (60.8 ± 18.1 vs. 35.8 ± 21.8, $P = 0.05$). This preliminary study provides a first evidence that vertebral adiposity is a marker of hypercortisolism-induced skeletal fragility and measurement of lumbar spine BMF by MRS may be a reliable tool for predicting VFs in endogenous CS.

Role of invasive and non-invasive diagnostic tests in differential diagnosis of ACTH-dependent Cushing's syndrome

Mattia Barbot[1], Emanuele Ferrante[2], Filippo Ceccato[1], Andrea Daniele[1], Laura Lizzul[1], Margherita Cuman[1], Valerio Monteleone[2], Andreea Serban[2,3], Elisa Sala[2], Marco Locatelli[4], Maura Arosio[2], Marco Boscaro[1], Carla Scaroni[1] & Giovanna Mantovani[2]
[1]Endocrinology Unit, Department of Medicine-DIMED, University of Padova, Padova, Italy; [2]Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Policlinico, University of Milan, Milan, Italy; [3]Department of Experimental Medicine, Sapienza University of Rome, Rome, Italy; [4]Neurosurgery Unit, Fondazione IRCCS Ca' Granda Ospedale Policlinico, University of Milan, Milan, Italy.

Background
Differential diagnosis of ACTH-dependent hypercortisolism is crucial to indicate a proper treatment and is based on CRH-, high-dose dexamethasone suppression-test (HDDST) and pituitary MRI. However, up to 50% of cases of Cushing's disease (CD) present a negative MRI or a visible lesion < 6 mm. In these patients, guidelines suggest to perform bilateral inferior petrosal sinus sampling (BIPSS) in order to establish a correct diagnosis. Aim of this study was to analyze the need of BIPSS in particular in those patients with inconclusive neuroradiological examination.
Materials and methods
We performed a retrospective analysis on 122 patients (F/M 93/29, mean age 43.9 ± 14 yrs) affected by ACTH-dependent CS followed at two tertiary care centers in Italy. CRH test and HDDST were performed on the suspect of CD and all patients were submitted to pituitary MRI; the whole cohort underwent pituitary surgery (TSS). The pituitary origin of ACTH secretion was confirmed by biochemical remission after TSS, histology and/or hypoadrenalism (at least 6 months).
Results
A negative MRI or a lesion <6 mm were detected in 74 patients (60.7%, Group A); 26 patients had a pituitary adenoma between 6-10 mm (21.3%, Group B), 22 patients a macroadenoma (18%, Group C). Patients of Group C showed higher basal ACTH levels compared to patients with microadenomas (Group A + B) (116.8 ± 107.2 vs 50.6 ± 29.4 ng/L, $P<0.05$). No difference in basal cortisol, urinary free cortisol and late night salivary cortisol levels was found. A positive response to CRH test and HDSST was recorded in 92% and 93% of cases, respectively. The diagnosis of CD was confirmed by BIPSS in 24 patients. Overall, surgical remission was achieved in 90/122 (73.8%) patients, without differences between groups. Finally, considering patients of Group A with concordant positive HDDST and CRH test, no difference in surgical outcome was found between patients who performed BIPSS and those who did not (24/35 (68.6%) without BIPPS vs 13/19 (68.4%) with BIPSS, $P=1$).
Conclusion
Our study confirms that CRH test and HDDST have high accuracy in differential diagnosis of ACTH-dependent CS. In patients with negative MRI or with a microadenoma <6 mm, the presence of concordant positive noninvasive tests seems sufficient to establish the diagnosis of CD. BIPSS should be reserved to discordant cases.

Results from the phase 3 multicenter SONICS study of levoketoconazole: subgroup analysis of Cushing's syndrome patients with diabetes mellitus

Maria Fleseriu[1], Rosario Pivonello[2], Atanaska Elenkova[3], Roberto Salvatori[4], Richard J. Auchus[5], Richard A. Feelders[6], Eliza B. Geer[7], Yona Greenman[8], Przemyslaw Witek[9], Frederic Cohen[10] & Beverly MK Biller[11]
[1]Oregon Health and Science University, Portland, OR, USA; [2]University of Naples Federico II, Naples, Italy; [3]Medical University Sofia, Sofia, Bulgaria; [4]Johns Hopkins University, Baltimore, MD, USA; [5]University of Michigan Medical School, Ann Arbor, MI, USA; [6]Erasmus Medical Center, Rotterdam, Netherlands; [7]Memorial Sloan Kettering Cancer Center, New York, NY, USA; [8]Tel Aviv University, Tel Aviv, Israel; [9]Military Institute of Medicine, Warsaw, Poland; [10]Strongbridge Biopharma, Trevose, PA, USA; [11]Massachusetts General Hospital, Boston, MA, USA.

Background
Cushing's syndrome (CS) has numerous comorbidities, including diabetes mellitus (DM). Levoketoconazole is a ketoconazole stereoisomer in clinical trials for treatment of CS.
Methods
SONICS is a prospective, open-label, phase 3 maintenance-of-benefit study in adults with confirmed CS and mean urinary free cortisol (mUFC) of ≥ 1.5x upper limit of normal (ULN). Repeated hospitalization due to hyperglycemia or any complication related to DM during the previous 12 months were exclusion criteria. There were 3 study phases: dose-titration (DT; to normalize mUFC; 2–21 weeks), maintenance (M; 6 months), and extension (6 months). The study met the primary end point of mUFC normalization at the end of M (EoM) without a preceding dose increase during M as recently described (Fleseriu M, et al. ICE 2018). Secondary end points included measures of glycemic control: fasting blood glucose (FBG) and hemoglobin A1c (HbA1c). This analysis compares patients with DM to overall study population.
Results
Intention-to-treat (ITT) population comprised 94 patients; 77 completed DT, 61 completed M. At baseline, overall median (range) age was 44 (18–75) years; 82% were female; 85% had Cushing's disease (CD); and 38% had DM at screening. In 36 patients with DM: median (range) age was 48 (22–75) years; 92% were female; 81% had CD. Median (range) baseline mUFC was similar for the DM subset (2.6x [1.2x–30x] ULN) and ITT population (3.0x [1.2x–30x] ULN). At EoM, 30% (95% CI, 21%–40%) of ITT population achieved the primary end point; DM was not a significant factor in the mUFC normalization model (odds ratio 1.25; $P=0.6058$). In the DM subset, 34% had mUFC normalization (95% CI, 19%–53%). Patients with versus without DM had mean baseline FBG of 123 mg/dL versus 92 mg/dL, and HbA1c of 6.9% versus 5.5%; at EoM, mean FBG was 105 mg/dL versus 84 mg/dL, and mean HbA1c was 6.2% versus 5.3%. Adverse events (AEs) were reported for 97% of DM and 98% of ITT patients; 11% with DM and 13% of ITT discontinued due to AEs. The most common AEs in DM patients were nausea (58%), vomiting (19%), and urinary tract infection (17%); and in ITT population were nausea (32%), headache (28%), and peripheral edema (19%).
Conclusions
In this prospective trial, levoketoconazole at a stable therapeutic dose maintained mUFC normalization for 6 months in 34% of patients with DM versus 30% in the ITT population. Improvements in HbA1c were more notable among patients with DM.

Epigenetic regulation by miRNAs in corticotroph tumors

Araceli García-Martínez[1], Beatriz López-Muñoz[2], Carmen Fajardo[3], Rosa Cámara[4], Cristina Lamas[5], María Eugenia Torregrosa[6], Ignacio Aranda[7] & Antonio Picó[2]
[1]Research Laboratory, Hospital General Universitario de Alicante-ISABIAL, Alicante, Spain; [2]Endocrinology Department, Hospital General Universitario de Alicante, Alicante, Spain; [3]Endocrinology Department, Hospital La Ribera, Alzira, Spain; [4]Endocrinology Department, Hospital Universitario y Politécnico La Fe, Valencia, Spain; [5]Endocrinology Department, Complejo Hospitalario Universitario de Albacete, Albacete, Spain; [6]Clinical Analysis Department, Hospital General Universitario de Alicante, Alicante, Spain; [7]Pathological Department, Hospital General Universitario de Alicante, Alicante, Spain.

Introduction
The silencing mechanisms of corticotroph tumors (CT) remain unclear. The most feasible hypothesis lies in a post-transcriptional deregulation of the *POMC* gene, precursor of ACTH. Micro RNAs (miRNAs) are small non-coding RNA molecules involved in the epigenetic regulation of gene expression through their inhibitory action on messenger RNA. miRNAs capable of inhibiting the expression of *POMC* have been described at the level of neurons of the hypothalamus, which gives us a basis to advance in the knowledge of CT.
Aim
The aim of the present study was to determine if epigenetic regulation by miRNAs is involved in the silencing mechanisms of CT.
Methods
We have quantified the relative gene expression of 8 factors (*PKA, MAP3K8, MEK, MAPK3, NGFIB, NURR1, PITX1, STAT3*) and 5 miRNAs (miR375, miR383, miR488, miR200a, miR103) related with the expression of *POMC* by qRT-PCR with TaqMan probes in 24 functioning CT (fCT) and 23 silent CT (sCT).
Results
sCT were significantly higher than fCT (maximum tumor diameter mean $\pm$ standard deviation: 22.44 mm ± 10.26 vs 13.76 mm ± 9.99, $P=0.003$). The expression of miR200a and miR103 was higher in sCT than in fCT ($P=0.007$ and $P=0.011$, respectively). No statistically significant data were found when we evaluated the correlations between gene expression of factors and miRNAs in

fCT. Conversely, we observed a strong negative correlation between miR488, miR200a and miR103 and the expression of *MAP3K8* (rho = −0.747, $P<0.001$, rho = −0.686, $P=0.001$ and rho = −0.782, $P<0.001$, respectively); between miR488 and miR103 and *MEK* expression (rho = −0.605, $P=0.006$ and rho = −0.665, $P=0.002$, respectively) and between miR383 and the expression of *STAT3* (rho = −0.544, $P=0.016$) in sCT. Finally, the maximum tumor diameter was positively correlated with the expression of miR488 (rho = 0.521, $P=0.027$) in sCT.

Conclusions

The inhibition of transcription factors (*STAT3*) and kinases related with proliferation, differentiation and transcription regulation (*MAP3K8* and *MEK*) could participate in the silencing of CT.

Evaluation of utility of salivary cortisol levels after suppression with 1 mg Dexamethasone in screening of Cushing's syndrome

Laura Correa-Martínez[1], María Eugenia Torregrosa[1], Victoria González[1], Beatriz López-Muñoz[2], Araceli García-Martínez[3], Eloy Oliveira[1], María Teresa Botella[1], Rocío Alfayate[1] & Antonio Picó[4]

[1]Clinical Analysis Department, Hospital General Universitario de Alicante, Alicante, Spain; [2]Endocrinology Department, Hospital General Universitario de Alicante, Alicante, Spain; [3]Research Laboratory, Hospital General Universitario de Alicante-ISABIAL, Alicante, Spain; [4]Endocrinology Department, Hospital General Universitario de Alicante-ISABIAL, Alicante, Spain.

Introduction

Salivary cortisol measurement is a non-invasive and easy test to carry out. It is painless and does not cause stress.

Aim

The aim of the present study was to evaluate the correlation between salivary cortisol (SaC) and serum cortisol (SeC) after 1 mg Dexamethasone (DXM) overnight and their diagnostic utility as screening test of Cushing's syndrome (CS).

Methods

We performed a prospective study in 92 patients with CS suspicion. Samples of saliva and peripheral blood were collected at 08:00h after oral administration of 1mg of DXM overnight (23:00h). CS diagnosis was confirmed in 10 patients. Salivary and serum cortisol measurements were performed by electrochemiluminscent immunoassay (ECLIA) method on an automated Cobas 8000 (Roche®). To analyze the correlation between SaC and SeC we used the Passing-Bablock nonparametric linear regression test with the statistical package Medcalc®. To calculate the sensitivity-specificity of SeC we used the stablished 1.8 mcg/dL cut-off value. To calculate the best cut-off point of SaC we used the Receiver Operating Characteristic (ROC) curves.

Results

There was a significant correlation between salivary and serum cortisol after 1 mg of DXM overnight, ($r=0.634$; $P<0.001$). The estimated cut-off point for SaC was 0.08 μg/dL. The sensitivity, specificity, PPV and NPV of this cut-off were: 60%, 82.93%, 18.18% and 93.22%, respectively. The sensitivity, specificity, PPV and NPV of 1.8 μg/dL cut-off point of SeC were 70%, 57.32%, 16.67% and 94% respectively.

Conclusion

If these results are reproduced in an independent and bigger sample, the measurement of salivary cortisol after 1 mg of DXM overnight could substitute the classical Nugent's test in the screening of Cushing's syndrome.

The role of copeptin and cortisol in critically ill patients

Marin Gergics[1,2], Gréta Pham-Dobor[1,2], Zita Tarjányi[2], Gergely Montskó[2,3], Tamás Kőszegi[2,3], Emese Mezősi[1,2] & László Bajnok[1,2]

[1]1st Department of Medicine, Division of Endocrinology and Metabolism, University of Pécs, Medical School, Pécs, Hungary; [2]Szentágothai Research Centre, University of Pécs, Pécs, Hungary; [3]Department of Laboratory Medicine, University of Pécs, Medical School, Pécs, Hungary.

Introduction

Both cortisol and vasopressin are stress hormones. Earlier, our group demonstrated that serum concentrations of free cortisol at admissions to the Intensive Care Unit (ICU) were independent predictors of survival in critically ill patients. Other investigators have demonstrated that serum copeptin, a surrogate marker of vasopressin may also be a predictive factor in this patient population. The aim of our present study was to compare the prognostic roles of serum levels of cortisol and copeptin.

Methods

In the 69 critically ill patients (39 male, 30 female, mean age 69 ± 11 ys) in whom cortisol levels were determined earlier, serum concentrations of copeptin were measured in their stored samples which had been taken shortly after admission to ICU, using ELISA kits (Abbexa Ltd). The severity of the disease was calculated based on the SAPS II and APACHE II scoring systems. Statistical analyses were performed using SPSS 22.0 and MedCalc 13.3.3.0.

Results

Copeptin, total and free cortisol levels were typically highly elevated: baseline values (ranges) were as follows: 1409.7 pg/mL (98.1–6143.9), 1101.6 nmol/L (112.6–8797.8) and 106.2 nmol/L (0.4–759.9), respectively. Furthermore, these concentrations were significantly (i) higher in non-survivors than in surviving patients with medians (inter-quartiles) 1130.5 pg/mL (778.0–2663.1) vs 770.2 pg/mL (415.9–1672.3), 1141.3 nm/L (744.6–2154.2) vs 634.0 nm/L (394.9–987.4), and 178.7 nm/L (33.3–278.7) vs 15.1 nm/L (4.4–80.4), respectively and (ii) correlated with APACHE II ($R=0.331$; 0.455; and 0.559, respectively) and SAPS II ($R=0.382$; 0.542; and 0.584, respectively) scores. However, in respect to predicting mortality, compared to free cortisol, copeptin (i) showed lower area under the curve during receiver operating characteristic (0.679 vs 0.801), and (ii) was not an independent predictor in multiple binary logistic regression analyses.

Conclusion

In respect of critically ill patients' prognosis, the predictive power of free cortisol is higher than of copeptin.

Microstructural white matter changes using diffusion tensor imaging in patients with Cushing's disease

Eesh Bhatia[1], Suyrit Jain[1], Sunil Kumar[2], Latha Satish[3], Rajesh Kumar[4] & Sanjay Behari[5]

[1]Department of Endocrinology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India; [2]Department of Radiodiagnosis, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India; [3]Krishnamacharya Yoga Mandiram, Bengaluru, India; [4]Department of Anaesthesiology, Radiological Sciences and Bioengineering, University of California, Los Angeles, USA; [5]Department of Neurosurgery, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India.

Cushing's disease (CD) results in chronic exposure to increased levels of cortisol leading to alterations in white matter microarchitecture and adverse effects on cognitive functioning. Diffusion tensor imaging (DTI) is a novel technique used to evaluate the integrity of white matter (WM) architecture. There is little information on DTI changes in CD. We studied WM changes in CD using diffusion tensor imaging and compared with healthy controls. 16 patients with active CD (abnormal low dose dexamethasone suppression test, elevated salivary cortisol, elevated ACTH, pituitary microadenoma on imaging) and 16 matched healthy controls were analysed through DTI (Voxel based analysis) for fractional anisotropy (FA), mean diffusivity (MD), axial diffusivity (AD) and radial diffusivity (RD). We also studied cognitive function using a standardized testing protocol for Indian subjects. There were widespread alterations (reduced FA, increased MD, AD, and RD) in patients with CD as compared with controls. Areas of the brain which are involved in cognitive function were significantly affected, included the hippocampus, cingulum and corpus callosum. On cognitive assessment impaired cognitive functioning affecting memory and learning (specifically verbal learning and logical memory) were significantly impaired in patients with CD. In summary, verbal learning and logical memory were impaired in CD. White matter alterations are seen in multiple areas associated with cognitive functioning.

[1]Maimonides Institute for Biomedical Research of Cordoba (IMIBIC), Cordoba, Spain; [2]Department of Cell Biology, Physiology and Immunology, University of Cordoba, Cordoba, Spain; [3]Reina Sofia University Hospital (HURS), Cordoba, Spain; [4]CIBER Physiopathology of Obesity and Nutrition (CIBERobn), Cordoba, Spain; [5]Service of Endocrinology and Nutrition, Reina Sofia University Hospital, Cordoba, Spain; [6]Metabolism and Nutrition Unit, Virgen del Rocio University Hospital, Institute of Biomedicine of Seville (IBiS), Sevilla, Spain; [7]Service of Neurosurgery, Reina Sofia University Hospital, Cordoba, Spain; [8]IPSEN Bioscience, Cambridge, MA, USA.

Pituitary neuroendocrine tumors (PitNETs) constitute approximately 15% of all intracranial tumors and comprise a varied type of neoplasms that, despite being rarely metastatic, can cause severe comorbidities and increased mortality related to the mass effects and hormonal hypersecretion. The high expression levels of somatostatin and dopamine receptors in these tumors has led to the use of somatostatin analogues (SSAs) and dopamine agonists (DAs) as pharmacological treatments. Nevertheless, a high proportion of patients are or become resistant to these drugs, in that they are unable to respond clinically or biochemically to these treatments. In this context, somatostatin-dopamine chimeric compounds (dopastatins) were developed to increase the efficacy and improve the control of the disease compared with SSAs and/or DAs. The main objective of this study was to determine the direct therapeutic effects of a new generation dopastatin chimeric compound, BIM-065, on primary cell cultures from different PitNETs subtypes. To that end, a total of 31 PitNETs [9 corticotropinomas, 9 somatotropinomas, 2 prolactinomas and 11 non-functioning pituitary tumors (NFPTs)] were collected and dispersed cells were treated with BIM-065 to evaluate different functional endpoints such as cell viability, apoptosis, hormone release, expression levels of key genes and free cytosolic [Ca2+]i dynamics. Additionally, AtT-20 cell-line was used to evaluate signaling pathways in response to this chimeric compound. Our results demonstrate that BIM-065 decreased cell viability in all corticotropinomas and somatotropinomas, as well as, in AtT-20 cells. In contrast, in NFPTs (a tumor type commonly resistant to SSAs and DAs treatment), BIM-065 did not alter cell viability. Remarkably, we observed an increase on apoptosis, and a reduction on ACTH, GH and chromogranin-A secretion in corticotropinomas, somatotropinomas and NFPTs in response to the chimeric compound, respectively. These results were possibly mediated through the modulation of pivotal signaling cascades like [Ca2+]i kinetics and Akt- or ERK1/2-phosphorylation. Taken together, our results reveal a clear antitumoral effect of this new chimeric compound on different PitNETs subtypes, which suggests that this compound could be an efficacious therapeutic option to consider in the treatment of this pathology.

Pituitary surgery as first-line therapy for microprolactinomas

Marie Teulade, Hélène Lasolle, Alexandre Vasiljevic, Françoise Borson-Chazot, Emmanuel Jouanneau & Gérald Raverot
CHU, Lyon, France.

Introduction
Dopamine agonists (DA), reference treatment for microprolactinomas, rarely allow long term remission. The performance of endoscopic pituitary surgery should be examined as first-line treatment.
Objective
To evaluate the remission rate of microprolactinoma operated by endoscopic transphenoidal approach
Methods
We retrospectively studied the surgical results of the 35 microprolactinomas operated between 2010 to 2017 in our institution by a single surgeon (EJ). We analyzed the immediate (3months) and long term (last follow-up) remission rates, as well as the post-operative complications.
Results
The sex ratio was 7.8 (F=31) and the mean age at diagnosis was 27±8 years. Seven patients were immediately operated (patient choice), 28 received pre-operative DA (median 7.5 (0.2–188) months)) with cabergoline ($n=17$), quinagolide ($n=6$), bromocriptine ($n=3$), or indetermined ($n=2$). DA achieved prolactin normalization in 13/28 patients (46%). Surgical indication was DA intolerance ($n=13$), patient choice ($n=13$), resistance despite DA high dose ($n=2$). Most of adenomas were noninvasive for cavernous or sphenoid sinus (34/35) and non-proliferative (grade 1a $n=26/35$). No patient presented pituitary deficiency after surgery. Two presented hyponatremia due to SIADH with spontaneous resolutions in few days. Other complications included sinusitis ($n=3$) and one cerebral fluid leak without meningitis. At 3-months ($n=33$), remission rate was 97% (32/33): one patient, intolerant to high dose DA, with 9 mm invasive tumour before surgery, required post-operative Cabergoline treatment (0.5 mg/day). Long term remission rate ($n=33$) after a median follow-up of 1.3 year [0.25; 9.4] was 81.8% (27/33). Only two patients required DA to control clinical symptoms, 3 presented slight elevation of prolactin level without clinical symptoms or tumor recurrence. The median time before recurrence was 5.4 years [0.7; 9.4]. All women (29) recovered a normal gonadotropic function, allowing 6 pregnancies in 5 patients. Sex, age at diagnosis, pre-operative DA,prolactin level, tumor size, cavernous sinus invasion (radiological or operative) and grade tumor were not significantly associated with long-term remission using univariate analysis. However, all recurrent patients were DA pretreated.
Conclusion
This study showed a high long term remission rate compared to the rate of prolactin normalization under medical treatment, while post-operative complications were acceptable. Surgery could be considered as first line treatment in microplactinomas. Remission rate being higher without preoperative DA, surgery may be proposed before any medical treatment.

Excellent tumor response to pasireotide therapy in an aggressive and dopamine-resistant prolactinoma

Eva Coopmans[1], Sebastiaan van Meyel[1], Kay Pieterman[1], Jolique van Ipenburg[1], Leo Hofland[1], Esther Donga[2], Adrian Daly[3], Albert Beckers[3], Aart-Jan van der Lely[1] & Sebastian Neggers[1]
[1]Erasmus University Medical Center, Rotterdam, Netherlands; [2]Elisabeth TweeSteden Hospital, Tilburg, Netherlands; [3]University of Liège, Liège, Belgium.

Background
Prolactinomas are the most frequent secreting pituitary adenomas encountered in the clinical setting. Cabergoline is considered the mainstay medical treatment and transsphenoidal surgery (TSS) is recommended for patients that are medically resistant to dopamine agonist therapy. Resistance to dopamine agonists is commonly defined as failure to normalize prolactin and less than 50% decrease in tumor diameter at a maximal labeled dose of 2.0 mg/week. Pasireotide LAR (PAS-LAR) is a 2nd generation multi-somatostatin receptor (SST) ligand, with particularly high affinity for SST_5 receptor.
Case presentation
A 61-year-old woman was referred for evaluation of a dopamine agonist-resistant prolactinoma. In 1993, she presented in a local hospital with only secondary amenorrhea since the age of 25. Her laboratory results showed hyperprolactinemia and her MRI revealed an invasive macro-adenoma in the anterior lobe of the pituitary. In the local hospital the patient received twice TSS and radiosurgery due to regrowth of the tumour with visual field defects on dopamine agonists. She was treated with cabergoline (weekly 3.0 mg), but eventually therapy failed and both hyperprolactinemia and clinically relevant tumor growth occurred again (227.36 ng per milliliter, tumour size 2549 mm^3). We tried higher dosages of dopamine agonists (up to weekly 7 mg) as well as in combination with 1st generation SST analogues. This again appeared to be unsuccessful (679.25 ng per milliliter, tumour size 3900 mm^3). Before the use of temozolomide, we attempted PAS-LAR in combination with cabergoline to which our patient responded excellently (0.47 ng per milliliter, tumour size 1300 mm^3). An important argument supporting to initiate PAS-LAR was the absence of visual field defects, which provided a window of opportunity. Immunohistochemistry showed membranous expression score of IRS 9 for SST_2 and IRS 12 for SST_5 and strong reactivity for prolactin. PAS-LAR markedly reduced the tumour size from 3900 mm^3 before initiation to 1300 mm^3 24 months after treatment. Also, it lowered prolactin levels below upper limit of normal (43.9 ng per milliliter) within 2 months of administration to 0.47 ng per milliliter. Furthermore,

T2-hyperintense signal and inhomogeneity on T1-signal intensity of the adenoma was observed after PAS-LAR treatment, indicating cystic degeneration/or tumour cell necrosis, which suggests an antitumour effect.
Conclusion
PAS-LAR therapy holds potential in dopamine agonist- and 1st generation SST analogue resistant prolactinomas that express high affinity for SST_5. Furthermore, switching to PAS-LAR can be considered in patients with an aggressive tumour as an in between treatment step before starting with Temozolomide.

Sleep disorders after craniopharyngioma surgery

Said Azzoug[1,2] & Djamila Meskine[1,2]
[1]Endocrine Diseases Department Beloghine Hospital, Algiers, Algeria; [2]Laboratory of Endocrinology and Metabolism Algiers 1 University, Algiers, Algeria.

Introduction
Vicinity and adherence of hypothalamic nuclei to craniopharyngioma explain the high rate of complications and difficulties of removal of these tumors.
Subjects and methods
In this retrospective study 50 patients (10 adults and 40 children or adolescents) harboring craniopharyngioma were included. These patients were operated mainly by a frontal approach. We evaluated the frequency of sleep disorders secondary to hypothalamic damage and their predictive factors.
Results
Eight patients (16%) developed hypothalamic syndrome following craniopharyngioma surgery. Sleep disorders in the form of hypersomnia were reported in 3 patients (6%). Other reported abnormalities were: appetite disorders in 8 patients (16%) (one case of anorexia complicated by fatal cachexia and seven cases of polyphagia complicated by morbid obesity, metabolic syndrome and/or steatohepatitis) and thermoregulation disorders in 3 patients (6%). Circulatory and respiratory disorders were not reported in our patients. Extent of surgery and young age were the main predictive factors for the occurrence of hypothalamic damage.
Discussion and conclusion
Sleep disorders were reported in 6% after surgery of craniopharyngioma. Young age and extent of surgery were the main predictive factors. These factors are foreseeable as pediatric craniopharyngioma are of adamantine type. This type of craniopharyngioma is characterized by infiltration of surrounding tissues and a more pronounced peri-tumorous fibrosis making surgical removal more laborious and raising the risk of hypothalamic damage.

Normal IGF-bioactivity and low free IGF-I in patients with Prader-Willi syndrome with high total serum IGF-I: immunoreactive IGF-I concentrations poorly reflect IGF bio-activity and bio-availability

Karlijn Pellikaan[1], Melitza Elizabeth[2], Stephany Donze[2], Sjoerd van den Berg[3], Jaap van Doorn[4,5], Robin P Peeters[1,6], Anita CS Hokken-Koelega[2,7,8] & Laura CG de Graaff[1,7]

Endocrinology, Erasmus MC, Rotterdam, Netherlands; [2]Dutch Growth Research Foundation, Rotterdam, Netherlands; [3]Laboratory for Clinical Chemistry, department of Endocrinology, Erasmus MC, Rotterdam, Netherlands; [4]Clinical Chemistry and Hematology, Laboratory of Endocrinology, UMC Utrecht, Utrecht, Netherlands; [5]Medical Genetics, Section Metabolic Diseases, UMC Utrecht, Utrecht, Netherlands; [6]Academic Center for Thyroid Diseases, Erasmus MC, Rotterdam, Netherlands; [7]Academic Center for Growth Disorders, Erasmus MC, Rotterdam, Netherlands; [8]Pediatrics, Subdiv. Endocrinology, Erasmus MC, Rotterdam, Netherlands.

Introduction
Prader-Willi Syndrome (PWS) is a complex syndrome including hyperphagia, pituitary hormone deficiencies, low muscle mass and cognitive impairment. Treatment with recombinant Growth Hormone (GH) has beneficial effects on body composition, physical performance, cognition, psychomotor development, respiratory function, and quality of life of patients with PWS. GH treatment has a narrow therapeutic range. Clinicians measure serum immunoreactive Insulin-like Growth Factor 1 ('total IGF-I') levels to titrate the dose of GH. However, in patients with PWS, IGF-I levels are often much higher than expected based on GH dose. As a result, clinicians have to reduce the GH dose, with consequent loss of beneficial effects of GH. Preliminary data[1] showed that IGF-bioactivity was low and not related with total IGF-I in children with PWS, suggesting that IGF might be less active, or less available, in PWS. Proof of low IGF bioactivity or bio-availability in PWS would have great clinical consequences, as this would imply that high levels of total IGF-I might not have negative side effects and can therefore be accepted in patients with PWS.
Methods
We measured total IGF-I, bioactive IGF and free ('bio-available') IGF in 22 PWS (15 with and 7 without GH) patients and 112 healthy controls. In order to measure IGF-bioactivity, we have set up and optimized an in-house IGF-I receptor kinase activation assay (KIRA). KIRA is a cell based system where IGF bioactivity is reflected by phosphorylation of the IGF receptor. In order to measure IGF-I bioavailability ('free IGF-I), we used a new commercially available ELISA (Ansh Labs, Webster, TX). Both IGF-I bioavailability and IGF-bioactivity were compared with total (immunoreactive) IGF-I values.
Results
We found a striking difference in free IGF-I between PWS and control samples. Free IGF-I levels were extremely low in PWS. Both free IGF-I and IGF-bioactivity correlated poorly with total IGF-1 levels. IGF bioactivity in GH-treated PWS patients was comparable to (non-GH treated) healthy individuals. GH-treated patients with extremely high total IGF-I levels have normal IGF-bioactivity.
Conclusion
Total IGF-I is a poor marker of IGF-bioactivity and bio-availability in PWS patients. Our results suggest that a GH dose reduction may not be needed in PWS patients with a high total IGF-I. Further studies are needed to confirm our data and to investigate whether IGF-I bioactivity and IGF bio-availability are more reliable parameters for GH dose titration in PWS.

Do different initial doses of L-T4 within the range of 10–15 mcg/kg/die influence neurodevelopment during the first two years of life in children with congenital hypothyroidism?

Cristina Moracas[1], Gian Paolo Ciccarelli[1], Carmela Bravaccio[1], Alessandra Cassio[2], Roberto Gastaldi[3], Alessandro Mussa[4], Miriam Polizzi[1], Maria Cristina Vigone[5], Malgorzata Gabriela Wasniewska[6], Giovanna Weber[5] & Mariacarolina Salerno[1]
[1]Pediatric Endocrine Unit, Department of Translational Medical Sciences, University of Naples Federico II, Naples, Italy; [2]Pediatric Department, Sant'Orsola-Malpighi Hospital, University of Bologna, Bologna, Italy; [3]Department of Pediatrics, Istituto Giannina Gaslini, Genoa, Italy; [4]Department of Pediatrics and Public Health, Regina Margherita Children's Hospital, University of Turin, Turin, Italy; [5]Department of Pediatrics, Vita-Salute San Raffaele University, IRCCS San Raffaele Hospital, Milan, Italy; [6]Department of Pediatrics, University of Messina, Messina, Italy.

Background
The initial L-T4 dose in the treatment of congenital hypothyroidism (CH) currently recommended is 10–15 mcg/kg/die.
Objective
We designed a multicenter randomized trial to evaluate the effects of different starting dose of L-T4 within the range 10–15 mcg/kg/die on neurocognitive development in children with CH.
Methods
Seventy-two children with CH diagnosed by neonatal screening were enrolled in the study. They were randomly assigned to receive an initial L-T4 dose of 10–12.5 mcg/kg/die (group A) or 12.6–15 mcg/kg/die (group B). All patients underwent clinical examination and FT4 and TSH measurement periodically during the first two years of life. At the age of 12 and 24 months they underwent Griffiths Mental Development Scales to evaluate cognitive development.
Results
Growth during the first two years of life was comparable in the two groups of patients. Neurodevelopmental evaluation showed no significant difference in Global and Subscales Quotients between the two groups – at 12 and at 24 months of age (Table 1).

Table 1

	Group A	Group B	P
Global Developmental Quotient 12 months	105.2±12.6	104.5±12.8	Ns
Locomotion DQ	99.1±14.7	96.7±18.4	Ns
Personal/social DQ	97.7±13.7	102.2±13.3	Ns
Language DQ	109.1±10.8	107.3±14.6	Ns
Eye-hand coordination DQ	107.6±17.5	104.4±17.8	Ns
Performance DQ	109.5±19.9	109.8±20.6	Ns
Global Developmental Quotient 24 months	96.9±16.6	100.6±16	Ns
Locomotion DQ	109.1±23.3	111.8±22.1	Ns
Personal/social DQ	93.3±25.3	99.9±21.4	Ns
Language DQ	87.7±21.7	91.2±20.1	Ns
Eye-hand coordination DQ	100.7±17.5	104.4±13.5	Ns
Performance DQ	102.4±15.4	105.4±15	Ns

Conclusion

Different initial doses of L-T4 within the range of 10–15 mcg/kg/die are not associated with differences in neurodevelopment during the first two years of life in CH patients.

Cystic fibrosis as a novel cause of thyroxine (l-t4) malabsorption and increased requirement

Giuseppe Giuffrida[1,2], Giuseppe Magazzù[3], Alfredo Campennì[4], Maria Cristina Lucanto[3], Francesco Trimarchi[5], Salvatore Cannavò[3,2] & Rosaria Maddalena Ruggeri[1,2]
[1]Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy; [2]Endocrine Unit at University Hospital, Messina, Italy; [3]Department of Human Pathology of Adulthood and Childhood 'Gaetano Barresi', University of Messina, Messina, Italy; [4]Department of Biomedical and Dental Sciences and Morpho-Functional Imaging, University of Messina, Messina, Italy; [5]Accademia Peloritana dei Pericolanti at the University of Messina, Messina, Italy.

Background

Cystic fibrosis (CF), a monogenic disease from mutations in the CFTR gene on chromosome 7, causes pancreatic insufficiency and impaired nutrients absorption. Unlike other malabsorption disorders, no data are available in literature on L-T4 absorption in CF. This study analyzed L-T4 absorption and requirement in hypothyroid CF patients.

Methods

Ten CF patients (7 F, 3 M; mean age 37 yr), with autoimmune ($n=6$) or post-thyroidectomy ($n=4$) hypothyroidism, were administered L-T4 tablets. None took medications known to alter L-T4 absorption or metabolism. Fifty age- and sex-matched subjects (43 F, 7 M; mean age 40 yr), with either autoimmune ($n=25$) or post-operative ($n=25$) hypothyroidism, served as internal reference group. All patients were advised to take oral L-T4 (starting dose 1.6 μg/kg/daily) at morning under fasting, at least 1 h before breakfast. Target serum TSH values were 0.5–3.0 μIU/ml, according to patients' age. In each patient, serum TSH and FT4 were measured at enrolment, 8 weeks after starting L-T4 and 4 weeks after every dose adjustment. Two CF patients (1F and 1 M) volunteered for an acute loading test of 600 μg L-T4.

Results

At enrolment, the 6 CF patients with HT had subclinical hypothyroidism (median TSH 6.1 uIU/ml; range 5.2–10) and the 4 patients who had undergone thyroidectomy were overt hypothyroid (median TSH 26.5 μIU/ml; range 11–61, on discharge). L-T4 was started as described. After 8 weeks, all CF patients had inappropriately high serum TSH (median 5.2 μIU/ml vs 2.0 μIU/ml in controls) despite an adequate L-T4 daily dosage, indicating T4 malabsorption. In such patients L-T4 dose has been increased by 25% to 50% or more (2.0 to 5 μg/kg/d) depending on the aetiology (autoimmune/post-operative) compared to controls (median dose 1.68 μg/kg/d; $P=0.001$). Also, target serum TSH (median 2.95 μIU/ml) was reached in 10±3 months compared to 4±2 months in controls ($P=0.001$). In the two patients participating to the acute loading test, T4 pharmacokinetic indices (total T4 at 0' = 4.38 μg/dl, normal values 5.1–14.1; Cmax = 5.62 μg/dl, AUC 0–4 h = 21.97 μg/dl) were compatible with malabsorption.

Conclusions

These preliminary observations provide the first evidence of increased need for T4 in CF patients. CF should be included among the digestive diseases causing intestinal malabsorption of L-T4, likely due to the combination of pancreatic insufficiency, chronic intestinal inflammation and reduced production of biliary salts.

Long-term cardiometabolic effects of maternal sub-optimal gestational thyroid function and relative treatment in the Controlled Antenatal Thyroid Screening (CATS) study II

Ilaria Muller[1], Peter Taylor[1], Rhian Daniel[2], Charlotte Hales[1], Anna Scholz[1], Xiaochen Yin[1], Toby Candler[3], Rebecca Pettit[4], William Evans[4], Dionne Shillabeer[1], Mohd Draman[1], Colin Dayan[1], Carolyn Tang[1], Onyebuchi Okosieme[1], John Gregory[2], John Lazarus[1], Aled Rees[5] & Marian Ludgate[1]
[1]Cardiff University School of Medicine, Division of Infection & Immunity, Cardiff, UK; [2]Cardiff University School of Medicine, Division of Population Medicine, Cardiff, UK; [3]MRC, The Gambia at the London School of Hygiene and Tropical Medicine, London, UK; [4]University Hospital of Wales, Department of Medical Physics and Clinical Engineering, Cardiff, UK; [5]Cardiff University School of Medicine, Neuroscience and Mental Health Research Institute, Cardiff, UK.

Introduction

The effects of maternal suboptimal gestational thyroid function (SGTF) on age 3 offspring's cognitive function were investigated in the Controlled Antenatal Thyroid Screening (CATS) randomised trial, comparing SGTF mothers who received (SGTF-T), or didn't (SGTF-U), levothyroxine during pregnancy. The analysis was repeated at age 9 in the CATS-II follow-up study, also including children of mothers with normal gestational thyroid function (NGTF). Here we report the long-term effects on anthropometric and cardiometabolic outcomes in both children and mothers assessed at CATS-II.

Methods

Evaluation of 332 mothers aged 41.2±5.3 years (mean±SD) and 326 paired children 9.3±1.0 years after birth: 197 NGTF, 56 SGTF-U, 79 SGTF-T. The BMI was calculated in the whole cohort; in children it was expressed as BMI standard deviation score (BMI-SDS) against UK standards. Subsets also underwent: i) dual-energy x-ray absorptiometry scan of lean/fat mass; ii) Vicorder analysis of systolic/diastolic blood pressure, augmentation index and aortic pulse wave velocity; iii) serum measurement of thyroid function, lipids, insulin and adiponectin. Linear regression was used to analyse the difference between means of the 3 groups (NGTF, SGTF-U, SGTF-T).

Results

Children analysis showed no significant differences between groups in any of the parameters evaluated. Despite baseline (at CATS) maternal BMI was similar among the three groups, at CATS-II SGTF-U mothers had significantly higher BMI, fat mass. triglyceride and insulin levels compared with NGTF and SGTF-T. At CATS-II SGTF-U mothers also had higher TSH levels, since only 24.0% of SGTF-U were started on levothyroxine after CATS, versus 84.5% of SGTF-T ($P<0.001$) (Table 1).

Conclusions

No impact of levothyroxine supplementation during pregnancy in women with SGTF was observed on children's cardiometabolic parameters evaluated at age 9. However levothyroxine treatment commenced after screening for SGTF provided significant metabolic benefits among mothers: treated women avoided the

sustained long-term increase of BMI, fat mass, triglyceride and insulin levels observed in the untreated group.

Table 1

	NGTF	SGTF-U	SGTF-T	P
BMI Kg/m^2 median (IQR)	25.8 (22.9–30.0)	28.3 (24.6–32.6)	25.8 (23.1–29.8)	0.029
Subtotal FAT % mean ± SD	40.2±7.2	42.8±7.2	40.4±7.4	0.017

Urinary concentration of iodotyrosines correlates with the severity of iodine deficiency in dehal1 knockout mice

Cristian González-Guerrero[1], Marco Borso[2], Jorge García-Giménez[1], Federico Salas-Lucia[1], Pouya Alikhani[1], Alessandro Saba[2], Riccardo Zucchi[2] & José C Moreno[1,3]
[1]Thyroid Molecular Laboratory, Institute for Medical and Molecular Genetics (INGEMM), La Paz Universitary Hospital, Madrid, Spain; [2]Laboratory of Biochemistry, Department of Surgical, Medical, Molecular and Critical Area Pathology, University of Pisa, Pisa, Italy; [3]Autonomus University of Madrid, Madrid, Spain.

Thyroid hormone (TH) synthesis requires iodine, a scarce element whose recycling is mediated by DEHAL1 through deiodination of iodotyrosines MIT and DIT. In humans, *DEHAL1* defects lead to severe congenital hypothyroidism (CH) non-detected by neonatal screening programs, which involves the risk of mental retardation in infants. The timing for establishment of this hypothyroidism remains unknown, but environmental iodine deficiency may represent a triggering factor. While urinary loss of iodotyrosines could represent early biomarkers for the disorder, its determination in fluids remains a technical challenge.
Objective
To measure urinary concentrations of iodotyrosines and test their correlation with urinary iodide in *Dehal1* knockout mice under experimentally controlled iodine deficiency.
Methods
Dehal$^{(-/-)}$ and wilttype (wt) mice were subjected to normal, low, and very low iodine diets (NID, LID, VLID) containing 5.6, 1 and 0.25 μgI/day, for 28 days. At d0, d15 and d28, urinary iodine concentration (UIC) was determined by Kolthoff method and MIT, DIT determined in urine using a novel LC/MS-MS protocol.
Results
At baseline andNID, MIT and DIT urinary levels were statistically higher in *Dehal1*$^{(-/-)}$ (5 and 8 ng/ml) than in wt (1 and 0.5 ng/ml), respectively ($P<0.02$). Accordingly, UIC was increased in *Dehal1*$^{(-/-)}$ (30 mg/dl) compared to wt (15 mg/dl) ($P<0.05$), suggesting that iodide content of iodotyrosines is freed during Kolthoff procedure and adds to the general iodide pool in the urine. This situation persists in time till d28. Under LID, MIT and DIT concentrations remain elevated in *Dehal1*$^{(-/-)}$ (5.5 and 8 ng/ml) compared to wt (0.5 and 0.5 ng/ml) ($P<0.05$) at d15, but start to decrease in both genotypes at d28. UIC was still higher in *Dehal1*$^{(-/-)}$ (4 mg/dl) versus wt (1 mg/dl) ($P<0.05$) at d15 and d28, but decreased with respect to NID. Under VLID, MIT and DIT levels were still remained significantly higher in *Dehal1*$^{(-/-)}$ (4 and 3 ng/ml) compared to wt (0.5 and 0.25 ng/ml ($P<0.05$) at d15. At d28, iodotyrosines lowered to barely detectable levels in wt mice. Finally, UIC levels in *Dehal1*$^{(-/-)}$ were intensely decreased (0.5 mg/dl) at d15 and d28, while wt mice showed undetectable levels, reflecting stringent iodine restriction.
Conclusion
Our data strongly suggest that the accurate measurement of increased urinary loss of MIT and DIT correlates with UIC increment in *Dehal1* deficient mice, which is triggered by iodine deficient intake. Therefore, urinary iodotyrosines may represent pre-clinical biomarkers for early detection and treatment of DEHAL1 deficiency and prevention of mental retardation risks related to late diagnosis of CH.

Effect of anti-streptavidin interference when diagnosing thyroid disease using immunoassay analyses

Louise K Dahll, Ellen M Haave, Finn Erik Aas, Sandra R Dahl & Per M Thorsby
The Hormone Laboratory, Department of Medical Biochemistry, Oslo University Hospital, Oslo, Norway.

Background
The purpose of this study was to register the frequency and cause of method-dependent interference in the Roche thyroid immunoassays observed in our laboratory.
Methods
Serum samples to confirm discordant thyroid results were collected from June 2013 to September 2018, in samples sent to the Hormone Laboratory, Oslo University Hospital. The laboratory serves as a reference laboratory on thyroid diseases for about 2/3 of the inhabitants of Norway. We registered 106 samples with discordant pathological thyroid results when analyzed with the Roche methods, but with normal results when analyzed with alternative methods. 42 of the samples were sent to Roche Diagnostics for investigation of the interfering substance.
Results
In the 42 samples investigated we found interference by anti-streptavidin antibodies in 34 cases, antibodies against ruthenium or the idiotype of the ruthenium labelled antibody in three cases and human mouse antibodies (HAMA) in one case. We estimated the frequency of method-dependent interference to 0.2%. Euthyroid persons with streptavidin antibodies may have falsely elevated freeT4, freeT3, anti-thyroxin peroxidase and TSH receptor antibodies and decreased thyroid-stimulating hormone when analyzed with the Roche methods, mimicking a hyperthyroid disease.
Conclusion
Method-dependent interference in Roche thyroid immunoassays is caused mainly by streptavidin-antibodies, which occur more frequently than previously anticipated. This may lead to misdiagnosis and inappropriate medical treatment. Method-dependent errors should be reported to the supplier of the assay. If diagnostic tests showing method-dependent interference are not promptly improved, the laboratory should consider alternative methods.

GP182

Can hepcidin be a useful marker in the diagnosis and monitoring of de Quervain thyroiditis?

Dorota Filipowicz, Aleksandra Hernik, Ewelina Szczepanek-Parulska & Marek Ruchała
Department of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Sciences, Poznań, Poland.

Introduction
Hepcidin is a reactive inflammatory protein, responsible for ferrum homeostasis. Its concentration was already measured in hyperthyroiditis in the course of Graves disease and after restoration of euthyroidism, but also in growth hormone deficiency, hyperprolactinemia, however no significant changes were noted. De Quervain thyroiditis is a rare type of subacute thyroid inflammation, caused by interplay of unknown infectious, genetic and autoimmune factors and resulting in thyroid hormones imbalance. Thyroid hormones disturbances are frequently accompanied by anemia and affect iron metabolism. The aim of the study is to prospectively assess hepcidin changes in patients with subacute thyroiditis at the time of diagnosis and after remission. To our knowledge it's the first study concerning the issue of hepcidin in patients with de Quervains thyroiditis.
Materials
Out of 40 patients due to restrictive inclusion criteria 21 patients (including 2 males) aged 45±10 years were enrolled to the study at the time of diagnosis and the same number of healthy controls. Hepcidin and thyroid parameters were measured in blood serum before and at 12th week of follow-up after 8 weeks of successful prednisolone treatment.
Methods
Hepcidin 25 was measured by the high sensitive ELISA kit (DRG Instruments GmbH, Germany). TSH, fT3, fT4, aTPO, aTG were measured by ECLIA (Roche, Diagnostics, Indianapolis, IN, USA). Additionally we assessed also complete blood count (RBC, HGB, HCT, MCH, MCHC, RDW-CV) and iron metabolism (Fe, ferritin).
Results
The median of Hepcidin 25 serum concentration was markedly elevated in the de Quervain's patients (48.8 vs. 18.2 ng/mL, $P=0.009$) in comparison to control subjects and decreased significantly after therapy (48.8 vs. 4.0 ng/mL, $P=0.007$). The area under curve (AUC) at ROC analysis for hepcidin in newly diagnosed subjects is 0.735 ($P=0.009$) with cut-off hepcidin value 48.8 ng/mL (sensitivity 0.52, specificity 0.95). Complete blood count parameters and Fe were significantly lower in de Quervain's patients and improved after achieving biochemical remission.
Conclusions
De Quervain's thyroiditis is characterized by increased hepcidin levels. With the cut-off value, establishment of the diagnosis of the disease is more likely. Hepcidin decreases after standard steroid anti-inflammatory therapy, which

favours this protein to be a practical monitoring tool facilitating the decision on tapering the dose of glucocorticoids and a potential predictive factor for the risk of the disease relapse. However, studies on larger group of de Quervain's patients are needed to confirm these observations.

High-dose intravenous levothyroxine treatment as a successful, safe and clinically effective therapy option in severe hypothyroidism: a retrospective study

Pablo Trincado Aznar[1], María Martínez García[1], Beatriz Lardiés Sánchez[2], María Elena López Alaminos[1], Mikel González Fernández[1], Karol Almendra Alvarado Rosas[1], Isabel Melchor Lacleta[1] & Javier Acha Pérez[1]
[1]Hospital Universitario Miguel Servet, Zaragoza, Spain; [2]Hospital Obispo Polanco, Teruel, Spain.

Introduction
Treatment of hypothyroidism with levothyroxine is effective and simple; however, international guidelines advise starting with low doses in case of severe hypothyroidism, cardiac illness and aged population. Interestingly, and in contradiction to this dogma, high doses of levothyroxine have been given to patients with myxedema coma without untoward effects. The difference between myxedema coma, which deserves an intensive treatment, and longstanding severe hypothyroidism is often a matter of precipitating event or time.
Material and methods
Retrospective analysis of clinical evolution of 70 patients (49 females) with ages between 21 and 92 years (mean: 52.8) with severe hypothyroidism (mean TSH levels of 104.1 mUI/L ($\pm$ 34.6), ranging 52.63 mUI/L to 239.53 mUI/L) treated from 2004 to 2018 at our institution with intravenous levothyroxine at variable doses (most frequently 500 micrograms (divided in 400 and 100 micrograms the next day) with a mean dose of 433.3 micrograms and 2.1 ($+0.5$) days of treatment. Hormonal profile and cardiac safety were assessed daily with electrocardiogram studies. Data were analyzed with the Statistical Package for Social Science (SPSS), version 20.0.
Results

	Pre-treatment	2-3 days post	10-30 days post	>30 days post
TSH(mU/L)	104.1 ($\pm$34.6)	69.25 ($\pm$25.7)	18.49 ($\pm$5.7)	7.01 ($\pm$3.4)
Free T4(ng/dl)	0.39 ($\pm$0.16)	0.67 ($\pm$0.3)	1.02 ($\pm$0.3)	1.21 ($\pm$0.3)
Free T3(pg/ml)	2.24 ($\pm$0.6)	2.59 ($\pm$0.7)	2.72 ($\pm$0.6)	2.80 ($\pm$0.4)

Free T4 became normal in 6.33 days, free T3 in 8.4 days and TSH in 33.5 days. No statistical differences after treatment were observed in blood pressure or electrocardiogram studies after analyzing heart rate, PR, QRS and QT intervals Analysis of data in patients aging more than 65 years or with a previous history of cardiac illness did not differ from the entire population. No serious adverse effects were observed (palpitations, angina pectoris, or other cardiac events) despite 17.14% of patients had some kind of previous heart disease. Up to 97.1% of patients described a sudden non-specific improvement of symptoms during admission,and no new admissions or visits to the emergency room were recorded for one month after treatment.
Conclusions
Intravenous intensive levothyroxine treatment in patients with severe hypothyroidism provides a fast and safe relief in clinical symptoms and biochemical alterations with no evidence of serious events. Moreover, our study also provides evidence that it is safe to treat patients older than 65 years with hypothyroidism with a full replacement dose of levothyroxine.

Effect of restoration of thyroid function on body composition, insulin resistance and visfatin concentrations in women with hypo- and hyperthyroidism

Nadia Sawicka-Gutaj[1], Ariadna Zybek-Kocik[1], Michal Kloska[2], Agata Czarnywojtek[1,3], Jerzy Sowiński[1], Dorota Mańkowska-Wierzbicka[4] & Marek Ruchała[1]
[1]Department of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Sciences, Poznan, Poland; [2]Lehigh Valley Health Network, Philadelphia, USA; [3]Department of Pharmacology, Poznan University of Medical Sciences, Poznan, Poland; [4]Department of Gastroenterology, Internal Medicine, Metabolic Diseases and Dietetics, Poznan University of Medical Sciences, Poznan, Poland.

Introduction
The adipose tissue secrets visfatin, that might have metabolic effect. Changes of visfatin serum concentrations have been observed in different thyroid pathologies. Thyroid hormones affect metabolism, thus, both hypo- and hyperthyroidism might significantly alter body composition.
Aims of the study
We aimed to investigate the effect of restoration of euthyroidism on serum visfatin in severe thyroid dysfunction, and its associations with insulin resistance and body composition. To limit the interference of individual factors, we have also analysed changes in three different thyrometabolic states in the same patients.
Patients and methods
The study was designed as an observational with consecutive enrollment. Newly diagnosed females with overt hypo- or hyperthyroidism caused by autoimmune thyroid diseases (Hashimoto's disease or Graves' disease, respectively) were included into the study. Laboratory parameters and body composition were assessed in each patient at the diagnosis and after restoration of thyroid function.
Results
Initially, 105 females were enrolled into the study: 49 hyperthyroid females (median age of 34 years) and 44 hypothyroid females (median age of 46) completed the study. In the hyperthyroid group, visfatin levels increased (<0.0001), while glucose levels decreased (<0.0001) after restoration of euthyroidism. Total body mass and fat mass in the trunk and limbs significantly increased during the treatment. In the hypothyroid group, significant weight loss after treatment resulted from decrease of fat and muscle masses in trunk and limbs. For pooled data of all women and all measurements, weak positive correlation between TSH concentrations and total body weight, as well as fat mass ($r=0.19$, $P=0.01$; $r=0.2$, $P=0.006$, respectively). There was also inverse correlation between FT4 and FT3 and total body weight ($r=-0.246$, $P=0.0008$; $r=-0.17$, $P=0.022$, respectively) and fat mass ($r=-0.16$, $P=0.026$; $r=-0.18$, $P=0.018$, respectively). Visfatin serum concentrations positively correlated with total fat mass ($r=0.19$, $P=0.01$) and insulin levels ($r=0.17$, $P=0.018$).
Conclusions
We may conclude that restoration of thyroid function is not associated with beneficial changes in body composition, especially among hyperthyroid females, reflected by the significant increase of fat mass followed by the increase of circulating visfatin concentrations.

Thyroid-related adverse events in patients treated with Nivolumab and Pembrolizumab

Emilia Sbardella[1], Marta Tenuta[1], Grazia Sirgiovanni[2], Carlotta Pozza[1], Daniele Gianfrilli[1], Paola Mazzotta[1], Carla Pandozzi[1], Enrico Cortesi[2], Andrea Lenzi[1], Alain J Gelibter[2] & Andrea M Isidori[1]
[1]Department of Experimental Medicine, 'Sapienza' University of Rome, Rome, Italy; [2]Department of Oncological Sciences, Unit B, 'Sapienza' University of Rome, Rome, Italy.

Introduction
Immune-Checkpoint Inhibitors (ICI) are frequently associated with thyroid-related adverse events (AE). Several studies analyzed thyroid disfunctions during ICI therapy, but many aspects remain to be characterized, especially for the most recent anti-PD-1 drugs. The aim of this study is to determine incidence and characteristics of PD-1 inhibitors associated thyroid dysfunction.
Methods
We retrospectively analyzed data of patients with advanced solid tumor treated with Programmed Death 1 (PD-1) inhibitors (Nivolumab, Pembrolizumab) in the Oncologic Unit B of Policlinico Umberto I of Rome, from January 2016 to December 2018. All patients performed baseline laboratory evaluations (TSH, FT3, FT4) that were repeated monthly over the duration of therapy.
Results
The cohort consisted of 126 patient, 66.7% males and 33.3% females with a mean age of 66.4 ± 9.7 years, treated for Non Small Cell Lung Carcinoma (73%), Renal Cell Carcinoma (16.7%), Metastatic Melanoma (7.9%) or other tumors (2.4%). 107 received Nivolumab, 19 Pembrolizumab. Thyroid AE occurred in 31.7% of patients and were asymptomatic in the majority (CTCAE grade 1). None of the patients developed grade 3–4 thyroid AE requiring therapy discontinuation. Hypothyroidism occurred in 17.5% of patients: in 15% it was subclinical (high TSH with normal free circulating hormones) and in 2.5% overt hypothyroidism. Mean TSH concentration at the time hypothyroidism was diagnosed was 10.7 ± 7.26 mUI/ml. Hyperthyroidism was observed in 14.3% of patients: in 9.5% subclinical and in 4.8% overt. The rate of thyroid AE was similar in Nivolumab (31.8%) compared to Pembrolizumab (31.6%). The median time of onset of thyroid AE was 6.5 ± 8.1 weeks (range 3–38): 6 ± 9.6 (4–38) for hypothyroidism, and 7 ± 5.7 (range 3–26) for hyperthyroidism. The majority of AE appeared

within the first 3 month (72.5%), none developed after 10 months. Of the 22 patients with hypothyroidism, 63.6% had received a previous treatment with tyrosine-kinase inhibitors (TKI). Logistic regression analysis showed that pre-treatment with TKI was the most potent predisposing factor (OR 8.19, 95%CI: 2.45 to 27.37, $P=0.001$) followed by female gender (OR 3.29, 95%CI: 1.26 to 8.57, $P=0.015$).
Conclusion
Thyroid AE are common during PD-1 inhibitors therapy and usually occur within the first 3 months of treatment, especially in subjects pretreated with TKI. Serial measurement of thyroid function is strictly recommended, especially in these patients, as thyroid disorders can be asymptomatic. No differences were found in thyroid effects between Nivolumab and Pembrolizumab.

Metformin reduces risk of benign nodular goiter in patients with type 2 diabetes mellitus

Chin-Hsiao Tseng
Department of Internal Medicine, National Taiwan University College of Medicine, Taipei, Taiwan.

Background
Whether metformin might affect the risk of benign nodular goiter in patients with type 2 diabetes mellitus has not been investigated.
Methods
Patients with new-onset type 2 diabetes mellitus during 1999-2005 were enrolled from Taiwan's National Health Insurance database. Analyses were conducted in a propensity score matched-pairs of 20,048 ever users and 20,048 never users of metformin. The patients were followed until December 31, 2011 for the incidence of benign nodular goiter. Hazard ratios were estimated by Cox regression incorporated with the inverse probability of treatment weighting using the propensity score.
Results
Among the never users and ever users of metformin, 392 and 221 cases were diagnosed of benign nodular goiter during follow-up, with incidence of 457.88 and 242.45 per 100,000 person-years, respectively. The overall hazard ratio for ever versus never users was 0.527 (95% confidence interval: 0.447−0.621). When cumulative duration of metformin therapy was divided into tertiles, the hazard ratios for the first (<25.3 months), second (25.3–57.3 months) and third (>57.3 months) tertiles were 0.815 (0.643–1.034), 0.648 (0.517–0.812) and 0.255 (0.187–0.348), respectively. Sensitivity analyses estimating the overall hazard ratios for patients enrolled in each specific year from 1999 to 2005 consistently showed a lower risk of benign nodular goiter among users of metformin.
Conclusion
Metformin use is associated with a lower risk of benign nodular goiter.

Background
Primary Adrenal Insufficiency (PAI) is a rare life-threatening disorder. Data on etiology and outcome of PAI in childhood are scanty, with the exception of Congenital Adrenal Hyperplasia (CAH) due to 21-hydroxylase deficiency (21OHD). The aim of our study is to evaluate etiology, morbidity and long-term outcome of PAI in a large cohort of children and characterize clinical presentation in subjects with PAI not due to 21OHD CAH.
Material and methods
802 children followed in 8 tertiary centers were retrospectively included.
Results
85% of patients ($n=682$) had 21OHD CAH and were not reviewed further. Different etiologies were found in 15% subjects ($n=120$): 37.5% had autoimmune PAI (10% isolated; 20.8% Autoimmune Polyendocrinopathy Syndrome type 1; 6.7% Autoimmune Polyendocrinopathy Syndrome type 2); 25% had steroid biosynthetic defects: 11-hydroxylase deficiency ($n=3$), 3β-hydroxysteroiddehydrogenase deficiency ($n=6$), 17α-hydroxylase deficiency ($n=1$), X-linked Adrenal Hypoplasia Congenita due to DAX1 mutations($n=13$), Familial Glucocorticoid Deficiency due to mutation in MC2R ($n=4$) or MRAP ($n=1$) and Glycerol Kinase Deficiency ($n=2$). 20.8% ($n=25$) had adrenoleukodystrophy; 6.7% ($n=8$) had rare syndromes (TripleA, Pearson); 2.5% ($n=3$) had a history of infection or hemorrhage. Finally in 7.5% of patients ($n=9$) no defined etiology was found. Mean age at diagnosis was 6.7 ± 5.2 yrs; time between onset and diagnosis ranged from 0 to 56 months. Common signs/symptoms were fatigue (76.7%), hyperpigmentation (48.3%), dehydration (31.7%), neurologic signs (32.5%) and hypotension (29.2%); most common biochemical finding was increased ACTH (89.2%), followed by hypocortisolism (64.2%) and hyponatremia (50%) whereas hyperkalemia and hypoglycemia were found in 28.3% and 25.8% of subjects, respectively. Overall mortality was <1%.
Conclusion
In our large cohort of pediatric patients with PAI, the most common cause of adrenal insufficiency is CAH due to 21OHD. Among patients with non 21OHD PAI we found that the second most frequent cause was autoimmunitiy, mostly represented by congenital autoimmune polyendocrine syndromes. Other causes were in order represented by rare steroid biosynthetic defects, adrenoleukodystrophy and rare congenital syndromes. 7.5% of our patients still remain without a definite diagnosis. With the exception of hyperpigmentation, which occurs late in the majority of cases, signs and symptoms at presentation of PAI in our cohort were highly aspecific leading to significant delay in diagnosis in particular in older children.

Increased risk of infections in Addison's disease and congenital adrenal hyperplasia patients: a longitudinal study based on a United Kingdom primary care database

Alberto S Tresoldi[1,2,3], Dana Sumilo[4], Mary Perrins[4], Konstantinos A Toulis[4], Alessandro Prete[2,3], Narendra Reddy[5], John A Wass[6], Krishnarajah Nirantharakumar[4] & Wiebke Arlt[2,3]
[1]Endocrinology and Medical Andrology Unit, Humanitas Research Hospital, Rozzano (Milan), Italy; [2]Institute of Metabolism and Systems Research, College of Medical and Dental Sciences, University of Birmingham, Birmingham, UK; [3]Centre for Endocrinology, Diabetes and Metabolism, Birmingham Health Partners, Birmingham, UK; [4]Institute of Applied Health Research, College of Medical and Dental Sciences, University of Birmingham, Birmingham, UK; [5]Department of Diabetes & Endocrinology, University Hospitals of Leicester NHS Trust, Leicester Royal Infirmary, Leicester, UK; [6]Oxford Centre for Diabetes, Endocrinology and Metabolism, Churchill Hospital, Oxford, UK.

Background
Primary adrenal insufficiency (PAI) can be of autoimmune origin (Addison's disease, AD) or due to inborn disorders of steroidogenesis (congenital adrenal hyperplasia, CAH). Prognosis of patients with PAI has improved considerably after glucocorticoid replacement therapy became available. However, even in recent years, an increased risk of death has been described in both AD and CAH patients. Moreover, even with the current state-of-the-art replacement therapy, PAI patients are at an increased risk of hospital admission for infections. However, the risk of primary-care managed infections is unknown.

Methods
We performed a retrospective longitudinal cohort study to estimate the risk of three specific infections (lower respiratory tract – LRTIs, urinary tract – UTIs, gastrointestinal – GIs) and the antimicrobial prescriptions rate in AD and CAH patients using data from a UK primary care database. Patients with a diagnosis of AD or CAH were compared with randomly matched unexposed patients (1:2 ratio).
Results
A diagnosis of AD and CAH was established in 1580 and 602 patients, respectively. Mean age was 51.7 years for AD patients and 35.4 years for CAH patients. All AD patients and 42% of CAH patients were prescribed glucocorticoids, most frequently hydrocortisone (82%) in AD and prednisolone in CAH (50%). Compared to controls, both AD and CAH patients exposed to glucocorticoids had a significantly increased risk of infection (LRTIs: AD adjusted incidence rate ratio (aIRR) 2.11 [95% confidence interval (CI) 1.64–2.70], CAH aIRR 3.33 [95% CI 1.22–9.11]; UTIs: AD aIRR 1.56 [95% CI 1.34–1.83], CAH aIRR 2.24 [95% CI 1.45–3.46]; GIs: AD aIRR 3.74 [95% CI 2.94–4.76], CAH aIRR 1.94 [95% CI 1.06–3.56]). This increased risk was also confirmed by an increased prescription rate for antibiotics (AD aIRR 1.74 [95% CI 1.70–1.78], CAH aIRR 1.44 [95% CI 1.38–1.50]) and antifungals (AD aIRR 1.85 [95% CI 1.71–2.01], CAH aIRR 1.63 [95% CI 1.38–1.91]) in both GC-exposed cohorts.
Conclusions
In this study we demonstrated for the first time a glucocorticoid-driven increase in LRTIs, UTIs and GI infections in AD and CAH patients in a primary care setting, with concurrently increased antibiotics and antifungal prescription rate. Future studies will need to address whether this increased infection risk could be reduced by more physiological GC replacement modes.

Plasma renin concentration is associated with cardiac function and morphology in primary adrenal insufficiency

Peter Wolf, Hannes Beiglböck, Paul Fellinger, Lorenz Pfleger, Stefan Aschauer, Alois Gessl, Siegfried Trattnig, Alexandra Kautzky-Willer, Anton Luger, Yvonne Winhofer, Martin Krssak & Michael Krebs
Medical University of Vienna, Vienna, Austria.

Background
Despite adequate glucocorticoid (GC) and mineralocorticoid (MC) replacement therapy, primary adrenal insufficiency (AI) is associated with an increased mortality, mainly due to cardiovascular disease. The role of MC replacement is not known. Therefore we assessed whether renin concentrations during routine GC and MC substitution therapy are associated with cardiac function and morphology.
Methods
17 patients with AI underwent magnetic resonance (MR) spectroscopy and imaging measurements to assess cardiac function and morphology, ectopic lipid content in myocardium and liver, pericardial fat mass and the ratio of visceral/subcutaneous fat mass. Additionally, blood was drawn to investigate glucose and lipid metabolism. They were compared to 34 healthy controls matched for age and BMI. Patients were divided according to their actual plasma renin concentration at the study visit (Actual-$Renin_{low}$ *vs* Actual-$Renin_{high}$) and their median plasma renin concentration of previous visits (Median-$Renin_{low}$ *vs* Median-$Renin_{high}$).
Results
Ejection fraction was higher (67 ± 5 *vs* $55\pm3\%$; $P=0.001$) and left ventricular mass was lower (60 ± 9 *vs* 73 ± 10 g/m^2; $P=0.025$) in Actual-$Renin_{high}$. Median-$Renin_{high}$ was associated with lower cardiac mass (64 ± 9 *vs* 76 ± 11 g/m^2; $P=0.029$). Blood pressure, glucose and lipid metabolism, as well as ectopic lipid content, pericardial fat mass and visceral/subcutaneous fat were not different between the groups. Compared to controls ejection was significantly lower in patients with AI (56 ± 4 *vs* $63\pm8\%$; $P=0.019$). No differences were found in patients with $\leq$ 20 mg compared to $>$ 20 mg hydrocortisone per day.
Conclusions
Higher renin concentrations are associated with more favorable cardiac function and morphology in patients with primary AI.

Background and aims
Recommendations for the management of pregnancies in patients with adrenal insufficiency (AI) are scarce. The aim of this study was to analyse current clinical approaches in seventeen specialized centers across Europe with a particular focus on maternal and fetal outcome.
Patients
95 pregnancies in 86 patients with AI of different aetiology [Addison's disease ($n=37$), secondary AI ($n=22$), congenital adrenal hyperplasia (CAH) ($n=22$), or other reasons of AI including bilateral adrenalectomy ($n=5$)] were followed since 2013. Clinical and biochemical parameters and treatment details were assessed before and during pregnancy and maternal and fetal outcomes were recalled.
Results
66.3% (59/89) of the pregnancies were substituted with hydrocortisone in two or three daily doses while 14.6% (13/89) were treated with modified hydrocortisone, 9% with prednisolone, 5.6% with cortisone acetate and 6.7% with a combination of different steroids. The mean hydrocortisone equivalent dose before pregnancy was significantly lower in comparison to that during pregnancy (21.0 ± 7.7mg/day before vs. 23.1 ± 8.0 during 1st trimester, 25.5 ± 10.6 during 2nd trimester und 25.9 ± 8.3 during 3rd trimester) but did not differ significantly between trimesters. Fludrocortisone was used in 92.9% of the Addison's cases and in 39.1% of women with CAH before pregnancy and dosage was increased in 51% (23/45) of patients. Overall, in 63.1% of all cases glucocorticoid or mineralocorticoid dosage was adapted at least once during pregnancy. For delivery, in 55.3% (47/85) of all pregnancies caesarian section was performed while only in 8/47 cases the reason was clearly documented or was conducted as an emergency procedure. Hydrocortisone administration during delivery varied among different centers with no clearly standardized practice followed. Considering the outcome, 24 of 86 women (27.9%) had a documented history of at least one previous abortion with further three miscarriages taking place during the first trimester within the observation interval. While no maternal or fetal deaths occurred later during pregnancies, in 7/95 pregnancies minor complications for maternal and in 3/95 for fetal outcome were reported.
Conclusion
Overall, these retrospective data indicate good maternal and fetal outcome of pregnancies in AI patients. However, optimized treatment adjustments during pregnancy and appropriate approaches during delivery remain challenging, considering the lack of evidence-based guidelines. A remaining proportion of reported adrenal crisis during pregnancy and histories of abortion highlight the need for appropriate education of patients and treating physicians as well as early diagnosis of adrenal insufficiency in general.

Pneumocystis pneumonia as a major complication of medical treatment for severe Cushing's syndrome linked either to ectopic ACTH secretion or to Cushing's disease

Justine Cristante[1], Michel Mallaret[2], Laura Tourvieilhe[2], Agnès Carreau[3], Tiphaine Vaillant[4], Isabelle Yoldjian[4] & Olivier Chabre[5]
[1]Endocrinologie CHU Grenoble Alpes, Grenoble, France; [2]Pharmacovigilance CHU Grenoble Alpes, Grenoble, France; [3]Endocrinologie CH Annecy Genevois, Annecy, France; [4]Agence Nationale de Sécurité du Médicament, Paris, France; [5]CHU Grenoble Alpes, Grenoble, France.

Several cases of pneumocystosis developing after lowering cortisol serum level have been reported, mostly in patients with ectopic Cushing's syndrome. We report here 2 cases of pneumocystosis which developed after initiation of treatment with metyrapone, one in a patient with Cushing's disease, and the second in a patient with ectopic ACTH secretion by a prostate endocrine carcinoma. Both cases presented severe Cushing's syndrome. We then analyzed the periodic safety update report (PSUR) on metyrapone from 02/2012 to 06/2018 and the litterature Patient 1, a 39 year-old-woman, was diagnosed with severe Cushing's disease and metyrapone treatment was started to improve her condition before pituitary surgery. She developed respiratory symptoms 4 days after starting treatment. Patient 2, a 82 year-old-man, was diagnosed for an ectopic Cushing's syndrome due to endocrine prostate cancer, with diffuse bones metastasis. Respiratory failure occurred 30 days after metyrapone treatment initiation. In both cases, chest CT scan performed after development of dyspnea showed lesional pulmonary oedema and Broncho alveolar lavage (BAL) allowed identification of Pneumocystis jirovecii by PCR (in patient 2, co infection with CMV). Both patients were treated by trimethoprim-sulfametoxazole. Patient 1 was cured, but patient 2 died several days later from severe sepsis with multivisceral failure. Analysis of PSUR identified 5 cases of pneumocystosis, none of which were letal. Analysis of the literature identified 12 cases of pneumocystis jirovecii pneumonia linked to metyrapone in patients with very high levels of cortisol and other cases revealing several days after lowering cortisol levels either with ketoconazole, etomidate bromide or mifepristone. Physiopathology remains unclear but the hypothesis of immune reconstitution inflammatory syndrome is compelling: on the one hand, severe hypercorticism leads to an immunodepression state which favors the colonization by opportunistic organisms, and on the other hand it decreases inflammatory response, which delays apparition of symptoms. After lowering cortisol level, recovery of immunity might trigger an inappropriate host inflammatory response as part of a 'cytokine storm', which would make clinical features appear. These case reports should draw attention to the risk for a potentially letal pulmonary infection that may reveal only after initiation of medical therapy aimed at lowering cortisol levels, in patients with severe Cushing's syndrome who do not show any pulmonary symptoms initially. This risk might justify systematic prophylactic treatment with trimethoprim-sulfametoxazole in such patients, a treatment which is so far not clearly recommanded in the current guidelines.

Diagnostic accuracy of captopril challenge test and saline infusion test in patients at high risk for primary aldosteronism

Filippo Ceccato[1], Mattia Barbot[1], Chiara Sabbadin[1], Jacopo Lolli[1], Giorgia Antonelli[2], Mario Plebani[2], Marco Boscaro[1] & Carla Scaroni[1]
[1]Endocrinology Unit, Department of Medicine DIMED, University-Hospital of Padova, Padova, Italy; [2]Laboratory Medicine Unit, Department of Medicine DIMED, University-Hospital of Padova, Padova, Italy.

Background and aim
Aldosterone-to-Renin Ratio (ARR) is recommended as initial test to screen for Primary Aldosteronism (PA), especially in high-risk hypertensive population. Endocrine Society (ES) Guidelines recommend that patients with an increased ARR should undergo one or more confirmatory tests in order to confirm or exclude PA diagnosis. Captopril Challenge Test (CCT) and Saline Infusion Test (SIT) are commonly used in routine clinical practice. The aim of our study was to evaluate the diagnostic accuracy of CCT and SIT in a large series of hypertensive patients with increased ARR.
Materials and methods
We retrospectively analysed data of 230 CCT and 120 SIT of 272 hypertensive patients (95 with PA and 177 with essential hypertension [EH]) with increased basal ARR (>30 ng/dL/ng/ml/h or >91 pmol/L/mU/L). Aldosterone was measured with radioimmunometric assay (RIA) and ARR calculated with Plasma Renin Activity (PRA) until April 2015; then Aldosterone was measured with electrochemiluminescence assay (ECLIA) and ARR calculated with Direct Renin Concentration (DRC). The accuracy of post-CCT ARR and post-SIT plasma aldosterone values for confirming PA was estimated with the area under the receiver operator curve (ROC), performed with SPSS, significance set at $P<0.05$.
Results
The median of post-CCT ARR, calculated both with PRA and with DRC, and post-CCT plasma aldosterone values, both in RIA and in ECLIA, were significantly higher in PA than in EH, as expected ($P<0.001$). Even the median of post-SIT plasma aldosterone values, both in RIA and in ECLIA, were significantly higher in PA than in EH ($P<0.001$). The ROC of post-CCT ARR and post-SIT plasma aldosterone values were 0.839 and 0.888, respectively, showing comparable diagnostic accuracy with a sensitivity of 75.8% and 83.3% and a specificity of 84.6% and 89.2, respectively. The optimal post-CCT ARR cutoff for identifying PA was 31 ng/dL/ng/ml/h, while the optimal plasma aldosterone cutoff value was 15.8 ng/dL post-CCT and 7 ng/dL post-SIT.
Conclusions
Post-CCT ARR, post-CCT and post-SIT plasma aldosterone values were all reliable for PA diagnosis, showing comparable diagnostic accuracy, especially to exclude rather than to confirm the PA. The optimal cutoffs were in line with those recommended by the ES.

Comparison of whole-genome expression analysis in patients with secondary adrenal insufficiency treated with conventional treatment versus modified-release hydrocortisone

Tania Pilli[1], Sandro Cardinale[1], Raffaella Forleo[1], Silvia Cantara[1], Manuela Ferracin[2], Cristian Bassi[3], Massimo Negrini[3] & Maria Grazia Castagna[1]
[1]Department of Medical, Surgical and Neurological Sciences, University of Siena, Siena, Italy; [2]Department of Experimental, Diagnostic and Specialty Medicine (DIMES), University of Bologna, Bologna, Italy; [3]Department of Morphology, Surgery and Experimental Medicine, University of Ferrara, Ferrara, Italy.

Background
Conventional treatment (cortisone acetate or hydrocortisone) of adrenal insufficiency (AI) is potentially associated with glycometabolic alterations, bone loss and reduced quality of life. There is an increasing evidence of a more physiological replacement therapy with modified-release hydrocortisone (Plenadren).
Aim
The objectives of our study were: 1) to compare the gene expression profile of patients under conventional treatment and Plenadren versus healthy controls; 2) to evaluate the effects of Plenadren on glucose, lipid and bone metabolism and clinical parameters.
Materials and Methods
Eleven patients with primary (PAI) and 13 with secondary (SAI) AI were switched from conventional treatment to Plenadren at equivalent dose. Basally, 1 and 3 months after Plenadren, a whole-genome expression analysis was performed in PBMC of 6 patients with SAI and in 6 age and sex-matched healthy controls. Clinical and metabolic parameters (body weight, BMI, blood pressure, HbA1c, total, HDL and LDL cholesterol, triglycerides) and bone turnover markers (osteocalcin, bone alkaline phosphatase [BAP], serum cross-laps [CTX]) were measured, at baseline and 1, 3, 6, 12, 18 and 24 months after Plenadren in patients with PAI and at baseline, 1 and 3 months after modified-release hydrocortisone in patients with SAI.
Results
1) The number of genes differentially expressed (mainly involved in inflammation and immune response) in treated patients compared to healthy controls was higher in samples collected under conventional treatment (t0, $n=247$) than 3 months after Plenadren (t3, $n=114$) and the global gene expression profile after Plenadren was more similar to healthy subject. 2) On Plenadren treatment we observed a decrease of LDL-cholesterol (up to 27.4%), systolic (3.7%) and diastolic (11.2%) blood pressure, fat mass (13.5%) and an increase of lean mass ($+9.2\%$), CTX and BAP, mainly in patients with PAI at 24 months, while HbA1c and T-score remained stable and triglycerides tended slightly to increase.
Conclusions.
Modified-release hydrocortisone may restore a normal gene expression profile and improve metabolic and bone parameters in AI patients compared to the conventional therapy.

New perioperative imaging techniques, immunohistochemistry and genetic analysis to investigate the suitability of laparoscopic partial adrenalectomy in primary aldosteronism

Elle van de Wiel[1], Benno Küsters[1], Andor Veltien[1], Kuniaki Mukai[2], Jaap Deinum[1] & Johan Langenhuijsen[1]
[1]Radboudumc, Nijmegen, Netherlands; [2]Keio University, Tokyo, Japan.

Introduction & Objectives
A laparoscopic radical adrenalectomy is the standard treatment option for unilateral primary aldosteronism. Partial adrenalectomy for solitary adenomas has been suggested to be feasible and adrenal cortex-sparing. However, solitary adenomas may be rare. The purpose of this study was to assess whether partial adrenalectomy in patients with a seemingly solitary adenoma might be worthwhile by relating perioperative imaging to pathologic findings of excised adrenal glands.
Materials & Methods
Fifteen patients with unilateral primary aldosteronism, based on preoperative CT scan and adrenal vein sampling, were treated by laparoscopic total adrenalectomy. We compared findings of intraoperative EUS, ex-vivo MRI of the adrenal specimen (using a 11.7T MR system), immunohistochemistry (CYP11B2 and CXCR4, a recently described marker for aldosterone producing adenomas) and mutation analysis (KCNJ5, ATP1B2, ATP2B3, CTNNB1) regarding the presence of a solitary adenoma or multinodular hyperplasia.
Results
Considering the final pathology report as the gold standard, sensitivity and specificity to detect multinodular glands with EUS were 41.6% and 33.3%, respectively. Ex-vivo MRI identified thirteen of fifteen adrenals (87%) as multinodular where the pathologist initially classified seven of fifteen (47%) adrenals as multinodular. In the final pathology report, wherein the pathologist combined ex-vivo MRI and histology, the pathologist classified twelve of fifteen (80%) adrenals as multinodular. Immunohistochemistry showed in four of twelve (33%) multinodular glands more than one nodule positive for aldosterone synthase. All nodules positive for aldosterone synthase were also positive for CXCR4. In four of fifteen adrenals (27%) somatic mutations were present. In every gland with a mutation only one nodule harbored this mutation, irrespective of glands with multiple aldosterone synthase positive nodules.
Conclusions
In this study we show that intraoperative endoscopic ultrasound is not sensitive enough to detect multinodular glands. Ex vivo MRI and immunohistochemistry detect adrenal nodules that are frequently missed by routine histopathology. Some of these usually small nodules also produce aldosterone. The results from our study show that multinodular hyperplasia is common and questions suitability of partial adrenalectomy in primary aldosteronism because a solitary adenoma cannot reliably be proven pre- or intraoperatively, not even by EUS.

Evaluation of clinical and biochemical cure and adrenal CYP11B2 and CYP11B1 immunostaining in primary aldosteronism operated after adrenal venous sampling

Niina Matikainen[1], Pasi I Nevalainen[2], Minna Soinio[3], Celso Gomez-Sanchez[4], Tiina Vesterinen[5] & Helena Leijon[5]
[1]1Endocrinology, Helsinki University Hospital and Helsinki University, Helsinki, Finland; [2]Department of Internal Medicine, University of Tampere, Tampere, Finland; [3]Department of Endocrinology and Turku PET Center, University of Turku, Turku, Finland; [4]G.V (Sonny) Montgomery VA Medical Center and University of Mississippi Medical Center, Jackson, MS, USA; [5]Department of Pathology, University of Helsinki, and HUSLAB, Helsinki University Hospital, Helsinki, Finland.

Background
The cure of unilateral primary aldosteronism (PA) after adrenalectomy can result in complete, partial or absent biochemical and clinical improvement[1]. Histological findings from HE samples are of little assistance in determining if adenoma or hyperplastic adrenal tissue is hormonally overactive. Our aim in the present study was to compare immunohistochemical (IHC) CYP11B1 and CYP11B2 staining in adrenal slices to histological diagnosis based on H&E staining.
Methods
We identified prospectively 34 patients with confirmed PA[2]. Surgery was based on lateralization of aldosterone concentration in AVS in 33 patients and on lateralization of ^{11}C-metomidate PET and CT findings in one patient. Post-operatively, clinical and biochemical cure were evaluated at about 3 months. Both H&E and immunohistochemical expression of CYP11B1 and CYP11B2 (rat monoclonal anti-human CYP11B1–80–ndash;7 and mouse monoclonal anti-human CYP11B2–41–17 primary antibodies[3]) were analyzed in 3.5 μm thick adrenal slices in one representative slide from each case. In addition to IHC analysis of aldosterone-producing adenomas (APAs) and hyperplasia, small extranodular CYP11B2 positive cell clusters, so-called aldosterone-producing cell clusters (APCCs) were identified.
Results
After adrenalectomy, 32/34 showed clinical partial or complete cure and 31/32 (data missing for two) biochemical partial or complete cure. The mean aldosterone concentrations, ARR, BP and potassium concentration improved significantly ($P<0.001$ for all). The number of antihypertensive agents used decreased from 2.5 to 1.0 and DDD decreased by 50% ($P<.001$ for both). In H&E staining, 22/34 (65%) subjects were diagnosed with APA and 11/34 (32%) with hyperplasia. One subject did not reveal pathologic findings in H&E. All adrenal samples showed CYP11B2 positivity and most some CYP11B1 positivity. The IHC diagnosis was APA in 16/34 (47%), hyperplastic leading nodule 13/34 (38%) and hyperplasia presenting as APCCs in only 6/34 (18%) subjects. IHC staining with CYP11B2 changed the diagnosis from APA to hyperplasia in 6/34 (18%) and from no pathologic findings to APA in 1/34 (3%). One subject with cortical hyperplasia showed CYP11B1 but not CYP11B2 positivity in main nodule together with multiple CYP11B2 positive APCCs. The degree of biochemical cure did not differ between hyperplasia and APA subgroups.
Conclusions
With IHC staining for CYP11B2, the proportion of histological APA diagnoses decrease. APCCs may be significant source of aldosterone excess in some subjects with PA. IHC staining of adrenal tissue improves subtype diagnostics of PA.

Sexual function in adrenal insufficiency: data from the DREAM trial

Valeria Hasenmajer[1], Emilia Sbardella[1], Carlotta Pozza[1], Chiara Simeoli[2], Paola Mazzotta[1], Claudio Lecis[1], Andrea Lenzi[1], Rosario Pivonello[2], Emmanuele Angelo Jannini[3], Daniele Gianfrilli[1] & Andrea Marcello Isidori[1]
[1]Department of Experimental Medicine, 'Sapienza' University of Rome, Rome, Italy; [2]Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Università Federico II di Napoli, Naples, Italy; [3]Department of Systems Medicine, University of Rome 'Tor Vergata', Rome, Italy.

Introduction
Adrenal Insufficiency (AI) is characterized by absolute or relative deficiency of glucocorticoids and adrenal androgen precursors. Patients with AI show an impaired quality of life, metabolic status, immune function and dysregulated circadian genes. Data on sexual function are scarce and often contradictory. The aims of the present study are to evaluate sexual dysfunction (SD) in women and men patients with AI and to investigate the effects of restoring a more physiological circadian rhythm of glucocorticoid administration on sexual function.
Methods
Outcome assessors blinded, randomized, multicenter, active comparator clinical trial. 89 AI patients and 25 adrenal-sufficient matched controls were enrolled in the DREAM trial. AI patients on established multiple times a day glucocorticoid therapy were randomly assigned to continue their therapy or to switch to an equivalent dose of once-daily, modified-release hydrocortisone. 63 patients (34 women and 29 males) consented and completed sexual function evaluation (FSFI, IIEF-5 and AddiQoL questionnaires and hormonal evaluation) at enrollment and study completion (24 weeks).
Results
Sexual dysfunction was found highly prevalent in men (30%) and pre-menopausal AI women (45%); in menopausal AI women it was even more frequent (85.7%), but similar to the general population. In AI women, sexual health positively correlated with duration of disease ($P=0.008$) and estrogenic status ($P=0.007$). The questionnaire's domain for 'arousal' negatively correlated with age. In pre-menopausal women there was no correlation with androgen levels, while sexual function positively correlated with the 'Symptom' score of AddiQoL ($P=0.022$).

In post-menopausal patients there was a positive correlation of sexual function with testosterone levels ($P=0.008$). In males, erectile dysfunction significantly correlated with quality of life ($P=0.020$), while there was no correlation with age, androgen levels and metabolic profile. At 24 weeks there was no detectable difference in sexual function between randomization groups (standard *vs.* switch).
Conclusions
Young patients with AI show an increased prevalence of sexual dysfunction. Sexual health correlated with estrogen levels and duration of disease in women and with QoL in men. Restoring a better circadian profile of glucocorticoid therapy was not effective in improving sexual function. The lack of correlation with androgens in males and pre-menopausal women suggest that sexual dysfunction in AI has a more complex multifactorial etiology.

Background
Adrenal insufficiency (AI) results from deficient production/action of glucocorticoids (GCs), with or without deficiency of mineralocorticoids (MC) and adrenal androgens. GC treatment is essential but some patient needs MC therapy to allow sodium(Na^+) retention, potassium(K^+) excretion and to maintain normal plasma volume and blood pressure. Much attention has focused on optimization of GC replacement but no consensus exists for optimization of MC therapy in primary AI. Our aim was to explore the relationship between MC dose, Plasma renin concentration (PRC) and clinically important variables to determine the most helpful in guiding MC dose titration.
Design
We performed an observational, retrospective analysis on 1107 assessments from 281 patients (242 with salt-wasting CAH(SW-CAH) and 39 with Addison's disease(AD)) recruited from local databases and the international congenital adrenal hyperplasia registry (www.i-cah.org). Subgroup analysis was made in adult patients (age$>=$18years) and a longitudinal analysis performed in 92 patients with SW-CAH(median time between assessments 560 days,range 33–2082). PRC, electrolytes, BP and anthropometric parameters were assessed for their utility in optimizing MC replacement dose.
Results
PRC (normal range 11-32 μUI/mL) was low, normal or high in 30%,15% and 55% of patients respectively with wide variability in MC dose (37.7%, 16.6%, 15.4% and 11.7% of patients were on fludrocortisone 100.50.150 and 200 μg/day respectively) and PRC (median 47 μUI/mL, range 0.1–3166). Patients with high PRC had lower Na^+ levels (with no change in K^+), higher mean arterial pressure (MAP), BMI, age and were on the highest total daily MC dose. Univariate analysis demonstrated a direct relationship between MC dose and PRC ($P<0.001$), and an inverse correlation with potassium ($P<0.001$). Using multiple regression modelling, only Na^+ was able to predicted PRC. MC dose predicted K^+, but not MAP or PRC. In the longitudinal analysis, Na^+ concentration at final follow-up visit was associated with the change (Δ) in PRC (B$=$139.538, $P<0.001$). There was no relationship between ΔPRC and final MAP, K^+ or MC dose. No correlation was found between ΔMC dose and ΔPRC,K^+, Na^+ or MAP. Observations were similar in patients with SW-CAH and AD.
Conclusions
The lack of relationship between MC dose and PRC calls into question its utility as an aid to optimise and titrate MC replacement dose. This may reflect variability in sampling with respect to posture, timing and concomitant medications, but suggests that in clinical practice, emphasis should be placed on ensuring normalization of serum electrolytes in the optimization of MC replacement.

Introduction
Primary aldosteronism (PA) is a major cause of secondary hypertension. The two major forms of sporadic PA (aldosterone producing adenoma – APA and bilateral adrenal hyperplasia – BAH) can only be reliably differentiated by adrenal venous sampling (AVS). Several mutations have been described for APA, but the pathogenesis of BAH is poorly elucidated. Differentiation of APA and BAH is clinically pivotal, as their treatment is different. There is no blood-borne marker for the differentiation of APA and BAH.
Aims
To determine and compare the circulating microRNA expression profiles of AVS-confirmed APA and BAH plasma samples, and to evaluate their applicability as minimally invasive markers.
Methods
81 AVS-confirmed plasma samples were included (43 APA and 38 BAH). Next-generation sequencing (NGS) on 30 EDTA-anticoagulated plasma samples (16 APA and 14 BAH) was performed by Illumina MiSDefault (discovery cohort) . Significantly differentially expressed microRNAs were validated by real-time RT-qPCR. The validation cohort included 30 samples of the discovery cohort (technical validation) and further 27 APAs and 24 BAHs.
Results
We have found relative overexpression of *miR-30e-5p, miR-223-3p, miR-30d-5p* and *miR-7-5p* in BAH compared to APA by NGS. Validation of 81 samples showed significant overexpression ($P=0.03$) of *miR-7-5p* in BAH samples compared to APA samples. A negative predictive value of 86.7% could be achieved to exclude BAH by a *miR-7-5p* dCT cut-off value of -18.9. No correlation between dCT values and hormonal parameters was found. APA samples displayed considerable heterogeneity in circulating microRNA expression, whereas BAH were much more homogeneous.
Conclusion
APA is more heterogeneous at the microRNA level compared to BAH. *miR-7-5p* was significantly overexpressed in BAH samples compared to APA samples, but its sensitivity and specificity values are not good enough for introduction to the clinical practice at present.

[12]INSERM UMR 970, Paris Cardiovascular Research Center, PARIS, France.

Objective
Primary aldosteronism (PA) is the first cause of endocrine hypertension accounting for about 6% of all cases of hypertension. According to international guidelines, PA screening is based on plasma aldosterone-to-renin concentration ratio (ARR) computation. Nevertheless, measurement of urine aldosterone excretion may be of interest since it integrates aldosterone secretion over 24 hours. However, available urine aldosterone immuno-assays have poor specificity.
Design and method
In this context, we developed a new aldosterone assay using liquid chromatography and tandem mass spectrometry detection (LC-MS/MS) to recover specifically urine free aldosterone and glucuronide metabolites after 18-hour acid hydrolysis. Our method was validated according to FDA recommendations, and covers the expected range of aldosterone concentrations found in 24-hour urine collection (from 1.10 to 75 nM) with improved specificity. It has a within-run precision below 2% and a maximum between-run precision of 5.6%. The diagnostic performance of the assay was assessed in a cross-sectional retrospective study that included 234 subjects: 63 healthy volunteers (HV), 107 patients with essential hypertension (EH) and 64 PA patients. Final diagnosis was based on routine hormone measurements in accordance with international guidelines.
Result
Median (5th to 95th percentile) of 24-hour urine aldosterone excretion was 19.5 (5.2–53.4) nmol/24h in HV, 39.1 (13.3–97.4) nmol/24h in EH and 91.4 (40.6–225.3) nmol/24h in PA subjects. By ROC curve analysis (area 0.864), a cutoff value of aldosterone excretion of 65 nmol/24h yielded a 76.6% sensitivity and 78.5% specificity to discriminate PA from EH patients. 24-hour urinary aldosterone:creatinine ratio was more discriminant than 24-hour aldosterone excretion, with ratios (nmol/mmol) of 1.42 (0.5–3.9) for HV, 3.4 (1.3–7.9) for EH and 6.9 (2.5–30.0) for PA. By ROC curve analysis (area 0.867) a cutoff value of 24-hour urinary aldosterone:creatinine ratio of 5.0 nmol/mmol had 81.3% sensitivity and 81.3% specificity to discriminate PA from EH patients. Finally, 11% of our 64 PA patients showed a urinary aldosterone: creatinine ratio above this suggested cutoff value while ARR was below cut-off value.
Conclusion
In conclusion, LC-MS/MS measurement of urinary aldosterone is a specific, sensitive and effective method that could improve the screening of PA.

A liver selective knockdown of Dpp4 by therapeutic siRNA affects lipid metabolism but fails to improve glucose control in diabetic mice

Sven Wolfgang Görgens, Kerstin Jahn-Hofmann, Christiane Metz-Weidmann, Uwe Schwahn, Paulus Wohlfart, Matthias Schäfer & Maximilian Bielohuby
Sanofi-Aventis Deutschland GmbH, R&D, Industriepark Hoechst, Frankfurt, Germany.

Objective
The exopeptidase dipeptidyl peptidase 4 (Dpp4) selectively cleaves N-terminal dipeptides from several substrates, including cytokines, growth factors, neuropeptides, and the incretin hormones. The systemic inhibition of Dpp4 by the so-called gliptins (oral Dpp4 inhibitors) represents an effective and established treatment option for type 2 diabetes (T2D). In the current study we investigated in healthy as well as in obese and diabetic mice if a liver selective knock-down of Dpp4 by therapeutic siRNAs could be a novel, similarly effective treatment option for T2D. Liver selective inhibition of Dpp4 by therapeutic siRNAs could potentially reduce unwanted side effects which are induced by systemic inhibition and has the potential to exert a sustained, long-lasting effect compared to the established daily oral treatment regimen. Furthermore, effects on hepatic steatosis, inflammation and lipid metabolism were analyzed in mice after hepatoselective Dpp4 knock-down.
Methods
The knock-down efficacy and IC_{50} values of siRNAs targeting Dpp4 were analyzed in PC3 cells. Diabetic db/db, respective lean controls and lean C57BL/6J mice were injected intravenously with a liposomal formulation of siRNAs targeting Dpp4 (3 injections during 13 days for C57BL/6 mice and 5 injections during 30 days for db/db mice). Mice were metabolically characterized by standard procedures approx. 2 weeks after knockdown of Dpp4. Additional mice were treated with an oral Dpp4 inhibitor as a positive control.
Results
In both mouse models we observed a robust knock-down ~75% of hepatic Dpp4. As expected, the systemic inhibition of the enzymatic Dpp4 activity by an oral inhibitor significantly improved glucose handling and reduced circulating IL-6 levels in diabetic animals. In contrast, the reduction of hepatic Dpp4 production via therapeutic siRNAs does not affect circulating active GLP-1/GIP levels and consequently also no modulation of glucose metabolism was observed in mice (as demonstrated by oGTT and fasting glucose and insulin concentrations). Furthermore, treated db/db mice did not display significant improvements of hepatic steatosis. However, circulating cholesterol and hepatic mRNA expression of genes involved in lipid metabolism, namely *Acaca*, *Scd1*, *Fasn* and *Pparg* were significantly reduced after Dpp4 siRNA treatment.
Conclusion
These results point out that the major source for circulating Dpp4 is probably not the liver and therefore hepatic Dpp4 silencing seems to be not an appropriate tool for the treatment of T2D. However, hepatocyte-derived Dpp4 regulates liver lipid metabolism, potentially though paracrine mechanisms. Thus, targeting this pathway may have benefits that are distinct from those observed with systemic oral Dpp4 inhibitors.

GP201

Blood intact incretin levels are related to beta-cell function and glycemia in patients with type 2 diabetes

Yeekyoung Ko[1], Soyeon Yoo[1,2] & Gwanpyo Koh[1,2]
[1]Department of Internal Medicine, Jeju National University Hospital, Jeju, Republic of Korea; [2]Department of Internal Medicine, Jeju National University School of Medicine, Jeju, Republic of Korea.

We performed this study to identify factors related to intact incretin levels in patients with type 2 diabetes (T2D). We cross-sectionally analyzed 336 patients with T2D. Intact glucagon-like peptide 1 (iGLP-1) and intact glucose-dependent insulinotropic polypeptide (iGIP) levels were measured in a fasted state and 30 min after ingestion of a standard mixed meal. The differences between 30 and 0 min iGLP-1 and iGIP levels were indicated as ΔiGLP-1 and ΔiGIP. After ingestion of a mixed meal, iGLP-1 (5.5 ± 3.0 to 10.4 ± 7.0 pmol/l; $P < 0.001$) and iGIP (3.8 ± 3.8 to 21.5 ± 7.1 pmol/l; $P < 0.001$) levels increased by 190% and 570%, respectively. In simple correlation analyses, fasting iGLP-1 was positively correlated with glucose ($r = 0.199$; $P < 0.001$), C-peptide ($r = 0.137$; $P < 0.05$), creatinine ($r = 0.124$; $P < 0.05$) and triglyceride ($r = 0.112$; $P < 0.05$) levels, and negatively correlated with eGFR ($r = -0.139$; $P < 0.05$). ΔiGLP-1 was positively correlated only with ΔC-peptide levels ($r = 0.194$; $P < 0.001$). Fasting iGIP showed positive correlations with HbA1c ($r = 0.146$; $P < 0.01$), fasting glucose ($r = 0.126$; $P < 0.05$) and C-peptide ($r = 0.153$; $P < 0.01$) levels, and negative correlations with ΔC-peptide ($r = -0.183$; $P < 0.01$) and HDL cholesterol ($r = -0.124$; $P < 0.05$) levels. ΔiGIP was negatively correlated with diabetes duration ($r = -0.118$; $P < 0.05$) and HbA1c ($r = -0.196$; $P < 0.001$) levels, and positively correlated with ΔGlucose ($r = 0.210$; $P < 0.001$) and ΔC-peptide ($r = 0.238$; $P < 0.01$) levels. In multivariate analyses adjusting for age, sex, and covariates, fasting iGLP-1 levels were significantly related to fasting glucose ($\beta = 0.189$, $P < 0.01$) and creatinine ($\beta = 0.158$, $P < 0.05$) levels, ΔiGLP-1 levels were positively related to ΔC-peptide levels ($\beta = 0.194$, $P < 0.001$), fasting iGIP levels were related to fasting C-peptide levels ($\beta = 0.160$, $P < 0.01$) and female sex ($\beta = 0.124$, $P < 0.05$), and ΔiGIP levels were positively related to ΔC-peptide ($\beta = 0.165$, $P < 0.01$) and Δglucose ($\beta = 0.138$, $P < 0.05$) levels. Taken together, intact incretin levels are primarily related to C-peptide and glucose levels. This result

suggests that glycemia and insulin secretion are the main factors associated with intact incretin levels in T2D patients.

The growth hormone effect blocked with pegvisomant did not alter the free fat acid plasma concentration in pre-diebetic or type 2 diabetic patients treated with empagliflozin

Aline Franco da Rocha[1], Paulo Sergio Pereira Junior[1], Gabriela Simonetti Calefi[1], Helena Kaminami Morimoto[1], Guilherme Figueiredo Marquezine[1], Tania Longo Mazzuco[1], Eliana Cotta de Faria[2], Mariana Ragassi Urbano[1] & Alexandre Jose Faria Carrilho[1]
[1]Universidade Estadual de Londrina, Londrina, Brazil; [2]Universidade Estadual de Campinas, Campinas, Brazil.

Context
Sodium-glucose cotransporter 2 (SGLT2) inhibitors induce glycosuria and improve glycemic control, β cell function and insulin sensitivity in type 2 diabetes mellitus (DM2). On the other hand, these drugs predispose to diabetic ketoacidosis by increasing the tonus of glucagon. Glucagon acts on the liver and has no relevant effect on peripheral lipolysis and release of free fatty acids (FFA) as a substrate for ketogenesis, an action attributed to growth hormone (GH). This study aimed to evaluate the role of GH in promoting FFA disposal for ketogenesis in pre-diabetic or DM2 patients treated with empagliflozin 25mg daily.
Design and methods
Seventeen individuals were included in the study. They were all over 18 years old, both sexes, with pre-diabetes or DM2 without use of any antidiabetic drug, excepted metformin; body mass index between 25 and 40 kg/m^2 and HbA1c $>$ 5.7 and $<$11%. Exclusion criteria were: presence of microalbuminuria or chronic renal disease, pregnancy, previous bariatric surgery, liver or heart disease that has repercussion on glycemic control and uncontrolled thyroid dysfunction. After an overnight fast, the participants were submitted to tests where blood samples were obtained at the times: -60, 0, 30, 60, 90, 120, 180, 240 minutes. At time -60 was administrated placebo (test 1) or empagliflozin 25 mg (test 2 and 3). All individuals ate a standard meal (1 boiled egg, parmesan cheese 50 g and bread 125 g) at time 0. After the test 1, all subjects were instructed to take empagliflozin 25 mg daily and the same procedure was done on day 21(test 2) and 28 (test 3). Thirty-six hours before the test 3, all subjects received pegvisomant 30 mg subcutaneous. Plasma concentrations of insulin, glucose, triglycerides, glucagon, GH, total cholesterol and fractions, FFA and IGF-1 were measured.
Result
When we compared to placebo (test 1), the treatment with empagliflozin diminished the plasma levels of glucose (-15.1, -16.7%, $P < 0.05$), insulin (-20.0, -23.3% $P < 0.05$), insulin/glucagon ratio (-21.6, -32.0%, $P < 0.05$) and FFA (-20.3, -23.4%, $P < 0.05$); and also increased the plasma glucagon levels (7.9, 10.7%, $P < 0.05$) - for test 2 and test 3 vs test 1, respectively for all. As expected, the plasma GH concentrations did not alter between test 1 and test 2, but increased dramatically at test 3 (3885%).
Conclusion
Blocking the effect of GH with pegvisomant did not alter the plasma concentrations of FFA in pre-diabetes or DM2 patients treated with empagliflozin.

Effects of cardiovascular function of SGLT-2 inhibitos versus DPP–4 inhibitors in type 2 diabetes with coronary artery disease

Chong Hwa Kim[1], Su Jin Jung[1], Ji Oh Mok[2], Ki Young Lee[3] & Sung Rae Kim[4]
[1]Division of Endocrinology and Metabolism, Department of Internal Medicine, Sejong General Hospital, Bucheon, Republic of Korea; [2]Division of Endocrinology and Metabolism, Department of Internal Medicine, Soonchunhyang University Bucheon Hospital, Bucheon, Republic of Korea; [3]Division of Endocrinology and Metabolism, Department of Internal Medicine, Gachon University Gil Hospital, Incheon, Incheon, Republic of Korea; [4]Division of Endocrinology and Metabolism, Department of Internal Medicine, The Catholic University of Korea, Bucheon, Republic of Korea.

Objective
Randomized trials demonstrated a lower risk of cardiovascular (CV) events with sodium – glucose cotransporter-2 inhibitors (SGLT-2i) in patients with type 2 diabetes(T2D) at high CV risk. SGLT2-i should be considered as a valuable therapy in T2D with established atherosclerotic cardiovascular disease (ASCVD) or heart failure (HF). We analyzed the effects of cardiovascular function of SGLT 2 inhibitors in T2D with ASCVD or HF compared with dipeptidyl peptidase-4(DPP-4) inhibitors.
Methods
This is a retrospective, observational study, data from 89 patients with established ASCVD or HF 6 months of the SGLT-2 inhibitors and DPP-4 inhibitors therapy were analyzed, visited medical center from January 2018 to June 2018. We had divided into two groups: one group was SGLT-2 inhibitors and the other was DPP-4 inhibitors and check echocardiography and pro BNP.
Results
A total of 89 patients with T2D were identified as group of SGLT2 inhibitor ($n=41$) or a DPP-4 inhibitor ($n=48$). In SGLT2 inhibitors,mean baseline age was 59 years, duration of diabetes 10 years, HbA1C 7.8%, eGFR 81 ml/min per 1.73 m^2 and body mass index (BMI) 26 kg/m^2. In DPP4 inhibitors,mean baseline age was 65 years, duration of diabetes 13 years, HbA1C 7.6%, eGFR 67 ml/min per 1.73 m^2 and body mass index (BMI) 26 kg/m^2. The mean follow-up time was 2 years, with a total of 89 patient-years. SGLT2 inhibitors had improvement of left ventricular ejection fraction ($+2\%$ vs -2.7%), E/E' (3/40% vs 5/21%)and pro BNP (-374 pg/ml vs $+735$ pg/ml) compared with DPP-4 inhibitors.
Conclusion
SGLT-2 inhibitors improved LV systol, diastolic function and proBNP compared with DPP-4 inhibitors in type 2 diabetes with coronary artery disease.

Fasting insulin levels correlate with the incidence of hypoglycemic events in patients with Type 2 Diabetes treated with sulfonylureas: a retrospective cross-sectional study

Konstantinos Kolokas[1], Theocharis Koufakis[2], Iakovos Avramidis[3], Spyridon Gerou[4], Maria Chatzidimitriou[5], Kyriakos Kazakos[6], Spyridon Karras[2] & Kalliopi Kotsa[2]
[1]3rd Local Primary Care Unit (TOMY), Thessaloniki, Greece; [2]Division of Endocrinology and Metabolism and Diabetes Center, First Department of Internal Medicine, Medical School, Aristotle University of Thessaloniki, AHEPA University Hospital, Thessaloniki, Greece; [3]Diabetes Center, Department of Internal Medicine, G. Papanikolaou General Hospital, Thessaloniki, Greece; [4]Medical Laboratories Analysi Iatriki S.A., Thessaloniki, Greece; [5]Medical Laboratories, Alexander Technological Educational Institute, Thessaloniki, Greece; [6]Nursing Department, Alexander Technological Educational Institute, Thessaloniki, Greece.

Background
Sulfonylureas (SUs) are known to increase fasting insulin levels in patients with Type 2 Diabetes (T2D) treated with these agents. Whether this increase is related to a greater risk of hypoglycemia has not yet been sufficiently elucidated.
Methods
The study included 58 patients with T2D who had been on treatment with SUs, but not insulin, for more than 2 years. Confirmed hypoglycemic episodes during the past year were self-reported by the patients on a retrospective basis, by completing the 'Hypoglycemia Patient Questionnaire' weighted scoring system. Potential relationship of hypoglycemic event frequency with fasting insulin levels and received therapy was investigated.
Results
Fasting insulin concentrations were found to have a low positive and statistically significant correlation with the number of cases of mild hypoglycemia per year (rho$=0.279/P=0.034$), and a moderately positive and statistically significant correlation with the number of severe hypoglycemic events per month (rho$=$ $0.349/P=0.007$) and per year (rho$=0.39/P=0.002$). Patients on glimepiride had significantly higher number of mild hypoglycemic episodes during the previous month ($P<0.001$) and the previous year ($P<0.001$), compared to patients receiving gliclazide. Regarding the relationship between received treatment with SU and fasting plasma insulin levels, no statistically significant difference between gliclazide and glimepiride was observed ($P=0.591$).
Conclusions
The incidence of hypoglycemia in patients treated with modern SUs seems to vary, depending on the specific medication used. Fasting insulin levels could be a predictor of risk of hypoglycemia in patients with T2D on treatment with SUs.

Metabolic changes in men undergoing androgen deprivation therapy for prostate cancer

Tatyana Demidova[1], Elena Gritskevich[1] & Sergey Mishugin[2]
[1]Pirogov Russian National Research Medical University, Moscow, Russian Federation; [2]D.D. Pletneva City Clinical Hospital, Moscow, Russian Federation.

Introduction
Androgen deprivation therapy (ADT) is widely used around the world for the treatment various stages of prostate cancer. Androgen deprivation therapy (ADT) in men with prostate cancer (PCa) increased chance of developing metabolic disorders in insulin sensitivity, lipid levels, glucose metabolism, body composition (increases fat accumulation concurrently with a decrease in lean mass). These changes are the risk factors for the development of adverse cardiovascular events, including fatal ones.
Objective
To study the development of disorders in glucose metabolism during various regimens of ADT.
Materials and methods
The study included 115 patients with metastatic PCa, observed from 2014 to 2017 in the D.D. Pletneva State Clinical Hospital. Patients were randomised into 2 groups: group 1 ($n=62$) received monotherapy with gonadotropin-releasing hormone agonist (aGnRH), group 2 ($n=53$) received therapy with aGnRH and antiandrogens (maximal androgen blockade (MAB). Among the group 1 mean age was 64.2 years, among the group 2 mean age was 67.5 years. Evaluation of metabolic changes was performed before the start of therapy, 6 months and 1 year after the start of therapy, according to the following parameters: weight, body mass index (BMI), waist circumference (WC), fasting blood glucose level and oral glucose tolerance test.
Results
In both groups, comparable changes in the parameters were detected. After 12 months of therapy there was an increase in body weight by 6.56% in the aGnRH group ($P=0.041$) and by 6.87% in the MAB group ($P=0.045$). BMI increased by 6.19 ($P=0.054$) and by 7.62% ($P=0.036$), respectively, WC increased by 5.1 ($P=0.025$) and 4.48% ($P=0.013$), respectively. Changes in the parameters of glucose metabolism were estimated after 6 and 12 months of therapy. Fasting glycemia increased by 2% in the aGnRH group ($P<0.05$) and 2.36% ($P=0.055$) in the MAB group in 6 months, and in 12 months it increased by 4.07 and 3.7% ($P<0.05$), respectively. In the aGnRH group in 10% patiens diagnosed new cases of diabetes mellitus (DM) and in 10% impaired glucose tolerance during treatment period, therefore 20% of patients demonstrated glucose metabolism disorders during the year of therapy, in the MAB group DM manifested in 8% of patients, impaired glucose tolerance in 10%.
The conclusion
The MAB and monotherapy aGnRH therapy were associated with increase in body weight, WC, impaired of glucose metabolism in the early time (6 months of continuous therapy). It is important to initiate further prospective studies, to provide opportunities to manage these adverse changes.

Antioxidant and hypoglycemic effects of gossitan

Talat Saatov[1], Mukhammadjon Mustafakulov[1], Tokhir Ishankhodjaev[1], Zafar Ibragimov[1], Elvira Ibragimova[1], Nodira Abdulladjanova[2], Sanobarkhon Irgasheva[1] & Bokhodyr Zainutdinov[1]
[1]Institute of Biophysics and Biochemistry, Mirzo Ulugbek National University of Uzbekistan, Tashkent, Uzbekistan; [2]Institute of Bioorganic Chemistry, Uzbekistan Academy of Sciences, Tashkent, Uzbekistan.

Causing production of free radicals and reduction of antioxidant system activity, in the pancreatic β-cells, in particular, resulting in reduction in insulin production and consequently to hyperglycemia, oxidative stress could be a pathogenetic mechanism of morbidity in diabetes mellitus. Search for and development of medicines with antioxidant and hypoglycemic activity remains urgent.
Aim
The work was initiated to study antioxidant and hypoglycemic effects of gossitan.
Materials and methods
Produced from the polyphenol compounds isolated from the upland cotton *(Gossypium hirsutum L)* gossitan is a medicine with interferon-producing and antiviral effects effective against various influenza strains. Antioxidant effects of gossitan were examined in the models of adrenalin autoxidation and ascorbate-dependent lipid peroxidation. Experimental diabetes mellitus was induced by three-fold intraperitoneal administration of diabetogenic doses of alloxan. Gossitan was administered intragastrically in the dose of 4.9 mg/kg within 10 days until blood glucose was 11 mmol/l. Quercetine, a polyphenol, and gliclazide, were used as the controls.
Results
Gossitan was found to cause reduction in adrenaline oxidation by 35.7%, while quercetine reduced it by 37.7%, and twofold reduction in malondialdehyde in the liver homogenate of rats with experimental diabetes mellitus. Per oral administration of gossitan to the rats was found to decrease their blood glucose by 43.6%.
Conclusions
A polyphenol-based medicine, gossitan was found to possess antioxidant activity similar to the one of quercetine and to facilitate blood glucose decrease in rats with experimental diabetes mellitus, which seems to be associated with partial restoration of glucokinase activity in the rat liver and insulin level.

GP207

Treatment with sitagliptin in patients with type 1 diabetes and type LADA diabetes

Paloma Moreno-Moreno, María Rosa Alhambra-Expósito, Ángel Rebollo-Román, Ana Martín-Barrera & María Ángeles Gálvez-Moreno
Hospital Universitario Reina Sofía, Córdoba, Spain.

Objective
Preclinical studies have shown that DPP-4 inhibitors (iDPP4) have beneficial effects on functional mass of beta cells and pancreatic insulin content. The aim of this study is to evaluate the efficacy of treatment with sitagliptin in monotherapy or in combination with insulin in person with type 1 diabetes (DM-1) or type LADA diabetes (DM-LADA) of recent diagnosis.
Patients and methods
Descriptive study: patients with DM-1 or DM-LADA in treatment with sitagliptin in monotherapy or in combination with insulin at diagnosis. Variables analyzed at baseline and at 6 and 12 months: type diabetes, age, sex, Body mass index (BMI), HbA1c, C-peptide, pancreatic autoimmunity (anti-GAD Antibody, anti-IA2 Antibody), treatment and adverse effects. Statistical analysis: ANOVA for comparison of means and McNemar for omparison of proportions.
Results
17 patients. 70.6% DM-1 (10 DM-1 patients with positive pancreatic autoimmunity and 2 negative pancreatic autoimmunity), 29.4% DM-LADA. Initial treatment: basal insulin + prandial insulin 35.29% ($n=6$), basal insulin + sitagliptin 29.41% ($n=5$), sitagliptin in monotherapy 35.29% ($n=6$). Treatment at 12 months: basal insulin + prandial insulin 29.41% ($n=5$), basal insulin + sitagliptin 23.52% ($n=4$), sitagliptin in monotherapy 47.05% ($n=8$). No adverse effects. Treatment at 12 months basal insulin + prandial insulin vs basal insulin + sitagliptin vs sitagliptin in monotherapy: age 39.60 ± 16 vs 37 ± 4.69 vs 32.5 ± 10.26 years ($P=0.54$); BMI initial 24.33 ± 3.59 vs 27.37 ± 4.75 vs 24.88 ± 2.76 Kg/m^2 ($P=0.41$); HbA1c initial 10.40 ± 3.55 vs 11 ± 2.12 vs 10.62 ± 3.04% ($P=0.95$); C-peptide initial 0.65 ± 0.36 vs 0.60 ± 0.53 vs 0.61 ± 0.20 pmol/ml ($P=0.96$); level of anti-GAD antibody 708.34 ± 822.51 vs 526.50 ± 982.59 vs 339.93 ± 733.16 U/ml ($P=0.32$); BMI at 12 months 24.44 ± 3.92 vs 27.54 ± 6.05 vs 24.54 ± 2.56 Kg/m^2 ($P=0.41$); HbA1c at 12 months 6.62 ± 0.37 vs 6.27 ± 0.45 vs 6.13 ± 0.60% ($P=0.36$). DM-1 with positive pancreatic autoimmunity 100% ($n=5$) vs 75% ($n=3$) vs 25% ($n=2$), DM-1 with negative pancreatic autoimmunity only sitagliptin in monotherapy 25% ($n=2$), DM-LADA 0% vs 25% ($n=1$) vs 50% ($n=4$)) ($P=0.89$); women 80% ($n=4$) vs 25% ($n=1$) vs 37.5% ($n=3$) ($P=0.19$).
Conclusions
Sitagliptin monotherapy achieves optimal metabolic control in almost half of patients with DM-1 or DM-LADA. The response to sitagliptin monotherapy is not related to any initial parameter. No adverse effects were observed in patients treated with sitagliptina in monotherapy.

Effects of glucagon-like peptide 1 receptor agonist on short-chain fatty acids, carbohydrate and lipid metabolism in patients with type 2 diabetes

Lilit Egshatyan[1,2], Nane Khachaturian[2,3], Svetlana Silvestrova[3] & Ashot Mkrtumyan[2,3]
[1]A.S. Loginov Moscow Clinical Scientific Center, Moscow, Russian Federation; [2]A.I. Evdokimov Moscow State University of Medicine and Dentistry, Moscow, Russian Federation; [3]The A.S. Loginov Moscow Clinical Scientific Center, Moscow, Russian Federation.

Background
Type 2 diabetes (T2D) is a progressive disease. The gut microbiota has recently been identified as a new potential diabetes risk factor. Short-chain fatty acids (SCFAs) are organic fatty acids produced in the distal gut by bacterial fermentation of macrofibrous material that might improve T2D.
Aims
To examine the effectiveness of glucagon-like peptide (GLP)-1 receptor agonist treatment on SCFAs, carbohydrate and lipid metabolism in patients with T2D.
Materials and methods
Sixteen patients with T2D were enrolled in this prospective study. The mean age of patients was 45 (30–60) years. The levels of SCFAs, lipoproteins, serum fasting glucose, glycated hemoglobin (HbA1c), and body mass index (BMI) were examined at baseline and at 8 weeks on aGLP-1 therapy.
Results
At baseline the average glucose levels were 8.18 [5.3; 15.2] mmol/l, HbA1c – 6.7 [4.6; 9.8] %; total serum cholesterol (TC) – 5.46 [3.49; 7.83] mmol/l, low-density lipoprotein (LDL) – 4.26 [2.46; 6.65] mmol/l, high-density lipoprotein (HDL) – 1.17 [0.85; 1.76] mmol/l, triglycerides (TG) – 1.82 [0.56; 3.4] mmol/l and BMI – 39.35 [31.9; 51.0] kg/m^2. After 8 weeks of aGLP-1 treatment was detected a significant decrease in mean glucose levels by 18.2%, HbA1c by 5.22%, TC by 5.31%, LDL by 10%, TG by 12%, BMI by 3.43%, and no significant increase in HDL by 4% from baseline. SCFAs were analyzed in 7 patients. Despite the small number of patients, a significant positive relationship between acetate and BMI ($r(s)=0.31$; $P=0.039$), HbA1c ($r(s)=0.28$; $P=0.015$), LDL ($r(s)=0.26$; $P=0.039$), and negative relationship between butyrate and glucose ($r(s)=-0.41$, $P=0.014$), TG ($r(s)=-0.29$, $P=0.04$) were revealed at baseline. There was no significant correlation between propionate and above parameters. GLP-1 therapy was associated with significant decrease in acetate (from 3.48 [1.26; 7.149] to 2.61 [1.43; 3.5]) ($P<0.01$); no significant in propionate (from 1.29 [0.74; 1.39] to 1.06 [0.77; 1, 39] mg/g) ($P>0.05$) and increase in butyrate (from 0.76 [0.4; 0.98] to 0.86 [0.42; 1.4]) ($P>0.05$). Acetate decrease is associated with decrease in BMI for more than 3% at baseline and an improvement in glycaemia.
Conclusions
The preliminary results are indicating a positive effect of GLP-1 on weight, carbohydrate and lipid metabolism and short-chain fatty acids in patients with T2D.
DOI: 10.1530/endoabs.63.GP208

Efficacy and tolerability of dulaglutide in patients with type 2 diabetes: Experience on a secondary Hospital

Paloma González Lázaro, Cristina Contreras Pascual, Florentino del Val Zaballos, Julia Silva Fernández, Francisco Javier Gomez Alfonso, Belvis Torres Arroyo, Álvaro García Manzanares Vazquez de Agredos & Inés Gómez García
La Mancha Centro, Alcazar de San Juan, Spain.

Introduction
Dulaglutide (Trulicity®) is a long-acting GLP-1 agonist that received US Food and Drug Administration (FDA) approval in 2014. Dulaglutide is a large sized molecule, which limits its renal clearance. This allows for once weekly dosing; which might improve patient compliance significantly. Extensive Phase III study data have been published with regard to dulaglutide, much of which was part of the AWARD studies, which provide evidence for its use in combination with several other antidiabetic agents.
Objective
The objective of the study was to evaluate the efficacy and tolerability of dulaglutide 1.5mg in patients with type 2 Diabetes, used in monotherapy and in combination with several agents including insulin.
Design and Methods
We present a restrospective, descriptive study. The included subjects were non pregnant adults with type 2 diabetes, who started on dulaglutide between March 2016 and September 2018. Patients were evaluated at 3, 6 and 12 months after the drug was started. Patients with less than 3 month follow-up were excluded.
Results
Data from 82 patients were analysed. Average age was 50.2 ± 9.09 years old with an average of diabetes duration of 9.87 ± 8.07 years. 13 patients (16.3%) were previously on treatment with another GLP-1RA and 52.4% were on insulin therapy. Patients enrolled were uncontrolled, with a baseline A1c of $8.6\%\pm1.5$. Throughout the 12-month study period great reduction in A1C was found (-1.5% at 3 month follow-up, which is mantained at 6 and 12 month follow up (-1.4 and -1.6% respectively)). An average weight reduction of -4.2 kg was observed throughout the study, specially at 6 month follow-up (-5.7 Kg). All results were statiscally significant ($P<0.01$). Only in 9.75% of the subjects ($n=8$), dulaglutide was discontinued due to nausea, vomiting, and diarrea, well-known dependent side effects of dulaglutide. In 4 subjets the drug was stopped because no efficacy was observed in terms of A1C and weight reduction.
Conclusions
Dulaglutide represents a well-tolerated and efficacious option in the treatment of T2DM. It is a viable second-line option after metformin, with demonstrated superior efficacy to other second-line agents. Ongoing trial data will better inform the future place in the therapy of dulaglutide considering the recent guideline emphasis on agents with beneficial effects on CV outcomes.

Introduction
Type 2 diabetes mellitus (T2DM) is characterized by progressive impairment/loss of pancreatic beta cell function Activation of endoplasmic reticulum (ER) stress by glucose variation has been suggested as an essential step towards beta cell dysfunction. Sodium-glucose co-transporter 2 inhibitors (SGLT2i) are widely used in the treatment of T2DM considering their beneficial cardiometabolic sequalae. In the present study, we aimed to investigate the effect of Empagliflozin on ER stress-induced apoptosis in murine pancreatic islet/beta cell lines.
Material and methods
Hamster HIT-T15 (islet) and mouse BTC-6 (Beta) pancreatic cell lines were maintained in RPMI media, supplemented with 15% FBS.Both cell lines were seeded in 12 well plates and serum starved 16 hrs prior to treatments. After starvation cells were incubated with various concentrations of tunicamycin (5 ug/ml, 10 ug/ml, 20 ug/ml) or Empagliflozin (10^{-8}, 10^{-9} and 10^{-10} M) alone or co-incubated with both agents simultaneously. The expression levels of SGLT-1, SGLT-2, GRP-94, Bip, PERK, elf-2α and CHOP were measured by quantitative real time PCR while protein levels of GRP-94, Bip, p-PERK, elf-2α, P- elf-2α and CHOP were measured by western blotting. Cell proliferation and apoptosis were measured by XTT and Annexin V FITC assays respectively.
Results
SGLT-1 mRNA was detected only in BTC-6 cells while SGLT-2 mRNA was not detected in either cell line. Incubation of BTC-6 cells, but not HIT-T15, with Empagliflozin (10^{-8}, 10^{-9} M. $P<0.05$) resulted in significant increase in cell proliferation compared to untreated cells. Both Hit-15 and BTC-6 cells were sensitive to tunicamycin and underwent significant cell death after 48h treatment ($P<0.01$). Co-incubation of cells with Empagliflozin significantly inhibited tunicamycin (5 ug/ml and 10 ug/ml) -induced cell apoptosis with more robust effect observed in BTC-6 cell line ($P<0.01$) as compared with HIT-T15 cell line. Particularly, co-incubation of BTC-6 cells with tunacamycin and Empagliflozin reduced (ER) stress-induced apoptosis through down regulation of p-elf-2α ($P<0.01$) and CHOP ($P<0.01$) while in HIT-T15 the ER stress was reduced through reduction of Bip ($P<0.01$), p-PERK ($P<0.05$) and CHOP ($P<0.05$) protein expression. These results were in line with mRNA expression results.
Conclusion
Our data indicate that Empagliflozin increases proliferation and reduces cell apoptosis in beta-pancreatic cells, at least in part, via reducing ER stress. The effect of Empagliflozin on beta-cell apoptosis/survival could be mediated through SGLT-1. More studies are needed to verify the efficacy of this class of drugs in maintenance of pancreatic cells survival and function.

New insights on strain-specific impacts of probiotics on insulin resistance

Nazarii Kobyliak[1], Tetyana Falalyeyeva[2], Olena Tsyryuk[2] & Liudmyla Ostapchenko[2]
[1]Bogomolets National Medical University, Kyiv, Ukraine; [2]Taras Shevchenko National University of Kyiv, Kyiv, Ukraine.

Background and aims
Comparative animal study of efficacy of intermittent short courses administration of lyophilized single-, three- and alive multistrain probiotic on insulin resistance in rats with experimental obesity.
Methods
We included 70 rats divided into 7 groups ($n=10$ in each). Rats of group I were intact. Newborn rats of groups II-VII were injected with monosodium glutamate (MSG) (4 mg/g). Rats of group II (MSG-obesity group) were untreated. The groups III-V received lyophilized mono-probiotics *B.animalis VKL*, *B.animalis VKB*, *L.casei IMVB−7280* respectively. The group VI received the mix of these three probiotic strains. The group VII was treated with multi-probiotic 'Symbiter' which contains 14 alive probiotic strains (*Lactobacillus*, *Bifidobacterium*, *Propionibacterium*, *Acetobacter* genera).
Results
Neonatal treatment with MSG lead to the development of obesity in all MSG-obesity rats and up to 20–70% after probiotic administration. Supplementation of probiotic composition, with preference to alive strains (group VII), led to a significantly lower prevalence of obesity, decreasing of HOMA-IR (2.31 ± 0.13 vs 3.07 ± 0.3; $P<0.001$), proinflammatory cytokines levels (IL-1β, IL-12Bp40) and elevation of adiponectin (5.67 ± 0.39 vs 2.27 ± 0.36; $P<0.001$) as compared to MSG-obesity. Furthermore, significant changes were absent between alive probiotic group (VII) and intact rats ($P=0.098$). Single-strain analysis (group III-V) shows significant decreasing of metabolic parameters, but changes were less pronounced as compared to mixture groups and did not achieved intact rats level.
Conclusion
Multistrain formed mutualistic interactions in mixtures and therefore able to share with different metabolites, affect different receptors, which synergistic overall effect greater than the sum of the single effects.

Gestational and Type 1 Diabetes

GP212

Prevalence of gestational diabetes during 14 pregnancies of acromegalic women

Magaly Vialon, Solange Grunenwald, Céline Mouly, Delphine Vezzosi, Antoine Bennet & Philippe Caron
Department of Endocrinology and Metabolic diseases, CHU Larrey, Toulouse, France.

Introduction
Abnormalities of glycoregulation are frequent in acromegaly (15-38%) secondary to insulin resistance related to GH/IGF-1 hyper-secretion. The frequency of gestational diabetes (GD) in women with acromegaly was reported in the French multicenter study (JCEM, 2010, 95, 4680) as increased mainly in the absence of pre-gestational control of GH/IGF-1 hyper-secretion. The aim of this study was to evaluate the frequency of GD in a cohort of acromegalic women, and compare characteristics of women with (GD+) or without GD (GD-).
Patients and methods
This is a descriptive monocentric study of 14 pregnancies in 11 women (mean age: 34.0 ± 3.6 years) followed for GH-secreting pituitary macro-adenomas. They were treated with first generation long-acting somatostatin analogues (octreotide LAR $n=3$, mean dose 30 mg/month; lanreotide Autogel $n=11$, mean dose 95 ± 26 mg/month) after a pituitary surgery ($n=6$) or as primary ($n=5$) treatment. Somatostatin analogues were discontinued during 1st trimester, at the time of pregnancy diagnosis. One acromegaly was diagnosed during pregnancy and was treated with octreotide LAR between 12 and 18 weeks of gestation. Before pregnancy, no woman had diabetes mellitus, and GH/IGF-1 hyper-secretion was uncontrolled in 6 women (mean IGF-1: 176% upper limit of normal range).
Results
A GD was diagnosed in 7 pregnancies (50%) on fasting blood glucose in 1st trimester ($n=5$) or an oral glucose tolerance test at 3rd trimester ($n=2$). Insulin treatment was necessary for 4 patients. Before pregnancy, IGF-1 was not controlled in 4 of GD+ and 2 in GD- women. Women with GD were older (GD+ 35.3 years, GD- 32.7 years, $P=0.20$), had increased pre-gestational BMI (GD+ 26 kg/m^2, GD- 20.7 kg/m^2, $P=0.02$), had frequently family history of type 2 diabetes mellitus (GD+3, GD- 0), no history of GD but a history of macrosomia for one patient. The percentile birth weight of newborns was on average 48.7 for GD + and 69.4 for GD- mothers ($P=0.15$).
Conclusion
In this cohort of acromegalic women, the prevalence of GD is increased compared to that reported in the literature, probably secondary to systematic GD screening and to the age of our women (73% were ≥35 years old). Therefore, routine screening of GD should be considered in all women with acromegaly, particularly those with risk factors for the occurrence of GD and with uncontrolled IGF-1.

The impact of the intrauterine hyperglycaemia on the expression of genes related to cardio-metabolic diseases in human umbilical vein endothelial cells: results from a randomised, controlled study of different glycaemic targets during gestational diabetes treatment

Polina Popova[1,2], Liudmila Vasileva[3], Alexandra Tkachuck[3], Maxim Puzanov[3], Alexey Golovkin[3], Yana Bolotko[3], Eugenii Pustozerov[3,4], Andrey Gerasimov[3], Irina Zazerskaya[3], Renata Dmitrieva[3], Anna Kostareva[3] & Elena Grineva[3]
[1]Almazov National Medical Research Centre, Saint-Petersburg, Russian Federation; [2]St Petersburg Pavlov State Medical University, Saint Petersburg, Russian Federation; [3]Almazov National Medical Research Centre, Saint Petersburg, Russian Federation; [4]Saint Petersburg State Electrotechnical University, Saint Petersburg, Russian Federation.

Background
Understanding the mechanism whereby the intrauterine hyperglycemia in women with gestational diabetes mellitus (GDM) affects the offspring' predisposition to metabolic and cardiovascular diseases may help prevent their intergenerational transmission. Our aim was to study the effect of the degree and duration of maternal hyperglycemia on the level of expression of genes associated with cardio-metabolic diseases in human umbilical vein endothelial cells (HUVECs) of newborns from women with GDM.
Materials and methods
HUVECs were isolated from 75 women with GDM and 28 women without GDM (control group). Women with GDM treated for GDM starting before 30-th week of gestation, were randomized to 2 groups per target glycaemic levels: GDM1 (tight glycaemic targets, fasting blood glucose <5.1 mmol/L and <7.0 mmol/L postprandial, N=34) and GDM2 (less tight glycaemic targets, <5.3 mmol/L and <7.8 mmol/L, respectively, N=29). Women with GDM who started treatment after 34-th week of gestation (N=11) were considered as late treatment group (GDM3). The level of ICAM1, VCAM1, ANGPTL4, ENG, TRIB1, MT-ND2, TFAM, PTGS1, MEST, PLAC8 and NR3C1 genes expression in HUVECs was determined by RT-PCR.
Results
The four groups did not differ by maternal age and pregestational body mass index. GDM groups (GDM1, GDM2 and GDM3) showed significantly reduced levels of ANGPTL4 gene expression compared to the control group (24.7 ± 26.1, 26.1 ± 40.1, 13.4 ± 11.9 vs 91.6 ± 100.5, respectively, $P=0.009$, 0.014 and 0.002) , but no difference was observed among GDM groups. NR3C1 gene expression also tended to be lower in all GDM groups compared to controls (4.6 ± 2.5, 4.6 ± 1.7, 3.4 ± 1.8 vs 6.0 ± 1.3, respectively, $P=0.093$, 0.051 and 0.006) with no difference among GDM groups. TRIB1 gene expression was lower in GDM3 compared to GDM1, GDM2 and control group (9.0 ± 4.9 vs 23.8 ± 23.9, 28.5 ± 27.2, 21.9 ± 4.1, respectively, $P=0.008$, $P=0.004$ and $P=0.001$) with no difference among GDM1, GDM2 and control group. GDM1 group achieved lower levels of 1 hour postprandial glucose compared to GDM2 during the whole period of the study (6.0 ± 0.4 vs 6.3 ± 0.5 mmol/L, $P=0.036$).
Conclusion
The decrease in ANGPTL4 and NR3C1 genes expression level has been detected in HUVECs of newborns from women with GDM compared to control group. However their expression was not associated with the intensity of glycaemic control and the duration of maternal hyperglycemia. The duration of maternal hyperglycemia was associated with TRIB1 gene expression which was decreased only in the late treatment group.

Association between sleep disturbances and fear of hypoglycemia in adults with type 1 diabetes, data from VARDIA Study

Valentine Suteau[1,2], Pierre-Jean Saulnier[3,4], Matthieu Wargny[5], Elise Gand[3], Lucy Chaillous[5], Séverine Dubois[2], Ingrid Allix[2], Fabrice Bonnet[6], Anne-Marie Leguerrier[6], Gérard Fradet[7], Isabelle Delcourt Crespin[7], Véronique Kerlan[8], Didier Gouet[9], Caroline Perlemoine[10], Pierre-Henri Ducluzeau[11], Matthieu Pichelin[5], Linda Gonder-Frederic[12], Stéphanie Ragot[4], Samy Hadjhadj[5], Bertrand Cariou[5] & Claire Briet[1,2]
[1]Institut MITOVASC, UMR CNRS 6015, INSERM 1083, Université d'Angers, Angers, France; [2]Diabetes Department, CHU d'Angers, Angers, France; [3]University of Poitiers, INSERM Clinical Investigation Center CIC1402, Poitiers, France; [4]CHU Poitiers, Diabetes Department, Poitiers, France; [5]L'institut du thorax, CHU Nantes, INSERM CIC1413, Nantes, France; [6]CHU Rennes, Diabetes Department, Rennes, France; [7]CH La Roche sur Yon, La Roche sur Yon, France; [8]CHU Brest, Diabetes Department, Brest, France; [9]CH La Rochelle, Diabetes Department, La Rochelle, France; [10]CH Lorient, Diabetes Departme, Lorient, France; [11]Diabetes Department, Tours, France; [12]University of Virginia, Charlotteville, USA.

Aims
To assess the relationship between sleep quality and fear of hypoglycemia, glycemic variability and other diabetes-related outcomes in type 1 diabetes.
Methods
Our data were provided by the VARDIA Study, a multicentric observational cross-sectional study conducted between June and December 2015. Sleep characteristics were assessed by Pittsburgh Sleep Quality Index (PQ1I). Fear of hypoglycemia was measured with the Hypoglycemia Fear Survey version II (HFS-II). Glycemic variability was determined using the CV of three 7-points self-monitoring blood glucose profiles and the mean amplitude of glycemic excursion (MAGE). Comparisons between 'good' (PQ1I $\leq$ 5) and 'poor' (PQ1I $>$ 5) sleepers and correlation between PQ1I and these different parameters were tested.
Results
315 patients were eligible for PQ1I questionnaire analysis: 54% women, mean age 47 $\pm$ 15 years old, mean diabetes duration of 24 $\pm$ 13 years, HbA1c of 7.6 $\pm$ 0.9% (60 $\pm$ 7.5 mmol/mol). Average PQ1I score was 6.0 $\pm$ 3.3 and 59.8% of the patients had a total PQ1I score $>$ 5. HFS-II score was significantly higher among patients with sleep disturbances ($P<0.0001$) and global PQ1I score was positively correlated with HFS-II ($\beta=0.19$; 95% CI $=0.07;0.30$). GV evaluated by CV or MAGE did not differ between 'poor' and 'good' sleepers ($P=0.28$ and 0.54, respectively).
Conclusions
Adult patients with type 1 diabetes have disturbed sleep quality which correlate with fear of hypoglycemia. This study suggests that fear of hypoglycemia is a target for intervention to improve sleep quality in adults with type 1 diabetes.

Brain volume and variability of glycemia in patients with type 1 diabetes mellitus

Maria Rotkank, Julia Samoylova, Natalia Zhukova, Mariia Matveeva & Ivan Tolmachev
Siberian State Medical University, Tomsk, Russian Federation.

Actuality
Currently, there is no doubt about the negative effect of diabetes mellitus (DM) on the state of the central nervous system. One of the pathological manifestations are anatomical changes in the brain, which in turn can lead to the development of functional disorders and cognitive decline. Conducting imaging research methods allows us to assess the presence or absence of brain atrophy at an early stage.
The aim
To identify the relationship between blood glucose indicators (including variability) and magnetic resonance imaging (MRI) of the brain in patients with DM type 1.
Materials and methods
58 patients with DM type 1 at the age of 29[25;32] and 20 people without diabetes (matched by sex and age) were examined. Using the EasyGV calculator was calculated the glycemia variability coefficients (standard deviation (SD), prolonged glycemic index (CONGA), glycemic lability index (LI), hypoglycemia risk index (LBGI), index risk of hyperglycemia (HBGI), mean daily differences (MODD),). Also MRI of the brain was performed to determine the volume of the gray matter of the cerebral cortex, white matter and hippocampus. Statistical processing - IBM SPSS Statistics 20.0.0 (significant differences - $P<0.05$).
Results
The average level of HbA1c in patients with type 1 diabetes was 8.4[7.5;8.9]%. Indicators of glycemia variability were: SD 6.25[3.1;7.7]mmol/l, CONGA 4.65[3.3;7.3]mmol/l, LI 4.25[3.3,5.1](mmol/l)^2/hour, LBGI 3.85[2.6,5.2], HBGI 7.75[5.6;12.5], MODD, 3.85[2.9;5.6]mmol/l. According to the results of MRI, the volumes of the brain structures of interest (patients with DM type 1/control group) were determined: the volume of the gray matter of the cerebral cortex, cm^3 – 516.95[504.71;542.1]/543.19[523.24;554.17] ($P=0.004$); white matter volume of the brain cm^3 – 675.37[661.33;687.68]/630.66[625.03;641.59] ($P=0.001$); the volume of the hippocampus on the left, cm^3 – 3.08[2.93;3.2]/3.09[3;3.24] ($P=0.325$); the volume of the hippocampus on the right, cm^3 – 3.09[2.92;3.23]/3.01[2.9;3.21] ($P=0.537$). Subsequently, the analysis of the relationship of the MRI results with the coefficients of glycemia variability was carried out. A positive correlation was found between the volume of gray matter of the cerebral cortex and HbA1c ($r=0.295$, $P=0.025$), as well as a negative correlation between the CONGA index and the left hippocampus ($r=-0.265$, $r=0.044$).
Conclusions
The study revealed the negative impact of chronic hyperglycemia on the state of the cerebral cortex. Atrophy of the cortex can be the cause of cognitive impairment, which is often found in patients with diabetes.

DOI: 10.1530/endoabs.63.GP215

GP216

Specific pattern of insulin delivery during pregnancy in tightly controlled type 1 diabetic patients treated with insulin pump; unchanged total daily insulin dose per kilogram with consecutive basal/prandial insulin ratio adjustment

Maja Baretić[1,2], Glorija Lekšić[1] & Marina Ivanišević[1,2]
[1]University Hospital Centre Zagreb, Zagreb, Croatia; [2]School of Medicine, University of Zagreb, Zagreb, Croatia.

Introduction
Insulin is standard of care for the treatment of type 1 diabetes (T1DM). Constant insulin adjustment is necessary to keep up with the different insulin requirements of pregnancy. Rapid, flexible and precise dosing of basal insulin and advanced options of bolus calculator settings for prandial insulin make insulin pump optimal solution.
Aim
The aim of the study was to explore pattern of insulin dynamic in pregnancies of T1DM patients with tight glycaemic control treated with insulin pump.
Material and methods
Data from 14 women with T1DM were retrospectively analyzed. Patients were treated with insulin pump, monthly followed by same endocrinologist and obstetrician at University Hospital Centre Zagreb, Department of Endocrinology and Diabetes and Croatian State Referral Centre for Diabetes in Pregnancy. Average time from pump initiation to conception was 19 months (2–78). At the time of conception median age was 28.5 years (25–34), median body mass index 23.1 kg/m^2 (19–33) and median weight gain during pregnancy 13 kg (4–16).
Results
All patient were *successfully* delivered by *caesarean* section without peripartal complications; median week of delivery was 38 (37–39), median APGAR score 10 (7–10), median birth weight 3190 g (2670–4440). At the time of conception median A1C was 6.5% (4.8–7.0). In the last trimester A1C was significantly lower with median 5.25% (4.6–7.1%), (P 0.020). Median total daily insulin dosage (TDD) at time of conception compared to 32nd week of pregnancy increased significantly (P 0.006) from 34.7 IU (13.4–50.6) to 43.85 IU (17.5–87.0). Contrary, total daily insulin dose per kilogram of body weight (TDD/kg) did not significantly change; at the time of conception it was 1.88 IU/kg (1.27–4.53) and at 32nd week of pregnancy 1.72 IU/kg (1.08–4.0). Basal/prandial insulin ratio at the time of conception was 52/48 changing significantly to 38/62 in the third trimester, (P 0.001).
Conclusion
In this study TDD increased for 21% throughout the pregnancy. Surprisingly, TDD/kg remained the same. Having in mind specific insulin demands in second and third trimester due to postprandial hyperglycemia, consecutive changes in insulin pump setting (bolus calculator) were made. The setting adjustments resulted in decrease of carbohydrate-to-insulin ratio followed by increase of prandial component of insulin and decrease of the basal one. This study points to the importance of redistribution of insulin components beyond weight-based dosing in pregnant patients with T1DM. Our findings suggest that such approach

with steady TDD/kg of exogenous insulin during pregnancy enables tight glycaemic control without hyperinsulinisation.

The rs2304256 A allele in the TYK2 gene is associated with protection for type 1 diabetes mellitus in a Brazilian population

Daisy Crispim[1,2], Felipe Mateus Pellenz[1,2], Guilherme Duarte[1,2], Cristine Dieter[1,2] & Bianca de Souza[1,2]
[1]Hospital de Clinicas de Porto Alegre, Porto Alegre, Brazil; [2]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil.

Background and Aims
Type 1 diabetes mellitus (T1DM) is caused by an autoimmune destruction of pancreatic beta cells, which renders patients insulin-dependent for life. The disease arises from a complex interaction among several genetic and environmental factors. To date, single nucleotide polymorphisms (SNPs) in >50 genes have been associated with T1DM, with *HLA class II* SNPs having the greatest impact on disease susceptibility. Other loci have minor effects on T1DM risk; however, the combination of *HLA* genotypes and non-HLA SNPs has been shown to improve disease prediction. Therefore, the identification of new non-HLA SNPs associated with T1DM might aid disease prediction. In this context, tyrosine kinase 2 (*TYK2*) is a new candidate gene for T1DM since it plays an important role in regulating apoptotic and proinflammatory pathways in beta cells through modulation of IFNα signaling. Accordingly, SNPs in *TYK2* gene have been associated with protection for autoimmune diseases. Thus, the aim of the present study was to investigate the association between a nonsynonymous SNP (rs2304256) in *TIK2* gene and T1DM in a Brazilian population.
Methods
This case-control study comprised 478 patients with T1DM (cases) and 522 non-diabetic subjects (controls) from Porto Alegre (Rio Grande do Sul, Brazil). The rs2304256 (C/A) SNP was genotyped by allele discrimination-real time PCR technique using TaqMan MGB probes (Thermo Fisher Scientific). In addition, *HLA class II DR/DQ* genotypes associated with high risk for T1DM were genotyped to control a possible association of the *TYK2* rs2304256 SNP with T1DM for these *HLA* genotypes.
Results
Genotype frequencies of the rs2304256 SNP differed significantly between T1DM patients and non-diabetic subjects (T1DM: C/C 59.4%, C/A 34.3%, A/A 6.3% *vs*. Controls: C/C 54.6%, C/A 32.2%, A/A 13.2%; P=0.001). The frequency of the minor allele (A) was 23% in T1DM group and 29% in control subjects, and this allele was significantly associated with T1DM protection under a dominant model of inheritance, adjusting for *HLA* high-risk genotypes, body mass index, ethnicity and hypertension (OR=0.60, 95% CI 0.39 – 0.95, $P=0.025$).
Conclusions
Our results demonstrated that the *TYK2* rs2304256 A allele is associated with protection for T1DM in a Brazilian population. No previous study has evaluated this SNP in Brazil.

Effect of HbA1c and hyperglycemia on hemostasis in patients with type 1 diabetes

Karina Sarkisova[1], Iwona-Renata Jarek-Martynowa[2], Marina Shestakova[2], Lydia Chirkova[2], Larisa Nikankina[2] & Minara Shamkhalova[2]
[1]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation; [2]Endocrinology Research Centre, Moscow, Russian Federation.

Background and aims
Hyperglycemia can be a risk factor for adverse cardiovascular and cerebrovascular events. However, changes in platelets and coagulation hemostasis during hyperglycemia have not been extensively studied. The aim of this study was to assess the impact of level of fasting plasma glucose, HbA_1c on the platelet activity, the physiological anticoagulant activity and fibrinolysis in patients with Diabetes Mellitus type 1 (DM1).
Materials and methods
We examined 88 patients with DM1 (39 male and 49 female; age 27[23;33] years; HbA_1c 8.9[7.8;9.9]%). On the background euglycemia (fasting plasma glucose(fpg) $\leq$6.5 (5.7$\pm$1.06) mmol/l), and hyperglycemia (fpg $\geq$12 (13.2$\pm$2.35) mmol/l) were measured induced platelet aggregation (IPA) in whole blood using thrombin, collagen, ADF, arachidonic acid, ristocetin by multiple electrode platelet aggregometry (Multiplate); physiological anticoagulants (protein S, protein C, AT-III), von Willebrand factor, plasminogen activator inhibitor (PAI-1) and tissue plasminogen activator (tPA) were determined by ELISA. Hyperglycemia was achieved by correcting insulin therapy. On the moment of the study, none of the patient was taking antiplatelet therapy or anticoagulants; 20 patients were taking antihypertensive drugs and 15 patients were taking statins. Statistical analysis was performed with SPSS 22,0 for Windows, $P<0.05$.
Results
Platelet aggregation after adding collagen, thrombin, ADF, arachidonic acid, ristocetin was significantly increased on the background of hyperglycemia compared with euglycemia ($P=0.004$, $P=0.000$, $P=0.000$, $P=0.044$, $P=0.023$ respectively, *W-test).* Additionally, tPA was increased on the background of hyperglycemia as compared with euglycemia ($P=0.000$,*W-test).* Increased level of plasma glucose was correlated positively with tPA ($P=0.008$; $r=0.469$) and increased platelet aggregation after adding collagen ($P=0.001$; $r=0.394$), thrombin ($P=0.001$; $r=0.410$), ADF ($P=0.000$; $r=0.482$). Level of HbA_1c was correlated positively with PAI-1 ($P=0.001$; $r=0.541$), protein C ($P=0.032$; $r=0.374$) and increased platelet aggregation after adding collagen ($P=0.028$; $r=0.268$), ADF ($P=0.035$; $r=0.262$), arachidonic acid ($P=0.018$; $r=0.297$).
Conclusions
Hyperglycemia and increased level of HbA_1c are associated with platelet hyperactivity and a decrease in the systemic fibrinolytic balance via increased PAI-1 activity. However, these changes are compensated by the activation of free protein C, an increase of tPA and the preservation of increased concentrations of Protein S and AT-III.

GP219

Impact of type 1 diabetes mellitus and its complications on markers of nitric oxide metabolism

Jelizaveta Sokolovska[1], Kristīne Ošina[2], Larisa Baumane[3], Leonora Pahirko[4] & Nikolajs Sjakste[1]
[1]University of Latvia, Faculty of Medicine, Riga, Latvia; [2]University of Latvia, Institute of Biology, Salaspils, Latvia; [3]Latvian Institute of Organic synthesis, Riga, Latvia; [4]University of Latvia, Faculty of Physics, Mathematics and Optometry, Riga, Latvia.

Background and aim
The role of derangements of nitric oxide (NO) metabolism in the pathogenesis of complications of type 1 diabetes mellitus (T1D) is not sufficiently clear. There is little data on simultaneous measurements of NO metabolites nitrite and nitrate (NO_2/NO_3) in urine and serum in T1D. Data about the measurement of NO production by electronparamagnetic spectroscopy (EPR) in whole blood in T1D were never published. To fill this gap we have characterised NO production and NO_2/NO_3 concentration in the biological fluids of patients with and without complications of T1D.
Methods
Two hundred and seventy-one patients with T1D duration > 1 year and 69 healthy volunteers were included. NO_2/NO_3 was measured by Griess reaction. Production of NO in whole blood was detected by EPR spectroscopy. Statistical analysis was performed by programme R.
Results
In T1D group *vs* control subjects, blood NO was higher, but serum NO_2/NO_3 was lower. There was a trend of higher serum NO_2/NO_3 in patients with diabetic nephropathy and chronic kidney disease (CKD), with concentrations reaching those of healthy subjects. Diabetic retinopathy, diabetic polyneuropathy, cardiovascular disease and arterial hypertension did not cause further changes in serum NO_2/NO_3 and whole blood NO as compared to the median value of T1D patients. Urine NO_2/NO_3 was lower in patients with microvascular T1D complications compared with milder phenotypes. In T1D, estimated glomerular filtration rate (eGFR) correlated with urine NO_2/NO_3 and whole blood NO.
Conclusions
Whole blood NO, serum NO_2/NO_3 and urine NO_2/NO_3 are affected differently by T1D and its complications. Decreased NO_2/NO_3 urine, but not in serum, is a marker of microvascular complications of T1D.

Definition of a third-trimester HbA1c cut-off point for an increased risk of Large-for-Gestational-Age in mothers with Gestational Diabetes

Liliana Fonseca[1], Diana Borges Duarte[1], Ana Amado[1], Eva Lau[1,2], Fernado Pichel[1], Joaquim Gonçalves[1], Clara Pinto[1], Joana Vilaverde[1], Jorge Dores[1] & Helena Cardoso[1]
[1]Centro Hospitalar e Universitário do Porto, Porto, Portugal; [2]Centro Hospitalar de São João, Porto, Portugal.

Introduction
Gestational diabetes mellitus (GDM) is associated with important neonatal risks and a higher incidence of large-for-gestational-age (LGA) newborns and fetal macrosomia. The aim of our work was to define a third-trimester HbA1c cut-off point for increased risk of fetal morbidity, macrosomia and LGA newborns.
Methodology
Observational retrospective study of all singleton pregnant women with GDM, followed at our Diabetes and Pregnancy Clinic between 2011 and 2017. Excess gestational weight gain was defined by the IOM guidelines. Adverse neonatal outcome included: neonatal respiratory distress, neonatal hypoglycemia, neonatal jaundice, shoulder dystocia, fractures, Erb's palsy and admission to neonatal intensive care unit. ROC curve was used to define the third-trimester HbA1c cut off point for increased risk of fetal morbidity, macrosomia and incidence of LGA.
Results
A total of 1085 singleton pregnant women were evaluated during the study period; their mean age was 32.9 ± 5.3 years and mean body mass index (BMI) of 26.5 ± 5.6 Kg/m^2. During the pregnancy, 36.3% (n = 395) of the women were started on insulin therapy and 31.5% (n = 337) had excess gestational weight gain at the time of the delivery. Mean gestational age at delivery was 38.5 ± 1.5 weeks. In 729 cases, third-trimester HbA1c was determined and mean third-trimester was HbA1c 5.3 ± 0.4%. Of the 1085 newborn, mean neonatal birth weight was 3188.5 ± 49.5 g, 4.5% (n = 49) of these were LGA, 4.8% (n = 52) were macrosomic and 19.1% (n = 208) had at least one adverse neonatal outcome. On univariate analysis, third-trimester HbA1c presented a 13.6 higher risk of LGA (CI95% 6.1 – 30.5, P < 0.001), 4.8 higher risk of fetal macrosomia (CI95% 2.4 – 9.6, P < 0.001) and 1.9 higher risk of fetal morbidity (CI95% 1.2 – 3.1, P = 0.006). ROC curves showed a cut-off point of third-trimester HbA1c > 5.4% for identifying newborns with a greater probability of LGA (Sensitivity: 82.8%; Specificity 72.0%; AUC 0.824; P < 0.001); cut-off point of third-trimester HbA1c > 5.6% for macrosomia (Sensitivity: 85.1%; Specificity 42.1%; AUC 0.664; P < 0.001) and a cut-off point of third-trimester HbA1c > 5.3% for fetal morbidity (Sensitivity: 50.4%; Specificity 62.4%; AUC 0.592; P = 0.026).
Conclusion
In this study, a cut-off point of third-trimester HbA1c > 5.4% was found to have a good sensitivity and specificity for the identification an increased risk of LGA.

Insulin requirements during lactation in women with diabetes mellitus type 1 in comparison with pre-pregnancy levels – a retrospective study

Ioannis Kakoulidis, Ioannis Ilias, Anastasia Linardi, Aikaterini Michou, Charalampos Milionis, Anastasia Lekkou, Evangelia Venaki & Eftychia Koukkou
Department of Endocrinology, Diabetes and Metabolism, Elena Venizelou General and Maternity Hospital, Athens, Greece.

Introduction
Lactation is a period of particular importance regarding the management of glycemia in women with Diabetes Mellitus type 1 (DM1), the aim being to prevent hypoglycemia during breastfeeding. The purpose of this study was to investigate the variation of insulin requirements during lactation in comparison with pre-pregnancy levels in women with DM1 and to find potential correlation factors.
Materials-methods
We conducted a retrospective case file study of women with DM1, on singleton pregnancies who breastfed. We assessed medical records in the last 8 years with data regarding management of their glycemic profile before pregnancy, during pregnancy and when breastfeeding for at least 3 months. Fourteen women were included in the study (mean age ± s.d. 38.6 ± 3.6 years; mean BMI ± s.d. 24.8 ± 3.8 kg/m^2; mean duration of pregnancy 37.8 ± 0.7 weeks). Seven women had a vaginal birth and 7 underwent a caesarian section (newborn mean weight was 3352.1 ± 729.8 g). We used non-parametric analysis of covariance to assess the mean daily insulin dosage during lactation, regarding the way of breastfeeding (exclusive or part-time) as a co-factor, in relation to age, duration of pregnancy, mean weight gain in pregnancy, the newborns' mean weight, hypoglycemic episodes in lactation and insulin requirements before and during pregnancy.
Results
Regarding the glycemic profile variability, the mean HbA1c before pregnancy was 7.5 ± 1.5%, with an average daily insulin dosage of 54.7 ± 14.1U. During pregnancy the average daily insulin requirements were increased at 98.8 ± 31.0U, with a mean HbA1c of 6.6 ± 0.5% and a mean weight gain of 15.78 ± 5,4 kg. Seven women breastfed exclusively and 7 part-time. At the first trimester of breastfeeding the average daily insulin dosage was 44.4 ± 12.6U with a mean HbA1c of 7.7 ± 1.9%. In the group of women who breastfed exclusively, a 26% reduction of median daily insulin dosage was noted compared to pre-pregnancy levels. In the group of part-time breastfeeding the insulin dosage reduction was 13,5% respectively. During breastfeeding, 42.8% (6/14) of women experienced repeated episodes of hypoglycemia, with an equal distribution (50%) in relation to the type of breastfeeding (exclusive/part-time). A trend (P = 0.10) was noted between exclusive breastfeeding with the need for slightly lower insulin dosage in correspondence with weight gain in pregnancy.
Conclusions
The expected changes in caloric needs, diet, timeline, and consequently of the metabolic profile of women with DM1 during breastfeeding, lead to a reassessment of their therapeutic algorithm, mainly to prevent hypoglycemic episodes.

The impact of gestational weight gain on subclinical atherosclerosis, placental circulation and neonatal complications

Marina Shargorodsky & Guilia Barda
Wolfson Medical Center, Tel aviv University, Tel Aviv, Israel.

Objective
Vascular atherosclerotic changes, mediated by environmental and genetic factors, develop years before an event. Detection of vascular damage, using ultrasonographic measurement of carotid IMT, is predictive of future cardiovascular events. The present study was designed to investigate the impact of gestational weight gain (GWG) on early atherosclerotic changes during late pregnancy, using intima media thickness (IMT), as well as placental vascular circulation and inflammatory lesions and pregnancy outcome.
Design and methods
59 women who gave birth at Wolfson Medical Center during 2018 were divided into two groups according weight gain during pregnancy: Group 1 included 32 women with pregnancy weight gain within recommended range, Group 2 included 27 wonen with exessive weight gain during pregnancy. IMT was measured by High-resolution B-mode ultrasound (Sonosite Titan/Sonosite, Inc., Bothell, Washington, USA). Placental histology was performed for vascular circulation, as well as inflammatory lesions of maternal and fetal origin. Metabolic measures such as fasting glucoe, lipids, hs-CRP, HOMA-IR were determined. Maternal and neonatal outcome parameters were collected.
Results
Weight gain during the pregnancy was significantly higher in Group 1, compared to Group 2 (17.5 ± 6.2 vs 6.8 ± 5.7, P < 0.0001), whereas pre-gestational BMI did not differ significantly between groups (P = 0.059). IMT levels differed between groups and was significantly higher in group 1 compared to Group 2 (0.7 ± 0.1 vs 0.6 ± 0/1, P = 0.028). In regression analisys, pregnancy weight gain remained a significant independent predictor of IMT. Rate of macrosomia was significantly higher in Group 1 than in Group 2 (P = 0.014). Maternal vascular supply (MVS) abnormalities of the placental bed did not differ significantly between groups (P = 0.297). Among placental lesions related to fetal vascular malperfusion, villous changes consistent with fetal thrombo-occlusive disease (FTOD) were significantly higher in Group 1 than in group 2 (P = 0.034).
Conclusion
In the present study, excessive weight gain during pregnancy was significantly and independently associated with an increased IMT. Among placental vascular lesions, villous changes consistent with fetal thrombo-occlusive disease (FTOD) were significantly higher women with excessive weight gain during pregnancy. Among neonatal complications, rate of macrosomia was significantly higher in women with excessive weight gain during pregnancy.

Small molecule allosteric agonist of relaxin receptor ML290 demonstrates antifibrotic properties in liver fibrosis

Elena Kaftanovskaya[1], Hooi Hooi Ng[1], Mariluz Soula[1], Bryan Rivas[1], Courtney Myhr[1], Brian Ho[1], Briana Cervantes[1], Colin Bishop[2], Thomas Shupe[2], Kenneth Wilson[3], Elena Barnaeva[3], Marc Ferrer[3], Noel Southall[3], Juan Marugan[3], Irina Agoulnik[1] & Alexander Agoulnik[1]
[1]Herbert Wertheim College of Medicine, Florida International University, Miami, USA; [2]Wake Forest Institute for Regenerative Medicine, Wake Forest School of Medicine, Winston-Salem, USA; [3]NIH Chemical Genomics Center, National Center for Advancing Translational Sciences, National Institutes of Health, Rockville, USA.

The beneficial effects of relaxin peptide treatment have been demonstrated in animal models of liver fibrosis. However, the low stability of peptide *in vivo* prevents using it in chronic treatments. We have identified a series of small molecule allosteric agonists of the human relaxin receptor, RXFP1. The therapeutic effects of lead compound ML290 was tested in various models of liver fibrosis. To analyze the anti-fibrotic effects of ML290 on gene expression, we used primary human hepatic stellate cells followed by RNAseq analysis of ML290 treatment in an established human stellate cell line, LX-2. We then tested the effects of ML290 in fibrotic human liver organoids and in a carbon tetrachloride model of mouse liver fibrosis. We demonstrated that RXFP1 expression is increased in fibrotic mouse liver, specifically in activated hepatic stellate cells. The lead compound, ML290, was selected based on its effects on the gene expression profile associated with fibrosis in primary human stellate cells. RNA-Seq analysis of TGFβ1-activated LX-2 cells showed that about 500 genes were misregulated by ML290. Gene Ontology analysis demonstrated that ML290 treatment primarily affects extracellular matrix remodeling and cytokine signaling. ML290 treatment in human liver organoids with lipopolysaccharide-induced fibrotic phenotype resulted in dramatic reduction of type I collagen. The pharmacokinetics of ML290 in mice after multiple daily injections demonstrated its high stability *in vivo*, as evidenced by the sustained concentration of compound in the liver. In mice expressing human RXFP1 gene treated with carbon tetrachloride, ML290 significantly reduced collagen content, alpha-smooth muscle actin expression, and cell proliferation around portal ducts. In summary, ML290, the small molecule agonist of relaxin receptor, has anti-fibrotic effects in liver fibrosis.

Caffeine upregulates hepatic SHBG production by increasing adiponectin in white adipose tissue

Laura Brianso-Llort, Lidia Fuertes-Rioja, Lorena Ramos Perez, Cristina Hernandez, Rafael Simo & David Selva
Vall d'Hebron Research Institute (VHIR), Barcelona, Spain.

Epidemiological studies have shown that caffeine increases plasma SHBG levels and also reduce the risk of type 2 diabetes. There are no reports describing any molecular mechanism by which caffeine regulates hepatic SHBG production. The aim of the present study was to explore whether caffeine regulates SHBG production and to determine the associated molecular mechanisms. For this purpose, *in vitro* and *in vivo* studies were performed using human HepG2 cells and human *SHBG* transgenic mice. Our results showed that caffeine treatment did not change SHBG production in HepG2 cells. By contrast, caffeine treatment increased significantly both plasma and hepatic mRNA SHBG levels in human *SHBG* transgenic mice when compared with control mice. Caffeine treatment increased adiponectin mRNA levels in epididymal adipose tissue of human *SHBG* transgenic mice and in differentiated 3T3-L1 mouse adipocytes. This caffeine-induced increase in adiponectin in turn upregulated the hepatic levels of HNF-4a in human *SHBG* transgenic mice. Our results showed for the first time that caffeine upregulates hepatic SHBG expression by increasing adiponectin production in the adipose tissue. These results suggest that the beneficial effects of caffeine in preventing type 2 diabetes development could be mediated by increasing SHBG plasma levels.

Activation of the ATM/Akt/CREB/eNOS expression signaling axis by aphidicolin increases nitric oxide production to attenuate endothelial cell death

Du-Hyong Cho[1], Jung-Hyun Park[2], Jee Young Lee[2], Hyeon-Ju Lee[2] & Inho Jo[2]
[1]Department of Pharmacology, College of Medicine, Yeungnam University, Daegu, Republic of Korea; [2]Department of Molecular Medicine, College of Medicine, Ewha Womans University, Seoul, Republic of Korea.

Previously, we reported that aphidicolin acutely increases nitric oxide (NO) production in bovine aortic endothelial cells (BAECs) by increasing phosphorylation of endothelial nitric oxide synthase at serine 1179 (p-eNOS-Ser^{1179}) and decreasing phosphorylation at serine 116 (p-eNOS-Ser^{116}) without altering eNOS protein expression. Here, we demonstrate that prolonged treatment with aphidicolin (over 24 h) also increased NO production in BAECs. Unlike the acute effects of aphidicolin, however, prolonged treatment increased expression of eNOS protein and dimerization with elevated level of tetrahydrobiopterin, an essential cofactor for eNOS dimerization. The NOS inhibitor, Nω-Nitro-l-arginine methyl ester hydrochloride (L-NAME), completely reduced aphidicolin-induced NO production, despite no change of eNOS protein. Prolonged treatment with aphidicolin increased mRNA expression of eNOS. A promoter assay using 5′-serially deleted eNOS gene promoters (−1600 to +22; −962 to +22; −873 to +22; −428 to +22) revealed that the Tax-responsive element (TRE) site, a cAMP response element (CRE)-like site, located at -962 to -873 of the eNOS promoter, was responsible for aphidicolin-stimulated eNOS gene expression. Ectopic expression of a dominant-negative inhibitor of CRE binding protein (CREB), A-CREB, repressed the stimulatory effects of aphidicolin on eNOS gene expression and its promoter activity. We also found that aphidicolin increased CREB activity, as evidenced by increased level of p-CREB-Ser^{133}. Co-treatment with LY294002, a phosphoinositide 3-kinase inhibitor, but not H-89, an inhibitor of protein kinase A, decreased the aphidicolin-stimulated increase in p-CREB-Ser^{133} levels, eNOS expression, and NO production. Furthermore, ectopic expression of a dominant-negative Akt construct attenuated aphidicolin-stimulated NO production. Aphidicolin also increased phosphorylation of ataxia telangiectasia mutated kinase (ATM) at Ser^{1981} (p-ATM-Ser^{1981}) and the knockdown of ATM using small interfering RNA (siRNA) attenuated all stimulatory effects of aphidicolin on p-Akt-Ser^{473}, p-CREB-Ser^{133}, eNOS expression, and NO production. Lastly, aphidicolin significantly decreased BAEC viability, which was further decreased by co-treatment with the NO scavenger, 2-phenyl–4, 4, 5, 5,-tetramethylimidazoline-1-oxyl 3-oxide or the NOS inhibitor, L-NAME. Similarly, the knockdown of eNOS using siRNA further aggravated EC damage, suggesting a protective role for NO in EC death caused by aphidicolin. Taken together, our results suggest that aphidicolin increases NO production in BAECs by increasing eNOS expression via an ATM/Akt/CREB signaling cascade, which contributes to the attenuation of aphidicolin-induced EC death.

Evaluation of the CCK-2 receptor agonist 177Lu-PP-F11N for radionuclide therapy of medullary thyroid carcinoma – final Results of the phase 0 'Lumed' Study

Christof Rottenburger[1], Guillaume Nicolas[1], Lisa McDougall[1], Felix Kaul[1], Michael Cachovan[2], Roger Schibli[3], Susanne Geistlich[3], Martin Béhé[3], Damian Wild[1] & Emanuel Christ[4]
[1]Division of Nuclear Medicine, University Hospital of Basel, Basel, Switzerland; [2]Siemens healthcare GmbH, Forcheim, Germany; [3]Center for Radiopharmaceutical Sciences, Paul Scherrer, Villigen, Switzerland; [4]Division of Endocrinology, Diabetology and Metabolism, Basel, Switzerland.

Objectives
Despite the introduction of new molecular targeted therapies, there is still an unmet need for an effective systemic therapy for advanced medullary thyroid carcinoma (MTC). As MTC expresses cholecystokinine-2 (CCK-2) receptors at a high incidence and density, targeting the CCK-2 receptor with radiolabelled gastrin analogues is a potential approach for radionuclide therapy. Unfortunately, kidney and bone marrow toxicity precluded therapeutic applications of CCK-2 receptor specific radiotracers until now. The aim of this prospective clinical study is to test the proof of principle that the novel gastrin analogue [^{177}Lu-DOTA-(DGlu)$_6$-Ala-Tyr-Gly-Trp-Nleu-Asp-PheNH$_2$] (^{177}Lu-PP-F11N) targets effectively metastases of MTC (ClinicalTrials.gov: NCT02088645).

Methods
Six patients received two injections of 1 GBq ^{177}Lu-PP-F11N, one injection with and the other without Physiogel (Gelofusin = plasma expander for nephroprotection) infusion. Planar scintigraphy and SPECT/CT scans were performed at several time points for up to 72 h post injection in order to calculate tumor- and organ doses using 3D volume based MIRD dosimetry (Dosimetry Research Tool v5.2, Siemens Medical Solutions, USA). Blood samples were taken for bone marrow dose calculations. ECG, blood count and blood chemistry were measured up to 12 weeks after the second administration of ^{177}Lu-PP-F11N in order to evaluate adverse events.
Results
Adverse reactions (mainly hypotension, flushing and hypokalemia) were self-limiting and not higher than grade 1, according to CTCAE version 4.03. In all patients, ^{177}Lu-PP-F11N accumulation was visible in tumor tissue, in the kidneys, stomach and the colon. Altogether, 13 tumors were eligible for dosimetry. The median (range) radiation dose for tumors, stomach, kidneys and bone marrow was 0.88 Gy/GBq (0.38–8.04), 0.42 (0.13–2.07), 0.1 (0.05–0.15) and 0.010 (0.008–0.016). These resulted in median tumor-to-kidney dose ratios of 12.3 (6.8–27.6) (without Physiogel) and 13.0 (6.4–21.8) (with Physiogel), which was not significantly different (Wilcoxon test $P=0.19$). The median tumor-to-bone marrow dose ratio was 77.7 (52.8–398.5).
Conclusions
The administration of the novel CCK-2 receptor ligand ^{177}Lu-PP-F11N was safe in all six examined patients. Visualization of metastasized/recurrent disease in all patients provides evidence that CCK-2 receptor targeting with ^{177}Lu-PP-F11N is feasible in patients with MTC. The dosimetry results indicate tumor doses that could enable radionuclide therapy. Dosimetry results for kidneys and bone marrow revealed low organ doses, as well as excellent tumor-to-kidney and tumor-to-bone marrow ratios. Further studies will be necessary to evaluate the theranostic potential of ^{177}Lu-PP-F11N in patients with CCK-2 receptor expressing tumors.

Multikinase inhibitors for the treatment of progressive, metastatic parathyroid cancer

Julia Krupinova[1], Natalia Mokrysheva[1], Ekaterina Pigarova[1], Vera Gorbunova[2], Iya Voronkova[1] & Liudmila Rozhinskaya[1]
[1]Endocrinology Research Centre, Moscow, Russian Federation; [2]Cancer Research Center, Moscow, Russian Federation.

Introduction
The treatment of choice for parathyroid carcinoma (PC) is a radical en bloc resection. Treatment options for patients with metastatic PC are limited especially if a complete tumor removal cannot be performed. We present four cases of PC patients with multiple metastasis and refractory hypercalcemia that eventually received a multikinase inhibitor with different response on therapy.
Clinical cases
The first patient was a 27-year-old woman with metastatic PC in the right lung (2.9 cm and 2.2 cm). Five months after the thoracoscopic resection of the lung lobe, PTH was 720 pmol/l, (15-65), ca – 2.74 mmol/l (2.10–2.55). Diffusional MRI (DW-MRI) showed multiple lesions in both lungs (0.2–0.5 cm). Based on the reports of successful sorafenib treatment in metastatic PC by Dr. Lerario A.M. we started a targeted therapy with 400 mg of sorafenib 2 times a day. The therapy showed good results: over the next three years of sorafenib treatment, we've observed stabilization of the metastatic process according to PET/CT (lesions in lungs without uptake of the 18-fluorodeoxyglucose) as well as normocalcemia and significant reduction of PTH in lab tests. The second and the third cases are very similar. Both patients (76 and 61 years old woman underwent 5 surgeries on the neck because of the recurrent disease and both had metastasis in lungs. Based on our own experience we started the sorafenib therapy. After a year, despite persistent elevated levels of PTH (2000–2500 pg/ml) and Ca (2.7–2.9 mmol/l) the PET/CT showed the significant reduction in metastases size regarded as the stabilization of the process. So we decided to continue the sorafenib therapy. The fourth patient (64-years old woman) had the most aggressive PC course with multiple metastases in the neck lymph nodes, lungs, liver, left clavicle, C6-7 and L4 vertebras. She referred to our centre after 6 reoperations on the neck, 3 sessions of radiation therapy (SOD 87.4 Gy), ineffective chemotherapy with capecitabinum (Ca− 3,10 mmol/l, PTH- 2090 pg/ml). 4 weeks after we initiated sorafenib therapy and noted a dramatic decrease in PTH to 98.2 pg/ml and Ca to 2,15 mmol/l (tested twice). However three months after the start treatment PET/CT showed the increase in metastasis size and the newly formed lesions. The sorafenib therapy was stopped because of the ineffectiveness.
Conclusions
Sorafenib seems to be a promising drug for targeted therapy in some PC cases.

Serine-threonine PAK1 as a novel common node for estrogen- and prolactin-dependent pathways in breast cancer

Maria Diakonova
University of Toledo, Toledo, USA.

Even though serine-threonine kinase PAK1 is activated by estrogen and plays an important role in breast cancer, the role of PAK1 in estrogen response is not fully understood. We have shown that estrogen activates PAK1 through both ERα and GPER1 plasma membrane receptors and that cytoplasmic Etk/Bmx directly phosphorylates Tyr153-PAK1 and activates PAK1 in response to estrogen. We have described a signaling complex composed of pTyr-PAK1, Etk, the heterotrimeric G-protein subunits, Gβ1, Gγ2 and/or Gγ5, βPIX (PAK-associated guanine nucleotide exchange factor) and PKA (protein kinase A) which, upon formation, activates PAK1 through positive feed-back manner. The PKA catalytic subunit (PKA-Cα) directly phosphorylates PAK1 while the PKA RIIβ subunit is a direct target of PAK1. In response to estrogen, activated pTyr-PAK1 complex reciprocally potentiates PKA activation. PKA phosphorylates Ser305-ERα in response to estrogen. However, in response to prolactin (PRL), Ser305-ERα is phosphorylated by pTyr-PAK1. Our data suggest that in cells exposed to both PRL and estrogen, Ser305-ERα is phosphorylated by both PKA and pTyr-PAK1 resulting in maximal signal. Furthermore, S305-ERα activation leads to enhanced phosphorylation of Ser118-ERα, and promotes cell proliferation and tumor growth. Together, our data strongly support a critical interplay between PRL and estrogen via PAK1. Ligand-independent activation of ERα suggests that PRL/PAK1 may contribute to resistance to anti-estrogen therapies. Thus, we propose that PAK1 serves as a common node for estrogen- and PRL-dependent pathways, making it an attractive target for anti-cancer therapy.

Melatonin prevented beta cell senescence against glucolipotoxicity

Mi-kyung Kim[1,2], Hye Sook Jung[2], Jeong Eun Jang[1], Tae Nyun Kim[1], Min Jeong Kwon[1], Soon Hee Lee[1], Byung Doo Rhee[1] & Jeong Hyun Park[1,2]
[1]Division of Endocrinology and Metabolism, Department of Internal Medicine, College of Medicine, Inje University, Busan, Republic of Korea; [2]Paik Institute for Clinical Research, Molecular Therapy Lab, Inje University, Busan, Republic of Korea.

Beta cell senescence is being regarded as the one of the mechanisms of beta cell dysfunction. Melatonin secreted primarily from the pineal glandregulates a variety of physiological functions, such as sleep, circadian rhythms, and neuroendocrine actions. Melatonin has also very strong anti-oxidant effects. The effects of melatonin on the pancreatic beta cell senescence induced by glucolipotoxicity have not been studied. INS-1 cells were exposed to 33mM glucose with palmitate 200uM (glucolipotoxicity: HG + palmitate (HGP)) with or without melatonin. Cell viability and apoptosis were assessed by MTT assay and Annexin V staining. We compared senescence β-Galactosidase (SA-β-Gal) staining and $p16^{INK4a}$immunostaining depending on melatonin treatment against HGP. We assessed phospho-p38 MAPK, Sirt1 and p16 protein expression with and without melatonin. CDK4 protein and anti-oxidant enzyme were assessed in both conditions. Melatonin increased INS-1 cell viability and decreased apoptosis against HGP. SA-β-Gal and $p16^{INK4a}$ immunostaining were increased in HGP, and melatonin significantly reversed them. Melatonin decreased phospho-p38 MAPK and $p16^{INK4a}$ protein expression in 24 hours. Melatonin increased Sirt1, Mn-SOD and catalase expression against HGP. In conclusion, we found that melatonin prevent beta cell senescence induced by metabolic stresses like glucolipotoxicity. The effects of melatonin on beta cell aging may be related with phospho-p38 MAPK and $p16^{INK4a}$ pathway, and anti-oxidant system.

Low-dose pollutant mixture triggers metabolic disturbances in ovariectomized mice and comparison with the effects of 17β-estradiol (E2) treatment

Benoit Julien, Nathalie Vega, Claudie Pinteur, Hubert Vidal, Danielle Naville & Brigitte Le Magueresse-Battistoni
Univ-Lyon, CarMeN laboratory, INSERM U1060, INRA U1397, Université Claude Bernard Lyon1, INSA Lyon, Charles Mérieux Medical School, Oullins, France.

Introduction
Environmental pollutants especially those endowed with endocrine disrupting activities have been shown to contribute to metabolic related diseases suggesting that hormonal deficit conditions as observed in post-menopausal women may constitute aggravating conditions. To explore this hypothesis, we used the model developed in the laboratory which consists in a chronically exposure of mice to low-dosed chemicals in mixture incorporated in a high-fat-high-sucrose diet (HFHSD). Within the present study, mice were ovariectomized to mimic hormonal deficit.
Methods
Five week-old C57Bl6/J mice fed a HFHSD were divided in sub-groups depending on surgery (sham, ovariectomy (Ovx), Ovx + E2 implants) performed by week 7. Half of the Ovx and Ovx + E2 were exposed to a mixture of 2,3,7,8-TCDD (dioxin), polychlorobiphenyl (PCB)153, DEHP (phthalate) and bisphenol A at doses resulting in mice exposure at the Tolerable Daily Intake dose range (TDI) for each pollutant. The other half received vehicle only. Protocol lasted 15 weeks. A glucose tolerance test was performed and we measured several blood parameters and hepatic TG and cholesterol accumulation. Gene expression studies were performed by RT-qPCR in the liver and adipose tissues.
Results
Ovariectomised mice exhibited enhanced body weight and fat pads, glucose intolerance and insulin resistance (normalized by E2 replacement) but no hepatic TG accumulation. A set of estrogen-regulated genes was also identified in the liver and the adipose tissues at the mRNA level. Exposure to the mixture of pollutants did not impact body weight or glucose tolerance but adiponectin levels were altered. In addition, it resulted in enhanced hepatic lipid deposition and in changes in the mRNA level of genes related to lipid metabolism. Specifically, genes impacted included Nr1h3, Nr0b2, Cd36 and Cyp7a1 but not Esr1 in a direction distinct from the one triggered by E2 replacement. Pollutant exposure also differentially impacted the subcutaneous and visceral adipose tissues at the gene expression mRNA level, especially estrogen receptors reproducing part of the effects elicited by E2 treatment.
Conclusion
These data support the concept of the cocktail effect if considering that the dosage of the pollutants in the mixture is based on the TDI dose, thus not expected to generate an adverse effect. Interestingly, we found that the pollutant mixture triggered effects distinct or mimicking E2 treatment, depending on the metabolic tissue considered. These findings may have implications for the understanding of the potential role of environmental contaminants in the development of metabolic diseases, especially in females during the menopausal transition.

In vitro effects of bisphenol A and its analogs on human melanocortin 4 receptor

Mathilde Louvigné[1,2], Louis Gourdin[1,3,4], Claire Briet[1,3,4], Patrice Rodien[1,3,4] & Mathilde Munier[1,3,4]
[1]Inserm1083-Cnrs6015, Angers, France; [2]Department of Pediatric Endocrinology, University Hospital, Angers, France; [3]Department of Endocrinology, University Hospital, Angers, France; [4]Reference Center for Rare Disease of Thyroid and Hormone Receptors, University Hospital, Angers, France.

Bisphenol A (BPA) is a widely used chemical and belongs to the list of metabolism-disrupting chemicals. BPA is banned in several countries and replaced by others BPA-analogs. We investigate the effects of BPA and 6 BPA-analogs (BPS, BPAF, BPF, BPB and BADGE) on the response of the human melanocortin 4 receptor (MC4R), a receptor involved in food intake and weight control, to its natural ligands. We used HEK293 cells line transiently transfected with human MC4R to determine the impact of bisphenols on MC4R-dependent cAMP production. BPAF (10^{-11}M) and BPF (10^{-11}M) were the most potent positive modulators of α Melanocortin-Stimulating Hormone (MSH) response, followed by BPB (10^{-9}M) = BADGE (10^{-9}M) > BPS (10^{-8}M) = BPA (10^{-8}M). Moreover, BPA (10^{-8}M) impaired the response of MC4R to the Agouti-related Peptide (AgRP), a natural inverse agonist of the receptor. In HEK293 mock-transfected cells, bisphenols had no effect on basal or adenosine induced cAMP response. Thus, the potentiating effect of bisphenols was dependent on and specific of the MC4R. In opposite, we showed that BPA and BPA-analogs reduced by half the response of melanocortin 3 receptor to α MSH. In conclusion, our *in vitro* findings suggest that human MC4R is a target for both BPA and BPA-analogs. These findings highlight that BPA analogs retain an activity similar to that of BPA and thus they may still remain potential metabolism-disrupting chemicals.

Can phthalates impair liver function?

Milica Medic-Stojanoska[1,2], Natasa Milosevic[1], Maja Milanovic[1], Stefan Stojanoski[1,3], Bojan Vukovic[1,2], Tijana Icin[1,2], Ivana Bajkin[1,2], Kristina Stepanovic[1,2], Jan Sudji[1] & Natasa Milic[1]
[1]University of Novi Sad, Faculty of Medicine, Novi Sad, Serbia; [2]Clinical Center of Vojvodina, Novi Sad, Serbia; [3]Oncology Institute of Vojvodina, Novi Sad, Serbia.

Introduction
The impairment of liver function and enhancement for NAFLD development may be attributed to the ubiquitous exposure to endocrine disrupting chemicals such as phthalates. In this study the urinary levels of monoethyl phthalate (MEP) and mono-(2-ethylhexyl) phthalate (MEHP) were compared with the parameters of hepatic function and lipids in overweight, diabetic patients and normal weight population.
Methods and patients
In 305 volunteers of both genders who were divided into three groups based on the body mass index, waist circumference and glucose levels: I -obese with central obesity, II -patients with diagnosed type 2 diabetes mellitus (T2DM) treated only with medical nutrition therapy and III-control, normal weight healthy volunteers, phthalate metabolites concentration was determined in the morning spot urine.
Results
The urine samples from 66 volunteers were positive on MEP while 72 were positive on MEHP. Aspartate Aminotrasferase (AST) and Alanine Aminotransferase (ALT) concentrations differed significantly between MEP+ and MEP-normal weight healthy volunteers ($P=0.02$ and $P=0.01$, respectively) while significantly higher Gamma-Glutamyl transferase GGT levels were observed in MEHP+ control subgroup ($P=0.017$). The positive correlation was observed between AST, ALT and $\log_{10}$MEP levels in obese patients ($P=0.02$ and $P=0.05$). GGT positively correlated with MEP concentration in T2DM patients ($P=0.048$). Negative correlation was found between $\log_{10}$MEP values in the control group and both total cholesterol and LDL levels ($P=0.0051$ and $P=0.0015$, respectively) while in obese group MEP was positively associated with serum triglycerides ($P=0.024$). The $\log_{10}$MEHP in the control group was correlated negatively with serum HDL ($P=0.0035$). BMI was significantly increased ($P=0.044$) in BMI in MEHP+ control subgroup compared to MEHP-.
Conclusions
The ubiquitous exposure to phthalates may be related to the impairment of normal liver function according to the results obtained in this study.

Evaluation of postoperative copeptin concentration as a predictive factor of diabetes insipidus after pituitary surgery. preliminary results

C Navarro-Hoyas[1], J Serrano Gotarredona, L Delegido-Gómez[1], R Alfayate[3], S Serrano Corredor[1], P Revert Marrahi[1], R Sánchez-Ortiga[1] & A Picó Alfonso[2]
[1]Endocrinology and Nutrition Department; Alicante University General Hospital; ISABIAL-FISABIO, Alicante, Spain; [2]Endocrinology and Nutrition Department; Alicante University General Hospital. Miguel Hernández University; ISABIAL-FISABIO, Alicante, Spain; [3]Hormone Laboratory, Alicante University General Hospital; Isabial-Fisabio, Alicante, Spain.

Introduction
Central diabetes insipidus (DI) is observed in up to 34% of patients undergoing pituitary surgery. Early postoperative diagnosis of DI is critical because its detection allows early treatment, reducing morbidity and hospital stay. AVP levels measurement is not commonly used to diagnose DI. As an alternative, copeptin determination has been proposed, but its usefulness has only been validated in one series.

Objective
To define the threshold and optimal measurement time of serum copeptin for early prediction of DI after pituitary surgery in an independent series.
Design
Observational, prospective study in a unique center. *Subjects*: Patients operated by endonasal surgery from 2017 to 2018, excluding those with pre-surgery DI. *Variables*: serum copeptin, sodium, potassium, glucose, creatinine, urea, plasma and urinary osmolality, and glomerular filtration before and at 4-6h, 24h and 48h after surgery, preoperative basal serum cortisol, TSH and free thyroxine, sex and tumor features (size, invasion, chiasmatic compression and functionality). *Statistical analysis*: SPSSv.21. Kolmogorov-Smirnov test to evaluate normality of the distribution. Descriptive of quantitative variables: mean and standard deviation in parametric distributions, median and *P*25–75 in nonparametric ones. Calculation of the best cut-off point by Receiver Operating Characteristic (ROC) curves in each time. Calculation of sensitivity (Se), specificity (Sp), negative (NPV) and positive predictive value (PPV).
Results
27 patients, 32% women. Age 49 ± 17years. Maximum diameter 20.3 ± 9mm. Clinical diagnosis: 55% non-functioning adenomas, 15% Prolactinomas, 19% acromegaly, 7% Cushing's disease, 4% pituitary apoplexy. Eight (30%) patients developed post-surgery DI. Copeptin concentrations at 4–6h after extubation was significantly lower (7.7 vs 16.5 pmol/L, $P = 0.037$) in patients who developed postoperative DI than those who did not. No other significant differences between groups were found in any of the studied variables, except for the development of cerebrospinal fluid leak ($P = 0.006$). The greater diagnostic validity of copeptin for the detection of DI in the postoperative period was obtained 24h after surgery, with a threshold point of 3 pmol/L (Se 62.5%, Sp 95%, PPV 83.3%, NPV 86.3%). All patients who presented DI normalized their neurohypophyseal function during the follow-up, except one with persistent DI two months after surgery.
Conclusions
The prevalence of post-surgery DI in the studied series (30%) agrees with that described in the literature. Our preliminary results suggest that copeptin measured 24h postoperatively may be a useful tool for early diagnosis of DI, although the optimal threshold differs from that previously reported.

Is the molecular study of pituitary transcription factors useful in the identification of Pituitary Neuroendocrine Tumor subtypes according to the new WHO 2017 criteria?

Araceli García-Martínez[1], Sebastián Martínez-López[1], María Eugenia Torregrosa[2], Sandra Silva[3], Carmen Fajardo[4], Rosa Cámara[5], Cristina Lamas[6], Ignacio Aranda[3] & Antonio Picó[7]
[1]Research Laboratory, Hospital General Universitario de Alicante-ISABIAL, Alicante, Spain; [2]Clinical Analysis Department, Hospital General Universitario de Alicante, Alicante, Spain; [3]Pathology Department, Hospital General Universitario de Alicante, Alicante, Spain; [4]Endocrinology Department, Hospital La Ribera, Alzira, Spain; [5]Endocrinology Department, Hospital Universitario y Politécnico La Fe, Valencia, Spain; [6]Endocrinology Department, Complejo Hospitalario Universitario de Albacete, Albacete, Spain; [7]Endocrinology Department, Hospital General Universitario de Alicante-ISABIAL, Alicante, Spain.

Introduction
Recently we have demonstrated the contribution of the quantification of expression of adenohypophyseal hormone genes in the identification of the different Pituitary Neuroendocrine Tumor (PitNET) subtypes according to the 2004 WHO criteria.
Aim
The aim of the present study was to evaluate the contribution of the quantification of expression of pituitary transcription factor genes to the identification of PitNETs according to 2017 WHO criteria.
Methods
From our collection of 300 PitNETs, we selected 93 tumors with complete clinical, immunohistochemical and molecular information with sufficient quality and quantity of remmanent biological material. In this study, we are reporting preliminary results of 41 tumors analyzed to date. The series analyzed include 6 corticotropinomas (CT), 7 somatotropinomas (3 mixed GH-PRL), 3 thyrotropinomas (TT), 14 gonadotropinomas (GT), 4 plurihormonal tumors (PH), 5 null cell tumors and 2 samples initially considered as normal pituitary gland. We quantified the gene expression of *TBX19* (Tpit), *POU1F1* (Pit1), *SF1, GATA2 and ESR1* by quantitative real-time-PCR (qRT-PCR). The relative differences in gene expression were expressed as fold change and were obtained with the $2^{-\Delta\Delta Ct}$ method. We relied on the dominant gene expression in the qRT-PCR of the transcription factors to identify the different subtypes of PitNETs.
Results
All ST (pure and mixed) and TT PitNETs predominantly expressed *POU1F1* (Pit1), confirming the previous molecular identification. Thirteen out of 14 GT expressed dominantly *GATA2*, confirming the GT lineage. The remaining tumour expressed *NEUROD1* suggesting a CT cell origin. Five out of 6 CT expressed *TBX19* (Tpit), verifying the CT origin. One CT expressed *GATA2*, suggesting a GT cell origin. t Two out of 5 null cell tumors, expressed *SF1* and 1 expressed *GATA2* suggesting a GT origin. The last two expressed both, *NEUROD1* and *GATA2*, indicating a CT-GT lineage. Among the 4 PH tumors, 3 expressed *POU1F1* (Pit1) and one expressed *GATA2*. Finally, one of the 2 samples initially considered as normal pituitary gland was identified as GT, since it predominantly expressed *GATA2*, while the other sample was confirmed as normal tissue.
Conclusion
In conclusion the molecular quantification of pituitary transcription factors validates the strength of our previous results of the contribution of the study of the expression of the adenohypophyseal hormone genes in the identification of PitNET subtypes. Moreover, allows us to reclassify the null cell and plurihormonal tumors and suggest the existence of a corticotroph-gonadotroph subtype. The complete series with molecular an immunohistochemical results will be presented in the congress.

DOI: 10.1530/endoabs.63.GP234

GP235

The effect of previous optic chiasm compression on the post-illumination pupil response in pituitary patients

Tessel Boertien[1,2], Wisse van der Meijden[3], Adriaan Coumou[4], Madeleine Drent[2], Eus Van Someren[3,5,6], Hans Romijn[7], Eric Fliers[1] & Peter Bisschop[1]
[1]Amsterdam UMC, University of Amsterdam, Dept. of Endocrinology & Metabolism, Meibergdreef 9, Amsterdam, Netherlands; [2]Amsterdam UMC, Vrije Universiteit Amsterdam, Dept. of Internal Medicine, Section of Endocrinology, De Boelelaan 1117, Amsterdam, Netherlands; [3]Netherlands Institute for Neuroscience, Amsterdam, Netherlands; [4]Amsterdam UMC, University of Amsterdam, Dept. of Ophthalmology, Meibergdreef 9, Amsterdam, Netherlands; [5]Amsterdam UMC, Vrije Universiteit Amsterdam, Dept. of Psychiatry, Amsterdam, Netherlands; [6]VU University Amsterdam, Dept. of Integrative Neurophysiology, Center for Neurogenomics and Cognitive Research, Amsterdam, Netherlands; [7]Amsterdam UMC, University of Amsterdam, Dept. of Internal Medicine, Meibergdreef 9, Amsterdam, Netherlands.

Rationale
A history of optic chiasm compression in patients treated for sellar tumors is associated with alterations in sleep-wake rhythm. The optic chiasm contains axons of intrinsically photosensitive retinal ganglion cells (ipRGCs) that mediate photoentrainment of the suprachiasmatic nucleus. Compression could disrupt this entrainment leading to desynchronization with the 24-hour light-dark cycle. The post-illumination pupil response (PIPR) after blue light exposure is a unique indicator of ipRGC function. PIPR measurement presents a promising tool to evaluate ipRGC impairment due to compression of the optic chiasm. This study is the first to compare the PIPR between pituitary patients with and without a history of chiasm compression.
Methods
Adult patients with at least one centrally impaired endocrine axis and normal ocular health were eligible for inclusion. Patients in the chiasm compression group all had visual field defects prior to treatment. Groups were matched for age, gender and BMI. The PIPR was assessed using a validated chromatic pupillometry protocol of five 5-minute blocks, ensuring reliable pupil measurements. The primary outcome parameters were defined as the absolute (PIPR-mm) and the relative (PIPR-%) difference between baseline and post-blue-stimulus pupil diameter averaged over the 2nd-4th minute of the corresponding block. For sufficient power, 25 patients were included in each group.
Results
For this analysis, pupillometry results of 23 patients in the chiasm compression group (CC+) and 22 patients in the control group (CC−) were available. Groups did not differ in relevant clinical characteristics or in baseline pupil diameter. No significant differences were found in PIPR-mm (mean ± SD, CC + 1.70 ± 0.74mm and CC− 2.14 ± 0.88mm; $P = 0.07$) and PIPR-% (CC + 36.80 ± 10.97% and CC− 41.62 ± 9.24%; $P = 0.12$). On further examination of the normalized (i.e. relative to baseline) pupil diameter data, a less sustained PIPR in the CC+ group was observed. The difference in PIPR-% reached significance during the last minute of the post-blue block (CC + 32.23 ± 12.34% and CC− 40.87 ± 8.23%; $P = 0.009$), suggesting at least partial impairment of ipRGC function.
Conclusion
These preliminary results do not show significant differences in our primary PIPR outcomes. However, a less sustained PIPR was demonstrated in the CC+ group, which might correspond to less robust ipRGC transduction. The study identifies the PIPR as a potential tool to evaluate dysfunction of ipRGCs in patients with optic chiasm compression.

Characteristics and natural history of a large cohort of non-functioning pituitary incidentalomas: a two-centers study

Nazarena Betella[1], Alberto Tresoldi[1], Giulia Carosi[2], Giulia Del Sindaco[2], Marco Locatelli[3], Gherardo Mazziotti[1,4], Davide Milani[5], Elena Morenghi[6], Anna Spada[7], Maura Arosio[2,8], Giovanna Mantovani[2,8] & Andrea Lania[1,4]
[1]Endocrine Unit, Humanitas Research Hospital, Rozzano, Italy; [2]UO Endocrinologia e Diabetologia, Fondazione IRCCS Ca' Granda, Milano, Italy; [3]UO Neurochirurgia, Fondazione IRCCS Ca' Granda, Milano, Italy; [4]Dept of Biomedical Sciences, Humanitas University, Rozzano, Italy; [5]UO Neurochirurgia, Humanitas Research Hospital, Rozzano, Italy; [6]UO Biometria, Humanitas Research Hospital, Rozzano, Italy; [7]University of Milan, Milano, Italy; [8]Department of Clinical Sciences and Community Health, University of Milan, Milano, Italy.

Context
Available data on the natural history of pituitary incidentalomas (PI) are not strong enough to draw any evidence-based conclusion on timing and length of follow up of these masses, due to heterogeneity and low sample sizes.
Objective
To describe the characteristics and the natural history of PI using data from a large cohort of patients investigated in two Italian Pituitary Centers.
Patients and methods
Retrospective study on patients diagnosed with PI with imaging characteristics and/or histology compatible with non-functioning pituitary adenoma between 1980 and 2018.
Results
371 patients were included (microadenomas 50.9%, males 35.6%). Men were older and were more likely to have a macroadenoma at diagnosis ($P < 0.01$). At the first hormonal evaluation, hypopituitarism was present in 23.7% of patients, with a higher percentage of deficit in males, older patients and macroadenomas. Follow up data were available for 294 patients; 86 (29.2%) required surgery after first evaluation; 208 patients were initially managed conservatively. During follow up, 14.7% adenomas increased in size (more macroadenomas). 5.2% of patients developed new deficits (4.8% micro and 5.3% macro; more males); 7 of 10 patients showed a deterioration of pituitary function not associated with an increase in the size of the adenomas. 14 additional patients (6.7%) required surgery during follow up (1 microadenoma), bringing the number of patients requiring surgery to 100 (34.1%).
Conclusion
Size at diagnosis $\geq$10 mm, male gender and age are risk factor for hypopituitarism in pituitary incidentalomas at diagnosis; a pituitary deficit is present in more than 1 in 5 patients, underlying the importance of correct evaluation at baseline in these patients. During follow up, macroadenomas tend to grow more often; however, deterioration of pituitary function occurs in both micro and macroadenomas, and it is not always related to a change of the size of the adenoma. Overall, a third of patients requires surgery.

Diagnostic accuracy of copeptin in the diagnosis of diabetes insipidus after pituitary surgery

Emanuele Ferrante[1], Andreea Serban[1,2], Elisa Sala[1], Arianna Cremaschi[1], Giorgia Grassi[1], Marco Locatelli[3], Maura Arosio[1] & Giovanna Mantovani[1]
[1]Endocrinology Unit, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, University of Milan, Milan, Italy; [2]Department of Experimental Medicine, Sapienza University of Rome, Rome, Italy; [3]Neurosurgery Unit, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, University of Milan, Milan, Italy.

Background
Routine clinical use of arginine-vasopressin (AVP) is limited by its small molecular size and pre-analytical errors. In contrast, copeptin – a peptide of 39 amino acids co-secreted with arginine-vasopressin (AVP) - is a stable protein and its measurement represents a reliable measure of AVP concentration. The aim of this study was to analyze diagnostic role of copeptin in diagnosis of diabetes insipidus (DI) in patients treated for hypothalamic-pituitary diseases.
Materials and methods
This study included patients who underwent pituitary surgery by a dedicated neurosurgical team and followed at our center. Daily assessment of polyuria-polydipsia signs/symptoms and fluid balance was performed. DI was defined as emission of high volume ($>$40 ml/kg/die) of hypoosmotic urine. Copeptin was measured: i) 24 hours before surgery; ii) at second post-operative (PO) day; iii) at discharge; iv) 6–8 weeks after surgery. A complete assessment of pituitary function was performed before and 6–8 weeks after surgery. Patients with DI before surgery were excluded.
Results
We selected 47 patients (F/M 27/20, mean age 55 ± 15 years). 44 patients were affected by pituitary adenoma, 2 patients by craniopharyngioma and one patient by meningioma. 16 patients (34.0%) developed DI, which was transient in 9 (56.3%) and permanent in 7 (43.7%). DI occurred shortly after surgery (median [range]: 2 [1–3] day). Patients with Cushing's disease presented a higher risk of post-surgical DI. An inverse correlation between tumor diameter and development of DI was found (24 ± 8 vs 12 ± 9 mm, $P=0.002$), while pituitary insufficiency and radiologic invasiveness at baseline did not show any significant difference. Median (IQR) copeptin levels was significantly lower at second PO day, at discharge and at follow-up in patients who developed DI in respect to those who did not [3.25(2.45–3.7) vs 4.5(3.6–7.4), 2.2(1.8–3.3) vs 3.8(3.2–5.6) and 3(2.5–4) vs 4.45(3.2–7) pmol/l, respectively, for all $P<0.05$). No difference in copeptin levels between patients with transient and permanent DI was found. Unadjusted binary logistic regression did not show a significant association between copeptin levels and DI development at baseline and at second PO day.
Conclusion
Consistently with diagnosis, postoperative copeptin levels is lower in patients who develop DI. However, in our restricted cohort of patients and at time points evaluated, copeptin did not represent an accurate marker for postoperative DI.

Immune checkpoint inhibitors therapy-induced hypophysitis is frequently associated with previous thyroid disorders: results from ImmuCare study

Manon Levy[1], Juliette Abeillon[2,3], Françoise Borson-Chazot[1,2], Stéphane Dalle[1,3,4], Gérald Raverot[1,2] & Christine Cugnet-Anceau[3,5]
[1]Université Lyon 1, Lyon, France; [2]Fédération d'endocrinologie, Hôpital Louis Pradel, Hospices Civils de Lyon, Lyon, France; [3]ImmuCare, Institut de Cancérologie des Hospices Civils de Lyon (IDCRC-HCL), Lyon, France; [4]Service de dermatologie, Centre Hospitalier Lyon Sud, Hospices Civils de Lyon, Lyon, France; [5]Service d'endocrinologie, diabétologie et nutrition, Centre Hospitalier Lyon Sud, Hospices Civils de Lyon, Lyon, France.

Context
The immune checkpoint inhibitor (ICI) therapy is frequently used to treat advanced cancers. Autoimmune adverse events have been reported, such as endocrine side effects including frequent thyroid disorders and more rarely hypophysitis. The aim of this study was to describe retrospectively the association thyroiditis-hypophysitis.
Patients and method
From 99 patients with endocrine side effects of the ImmuCare cohort, 18 patients with hypophysitis were included from 2014: eight patients with hypophysitis alone (H group) and ten patients with association thyroiditis-hypophysitis (ATH group). The median age was 59 years, sex ratio M/F was 14/4. Thirteen patients received anti PD1, four patients anti CTLA4 and one patient a combination of both.
Results
Hypophysitis occurred after a median of five courses and 120 days (72 to 323 days). Ten cases were grade $\leq$2 and eight cases were grade 3. The discovery was clinical in 14 cases (77%). MRI was available in 17 cases and showed pituitary enlargement in two cases (11%). ACTH deficiency was present in 100% of cases and eight patients (44%) had another associated deficiency (4 gonadotropic deficiency, 3 somatotropic deficiency, 3 thyrotropic deficiency). After a median time of 13 months follow-up, ACTH recovery was observed in one case (5%) at 2 months. Thyroiditis occurred after a median of three courses and 42 days (20 to 180 days). All cases were low grade. The thyroid dysfunction was new-onset hypothyroidism for five patients (50%), sub clinical transient hyperthyroidism for one patient (10%) and hyperthyroidism progressing to hypothyroidism for four patients (40%). Antithyroid peroxidase and antithyroglobulin antibodies were positive for three patients. Levothyroxine therapy was introduced and continued after a median time of 20 months follow-up in 70% of cases. Hypophysitis occurred after the primary thyroid dysfunction in 70% of cases, within a median time of 65 days. In two cases the discovery was simultaneous and in one case hypophysitis occurred 80 days before thyroid dysfunction. Hypophysitis occurred earlier in the ATH group (108 vs. 143 days). The use of anti CTLA4 or combination was more frequent in the ATH group (40% vs 12.5%). In addition to the ACTH deficiency, four patients had another deficiency in the ATH group (40%, vs 50% in the H group). The sex ratio, median age and clinical presentation were not different between groups.

Conclusion
In our cohort, hypophysitis was frequently preceded by a primary thyroid dysfunction. Hypophysitis occurred earlier when it was associated with thyroiditis.

Peptide receptor radionuclide therapy (PRRT) in patients with giant aggressive pituitary tumors: experience of an Italian referral center and review of literature

Giuseppe Giuffrida[1,2], Francesco Ferraù[1,3], Riccardo Laudicella[4,5], Oana Ruxandra Cotta[1], Antonio Vento[4,5], Sergio Baldari[4,5] & Salvatore Cannavò[1,3]
[1]Endocrine Unit of University Hospital 'AOU Policlinico G. Martino' of Messina, Messina, Italy; [2]Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy; [3]Department of Human Pathology 'G. Barresi', University of Messina, Messina, Italy; [4]Nuclear Medicine Unit of University Hospital 'AOU Policlinico G. Martino' of Messina, Messina, Italy; [5]Department of Biomorphology, University of Messina, Messina, Italy.

Background
Pituitary tumours (PT) are generally benign, but they can rarely show an aggressive behaviour, invade surrounding structures and/or grow/recur despite multimodal treatment, making their management extremely challenging. According to the latest guidelines, temozolomide (TMZ) can be an option after failure of standard therapies in aggressive PT, while little data are available on alternative approaches such as peptide receptor radionuclide therapy (PRRT). Herein we report on the effectiveness, safety and long-term outcome of PRRT in three patients with aggressive giant PT, also reviewing data from literature.
Patients and methods
Two patients (1 F, 1 M) were affected by giant prolactinoma, and one (F) by a non-functioning pituitary adenoma (NFPA). Patient #1 received 5 cycles of ^{111}In-DTPA-octreotide (total dose 37 GBq) over a 23-month period, after unsuccessful surgery and long-term dopamine-agonist treatment. Patient #2 underwent 2 cycles (12.6 GBq) of PRRT with ^{177}Lu-DOTATOC, after failure of multiple surgeries, radiosurgery and TMZ. In Patient #3, five cycles (29.8 GBq) of ^{177}Lu-DOTATOC were administered after five unsuccessful trans-sphenoidal approaches, radiotherapy and TMZ. A systematic review of the current literature retrieved nine more cases of aggressive PT treated with PRRT.
Results
PRRT was successful in patient #1, leading to significant shrinkage of the tumor (from 63 to 3.1 cc) and remarkable visual/neurological amelioration over an eight-year follow-up period. Patient #2 and #3 did not take advantage from treatment, since PT continued to grow leading to blindness and neuro-cognitive disorders in patient #2, and monolateral amaurosis in patient #3. No PRRT-related adverse effects were reported in any subject. Overall, also including 9 patients reported in literature (3 carcinomas and 6 adenomas), PRRT induced tumor shrinkage and clinical/biochemical improvement in 4/11 patients (36.3%). Response to PRRT did not correlate with gender or age of patients, neither with radionuclide or peptide used for treatment, but PRRT failure was significantly associated with previous TMZ treatment. Overall, PRRT was well tolerated and significant adverse effects were reported only in 2 patients (18.2%).
Conclusions
PRRT induced PT shrinkage and clinical and/or biochemical improvement in one-third of patients with aggressive PT overall, and in 80% of those not previously treated with TMZ. PRRT is a safe therapeutic option when surgery and radiosurgery fail to control PT progression. However, at present, considering the few available studies, PRRT should be proposed for aggressive PT only in an experimental setting, after conventional therapies.

Adrenal axis deterioration in the families/sporadic patients with PROP1 mutation, over 30 years of single center longitudinal observation

Aleksandra Gilis-Januszewska[1], Damian Rogoziński[1], Łukasz Kluczyński[1], Agata Zygmunt-Górska[2], Małgorzata Wójcik[2], Jerzy Starzyk[2] & Alicja Hubalewska-Dydejczyk[1]
[1]Department of Endocrinology, Jagiellonian University, Medical College, Kraków, Poland; [2]Department of Pediatric and Adolescent Endocrinology, Chair of Pediatrics, Pediatric Institute, Jagiellonian University, Medical College, Kraków, Poland.

Introduction
The time, degree and mode of pituitary function deterioration in patients with PROP1 mutation is not fully known and understood.
Aim
To investigate the time and mode of pituitary function deterioration in the families/sporadic patients with PROP1 mutation during longitudinal observation.
Methods
We performed a retrospective longitudinal (33 years, SD = 12) analysis of 22 patients (11M/11W) with PROP1 mutation, including 5 families (13/22, 59% of investigated population), with 2–3 affected siblings who were under medical supervision of the pediatric/adult endocrinology departments of our university.
Results
All patients initially presented with growth failure at mean age (MA) 7.4 years (SD = 4,3). 14/22 patients were first diagnosed with GH and TSH deficiency occured simultaneously and replacement therapy was instituted MA 6.6 years (SD = 3.0). 5/22 (older patients) received delayed/intermittently GH treatment. Gonadal deficiency was diagnosed in 22/22 patients MA 15.6 years (SD = 5.1). 20/22 (91%) patients developed adrenal deficiency MA 23.3 years (SD = 15.0). In 2 patients with low morning cortisol/symptoms of adrenal insufficiency hydrocortisone supplementation was implemented during the transition period however reevaluation of the gonadal axis at age 21 revealed normal adrenal function. The age of deficiencies determination in siblings are given in the Table 1.

Table 1

Families Sex/ Actual age	Age when insufficiency was diagnosed	HGH	TSH	LH/FSH	ACTH
1	F/25	5	5	16	7
	M/19	4	1	12	12
2	M/35	9	8	16	16
	M/33	5	5	15	No
	M/29	4	2	14	21
3	M/52	5	5	5	46
	F/42	3	3	19	29
	F/40	5	16	16	31
4	F/39	8	8	15	No

Conclusions
The pituitary function deteriorates progressively in patients with PROP1 mutation, however there is no specific order of deterioration even among affected siblings. The adrenal axis can deteriorate long after other axis insufficiencies, however there are patients with no adrenal insufficiency even during lifelong observation. Patients with PROP1 mutation should be carefully monitored for possible adrenal insufficiency including stimulation tests regardless of the time of observation.

Inflammatory response to osmotic stimulus in healthy volunteers

Clara O Sailer[1,2], Sophia Wiedemann[1], Wiebke K Fenske[3], Ingeborg Schnyder[1], Konrad Strauss[4] & Mirjam Christ-Crain[2,5]
[1]Department of Endocrinology, Diabetology and Metabolism, University Hospital Basel, Basel, Switzerland, Basel, Switzerland; [2]University of Basel, Department of Clinical Research, Basel, Switzerland; [3]Leipzig University Medical Center, Integrated Center for Research and Treatment Adiposity Diseases, Leipzig, Germany; [4]Division of Endocrinology and Diabetes, Department of Internal Medicine I, University Hospital, Würzburg, Germany; [5]Department of Endocrinology, Diabetology and Metabolism, University Hospital Basel, Basel, Switzerland.

Context
Osmotic stimulus or stress results in release of vasopressin. Animal studies have shown that inflammatory parameters such as interleukin-6 (IL-6) and interleukin-8 (IL-8) increase in parallel, mainly in central brain regions. Whether osmotic stimulation leads to an inflammatory response in humans is unknown. We therefore investigated the influence of osmotic stimulation on the inflammatory system in healthy volunteers.
Method
In this prospective cohort study, 44 healthy volunteers underwent a standardized test protocol leading to an osmotic stimulation into the hypertonic range by hypertonic-saline infusion (serum sodium > 150 mmol/l). Copeptin, a marker to

indicate vasopressin activity, sodium, osmolality, IL-6, IL-8 and TNF-a was measured at baseline and directly after osmotic after stimulation.
Results
Median serum sodium increased from 141 mmol/l (IQR 140, 142) to 151 mmol/l (IQR 150; 153) (*P*-value <0.01), median serum osmolality increased from 295 mmol/l (IQR 291; 298) to 315 mmol/l (312; 317) (*P*-value <0.01). Copeptin increased form 4.3 pg/l (IQR 3.3; 6.7) to 28.8 pg/l (19.9; 43.4) (*P*-value <0.01). IL-8 levels decreased from 0.79 pg/ml (IQR 0.65; 1.1) to 0.7 pg/ml (IQR 0.57; 0.9) (*P*-value 0.09) and TNF-a decreased from 0.53 pg/ml (IQR 0.38; 0.69) to 0.45 pg/ml (IQR 0.3; 0.5) (*P*-value 0.036). There was no significant change in IL-6 levels.
Conclusions
Contrary to animal data, inflammatory markers remain unchanged or decrease in human serum after osmotic stimulation. Increased vasopressin/copeptin seems not to stimulate inflammatory markers; whether a negative feedback exists remains unclear.

Copeptin levels in SIADH – a marker of malignant disease?

Bettina Winzeler[1], Michelle Steinmetz[1], Julie Refardt[1], Nicole Cesana-Nigro[2], Milica Popovic[1], Wiebke Fenske[3] & Mirjam Christ-Crain[1]
[1]University Hospital of Basel, Basel, Switzerland; [2]Bürgerspital Solothurn, Solothurn, Switzerland; [3]University of Leipzig, Leipzig, Germany.

Context
Hyponatremia due to the syndrome of inappropriate antidiuretic hormone secretion (SIADH) is a very common condition in hospitalized patients. It is crucial to establish the cause of SIADH especially in order to exclude or detect an underlying malignancy. As SIADH can be caused by paraneoplastically produced arginine vasopressin (AVP), we hypothesized that its stable surrogate marker copeptin may be used as a diagnostic tool.
Methods
We analyzed data from 146 patients with SIADH from two prospective observational studies, conducted in Switzerland and Germany, who were included while presenting at the emergency department. Patients underwent a standardized diagnostic assessment at admission including the measurement of copeptin levels.
Results
39 patients (median age: 63 years, 51% female) were diagnosed with cancer-related and 107 (median age: 73 years, 68% female) with non-malignant SIADH. Serum sodium levels were higher in cancer-related versus non-malignant SIADH: median (IQR) 124 mmol/l (120; 127) versus 120 mmol/l (117; 123) ($P < 0.001$). Median (IQR) copeptin levels of patients with cancer-related SIADH were 11.1 pmol/l (5.2; 37.1) and 10.5 pmol/l (5.2; 25.2) with non-malignant SIADH ($P = 0.21$). Among different cancer entities, patients suffering from small cell lung cancer showed the highest copeptin values, but overall no significant difference in copeptin levels between cancer types was observed ($P = 0.47$).
Conclusion
We found no difference in copeptin levels between cancer-related and non-malignant SIADH. Copeptin is not suitable as diagnostic tool to exclude or detect an underlying malignancy in SIADH.

The 2017 World Health Organization (WHO) classification of pituitary adenomas is based on cell lineage and transcription factors (TFs). Pituitary progenitors expressing Pit-1 are driven towards the somato-lacto-thyrotroph differentiation, T-Pit towards corticotroph, and SF-1 towards gonadotroph. We recently generated a multi-genomic classification of pituitary neuroendocrine tumors (PitNETs) (abstract submitted to ECE2019 by Neou M.). Transcriptome classification identified six groups: corticotroph overt Cushing; lactotroph; silent corticotroph; gonadotroph and null-cell; thyrotroph, Pit-1 plurihormonal and sparsely-granulated somatotroph; somatotroph and mixed GH-PRL.
Aim
To characterize the lineage differentiation in PitNETs.
Methods
Transcriptome of 134 PitNETs (RNA sequencing) was used to determine TFs expression at mRNA level, and to provide a canonical transcriptome signature for each cell-type (cortico-, lacto-, somato-, thyro- and gonadotroph). Pathological study of the present serie of PitNETs included the histological examination and the immunohistochemical tests for all pituitary hormones, proliferation markers and TFs including GATA3.
Results
Pit1 lineage. As expected, Pit1 mRNA showed expression exclusively in somatotroph (23/23), mixed GH-PRL(8/8), thyrotroph (6/6), lactotroph (16/16) and Pit-1 plurihormonal (9/9) PitNETs. Immunohistochemistry confirmed this observation. Based on transcriptome classification, accurate thresholds of immunoexpression for GH, PRL and TSH were established in order to define the different Pit-1 subtypes:
PRL >10%, with GH ≤5% for lactotroh
GH >10%, with PRL ≤5% for somatotroph
TSH >10%, with GH and PRL <5% for thyrotroph
PRL and GH positivity >5% for mixed GH-PRL
Combined PRL, GH, TSH, FSH, and LH positivity for Pit-1 plurihormonal.
T-Pit lineage
T-Pit mRNA showed the expected expression in corticotroph PitNETs (35/35), lower in silent ones (Wilcoxon $P < 10–5$). Immunohistochemistry confirmed this profile.
SF1 lineage
SF1 mRNA expression showed the expected high expression in gonadotroph PitNETs (29/29), but also in a subset of somatotroph PitNETs (9/21). SF1 immunopositivity was confirmed in this somatotroph subgroup.
The cell-type specific transcriptome signatures revealed an unexpected gonadotroph signature in silent corticotroph PitNETs, accounting for 40% (median) of silent corticotroph signature. GATA3 TF was one of the gonadotroph signature genes. Immunohistochemistry for GATA3 confirmed positivity in gonadotroph (29/29) and in silent corticotroph PitNETs (6/8).
Conclusion
This study showed for the first time on a large series of PitNETs the correlation between pathological and molecular classifications. The Pit1 and T-Pit TFs are strong determinants of PitNETs molecular classification. In contrast, gonadotroph lineage is more complex, with possible transdifferentiation in silent corticotroph and in a subset of somatotroph PitNETs.

Tomosyn negatively regulates arginine vasopressin secretion in embryonic stem cell-derived neurons

Yoshihisa Sugimura[1], Seiji Takeuchi[2], Takashi Watanabe[3], Atsushi Kiyota[4], Haruki Fujisawa[1], Yusuke Seino[1] & Atsushi Suzuki[1]
[1]Department of Endocrinology and Metabolism, Fujita Health University, Toyoake, Japan; [2]Sakai Naika Medical Clinic, Handa, Japan; [3]The University of North Carolina at Chapel Hill, School of Medicine, Chapel Hill, USA; [4]Japanese Red Cross Nagoya Daiichi Hospital, Nagoya, Japan.

Arginine vasopressin (AVP) is secreted via exocytosis; however, the precise molecular mechanism underlying the exocytosis of AVP is unknown. To better understand the mechanisms of AVP secretion, here we study to identify proteins that bind with a 25 kDa synaptosomal-associated protein (SNAP25), a protein that plays a crucial role in exocytosis, in the posterior pituitary. Embryonic stem (ES) cell-derived AVP neurons were established to investigate the functions of the identified proteins. Using glutathione S-transferase (GST)-pulldown assays and proteomic analyses, we identified tomosyn as a SNAP25-binding protein in the posterior pituitary. Coimmunoprecipitation assays indicated that tomosyn formed N-ethylmaleimide-sensitive factor attachment protein receptor (SNARE) complexes with SNAP25 and syntaxin1. Immunohistochemistry showed that

tomosyn localized to the posterior pituitary. Mouse ES cells self-differentiated into AVP neurons (mES-AVP) that expressed tomosyn and two transmembrane SNARE proteins, including SNAP25 and syntaxin1. KCl increased AVP secretion in mES-AVP, and overexpression of tomosyn reduced KCl-stimulated AVP secretion. Downregulation of tomosyn with siRNA increased KCl-stimulated AVP secretion. In addition, pituitary adenylate cyclase-activating polypeptide (PACAP) increased the PKA-catalysed phosphorylation of tomosyn and thus increased AVP secretion. These results suggest that tomosyn negatively regulates AVP secretion and that phosphorylation of tomosyn by PKA is involved in tomosyn-regulated AVP secretion in mES-AVP.An important next step would be to screen for gene mutations in tomosyn in patients with idiopathic CDI. We anticipate our methods of mES-AVP culturing to provide a more sophisticated *in vitro* model of secretion of AVP, including application to studies of CDI-specific human samples and induced pluripotent stem cells.

MRI detection of aortic anomalies in 204 adult patients with Turner syndrome: a longitudinal study

Bruno Donadille[1], Sophie Tuffet[2], Nathalie Bourcigaux[1], Mariana Nedelcu[1], Laurence Monnier-Cholley[3], Alexandra Rousseau[2,4], Sophie Christin-Maitre[1,4,5] & Turner And Heart Study Group[6]
[1]Endocrinology department, St Antoine hospital, Reference Center for Rare Growth Diseases, FIRENDO, ENDO-ERN, Assistance Publique-Hopitaux de Paris, PARIS, France; [2]Clinical Research Unit (URC-EST), St Antoine Hospital and Functional Unit of Pharmacology, PARIS, France; [3]Radiology department, St Antoine hospital, Assistance Publique-Hôpitaux de Paris, PARIS, France; [4]Sorbonne Université, PARIS, France; [5]INSERM UMR-S933, PARIS, France; [6]Endocrinology departments, Reference Center for Rare Growth Diseases, FIRENDO, ENDO-ERN, Assistance Publique-Hopitaux de Paris, PARIS, France.

Mortality is 3 fold higher in patients with Turner syndrome (TS) than in the general population, primarily due to cardiovascular complications. Recent clinical guidelines (Gravholt et al. EJE 2017) underlined the need of a lifelong cardiovascular follow-up. However, prospective studies evaluating the aortic natural history in clinical practice are scarce. We performed a monocentric longitudinal study including 204 adult TS patients, between 2005 and 2018. Inclusion criteria were a karyotype $\geq$10% 45,X cells and a 1.5 Tesla magnetic resonance imaging (MRI). Aortic root diameters were measured at the 5 recommended levels: annulus, valsalva sinuses, sino-tubular junction, tubular ascending aorta and aortic cross. Aortic dilatation (AD) was defined by a diameter $>$32 mm or $>$ 20 mm/m^2 when indexed to body surface area (BSA). History of cardiovascular surgery, valvular abnormalities and cardiovascular risk factors were recorded. Kaplan-Meier curves and uni/multivariate cox regressions were performed using SAS-V9.3 software. TS patients' median age was 25.4 [P25; P75: 19.5; 34.2]. Their median BMI was 22.9 [20.3; 25.6] Kg/m^2. A 45,X monosomy was present in 82/204 (40.2%) of cases. Cardiovascular surgery had been performed at a median age of 13.0 [1.5; 24.0] in 5.9% of cases. Bicuspid aortic valve (BAV) and coarctation were detected in 22.1% and 8.8% of cases, respectively. Treated diabetes, dyslipidemia, and hypertension were found in 5.9%, 5% and 4.9% of cases, respectively. At baseline and at last follow-up, AD was observed in 65/204 (31.9%) and 85/204 (41.7%), respectively. Age at detection of AD $>$ 20 mm/m^2 and $>$ 25 mm/m^2 was 29.3 [21.5; 36.8] and 35.8 [24.8; 58.2] years. Kaplan-Meier modelization showed a median age of survival without AD of 35 years. Univariate cox regression showed that age of the patient (P $<$0.001); age at diagnosis of TS (P 0.006); presence of BAV (P $<$.001); coarctation ($P<.001$); hypertension (P 0.02); history of cardiovascular surgery (P 0.008) were significantly associated with AD. After multivariate cox modelization, only age at diagnosis ($<$.0001) and BAV ($<$.004) remained associated with AD. Preliminary data found a mean aortic progression of 0.17 mm/year over this period. Overall, AD risk is increased by 2.15 [IC95% 1.27–3.64] in presence of BAV. In conclusion, our prospective study on a large cohort of adult TS patients identified risk factors for aortic dilatation. Our results should help identifying TS patients with a higher risk of AD. It should therefore optimize the timing of MRIs during the patients' lifelong follow-up.

Is monosomia related to poorer cardiometabolic state in Turner syndrome?

Ruta Kriksciuniene[1], Birute Zilaitiene[1], Saulius Lukosevicius[2] & Rasa Verkauskiene[1]
[1]Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Lithuanian University of Health Sciences Department of Radiology, Medical Academy, Kaunas, Lithuania.

Introduction
45,X karyotype is known to be related to more severe phenotype disorders, still comparative analysis of the karyotypes and phenotypes in Turner syndrome (TS) is difficult, even in the largest studies, mainly due to differences in patient's age and variability in the definition of clinical features (1). We aimed: to assess if monosomia in Turner syndrome patients is related to their cardiometabolic features.
Methods
75 females with confirmed TS $\geq$18 yrs were enrolled into the cross-sectional study. Patients were divided into 2 groups: 45,X group and non-45,X group (mosaicism, isochromosome, etc.). Standard clinical evaluation was performed (height, weight, body mass index (BMI), blood pressure (BP), heart rate (HR)). Levels of plasma glucose and lipids were assessed. Size of ascending aorta (adjusted for body surface area (BSA)) was evaluated by means of thoracic magnetic resonance angiography (1.5T) in four positions: aortic sinus (D1), sinotubular junction (D2), ascending aorta at the bottom edge of the right pulmonary artery (D3) and ascending aorta at the right proximal brachiocephalic artery (D4).
Results
45,X karyotype was identified in 65.3% of the TS cohort. Age at investigation was similar in monosomia vs. non-45-TS groups ($P=0.075$). Lower BMI was found in non-45,X compared to 45, X patients (23.0 vs. 25.6 kg/m^2, respectively, $P=$ 0.028), they were significant taller (155 cm vs. 150 cm, respectively, $P=0.004$). Duration of Growth hormone treatment was comparable in both study groups ($P=$ 0.105). The diameter of aorta in D2 and D3 positions was larger in 45,X group (16.4 mm/m^2 vs. 14.8 cm/m^2, $P=0.046$ and18,2 mm/m^2 vs. 15.9 mm/m^2, $P=$ 0.028, respectively). The prevalence of congenital cardiovascular anomalies (bicuspid aortic valve, coarctation of aorta) was higher in 45,X patients (28.6% vs. 0%, $P=0.001$). No difference in BP, HR, levels of glucose and lipids was observed between the groups.
Conclusion
High prevalence of 45,X was found in Lithuanian Turner syndrome cohort. Monosomia was related to larger size of ascending aorta and higher body mass index.

GP247

The efficacy of long-term metformin treatment in overweight and obese women with PCOS: A 10-year database study

Mojca Jensterle[1], Nika Aleksandra Kravos[2], Katja Goricar[3] & Andrej Janez[2]
[1]Department of Endocrinology, Diabetes and Metabolic Diseases, University Medical Centre Ljubljana, Ljubljana, Slovenia; [2]Department of Endocrinology, Diabetes and Metabolic Diseases, University Medical Centre Ljubljana, Ljubljana, Slovenia; [3]University of Ljubljana, Faculty of Medicine, Institute of Biochemistry, Pharmacogenetics Laboratory, Ljubljana, Slovenia.

Context
Metformin is an established therapy for women with PCOS and pre-diabetes or diabetes when lifestyle modification is insufficient. Metformin should also be considered in women with PCOS with BMI$\geq$25 kg/m^2 independently of the presence of metabolic disturbances. However, its long-term efficacy in this subset of patients is inadequately studied.
Aim
We analyzed collection data of 10 years for the efficacy of metformin on body mass (BM), menstrual frequencies (MF), metabolic and hormonal outcomes in women with PCOS and BMI$\geq$ 25 kg/m^2.
Methods
Collection data from endocrine outpatient clinic at the university medical centre for 10 years comprising 800 patients with PCOS defined by Rotterdam criteria including 180 patients with PCOS and BMI$\geq$25 kg/m^2 (age 28.8$\pm$6.6 years, BM 96.4$\pm$18.7 kg, BMI 34.8$\pm$6.4 kg/m^2) all receiving uniform monotherapy with metformin 1000 mg BID.
Results
The registry contained 7143 time-points with a subset of anthropometric, reproductive, hormonal and metabolic parameters. The drop out rate in the 1st year was 13%, in the 2nd 24%, in the 3rd 26%, in the 4th 32% and in the 5th year

40%. Only 18% of patients continued with metformin for 10 years. After the 1st year BM decreased for 4.2 ± 1.1 kg ($P < 0.001$) and remained in a steady state until the 10th year in those that continued with the therapy. MF increased from 7.5 ± 3.8 to 10.7 ± 2.9 bleeds/year ($P < 0.001$) after 1st year to over 11 bleeds/year in the following years. The total testosterone and androstendione decerased for 25% after the 1st year, with further decrease in androstendione for 50% from the initial values within the 5 years. LH, FSH and fasting glucose did not changed significantly over the treatment period. Increased MF correlated with the decreases in BM and total testosterone, with no correlation with the change in LH/FSH ratio. Initially, 10% had pre-diabetes and 1.7% had diabetes. After the 1st year 5.7% had pre-diabtes and 1.9% diabetes, after 3rd year 2.2% of women that continued with metformin had pre-diabetes and none had diabetes. The remission rate from pre-diabetes to normal glucose homeostasis in the 1st year was 72%.
Conclusions
Long-term metformin treatment of women with PCOS and BMI ≥ 25 kg/m^2 independently of their initial metabolic status resulted in maximum treatment response after the 1st year, with the improvements in BM, MF and androgen profile. A great drop out was seen after the 3rd year. In women that subsequently remained on therapy an overall beneficial steady state was observed up to the 10th year.

GP248

Gut microbiota-dependent cardiometabolic risk and oral contraceptive use in polycystic ovary syndrome: A prospective study

Damla Eyupoglu[1], Ezgi Caliskan Guzelce[1], Aylin Acikgoz[2], Esra Uyanik[3], Bodil Bjørndal[4], Rolf Berge[4], Asbjørn Svardal[4] & Bulent Okan Yildiz[1]
[1]Department of Internal Medicine, Division of Endocrinology and Metabolism, Hacettepe University, Ankara, Turkey; [2]Department of Nutrition and Dietetics, Hacettepe University, Ankara, Turkey; [3]Department of Gynecology and Obstetrics, Hacettepe University, Ankara, Turkey; [4]Department of Clinical Sciences, The Lipid Research Group, University of Bergen, Bergen, Norway.

Context
Polycystic ovary syndrome (PCOS) is associated with an increased cardiometabolic risk that might not necessarily translate into adverse cardiovascular outcome later in life. Recently, alterations in gut microbial composition have been reported in the syndrome. Microbiota-dependent metabolite trimethylamine N-oxide (TMAO) and its precursors are closely linked with development of atherosclerotic cardiovascular disease, independently of traditional risk factors.
Objective
To assess whether TMAO and its precursors are altered in PCOS and to determine potential impact of oral contraceptive (OC) use on these metabolites**.**
Materials and methods
The study included 27 overweight/obese patients with PCOS and 25 age- and BMI-matched healthy control women. At baseline, fasting serum TMAO and its precursors were measured after a 3-day standardized diet. Patients received dienogest-ethinylestradiol (2 mg/0.03 mg) therapy along with general dietary advice for three months after which all measurements were repeated. Four patients were excluded from the second analysis due to antibiotic use during the study period.
Results
The median age and BMI of patients and controls were 21 (IQR: 19–22) versus 23 (IQR:20.5–27) years and 30.7 (IQR:27.8–33.3) versus 31.5 (IQR:27.8–37) kg/m^2 respectively (P=NS for both). Patients had higher total testosterone (T) and free androgen index (FAI) whereas whole body fat mass, fasting plasma glucose, insulin and lipids were similar between the groups. PCOS group showed significantly higher serum levels of TMAO and its precursors: TMAO (2.39 [IQR:2.15–4.49]vs 2.05 [IQR: 1.36–3.33][Mol/L, $P=0.042$), choline (43.2 [IQR:39.5–48.9] vs. 36.6 [IQR:29.85–41.3][Mol/L, $P=0.001$), betaine (49.4 [IQR: 38.3–53.3]vs. 39.8 [IQR: 33.8–50.9][Mol/L, $P=0.034$), and carnitine (10.7 [IQR: 9.9–12.3]vs. 9.7 [IQR:8.15–11.6][Mol/L, $P=0.024$). TMAO and choline showed correlations with T ($r=0.292$, $P=0.037$, and $r=0.353$, $P=0.010$). After 3 months of OC use, there were decreases in BMI (30.3 [IQR: 27.5–33.3]vs. 29.4 [IQR:25.8–31.4] kg/m^2, $P<0.001$) and FAI levels(11.2 [IQR: 5.6–15.5]vs. 1.74 [IQR:0.76–2.53] ng/dl, $P<0.001$). TMAO and all its precursors significantly reduced after therapy: TMAO (3.35 [IQR: 2.18–4.93]vs. 2.05 [IQR:1.7–2.93][Mol/L $P=0.002$), choline (43.6 ([IQR: 39.5–49]vs. 33.8 [IQR: 31.5–36.9][Mol/L, $P<0.001$), betaine (49.4 [IQR: 39.9–57.1]vs 24.4 [IQR:20.2–32.6][Mol/L $P<0.001$), and carnitine (10.7 [IQR: 9.9–12.3]vs 8.9 [IQR: 8.2–9.7][Mol/L $P<0.001$).
Conclusion
This study reports for the first time that TMAO and its precursors are elevated in PCOS which might contribute to increased cardiometabolic risk of the syndrome and that OC use is associated with reduction of these microbiome-dependent metabolites.

Maternal 3rd trimester cortisol status was associated with offspring sex and PCOS status. Odense Child Cohort

Marianne Andersen[1], Richard Jensen[1], Anne Schmedes[2], Ivan Brandslund[2], Henriette Kyhl[3], Tina Jensen[4] & Dorte Glintborg[1]
[1]SDU, OUH, Odense, Denmark; [2]Sygehus Lillebaelt, Vejle, Denmark; [3]OUH, OPEN, Odense, Denmark; [4]SDU, OPEN, Odense, Denmark.

Background
Maternal circulating cortisol and 24-h urinary free cortisol levels are up to three times higher in third trimester pregnant women compared to non-pregnant women. Maternal cortisol status could be associated with offspring sex, maternal PCOS and testosterone levels.
Aims
To determine predictors of maternal serum (S) and urinary (U) cortisol and cortisone levels during 3rd trimester and to examine associations between maternal cortisol status, offspring sex, and maternal PCOS status.
Methods
The study is part of the prospective Odense Child Cohort. This study cohort included 1489 women (PCOS, $n=145$ and controls, $n=1{,}344$). Fasting morning S-cortisol and 24h U-cortisol/U-cortisone (24h U-C/C) were collected at gestational week 28 and measured by liquid chromatography-tandem mass spectrometry.
Results
Maternal S-cortisol levels were significantly higher in women pregnant with girls ($n=702$) vs. boys ($n=787$): 833 (643; 1,077) vs. 799 (588; 1,084) nmol/L, $P=0.014$. In multiple regression analyses, maternal S-cortisol was positively associated with female offspring, maternal testosterone levels and inversely associated with maternal age and parity. When women were divided according to PCOS status, 24h U-cortisone was higher (467 (334; 652) vs. 415 (286; 604) nmol/24 h) and 24h U-C/C was lower in women with PCOS compared to controls.
Conclusions
Maternal 3rd trimester S-cortisol levels were positively associated with female offspring and circulating testosterone levels. Cortisol metabolism was higher in women with PCOS vs. controls.

Diagnostic potential of a 'mouse azoospermia' gene panel in human azoospermia: identification of novel genetic causes of meiotic arrest

Antoni Riera-Escamilla[1], Andrea Enguita-Marruedo[2], Daniel Moreno-Mendoza[1], Chiara Chianese[3], Eduard Ruiz-Castañé[1], Mario Maggi[3], Willy Baarends[2] & Csilla Krausz[3]
[1]Andrology Department, Fundació Puigvert, Universitat Autònoma de Barcelona Barcelona, Barcelona, Spain; [2]Department of Developmental Biology, Erasmus MC University Medical Centre Rotterdam, Rotterdam, Netherlands; [3]Department of Experimental and Clinical Biomedical Sciences 'Mario Serio'. University of Florence Firenze, Florence, Italy.

Purpose
Non-Obstructive Azoospermia (NOA), occurring in approximately 1% of men, has an unknown etiology in the majority of cases. This study aims at evaluating the diagnostic efficiency of a gene panel contemplating all known genes associated with azoospermia in mice.
Subjects and methods
Design of a 'mouse azoospermia' gene panel through the consultation of MGI; selection of 175 mouse azoospermia genes with human orthologues; selection of 31 idiopathic NOA patients from a total of 1300 infertile patients and selection of a familial case (2 brothers) of NOA. Next-Generation Sequencing in the 33 selected NOA men. Characterization of the discovered gene defects in human testis tissue: i) meiotic studies in carriers of *RNF212* and *STAG3* mutations; ii) *RNF212* and *STAG3* expression profile through qPCR.
Results
Homozygous pathogenic *RNF212* variant was identified in two brothers (consanguineous parents) and biallelic variants in *STAG3* in a sporadic patient. Meiotic studies in the siblings revealed normal meiotic entry/XY body formation but an increase of apoptotic metaphases while in the *STAG3* mutation carrier normal meiotic entry but no XY body formation.
Conclusion
By using a hypothesis-driven approach which consisted in the sequencing of 175 genes, for the first time, we report biallelic variants in *STAG3* in one sporadic patient, and a homozygous *RNF212* variant in the two brothers as the genetic cause of NOA. Meiotic studies allowed the detection of the functional consequences of the mutations and provided information on the role of STAG3 and RNF212 in human male meiosis. Our approach was relatively successful since we could diagnose a candidate gene mutation in 9% of idiopathic NOA

cases (2/33). This proportion increases up to 40–50% if we consider only patients affected by meiotic arrest. Our study represents an additional step towards elucidating the genetic basis of early spermatogenic failure. We propose the inclusion of *RNF212* and *STAG3* in a future male infertility diagnostic gene panel. More than half of the 175 sequenced genes are reported to affect also female reproduction in mice (among them Rnf212 and Stag3) and *STAG3* mutations were first described as a cause of female infertility (POI) and ovarian cancer. Hence, our results stimulate further research on shared genetic factors causing both POI and NOA. The diagnosis of such genetic factors implies that genetic counselling for NOA has relevance not only to the male family members and male descendants but also to female relatives.

Free Testosterone (FT) is inversely related to frailty in Human Immunodeficiency Virus (HIV)-Infected Men

Sara De Vincentis[1,2], Maria Chiara Decaroli[1,2], Chiara Diazzi[2], Fabio Morini[1], Davide Bertani[1], Flaminia Fanelli[3], Marco Mezzullo[3], Daniele Santi[1,2], Giulia Tartaro[1,2], Enrica Baraldi[4], Simonetta Tagliavini[4], Uberto Pagotto[3], Giovanni Guaraldi[5] & Vincenzo Rochira[1,2]
[1]Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; [2]Unit of Endocrinology, Department of Medical Specialties, Azienda Ospedaliero-Universitaria of Modena, Modena, Italy; [3]Endocrinology Unit and Center for Applied Biomedical Research (CRBA), Department of Medical and Surgical Sciences, University of Bologna – S. Orsola-Malpighi Hospital, Bologna, Italy; [4]Department of Laboratory Medicine and Anatomy Pathology, Azienda USL of Modena, Modena, Italy; [5]Multidisciplinary Metabolic Clinic, Unit of Infectious Diseases, University of Modena and Reggio Emilia, Modena, Italy.

Background
HIV-infection is associated to several age-related comorbidities, such as a premature decline of serum testosterone (T). There is evidence about the relationship between health status, represented by frailty and comorbidities, and serum T levels in general population, while only one previous retrospective study investigated it in HIV-infected men.
Aim
To investigate the association between frailty and gonadal status by assessing serum total T (TT) with Liquid Chromatography tandem Mass Spectrometry (LC-MS/MS) in a cohort of HIV-infected men.
Methods
Prospective, cross-sectional, observational study on HIV-infected men (age <50 years) with ongoing Highly Active Antiretroviral Therapy (HAART). Serum TT was assessed by the gold standard ID-LC-MS/MS. Sex hormone-binding globulin (SHBG) was measured by chemiluminescent immunoassay. Free T (FT) was calculated by Vermeulen equation. Frailty was calculated through 38-items multimorbidity frailty index. *Statistical analysis:* Parameters were not normally distributed and Mann-Whitney *U* test was used to compare continuous variables. Correlations were performed using linear regression models.
Results
315 consecutive HIV-infected men were enrolled (mean age 45.56 ± 5.61 years; average duration of HIV-infection 16.30 ± 8.57 years). 17 patients (5.4%) had TT below 320 ng/dl and 31 patients (9.8%) had calculated FT below 64 pg/ml. Overall, 37 patients (11.7%) had T deficiency defined by low TT levels and/or low FT. 56 patients (17.8%) showed SHBG above the normal range (>71.4 nmol/l). Frailty score ($P=0.031$), age ($P=0.001$), duration of HIV-infection and of HAART ($P<0.0001$) significantly differed between eugonadic and hypogonadic patients, while no difference was found for BMI ($P=0.209$). FT inversely correlated with frailty score ($P=0.038$, $R^2=0.014$), while TT did not ($P=0.235$). At stepwise multivariate regression analysis, FT showed an inverse relation with age ($P<0.0001$, $R^2=0.150$), years of infection (-0.339, $P<0.0001$, $R^2=0.125$) and years of HAART (-0.346, $P<0.0001$, $R^2=0.117$), but not with frailty score and BMI of patients.
Conclusions
To the best of our knowledge, this is the first properly-designed prospective study aiming to investigate the relationship between general health status and gonadal function in a cohort of HIV-infected men. FT is inversely related to frailty score, suggesting an impairment of gonadal function in those patients affected by more multimorbidities in this setting as well as in general population. At the same time, the age of patient and the duration of HIV-infection seem to be more potent predictive factors for serum FT levels than frailty score. In clinical practice it is important to check for testosterone in these patients due to frequent alterations of SHBG.

Prolactin and prostate: an observational case-control study in men with prolactinoma under cabergoline treatment

Francesco Garifalos, Dario De Alcubierre, Nunzia Verde, Davide Menafra, Mauro Arnesi, Cristina de Angelis, Annamaria Colao, Renata Simona Auriemma & Rosario Pivonello
Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Università 'Federico II' di Napoli, Centro di Andrologia e Medicina della Riproduzione e della Sessualità Maschile e Femminile (FertiCaresSex), AOU 'Federico II', Naples, Italy.

Prolactin (PRL) exerts independent hypertrophic effects on prostate in *in vivo* and *in vitro* experimental models, and prostatic PRL receptors are known to activate cell proliferation pathways such as MAPK and STAT. Nevertheless, in men with hyperprolactinemia the risk of prostate cancer has been found reduced suggesting a role of concomitant hypogonadism. Chronic cabergoline treatment generally normalizes PRL treatment and improves gonadal function. The current study aimed at investigating prostate morphology in patients with prolactinoma under cabergoline treatment as compared to healthy control subjects. Twenty men with prolactinoma on chronic cabergoline treatment (CAB, 6–12 months, median dose 0.5 mg/week), including 6 (30%) on testosterone replacement therapy (TR, 6 months, median dose 30 mg/day) and 20 healthy age-matched controls entered the study. In patients and controls, hormonal levels (PRL, FSH, LH, testosterone) were evaluated and transrectal prostate ultrasound was performed. In patients, LH ($P=0.04$) and testosterone ($P=0.026$) levels were significantly lower than in controls, with no significant difference in PRL levels. Prostate volume was slightly but not significantly lower in patients than in controls. Prevalence of normal prostate morphology was significantly higher ($P=0.05$) in controls as compared to patients, whereas ultrasound signs of prostatitis resulted significantly more frequent in patients ($P=0.027$) as compared to controls. Prevalence of prostate adenoma and carcinoma was similar in patients and controls, with two cases being recorded in each group. PRL levels ($r=-0.44$, $P=0.05$), but not testosterone levels and CAB or TR dose, significantly and inversely correlated with prostate volume. In conclusion, in men with prolactinoma on chronic CAB treatment the risk of prostate hypertrophy is lower compared to healthy subjects, whereas prostatitis is more prevalent in patients than in controls. Concomitant testosterone deficiency, together with the known action of PRL as regulator of inflammation and autoimmune pathology, might represent potential mechanisms responsible for these findings. Further studies are required to better elucidate the burden and the role of PRL, hypogonadism, CAB and TR on prostate morphology in prolactinomas.

Genetic architecture of greek patients with isolated GnRH deficiency

Maria Stamou[1,2,3], Petros Varnavas[4], Lacey Plummer[1], Vassiliki Koika[4] & Neoklis Georgopoulos[4]
[1]Massachusetts General Hospital, Boston, USA; [2]University Hospital of Patras, Greece, Patras, Greece; [3]Mount Auburn Hospital, Cambridge, USA; [4]University Hospital of Patras, Patras, Greece.

Introduction
Isolated Gonadotropin Releasing Hormone (GnRH) Deficiency (IGD) is a rare disease with a wide spectrum of reproductive and non- reproductive clinical characteristics and is mainly characterized by hypogonadotropic hypogonadism with anosmia (Kallmann Syndrome) or normal olfactory function (Normosmic Idiopathic Hypogonadotropic Hypogonadism- nIHH). Apart from the phenotypic heterogeneity IGD is also highly genetically heterogeneous with >35 genes implicated in the disease. Despite this genetic heterogeneity, genetic enrichment in specific subpopulations has been described.
Methods
A cohort of 87 IGD patients underwent Sanger and Whole Exome Sequencing (WES) with the goal to discover rare sequence variants (RSVs) in genes that cause IGD. Sanger sequencing was performed in 14 known IGD genes, whereas WES expanded the analysis to 37 genes. All patients were phenotyped in detail and segregation of the detected variants was performed in family members via Sanger Sequencing.
Results
The cohort consisted of 58 male and 29 female probands and was represented by a large number of normosmic patients (57 nIHH probands) compared to patients with Kallmann Syndrome (30 probands) suggestive of a phenotypic enrichment of the normosmic feature. The majority of cases were sporadic (79/87) and most patients carried non- reproductive features. Even though, Sanger sequencing detected RSVs in 25% (21/81) of IGD patients in 7/14 IGD genes without any evidence of oligogenicity, WES revealed that 31% (27/87) of IGD patients carried

a rare genetic change in a total of 15 genes with 4 IGD cases being oligogenic (i.e. carrying RSVs in more than 1 genes).
Discussion
This is the first analysis on the largest IGD Greek cohort that has ever being studied. Our findings suggest that next generation sequencing (NGS) techniques can discover previously undetected variation, making them the standardized method for screening patients with rare and/or more common disorders.

Recurrent laryngeal nerve liberation technique for phonation recovery

Radan Dzodic[1,2], Nada Santrac[2], Ivan Markovic[1,2], Marko Buta[1,2] & Predrag Stankovic[3]
[1]Medical Faculty, University of Belgrade, Belgrade, Serbia; [2]Surgical Oncology Clinic, Institute for Oncology and Radiology of Serbia, Belgrade, Serbia; [3]Clinic for Otorhinolaryngology and Maxillofacial Surgery, Clinical Center of Serbia, Belgrade, Serbia.

Introduction
Recurrent laryngeal nerve (RLN) dysfunction is a major complication in thyroid surgery, caused commonly by thermal damage, transection or misplaced ligations. It can also be caused by RLN distension by thyroid tumors or thyroid goiter. Permanent paralysis decreases significantly quality of life and should be treated. Some surgical techniques can provide improvement in phonation, even complete recovery. The aim of this study was to analyze usefulness of RLN liberation technique in patients with RLN paresis/paralysis of various origins, based on symptoms improvement and laryngoscopy.
Materials & methods
From 2000 to 2018, 19 patients with RLN paresis/paralysis on laryngoscopy had RLN liberation as a part of thyroid surgery for various indications. If RLN dysfunction was caused by nerve distension over the enlarged thyroid lobe, the nerve was liberated during primary surgery from the lobe and repositioned. If RLN dysfunction was a consequence of previous surgery, misplaced ligation or postoperative adhesions were removed from the nerve, with its preservation. If patients had bilateral RLN paralysis, RLN liberation was performed in a two-step surgery, to avoid the risk for tracheostoma. Patient's recovery was assessed by laryngoscopy and qualitative scoring scale (QSS) at 4 time points: preoperatively, in 1st, 6th and 12th postoperative month. This *original Dzodic's liberation technique* was first reported in 2008 and published in *World J Surg* in 2016.
Results
One patient with RLN paralysis due to distension by a large follicular adenoma restored normal vocal cord mobility after lobectomy with RLN liberation (score 5 on QSS). In remaining 18 patients RLN liberation was done in a reoperation 2 months to 16 years after primary surgery – in 12 of them thyroid cancer was a primary surgical indication, in 6 reoperation was performed for alleviating the symptoms of severe dysphonia or stridorous breathing. Fifteen patients with redo surgeries scored 4 on QSS. Three patients with RLN liberation 6 months, 3 and 16 years after primary surgery restored normal vocal cord mobility on laryngoscopy (score 5 on QSS).
Conclusion
The *original Dzodic's technique of RLN liberation*, accompanied by phono-rehabilitation, enables patients with RLN paresis/paralysis a significant improvement in phonation, even complete voice recovery. It is possible to achieve complete vocal cord mobility many years after RLN injury.

Are clinicopathological features of isthmic thyroid nodules different from nodules located in thyroid lobes?

Fatma Dilek Dellal[1], Oya Topaloglu[2], Husniye Baser[2], Ahmet Dirikoc[2], Aysegul Aksoy Altınboga[3], Ibrahim Kilinc[4], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Ataturk Training and Research Hospital, Endocrinology Department, Ankara, Turkey; [2]Yildirim Beyazit University, Faculty of Medicine, Endocrinology Clinic, Ankara, Turkey; [3]Yildirim Beyazit University, Faculty of Medicine, Pathology Clinic, Ankara, Turkey; [4]Yildirim Beyazit University, Faculty of Medicine, General Surgery Clinic, Ankara, Turkey.

Aim
Although thyroid nodules located in isthmus were less frequent, papillary thyroid cancer in this location was reported to be more aggressive in some studies. Our aim was to evaluate hormonal, ultrasonographic, and cytopathologic features of nodules located in isthmus (isthmic nodules).
Material and methods
Data of patients who underwent thyroidectomy between 2006–2014 were reviewed retrospectively. Hormonal, ultrasonographic, and cytopathologic features of patients with isthmic and with lober (non-isthmic) nodules were compared.
Results
Patients with isthmic nodules (Group-1) and non-isthmic nodules (Group-2) consisted of 260 and 2171 patients, respectively. Age and gender distributions were similar. AntiTg positivity was higher in Group-1 (28.6% vs 21.2%; $P=0.018$). Subsequently, 268 isthmic (10.7%) and 5347 non-isthmic (89.3%) nodules were compared. Although ultrasonographical features such as presence of microcalcification and halo, nodule diameters, echogenicity, texture, margin, and vascularity were similar between groups, macrocalcification rate was lower in isthmic nodules (19% vs 27%; $P=0.004$). Furthermore, cytologic results were also similar. However, malignancy rate was lower in isthmic nodules (6.0% vs 11.4%; $P=0.006$), type of thyroid cancer was similar in isthmic and non-isthmic nodules. When malign isthmic ($n=16$, 2.6%) and malign non-isthmic nodules ($n=605$, 97.4%) were compared, diameter and type of tumor, lymphovascular and capsular invasion, extrathyroidal extension and multifocality rates were statistically insignificant. Malign isthmic nodules ($n=16$, 6%) had smaller size [10.05(4.00–34.50)mm vs 20.05(8.40–74.10)mm; $P=0.002$], higher hypoechogenity (31.2% vs 5.6%, $P<0.001$) and exophyticity rates (28.6% vs 4.9%; $P=0.007$) compared to benign isthmic nodules ($n=251$, 94%).
Conclusion
Although isthmic nodules had lower malignancy rate compared to non-isthmic ones, histopathologic features were similar in isthmic and non-isthmic nodules. Relatively small, hypoechoic, and exophytic nodules located in isthmus should be evaluated immediately for malignancy.

Impact of age at the diagnosis of radioiodine resistance in differentiated thyroid cancer patients

Clotilde Saie[1], Johanna Wassermann[2], Elise Mathy[1], Sophie Tezenas[1], Nathalie Chereau[1], Laurence Leenhardt[1] & Camille Buffet[3]
[1]Sorbonne Université, GRC tumeurs thyroïdiennes, AP-HP, Hôpital Pitié-Salpêtrière, Paris, France; [2]Sorbonne Université, oncology, AP-HP, Hôpital Pitié-Salpêtrière, Paris, France; [3]Sorbonne Université, GRC n°16, GRC tumeurs thyroïdiennes, AP-HP, Hôpital Pitié-Salpêtrière, Paris, France.

Background
Clinical predictors of survival of radioiodine-refractory differentiated thyroid cancer (RR-DTC) are poorly described. Age has been identified as a major prognostic factor in differentiated thyroid cancer. We asked whether age was a valuable predictor of poor prognosis in RR-DTC.
Patients and method
This single centre, retrospective study enrolled all patients diagnosed with a RR-DTC between 1991 and 2017. The primary end point was overall survival. Secondary endpoint was progression free survival. Log-rank test was used to compare population.
Results
Between 1991 and 2017, 155 patients was diagnosed with a RR-DCT. Diagnosis of RR-DTC was done before the age of 65 (younger group) in 71 cases and in 84 cases after 65 years-old (older group). Mean follow-up was 50 months (1–231). During follow up, 75 patients died, 35 in younger group and 41 in older group. Median overall survival was 4.19 years for younger group and 4.22 years for older group, with no statistical difference ($P=0.5$). Progression free survival was 1.5 years in younger group and 0.98 years in older group, but without statistical difference ($P=0.2$). There was no difference between the two groups especially regarding sex, histological subtype, or number of distant metastases. Therapeutic management did not differ between the 2 groups. Forty eight patients received tyrosine kinase inhibitor (TKI), 20 (28%) in younger group and 28 (33%) in older group ($P=0.5$). There was also no difference for radiotherapy ($P=0.6$), cervical surgery ($P=0.391$) or local treatments (cementoplasty, radiofrequency, metastases' surgery ($Ps=$ns)).
Conclusion
In RR-DTC patients, age was not predictive of the outcome. Continual progress made in the management of RR-DTC, especially in the last 15 years with the implementation of systemic therapies (i.e. TKI) should probably make reconsider the natural history and conventional prognostic factors of RR-DTC.

Effects of hospital volume on clinical outcomes after thyroidectomy - a Swiss nation-wide study

Fahim Ebrahimi[1], Alexander Kutz[1,2], Emanuel Christ[1], Philipp Schuetz[2] & Beat Mueller[2]
[1]University of Basel Hospital, Basel, Switzerland; [2]University Department of Medicine, Kantonsspital Aarau, Aarau, Switzerland.

Background
Epidemiologocal data suggest an continuous increase in thyroid carcinoma diagnosis. Therefore, thyroidectomy rates are projected to increase world-wide in exponential scale. In Switzerland, the institutional number of thyroidectomies varies, however there is no data yet on the association between institutional thyroidectomy volume and clinical outcome.
Methods
Cross-sectional analysis of adult inpatients in Swiss hospitals using a nation-wide inpatient database covering the years 2011–2015. The study population consisted of adult ($\geq$18 years) inpatients who underwent total thyroidectomy or hemithyroidectomy as the primary procedure. Hospitals were stratified into very low ($<$20 thyroidectomies per year), low (20–100 thyroidectomies per year), intermediate (101–200 thyroidectomies per year) and high ($>$200 thyroidectomies per year) thyroidectomy volume institutions. Multivariate regression models were used to determine complications, length of hospital stay (LOS), intensive care unit admission (ICU), 30-day readmission rates, and mortality in relation to hospital volume.
Results
A total of 17,410 patients were included whereof two-thirds (11,613; 66.7%) of thyroidectomies were performed at very low and low volume hospitals and one-third (5,797, 33.3%) at intermediate and high-volume hospitals, respectively. Operations of malignant thyroid diseases were more frequent among high-volume hospitals compared to low-volume hospitals (27.7% vs. 17.4%; $P<0.001$). Rates of hypocalcemia following thyroidectomy were lowest in high-volume hospitals (very low 6.7%, low 9.5%, intermediate 9.7%, and high 3.7%) with an overall adjusted odds ratio of 0.34 (95% CI, 0.29–0.42; $P<0.001$). Rates of recurrent laryngeal nerve paralysis were overall low at 2.1% (SD 14.5) for both total and hemithyroidectomies, just as mortality rates which did not show significant differences in relation to institutional number of thyreoidectomies (overall 8 deaths (0.05%). Length of stay revealed a bell-shaped curve and was lowest among high-volume hospitals when compared to other hospital volume with a mean difference of 0.61 days (95% CI; ($-$0.72)–($-$0.50); $P<0.001$).
Conclusions
Despite higher rates of malignant thyroid diseases, high-volume hospitals had less or comparable complications and shorter length of stay following thyroidectomy when compared to hospitals with low thyroidectomy volume. Mortality rate was low and independent of institutional thyroidectomy volume.

Predictors of malignancy in thyroid FNA classified as high-risk indeterminate lesions (TIR3B): combining ultrasonographic and cytology features

Alessia Cozzolino[1], Carlotta Pozza[1], Antongiulio Faggiano[1], Riccardo Pofi[1], Valeria Ascoli[2], Cira Di Gioia[2], Daniela Bosco[2], Andrea Lenzi[1], Andrea M Isidori[1], Elisa Giannetta[1] & Daniele Gianfrilli[1]
[1]Department of Experimental Medicine, 'Sapienza' University of Rome, Rome, Italy; [2]Department of Radiology, Oncology and Pathological Science, 'Sapienza' University of Rome, Rome, Italy.

Introduction
The new Italian cytological classification of thyroid nodules published in 2014 has replaced the TIR3 'indeterminate' category into two subcategory with different risk of thyroid cancer (TC): TIR3A, low-risk indeterminate lesion and TIR3B, high-risk indeterminate lesion. The aim of our study was to describe the incidence of TIR3B in a large prospective cohort of patients, the risk of TC, and its correlation with anamnestic, ultrasonographic (US) and cytological features.
Methods
Anamnestic, US and cytological features from all thyroid nodules undergoing FNA from June 2014 to January 2019 have been prospectively recorded. All patients receiving a cytological diagnosis of TIR3B have been referred to surgery and patients for whom histological examination was available have been divided into two groups: 1) TC; 2) benign lesions. Anamnestic, US and cytological features have been compared between the two groups.
Results
From June 2014 to January 2019, 1844 thyroid nodules underwent FNA in our institution and among these 96 (5%) have been diagnosed as TIR3B. Histological examination was available for 66 patients and among these 28 (42%) had TC and 38 (58%) had a benign lesion. At univariate analysis, patients aged $\leq$54 yrs had a significantly higher risk of TC than older ones (OR = 7.9, 95% CI 2.45–25.42, $P<0.001$), as well as patients with family history for extrathyroid malignancy (OR = 2.8, 95% CI 1.00–7.58, $P=0.04$) and for any malignancy (thyroid + extrathyroid) (OR = 3.1, 95% CI 1.09–8.73, $P=0.02$) as compared to those with negative family history. At US, nodule size $\leq$20 mm (OR = 5.6, 95% CI 1.84–17.10, $P=0.02$) and hyperechoic spots (OR = 5.7, 95% CI 1.72–18.96, $P=0.003$) were significantly associated with TC. Among cytological parameters, nuclear grooves (OR = 3.4, 95% CI 1.21–9.75, $P=0.017$), nuclear inclusions ($P=0.002$) and 'frosted-glass core' appearance (OR = 5.1, 95% CI 1.69–15.45, $P=0.003$) had a significantly higher risk of TC. After multivariate analysis, age $\leq$54 yrs was found an independent risk factor for TC (OR 8.84, 95% CI 1.75–44.58, $P=0.008$).
Conclusions
Thyroid nodules with a TIR3B FNA diagnosis that turned out to be thyroid cancer at the histological examination were not larger than those who were benign at final diagnosis, but more often presented hyperecoic spots at US. Cytologically, these nodules more frequently exhibited nuclear grooves, inclusions and 'frosted-glass core' appearance. Patients harboring a malignant lesion were younger and had a family history for any malignancy. The combination of anamnestic, US and cytological features could help in discriminating which high-risk indeterminate specimens should effectively be referred to surgery.

Sentinel lymph node biopsy using methylene blue dye in clinically N0 papillary and medullary thyroid carcinomas for decision on one-time lateral neck dissection

Nada Santrac[1], Ivan Markovic[1,2], Merima Goran[1,2], Marko Buta[1,2], Gordana Pupic[3] & Radan Dzodic[1,2]
[1]Surgical Oncology Clinic, Institute for Oncology and Radiology of Serbia, Belgrade, Serbia; [2]Medical Faculty, University of Belgrade, Belgrade, Serbia; [3]Department of Pathology, Institute for Oncology and Radiology of Serbia, Belgrade, Serbia.

Introduction
Surgical management of clinically N0 (cN0) patients with thyroid carcinomas remains debatable due to various reported frequencies of lymph node (LN) metastases. The aim of this paper was to present usefulness of sentinel lymph node biopsy (SLNB) of jugulo-carotid regions after methylene blue dye (MBD) mapping in intraoperative selection of cN0 patients with papillary and medullary thyroid carcinomas for one-time lateral neck dissection (LND).
Materials & methods
We present results of three studies from our Surgical Oncology Clinic that analyzed usefulness of *Dzodic's original SLNB method for LN staging in thyroid carcinomas* (published in *Word J Surg, 2006*): the first with 153 cN0 papillary thyroid carcinomas (PTC), the second with 111 cN0 micro-PTCs and the third with 17 cN0 medullary thyroid microcarcinomas (micro-MTC) with serum calcitonin levels $<$1000 pg/ml. All patients underwent injection of 1%-MBD subcapsullary in both lobes, total thyroidectomy, prophylactic central neck dissection and SLNB of jugulo-carotid regions. All sentinel-LNs were examined by frozen section analysis (FSA). One-time LND was performed only in patients with sentinel-LN metastases on FSA. Otherwise, surgery was not extended.
Results
None of the patients had allergic reactions to MBD. LN metastases were histologically verified in 40.9% of cN0 PTCs and 25% of cN0 micro-PTCs. Only one patient with hereditary micro-MTC had LN metastases in central and both lateral regions. *Dzodic's SLNB method* enabled detection of LN metastases in lateral neck compartments in 21% of patients. Skip metastases were detected in about 4% of patients with PTCs and micro-PTCs, while there were no skip metastases in micro-MTCs. Method's overall accuracy was high in all studies, but the highest in the study with micro-MTCs (100%).
Conclusion
Dzodic's SLNB method with MBD mapping and FSA of sentinel-LNs from jugulo-carotid regions is accurate in detection of lateral LN metastases in cN0 patients with papillary and medullary thyroid carcinomas and microcarcinomas. It prevents over-treatment of patients without metastases in sentinel-LNs and helps in decision for one-time LND in patients with histologically proven sentinel-LN metastases. This method additionally facilitates central neck dissection and diminishes the possibility of accidental removal of parathyroid glands (that remain non-colored), even in less experienced surgeons' hands.

Factors influencing nodular goiter – An analysis of the growth rates in long-term follow-up patients

Takao Kunori, Noriko Nemoto, Shinya Kawaguchi, Akihiko Hashimoto, Hiroshi Yoshida, Satoru Shiraso, Nanako Fujikawa & Fumiaki Shinya
Iwaki City Medical Center, Iwaki, Japan.

Background
Nodular goiter (NOD) is one of the most common disease (69% in our thyroid clinic). Although the nodular growth is generally slow, it may be influenced by thyroid hormones, autoimmunity or other factors. The analysis may contribute to predict the outcomes.
Patients and methods
2,213 Japanese patients (2007–2018; Fukushima coast area) with NOD were enrolled in this study. Mean observation period was 6.4 years with 7 visits (1–50). They consist of female (80%, mean age 57) and man (20%, 66). Serology was performed for thyroid peroxidase antibody (TPO), anti-thyroglobulin antibody (TgAb), thyroid stimulating hormone receptor antibody (TSH-RAb) and, in some patients, thyroid stimulating hormone antibody (TSAb). Hormonal assay was performed for free thyroxine (F-T4), free triiodo-thyronine (F-T3), thyroid stimulating hormone (TSH) and thyroglobulin (Tg). Nodules were examined by ultrasonogram to estimate total volumes of nodules (VOL). Pathological diagnosis was made by a fine needle aspiration cytology. Growth rates of nodules (VR%) were calculated from a formula; (current VOL/initial VOL)/ years.
Results
1. VR: 33% of NOD remained unchanged after 2 years of follow-up period, whereas 29% reduced and 38% enlarged. 2. TSH: TSH decreased from 1.46 IU/ml (mean) to 0.79 IU/ml after 8 years ($P<0.05$). 3. TSH and NOD: VR (/year) yearly decreased from 7% (0–2 years) to 0.9% (16 years). Patients with high TSH(>3 IU/ml) showed high VR (26–68%). 4. Thyroid antibodies: Positive (+) rates were 28% in TPO and 22% in TgAb. Both were associated with reduction of VR: no increase of VR in TPO+, whereas an increase (up to 3–8%) in TPO- ($P<0.05$). TSH-R was associated with an increase of VR (from 2% to 11%). 5. Cytology: VR was highest in cancer ($P<0.001$). 6. Physical states: VR was high in youth (age 10–30) and decreased in aging ($P<0.001$). Female had higher VR (3.9) than man (0.13, $P<0.05$). 7. Drugs: Patients treated with Levothyroxine showed low VR (−2%), whereas those with Methimazole showed high VR (+20%).
Conclusions
Growth of NOD was associated with various factors including TSH, thyroid autoantibodies and age. The activity appeared to be lost according to the follow-up periods.

Evaluating effects of thyrotrophin receptor antibody positivity on cytology and histopathology in patients with graves disease

Husniye Baser[1], Oya Topaloglu[1], Cevdet Aydın[1], Mustafa Omer Yazicioglu[2], Hayriye Tatli Dogan[3], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Ankara Yildirim Beyazit University, Faculty of Medicine, Department of Endocrinology and Metabolism,, Ankara, Turkey; [2]Ankara Ataturk Education and Research Hospital, Department of General Surgery, Ankara, Turkey; [3]Ankara Yildirim Beyazit University, Faculty of Medicine, Department of Pathology, Ankara, Turkey.

Aim
It has been reported that thyrotrophin receptor antibody (TRAb) is associated with frequency and aggressiveness of thyroid cancer in patients with Graves disease (GD). However, there is not any data regarding the effects of TRAb on cytology and histopathology results of patients with nodular GD. Thus, the aim of the present study is to evaluate the effects of TRAb on cytology and histopathology results in patients with nodular or multinodular thyroid disease on the basis of GD.
Materials and methods
Clinical data of patients with GD who had thyroidectomy and preoperative TRAb levels were reviewed retrospectively. The cytology and histopathology results of 548 nodules from 598 patients with GD were evaluated for the present study.
Results
Of 598 patients, 189 (31.6%) were men and 409 (68.4%) were women. However 352 patients did not have nodular disease on preoperative thyroid ultrasound, 74 had only one nodule and 172 had ≥ 2 nodules. 517 (86.5%) patients had benign and 81 (13.5%) had malignant final histopathology. In malignant group, 77 (95.1%) patients had papillary throid carcinoma, 2 (2.5%) had follicular thyroid carcinoma, 1 (1.2%) had thyroid tumor of uncertain malignant potential, and 1 (1.2%) had hurthle cell thyroid carcinoma. However, TRAb was detected as positive in 359 (60%) patients, it was found as negative in 239 (40%) patients. There were 185 nodules in TRAb positive group and 363 nodules in TRAb negative group, and there was no significant difference in cytology results between groups ($P=0.181$). Malignancy was detected in 48 (13.4%) and 33 (13.8%) patients with TRAb positive and negative patients, respectively ($P=0.878$), and there was not any difference in histopathology results between groups ($P=0.161$). Furthermore, there was no difference in features of carcinoma such as capsular, vascular, and lymphatic invasions between TRAb positive and negative groups ($P>0.05$).
Conclusion
In the present study, it was found that malignancy rate was similar in TRAb positive and negative patients. Contrary to literature, TRAb positivity was not associated with increased malignancy rate and also had no effect on cytology and histopathology results in patients with GD.

Classification of thyroid nodules by ultrasound in clinical practice: the added value of the judgment of the skilled endocrinologist

Bruno Madeo[1,2], Giulia Brigante[1,2], Anna Ansaloni[1,2], Erica Taliani[1,2], Shaniko Kaleci[3], Maria Laura Monzani[1,2], Manuela Simoni[1,2] & Vincenzo Rochira[1,2]
[1]Unit of Endocrinology, Dept. Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; [2]Department of Medical Specialties, Azienda Ospedaliero-Universitaria di Modena, Modena, Italy; [3]Department of Diagnostic Medicine, Clinics and Public Health, Azienda Ospedaliero-Universitaria di Modena, Modena, Italy.

Background and aim
Several ultrasound (US) classifications for thyroid nodules have been proposed. Since most of them are hardly applicable in clinical practice, we set up the Modena US Thyroid Classification (MUT) that stratifies the risk of malignancy considering both knowledge derived from scientific literature and clinician subjective impression. The aim of the present study was to test the diagnostic accuracy of different thyroid US classification systems, AACE/ACE-AME, American Thyroid Association (ATA), British Thyroid Association (BTA), and MUT, and to evaluate inter-classification agreement.
Methods
We prospectively enrolled 111 patients (33M, 78F; age 19–75) candidate for surgery because of indeterminate, suspicious or malignant cytology. All patients underwent neck US before surgery and a score according to MUT was assigned: 1 not certainly nodular; 2 not suspect; 3 indeterminate; 4 suspect; 5 very suspect. Then, we retrospectively classified nodules according to AACE/ACE-AME, ATA and BTA, thanks to the detailed collection of each nodule US features in a preformed checklist. US pattern was related to histology. Sensitivity, specificity, diagnostic cut-off value and accuracy of each classification were calculated. The overall agreement between classifications was quantified by Bland-Altman test. The agreement between single nodule analysis by different classifications was evaluated considering Weighted Cohen's Kappa.
Results
Fifteen patients had uninodular and 96 multinodular goiter, for a total of 457 nodules. MUT has the highest accuracy (AUC 0.808) and specificity (89%), followed by ATA and BTA, and finally by AACE/ACE-AME. ATA and BTA are highly interchangeable and MUT is comparable to both of them. AACE/ACE-AME is the least interchangeable with all the other classifications. Considering agreement between single nodule analyses by different classifications, ATA and BTA had the best ($\kappa=0.723$); AACE/ACE-AME showed slight agreement with BTA ($\kappa=0.177$) and MUT ($\kappa=0.183$), and fair agreement with ATA ($\kappa=0.282$); MUT had fair agreement with both ATA ($\kappa=0.291$) and BTA ($\kappa=0.271$).
Conclusions
Our data analysis to quantify the agreement between different classification systems confirms the reliability and reproducibility to classify malignancy. However, results bring out the limit in specificity of the current reference classifications, which improves when the subjective impression of the clinician is considered.

Predictive factors of short and long-term vandetanib response in locally advanced or metastatic medullary thyroid cancer: a single center experience

Laura Valerio[1], Valeria Bottici[1], Antonio Matrone[1], Alessia Tacito[1], Cristina Romei[1], Paolo Piaggi[2] & Rossella Elisei[1]
[1]Endocrine Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy; [2]Phoenix Epidemiology and Clinical Research Branch National Institute of Diabetes and Digestive and Kidney Disease, National Institutes of Health, Phoenix, Arizona, USA.

Objectives
Vandetanib (V) is an important drug in the metastatic medullary thyroid cancer (MTC) treatment. The objective of this study was to evaluate the presence of predictors of V response, in short and long period, in locally advanced or metastatic MTC patients (pts).
Methods
Seventy-nine locally advanced or metastatic MTC pts with progressive or symptomatic disease, referred to our Center between 2007 and 2018 and already treated surgically and with other systemic therapies, were treated with V. During follow-up it was performed clinical examination, biochemical and morphological evaluation. Twenty-five pts were treated with V for less than 12 months (short responders, Group 1), 54 patients were treated with V for at least 12 months (long responders, Group 2).
Results
The genetic screening showed that in the Group 1, 4/25 (16%) pts were inherited forms and 21/25 (84%) pts were sporadic cases. In the Group 2, 8/54 (14.8%) pts were inherited forms and 46/54 (85.2%) pts were sporadic cases. The evaluation of somatic mutations showed that RET mutation was present in 82.3% and in 95.3% of pts in Group 1 and in Group 2, respectively. However, the presence of RET mutations, it wasn't a predictor of response to treatment. The metastases site wasn't correlated with the outcome. Otherwise, we observed that in long responders group, 47/54 (87%) pts showed at least one adverse events (AE) during V treatment with a correlation between AE and V response ($P=0.02$). In this group we also observed a statistically significant correlation between the younger age (<45 yrs) at screening and a greater response to V ($P=0.01$) and between the absence of progression disease at screening and response to V ($P<0.0001$). In the long term outcome, considering the last CT scan performed at the data cut-off during the treatment, 29/54 (53.7%) pts showed a persistent response to V after a median follow-up of 41 months. Moreover, we observed that the pts in the Group1 had a more aggressive disease and a more advanced age at screening than pts in Group 2. The estimated median Progression Free-Survival of all patients was 47 months.
Conclusions
In our study, it was observed that the appearance of AE during V treatment, the younger age and the absence of progression disease at screening were predictive factors of long-term response to V in MTC pts. Moreover, RET somatic mutations were very frequent in the metastatic MTC patients but it wasn't a predictor of response to V.

Assessment of different ti-rads systems using computer-aided detection technology

Kuen-Yuan Chen[1], Ming-Hsun Wu[1], Chiung-Nien Chen[1] & Argon Chen[2]
[1]Department of Surgery, National Taiwan University Hospital, Taipei, Taiwan; [2]College of Engineering, National Taiwan University, Taipei, Taiwan.

Aims
Different guidelines of Thyroid Imaging, Reporting, and Data System (TI-RADS) have been published to determine whether FNAC is required. Most of the guidelines recommended observation for nodules less than one centimeter and FNAC for nodule larger than two centimeters. In this study, we focus on the management of nodules size between one and two centimeters. We aim to evaluate the different guidelines on the treatment of thyroid nodules with the computer-aided detection (CADe) technology. We also propose a novel guideline for FNAC to reduce unnecessary procedures.
Methods and materials
The thyroid ultrasound pictures database collected prospectively were used. From July 2008 to December 2015, 369 patients with 422 nodules size between one and two centimeters were recruited, which were pathologically proven. (191 benign and 231 malignant) Eight guidelines, i.e., ACR (2017), ATA (2015), AACE (2016), Russ (2016), Seo (2016), BTA (2014), Kwak (2011) and Kwak (2013), were evaluated with sonographic features computerized by a USFDA-cleared CADe software device (AmCAD UT Detection). This CADe device quantifies and visualizes six sonographic features: hypoechogenicity, echogenic foci, heterogeneous texture, irregular margin, anechoic area, and taller-than-wide features, to assist physicians in making their diagnostic decisions with structural reports. The novel guidelines for the recommendation of FNAC were proposed using the quantified sonographic features.
Results
The ultrasound images were further divided into two groups, one is the size less 1.5 cm (1–1.5 cm) and the other is the size larger than 1.5 cm (1.5–2 cm). For group (1–1.5 cm), we presumed that the sensitivity above 90% was acceptable. The BTA (2014) had the sensitivity of 91%, with the specificity 23%. For group (1.5–2 cm), higher sensitivity is demanded. The Russ (2016) had the sensitivity of 96%, with the specificity 19%. The novel guideline was proposed and tested. For group (1–1.5 cm), if either one of US features including hypoechogenicity, calcifications and taller than wide was present, then sensitivity is 91% and specificity is 26%. For group (1.5–2 cm), if either one of US features including hypoechogenicity, calcifications and heterogeneity were present, the sensitivity is 95% and specificity is 21%. The guideline is simple and effective in reducing unnecessary FNAC procedures.
Conclusion
The CADe device is an effective tool to assist physicians in following the TI-RADS guidelines. With the proposed novel guideline, it's shown that 91% of malignant nodules (1–1.5 cm) and 95% of malignant nodules (1.5–2) could be successfully identified and proceed to FNAC for further treatment with better specificity compared to other guidelines.

A novel heterozygous mutation in exon 3 of VHL gene leading to Von Hippel-Lindau disease in a Turkish family

Ozge Tasgin Yildirim[1], Ismail Yildiz[2], Fatih Horozoglu[3], Aysun Gonen[4], Cenk Murat Yazici[5], Gulsah Elbuken[2] & Sayid Zuhur[2]
[1]Namik Kemal University Faculty of Medicine Department of Internal Medicine, Tekirdag, Turkey; [2]Namik Kemal University Faculty of Medicine Department of Endocrinology and Metabolism, Tekirdag, Turkey; [3]Namik Kemal University Faculty of Medicine Department of Ophtalmology, Tekirdag, Turkey; [4]Namik Kemal University Faculty of Medicine Department of Radiology, Tekirdag, Turkey; [5]Namik Kemal University Faculty of Medicine Department of Urology, Tekirdag, Turkey.

Background
Von Hippel-Lindau disease (VHL) is an autosomal dominant disease, characterized by haemangioblastomas of the retina and CNS, renal cell carcinomas (RCC) and renal cysts, pheochromocytomas, pancreatic neuroendocrine tumors and cysts, and endolymphatic sac tumors. VHL is associated with a germline mutation of the *VHL* tumor suppressor gene on the short arm of chromosome 3. The type-1 disease is caused by mutations, leading to severe disruption of protein activity, including deletions, missense and nonsense mutations, and other microdeletions/insertions. However, the type-2 disease is generally associated with missense mutations in approximately 96% of the cases. Herein, we report a family with pheochromocytomas in 3 generations and 4 affected members. The family had recurrent pheochromocytomas with retinal angiomas and spinal cord hemangioblastomas. However, none of the family members had RCC. A novel heterozygous class-2 mutation in exon3 of VHL gene (c.572_574delACC/p.His191del) was determined by DNA sequence analysis in all affected family members.
Cases
The first case is a 63 years old female who had been operated for bilateral pheochromocytomas when she was 38. MRI of the spinal cord demonstrated a 19×68 mm hemangioblastoma at the T12-L1 vertebra levels. The second case is a 38 years old female who had been operated for bilateral pheochromocytomas when she was 16. Ophthalmological examination demonstrated an optic nerve and a peripheral angioma. Abdominal and spinal cord MRI demonstrated a 14× 6 mm hemangioblastoma at the T12-L1 vertebra levels and a 45×35 mm broad ligament cyst. The third case is a 42 years old male who had been operated for bilateral pheochromocytomas when he was 22. An asymptomatic recurrent 3.5× 14 mm right adrenal pheochromocytoma was diagnosed by high plasma normetanephrine and serum chromogranin A levels and confirmed by abdominal MRI and GA-68 DOTATATE PET/CT. The fourth case is a 17 years old male, who had been operated for bilateral pheochromocytomas when he was 9. He admitted for hypertension 9 months before. His plasma normetanephrine, and serum chromogranin A level was high. A 2×15 mm mass at the right adrenal area was determined by MRI and GA-68 DOTATATE PET/CT. Ophthalmological examination demonstrated a peripheral retinal angioma.
Conclusions
In this family, we found a novel class-2 heterozygous mutation in the VHL gene in all family members, that has not previously been reported. This mutation leads to the development of recurrent bilateral pheochromocytomas at a very young age, spinal hemangioblastomas, and retinal angiomas, but probably doesn't lead to RCC.

Long evolution of Connshing syndrome?

Hamza Elfekih, Hanene Sayadi, Dhia El Hak Abid, Malak Kechida, Om Kalthoum Sallem, Hela Marmouche, Rim Klii & Ines Khochtali
Department of Endocrinology and Internal Medicine, Fattouma Bourguiba University Hospital, Monastir, Tunisia.

Introduction
Primary hyperaldosteronism is the main endocrine cause of secondary hypertension. Its association with an autonomous cortisol secretion is rarely described in the literature. Here we report the case of a patient having a unilateral adrenal adenoma responsible for both mineralocorticoids and glucocorticoids excess.
Observation
A 54-years-old female diagnosed at the age of 26 years with hypertension. She received up to four antihypertensive treatments including thiazide diuretics without prior investigation. At the age of 52 years, she was admitted for angina with normal coronary arteries where a severe hypokalemia was detected and treated with potassium supplementation in addition to the withdrawal of diuretics. The diagnosis of renal artery stenosis was ruled out and the CT scan revealed a 2 cm unilateral left adrenal adenoma. The patient was hospitalized later in our department for hormonal investigation. At admission she presented clinical symptoms of tetany, U wave in electrocardiogram with low serum potassium (2.5 mmol/l). The hypokalemia required up to 20.8 g per day of oral and IV potassium supplementation in order to maintain normokalemia. Renin dosage was low (3.6 mIU/l) despite the use of ACE inhibitor which cannot be stopped due to the severity of hypokalemia and hypertension. Once spironolactone (50 mg per day) was introduced in addition to captopril (150 mg per day) and amlodipine (10 mg per day), blood pressure and potassium was stabilized and the patient didn't require additional supplementation. 1 mg overnight dexamethasone suppression and 2-day low-dose dexamethasone tests were elevated 20 and 24 ng/ml successively. The patient didn't have catabolic signs. ACTH level was incompletely suppressed (14.9 pg/ml) and the pituitary imaging was normal. Surgical treatment was chosen due to the glucocorticoids excess in addition to prediabetes and bone demineralization.
Discussion
Connshing syndrome is a challenging disease characterized by overproduction of mineralocorticoids and glucocorticoids from adrenal adenoma. Hypercortisolism, although generally mild, is able to increase the risk of developing diabetes mellitus and osteoporosis. Medical treatment could normalize hypertension and hypokalemia but it has no effect on glucocorticoids excess which requires adrenalectomy to be cured. The long evolution of resistant hypertension in our patient without clinical feature of Cushing syndrome may rise the question whether the overproduction of glucocorticoids is concomitant or not to primary hyperaldosteronism.

Effect of Glucocorticoid receptor antagonist administration in a Cushing's syndrome model rat

Toshiro Seki[1], Atsushi Yasuda[1], Natsumi Kitajima[1], Masami Seki[2], Masayuki Oki[1] & Masafumi Fukagawa[1]
[1]Tokai University School of Medicine, Kanagawa, Japan; [2]Seirei Numazu Hospital, Shizuoka, Japan.

In Cushing's syndrome (CS), hypercortisolemia due to cortisol-producing adrenal adenomas suppresses the hypothalamic-pituitary-adrenal (HPA) axis, so the normal adrenal tissue is atrophied without ACTH stimulation and its function impairs. As a result of surgical resection of cortisol-secreting adenoma, postoperative adrenal insufficiency occurs. Therefore, we thought that administering glucocorticoid receptor antagonist (mifepristone) in order to release suppression of HPA axis caused by hypercortisolemia enables early recovery of adrenal function due to stimulation of ACTH for normal adrenal glands. We thus compared adrenal function in a dexamethasone (DEX)-induced CS model rat ($n=4$) with or without mifepristone (MIF). In this study, MIF-treated rats demonstrated less suppression of plasma ACTH levels (55.13 ± 15.87 pg/ml) and increased adrenal weight (26.3 ± 5.3 mg). In addition, we confirmed that atrophic changes were less on pathological findings in the adrenal glands of MIF-treated rats. These results suggest that preoperative mifepristone administration may improve the residual adrenal function for CS. Our group is currently conducting experiments to investigate the levels of mRNAs for *CYP11B1* in adrenal glands as assessment of the recovery of adrenal function.

Ectopic adrenocorticotropic hormone (ACTH-ectopic) syndrome and osteoporosis: Rare cases and difficult treatment

Vadim Krylov[1], Ekaterina Dobreva[2], Sergey Kharnas[1] & Nikolay Kuznetsov[2]
[1]Sechenov University, Moscow, Russian Federation; [2]Endocrine Research Centre, Moscow, Russian Federation.

Objective
Ectopic adrenocorticotropic hormone (ACTH-ectopic) syndrome (EAS) is a rare cause of ACTH-dependent endogenous hypercortisolism. The objective of this study was to analyze the clinical, biochemical, and radiological features, management, and treatment outcome of patients with EAS.

Methods
It was a retrospective case-record study of 47 patients with EAS. Clinical, biochemical, and radiological features and response to therapy and survival rate were measured.
Results
The median follow-up was 7 years. (range, 1–13 years.). None of the dynamic tests achieved 100% accuracy. Imaging correctly identified the lesion at first investigation in 80.9% of cases. Bronchial carcinoid tumors were the most common cause of EAS ($n=27$; 57.5%), followed by other neuroendocrine tumors ($n=11$, 23.4%). In 19.1% (9) of patients, the source of EAS was never found. Tumor histology and the presence of distant metastases were the main predictors of overall survival ($P < 0.05$). It is interesting that 40 patients (85,1%) have steroid osteoporosis. 10 patients were treated with calcium and vitamin D, 35 patients by bisphosphonates, 2 patients by denosumab and 3 by teriparatide.
Conclusions
ACTH-ectopic syndrome is a very rare condition with severe complications. There is no significant data and guidelines for osteoporosis treatment in such disease. So we need to improve our to improve the quality of life of such difficult patients.

Paraganglioma of the urinary bladder wall: 2 cases with 2 different presentations

Cynthia Salloum, Carla Sawan & George Assaf
St. George Hospital University Medical Center, Beirut, Lebanon.

Objective
We present two cases of patients with Paraganglioma of the urinary bladder wall, illustrating the differences in diagnosis and management.
Case 1: An 80-year-old female known to have diabetes and hyperthyroidism (treated) presented to her urologist with painless hematuria. Cystoscopy was done and bladder polyps were biopsied. Results of the tumors sampled showed paraganglioma of the urinary bladder wall, although patient was asymptomatic. She presented to the endocrinology clinic to rule out pheochromocytoma. She has long-standing hypertension well-controlled with three medications (CCB, ARB, BB). She denied headaches or syncope especially upon micturition. No flushes or palpitations. Plasma metanephrines, dopamine and normetanephrines were checked and were negative, ruling out secretory pheochromocytomas. She underwent TURBT later for complete resection of the tumor, the pathology of which was consistent again with Paraganglioma of the urinary bladder wall. Patient remains asymptomatic afterwards with good control of her blood pressure despite the diagnosis.
Case 2: A 32-year-old male previously healthy presented to the urology clinic with 9 months history of headaches and palpitations following micturition. He denied any obstructive or irritative lower urinary tract symptoms. Family history was unremarkable for any related conditions. Patient had his vital signs monitored before and after micturition, and were found to be: Blood pressure and heart rate were 130/80 mmHg and 75 bpm before voiding, rising to 170/100 mmHg and 100 bpm upon bladder emptying. His urinalysis showed microscopic hematuria. Pelvic ultrasound revealed a left bladder wall polyp measuring 35 × 23 mm seen also on CT scan. Cystoscopy showed a submucosal pulsating mass 3 cm in size. He had elevated plasma free normetanephrines (1.90 nmol/l; normal < 0.93). His 24 h urine catecholamine and metanephrine levels were within normal limits. Iodine 131-MIBG scintigraphy showed no other sites involved. Patient received an α-adrenergic blocker as a preparation for surgery, along with vigorous hydration. A successful partial cystectomy was done and was uneventful, without blood pressure fluctuations. Immunostaining was strongly positive for synaptophysin and chromogranin, in favor of a paraganglioma. Patient remained asymptomatic upon long term follow-up.
Conclusion
Bladder wall paragangliomas are variable in their nature and their presentation. Tumors range from non-secretory masses in asymptomatic individuals to excessively secreting catecholamine leading to life threatening hypertension and tachycardia.

Adrenal insufficiency secondary to bilateral adrenal diffuse large B-cell lymphoma: a case report

María Laura García, Romina Speroni & Ana Paula Lisdero
Sanatorio Dr Julio Méndez, Buenos Aires, Argentina.

Introduction
Primary adrenal lymphoma is extremely rare. It accounts for <1% of extranodal lymphoma. It affects typically old males with bilateral adrenal gland involvement that leads to adrenal hypofunction. Prognosis is very poor due to the lack of optimum chemotherapeutic regimens.
Case Report
A 71 yearr old man with prior history of non insulin dependent diabetes, was admitted to the emergency department with symptoms of progressive weakness, fatigue, anorexia, and 15 kg weight loss in the previous 6 months. These symptoms were associated with hypotension, nausea, vomiting and unsteady gait. On physical examination the patient looked caquectic, chronically ill but alert. He had orthostatic hypotension. Skin hyperpigmentation was absent. Laboratory assays showed hyponatraemia (127 mEq/l) and a sligthly high potassium (5.6 mEq/l), normoglycemia and anemia. The patient initially responded to intravenous hydrocortisone in large doses with remission of symptoms. But orthostatic hypotension and ionogram alterations persisted so fludrocortisone was added with good results. Screening for malignancy was made with a hole body computed tomography scan (CT) that showed bilateral adrenal masses with more than 10 HU. Further assesment by adrenal MNR scan showed hypointense nodular images in T1 and T2 in both adrenal glands. With a nodule of 4 cm on the right gland and another of 4.5 cm on the left one. They appeared hyperintense in Out Phase, and had a post-gadolinium heterogeneous reinforcement. The ACTH test showed a complete failure of response (Basal Cortisol 0.3 ug/dl post-ACTH Cortisol 30 min: 0.4 ug/dl. Urine metanephrines and catecholamines were normal excluding phaeochromocytoma. Urgent needle biopsy of the left adrenal gland was performed wich revealed diffuse large B-cell lymphoma. Bone marrow biopsy was negative for lymphomatous involvement. After the diagnosis was made the patient deteriorated rapidly and passed away as a result of his condition.
Conclusion
Primary adrenal lymphoma is extremely rare. When it occurs, diffuse large B-cell lymphoma is the most common subtype involved. This case highlights the importance of considering diffuse large B-cell lymphoma (PAL) as an unusual cause of adrenal insufficiency. Specially in older patients who present with adrenal insufficiency associated with bilateral adrenal masses.

P7

A rare association of Adrenocortical carcinoma with haematological and breast malignancy in a young female

Muhammad Murtaza Shafqat[1], Naveed Khalily[1], Herpret Deol[1], Aamir Naeem[2] & Shujah Dar[2]
[1]University Hospital Coventry, Coventry, UK; [2]University Hospitals Birmingham, Birmingham, UK.

A 20-year-old female admitted under haematology team for acute myeloid leukaemia. During her admission, she had a whole body CT scan and was found to have a left breast lesion (proven on biopsy to have invasive ductal carcinoma) and a right adrenal mass measuring 6.5 × 7.5 cm with radiological features suggestive of an adrenocortical cancer. Biochemical workup showed raised adrenal androgens: DHA Sulphate 14.9 umol/l (4.0–11.0), 17-OH Progesterone 7.6 nmol/l (0.6–6.0), androsteinedione 59.4 nmol/l (0.9–7.5), testosterone 39.1 nmol/l (<1.8), plasma metanephrines and 24hour urinary cortisol were within the normal range. This patient had three synchronous malignancies diagnosed around same time at 20 years of age. Further detailed family history revealed that the patient had strong family history of deaths in younger age from malignancies including younger brother died at the age of 9 from sarcoma, mother at the age of 35 with breast cancer and the maternal aunt aged 40 from an unknown cancer. Doing Literature search, we found that this strong family history of malignancies could be suggestive of Li-Fraumeni Syndrome (LFS) which is an inherited condition with a predisposition to the development of malignancies secondary to a mutation in the tumour suppressor gene TP53. This mutation make individuals susceptible to develop multiple malignancies like bone sarcoma, breast cancer, brain tumour, adrenocortical carcinoma and acute leukaemia. Li-Fraumeni Syndrome (LFS) is a rare condition in which affected Individuals have a lifetime cancer risk that approaches 100% by age 70 years. In her case, genetic testing confirmed diagnosis of Li-Freemen Syndrome (LFS).Patient had chemotherapy for her breast cancer alongside her treatment for AML. She underwent Right sided adrenalectomy and histology confirmed adrenocortical carcinoma with high mitotic index.Few days after Surgery patient was re-admitted with severe neutropenic sepsis and multi organ failure and despite critical care interventions including organ support, unfortunately she died.

Metabolic and cardiovascular profile of 143 adrenal incidentalomas

Marta Araujo-Castro[1], Miguel Sampedro Núñez[1], Paola Parra Ramírez[2], Cristina Robles Lázaro[3], Martín Cuesta Hernández[4] & Mónica Marazuela[1]
[1]Hospital Universitario de la Princesa, Madrid, Spain; [2]Hospital Universitario de La Paz, Madrid, Spain; [3]Hospital Clínico Universitario de Salamanca, Salamanca, Spain; [4]Hospital Clínico San Carlos, Madrid, Spain.

Objective
To study the differences in the metabolic profile of patients with non-functioning adrenal adenomas (NFA) and autonomous cortisol secretion (ACS).
Methods
143 patients diagnosed of adrenal incidentaloma (AI) between 2010 and 2018 were retrospectively analyzed. AI was defined as an adrenal mass $\geq$1 cm, accidentally discovered by radiologic examination. ACS was confirmed by serum cortisol post-dexamethasone suppression test (Nugent) $\geq$3 µg/dl and no typical features of Cushing's Syndrome (CS). NFA were considered when the whole hormonal evaluation was normal (Nugent test $<$3 µg/dl, aldosterone/renin ratio (when appropriate) and urinary metanephrines). The statistical analysis was performed with STATA 15.0 and ACS and NFA patients were included (n=132).
Results
The mean age was 63.2(10.74) years and 55.9% were women. 78.3% patients had NFA, 11.9% ACS, 1.4% CS and 8.4% other diagnoses. In the univariate analysis, we found no statistically significant differences between ACS and NFA in the prevalence of hypertension (70.6 vs 47.8%, P=0.08), diabetes (35.3 vs 26.1%, P=0.4), dyslipidemia (47.1 vs 48.7%, P=0.9), cardiovascular (17.7 vs 8.8%, P=0.3) and cerebrovascular disease (11.8 vs 3.5%, P=0.1). The prevalence of obesity was significantly lower in ACS than in NFA (17.7 vs 37.7%, P=0.01), however no statistically significant differences were found in the BMI (28.0 vs 30.0 kg/m^2, P=0.4). Neither significant differences were found in the mean of systolic or diastolic blood pressure (128.4 vs 131.5 mmHg (P=0.48) and 76.6 vs 78.8 mmHg, (P=0.47), respectively); fasting plasma glucose (FPG) (109.4 vs 107.8 mg/dl, P=0.83), total cholesterol (188.5 vs 188.2 mg/dl, P=0.98); LDL (108.5 vs 115.1 mg/dl, P=0.52), HDL (52.5 vs 53.1 mg/dl, P=0.93) and triglycerides (133.2 vs 125.9 mg/dl, P=0.68). No significant correlation was found between Nugent test and cardiovascular risk factors ($p>0.05$ in the Pearson correlation). In the linear regression model, Nugent test was a good predictor of the maximum adenoma diameter (R-squared=0.13, P=0.01) and urinary free cortisol (R-squared=0.23, P=0.00) but it was inadequate to predict ACTH, basal cortisol, DHEAS, FPG, cholesterol, LDL, HDL or triglycerides ($P>0.05$). There was no progression to CS in any case and only 3 NFA developed ACS during the study period (mean=27.7 months). In both groups, the metabolic profile remained stable throughout the follow-up.
Conclusions
Our data suggest a higher prevalence of hypertension, diabetes mellitus, cardiovascular and cerebrovascular disease in patients with ACS compared to NFA. However, there were no statistically significantly differences probably due to small sample size. We did not find the Nugent test to be a reliable predictor of the metabolic profile in AI patients.

HNRNP Q suppresses polyglutamine huntingtin aggregationby post-transcriptional regulation of Vaccinia-related kinase 2

Kyong-Tai Kim & Hye Guk Ryu
Pohang University of Science and Technology, Pohang, Republic of Korea.

The misfolded proteins with abnormal polyglutamine (polyQ) expansion cause neurodegenerative disorders including Huntington's disease (HD). Recently, Vaccinia-related kinase 2 (VRK2) were found to accumulate polyQ aggregates by controlling TCP-1 ring complex (TRiC)/Chaperonin-containing TCP-1 (CCT), which has an essential role in preventing against the aggregation and cytotoxicity of polyQ proteins. Interestingly, VRK2 expression is known to be much higher in actively proliferating cells, but is maintained at a low level in the brain via unknown mechanism. Here we found that neuronal cell-specific basal level of VRK2 is regulated by post-transcriptional regulation rather than the regulation in transcription itself. Moreover, heterogeneous nuclear ribonucleoprotein Q (hnRNP Q) specifically binds to 3'UTR of *VRK2* mRNA in neuronal cells and reduces its mRNA stability. In relation to that we found a dramatic decrease in CCT4 protein level due to a reduction in hnRNP Q, followed by an increase in polyQ aggregation. Taken together, these studies could provide new insights into how neuronal hnRNP Q regulates *VRK2* mRNA stability and contributes to HD prevention, and open new prognostic marker of HD.

Study of body composition and phase angle in relation to nutritional parameters in patients with neuroendocrine tumors

Carmen Hernández-García, Isabel María Cornejo-Pareja, Miguel Damas-Fuentes, José Ignacio Martínez-Montoro, Cristina María Díaz-Perdigones, Borja Bandera-Merchán, José Manuel García-Almeida & Francisco José Tinahones-Madueño
Hospital Clínico Universitario Virgen de la Victoria, Málaga, Spain.

Introduction
Neuroendocrine tumors are an heterogeneous group of neoplasms with increasing incidence and high survival. The therapies, could be have a negative impact on nutrition and pronogsis of these patients.
Objetives
To analyze analytical and anthropometric parameters in relation to disease stage and survival.
Material and methods
An observational, retrospective and cross-sectional study that includes patients with neuroendocrine tumors. Data are collected at first nutrition appointment in Virgen de la Victoria Clinical Hospital, since 2015 to 2018.
Results
We analyzed data from 42 patients of 59.9$\pm$17.6 years of age, 47.6% males; with diagnosis of intestinal neuroendocrine tumor 35.8%, pancreatic 33%, carcinoid 11.9%, gastrinoma 14.3%, other locations 4.8%; Ki67 proliferation index medium 8.9$\pm$11.7, stages 1 and 2 95% and non-functioning (73.2%). 36.6% of the patients underwere subjected with pancreatic resection, 29.3% had bowel resection, 2.4% had another type and 31.7% had not surgery, and 28.6% had SSA; SSA + everolimus, QT or imatinib 16.8% and only QT 11.9%. Without treatment 33.3%. No evidence of disease was found in 19%, localized 19% and disseminated 61.9% with a follow-up time of 4.48$\pm$4 years. They presented diabetes mellitus previously 23.8%, 14.3% with oral antidiabetics; after diagnosis, increase a 14.3%, treated with ADOs 23.8%, insulin 9.5% and both 4.8%. 43% present steatorrhea, treatment with pancreatin 52.4%, adequate intake 62%; enteral supplements 35.8%, supplements of vitamin D 33.3% and multivitamins 33.3%. Anthropometric parameters: weight 67.4$\pm$12.2 kg (decrease of 4.8 Kg compared to usual), BMI 25.1$\pm$4.2, MM 48$\pm$11 Kg; MG 17.9$\pm$7.8 Kg (27$\pm$8.8%); AT 35.8$\pm$7.2 Kg; IMP 505$\pm$109, MB 1373$\pm$212 Kcal, AF 5.7$\pm$1.2. And analytical: Glucose 102.5$\pm$25.8 mg/dl, HbA1c 6.09$\pm$1.1, CT 174$\pm$51 mg/dl, TG 115$\pm$54 mg/dl, Albumin 3.8$\pm$0.5 mg/dl, prealbumin 26,2$\pm$7.5 mg/dl, vitamin D 26.6$\pm$12.2 mg/dl, magnesium 2.2$\pm$0.2 mg/dl. In the follow-up there were 4 deaths (9.5%).
Conclusions
Our patients have an acceptable nutritional status, some of them with supplementation. It would be advisable to perform an early screening for an adequate approach.

A case series of two patients with intrapericardial paragangliomas

Gaurav Puri[1], Hannah Farquhar[1], Julie Mundy[2] & Ashim Kumar Sinha[1]
[1]Cairns Hospital, Cairns, Australia; [2]Princess Alexandra Hospital, Brisbane, Australia.

Two patients have presented to a regional Australian Hospital with intrapericardial paragangliomas in the last decade. In 2011, a 28-year-old Indigenous male presented with a hypertensive crisis. He had a two-year history of symptoms during physical exertion, including abdominal pain, nausea, and vomiting. He had also experienced paroxysmal light-headedness and sweats, and had been previously diagnosed with hypertension. Urinary and serum catecholamine testing revealed markedly elevated noradrenaline. Subsequent imaging showed a synchronous functioning paraganglioma in the right atrium and retrocaval region. He had a surgical resection of both lesions, with normalisation of catecholamines post-operatively. The SDHB gene mutation was identified, however the ongoing follow-up of this patient has since been limited. The second case, a 38-year-old female, presented in 2018 with a 12-month history of paroxysmal severe headaches, flushing, tachycardia and eight kilograms of weight loss. Workup revealed significantly elevated urine and plasma fractionated metanephrines, including noradrenaline, dopamine, vanillylmandelic acid, normetanephrine, and 3 methoxytyramine. Gallium-68 DOTATE PET revealed an intensely DOTATATE avid left atrial/atrial-septum lesion consistent with paraganglioma. Further imaging included a cardiac MRI and echocardiogram. She underwent pre-operative assessment with a coronary

angiogram, which showed 3 coronary artery tributaries feeding the tumour. She was pre-operatively treated with phenoxybenzamine, followed by metoprolol. She had a surgical resection which revealed a highly vascular 70 mm tumour in the inter-atrial groove. Histopathology was consistent with paraganglioma and her genetic studies showed SDHC mutation.

Combined autophagy and mTOR inhibition reduces cells proliferation and induces apoptosis in a lung carcinoid in-vitro model

Adi Knigin, Shani Avniel-Polak, David J Gross & Simona Grozinsky-Glasberg
Hadassah-Hebrew University Medical Center, Neuroendocrine Tumor Unit, Jerusalem, Israel.

Introduction
Treatment options for patients with metastatic lung carcinoids (LC) are limited. Everolimus (RAD001), an mTOR inhibitor (mTORi) which suppresses tumor cells growth & proliferation, appears to be efficient in these patients; however, it promotes autophagy, thereby paradoxically supporting tumor cell survival and development of drug-resistance. We have previously demonstrated in a BON1 pancreatic NEN model that adding chloroquine (CQ, an autophagy inhibitor) to mTORi inhibited cell proliferation and induced apoptosis compared to mTORi alone.
Aim(s)
To investigate the effect of CQ $\pm$ mTORi on LC cell viability, proliferation and apoptosis.
Materials and methods
The LC cell line NCI-H727 was treated with CQ, RAD001 and Torin1, alone or in combination. Cell viability and proliferation were examined by XTT and Ki67 staining. Flow cytometry and Western blot were used to assess drug effects on cell cycle, apoptosis, PI3K/Akt/mTOR and autophagy pathways. The effect of differential timing of drug administration was examined by using a cytotoxicity kit.
Results
CQ alone reduced LC cell viability by $\sim$ 30%; the addition of CQ to RAD001 or Torin1 significantly reduced cell viability by 60% and 98%, respectively. Torin1 or RAD001 combined with CQ induced a higher degree of apoptosis and accumulation of LC3-II (a marker of autophagy). Our results imply that the inhibition of cell proliferation may result from CQ effects on cytosol and lysosomes nutrient content causing an indirect inhibition of mTOR.
Conclusion
In the present LC model, CQ alone and mainly in addition to a mTORi, promotes apoptosis and suppresses cell proliferation, potentiating the effect of mTORi. Further experiments are needed to understand the role of CQ in the treatment arsenal of patients with metastatic LC.

Pheochromocytoma – 3 sides of the same story

Cristina Ene[1], Angelica Nour-Dinca[1], Eliza Acatrinei[1], Marioara Casian[1], Mihaly Enyedi[1], Dana Terzea[2], Adrian Istrate[3] & Constantin Grozavu[3]
[1]'Dr Victor Babes' Foundation, Bucharest, Romania; [2]Oncoteam, Bucharest, Romania; [3]Central Military Hospital, Bucharest, Romania.

Background
Pheochromocytomas are rare tumors, with prevalence less than 0.2% of hypertensive patients, in general population being unknown. With increasing access to imaging and hormonal workup, more pheochromocytomas are diagnosed. This may have changed the occurrence of the classic presentation with hypertension and the classic triad.
Methods
We present 3 cases of pheochromocytoma diagnosed in our departments over the last 2 years, with 3 different phenotypes: the classic form, a resistant form of secondary hypertension and a normotensive patient.
Case reports
Case 1- classic triad: A 62 years old man was referred with classic symptoms: headache, palpitations, diaphoresis, severe hypertension, with paroxysmal rises. Hormonal workup confirmed the diagnosis: elevated metanephrines and normetanephrines level, dyslipidemia, hyperglycemia. The imagistic evaluation revealed right adrenal tumor. The histopathological and immunohistochemical exam suggested a malignant pheochromocytoma. After suprarenalectomy, we obtain a proper control of the arterial tension, with no paroxysm, normal hormonal profile. *Case 2- resistant secondary hypertension:* The second case is a 30 years old man, that complained of resistant hypertension, without a specific pattern and no other signs. He had a significant family history of cardio-vascular diseases, both his parents died in their 30's. Hormonal profile shown pheochromocytoma: elevated normetaphrines level with normal metanephrines, normal aldosteron/renin ratio, normal Dexamethasone suppression of Cortisol; normal calcemia and PTH level. Imagistic evaluation identified right adrenal tumor. The patient was treated with doxazosin and perindopril/indapamid/amlodipin association. Despite high normal calcitonin level, he refused all other investigation, therefore no data about a genetic disorder is available. *Case 3- normotensive:* A 57 years old woman, with history of thyroidectomy for benign nodular goiter, was evaluated for an inferior deep cervical mass; she presented mild tachycardia, anxiety and insomnia. Hormonal workup: normal metanephrines level and elevated plasma and urinary normetanephrines level, high cromogranine A and serotonine level; normal Calcitonin and PTH level, without any other sign of a genetic disorder. CT/MRI scans describes 3 masses: an inferior deep cervical tumor, a paravertebral thoracic lesion and left adrenal mass. After treatment with doxazosin well tolerated, the surgical cure with histopathological and immunohistochemical exam revealed a benign neck schwannoma and adrenal pheochromocytoma; the patient is still in investigation for genetic disorders, given association of schwannoma with pheochromocytoma.
Conclusion
Though hypertension is common, hypo to normotensive presentation is possible. The spectrum of the presentation of pheochromocytoma continues to expand. In some cases, genetic disorders should be considered.

Analysis of the 22-years experience of surgical treatment of adrenal tumor in single specialized endocrinological center

Sergii Tarasenko, Olersander Tovkay, Mikhailo Kunatovskiy & Olena Yefimova
Ukrainian Scientific and Practical Center of Endocrine Surgery, Transplantation of Endocrine Organs and Tissues of MoH of Ukraine, Kyiv, Ukraine.

Objectives
To analyze the data of the 22-year-old clinical experience surgical treatment of the adrenal tumor patients in the single specialized endocrinological center.
Materials and methods
There were analyzed the diseases stories of the perioperative period in 1256 patients with adrenal gland tumors who underwent adrenalectomy for the period 1995–2017 in specialized endocrinological center. Average data are given in the format $M \pm \sigma$.
Results
Having analyzed the surgical access, we have been noted that 255 (20.3%) out of total 1256 were performed with open, laparotomic or lumbol-aparotomic access (LTA) operations and 1001 (79.7%) operations were performed using the laparoscopic access (LSA). Among of the total 256 pheochromocytoma patients 81 (31.8%) surgical interventions were performed by using LTA and rest 174 (68.2%) of the operations were performed using the LSA. In terms of gender, men were 334 (26.6%), women – 922 (73.4%), and among patients with the adrenal gland pheochromocytoma – 80 (31.4%) men, 175 (68.6%) women. The average age of the adult patients operated on adrenal glands were 47.7 ± 14.6 years. The average blood loss with LTA was 357.5 ± 192.7 ml, with LSA - 42.2 ± 31.6 ml (significant difference ($P = 0.012$) according to the Wilcoxon test). Total intravenous anesthesia was applied in 93.3% patients with LTA, and in 73.0% of the LSA patients. The inhalative sevoflurane anesthesia was used in 6.7% of LTA patients and in 27.0% of LSA cases (significant difference ($P = 0.024$) according to the Pearson's chi-square test). The intervention duration was 130.3 ± 46.9 min. and 63.1 ± 19.2 min. with LTA and LSA respectively (significant difference, $P = 0.013$). The duration of inpatient stay in the LSA patients was 7.3 ± 4.9 days, in the LTA patients was 12.3 ± 6.9 days (significant difference, $P = 0.028$). The using of narcotic analgesics in the LTA patients were on average 4.2 ± 2.7 days, in the LSA patients was 1.2 ± 0.9 days (significant difference, $P = 0.012$). The average dose of morphine was 94.5 ± 41.3 mg for LTA interventions, and 24.5 ± 11.3 mg for LSA (significant difference, $P = 0.021$).
Conclusion
Thus, the introduction of laparoscopic methods of surgical intervention for adrenal tumors contributes to a more rapid recovery of patients, a reduction in the hospital stay, accompanied by less blood loss, less expressive pain syndrome.

Immunohistochemical characteristics of adrenal tumors in patients with primary aldosteronism

Natalia Romanova, Lilya Selivanova, Nadezhda Platonova, Ekaterina Troshina & Aleksandr Abrosimov
The National Medical Research Center for Endocrinology, Moscow, Russian Federation.

Introduction
CYP11B2 is a key enzyme of primary aldosteronism, and several factors are involved in the regulation of CYP11B2 expression and the overproduction of aldosterone. Somatic mutations in aldosterone-driver genes are strongly associated with CYP11B2 expression and have been only detected in the CYP11B2-positive tumor area, indicating that aldosterone producing adenoma (APA) intratumoral heterogeneity corresponds to non-uniform CYP11B2 expression in neoplastic cells. In addition, CYP11B2 can contribute to the clinical diagnosis of primary aldosteronism. CYP11B2 has the potential to synthesize hybrid steroids, which is a unique and characteristic behavior of APA that is distinctive from bilateral hyperaldosteronism (BHA). However, the pathophysiology of primary aldosteronism in both APA and non-neoplastic subtypes remains controversial.
Objective
To assess the functional heterogeneity of adrenal tumors in primary aldosteronism
Material and methods
Retrospective evaluation adrenal tumors from patients with primary aldosteronism ($n=20$). According to CT unilateral macrohyperplasia was detected in 19 patients (95% of total), all of them were confirmed to have unilateral hyperproduction of aldosterone according to AVS. Selected tumors were stained with anty-CYP11B2 antibody.We evaluated the CYP11B2 expression in the adenoma and in the adjacent adrenal cortex.
Results
Immunohistochemistry studies of the resected adrenals from 20 patients with PA operated due to unilateral production of aldosterone using CYP11B2 staining showed that 10 of those with an adenoma on CT scanning showed CYP11B2 staining in the adenoma. Furthermore, 5 cases of an unilateral adenoma, showed CYP11B2 staining in the adjacent adrenal cortex and an absence of staining for CYP11B2 in the adenoma. 5 cases showed CYP11B2 expression is heterogeneously immunolocalized throughout the tumor area.
Conclusions
Thus, the functional heterogeneity of adrenal tumors in primary aldosteronism has been proven. It is necessary to compare the data of immunohistochemical studies on the expression of CYP11B2 with the indicators of the level of 18-hydroxycortisol, 18-oxocortisol.

Cortex protecting surgery in MEN 2A

Hatice Sebile Dokmetas[1], Fatih Kilicli[1], Yasar Ozdenkaya[2], Gunes Cavusuglu[3], Meric Dokmetas[3], Bugra Erol[3] & Kubra Karaipek[3]
[1]İstanbul Medipol University, Department of Endocrinology, İstanbul, Turkey; [2]İstanbul Medipol University, Department of General Surgery, İstanbul, Turkey; [3]İstanbul Medipol University, Department of Internal Medicine, İstanbul, Turkey.

Cortex protecting surgery for bilateral pheochromocytoma protects the patient from adrenal insufficiency. Risk of relapse is low. 35 years old woman had paroxysmal seizures and hypertension crises for the last year which became more frequent in the last 10 days. She had thyroidectomy and under the use of levothyroxine the patient. Because of a nodule on ultrasonography and paternal history of MEN 2A which led to a check of calcitonin level that resulted 8 times higher than the upper limit, at the age of 23 she had had a thyroid surgery. Patology: 0.4 and 0.9 mm medullary thyroid carcinoma. Her father had a surgery for MEN 2A years ago. Abdominal MRI: Right adrenal gland had a mass of pheochromocytoma at the size of 42×41 mm, and the left one had a mass at the size of 331×32 mm. Urine metanephrin: 3093 (N: $<$298 ug/24 hours), normetanephrin: 6837 (N: $<$354 ug/ml), PTH:244 (N:15–65 pg/ml), Neck ultrasonography showed no enlarged parathyroid gland. RET protooncogen: Exon 11 and Codon 634 mutation. Surgery was scheduled for bilateral cortex protecting adrenalectomy and 3.5 parathyroidectomy. Pathology report: Parathyroid hyperplasia and pheochromocytoma. Postopetative follow up revealed normal calcium levels, cortisol: 11 mcg/dl, no hypertension. Because of the normal serum cortisol levels without any replacement, we recommend cortex protecting adrenalectomy for patients with bilateral pheochromocytoma on the condition of an experienced surgeon.

Unilateral non-haemorrhagic adrenal infarction (NHAI) as a cause of abdominal pain during pregnancy

Fanny Chasseloup, Nathalie Bourcigaux & Sophie Christin-Maitre
Department of Endocrinology, University Hospital Saint-Antoine, Paris, France.

Adrenal infarction is usually associated with bilateral adrenal hemorrhage in the setting of antiphospholipid syndrome or hemodynamic variation. A few cases of unilateral non-hemorrhagic adrenal infarction (NHAI) have been described in the literature. Here, we report a case of unilateral non-haemorrhagic adrenal infarction occurring during pregnancy and a literature review of this clinical entity. A 30-year-old woman presented at 32 weeks of gestation with sudden-onset right abdominal pain and contractions. Unilateral adrenal infarction was diagnosed following computed tomography (CT). It showed an enlarged right adrenal, without uptake after injection. Contractions persisted despite medical care and she delivered a healthy girl, weighting around 2500 g. Abdominal pain decreased right after delivery. No treatment was administered as the patient was healthy. At 3 month, CT scan imaging showed an atrophy of the right adrenal and a normal left adrenal. The patient's adrenal hormonal function was normal. Accurate diagnosis of NHAI may be difficult as its clinical presentation is not specific. It can only be performed with adrenal imaging. Magnetic resonance imaging (MRI) shows diffuse enlargement of one or both adrenals as well as increased signal intensity on T2-weighted images. Anticoagulation therapy may be discussed. Patients should be evaluated between 3 and 6 months after the event to assess adrenal's size and function. In summary, NHAI during pregnancy is probably underdiagnosed and obstetricians should be aware of this diagnosis.

Evaluating the applicability of urinary miR-483-5p as a non-invasive marker in adrenocortical cancer patients

Abel Decmann[1], Irina Bancos[2], Melinda A Thomas[2], Péter Turai[1], Pál Perge[1], Miklós Tóth[1], Attila Patócs[3] & Peter Igaz[1,4]
[1]2nd Department of Internal Medicine, Faculty of Medicine, Semmelweis University, Budapest, Hungary; [2]Division of Endocrinology, Diabetes, Metabolism and Nutrition, Department of Internal Medicine, Mayo Clinic, Rochester, USA; [3]Hereditary Endocrine Tumors Research Group, Hungarian Academy of Sciences and Semmelweis University, Budapest, Hungary; [4]MTA-SE Molecular Medicine Research Group, Hungarian Academy of Sciences and Semmelweis University, Budapest, Hungary.

Introduction
Minimally invasive blood-borne circulating microRNAs might be used for the preoperative differentiation of adrenocortical carcinoma (ACC) and adrenocortical adenoma (ACA). Circulating *hsa-miR-483-5p* is so far the best microRNA biomarker of ACC. To the best of our knowledge, there have been no studies concerning the potential applicability of urinary *has-miR-483-5p* as a non-invasive biomarker of ACC and its correlation with plasma *hsa-miR-483-5p.*
Aim
Our aim was to investigate the expression of urinary *hsa-miR-483-5p* and its correlation with its plasma counterpart.
Methods
Plasma and urinary samples from 23 ACC and 23 ACA patients were analysed using real-time RT-qPCR. To evaluate the diagnostic applicability of *hsa-miR-483-5p*, ROC-analysis was performed.
Results
Significant overexpression of *hsa-miR-483-5p* was observed in carcinoma patients' plasma samples compared to adenoma patients' ($P<0.0001$, sensitivity: 87%, specificity: 78.3%). In urinary samples, however, no significant difference could be detected between ACC and ACA patients.
Conclusions
Plasma *hsa-miR-483-5p* has been confirmed as significantly overexpressed in adrenocortical cancer patients and thus might be exploited as a minimally

invasive preoperative marker of malignancy. The applicability of urinary *hsa-miR-483-5p* for the diagnosis of adrenocortical malignancy could not be confirmed.

Allgrove syndrome (Triple A syndrome): A case report

Heba Moustafa, Amira M El Gohary, Kareem Essam, Yasmine Abd El Fatah & Randa F Salam
Cairo University, Cairo, Egypt.

Introduction
Allgrove syndrome is a rare autosomal recessive disorder characterized by a Lacrima, achalasia, adrenal Insufficiency and Neurologic disorders. Mutation in (AAAS) gene on chromosome 12q13, has been implicated.
Case report
Eighteen-year-old male referred to the Endocrinology clinic for evaluation of suspected adrenal insufficiency. The patient reported generalized weakness, fatigue, anorexia recurrent fainting attacks, and progressive hyperpigmentation of the skin for 6 months. Regarding his past history. His mother noticed absence of tears since early childhood for which he was diagnosed as alacrimia and given tear substitutes. At the age of 12 he presented with progressive dysphagia more for liquids than solids. Clinical findings included; Weight: 38.5 kg, height: 163 cm, BMI: 14.5 kg/M^2. Pluse: 80/min, blood pressure was 80/60 with no postural variation. Dark pigmentation generalized more in back, side of chest and face. Neurological examination revealed wasting of thenar and hypothenar muscles, bilateral partial claw hand, he has generalized wasting but normal tone, power and reflexes, with preserved superficial and deep sensation, nasal twang of voice. pubic hair Tanner stage 4, peins (8 cm), and testis (5×3×2 cm). Baseline investigations revealed normal complete blood counts, serum creatinine and normal electrolytes (serum Na,137 mmol/L; serum K, 4.14 mmol/L). TSH: 3.7 μIU/ml (normal: 0. 33–5.5), free T4; 1.2 ng/dl (0.8–1.9), Free T3: 2.3 pg/ml. Basal serum cortisol (8:00 AM) was very low (0.5 μg/dL) normal range (10–20 μg/dL). Plasma ACTH levels were markedly elevated (1,250 pg/mL; normal range, 9 to 52 pg/mL). CT abdomen and pelvis were normal with no definite adrenal mass. Diagnosis of primary adrenal insufficiency was established. Barium swallow showed dilated thoracic oesophagus above the lower oesophageal. sphincter and bird beak appearance. Esophageal manometry showed; lower esophageal resting pressure was 27 mmHg,incomplete relaxation with swallows of 56% (N: 85–100%). The average amplitude of the distal esophageal body was low of 16 mmHg (N: 40–120 mmHg) confirming the diagnosis of achalasia cardia. Nerve conduction tests revealed radiculoneuropathy. On the basis of primary adrenal insufficiency (with normal mineralocorticoid balance), alacrimia, achalasia cardia, and peripheral neuropathy a diagnosis of Allgrove syndrome was established.
Conclusion
Allgrove syndrome is a multisystem disease and the cardinal manifestations may appear at any time from infancy to adulthood. Patients are likely prone to complications like Addisonian crisis, recurrent aspiration and failure to thrive.

A case series of metastatic pheochromocytomas and paragangliomas: patients characteristics, therapeutic approach and follow-up

Anna Angelousi[1], Eva Kassi[1], Melpomeni Peppa[1], Alexandra Chrysoulidou[2], George Zografos[3], Chrysanthi Aggeli[4] & Grigorios Kaltsas[5]
[1]National and Kapodistrian University of Athens, Athens, Greece; [2]Theageneio Hospital, Thessaloniki, Greece; [3]Gennimatas Hospital, Athens, Greece; [4]Gennimata hospital, Athens, Greece; [5]National and Kapodistrian University of Athens, Athens, Greece.

Background
Metastatic pheochromocytomas (PCs) and paragangliomas (PGLs) are rare neuroendocrine neoplasms with a $<1{:}10^6$ incidence, defined by the presence of metastatic disease besides recurrent or locally invasive disease.
Aim
Retrospective analysis of clinical, biochemical/hormonal, imaging, genetic and histopathological features of patients with malignant PCs/PGLs diagnosed over 15 years.
Results
Thirteen patients (aged 49.5 ± 15.5 years old) with either metastatic PCs ($n=6$) or PGLs ($n=6$) were collected; one had both PCs and PGLs. The mean follow-up period was 6.38 years (range: 1–14 years). Almost half of the patients presented with synchronous metastases mostly in lymph nodes (cervical and abdominal); the remaining developed metastases after a mean follow-up of 4 years (range 2–10 years). Seventy per cent of the patients had functional neoplasms; 6 (46%) had concomitant normetanephrine and metanephrine secretion, one only dopamine and 2 only normetanephrine secretion. Out of 6 patients tested genetically, one had SDHB mutation and another SDHD. The mean Ki-67% proliferative index of the primary and metastatic sites were 11 ± 3.8% and 44 ± 7% respectively. Eight patients (62%) underwent surgical resection of the primary tumour or multiple surgical interventions. Two developed stable disease (SD) without further treatment whereas the remaining progressed (PD) and received additional therapeutic modalities. Four patients had treatment with radiopeptides (PRRTs) (2 with 17Lu-DOTATE and 2 with 131I-MIBG) either as monotherapy or after surgery; two exhibited SD. Four patients received chemotherapy, either as monotherapy or after surgery but all developed PD. Two patients had localised radiotherapy, the first as monotherapy and the second after chemotherapy and they both progressed. Two patients (15%), deceased during the follow-up period: the first one year after the detection of metastases and the second 8 months after initial diagnosis.
Conclusions
Metastatic PGLs and PCs are rare tumours that can achieve prolonged survival. In our small series, it seems that PRRTs could be a promising treatment for advanced and/or non operable PCs/PGLs. However, allthese patients require multiple therapeutic modalities either local or systemic best dealt in a multidisciplinary setting.

Retroperitoneal paraganglioma: clinical case

Natalya Volkova, Ilya Davidenko, Alexander Zibarev, Alexey Harlamov, Anastasia Shevchenko & Alexandra Raksha
Rostov State Medical University, Rostov-on-Don, Russian Federation.

Background
Paraganglioma is a rare neuroendocrine tumor from extra-adrenal chromaffin cells of the sympathetic paravertebral ganglia of thorax, abdomen, and pelvis. About 15–20% of chromaffin-cell tumors are paragangliomas. In most cases paragangliomas produce catecholamines in large concentrations and the lack of treatment can lead to cardiovascular and cerebral catastrophes. That is why early diagnosis of this tumor is so important and, consequently, knowledge of its diagnostic criterion, too.
Clinical case
A 59-year-old man was presented to a cardiologist for rapid increasing of blood pressure (BP) (>220/120 mmHg), which was accompanied by severe headache and epigastric pain in September 2017. From anamnesis it is known: the disease began suddenly and had paroxysmal flow. The first attack lasted for about 3 minutes and finished itself. Then such attacks occured with different frequency (from 1 per month to several times per week) and were connected with physical activity. The cardiologist suspected diagnosis of pheochromocytoma. The result of urinary fractionated metanephrines measurement showed its levels higher than normal rage but did not confirm suspected diagnosis reliably. Then patient referred to a surgeon in May 2018. On the basis of patient's complaints on epigastric pain during the attacks and the neck inflection of the gallbladder revealed by ultrasonography, it was decided to carry out cholecystectomy. A week after the operation the patient referred to the endocrinologist because of the continuing attacks. The diagnosis of pheochromocytoma was suspected again, the urinary fractionated metanephrines measurement was repeated, which revealed elevated normetanephrine level of 1008 μg/day (normal rage:<700 μg/day). A CT of retroperitoneal space revealed a spherical mass sized about 17×16×18 mm in paraaortal region under left renal vein. The retroperitoneal tumor was removed laparoscopically in August 2018. Pathological examination of the removed mass showed a paraganglioma with uncertain potential of biological behaviour. BP was normal and remained within range without the need of any antihypertensive medication until discharge from hospital. The patient is asymptomatic and normotensive during his follow-up visits.
Conclusion
This clinical case shows how a tumor with bright and specific symptoms can be revealed only in several years and after referring to several specialists. Also, this case highlights the importance of knowledge of diagnostic process of different diseases. In the present case the paraganglioma would have been revealed earlier if only the CT of retroperitoneal space had been done just after getting the results of free metanephrines, which were higher than normal.

The frequency of confirmed primary hyperaldosteronism in patients with high aldosteron renin ratio

Didem Ozdemir, Oya Topaloglu, Leyla Aydogan, Reyhan Ersoy & Bekir Cakir
Ankara Yildirim Beyazit University, Ataturk Education and Research Hospital, Department of Endocrinology and Metabolism Diseases, Ankara, Turkey.

Introduction
The aldosterone-to-renin ratio (A/R) is the most frequently used screening test for primary hyperaldosteronism (PH) and a confirmation test is recommended when it is high. We aimed to determine the frequency of PH in patients with high A/R and investigated possible clinical features that might help to prevent unnecesary confirmation tests.
Method
Patients who underwent saline infusion test because of high A/R (>3.8) were retrospectively reviewed. PH was diagnosed in patients with plasma aldosteron >10 ng/dl after 4 hours of saline infusion. Patients with postinfusion aldosteron level between 5–10 ng/dl and with <5 ng/dl were defined as indeterminate and not to have PH, respectively. Patients with and without PH were compared.
Results
There were 38 patients (27 female and 11 male) with a mean age of 55.18 ± 10.13. Mean serum potassium (K) was 4.01 ± 0.69 mmol/l and aldosteron was 30.24 ± 14.61 ng/dl. Median renin and A/R were 2.015 ng/l and 12.913, respectively. After saline infusion test, the diagnosis of PH was confirmed in 17 (43.6%) and excluded in 11 (28.2%) patients. Indeterminate results were obtained in 10 (25.6%) patients. There were 9 female and 8 male patients with PH, while all 11 patients without PH were female ($P=0.007$). 16 (94.1%) patients with PH and 7 (63.6%) without PH were hypertensive ($P=0.040$). The age, presentation, adrenal imaging findings, sodium and renin were similar in patients with and without PH. Mean serum K were 3.57 ± 0.65 mmol/l and 4.31 ± 051 mmol/l in patients with and without PH, respectively ($P=0.003$). Mean aldosteron and median A/R were higher in patients with PH, however the differences were not statistically significant [For aldosteron; 36.67 ± 15.38 ng/dl vs 25.14 ± 13.02 ng/dl, $P=0.050$, for A/R 16.27 (4.90–264.50) and 7.36 (3.97–53.84), $P=0.051$]. Median aldosteron after saline infusion was 19.40 ng/dl (10.26–64.35) in patients with PH and 3.70 ng/dl (1.50–4.83) in patients without PH ($P<0.001$).
Conclusion
Confirmation of PH in less than half of patients with high A/R is suggestive for high false positivity of this screening method. It may be rational to repeat measurements before confirmation tests in women, patients without HT and without hypokalemia. However, male sex, presence of HT and hypokalemia seem to be stronger clinical findings that requires confirmation tests in patients with high A/R.

Evaluation of angiotensin II in primary aldosteronism and other forms of hypertension – a preliminary study

Agnieszka Łebek-Szatańska[1], Piotr Glinicki[1], Maria Walczak[2], Karolina M Nowak[1], Monika Rdzanek[1], Wojciech Zgliczyński[1] & Lucyna Papierska[1]
[1]Department of Endocrinology, Centre of Postgraduate Medical Education, Warszawa, Poland; [2]Jagiellonian University Medical College, Faculty of Pharmacy, Chair and Department of Toxicology, Cracov, Poland.

Background
The renin-angiotensin-aldosterone system (RAS) constitutes a key hormonal system in the physiological and pathological regulation of blood pressure. In effort to understand complex and multifunctional aspects of this system, current biochemical approaches target to characterize and define its various components with angiotensin II being in the mainstream.
Objective
The aim of this study was to evaluate concentrations of angiotensin II in hypertensive patients undergoing laboratory screening for primary aldosteronism.
Methodology
Plasma aldosterone, angiotensin II and direct renin concentrations from 49 patients (including 11 with primary hyperaldosteronism, 22%) were analyzed. Patients were taking most of their antihypertensive drugs, excluding mineralocorticoid receptor blockers. Angiotensin II was measured by two distinct, thus available in our conditions, methods: immunoassay (ELISA without previous chromatographic separation) and LC-MS/MS.
Results
Median ELISA Angiotensin II concentrations in primary aldosteronism patients were lower than in the control group: 689 pg/ml (IQR: 444.49–897.3) vs 873.18 pg/ml (IQR: 689.99–1267.63). However, the difference was not statistically significant. Surprisingly, if measured by LC-MS/MS, Angiotensin II showed the opposite trend. Median LC-MS/MS Ang II was 475.34 pg/ml (IQR: 253.77–520.79) in primary aldosteronism patients compared to median 123.66 pg/ml (IQR: 72.15–251.87) in the control group ($P=0.0248$). If calculated as ratios with aldosterone, only ELISA angiotensin II concentrations showed statistical significance. Areas under the receiver operation characteristic curve (AUROC) for aldosterone-to-angiotensin II ratio (AA2R) and aldosterone-to-renin ratio (ARR) were 0.79 and 0.92 accordingly, despite ongoing antihypertensive therapy.
Conclusions
The accurate assessment of angiotensin peptides is the next step to ascertain the status of the RAS, particularly in pathological conditions or under the influence of interfering therapeutic agents. However, such evaluation is hampered by many factors. They contribute to the marked variability in angiotensin values evident in the literature and raise concerns on the identity of angiotensin II detected in the circulation. Therefore, the question if the extent to that altered peptide content truly reflects or contributes to a particular phenotype, still requires more studies and, most of all, ubiquitous technical progress.

Background and objective
Mitotane is widely used as post-operative adjuvant treatment of adrenocortical carcinoma. However, the management of therapy is largely empirical. Mitotane monitoring is recommended but we do not know what impact target concentrations do have on patient outcome. The aim of the study is to evaluate its use in expert Italian centers, analyzing data of Lysosafe Online® database.
Methods
Retrospective analysis of patients reported on the Lysosafe Online® database, treated with mitotane for ≥ 6 months and with >3 measurements of plasma mitotane levels during follow-up. Data are expressed as median and interquartile range.
Results
We identified 110 patients (F/M = 67/43, aged 47, 35–58 years), treated with adjuvant mitotane for 47 (28–62) months with a maintainment dose of 2.0 (1.5–2.5) g/day. Adjuvant treatment was initiated after 1 (1–2) months from first surgery in 92.7% and discontinued permanently in 53.6% of cases, of which 61.0% for end of treatment and 8.5% for toxicity. Achievement of target mitotane levels required 8 (5–19) months. At multivariate analysis, Ki67 index (HR 2.71, 95% CI, 1.06–6.90; $P=0.048$) and time to the first target level (HR 1.35, 95% CI, 1.02–1.80; $P=0.046$) were predictive factors of recurrence. In a separate model considering only the first 3 years of treatment, peak mitotane concentration was associated with lower risk of recurrence (HR 0.56, 95% CI, 0.38–0.85; $P=0.006$).

Conclusions
In Italy, a low-dose regimen of adjuvant mitotane therapy is used that has the likely advantage of being rather well tolerated for long time with the drawback of a slow rise of mitotane levels to target. The study shows that monitoring of mitotane levels may have an impact on patient outcome.

Background and objective
Mitotane is the main option of treatment for advanced adrenocortical carcinoma (ACC). However, limited evidence is available regarding practical management of mitotane treatment and its eventual combination with chemotherapy or radiotherapy. The aim of the study is to do a survey on the use of mitotane for advanced ACC in expert Italian centers, analyzing data of the LYSOSAFE database.
Methods
Retrospective analysis of patients with advanced ACC treated with mitotane for $\geq$3 months and with at least 2 measurements of plasma mitotane levels during follow-up reported in the LYSOSAFE database. Data are expressed as median and interquartile ranges.
Results
We identified 90 patients (F/M = 61/29, age 50, 36–59 years). One group of 29 patients have been previously treated with adjuvant mitotane, while 61 patients started *de novo* palliative mitotane. Median duration of palliative treatment was 28 months (14–47) with a median dose of 2.5 g/day (2.0–3.0). Achievement of mitotane levels $>$14 mg/l required 7 months (3–11) from the start of therapy, considering that only 2 patients had values in range during adjuvant therapy. The palliative treatment was discontinued in 64 patients, of which 50 for death and 9 for ACC progression, without any discontinuation for toxicity. A group of 21 patients received only mitotane, while 69 patients were treated with a combination of mitotane and other treatments (22 patients underwent 1 chemotherapy treatment, 21 patients 2 chemotherapy treatments and 26 patients $>$3 radiotherapy and/or chemotherapy treatments). The most common drug used in combination with mitotane was cisplatin (61/69 patients). Twenty-one patients had no mitotane level $>$14 mg/l, while the remaining 69 had mitotane in range in 35% (25–50%) of the measurements, and 18 patients had more than 50% of mitotane levels in range. At the end of the follow-up (39, 24–65 months), 59/90 patients were dead.
Conclusions
In Italy, mitotane therapy of advanced ACC is usually done in combination with chemotherapy. However, toxicity of the treatment remains acceptable, and most patients are able to achieve the therapeutic range, although with significant fluctuations of mitotane levels during follow-up. Mitotane is often continued as background treatment in addition to different chemotherapy regimens for quite a long period of time.

How do sex and BMI affect glucocorticoid treatment in adrenal insufficiency?

Soraya Puglisi[1], Isabella Tabaro[1], Salvatore Cannavò[2], Giorgio Borretta[3], Micaela Pellegrino[3], Francesca Chiappo[1], Anna Pia[1], Massimo Terzolo[1] & Giuseppe Reimondo[1]
[1]Internal Medicine, Department of Clinical and Biological Sciences, University of Turin, Orbassano, Italy; [2]Department of Human Pathology of Adulthood and Childhood 'G. Barresi', University of Messina, Messina, Italy; [3]Division of Endocrinology, AO S. Croce e Carle, Cuneo, Italy.

Background and objective
Optimization of glucocorticoid (GC) replacement therapy in adrenal insufficiency (AI) is crucial to avoid consequences of under- or overtreatment. Dosing of GC replacement is mainly based on clinical grounds; however, the impact of patient's characteristics on daily GC requirement is poorly evaluated. The aim of the study is to assess the influence of sex (M/F) and BMI on dosing GC in patients with AI of different etiology.
Patients and methods
We retrospectively analysed 203 patients (104 primary AI [pAI], and 99 secondary AI [sAI]) followed-up for $>$12 months over the last 2 decades treated with hydrocortisone (HC), HC modified release (HCMR) or cortisone acetate (CA). We evaluated the total daily dose (TDD) and per-Kg-daily dose (KDD) of GC either at baseline or at the last visit. We considered comorbidities (arterial hypertension, diabetes mellitus and dyslipidemia) at each time point.
Results
At baseline, we did not observe any difference in clinical characteristics and comorbidities between F and M patients with pAI (65 F, 39 M). KDD was higher in F than in M (F, 0.47 ± 0.19 vs M, 0.38 ± 0.47 mg/kg per day, $P = 0.016$). At last visit, BMI was stable in F, but KDD and TDD were significant lower than at baseline (0.47 ± 0.19 vs 0.38 ± 0.14 mg/kg per day, $P = 0.014$ and 25.77 ± 8.02 vs 23.24 ± 6.33 mg/day, $P = 0.048$, respectively). In M with pAI, BMI, KDD and TDD were not different between baseline and last visit. Therefore, KDD and TDD were not significant different between genders at last visit. In patients with sAI (53 F, 46 M) both at baseline and at last visit, KDD was not significant different between genders. Conversely, TDD at last visit was significantly lower in F than in M (F 18.40 ± 6.95 vs M 23.37 ± 8.14 mg/day, $P = 0.001$). Comorbidities were comparable between groups. At baseline, the use of hydrocortisone was preferred in pAI, while the use of CA was more frequent in sAI. At last visit, the rate of patients in HCMR was higher in pAI than in sAI. BMI was higher in sAI than in pAI, as well as TDD and KDD.
Conclusions
Our real life study demonstrates that in pAI GC replacement is likely overdosed in F when treatment is initiated. Optimization of replacement and a more extensive use of HCMR lead to a marked GC dose reduction in F patients with pAI during follow-up. In sAI patients, lower GC starting doses are used with minimal dose adjustment during follow-up.

Congenital adrenal hyperplasia due to 11-beta-hydroxylase deficiency

Hamide Piskinpasa, Sema Ciftci Dogansen, Ilkay Cakır, Yasemin Sefika Akdeniz, Ayse Esen, Evin Bozkur & Meral Mert
Department of Internal Medicine, Division of Endocrinology and Metabolism, Bakirkoy Dr Sadi Konuk Training and Research Hospital, Istanbul, Turkey.

Introduction
Congenital adrenal hyperplasia (CAH) due to 11 beta-hydroxylase deficiency (11βOHD) is a rare autosomal recessive genetic disorder. It results defects in adrenal cortisol and aldosterone synthesis. Early diagnosis and initiation of treatment in

male patients are essential in order to prevent serious complications. We report a male patient with CAH who developed complications because of late diagnosis
Case Report
44-year-old male patient who admitted to emergency department with hypokalemia. Azoospermia was identified with the complaints of infertility two years ago. At andrology depatment; the laboratory tests were consistent with hypergonadotropic hypogonadism, chromosome analysis revealed a 46XY karyotype and scrotal ultrasonography showed bilateral testicular atrophy. The patient had a history of gynecomastia operation six years ago. Medical history revealed a growth retardiation observed at the age of 11 years. He did not have ambiguous external genitalia. He had a history of bilateral orchitis when he was 13 years old. The patient was consulted in the endocrinology department for bilateral adrenal masses, hypokalemia and hypertension. In the physical examination, body height was 162 cm and weight was 80 kg. His blood pressure was 160/80 mm/Hg. The other systems were examined and found normal. Laboratory assessments showed elevated levels of adrenocorticotropic hormone (ACTH) (76.2 pg/ml), androstenedion (2.17 ng/ml) and 11-deoxycortisol (13.82 ng/ml). After correction of hypokalemia; plasma renin and aldosterone concentrations were under normal limits. After ACTH stimulation test, 17-hydroxyprogesterone (17-OHP), 11-deoxycortisol and cortisol levels were 11 ng/ml, 289 ng/ml and 17 µg/dl at 60th minute, respectively. The hypokalemic hypertension, elevated 17-OHP, 11-deoxycortisol, androstenedione and low renin, aldosterone levels were all suggestive for an 11βOHD diagnosis. Abdomen magnetic resonance imaging scan showed bilateral adrenal masses with the sizes of the masses were 14.5×7 mm on the right adrenal and 32×28 mm on the left adrenal. Bilateral adrenal masses were thought to be related with CAH. Impaired gonadal function is common in adult men with CAH. This is indicated by the presence of testicular adrenal rest tissue and/or hypogonadotropic or hypergonadotropic hypogonadism. Our patient has hypergonadotropic hypogonadism and bilateral testicular atrophy without mass. This unpredictable feature is thought to be due to the history of bilateral orchitis.
Conclusion
CAH due to 11βOHD is a rare disorder with significant challenges in diagnosis and management. Wide spectrum of clinical presentation depending on the underlying enzymatic deficiency can cause late diagnosis. Both fertility and adrenal glands can be protected with an early diagnosis and an early glucocorticoid treatment.

Pheocromocytoma, newly diagnosed during pregnancy in a subject with neurofibromatosis type 1: A case report and review of literature

Marjeta Kermaj[1], Alma Isufi[2], Adriana Misja[2], Violeta Hoxha[1], Thanas Fureraj[1], Ermira Muco[3], Mirjeta Guni[4], Klotilda Resuli[5] & Agron Ylli[1]
[1]Department of Endocrinology, UHC 'Mother Tereza', Tirana, Albania; [2]Department of Anesthesiology, Intensive Care, UH of Obstetrics and Gynecology 'Koco Glozheni', Tirana, Albania; [3]Department of Infectious Disease, UHC 'Mother Tereza', Tirana, Albania; [4]American Hospital, Tirana, Albania; [5]Regional Hospital of Vlora, Vlora, Albania.

Introduction
Pheocromocytoma, is a rare cause of hypertension diagnosed during pregnancy, with a prevalence 0.002%, due to its non-specific presentation and difficulty to distinguish its hypertension from other clinical conditions during pregnancy. Early diagnosis and appropriate treatment have a great impact on maternal and fetal mortality. Pheocromocytoma is sporadic in the majority of cases, but up to 25% may be syndrome-associated.
Case report
We report a clinical case of a woman 29 years old, with neurofibromatosis type 1, presented during the third trimester (31 weeks) of her first pregnancy with severe hypertension, at maternity hospital.
Medical history
She was diagnosed since child with neurofibromatosis type 1. Without other medical problems during her life. Negative familiar history. She referred episodes of severe hypertension till 280/160 mmHg, initiated during the second trimester (13 weeks), characterized by headache, palpitation, tachycardia, tachypnea, sweeting, pallor that lasted some minutes. The situation was normalized without treatment. Out these crises, the blood pression was normal (120/80 mmHg). At the beginning, these episodes were not frequent (1 per month), but after 31 weeks of pregnancy, they became more frequent (1 per week). It was started treatment with α/β blockers (Methyldope 250 mg 4×2 pills, aspirine 100 mg per day) but after 33 weeks they became very frequent, 1 episode per day at different time of the day, without any specific trigger. It was suspected for pheocromocytoma. Catecholamines and metanephrines were measured in 24-hour urine that resulted high: 566 µg/24h (N<565) and 600 µg/24h (N 30–180 for >17-year-old) respectively. Magnetic resonance of abdomen resulted with a solid regular mass in left adrenal gland with dimensions 58×40 mm. It was started doxazosine 2 mg/day, and atenolol 100 mg 2×1/2. After that, she was stabilized. At 38 weeks, she underwent section cesarean under a multidisciplinary team assistance and everything went well. Four months after delivery, she continues to be stabilized under treatment with doxazosine and atenolol, waiting for surgery (left adrenalectomy) in a second time, hoping a definitive resolution of pheocromocytoma.
Conclusion
Given the low frequency of hypertension due to pheocromocytoma diagnosed during pregnancy, and the important role of early diagnosis and adequate treatment, on maternal and fetal mortality, physicians should beware of possible pheocromocytoma (especially in a subject with neurofibromatosis type 1) as cause of hypertension during pregnancy. A multidisciplinary team assistance is important to provide the better pregnancy outcomes.

Becoming of patients with primary aldosteronism according to their treatment

Ines Belmihoub, Erika Cornu, Camille Nevoret, Anne-Sophie Jannot, Michel Azizi & Laurence Amar
Hôpital Européen Georges Pompidou, Paris, France.

Introduction
Unilateral forms or primary aldosteronism (PA) can be treated by adrenalectomy of by mineralocorticoid receptor antagonists, whereas bilateral forms are always treated by mineralocorticoid receptor antagonists. Most studies find similar results for the control of blood pressure and kalemia, but also to reverse organ damages, however recent studies are discordant and show a benefit of adrenalectomy regarding cardiovascular events and blood pressure (BP). Regarding these discrepancies, we wanted to evaluate the outcomes of PA treatments in clinical practice.
Methods
148 patients diagnosed for PA in our center with the realization of an adrenal venous sampling between January 2009 and December 2012 and evaluated after five years were included. Patients with no active follow-up in our center were contacted for a medical consultation or a telephonic standardized interview.
Results
Surgical and medical treatments provided similarly BP (OR=0,308 [0,277–1,335]) and kalemia control, for 70% of followed patients. Hypokalemia was persistent in 15.9% of patients in the medically treated group versus none among the patients who underwent surgery. We observed 7% of cardiovascular events without differences according to the treatment ($P=0.246$). Renal function was slightly better after surgery. Surgical treatment allowed 39% of cure rate and a significant decrease of the daily defined dose (DDD) of 2.5.
Conclusion
80 months after the diagnosis, medical and surgical treatment of PA are similar for the control of blood pressure. No difference in the occurrence of cardiovascular events appears according to the treatment. The benefice of surgery is especially represented by the reduction of antihypertensive drugs, the cure of hypokalemia and the cure rate of 39%.

Predictors of bilateral and unilateral primary aldosteronism: a retrospective observational study

Takuya Ishikawa[1], Hirotsugu Suwanai[1], Hironori Abe[1], Keitaro Ishii[1], Hajime Iwasaki[1], Fumiyoshi Yakou[1], Mariko Ito[1], Jumpei Shikuma[1], Ryo Suzuki[1], Kazuo Hara[2], Takashi Miwa[1], Tomoko Takamiya[3], Shigeru Inoue[3], Kazuhiro Saito[4] & Masato Odawara[1]
[1]Tokyo Medical University, Department of Diabetes, Metabolism and Endocrinology, Tokyo, Japan; [2]Jichi Medical University Saitama Medical Center, Department of Medicine, Division of Endocrinology and Metabolism, Saitama, Japan; [3]Tokyo Medical University, Department of Preventive Medicine and Public Health, Tokyo, Japan; [4]Tokyo Medical University, Department of Radiology, Tokyo, Japan.

Primary aldosteronism is a frequent cause of secondary hypertension, with early diagnosis being important for appropriate treatment and minimizing the risk of

organ damage due to excessive aldosterone. Treatment, however, varies for unilateral and bilateral primary aldosteronism, with oral aldosterone antagonist being the treatment of choice for the bilateral form and adrenalectomy, for the unilateral form. As surgical treatment for unilateral primary aldosteronism is effective, early and accurate differentiation of the unilateral and bilateral forms is important. However, there has not been established an alternative diagnostic method except adrenal vein sampling to distinguish them. In this study, we undertook a retrospective comparison of the clinical and serum markers between patients with bilateral and unilateral primary aldosteronism, diagnosed by adrenal vein sampling, to identify factors strongly associated with the unilateral form. We also evaluated the outcomes of surgical treatment in unilateral cases to confirm the usefulness of adrenalectomy. The prospective study group was formed of patients with suspected PA, based on findings of juvenile hypertension, hypokalemia and resistance to antihypertensive treatment. Of these, 249 completed the Captopril challenge, saline infusion and the furosemide upright tests for PA diagnosis, with a positive diagnosis in 239 patients. 96 out of 239 patients underwent adrenal vein sampling for localization of primary aldosteronism diagnosis at our hospital between 2010 and 2018. On univariate analyses, systolic blood pressure, plasma aldosterone concentration, and the aldosterone-to-renin ratio were significantly higher in the unilateral than in the bilateral group, whereas the serum potassium level was lower. On multivariate analysis, Captopril challenge test results and serum potassium level were retained as independent predictors of unilateral primary aldosteronism. Adrenalectomy was effective in lowering systolic blood pressure, plasma aldosterone concentration, and serum potassium levels, as well as decreasing the number of therapeutic drugs used. Therefore, unilateral primary aldosteronism is differentiated from bilateral aldosteronism by a higher plasma aldosterone concentration and aldosterone-to-renin ratio, indicative of excessive aldosterone being secreted, with serum potassium and Captopril challenge test results being reliable diagnostic predictors as it resulted good sensitivity and specificity.

18-oxocortisol synthesis in aldosterone-producing adrenocortical adenoma and significance of KCNJ5 mutation status

Fumitoshi Satoh[1,2], Yuto Yamazaki[3], Ryo Morimoto[2], Masataka Kudo[2], Celso E Gomez-Sanchez[4], Sadayoshi Ito[2], Hironobu Sasano[3] & Fumitoshi Satoh[1,2]
[1]Division of Clinical Hypertension, Endocrinology and Metabolism, Tohoku University Graduate School of Medicine, Sendai, Japan; [2]Division of Nephrology, Endocrinology and Vascular Medicine, Tohoku University Hospital, Sendai, Japan; [3]Department of Pathology, Tohoku University Hospital, Sendai, Japan; [4]Division of Endocrinology, University of Mississippi Medical Center, Jackson, USA.

Peripheral 18-oxocortisol level could contribute to the detection of aldosterone-producing adenoma in patients with primary aldosteronism. However, peripheral 18-oxocortisol varies among such patients, which is a big drawback concerning its clinical application. We studied 48 cases of aldosterone-producing adenoma, 35 harboring *KCNJ5* mutation, to clarify the significance of clinical and pathological parameters regarding peripheral 18-oxocortisol. Peripheral 18-oxocortisol concentration ranged widely from 0.50 to 183.13 ng/dL and correlated positively with intra-tumoral areas stained positively for steroidogenic enzymes ($P<0.0001$). The peripheral 18-oxocortisol level also correlated significantly with that of circulating aldosterone ($P<0.0001$) but not with that of cortisol, a precursor of 18-oxocortisol. However, a significant correlation was detected between peripheral 18-oxocortisol and intra-tumoral glucocorticoids ($P<0.05$). In addition, peripheral 18-oxocortisol correlated positively with the number of hybrid cells double positive for CYP11B1 and CYP11B2 ($P<0.0001$). Comparing between the cases with and those without *KCNJ5* mutation, the *KCNJ5*-mutated group demonstrated a significantly higher concentration of peripheral 18-oxocortisol (28.4 ± 5.6 ng/dL vs 3.0 ± 0.9 ng/dL, $P<0.0001$) and a larger intra-tumoral environment including the hybrid cells ($P<0.001$), possibly representing a deviation from normal aldosterone biosynthesis. Following multivariate analysis, *KCNJ5* mutation status turned out to be the most influential factor involved in 18-oxocortisol synthesis in aldosterone-producing adenoma ($P<0.0001$). Results of our present study firstly revealed that enhanced 18-oxocortisol synthesis in aldosterone-producing adenoma could come from a functional deviation of aldosterone biosynthesis from the normal zona glomerulosa and the utility of peripheral 18-oxocortisol measurement could be influenced by the prevalence of *KCNJ5* mutation in an aldosterone-producing adenoma.

Complete remission of a highly aggressive, metastasized, SDHB-related paraganglioma after chemotherapy with CVD and peptide-receptor radiotherapy

Gesine Meyer, Christine Koch & Jörg Bojunga
Department of Internal Medicine 1, Goethe-University Hospital, Frankfurt, Germany.

Case
A 40-year-old woman presented in 04/2015 with pain in the upper abdomen and a history of paroxysmal tachycardia. Plasma normetanephrines were highly elevated. Imaging revealed a large retroperitoneal tumor ($15\times12\times8$ cm), which could be completely resected after pre-treatment with urapidil. Histology confirmed diagnosis of a paraganglioma. Genetic diagnostics detected a previously unknown mutation in intron 2 of the SDHB-gene (c.200+5G>C). Six month after initial surgery, plasma normetanephrines increased and imaging showed a single liver metastasis, which was successfully resected. A further five month later, increasing normetanephrine levels and MR-imaging indicated pulmonary, osseous and lymphatic metastatic spread. According to the recommendation of our multidisciplinary tumor board, palliative chemotherapy with monthly administrations of cyclophosphamide, vincristine and dacarbazine (CVD) was initiated in 05/2016, complemented by two peptide-receptor radiotherapies (PRRT) with ^{177}Lu-DOTATATE in 09/2016 (6.03GBq) and 03/2017 (6.8GBq). Follow up in 11/2016 and 02/2017 revealed a significant reduction of metastases. Normetanephrine levels normalized and remained stable. Due to considerable bone marrow toxicity, both therapies had to be stopped after ten cycles of CVD in spring 2017. Quarterly staging images during follow up showed further regression of metastases, which were no longer detectable in MRI since 09/2018.
Conclusions
Malignant paragangliomas are rare and evidence for treatment of patients with metastases is very limited. Studies available show a rather moderate response to chemotherapies as well as radiotherapeutics. We report the encouraging case of a complete, ongoing remission of an initially rapid progressive malignant paraganglioma under multimodal treatment with CVD and PRRT. Considerable side effect was a, yet reversable, bone marrow toxicity.

Aldosterone measurement in the Diagnosis of primary aldosteronism – comparison between two automated immunoassays and two liquid chromatography tandem mass-spectrometry methods

Valentina Fagotto[1,2], Olaf Uhl[1], Daniel Heinrich[1], Nina Nirschl[1], Lisa Sturm[1], Jürgen Kratzsch[3], Yoon Ju Bae[3], Charlotte Fries[4], Wiebke Fenske[4,5], Martin Reincke[1] & Martin Bidlingmaier[1]
[1]Medizinische Klinik und Poliklinik IV, Klinikum der Universität München, Munich, Germany; [2]Department of Experimental and Clinical Sciences, University of Udine, Udine, Italy; [3]Institute of Laboratory Medicine, Clinical Chemistry, and Molecular Diagnostics, University of Leipzig, Leipzig, Germany; [4]Medical Department III, Endocrinology, Nephrology, Rheumatology, University Hospital of Leipzig, Leipzig, Germany; [5]Integrated Research and Treatment Centre for Adiposity Diseases, Department of Medicine, University of Leipzig, Leipzig, Germany.

Poor agreement between different analytical methods measuring aldosterone concentrations impedes applicability of uniform cut-offs in the diagnostic work-up of primary aldosteronism (PA). We compared 4 analytical methods (2 immunoassays and 2 LC-MS/MS) in plasma samples before and after saline infusion test (SIT). 80 hypertensive patients underwent the standardized diagnostic work-up within the German Conn's registry. Patients (PA $n=39$/non-PA $n=41$) were classified by a experienced endocrinologists panel based on suppression of aldosterone as measured by our routine immunoassay (LIAISON, Diasorin, LSN) to concentrations <50 pg/mL, imaging, adrenal vein sampling findings, immunohistochemistry and treatment response. Aliquots from all blood samples were used to also measure aldosterone by the IDS iSYS immunoassay (iSYS) and 2 different LC-MS/MS methods (Munich LC-MS, Agilent 1290/Sciex 6500+, utilizing a Chromsystems commercial kit, and Leipzig LC-MS, an in-house method published before). Aldosterone concentrations measured by the 3 alternative methods moderately correlated to those

obtained by LSN (Pearson's r from 0.917 to 0.959), but agreement was limited (slope vs. LSN from 0.6486 to 0.9635, intercept from −24.3 to −10.0). Correlation was best between Leipzig LC-MS and iSYS. Mean and median aldosterone concentrations of all samples ($n=160$) were significantly higher with LSN as compared to all other assays. Bland-Altman plots showed significant mean bias (−81.15% to 14.78%) with higher scatter at concentrations <100 pg/mL. Compared to the expert panel classification, LSN post SIT aldosterone was falsely high (>50 pg/mL) in 7 cases (17%), but there were no false negatives. Because all other methods reported lower absolute aldosterone concentrations, applying the same cut-off would have resulted in a high number of false negatives (iSYS 38.5%, Leipzig LC-MS 28.2%, Munich LC-MS 56.4%). Accordingly, applying the cut-off of 50 pg/mL to ROC analysis AUC was 0.967 for LSN, but lower for iSYS (0.838), Munich LC-MS (0.883) and Leipzig LC-MS (0.916). Using the expert panel classification as 'gold standard', the best cut-offs for aldosterone during SIT are 61 pg/mL (LSN), 37 pg/mL (iSYS), 34 pg/mL (Leipzig LC-MS) and 20 pg/mL (Munich LC-MS). Aldosterone concentrations measured by different analytical methods differ significantly, particularly at lower concentrations, crucial for interpretation of SIT. Discrepancies occur between different immunoassays, between immunoassays and LC-MS methods, but also between different LC-MS methods. Our data emphasize the need for method-specific aldosterone cut-offs, even when LC-MS methods are used. Compared to the cut-off of 50 pg/mL traditionally used with LSN, other methods evaluated require significantly lower cut-offs to achieve the same sensitivity in detecting PA.

Embolization of the adrenal artery to control severe adrenal hemorrhage

Lionel Medenou
Hopital Avicenne, Paris, France. Centre Hospitalier Universitaire, Cotonou, Benin.

Background
The adrenal hemorrhage is rare and potentially lethal. Its diagnosis is difficult because atypical. We report the case of a patient beautifully treated by embolization of the adrenal artery.
Case report
A 68-year-old female patient admitted for abdominal pain, with as background, a diabetes, atrial fibrillation under anticoagulation with recent relay Previscan Innohep and a right adrenal incidentaloma (for 9 years, 43 mm of centerline and density spontaneous < 10 UH, never explored). Explorations concluded unilateral active bleeding on right adrenal adenoma. Evolution was made towards a deglobulisation motivating the transfusion of two globular units and the realization of an embolization of the right adrenal artery, in less than 10 minutes (see images) to postpone surgery. Given the non-embolic nature of the atrial fibrillation, anticoagulants were arrested and 3 weeks later, the scanner objective regression of the hematoma. Hormonal exploration of adenoma was normal and the patient, waiting for its resection.
Discussion-conclusion
This case reports an unusual and efficient treatment of adrenal hemorrhage. On 24 patients with adrenal hemorrhage after adrenal catheterization, no gesture was made[1]. Another series reported surgery in 40%, but not selective embolization[2]. A few gestures of embolization have been described in the context of bleeding on the adrenal artery aneurysms[3]. An adequate technical platform and a confirmed radiologist is vital. We do not know if this gesture can improve the subsequent functional prognosis of the adrenal and would therefore be preferable to an adrenalectomy.

Vitamin D deficiency is a predictor marker of tumor aggressiveness in sporadic and MEN1-related well-differentiated, low-grade GEP-NET

Barbara Altieri[1,2], Luigi Barrea[1], Roberta Modica[1], Luisa Circelli[3], Filomena Bottiglieri[1], Federica De Cicco[1], Giovanni Savarese[3], Carolina Di Somma[1], Annamaria Colao[1], Silvia Savastano[1] & Antongiulio Faggiano[4]
[1]Department of Clinical Medicine and Surgery, Federico II University, Naples, Italy; [2]Division of Endocrinology and Diabetes, University Hospital of Wuerzburg, Wuerzburg, Germany; [3]Medical Genetics Lab, AMES–Centro Polispecialistico Strumentale Srl, Naples, Italy; [4]Department of Experimental Medicine, Sapienza University of Rome, Rome, Italy.

Background
Vitamin D has several 'noncalcemic' implications, including effects on cell signaling and differentiation. Patients with gastroenteropancreatic (GEP) neuroendocrine tumors (NET) have an increased risk of vitamin D deficiency, due to the tumor itself, systemic therapies and abdominal surgery. However, data regarding vitamin D status are limited. Aim of this study was to evaluate 25-hydroxy-vitamin-D (25(OH)D) levels in GEP-NET patients and correlated them with markers of tumor aggressiveness.
Methods
A retrospective cross-sectional study including 101 patients affected by well-differentiated, low-grade (G)1 and G2 GEP-NET (65 sporadic and 36 with multiple endocrine neoplasia type 1 (MEN1)) and 123 healthy controls, belonging from the same geographic area and matched for age, gender and BMI, was performed. Concentration of 25(OH)D, calcium, albumin, phosphorus and PTH were measured at baseline. Regarding MEN1 patients, only those with normocalcemic primary hyperparathyroidism were included. In GEP-NET, the association of 25(OH)D with tumor grading, stage, progression-free survival (PFS) and disease-specific survival (DSS) were analyzed.
Results
No difference in 25(OH)D levels was observed between patients with sporadic and MEN1-related tumors ($P=0.29$). Considering those patients as one group, concentration of 25(OH)D was significantly lower compared to controls (mean levels 18.3±8.5 *vs* 24.2±7.7 ng/mL, $P<0.001$). Particularly, 58.4% of GEP-NET *vs* 29.2% controls had vitamin D deficiency (≤20 ng/mL), comprising 17.8% *vs* 1.6% with severe deficiency (<10 ng/mL;$P<0.0001$). Patients with G2 tumors and metastasis at diagnosis had significantly lower 25(OH)D levels than those with G1 (mean levels 15.6±7.7 *vs* 20.1±8.6 ng/mL, $P=0.02$) or localized tumor (mean levels 13.1±5.3 *vs* 19.8±8.7 ng/mL, $P=0.001$). A cut-off of 25(OH)D<15.7 ng/mL was associated with increased risk of G2 ($P=0.01$, sensitivity 66.7%, specificity 68%) and metastasis at diagnosis ($P<0.0001$, sensitivity 83.3%, specificity 69%) by ROC analysis. Patients with vitamin D deficiency had shorter PFS compared to those with insufficiency (median PFS 204 *vs* 377 months, $P=0.02$, HR=2.64, 95%CI 1.13–1.26) and sufficiency (median PFS undefined, $P=0.002$, HR=5.66, 95%CI 1.90–16.9). No correlation was observed between vitamin D status and other investigated parameters, including DSS.
Conclusion
We confirmed that vitamin D deficiency is highly prevalent among sporadic and MEN1-related GEP-NET patients and it is associated with G2 and metastasized tumors. Thus, vitamin D deficiency might represent a marker of tumor aggressiveness that might help us to identify those patients with higher risk of disease progression.

Role of KCNJ5 mutations in mediating cell growth in aldosterone-producing adenomas

Yuhong Yang[1], Lucie S Meyer[1], Diana Jaquin[1], Holger Schneider[1], Maria Ploncynski[2], Felix Beuschlein[3], Celso E Gomez-Sanchez[2], Martin Reincke[1] & Tracy Ann Williams[1,4]
[1]Medizinische Klinik und Poliklinik IV, Klinikum der Universität München, Ludwig-Maximilians-Universität München, Munich, Germany; [2]Endocrine Division, G.V. (Sonny) Montgomery VA Medical Center, University of Mississippi Medical Center, Jackson, MS, USA; [3]Klinik für Endokrinologie, Diabetologie und Klinische Ernährung, Universitätsspital Zürich, Zürich, Switzerland; [4]Division of Internal Medicine and Hypertension, Department of Medical Sciences, University of Turin, Turin, Italy.

Background
Primary aldosteronism is commonly caused by an aldosterone-producing adenoma (APA). Somatic mutations in the *KCNJ5* gene (encoding an inwardly rectifying potassium channel) are found in around 40% of APAs, *KCNJ5*

germline mutations cause familial hyperaldosteronism type III. The role of *KCNJ5* mutations in excessive aldosterone production is established but their role in cell growth is unclear.
Objective
To study the effects of *KCNJ5* mutations on cell viability and apoptosis under controlled conditions of gene expression and to assess the expression level of KCNJ5 in APAs.
Methods
Human adrenocortical (HAC15) cell lines stably expressing either a KCNJ5 mutant (G151R, L168R, G151E or T158A) or wild type KCNJ5 and a control cell line transfected with empty vector were established using a cumate-inducible PiggyBac vector system. Cell viability and cell death by apoptosis were quantified using specific assays following induction with cumate. A highly specific monoclonal antibody for KCNJ5 was developed and used in immunohistochemistry and immunofluoresence to demonstrate the distribution and expression level of KCNJ5 in normal adrenals, APAs and corresponding adjacent cortex.
Findings
Under the conditions tested, expression of KCNJ5 G151R, L168R and G151E mutants in HAC15 cells induced apoptosis, KCNJ5 T158A had no effect on cell death. After 12 hours, low level expression of mutated KCNJ5 caused a significant increase in cell proliferation compared with control cells. KCNJ5 displayed low level expression in APAs carrying a KCNJ5 mutation but high expression in APAs with wild type KCNJ5 or with somatic mutations in other genes.
Interpretation
Expression of mutated KCNJ5 at a low level induces cell proliferation in adrenocortical cells. In APAs with *KCNJ5* mutations, cell growth is sustained when expression of mutated KCNJ5 is low.

Influence of Tumor Microenviroment in response modulation to treatment in human BP-NENs

Giulia Bresciani[1], Angeliki Ditsiou[2], Chiara Cilibrasi[3], Viviana Vella[4], Georgios Giamas[3], Maria Chiara Zatelli[1] & Teresa Gagliano[3]
[1]University of Ferrara, Department of Medical Sciences, Section of Endocrinology and Internal Medicine, Ferrara, Italy; [2]University of Sussex, Department of Biochemistry and Biomedicine, School of Life Sciences, Falmer, Brighton, UK; [3]University of Sussex, Department of Biochemistry and Biomedicine, School of Life Sciences, Falmer, Brighton, UK; [4]University of Sussex, Falmer, Brighton, UK.

Introduction
Broncho-Pulmonary Neoplasms (BP-NENs) are rare neoplasms arising from neuroendocrine cells of the respiratory epithelium. Since previous studies in our lab have demonstrated the efficacy ofEverolimus, approved for BP-NENs treatment, and Dinaciclib, a Cyclins and CdKs inhibitor, on monolayer system we have investigated if a more complex tumour system could generate a change in drugs effects and cell resistance. Therefore, through the use of 3D culture model, we have cultured BP-NENs tumour cells alone or together with a lung fibroblasts cell line in order to verify the possible role of Tumour Microenvironment in BP-NENs development and drug resistance.
Material and Methods
NCI-H720 and NCI-H727 cell lines were used as BP-NENs model while MRC5 cell line was used as lung fibroblast model. Two lipophilic tracers were used to stain tumour cells and fibroblasts. Everolimus and Dinaciclib were used at 100 nM. Ultra-low attachment 96-well plates with clear round bottomwere used to obtain Spheroids while metabolic activity was assed using MTT assay.
Results
For both cell lines, when tumour cells were co-cultured with MRC5, spheroids appeared more solid and compact. Our results also showed how the spheroids were different: NCI-H727 spheroids were denser in comparison with NCI-H720 and, in addition, when synthetic extracellular matrix was added the latter failed to invade. Tracers analysis also revealed spheroids cellular distribution underlying a tumour cells core with peripheral collocation of fibroblasts. MTT analysis on tumours cells spheroids showed a 20% significant metabolic activity reduction (vs. vehicle DMSO spheroids) for spheroids treated with Dinaciclib while Everolimus treatment didn't affect basal cell metabolic activity in both cell lines. On the other hand, once in co-culture with MRC5 cells, the cell metabolic reduction observed with Dinaciclib treatment was lost.
Conclusions
Our preliminary results indicate that TME could be important in cell aggregation and spheroids formation and might have a role in drug resistance.

A novel CYP11B1 mutation presenting as a classical congenital adrenal hyperplasia due to 11beta-hydroxylase deficiency

Isabel Mazarico[1], Olga Giménez-Palop[1], Lara Albert[1], Luchtenberg Florencia[1], Laia Casamitjana[1], Ismael Capel[1], David Subías[1], Albert Cano[1], Miriam Guitart[2], Assumpta Caixàs[1] & Mercedes Rigla[1]
[1]Endocrinology and Nutrition Department, Parc Taulí Hospital Universitari. Institut d'Investigació i Innovació Parc Taulí I3PT, Universitat Autònoma de Barcelona, Sabadell, Spain; [2]Genetics Laboratory, UDIAT-Centre Diagnòstic, Parc Taulí Hospital Universitari, Institut d'Investigació i Innovació Parc Taulí I3PT, Universitat Autònoma de Barcelona, Sabadell, Spain.

Background
Congenital adrenal hyperplasia (CAH) is a rare autosomal recessive disorder, of which 21-hydroxylase deficiency (21OHD) is the most frequent form. 11 beta-hydroxylase deficiency (11bOHD) is the second most common type of CAH. This pathology results from inactivating mutations in *CYP11B1* gene.
Case presentation
We describe a case of a 48-year-old woman with 11bOHD, presented with hypokalemia hypertension, early adrenarche and mild virilization at age of 11 years. She was referred to our department at age of 46, after presenting an adrenal crisis, while suffering a pneumonia process, which was resolved with high dose corticoids. She had received over-replacement with glucocorticoids (hydrocortisone 40 mg/day) since she was 11 and developed long-term complications such as osteopenia and poorly controlled hypertension in spite of use of 4 drugs. Physical examination showed cushingoid appearance, with excessive hair growth, short adult stature (145 cm) and central obesity (BMI 38 kg/m^2). She had neither obvious abnormalities in external genitalia at birth nor menstrual disorders. She presented mild left ventricular hypertrophy and hypertensive nephropathy as end-organ damage secondary to hypertension. The biochemical results of the diagnosis during childhood were not available and genetic study was not previously performed. Laboratory examination, under glucocorticoid treatment, revealed low ACTH levels, low androgen levels, normal serum aldosterone and rennin activity and high deoxycorticosterone (DOC) levels. A molecular analysis by sequencing *CYP11B1* gene exome identified a homozygous splicing mutation, c.596-2A>G, not previously reported. This modification in the splice site consensus sequence affects the acceptor critical site in the intron 3- exon 4 boundary. The mutation will most likely lead to a loss of enzymatic activity. Therefore, we confirmed the diagnosis of CAH due to 11bOHD. Following the diagnosis, the patient was advised to reduce the dosage of hydrocortisone to 20 mg day (10 mg in the morning, 5 mg in midday and 5 mg in the afternoon). After dose adjustment of glucocorticoid, blood pressure improved, she lost weight and clinical parameters ameliorated. We did not prescribe treatment with spironolactone because she had high concentration of potassium and her hirsutism disappeared only with glucocorticoid treatment.
Conclusions
We have identified a novel mutation of *CYP11B1* causing CAH. Recognition of novel mutations is clinically significant and would contribute to the knowledge of the phenotype-genotype relationship of CAH in the future.

Available 3D cultures methods: study on a Pancreatic Neuroendocrine Neoplasm cell line

Giulia Bresciani[1], Leo J Hofland[2], Georgios Giamas[3], Teresa Gagliano[4] & Maria Chiara Zatelli[5]
[1]University of Ferrara, Department of Medical Sciences, Section of Endocrinology and Internal Medicine, Ferrara, Italy; [2]Erasmus Medical Centre, Department of Internal Medicine, Rotterdam, Netherlands; [3]Department of Biochemistry and Biomedicine, School of Life Sciences, Falmer, Brighton, UK; [4]University of Sussex, Department of Biochemistry and Biomedicine, School of Life Sciences, Falmer, Brighton, UK; [5]University of Ferrara, Department of Medical Sciences, Section of Endocrinology and Internal Medicine, Italy.

Background
Pancreatic Neuroendocrine Neoplasms (pNENs) are malignancies arising from the endocrine pancreas. Past *in vitro* studies have led to a better comprehension and characterization of this malignancy under several points of view. However, effective medical therapies are still not available, therefore, it is essential to continue studying this malignancy in order to identify a successful approach. Due to tumour complexity, techniques such as 3D cultures, able to generate a more realistic model, have been important to study the topic more accurately. On the other hand, several approaches are available to generate 3D cultures and it is still difficult to understand which one should be used to obtain the best results. This study aims to compare three different 3D culture systems in order to possibly identify the most suitable option in studying pNEN.
Methods
The BON1 cell line has been used as a pNEN model and spheroids were treated with Sunitinib 2,5 uM, 5 uM, 7 uM and 10 uM. The first method employed a 48-well plate with a cell-repellent surface and, in order to obtain spheroids formation, the plates were shaken overnight. Subsequently, spheroids were treated and theirsize was measured using Image J software.The second technique employed a 96-well hanging drop plate and spheroids were generated by self-assembly of tumour colonies.Spheroids were moved into another 96-well plate for treatment and MTT analysis was performed to assess metabolic activity. The third method involved the use of ultra-low attachment 96-well plates with clear round bottom: cells were centrifuged in order to generate spheroids and treated by addition of fresh medium and compound to each well. Also in this case MTT analysis was performed.
Results
Spheroids size measurements didn't highlighted a decrease in spheroids diameter after treatments with Sunitinib at different concentrations while MTT analysis on spheroids cultured with the second method indicated a decrease in metabolic activity after treatment with Sunitinib 2,5 uM, 5 uM, 7 uM of a 10% (treated cells vs. vehicle cells treated with DMSO). MTT results for spheroids cultured with the third approach have shown a decrease of metabolic activity of a 20% (treated cells vs. vehicle cells treated with DMSO) after treatment with Sunitinib 2,5 uM, 5 uM, 7 uM. Results were more homogeneous for cells seeded with the third method in comparison to the second one.
Conclusions
According to our results the third method appears to represent the easiest and most reliable technique to culture spheroids and obtain reproducible results.

Prevalence and prognosis of bone metastases in pancreatic and small intestinal neuroendocrine tumours

Emin Mammadov[1,2], Nicola Hughes[2], Asma Alnuaimi[2,3], Jun Liong Chin[2,4], Dermot O'Toole[2,5], Donal O 'Shea[2], Eric Heffernan[2] & Rachel K Crowley[2]
[1]Sanador Hospital, Bucharest, Romania; [2]St Vincent's Hospital, Dublin, Ireland; [3]Sheikh Khalifa Medical City, Abu Dhabi, UAE; [4]Homerton University Hospital, London, UK; [5]St James's Hospital, Dublin, Ireland.

Background
Neuroendocrine tumours (NET) can affect various tissues and organs, have different clinical presentation and prognosis, depending on the primary tumour site, grading, differentiation and functional status. Reported prevalence of bone metastases (BM) from NETs has been increasing with improved imaging modalities, reaching >40% in some reports. The BM diagnosis is associated with reduced overall survival; however, this was not confirmed by all studies.
Methods
We performed a retrospective single centre analysis of patients with pancreatic (pNET) and small intestinal (siNET) primaries ($n=377$) and identified 40 patients diagnosed with BM (19 with pNET, 21 with siNET). The scans were assessed by an independent radiologist blinded to the primary site diagnosis and to the history. IBM SPSS-24 was used to compare overall survival. The survival was calculated based on 'alive' status as per 1st December 2017. Statistical significance was accepted at $P<0.05$.
Results
The prevalence of BM was 10% for pNET and 11.2% for siNET; BM were present at the time of diagnosis in 23 patients (57.5%), including 68.4% pNET patients who developed BM at some point in their disease course, as opposed to 47.6% siNET, $P=0.249$. Nine patients had lytic, 24 sclerotic and 3 mixed bone lesions. Data regarding fractures was available in 33 patients, 4 of them had fractures identified, however only 2 had fractures related to the BM, in both of them tumours originating from pancreas. Almost half of pNET patients who developed BM had grade 3 tumours, as opposed to only about 10% of siNET. We observed a significantly higher prevalence of lytic lesions in pNET as compared to siNET. Interestingly, 2/3 of pNET with lytic BM were grade 3 tumours vs grade 1 for siNET. Overall survival (OS) was better for siNET in our analysed cohort of patients, having a longer survival since the time of diagnosis of NET ($P=0.034$); the difference in survival post diagnosis of BM was not statistically significant. The median OS for the whole cohort of pNET and siNET since the time of detection of BM ranged from 12 months in G3 pNET to 58 months in G2 siNET. The sclerotic BM were associated with more favourable prognosis; however, the difference did not reach the statistical significance.
Conclusions
A substantial proportion of NET patients with BM have skeletal lesions at the time of initial diagnosis of NET. BM from pNET are associated with higher grade primaries, lytic lesions and shorter OS.

Endocrine hypertension?

Silvia Maraver-Selfa, Miguel Damas-Fuentes, Isabel María Cornejo-Pareja, María Molina-Vega, Araceli Muñoz-Garach, Carmen Hernández-García, Isabel Mancha-Doblas & Francisco Tinahones
Endocrinology and Nutrition Department, Virgen de la Victoria Universitary Hospital, Malaga, Spain.

An 18-years-old woman without medical history was referred for study of hypertension and an adrenal incidentaloma. The family history was significant for essential well-controlled hypertension in her father; diagnosed at 39 years-old. The patient complained of headache, asthenia, edema in lower limbs, high blood pressure values (200/150 mmHg) for one year (well controlled with losartan 100 mg/12 h, amlodipine 10 mg/24 h and doxazosin 4 mg/24 h) and marked facial acne previous months; without hirsutism. She had regular menstrual cycles. Physical examination: weight 82.4 kg, BMI 28 kg/m^2, BP 131/89 mmHg, no acanthosis nigricans and no clinical stigmata of hypercortisolism. Patient provided abdominal CT without contrast with a hypodense nodular 0.8 cm thickening in left adrenal gland, normal renal Doppler ultrasound and echocardiogram with moderate left ventricle eccentric hypertrophy. We requested laboratory tests: glycemia 92 mg/dl, creatinine 0.75 mg/dl, glomerular filtration rate >90 ml/min/1.73 m^2, sodium 140 mEq/l, potassium 3.56 mEq/l, TSH 0.88 µUI/ml, FT4 1.1 ng/dl, cortisol 23 mcg/dl, ACTH 11 pg/ml, aldosterone 5.1 ng/dL, PRA 14.9 ng/ml/h, ratio aldosterone/PRA 0.34 (<30), urinary free cortisol 258 µg/24h (<180), dopamine 573 µg/24h (<500), adrenaline 4.4 µg/24h (<35), noradrenaline 140 µg/24h (<100), normetanefrin 508 µg/24h (<500), metanephrines 186 µg/24h (<300) and Nugent test 14 mcg/dl. Due to discordance with initial study, we requested a new study interrupting antihypertensive treatment and administering verapamil 240 mg/24h and doxazosin 8 mg/24h, with result: potassium 2.8 mEq/l (<3.5), ACTH 20 pg/ml, cortisol 29 mcg/dl, PRA 20 ng/ml/h, aldosterone 24 ng/dl, aldosterone/PRA 1 (<30), Liddle test 0.6 mcg/dl and catecholamines and metanephrines in urine in range. Suspecting secondary hyperaldosteronism (reninoma) we requested an abdomen CT with contrast showing a solid, well-defined rounded focal 22 mm. cortical lesion in right kidney lower pole, and subtle 8 mm thickening in left adrenal gland. It is derived to Urology for laparoscopic right partial nephrectomy. Histological examination: well-delimited, not encapsulated tumor, without atypia, necrosis, mitosis, vascular invasion or adjacent renal parenchyma invasion. Immunohistochemistry: CD34 and vimentin intensely positive, with no evidence of immunoexpression for actin, CD117 or CK7, compatible with a juxtaglomerular cell tumor (immunoexpression of CD117/actin are pending in a reference center to confirm the lesion). After surgery, the patient remains normotensive without treatment and with normality on the renin-aldosterone axis (PRA 1.2 ng/ml/h, aldosterone 7.6 ng/dl).

Ninety-four serum steroids measured by gas chromatography tandem mass spectrometry (GC-MS/MS) in patients with Cushing's syndrome

Václav Hána Jr[1], Jana Ježková[1], Mikuláš Kosák[1], Michal Kršek[1], Václav Hána[1] & Martin Hill[2]
[1]3rd Department of Internal Medicine, General University Hospital and 1st Faculty of Medicine, Charles University, Prague, Czech Republic; [2]Steroid Hormone Unit, Institute of Endocrinology, Prague, Czech Republic.

Introduction
Gas chromatography tandem mass spectrometry (GC-MS/MS) quantitatively detects many steroids at one time in a single serum sample. Cushing's syndrome (CS) caused by adrenal adenoma is often associated with decreased DHEAS, whereas low levels of aldosterone in ACTH dependent CS and also low levels of 18-oxocortisol were observed in ectopic CS. We aimed to evaluate steroid differences in various types of CS.
Methods
In serum from patients with CS (51 with Cushing's disease, 6 with ectopic ACTH-dependent CS, 16 with adrenal adenoma, 7 bilateral adrenal hyperplasia (BMAH) with overt CS, 23 controls) using novel gas chromatography-tandem mass spectrometry (GC-MS/MS) method we measured 94 steroids to evaluate differences between groups.
Results
In Cushing's disease and ectopic ACTH producing tumors we observed elevated levels of androgens and their metabolites when compared with healthy controls. Mineralocorticoid precursors were elevated in ectopic ACTH syndrome. The levels of androgens were decreased in adrenal adenomas and BMAH. ROC analysis showed 100% sensitivity and 93.6% specificity of 11β-hydroxyepiandrosterone sulfate for discrimination of Cushing's disease from ectopic ACTH secretion (where it was more elevated). We did not find any significant ($P < 0.05$) difference in steroids that would discriminate BMAH from unilateral adenomas causing Cushing's syndrome.
Conclusion
Steroid profiling in CS patients shows significant differences between CS types that could ease the achievement of appropriate diagnosis. Further prospective studies are needed for the confirmation of these results.

Comparative study between autoimmune metaplastic atrophic gastritis (AMAG) and type 1 gastric neuroendocrine tumors (G-NETs) in Hospital Clínico San Carlos (HCSC), Madrid

Elvira Ramos, Ignacio Vargas-Zuñiga, Elvira Barrio, Pablo Suárez, Mario Pazos, Raquel Pallarés, Paula Aldama, Nuria García De La Torre, Concepción Sevilla & Jose Ángel Díaz
Hospital Clínico San Carlos, Madrid, Spain.

Introduction
Type 1 Gastric neuroendocrine tumors account for 70 to 80 percent of all gastric neuroendocrine tumors (G-NETs) and they are found more commonly in older adults, particularly women. They are associated with autoimmune metaplastic atrophic gastritis (AMAG) with or without pernicious anemia. Endoscopically, they are usually smaller than 1 cm and often multiple. These tumors usually present a non-aggressive evolution. Our goal is to approach the presence of risk factors to develop G-NET in patients with AMAG.
Material and methods
Descriptive and observational study of 16 patients diagnosed with AMAG (controls) and 31 patients diagnosed additionally with type 1 G-NET (cases). The 47 patients were retrieved from the Endocrinology department of HCSC in the last 15 years. Variables between both groups were compared using the statistical program SPSS 23.0.
Results
Mean age was 64.75 (SD 12.03) in controls and 63.47 (SD 11.35) in cases. 75% of controls and 62% of cases were female. The diagnosis of AMAG in controls was due to vitamin B12 deficiency in 68.8%. In cases the diagnosis of G-NET was due to follow-up AMAG in 40.6%. We did not find differences between the personal and family history in both groups. 86.7% of controls and 71.8% of cases were non-smokers without reaching statistical significance. The presence of H. pylori was found in 18.8% of controls and in 3.1% of cases ($P = 0.101$). The median of vitamin B12 in controls was 186 pg/ml (IQR 141.5–398.5) and 288 pg/ml (IQR 204–386) in cases ($P < 0.05$). There were no statistically significant differences in the levels of hemoglobin, ferritin or serum iron although the median values were lower in controls. Regarding autoimmunity, anti-parietal cell antibodies could protect the development of G-NET OR: 0.192 (0.038–0.956). We found a higher prevalence of intrinsic factor antibodies in controls (41.2% vs 21.7) that was not statistically significant ($P = 0.185$).
Conclusions
In our sample, the presence of anti-parietal cell antibodies might be a protective factor against G-NET development. However other studies are needed to support these results in other populations. Vitamin B12 levels were significantly higher in cases than in controls. Further research confirming these data might help to establish the usefulness of Vitamin B12 levels in early diagnosis of G-NET in patients with AMAG. Larger studies are necessary to assess whether the presence of intrinsic factor antibodies and H.Pylori infection are indeed associated with a lower risk of developing G-NETs in patients with AMAG.

Pheochromocytoma and disorders of carbohydrate metabolism

Siham E lmir, Yousef Yaden, Siham Rouf & Hanene Latrech
Endocrinology and Diabetology Department, Mohammed VI University Hospital, Faculty of Medicine and Pharmacy, Oujda, Morocco.

Introduction
Pheochromocytoma is a rare tumor secreting catecholamines, which are part of the hormones of carbohydrate counter-regulation. The aim of our work is to evaluate the glycemic balance in patients in pre- and post-operative pheochromocytoma.
Material and methods
A retrospective study of 18 cases of pheochromocytoma over a period of 5 years. A pre- and post-operative metabolic assessment was performed as well as an evaluation of the other clinical parameters.
Results
The mean age of the patients was 47 years (Sex F/H ratio: 2.6). Diabetes is found in 50% of patients and had the following characteristics: the average evolution of 5.7 years, with a strong type II diabetic heredity in 67.1% of cases and an average body mass index of 26.4 kg/m^2. One-third of patients had HBA1C greater than 8%. No diabetic patient had a ketoacidosis decompensation, and 55.5% of our diabetic patients were under INSULNE + oral anti-diabetic on admission. In postoperative: only 22% of our patients were on oral anti-diabetic + Insulin, blood glucose level normalized in 22% of cases under no treatment, improved in 33% of cases under the same treatment and average HBA1C decreased from 7.57% in pre-op to 6.65% in post-op.
Discussion
The glucoregulation disorder of pheochromocytoma is quite common in our series as in some literature results. The radical surgery of pheochromocytoma has a remarkable impact on the glycemic balance.

DOI: 10.1530/endoabs.63.P45

Heart and vessels after a pheochromocytoma: which outcomes?

Siham Elmir, Boujtat Khadija, Siham Rouf & Hanane Laterch
Endocrinology and Diabetology Department, Mohammed VI University Hospital, Faculty of Medicine and Pharmacy, Oujda, Morocco.

Introduction
Pheochromocytoma is a rare tumor. It can be revealed or complicated by cardiovascular manifestations. The aim of our work is to study the cardiovascular manifestations of pheochromocytoma and the evolution of hypertension after surgery.
Patients and methods
A retrospective study of 18 cases of pheochromocytoma followed at the endocrinology and metabolic diseases department of Mohammed VI university hospital of Oujda during a period of 5 years. Clinical data, electrocardiogram and trans-thoracic ultrasound were recorded for each patient.
Results
The mean age of the patients was 47 years. Discovery conditions were dominated by the Menard triad in 7 cases and incidentaloma exploration in 6 cases. The dosage of urinary methoxylated derivatives was greater than 3 times the normal value in 94.4% of cases. Half of the patients were hypertensive, 8 of whom were diabetic. On electrocardiogram: Left ventricular hypertrophy was noted in 4 cases, tachycardia in 2 cases, bradycardia in 1 case, and repolarization disorders in 2 cases. Trans-thoracic ultrasound was normal in 5 cases, and showed a left ventricular hypertrophy in 4 cases, an aneurysmal dilatation of the ascending aorta in one case and a pericardial detachment in 1 case. The evolution after the

surgical cure was marked by the normalization of the blood pressure values under no treatment in 44% of the cases, and improvement with a reduction in the number of antihypertensives drugs in 22% of cases.
Conclusion
Pheochromocytomas are high-risk cardiovascular tumors that can be life-threatening. Surgical treatment normalized blood pressure in 44% of cases.

First presentation of Addison's disease as hyperkalaemia: a rare case report

Salma Ben Yakhlef, Nada Derkaoui, Siham Rouf & Hanane Latrech
Diabetology-Endocrinology Department of Oujda's Mohammed VI University Hospital, Oujda, Morocco.

Introduction
Addisson's disease is a rare endocrine disorder; that continues to be a diagnostic challenge in the 21st century; mainly due to the slow and non specific progression of symptoms. We report the case of a 45-year-old woman who was admitted with acute adrenal insufficiency discovered in the context of a severe hyperkalemia.
Case report
A 45-year-old woman was admitted in our institution with a history of extreme weakness and vomiting. On physical examination we noticed a significant dehydration and a blood pressure of 60/40 mmHg. Initial blood tests revealed hyponatremia 124 mmol/l and severe persistant hyperkalemia higher than 10 meq/l with estimated glomerular rate 42.42 ml/min. Her ECG showed tall tented T waves in all leads besides wide QRS complexes. Furthermore, 0800 h serum cortisol was low. The patient was started on intravenous hydrocortisone and fluids according to local treatment protocol for acute adrenal insufficiency. At the same time, she underwent urgent haemofiltration along with conventional medical management of hyperkalemia resulting in subsequent improvement. Elevation of ACTH with low cortisol taken at 0800 h at discharge confirmed the diagnosis of primary adrenal insufficiency. After the resolution of the electrolyte abnormalities and the improvement of hemodynamic statement; she was discharged on oral hydrocortisone and fludrocortisone tablets.The patient was followed up in the endocrinology department of Oujda's Mohammed VI university hospital, for further investigations and a well conducted disease's education.
Conclusion
This report describes a non-specific presentation of Addison's disease. Therefore, a high index of suspicion is warranted in patients with a life-threatening hyperkalemia and may requires haemofiltration in spite of a prompt management of acute adrenal insufficiency based on preliminary clinical diagnosis.

Pharmacokinetic Interaction Study of the Effects of Multiple-dose Gastric Acid Reducers Omeprazole (OMP) and Famotidine (FAM on the Pharmacokinetics (PK) of Single-dose Telotristat Etiprate (TE) in Healthy Subjects

Alan Wilson[1], Christine Qubeck[1], Chris Warner[1], Eshetu Tesfaye[1], Quyen Nguyen[2] & Suman Wason[1]
[1]Lexicon Pharmaceuticals, The Woodlands, TX, USA; [2]Ipsen Innovation, les Ulis, France.

Background
TE is indicated for the treatment of carcinoid syndrome diarrhea in patients with metastatic neuroendocrine tumors.
Objective
To evaluate the effects of a proton pump inhibitor (OMP) and H2 antagonist (FAM) on the PK of TE and its active metabolite LP-778902 via an open-label study of OMP (40 mg orally QD $\times$ 4 days) or FAM (40 mg orally BID $\times$ 4 days) with a single 250 mg oral dose of TE. Eligible subjects: healthy, nonsmoking, aged $\geq$18-$\leq$65 years/BMI $\geq$18.0-$\leq$32.0 kg/m^2. Parallel cohorts of 16 subjects each received 250 mg TE on Day 1 followed by a 72-hour washout. On Day 4–6 subjects received either OMP ($n=16$) or FAM alone ($n=16$). On Day 7 subjects received 250 mg TE and OMP or FAM. Fasting and meals were controlled. PK blood samples were collected on Day 1 and 7. Safety assessments were conducted at Screening and throughout the study.
Analysis
PK parameters included maximum observed concentration (C_{max}), time of maximum concentration (T_{max}), area under the plasma concentration-time curve extrapolated to infinity (AUC_{inf}), and AUC from first dose until the last quantifiable concentration (AUC_t). A lack of DDI was declared if the 90% confidence intervals (CIs) for the ratios of geometric least square means fell within the accepted range of 0.8 – 1.25 for AUC_t, AUC_{inf}, and C_{max}.
Results
For TE alone, mean AUC_t, AUC_{inf}, and C_{max} were 3.4, 2.8, 1.7 and 2.2, 2.1, and 1.2 times higher when TE was co-administered with OMP or FAM, respectively. Median T_{max} for TE was delayed by 1.3 hours and 0.5 hours, respectively. Boundaries of the 90% CIs were not within the 0.8–1.25 interval, indicating a DDI with OMP and FAM on TE exposure. However, no-significant difference in exposure (AUC_t, AUC_{inf}) to LP-778902 was observed and there was a $<$7% decrease in C_{max}, following coadministration of TE with either OMP or FAM. There were no clinically significant findings in any safety assessments. One subject who received FAM experienced mild pruritis that was considered unlikely related to either study drug and resolved by the end of the study.
Conclusion
Single oral doses of 250 mg TE administered alone or with either OMP or FAM were safe and well tolerated. Coadministration with either OMP or FAM alters the exposure of TE but has no marked effect on exposure to the active, more potent metabolite, LP-778902, and therefore, is unlikely to be clinically significant.

Endocrine hypertension: before and after treatment of the endocrinopathy

Marwa Khiari[1], Ibtissem Ben Nacef[2], Imene Rojbi[2], Karima Khiari[2], M Jerbi[2], Nadia Mchirgui[2], Youssef Lakhoua[2] & Nejib Ben Abdallah[2]
[1]National institute of Nutrition, Tunis, Tunisia; [2]M8 Endocrine Department, Charles Nicoles Hospital, Tunis, Tunisia.

High blood pressure of endocrine origin remains a rare cause of hypertension. The interest of the research of endocrine hypertension lies in the severity of certain forms and its potentially curable and reversible nature, hence the interest of oriented screening. The aim of our work was to study the profile of endocrine hypertension among a population suffering from secondary diabetes. This is a retrospective descriptive study of 55 patients followed in endocrinology department of the M8 ward, Charles Nicole Hospital, Tunis between 1985 and 2015. Dysthyroidism was excluded. The average age of our population was 44.85$\pm$12.74 years with a female predominance of 72.2%. It included Cushing's syndrome in 40.7%, acromegaly in 22.2%, pheochromocytoma in 16.7% and primary hyperaldosteronism in 20.4% of cases. Mean systolic and diastolic arterial pressures were 166.3$\pm$23.2 mmHg and 97.00$\pm$15.2 mmHg, respectively. Hypertension was severe in 31.5% and resistant in 13% of cases. It was controlled by tritherapy in 22.2%, dual therapy in 24.1% and monotherapy in 27.8% of cases. We did not find a correlation between the severity of hypertension and the baseline hormonal level. After remission of the underlying endocrinopathy, blood pressure was statistically improved in all cases. Antihypertensive treatment was even discontinued in 61.1% of patients with Cushing's syndrome, 66.7% of acromegalic patients, 44.4% of patients with pheochromocytoma and 9.1% of patients with primary hyperaldosteronism. Endocrine hypertension is a severe but often curable form of high blood pressure. Associated with diabetes, it increases cardiovascular risk during endocrinopathies. It is therefore imperative to detect and balance it while waiting for the treatment of the underlying endocrinopathy.

A seminoma with entrapped nerve ganglion masquerading as a paraganglioma

Rachel Chava Rosenblum[1], Karine Atlan[2], Judith Diment[2], Haggi Mazeh[3], Pnina Rotman-Pikielny[1] & Orit Twito[1]
[1]Endocrinology Unit, Meir Medical Center, Kfar Saba, Israel; [2]Department of Pathology, Hadassah-Hebrew University Medical Center, Jerusalem, Israel; [3]Department of General Surgery, Hadassah-Hebrew University Medical Center, Jerusalem, Israel.

Background
The differential diagnosis of retroperitoneal tumors includes lymphoid, germ cell and neurogenic tumors such as paraganglioma. Paragangliomas are rare neuroendocrine tumors of the autonomic nervous system, which may secrete catecholamines and their metabolites. Clinical features include sustained or

paroxysmal hypertension, headaches, sweating and palpitations. Here we present an unusual case of a retroperitoneal tumor entrapping a sympathetic nerve ganglion and mimicking paraganglioma.
Case study
A fifty-seven-year-old man with a history of controlled hypertension presented with paroxysms of tachycardia, flushing, high blood pressure and headache. Ambulatory blood pressure monitoring showed uncontrolled labile hypertension with a normal nocturnal dip. Abdominal CT demonstrated a 6.1 cm mass in the right retroperitoneum with adjacent lymphadenopathy. Paraganglioma was suspected and urinary 24-hour collection was performed, demonstrating mildly elevated normetanephrines (575 μg/24 h, norm 5-290) and VMA (8.3 mg/24 h, norm 0.5–6.6). 68-Gallium DOTATATE PET/CT showed weak uptake in the retroperitoneal mass and no other mass lesions. Following preparation with alpha-adrenergic blockers, surgical excision was performed with diagnostic and curative intent. Post-operatively, hypertension and paroxysmal symptoms resolved completely. The histopathology report described seminoma with an entrapped large ganglion within the tumor.
Conclusion
We describe a retroperitoneal seminoma with an entrapped ganglion causing hypertension and paroxysmal symptoms, with laboratory and imaging features compatible with paraganglioma. Awareness of the rare possibility of mechanical pressure on a ganglion, within the differential diagnosis of retroperitoneal mass and sympathetic symptoms may aid in clinical decision making in atypical cases.

Magnetic resonance imaging in the initial diagnosis of pancreatic insulinoma: primary data analysis

Marina Yukina, Nurana Nuralieva, Ekaterina Troshina, Aleksandr Vorontsov, Victoria Vladimirova, Natalia Tarbaeva & Olga Rebrova
Endocrinology Research Centre, Moscow, Russian Federation.

Introduction
Insulinoma visualization is the most difficult stage of diagnosis of this disease. Currently, in most cases the contrast-enhanced multislice computer tomography of abdomen and retroperitoneal space (CE-MSCT) is the method of choice in topical diagnosis of insulinoma. This method is associated with radiation exposure and administration of contrast agents, so it is invasive. Thus, an alternative highly informative and safe method for initial topical diagnosis of insulinoma is necessary. In particular, the magnetic resonance imaging without contrast enhancement (MRI without CE) is a promising imaging method.
Materials and methods
In 24 patients aged 20–72 years with hypoglycemic syndrome the MRI without CE and CE-MSCT were performed.
Results
According to MRI, pancreatic neuroendocrine tumor was detected in 96% of patients ($n=23$). CE-MSCT revealed the pancreatic tumor in 100% of patients ($n=24$), among them the tumor in the head of pancreas in patient with negative result of MRI. According to CE-MSCT, there were 23 neuroendocrine and one solid pseudopapillary tumor. In all patients ($n=24$) the surgery was performed. Intraoperative revision confirmed the localization of pancreatic tumor in 100% of patients with positive result of MRI, and in patient with negative result of MRI the tumor in the tail of pancreas was revealed. Data of intraoperative revision were confirmed by the pathomorphological investigation in all patients. The immunomorphological features of insulin-producing tumor were revealed in 23 patients (96%) and in one patient the solid pseudopapillary tumor was diagnosed, in accordance with data of MSCT. Thus, the sensitivity of MRI without CE and CE-MSCT in detection of pancreatic tumors (reference is the localization according to intraoperative revision) is identical (96%), 95% confidence interval (79%; 100%). The sensitivity of methods in identifying the origin of tissue (reference is the result of histological investigation) is also not statistically different – 96% (79%; 100%) and 100% (86%; 100%) respectively.
Conclusion
MRI without CE and CE-MSCT are equivalent highly sensitive methods of topical diagnosis of insulin-producing neuroendocrine pancreatic tumors, but MRI without CE has additional advantages: the lack of ionizing radiation and necessity for contrast agents administration. Thus, for diagnosis of insulinoma it is advisable to use the MRI without CE as the first-line imaging modality, and the CE-MSCT should be used in difficult cases as additional method.
Funding
The work was supported by the state assignment ‘Hereditary tumor syndromes and multiple endocrine neoplasias: personalization of diagnostics and treatment, risk prediction, identification of nuclear families’ for 2018–2020 years.

Exome analysis of pituitary adenoma tissue derived cell cultures

Vita Rovite[1], Raitis Peculis[1], Ilona Mandrika[1], Ramona Petrovska[1], Kaspars Megnis[1], Inga Balcere[2,3], Ilze Konrade[2,3], Janis Stukens[4], Austra Breiksa[4], Jurijs Nazarovs[4], Valdis Pirags[4,5] & Janis Klovins[1]
[1]Latvian Biomedical Research and Study Centre, Riga, Latvia; [2]Riga Eastern Clinical University Hospital, Riga, Latvia; [3]Riga Stradins University, Riga, Latvia; [4]Pauls Stradins Clinical University Hospital, Riga, Latvia; [5]University of Latvia Faculty of Medicine, Riga, Latvia.

Introduction
Pituitary adenomas (PA) are tumours of the anterior pituitary. Despite the benign nature these neoplasms cause increased mortality and morbidity. Clinically relevant PAs affect around 0.1% of population during their lifetime. Currently, there is no human PA cell culture models. Tissue cultures derived from PA surgery materials depending on harvesting conditions can form free floating aggregates called pituispheres (PS) or adherent mesenchymal stromal cells (MSC). We studied genetic relationship between patients’ germline DNA, tumour tissue somatic DNA, DNA of PS and MSC obtained from culture of primary surgery material to investigate usability of these culture cells as human PA model.
Methods
Five PA patients were enrolled to national biobank – Genome Database of Latvian Population from Pauls Stradins Clinical University Hospital where transsphenoidal surgery of PA was performed for all patients. Germline DNA was isolated from white blood cells using phenol-chloroform method, tumour somatic DNS was isolated using AllPrep DNA/RNA Mini Kit (Qiagen, Netherlands). To obtain PS primary PA tissue material was harvested using EGF, FGF, and B-27 supplement methodology, but adherent MSCs were developed using DMEM/serum supplemented culturing. PS and MSC were used as DNA source in whole genome amplification (WGA) to obtain sufficient DNA for library preparation. Exomes (Illumina TruSeq_Rapid_Exome_TargetedRegions_v1.2) of germline, tumour somatic, PS and MSC were sequenced using Illumina NextSeq with 75bp paired end reads. Sequencing data were analyzed with Illumina Basespace Enrichment App (v3.0.0) aligning to human HG19 reference genome using Isaac Genome Alignment Software, variants called with Starling algorithm and variants annotated with Illumina Annotation Engine. Filtered variants were reviewed using IGV 2.3.14.
Results
Germline and somatic DNA sequencing captured median 98.4% of the target regions (range 96.4–99.0%). WGA region capture was lower with median 95.6% (range 79.6–99.2%). Variation analysis revealed low amount of somatic mutations (median 4, range 0–5) in the PAs. Somatic mutations of the primary tumour can be detected in the respective PS, but not in the respective MSC. Genetic alterations of MSCs corresponded to mutations in PA patients’ germline DNA.
Conclusions
For the first time we show that genome of PS represents genome of PA while MSC derived from the same primary surgery material does not contain PA characterizing mutations in their genome therefore most likely representing normal cells of pituitary or surrounding tissues. This indicates that PS can be used as a model to study PAs.

A rare association of neuroendocrine tumor with adenocarcinoma of ampulla of vater: difficulties for diagnosis and effects of multi therapeutic approach

Oana Stefania Stanca[1], Cristina Olariu[1] & Corin Badiu[1,2]
[1]National Institute of Endocrinology C. I. Parhon, Bucharest, Romania; [2]University of Medicine and Pharmacy Carol Davila, Bucharest, Romania.

Introduction
The neuroendocrine tumor of the ampulla of Vater represent a very rare disease, corresponding up to 2% of the periampullary malignancies and less than 1% of gastrointestinal NET. Less than 130 patients have been reported until 2013. The biological and clinical behavior is very unpredictable especially if it’s associated with another tumor, like adenocarcinoma. We present a case of a fifty-one-years-old woman who complained of weight loss, jaundice, abdominal pain and anemia. MR-cholangiography revealed an ampullary ulcerated tumor with duodenal invasion, Forrest IIA and biopsy and endoscopic hemostasis was practiced. Also

multiple liver tumors were described, the larger one in segment III, about 6 cm. The patient underwent a Whipple procedure and hepatectomy in segments II-III for bulky necrotic metastases. The immunohistochemical study of the neoplasia showed the expression of chromogranin A, synaptophysin, CD56 and also cytokeratin7, CEAm, CA19-9, beta-catenine with a proliferation index Ki67-12%. The TNM classification was pT3N1M1a- stage IV and by WHO was NET well differentiated G2 with adenocarcinoma associated (<10%), non-MANEC. The evolutive CT revealed incomplete thrombosis of right hepatic artery and the Octreoscan showed multiple bone metastases. The patient started chemotherapy with Capecitabine, Lanreotide and Zoledronic acid for bone metastases. Because of the elevated serum markers (chromogranin A, neuron specific enolase, carcinoembryonic antigen), postsurgical complications (acute superior digestive hemorrhage) and disseminated disease (liver, bones) the patient was recommended undergo radioisotope therapy cycle with Lutetium 171/Yttrium 90 in Europe, therapy not currently available in Romania. The particularity of this case of ampullary neuroendocrine tumor associated with adenocarcinoma make more insidious the progress and worsen prognosis of the disease, by being difficult to predict the effects of multisystemic therapy- chemotherapy, somatostatin analogs and newly, peptide receptor-targeted radiotherapy.
Conclusions
Although neuroendocrine tumors of the ampulla of Vater represents a rare disease, it has been increasingly reported in the last years. Radical surgery should be the standard approach. The presence of distant metastases is the most important prognostic factor in determining survival.

Continuous glucose monitoring during the prolonged fast test for the diagnosis of hypoglycemic diseases: primary data analysis

Marina Yukina, Nurana Nuralieva & Ekaterina Troshina
Endocrinology Research Centre, Moscow, Russian Federation.

Introduction
To diagnose the hypoglycemic diseases (HD), firstly, proving the hypoglycemia presence is necessary. For this purpose, the prolonged fast test, which can reach 72 h, is performed. In case of late completion this test has a potential risk of hypoglycemic coma. Repeated glycemia control by glucometer brings discomfort to patients and increases the labor costs of medical workers. In this regard, it was relevant to conduct a study on the comparison of continuous glucose monitoring by portative system (CGMS) in interstitial fluid and regular glucose monitoring by glucometer in capillary blood.
Methods
We performed the fast test in 38 patients aged 18–72 years with suspicion of HD. In the ranges of glycemia 2.6–3.0 and 2.2–2.5 according to glucometer data and at the time of finishing the test we fixed the glycemia according to CGMS data and took the venous blood. We estimated the CGMS accuracy in relation to venous glycemia and glucometer data: in normoglycemia (venous glycemia more than 3 mmol/l), in hypoglycemia (venous glycemia 3 mmol/l and less). The comparative estimation of financial cost and labor costs (CGMS calibration and glycemia determination by glucometer) was performed. We compared the test duration: actual and hypothetical (provided that completion criteria were determined in accordance with CGMS data - glycemia less than 2.8 mmol/l).
Results
Mean deviation of CGMS indicators compared to laboratory values in normoglycemia is +0.57, in hypoglycemia is +0.9; compared to glucometer: in normoglycemia is +0.14, in hypoglycemia is +0.59. Mean actual test duration in patients with confirmed HD ($n=25$) is 35.3 h, mean hypothetical test duration is 19.3 h. Mean frequency of CGMS calibration is 2.2 per day, mean frequency of glycemia determination by glucometer is 7.2 per day. Taking into account the cost of in-patient stay in a hospital, sensors for CGMS, test strips for glucometer, the expenses of measuring glucose by CGMS and by glucometer do not differ significantly.
Conclusion
The CGMS accuracy is higher in high glycemia and comparable to a glucometer. Using CGMS has the same financial cost like glucometer using. The CGMS timely warns about glycemia decreasing. CGMS reduces the labor costs and, in certain conditions, decreases the test duration. Doctors can orientate on CGMS indicators given the fact of their overstatement. We need to accumulate data for the final conclusion and recommendations for using CGMS in diagnosis of HD.

Clinical case of a repeated life-threatening upper gastrointestinal bleeding due to previously unknown primary hyperparathyroidism

Natalia Budul & Irina Komerdus
Moscow Regional Research Clinical Institute, Moscow, Russian Federation.

Background
Peptic ulcer bleeding due to primary hyperparathyroidism is extremely rare and only a few cases have been reported in the literature.
Material and methods
Man with repeated upper gastrointestinal bleeding, with a history of kidney stones and previously unknown primary hyperparathyroidism.
Case
Man M., 46 y.o., with a history of 4 episodes of gastrointestinal bleeding and a ten-year history of multiple kidney stones. In 2014 resection of the stomach with Roux anastomosis was conducted to arrest the hemorrhages. High level of calcium was first diagnosed. However, he had been consistently treated for ulcer and kidney stones without any further work-up. In 2018 in the therapeutic department with ulcer rebleeding: PTH – 48.7 pmol/l (1.7–6.4), calcium – 3.06 mmol/l (2.2–2.65), phosphorus – 0.8 mmol/l (0.81–1.45). Primary hyperparathyroidism was confirmed. On a neck and abdomen CT scan with contrast: two parathyroid adenomas (larger mass size 7×12×15 mm), adenoma of the right adrenal gland (18×15×21 mm) and polycystic kidney disease. Urine metanephrine – 709 μg/24 hours (20–345) and normetanephrine – 507.3 μg/24 hours (30–440), GFR level –46 ml/min/1.73 m^2. MRI performed and pituitary adenoma (10×8×9 mm) was found. After laboratory evaluation prolactinoma was diagnosed (PRL – 5925 mE/l (72–229). Gastrinoma was also supposed because of repeated GI-bleeding. An immunohistochemistry analysis of stomach sample from 2014 revealed neuroendocrine pancreatic tumor Ki67-25% (PPoma). Genetic examination was performed: result in processing. Parathyroidectomy and adrenalectomy were performed. Postoperatively, calcium and PTH levels were normalized. The ulcer healed – 3 months after parathyroidectomy.
Conclusion
The serum calcium level and PTH level must be considered routine tests in patients with a peptic ulcer bleeding, especially when it is accompanied by a history of kidney stones and repeated gastrointestinal bleeding.
Keywords: primary hyperparathyroidism, neuroendocrine, multiple endocrine neoplasia.

A difficult diagnosis: pheochromocytoma or methamphetamine abuse?

Georgiana Constantinescu, Steffen Leike[1], Carola Kunath[1], Katharina Langton[1], Matthias Gruber[1], Mirko Peitzsch[1], Jaap Deinum[1,2], Jacques Lenders[1,2] & Graeme Eisenhofer[1]
[1]University Hospital Carl Gustav Carus at the TU Dresden, Dresden, Germany; [2]Radboud University Medical Center, Nijmegen, Netherlands.

Introduction
Pheochromocytomas represent rare but potential lethal tumors arising from the adrenal medulla. Early recognition and diagnosis represent a challenge due to the non-specific character of signs and symptoms. The classic presentation includes headache, sweating, palpitations and other signs and symptoms of apparent catecholamine excess occurring in paroxysms. Sympathomimetics may result in a similar presentation, potentially complicating the diagnosis.
Clinical case
We report the case of a 35-year old male with a 17-year history of drug addiction. For a long time, he complained of daily short spells of severe headache, nausea, vomiting, profuse sweating, palpitations, pallor, anxiety, tremor and constipation that were present even though the patient claimed to have given up his amphetamine addiction 18 months before referral to our clinic. During that 18-month period the patient was prescribed escitalopram, which was reported to amplify the intensity of symptoms. The patient was without a history of hypertension or other comorbidities but reported lumbar pain and digestive complaints. Due to the latter complaints, his general practitioner performed an ultrasound, which revealed a large mass in the region of the right adrenal. A 5 cm adrenal mass was confirmed by magnetic resonance imaging and the patient was referred to the Departments of Urology for adrenalectomy and Endocrinology to exclude hormonal activity. Twenty-four-hour blood pressure monitoring revealed episodic hypertension, tachycardia, and no nocturnal dipping, while biochemical

testing revealed a plasma metanephrine of 2111 pg/ml (N < 84 pg/ml) and normetanephrine of 701 pg/ml (N < 125 pg/ml). This was interpreted as unlikely to reflect amphetamine abuse. The tumor was confirmed after surgical resection by pathology. All signs and symptoms were resolved after adrenalectomy.
Discussion
In this patient, the almost complete constellation of typical signs and symptoms of a catecholamine-producing tumor was possibly ignored for some time due to the long history of amphetamine abuse. The presence of the tumor was only discovered incidentally due to abdominal complaints. It is unlikely that the persistent signs and symptoms were due to continued use of methamphetamine since all signs and symptoms completely resolved after removal of the tumor.

Association of the BclI glucocorticoid receptor polymorphism with body composition and metabolic parameters in female patients with adrenal incidentalomas

Sanja Ognjanovic, Djuro Macut, Jadranka Antic, Valentina Elezovic Kovacevic, Tatjana Isailovic, Dusan Ilic, Ivana Bozic Antic, Bojana Popovic, Tamara Bogavac & Svetozar Damjanovic
Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Centre of Serbia, Belgrade, Serbia.

Interindividual variations in tissue sensitivity to glucocorticoids (GC) have been partly attributed to polymorphisms in the glucocorticoid receptor (GR) gene. The aim of this study was to investigate whether *Bcl*I variant of the GR gene may contribute to metabolic abnormalities frequently present in patients with adrenal incidentaloma (AI). Biochemical tests and hormonal evaluation were performed in 106 consecutive women with AI. Non-diabetic patients underwent an oral glucose tolerance test with 75g glucose. Insulin resistance was assessed by homeostasis model assessment (HOMA-IR) index. The hypothalamic-pituitary-adrenal axis (HPA) activity was evaluated using the dexamethasone suppression *tests* (DST). Body composition was measured with dual-energy X-ray absorptiometry. DNA was obtained from peripheral blood leucocytes. The polymorphism was detected using PCR, RFLP and DNA sequencing. Carriers of the C allele of *Bcl*I had significantly less suppression of cortisol levels after 0.5 mg dexametasone (126.4 ± 111.4 *vs* 80.9 ± 75.7 nmol/l, $P = 0.026$). Post low-dose DST cortisol levels negatively correlated with appendicular skeletal muscle mass (AMSS) ($r = -0.023$, $P = 0.004$). 24-h urinary free cortisol level inversely correlated with total lean body mass (TLBM) ($r = -0.196$, $P = 0.007$) and lag fat mass ($r = -0.430$, $P = 0.016$). Fasting glucose (4.5 ± 0.6 *vs* 4.8 ± 0.8, $P = 0.046$) and the 2-h post-challenge glucose levels (5.4 ± 1.5 *vs* 6.7 ± 2.6, $P = 0.010$) were lower in carriers than non-carriers, as well as prevalence of type 2 diabetes mellitus (T2DM) (9.1% *vs* 26%, $P = 0.034$) and impaired glucose tolerance (IGT) (2.6% *vs* 17.5%, $P = 0.031$). We observed no differences in mean age (57 ± 9.6 *vs* 56.5 ± 11.8, $P = 0.823$), BMI (29.3 ± 6.0 *vs* 28.0 ± 6.5, $P = 0.316$), abdominal fat mass, dyslipidemia, HOMA-IR and hypertension. *BclI* polymorphism negatively correlated with T2DM ($r = -0.219$, $P = 0.034$), IGT ($r = -0.245$, $P = 0.031$), TLBM ($r = -0.232$, $P = 0.037$), ASMM ($r = -0.319$, $P = 0.004$), and positively correlated with percentage of leg fat ($r = 0.221$, $P = 0.047$). Our results indicate intra-individual tissue-specific sensitivity to GC. *BclI* polymorphism has been associated with relative GC resistance of the HPA axis and peripheral fat tissue, and GC hypersensitivity at the muscle level. Insulin sensitivity and glucose homeostasis could be possibly modulated by muscle and leg fat masses. This polymorphism has a protective role and reduces the risk of diabetes in women with AI, particularly in a state of subtle cortisol excess.

A case of Von Hippel-Lindau disease with bilateral pheochromocytoma and ectopic hypersecretion of intact parathyroid hormone

Marwa Bennour, Ibtissem Oueslati, Ons Rejeb, Sabrine Mekni, Meriem Yazidi, Wafa Grira, Fatma Chaker & Melika Chihaoui
Department of Endocrinology, La Rabta Hospital, Tunis, Tunisia.

Introduction
Von Hippel-Lindau (VHL) disease is an autosomal dominant inherited syndrome predisposing to a variety of highly vascularised tumors in different organs. Although bilateral pheochromocytoma was reported in patient with VHL disease, the coexistence of primary hyperparathyroidism is not a common condition. Herein we report a case of a primary hyperparathyroidism secondary to an ectopic secretion of intact parathyroid hormone (PTH) in a patient with VHL disease and bilateral pheochromocytomas.
Observation
A 17-year-old woman was referred to our department for exploration of a newly diagnosed diabetes mellitus with severe arterial hypertension. Her past medical history was unremarkable. As symptoms, she had headaches, palpitations and hot flashes. On examination, she had a body mass index of 21 kg/m^2, a blood pressure of 200/100 mmHg, a regular pulse of 120 bpm and multiple café-au-lait spots. Thyroid exam was normal. Blood tests disclosed hypercalcemia (111 mg/l, normal range: 85–105) with increased intact PTH level (182 pg/ml, normal range: 10–65) consisting with the diagnosis of primary hyperparathyroidism. 24-hour urinary nor*metanephrine* level was elevated (3150 µg/24h, normal range: 30–440) pointing to a catecholamine-secreting tumor. Thyroid functions, 25 OH vitamin D and calcitonin tests were normal. The abdominal computed tomography showed two adrenal masses; the first in the right measuring 35 * 55 * 70 mm with a spontaneous density of 130 UH enhanced in the arterial time heterogeneously showing areas of necrosis with an absolute washout of 40%, the second in the left measuring 24 * 27 mm and is well limited. MIBG scintigraphy exhibited a high accumulation of tracer in both adrenal tumors. Cervical ultrasound and (99mTc)-sestamibi scintigraphy were normal. Genetic testing revealed a mutation of the VHL gene. After medical preparation, patient underwent a bilateral adrenalectomy and the pathological examination confirmed bilateral adrenal pheochromocytoma. The postoperative evolution was marked by the spontaneous normalization of calcium and PTH levels.
Discussion and conclusion
Coexisting pheochromocytoma and primary hyperparathyroidism usually occurs as a part of multiple endocrine neoplasia and was rarely reported in VHL disease. In our case, the elevation of intact PTH and its spontaneous normalization after surgical treatment of pheochromocytoma confirm its ectopic secretion. Therefore, we consider that controlling calcium and PTH levels postoperatively remains useful if the topographic assessment of primary hyperparathyroidism associated with pheochromocytoma was negative.

Adrenal pheocromocytoma during childhood – a case report

Eugénia Silva, Clara Cunha, Cátia Ferrinho, Rute Ferreira & Manuela Oliveira
Hospital Egas Moniz, Lisbon, Portugal.

Pheochromocytoma is a rare tumor made up of chromaffin cells from the adrenal medulla that secrete catecholamines. It can occur at any age, with a peak incidence between the fourth and fifth decade of life, and only 10% of cases occur in children. The majority of cases are sporadic and approximately 10% are malignant. The existence of familial syndrome, multiple or extra adrenal tumors is more common at younger ages. The clinic is very variable, and hypertension (HTA) is the most frequent manifestation (90% of cases). We present a case report of a 15-year-old girl with no relevant personal history taken to the Emergency Department with complaints of intense headaches with progressive aggravation accompanied by visual disturbances. At physical evaluation, she was hypertensive and the ophthalmologic observation revealed severe hypertensive retinopathy. There was no family history of hypertension, or use of oral contraception. Laboratory tests showed elevation of urinary metanephrines (1302.2 ug/24h N: 64–302), urinary normetanephrines (4178.1 ug /24 h, N: 162–527), serum cromogranin A (47.7 mmol/l N < 3) and parathyroid hormone (PTH) (111.5 pg/ml, N: 15–65); normal calcium and calcitonin; and vitamin D deficiency. Abdominal CT revealed a 6.5 × 5.3 × 6 cm mass in the left adrenal gland, with nodular morphology and regular contours. MIBG scintigraphy was compatible with a tumor of cells derived from the neural crest at the left adrenal gland without other images of uptake. The patient underwent a left laparoscopic supradrenalectomy, and the histology confirmed the diagnosis of pheochromocytoma. Genetic study was negative for mutations of the RET, SDHB, SDHD and VHL genes. In the last evaluation, the patient was asymptomatic, normotensive and without biochemical or imagiologic evidence of the disease. Although unusual, it is intended with this case to recall the importance of considering the diagnosis of pheochromocytoma in the investigation of hypertension in the child/adolescent. It is a treatable cause of hypertension and potentially lethal if not diagnosed in a timely manner. Family syndromes should always be excluded in this age group.

Adrenal morphology in a large cohort of adult subjects with congenital adrenal hyperplasia due to 21-hydroxylase deficiency

Claudia Oriolo, Daniela Ibarra Gasparini, Paola Altieri, Francesca Ruffilli, Francesca Corzani, Guido Di Dalmazi, Valentina Vicennati, Uberto Pagotto & Alessandra Gambineri
Endocrinology Unit, Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy.

Introduction
The adrenal morphology in congenital adrenal hyperplasia (CAH) is poorly described in the literature, so that adrenal radiological evaluation is not recommended in patients with CAH. The aim of this study was to evaluate the adrenal morphology in a large cohort of adult patients with CAH due to 21-hydroxylase deficiency and its correlation with the subtype of CAH (non-classical-NCAH, simple virilizing-SV, or salt wasting-SW), the hormonal status and the treatment regimen, respectively.
Methods
We conducted a retrospective study on a population of 96 adult CAH patients in care at our Endocrinology Unit since 2002; 54 patients had the NCAH, 12 the SV and 30 the SW form. At the first visit all patients performed an abdominal Computed Tomography (CT) prior to and after administration of the contrast medium. Clinical parameters, hormonal status and the cumulative dose of glucocorticoid therapy in pediatric agewere analyzed.
Results
Based on CT scan, 51 patients (53%) resulted with normal (NM group) and 45 (47%) with abnormal adrenal morphology (AM group), of which 40 subjects (89%) had micronodular hyperplasia (microH subgroup), whereas 5 (11%) had macronodular hyperplasia (macroH subgroup). ACTH and 17OH-progesterone measured at the time of the CT scan and the cumulative dose of hydrocortisone taken by the time of the diagnosis differed between NM and AM groups. In particular, ACTH levels were 31.8 ± 5.7 pg/ml in NM group and 70.4 ± 11.5 pg/ml in AM group (P value <0.01); 17OH-progesterone levels were 1344 ± 396 ng/dl in NM group and 3342 ± 746 ng/dl in AM group (P value <0.05); and the cumulative dose of hydrocortisone was 104.6 ± 6.6 g in NM group and 68.5 ± 8.1 g in AM group (P value <0.05). When analyzed according to the subgroups, ACTH levels were 65.1 ± 10.6 pg/ml in microH subgroup and 112.6 ± 62.7 pg/ml in macroH subgroup (P value <0.01); 17OH-progesterone levels were 3038 ± 647 ng/dl in microH subgroup and 5773 ± 4559 ng/dl in macroH subgroup (P value <0.01); and the cumulative dose of hydrocortisone was 58.7 ± 7.4 g in microH subgroup and 141.4 ± 29.4 g in macroH subgroup (P value <0.05).
Conclusions
The insufficient treatment of CAH seems to be associated with adrenal hyperplasia and its progression towards adrenal micro and macronodules. Clinicians should be aware that an evaluation of adrenal morphology is recommended in these adult patients, regardless of the subtype of CAH.

Vitamin D status and linear growth in a sample of Egyptian adolescents

Maram M Aboromia, Raef Malak, Laila Hindawy, Heba Abdelmonem & Inas Sabry
Ain Shams University, Cairo, Egypt.

Vitamin D deficiency is a worldwide health problem. The lack of appreciation of the importance of sensible sun exposure for providing children and adults with their vitamin D requirement has led to a worldwide vitamin D deficiency pandemic,vitamin D deficiency can have a negative influence on bone development, causing not only rickets, but also interfering with attainment of genetically programmed height.
Aim of the study
To assess vitamin D status among healthy egyptian adolescents and its relation to height percentile.
Methods
Our study was conducted on 180 healthy adolescent males and females aged 10–19 years, Subjects with chronic systemic diseases and those with height <2 S.D. below the mean of their age were excluded from our study, detailed history including sun exposure, dietary pattern, socioeconomic status, physical and anthropometric evaluation, Laboratory investigations including: Hb concentration, serum creatinine, Serum albumin, corrected serum total calcium, serum phosphorus, serum 25 hydroxy-vitamin D level by Elisa.
Results
The prevalence of vitamin D deficiency was 142 out of 180 (78.9%), 88 out of 180 (48.89%) had moderate deficiency (10–20 ng/ml, this was significantly higher among females, mean serum 25 (OH) D3 level was 22.45 ± 9.114, therewas a positive significant correlation between vitamin D level and stature for age percentile ($r=0.174$) ($P=0.019$).
Conclusion
Subclinical vitamin D insufficiency and deficiency are common problems in apparently healthy Egyptian adolescents with negative impact on height percentile.

The effectiveness of colecalciferol and selective vitamin D receptor agonists treatment on secondary hyperparathyroidism in chronic kidney diseases patients

Lilit Egshatyan[1,2,3], Natalia Mokrisheva[4] & Alexander Lutsenko[1]
[1]Endocrinology Research Centr, Moscow, Russian Federation; [2]A.S. Loginov Moscow Clinical Scientific Center, Moscow, Russian Federation; [3]A.I. Evdokimov Moscow State University of Medicine and Dentistry, Moscow, Russian Federation; [4]Endocrinology Research Centre, Moscow, Russian Federation.

Background
Secondary hyperparathyroidism (SHPT) is an early complication of chronic kidney disease (CKD). Maintaining the level of 25(OH)D and parathyroid hormone concentrations in the target range reduce its associated complications (fractures and cardiovascular calcification).
Aims
To examine the effectiveness of vitamin D supplementation and selective vitamin D receptor agonists treatment on SHPT in CKD.
Materials and methods
Prospective observational study to evaluate the efficacy and safety of vitamin D therapy SHPT in 54 in patients with CKD. The first phase (24 weeks) – treatment of suboptimal 25-hydroxycalciferol (25(OH)D) levels. The second (16 weeks) – treatment colecalciferol-resistant SHPT by combination of cholecalciferol with paricalcitol. Blood samples were taken to assess parathyroid hormone (PTH), 25(OH)D, creatinine, calcium, phosphorus levels and calcium excretion.
Results
After 8 weeks of cholecalciferol treatment all patients achieved 25(OH)D levels above 20 ng/ml, however 78% of patients still had SHPT. After 16 weeks, the decrease of PTH was achieved in all patients, but significantly only in patients with CKD 2 (19.2%, $P<0.01$) and 3 (31%, $P<0.05$), compared with CKD 4 (17%, $P>0.05$). After 24 weeks of therapy, PTH normalized in all patients with CKD 2, in 15 (79%) with CKD 3 and in 9 (50%) patients with CKD 4. Cholecalciferol treatment resulted in a substantial increase in 25(OH)D levels with minimal or no impact on calcium, phosphorus levels and kidney function. After 24 weeks we initiated combination therapy (cholecalciferol and paricalcitol) for patients with colecalciferol-resistant SHPT ($n=13$). PTH levels decreased from 149.1 ± 13.4 to 118.2 ± 14.1 pg/ml at 8 weeks, and to 93.1 ± 9.7 pg/ml ($P<0.05$) at 16 weeks of treatment. No significant differences in serum calcium, phosphorus or urinary calcium levels. Normalization of PTH was achieved in all patients with CKD 3 and in 8 patients with stage 4. One patient with CKD 4 needed an increase in paricalcitol dose.
Conclusions
Cholecalciferol can be used in correcting vitamin D deficiency in patients with all stages of CKD, however, its effectiveness in reducing PTH in stage 4 is limited. Selective analogs, such as paricalcitol, were well-tolerated and effectively decreased PTH levels.

Osteoporosis in developing-nations: need for centralized-data-collection & treatment-guidance centers to study epidemiology

S Pal, G Gupta & T Roy
SFCCP, Meerut, India.

Issues
This is non-interventional, Demographic, observational study in asian population. Osteoporosis common in Developing-nations. Not-a-single Center exist designated for diagnosis/treatment. No proper epidemiological, mortality/

morbidity data available. In asian population Osteoporosis is diagnosed at advanced stage hence poor-prognosis. Worsened by High incidence of malnourished. Increased awareness/improved diagnosis needed to identify cases.
Aim
To study osteoporosis treatment issues by survey among 40 endocrine practitioners.
Methodology
$n=40$, survey questionnaire distributed among these 40 endocrine practitioners. 27 from private clinics and 13 from government hospitals. From July 2016 to April 2017 all responses evaluated and suggestions compiled.
Current therapy problems
High incidence of crude-tobacco-smoking in Asian countries increases osteoporosis-rate. Therapy restricted to supportive care, as diet-modification. Treatment drugs needs to be provided at subsidized cost to rural/tribal areas to decrease Osteoporosis related fractures mortality. Lack of diagnosis, Rx-expertise in rural/tribal india makes poor Rx-Outcome. We need national-Osteoporosis-registry, educate doctors about diagnosis/treatment to improve QOL. Treatment-cost non-affordable to majority sufferers.
Conclusion
Alternative Therapies as antioxidants gaining reputation in endocrine disorders. we patient advocates from NGO's working in rural/tribal areas of developing-nations can collaborate with Osteoporosis-care-centers from USA-Europe for training/upgrading staff. we participants need collaboration with ESE in research-projects in resource-poor-nations. We asian-representatives need exposure to research methodologies used by European-experts in endocrinolohy. Our institute working since 2007 on health-education & Osteoporosis prevention intends to raise these issues at congress venue.

Prevalence and the main risk factors for vitamin D deficiency in pregnant women living in a locality of Algiers

Mouna Mezoued[1,2], Djamila Meskine[1,2] & Ramezzedine Belaidoumou[3]
[1]Algiers University, Algiers, Algeria; [2]Eph Bologhine, Algiers, Algeria; [3]chu bab eloued, Algiers, Algeria.

Introduction
Vitamin D deficiency seems to be common in pregnant women and would be associated with an increased risk of maternal and fetal poor outcomes.
Aim of the study
Determine the prevalence and the main risk factors for vitamin D deficiency in pregnant women living in a locality of Algiers.
Material and method
It is a cross-sectional prospective and descriptive study. 310 pregnant women of west Algiers were followed during their pregnancy, by Plasma 25-hydroxyvitamin D (25-OHD) sampling between 24 and 28 weeks of amenorrhea and a second one between 37 and 40 weeks. An univariate and a logistic regression test was assessed to identify potential factors for vitamin D deficiency, and an univariate analysis to assess impact of this deficiency on the course of the pregnancy and on the newborn.
Results
We have followed 310 pregnant women with a mean age of 30.36 ± 5.38 years. Mean BMI is 26.67 ± 4.49 kg/m^2. Mean plasmatic level of Vitamin D in the second trimester of pregnancy is 7.80 ± 5.06 ng/ml 4–33.6 ng/ml. 96.1% of pregnant women had levels of vitamin D under 20 ng/ml; 88.7% levels of vitamin D under 12 ng/ml, and a severe deficiency under 5 ng/ml in 27.1% of the women. The same results are found at the end of the pregnancy with a mean level of vitamin D of 7.39 ± 5.11 ng/ml 4–42,4 ng/ml. 96.2% of the pregnant women have a vitamin D level inferior to 20 ng/ml, 89.3% inferior to 12 ng/ml, and a severe deficiency in 33.8% of the cohort. The daily dietary intake of vitamin D is estimated at 260.00 ± 254.80 UI/j, clearly lower than the recommended dose. Vitamin D deficiency risks factors founded in the logistic regression analyse are seasons of low sunshine, ORa 3,116, IC à 95% 1,524–6,371, $P=0{,}002$, the wear of covering clothes ORa 13,131(IC à 95%: 4,084–42,217), $P<10^{-3}$, and non vitamin D supplementation during pregnancy ORa 5,841(IC à 95% 2,890–13,105) $P<10^{-3}$. We did not find any statistic link between vitamin D deficiency and obstetric complications: pre-eclampsia, gestational diabetes, premature delivery and Caesarean Delivery. Neither the link with low birth weight and neonatal hypocalcaemia.
Conclusion
It is the First study evaluating the status of vitamin D in pregnant women carried out in Algeria. High prevalence of vitamin D deficiency indicates the need for urgent implementation of national recommendations.

Effects of dexamethasone for calcium channels and mucin-related genes regulation on A549 cell line

Bo-Hui Jeon, Dinh Nam Tran, Yeong-Min Yoo & Eui-Bae Jeung
Chungbuk National University, Cheongju, Republic of Korea.

Calcium is important for physiological functioning in many tissues and is essential in mucus secretion. Previously reported, Mucin secretion is regulated predominantly by cytosolic calcium-dependent pathways. Cytosolic of calcium are regulated by calcium channels such as TRPV6, NCX1, and PMCA1. A549 cell line was treated with 10^{-8} M dexamethasone (DEX) and 10^{-6} M RU486. Subsequently, the expression of TRPV6, NCX1, and PMCA1 in A549 cell line were examined. There was no significant differences in PMCA1 expressions in DEX-treated groups, but TRPV6 was increased in DEX-treated groups and was recovered by DEX + RU486 treatment. NCX1 was decreased in DEX-treated groups and was recovered by RU486 treatment. In addition, mucin secretion, related genes MUC4 and MUC5AC, was also decreased by DEX treatment. Control of calcium channel gene expression may affect the control of mucus secretion in the lung cancer. These results could be used for understanding the basis of treatment mucin secretion related disease such as cancer.

Regulatory effect of dexamethasone on tracheal calcium processing proteins and mucosal secretion

Bo-Hui Jeon, Bonn Lee, Eui-Man Jung & Eui-Bae Jeung
Chungbuk National University, Cheongju, Republic of Korea.

Introduction
Dexamethasone inhibits mucin secretion considering the primary option for treating acute asthma exacerbation. However, the mechanism underlying dexamethasone-induced decreased in mucosecretion is unclear. Recent studies have reported that dexamethasone exerts an inhibitory effect on mucosecretion in the lung by modulating the expression of calcium-processing genes. However, the expression of the calcium-processing genes in trachea are not examined yet. Thus, the present study is the first to report glucocorticoid-induced regulation of calcium processing genes such as transient receptor potential vanilloid-4 (*Trpv4*), transient receptor potential vanilloid-6 (*Trpv6*), calbindin-D_{9k} (*CaBP-9k*), and plasma membrane Ca^{2+}-ATPase (*Pmca1*) in the mouse trachea.
Materials and methods
In this study, mice were subcutaneously injected with dexamethasone for 5 days, or injected with estradiol or progesterone for 3 days. The tracheal tissues were collected by dividing the trachea into cervical and thoracic sections based on its anatomical structure. Real-time PCR was performed to investigate mRNA expression of calcium-processing genes. Immunohistochemistry and immuno-fluorescence were performed to localize the calcium-processing proteins. Tracheal mucosubstances were detected by performing Alcian blue-periodic acid-Schiff staining.
Results
The localization of TRPV4, TRPV6, CaBP-9k, and PMCA1 proteins was detected in the tracheal epithelium, submucosal glands, cartilages and muscles. Dexamethasone treatment downregulated the mRNA expression of the four calcium-processing genes and mucin 1, mucin 4, mucin 5ac, and mucin 5b genes. Dexamethasone decrease in the secretion of mucosubstances in the trachea.
Conclusions
The findings of the present study suggest that glucocorticoids regulate the tracheal expression of calcium-processing genes and tracheal mucosecretion.

The effect of steroid hormone on the expression of the calcium-processing proteins in the immature rat brain

Seon Myeong Go, Seon Young Park, Jae-Hwan Lee & Eui-Bae Jeung
Chungbuk National University, Cheongju, Republic of Korea.

The cytosolic calcium concentration is regulated by calcium-processing proteins such as transient receptor potential cation channel subfamily V member 5 (TRPV5), TRPV6, sodium-calcium exchanger 1 (NCX1) and plasma membrane Ca^{2+} ATPase 1 (PMCA1). Those calcium-processing proteins are important for physiological functions in the brain. The effects of steroid hormones on

calcium-processing protein expressions in the brains are undescribed. Thus, the effects of steroid hormones on the distribution, localization, and expressions of calcium-processing proteins in the brain were analyzed. Immature female rats were injected for 5 days with estrogen (E2), progesterone (P4), dexamethasone (DEX), and their antagonists (ICI 182,780 and RU486). The localization and expression of calcium-processing proteins in rat brain were observed by immunofluorescence and western blot analyses, respectively. We found that TRPV5 and TRPV6 proteins were highly expressed in the cerebral cortex (CT), hypothalamus (HY), and brain stem (BS) compared to that in the olfactory bulb (OB) and cerebellum (CB). Also, the NCX1 protein was highly expressed in CT and BS compared to that in OB, HY, and CB, and PMCA1 protein was highly expressed in CT compared to that in other brain regions. Furthermore, expression levels of TRPV5, TRPV6, NCX1, and PMCA1 proteins were regulated by E2, P4, and/or DEX in the CT and HY. In summary, calcium-processing proteins are widely expressed in the immature rat brain, and expressions of calcium-processing proteins in CT and HY are regulated by E2, P4, and/or DEX and can be recovered by antagonist treatment. These results indicate that steroid hormone regulation of TRPV5, TRPV6, NCX1, and PMCA1 proteins may serve as a critical regulator of cytosolic calcium absorption and release in the brain.

Distribution of and steroid hormone effects on calbindin-D9k in the immature rat brain

Seon Mi Park, Seon Young Park, Dinh Nam Tran & Eui-Bae Jeung
Chungbuk National University, Cheongju, Republic of Korea.

Calbindin-D_{9k} (CaBP-9k), one of the major calcium-binding and calcium-buffering proteins, is important in the physiological functioning of organs. The neuroanatomical localization of CaBP-9k in the rodent brain has not been reported; thus, this study investigated the neuroanatomical distribution of CaBP-9k and the regulation of CaBP-9k expression on steroid hormones in the immature rat brain. To confirm the influence of steroid hormones on CaBP-9k expression, immature female rats were injected for 5 days with estrogen (E2), progesterone (P4), dexamethasone (DEX), and their antagonists (ICI 182, 780 and RU486). The localization and expression of the CaBP-9k protein in brain regions were identified by immunofluorescence and western blot assays, respectively. We observed that CaBP-9k expression was especially strong in hypothalamus, cerebellum, and brain stem. In addition, CaBP-9k was colocalized with mature-, GABAergic, dopaminergic, and oxytocinergic neurons. We also observed that the CaBP-9k protein level was significantly increased by P4 and reversed by antagonist RU486 treatment in immature rat brain. In summary, CaBP-9k positive cells have a wide distribution in the immature rat brain, and CaBP-9k expression is regulated by P4. We suggest that CaBP-9k regulated by steroid hormone may serve as an important regulator of cytosolic calcium concentration in the brain.

Pledoary for using Trabecular Bone Score as a method for osteoporosis diagnosis, not only for the risk

Adrian Sarbu[1,2], Serban Motoiu[3], Mara Carsote[4], Cosmina Ilie[3], Mihaela Tocilescu[3], Dana Cristina Staicu[3], Dan Peretianu[3] & Bogdan Oprisan[5]
[1]SANA Monitoring, Bucharest, Romania; [2]SANA Medical Center, Bucharest, Romania; [3]Medical Center Povernei, Bucharest, Romania; [4]Institute of Endocrinology, Bucharest, Romania; [5]Department of Biophysics, Faculty of Medicine, Iassy, Romania.

Introduction
Trabecular bone score (TBS) was introduced in FRAX, to evaluate more precisely the risk for fracture. However, FRAX is a method for editing a risk, not for making a diagnosis. WHO established conventionally, based on the level of standard deviation (SD), named T score, for Bone Mineral Density (BMD) that $< -2,5$ SD is compatible with the diagnosis of osteoporosis.
Aim
Our aim was to analyze if it is possible to used T score (SD) for TBS in the diagnosis of vertebral osteoporosis, in the same manner, i.e. conventionally, as it is used BMD. Two arguments could sustain our goal: 1. since the predictive ability to show the fractures of TBS is independent of FRAX clinical risk factors and femoral neck BMD; and 2. the calculated probabilities for fracture have been shown to be more accurate when classical FRAX was computed with TBS.
Method
1. DEXA machine - GE-Lunar Prodigy Pro #500074. TBS soft - TBS iNsight®, version 3.0.2.0. 2. There were registered 4 TBS/BMD T scores: a. the highest T scores; b. the lowest TBS T score; c. BMD T scores corresponding to 'a' and, respectively, 'b'. 3. T test was performed for analyzing the difference between scores. 4. Conventionally - 2,5, and -1 T scores were used for an interference graphic between TBS and BMD.
Results
A. Patients: no. 536 women: 508 men: 28 (5.22%), mean age: 65.94 years. B. T score averages: Lowest TBS: -3.48. Corresponding BMD: -1.61. Highest TBS: -1.43. Corresponding DMO: -1.32. C. T tests: for highest TBS/BMD scores: $P \ll 0.001$. For lowest TBS/BMD scores: $P = 0.19$. D. Interference graphic: a. TBS > -1: BMD $> -1 = 24/4.5\%$; BMD -1 - $-2.5 = 6/1.1\%$, BMD $< -2.5 = 4/0.7\%$. b. TBS -1 - -2.5: BMD $> -1 = 41/7.6\%$; BMD -1 - $-2.5 = 51/9.5\%$, BMD $< -2.5 = 21/3.9\%$. c. TBS < -2.5: BMD $> -1 = 69/12.9\%$ (lack of diagnostic); BMD -1 - $-2.5 = 187/34.9\%$ (lack of diagnostic), BMD $< -2.5 = 133/24.8\%$.
Conclusions
1. The lowest TBS T score was more altered than the lowest BMD T score, $P \ll 0.001$, suggesting that the vertebral microarchitecture modify before losing bone. 2. This should be the moment when considering the starting treatment. 3. When interfering TBS T score with BMD T score, it seems that 47.8% (12.9 + 34.9) of patients lack the osteoporosis diagnostic. 4. Therefore, TBS should be used as a tool for osteoporosis diagnostic not only for calculating risks.

Relationship between leptin level, body mass index and parathyroid hormone in chronic hemodialysis patients

Ivona Risovic[1,2], Snjezana Popovic Pejicic[1,2], Vlastimir Vlatkovic[1,2] & Gabrijela Malesevic[1,2]
[1]University Clinical Center of the Republic of Srpska, Banja Luka, Bosnia and Herzegovina; [2]University of Banja Luka, Faculty of Medicine, Banja Luka, Bosnia and Herzegovina.

Bone metabolism disorders in hemodialysed patients (HD) involve several humoral factors, of which PTH plays the central role. Leptin is a protein hormon secreted by the adipocytes and related to malnutrition, anemia and bone metabolism disorders in chronic kidney disease patients. The aim of the study was to was to evaluate serum leptin levels and bone metabolism in chronic HD patients depending on body mass index (BMI). This cross section study included 93 HD patients distributed based on BMI in: underweight ($n = 7$), normal weight ($n = 38$), overweight ($n = 38$) and obesity ($n = 10$). Underweight patients had significantly significantly lower leptin level (2.02 ± 1.7 vs 8.62 ± 10.66 vs 32.99 ± 34.52 vs 78.02 ± 51.61, $P < 0.001$), higher PTH level (686.42 ± 1100.43 vs 271.60 ± 321.47 vs 242.0 ± 271.54 vs 254.20 ± 280.68 $P < 0.001$) and higher alkalne phosphatase (156.27 ± 27.13 vs 81.92 ± 44.69 vs 84.50 ± 28.16 vs 66.70 ± 19.27, $P < 0.001$). There were no significant differance in calcium and phosphate level between groups. A significant direct correlation was observed in all groups between leptin level and BMI ($P < 0.001$) and indirect correlation between leptin and PTH level in underweight and obesity group ($P < 0.05$). Hypoleptinemia in chronic HD patients was associated with high PTH and undernutrition.

Challenging clinical case of primary hyperparathyroidism caused by atypical adenoma

Hamza Elfekih, Hanene Sayadi, Dhia El Hak Abid, Malak Kechida, Om Kalthoum Sallem, Hela Marmouche, Rim Klii & Ines Khochtali
Department of Endocrinology and Internal Medicine, Fattouma Bourguiba University Hospital, Monastir, Tunisia.

Introduction
Primary hyperparathyroidism (PHPT) is a frequent endocrinopathy caused mostly by parathyroid adenoma. Classic manifestations, less prevalent nowadays, may have a misleading aspect. Here we describe the case of a patient presenting nephrolithiasis, multiple brown tumors revealing PHPT.

Observation
A 37-years-old female was diagnosed with nephrolithiasis treated by shockwave lithotripsy without success. CT scan showed coralliform lithiasis in addition to multiple lytic lesion in the pelvis and the fourth lumbar spine suggestive of metastasis. Bone biopsy was done revealing a brown tumors aspect. High blood level of calcium (3.46 mmol/l) and PTH (836 pg/ml) confirmed the diagnosis of PHPT associated with low 25-Hydroxy-vitamin D concentration (11.9 ng/ml). She had constipation, bone pain, asthenia and weight loss. The neck examination showed a lateral neck tumefaction corresponding to a 3 cm nodule. The ultrasonography and MIBI scan confirmed an upper left parathyroid adenoma which was resected after a medical preparation. The anatomopathological examination found an atypical adenoma due to mitosis and necrosis. After surgery, the patient developed hypocalcemia requiring alfacalcidiol and calcium supplementation. PTH level, dropped initially after surgery to 57 pg/ml, kept increasing to 187–264 pg/ml although the normal postoperative MIBI scan and the absence of hungry bone syndrome. A molecular analysis of CDC73 gene was done since the diagnosis of parathyroid carcinoma is highly suspected.
Conclusion
Palpable parathyroid tumor, high serum calcium and PTH levels must attract attention to suspect the diagnosis of parathyroid carcinoma which remains difficult to differentiate it from atypical adenoma.

Severe hypocalcemia: when the skin expresses itself

Sara Askaoui, Guizlane Lmghari, Sana Rafi & Nawal El Ansari
Departement of Endocrinolyg, Marrakech, Morocco.

Introduction
Impetigo herpetiformis is a rare dermatological disorder, mimicking generalized pustular psoriasis. It is characterized by a generalized erythema-pustular eruption accompanied by fever. Its etiopathogenesis is poorly coded but triggers have been identified such as hypocalcemia in more than half of cases and pregnancy. We report a case of severe hypocalcemia secondary to hypoparathyroidism revealed by impetigo herpetiformis.
Case report
Forty-six-year-old patient with lobo-ishmectomy at 12 years of age with iatrogenic hypoparathyroidism undergoing replacement therapy, had been presenting for 15 days erythematous cupboards which had recently confused, with a notion of stopping the ergocalciferol for 2 months. The admission examination found a febrile patient at 38.5°C with erythroderma covering more than 80% of the skin surface, strewn with afollicular pustules. The mucous membranes were spared. The neurological examination was without abnormalities. Biology revealed severe hypocalcemia at 57 mg/l, hyperphosphoremia, with PTH at 2 µg/ml (VN> 24). The ECG showed a long corrected QT space. The histological aspect was that of impetigo herpetiformis. The patient was treated with calcium infusion and 3 g/day of oral calcium and 2 microgram of ergocalciferol per day. The evolution was marked by the regression of the pustules of more than 90% of the lesions with appearance of desquamation plaques wide at the 4th day, with a complete disappearance of the lesions at the 8th day, concomitant with the correction of the calcemia.
Discussion
Impetigo Herpetiformis is a rare skin disorder. The factors implicated are mainly hypocalcemia and pregnancy, then cortisone withdrawal, topical corticosteroids with high activity under occlusive dressing, bethalactamines, lithium, stress and alcohol intoxication. Cadherins are essential for cell adhesion and these molecules are calcium-dependent. Vitamin D plays an important role in the differentiation and proliferation of skin cells.
Conclusion
All observations of amicrobial pustulosis illustrate the definite relationship between the rash and the calcium-PTH-vitamin D axis, presumably by hypocalcemia.

Ultrasound detection of parathyroid hyperplasia in patients with chronic kidney disease treated by dialysis

Gergana Tosheva, Mira Siderova & Kiril Hristozov
University Hospital ‘St. Marina’, Varna, Bulgaria.

Aim
The aim of this prospective study is to assess if there is any correlation between parathyroid hyperplasia detected by ultrasound and variables connected with secondary hyperparathyroidism (SHPT) in patients with chronic kidney disease (CKD) stage 5, treated by dialysis and to determine the PTH level, above which the hyperplasia of parathyroid glands could be visualized.
Methods
Thirty-one patients (14 men and 17 women) with CKD stage 5, treated by haemodialysis for more than 6 months in The University Hospital ‘St. Marina’ in Varna, Bulgaria participated in the study. There are divided in two groups according to the presence of parathyroid hyperplasia visible by high- resolution ultrasound: group 1- patients without parathyroid hyperplasia and group 2- patients with visible hyperplasia. We analysed variables such as duration of dialysis and CKD, levels of parathyroid hormone (PTH), calcium, phosphorus, calcium x phosphorus, alkaline phosphatase. In group 2 we also assessed the number of enlarged parathyroid glands, their total volume, the volume of the most enlarged parathyroid gland and the cut-off value for PTH above which the hyperplasia is visualized by ultrasound.
Results
Using a high-resolution ultrasound we detected parathyroid hyperplasia in 24 patients (77.4%). In group 2 the average PTH level is significantly higher compared to group 1 (P 0.00) with higher levels of phosphorus, calcium x phosphorus, alkaline phosphatase, duration of the CKD and time on dialysis therapy. Significant difference in alkaline phosphatase levels between the two groups is also observed (P 0.004). There is moderate significant correlation between the total volume of enlarged parathyroid glands and levels of phosphorus (r 0,443) and calcium x phosphorus (r 0.466). According to our results the level of PTH above which the hyperplasia becomes visible is 617.5 pg/ml.
Conclusions
SHPT is a relatively common abnormality seen among patients suffering from chronic kidney disease. Its early detection is very important for starting an appropriate therapy, preventing bone and cardiovascular complications.

Multiple fragility fractures in young female patients caused by FGF23-induced hypophoshatemic osteomalacia

Tatiana Grebennikova[1], Konstantin Slashchuk[1], Natalia Tarbaeva[1], Liudmila Rozhinskaya[1], Svetlana Rodionova[2], Galina Melnichenko[1], Pavel Rumjantsev[1] & Zhanna Belaya[1]
[1]The National Medical Research Centre for Endocrinology, Moscow, Russian Federation; [2]N.N. Priorov Central Scientific Research Institute of Traumatology and Orthopedics, Moscow, Russian Federation.

Tumor-induced osteomalacia (TIO) is a rare paraneoplastic syndrome of abnormal phosphate metabolism caused by a small mesenchymal tumor that secrete fibroblast growth factor 23 (FGF23). A 29-year-old female has suffered from two low-traumatic hip fractures, multiple fractures at the pelvic and sacrum, and diffuse bone pain for more than 3 years. Her mobility was limited in the last year (used crutches) because she had severe muscle weakness. Laboratory examination at the time of admission showed serum phosphate – 0.4 mmol/l (0.87–1.45), alkaline phosphatase 490 U/l (50–150), tubular reabsorption of phosphate (TRP) 45% (85–95%). Somatostatin receptor scintigraphy with 99 mTc-HYNIC-TOC revealed subcutaneous tumor in the left femur. CT scan confirmed the location of a tumor in the proximal left femur, 10×11×29 mm in size. The patient had complete recovery in phosphate levels the next day after surgical treatment, which remained within the reference range after 6 months of follow-up. The clinical improvement was evident after 3 months of observation when the patient fully restored the normal ability to walk without crutches. Histopathology confirmed mesenchymal tumor. A 34-year-old female suffered from bone pain, muscle weakness and decrease in height by 20 cm more than 8 years. At the age of 31, the patient developed two low-traumatic hip fractures and multiple vertebral fractures. The routine investigation at the time of admission revealed: serum phosphate 0.54 mmol/l (0.87–1.45), alkaline phosphatase 656 U/l (50–150), TRP 57.5% (85–95%). Somatostatin receptor scintigraphy with 99 mTc-HYNIC-TOC showed lesion in the subcutaneous tissue of left hip. CT scan confirmed the location of the tumor, 30 mm in diameter. Surgical treatment was effective for phosphate normalization and clinical improvement of the patient. Conclusion: tumor-induced osteomalatia should be suspected in young patients with fragility fractures. Serum phosphate and tubular reabsorption

phosphate measurements along with somatostatin receptor scintigraphy with 99mTc-HYNIC-TOC are sufficient for TIO diagnostics with a good prognosis after successful treatment.

Clinical significance of parathyroid incidentalomas during thyroidectomy: a South Indian experience

Ramakanth Bhargav Panchangam[1], Chakrapani B[2] & Sabaretnam M[3]
[1]Endocare Hospital, Vijayawada, India; [2]SGPGIMS, Lucknow, India; [3]Neuro Hospital, Nizamabad, India.

Background
Often parathyroid indicentalomas (PI) in the form macroscopically enlarged single or multiple parathyroid glands are encountered during surgical thyroidectomy. The reported incidence in literature is variable (0.4–4.5%), but we feel its underreported compared to its frequency, as only less than 500 cases were reported thus far. Another enigma about PI is their clinical significance and natural history. In this context, we analysed our own experience and tried to derive lessons on its clinical relevance.
Methods
This is a retrospective study conducted in Endocrine Surgery department of tertiary care Hospital. All surgical thyroidectomies were performed by single primary endocrine surgeon. Study spanned over 10 years from 2009 to 2018. In all 2105 cases of thyroidectomies with no preoperative diagnosis of hyperparathyroidism are included in this study. A retrospective analysis was performed to identify patients in whom abnormal parathyroid tissue was removed at surgery.
Results
31/ 2105 patients (1.47%) had a single macroscopically abnormal parathyroid gland removed (29 patients) and two glands (in 2 cases) sent for histopathology. Twenty eight patients were found to have histological evidence of a parathyroid adenoma or hyperplasia. Three patients had normal parathyroid histology. Preoperatively, 26 patients had no abnormal serum calcium detected, 3 patients had raised serum calcium level and in 3 patients serum calcium testing was not done. Postoperatively, 25 patients had normal calcium, six had temporary hypocalcaemia. Two patients had temporary recurrent laryngeal nerve palsy.
Conclusions
1) We opine that the entity of PI is underreported and underinvestigated, 2) Though there is risk of removing a histologically normal gland, we believe that PI found during surgery should be excised as majority of them may be causing subclinical or early or normocalcemic hyperparathyroidism. Moreover, we have found this to be a safe procedure with minimal morbidity to the patient. By removing them at the original operation, the patient is saved complicated redo neck surgery, when clinically apparent primary hyperparthryoidism develops later, 3) The scenario of PI also emphasizes the need and provides a chance for routine clinical and biochemical evaluation for associated hyperparathyroidism in all cases of thyroid disease.

Value of ultrasonography guided fine-needle-aspiration in the diagnosis of an intrathyroidal parathyroid adenoma associated with thyroid pathology

Maria Concepcion Terroba Larumbe, Cristina Crespo Soto, Jose Maria Palacio Mures, Manuel Acuña Garcia, Marcelino Mendo Gonzalez, Marta Ventosa Viña, Itciar Anacabe Goyogana, Mar Calleja Baranda, Elisa Gil-Carcedo Sañudo & Luis Cuellar Olmedo
Hospital Rio Hortega, Valladolid, Spain.

Introduction
Intrathyroidal parathyroid adenomas (IPA) are a rare cause of primary hyperparathyroidism (PHP) and their differential diagnosis includes other parathyroid and thyroid lesions. Although $<7\%$ of parathyroid adenomas are intrathyroidal, this location represents almost 20% of ectopic cases and their preoperative identification can pose difficulties, often being an intraoperative finding.
Clinical case
A 70-year-old woman diagnosed with breast carcinoma in remission, nephrolithiasis, osteopenia, vitamin D deficiency and hypertension, was evaluated to complete the study of PHP detected in September 2016. In the laboratory tests the following was observed: calcium 12.56 mg/dl, albumin 4 g/dl, PTH 335.2 pg/ml, 25-OH-vitamin D 20 µg/l, phosphorus 2 mg/dl; renal and thyroid function were normal. The cervical CT showed 'indeterminate' hypodense thyroid nodules whose size ranges from 7 to 10 mm and the Tc99 m-sestamibi scintigraphy, a nodule in the left thyroid lobe with little probability of corresponding to a parathyroid adenoma. Therapy with cinacalcet was started but, at a 60/90 mg/day alternation, it did not control calcium and PTH, and more imaging tests were performed. In the 2nd cervical CT, 2 nodules <1 cm were identified in the right thyroid lobe and a nodular lesion of $1.2\times1.4\times2.8$ cm, with a central cystic area measuring 0.4×1.7 cm of tubular morphology and thickened walls in the left thyroid lobe. Thyroid ultrasonography-guided fine-needle-aspiration (US-FNA) showed multiple nodules <1 cm in both thyroid lobes and the nodule described in the left lobe, of $3.12\times1.26\times1.14$ cm, was heterogeneous, lobed, with thick hypoechoic halo and increased peripheral flow, and was sonographically suspicious. The cytology was compatible with parathyroid tissue and negative for malignant cells and PTH in the wash fluid was $>3{,}230$ pg/ml with a wash fluid/serum PTH ratio >18. In August 2018, left hemithyroidectomy was performed and total and ionic calcium were normal 1 day later; PTH was 3.4 pg/ml. Histopathological diagnosis: Intrathyroid parathyroid adenoma associated with nodular hyperplasia.
Discussion
In this patient, the IPA was identified by US-FNA cytology but, according to literature, this test is not always useful in recognizing the parathyroid origin of an intrathyroid nodule and PTH estimation in aspirate had an important role in diagnosis. Especially when there is concomitant thyroid pathology or it is necessary to rule out malignancy, application of both methods facilitates planning minimally invasive parathyroidectomy techniques.

The effect of parathyroidectomy on the BMD in postmenopausal women with mild primary hyperparathyroidism: the results of comparative retrospective dynamic study

Elena Brutskaya-Stempkovskaya[1], Alla Shepelkevich[1], Tatiana Leonova[2], Natalia Rekechinskaya[2], Artur Pisarenko[2] & Natalia Vasilieva[3]
[1]Belorussian State Medical University, Minsk, Belarus; [2]Minsk City Clinical Oncologic Dispensary, Minsk, Belarus; [3]Republic Center of Medical Rehabilitation, Minsk, Belarus.

Objective
To study the effect of parathyroidectomy (PTE) on the BMD in postmenopausal women with primary hyperparathyroidism (PHPT).
Materials and methods
We studied 38 postmenopausal women with mild PHPT without osteoporosis (T-score $\geq -2{,}5$ by DXA). In 20 patients was performed PTE, the comparison group:18 postmenopausal patients with PHPT. The duration of observation was 1 year. Examination: total calcium, Ca^{++}, phosphorus, PTH, DXA.
Results
The average age was 63.1 ± 8.74 years, the duration of menopause was 13.4 ± 3.52 years. The were no differences in the age ($U=126.5$, $P=0.120$), height, m ($U=504.5$, $P=0.478$), weight, kg ($U=3556.0$, $P=0.318$), BMI, kg/m^2 ($U=3578.5$, $P=0.350$), duration of menopause, years ($U=146.5$, $P=0.022$), calcium total, mmol/l ($U=0$, $P=1.000$), PTH ($U=11.5$, $P=0.655$), BMD L1-L4$_{total}$ ($U=158$, $P=0.530$), BMD Hip$_{total}$ ($U=157.0$, $P=0.520$) in the both group. After surgical treatment, a significant decrease in calcium and PTH was detected. Against the background of the normalization of indicators of calcium-phosphorus metabolism, a significant increase in BMD L1-L4$_{total}$ ($T=38.5$, $P=0.041$) and BMD Hip$_{total}$ ($T=51.5$, $P=0.046$) was observed. In the group of patients without PTE, there was a significant decrease in BMD L1-L4$_{total}$ ($T=20.0$, $P=0.013$), BMD Hip$_{total}$ ($T=22.0$, $P=0.017$) against the background of continuing hypercalcemia ($T=59.5$, $P=0.420$) and elevated PTH ($T=64.0$, $P=0.836$) content in the blood serum.
Conclusion
The results of a retrospective study confirm the high efficacy of PTE in the postmenopausal women with mild PHPT to prevent bone loss.

Obstructive urolithiasis as first sign of primary hyperparathyroidism caused by a large parathyroid hyperplasia

Codruta Ioana Nemes[1], Valentin Muntean[2], Laura Dragomir[3], Bogdan Feciche[4] & Cristina Ghervan[3]
[1]Emergency County Hospital – Endocrinology, Satu Mare, Romania; [2]'Iuliu Hatieganu' University of Medicine and Pharmacy – Surgery II, Cluj Napoca, Romania; [3]'Iuliu Hatieganu' University of Medicine and Pharmacy – Endocrinology, Cluj Napoca, Romania; [4]Emergency County Hospital – Urology, Satu Mare, Romania.

Introduction
Primary hyperparathyroidism (PHPT) is a well-known risk factor for urolithiasis and nephrocalcinosis, wich are now less commonly reported due to an early detection of hypercalcemia by routine measurement of serum calcium. PHPT is most commonly caused by a single adenoma of the parathyroid gland. The incidence of multiglandular disease (MGD) range from 2.4–34%. In case of large tumor differential diagnosis is necessary to rule out malignancy.
Case report
We report the case of a 36 years old man presenting with multiple obstructive lithiasis in the left ureter with consecutive hydronephrosis. Biochemical evaluation revealed hypercalcemia (serum calcium = 13.84 mg/dl, n.v. = 8.6−10, ionizing calcium = 5.97 mg/dl, n.v. = 3.82−4.82) due to PHPT (PTH = 565.7 pg/ml, n.v. = 15−65, serum phosphate = 1.7 mg/dl, n.v. = 2.5−4.5, alkaline phosphatase = 192 U/l, n.v. = 40−129). In order to reduce calcium level the patient received bisphosphonate and calcitonine and, after ureteral stenting, diuretics and hydration. Ultrasound revealed a 5 cm tumor of the right inferior parathyroid gland, with necrotic areas, confirmed also by SPECT- CT. During surgery, beside the tumor, the hyperplasia of the other 3 parathyroid glands was observed. Right lobectomy with tumor, right superior and 50% of the left inferior parathyroid gland resection was performed. A reduction with more than 50% of PTH level was observed 10 minutes after tumor resection. The histopathological examination confirmed the hyperplasia including in the tumoral gland. The PTH level initially dropped off, but then rapidly raised around 150 pg/ml, maintaining this level more than 6 months, despite normal calcemia and then normalised. No recurrence of nephrolithiasis after surgery. There were insufficient criteria for MEN 1 syndrome.
Conclusions
Serum calcium level should be measured in all patients with urolithiasis. The preoperatory diagnose of MGD can be challenging. Elevated PTH levels can be observed after successful surgery as a transient phenomen.

Parathyroid adenoma in pregnancy: a case report

Hatice Sebile Dokmetas, Fatih Kilicli, Meric Dokmetas, Yasar Ozdenkaya, Kubra Karaipek & Bugra Erol
Istanbul Medipol University, Istanbul, Turkey.

Although primary hyperparathyroidism (PHPT) is seen in young women at 8/million ratio, it is more rare to be seen with pregnancy. If diagnosed and not treated during pregnancy, the mother may have nephrolithiasis, hypercalcemic crisis, hypertension, preeclampsia, pancreatitis, death and intrauterine growth retardation in the fetus, low birth weight, preterm delivery, intrauterine death or postpartum tetany. Forty-year-old woman at the 14th week of gestation was diagnosed with Ca: 11,03 (N:8,6−10 mg/dl), P: 2,38 (N: 2,6−4), 5 mg/dl), 25-OH-D: 13.87 (N: 30−80 ng/ml), Parathormone: 141.9 (N: 15−65 pg/ml), creatinine: 0.37 (N: 0.5−0.9 mg/dl), 24 hour urine was Ca: 610 (N: 100−300 mg/24 h). Ultrasonography revealed a parathyroid adenoma in the right lower pole. The patient was diagnosed as primary hyperparathyroidism. The patient was informed about mortality and morbidity and treatment options for PHPT in pregnancy. The patient was operated at the second trimester (17 weeks of gestation). All parathyroids were explored in the operation and the adenoma was removed in the right lower pole. Intraoperative PTH level was found to be 9.47 pg/ml and the operation was terminated. Pathology: Parathyroid adenoma. Postoperative calcitriol 0.5 mg/day, 1×1000 mg calcium was given. On postoperative first day, Ca: 9.71, 8.91 on the second day and 8.87 mg/dl on the fifth day. In patients with parathyroid adenoma in pregnancy, the high complication and mortality rate for the mother and baby can be significantly reduced by the operation of the adenoma in the second trimester.

Effects of bariatric surgery on bone health

María Rosa Alhambra Expósito[1,2,3], Ana Barrera Martín[1,2,3], Concepción Muñoz Jiménez[1,2,3], María José Molina Puerta[1,2,3] & María Ángeles Gálvez Moreno[1,2,3]
[1]Maimonides Institute of Biomedical Research of Cordoba, Córdoba, 14004, Spain; [2]Reina Sofia University Hospital (HURS), Córdoba, 14004, Spain; [3]Service of Endocrinology and Nutrition, HURS, CÓRDOBA, Spain.

Introduction
Bariatric surgery has important metabolic complications such as bone mass loss.
Goal
To assess bone mineral density (BMD) after Roux-en-Y gastric by-pass (RYGB) in patients under standard calcium and vitamin D supplementation.
Method
In patients with morbid obesity submitted to RYGB, we measured BMD with a dual X-ray densitometer. Using World Health Organization (WHO) criteria's, values were compared with young controls and same age and sex population, evaluating osteopenia and osteoporosis.
Results
375 pacients were inclueded, 290 women and 85 men. Positive correlation was observed between BMI and BMD lumbar spine (LS) (Femur (F) 0.104, *P* 0.001 y LS 0.104, *P* 0.001) and inverse correlation was observed between BMI postoperative and preoperative BMD lossed (F 0.223, *P* 0.780; LS 0.189, *P* 0.022). Inverse correlation was observed between BMD and age (F −0.314, *P* 0.000 y LS-0.161, *P* 0.000) as well as with preoperative weight excess (−0.284, *P* 0.000). Group correlations are maintained when separated by sex. In women we observed a diminished BMD in femur from 1.086±0.150 g/cm^2 (T-score 0.558±1.188) to 1.00±.150 g/cm^2 (T-score 0.150±1.206) and in LS from 1.206±0.197 g/cm^2 (T-score 0.171±1.22) to 1.192±0.155 g/cm^2 (*P* 0.001) (T-score 0.094±1.267) (*P* 0.000). In femur 8.6% of them were osteopenia, with no cases of osteoporosis, in LS corresponding to 12.9% of osteopenia. Following the follow-up, BMD diminished progressively mainly in left hip, 14.8% osteopenia and 2.1% osteoporosis were found in left hip; 17.2% osteopenia y 2.8% osteoporosis. In men, we observed a BMD F 1.154±0.148 g/cm^2 (T-score 0.490±1.083) and in LS 1.108±0.160 g/cm^2 (T-score 0.180±1.174). After the follow-up BMD were 1.107±0.160 g/cm^2 and 1.247±0.160 g/cm^2 respectively (*P* 0.000 y 0.030) and T-score F 0.274±1.215 and LS 0.245±1.327 (*P* 0.000). In femur 12% of them were osteopenia, with no cases of osteoporosis, in LS corresponding to 16% osteopenia. Following the follow-up, BMD diminished progressively, 14.1% osteopenia and 1.2% osteoporosis were found in left hip; and 17.6% osteopenia in LS.
Conclusion
Patients from both genders and diverse ages after BPYR presented osteopenia and osteoporosis, despite early supplement prescription of calcium and vitamin D (Table 1).

Table 1

	Women 290	Men 85	*P*

A rare case of hypoparathyroidism due to MELAS syndrome

Tatiana Grebennikova, Tatjana Zenkova, Natalia Tarbaeva, Ekaterina Sorkina & Zhanna Belaya
The National Medical Research Centre for Endocrinology, Moscow, Russian Federation.

MELAS syndrome is a progressive neurodegenerative disorder characterized by a combination of mitochondrial encephalomyopathy, lactic acidosis, stroke-like episodes and endocrine disorders. The frequency of hypoparathyroidism in MELAS syndrome is less than 0.5%. A 22-year-old female was admitted to our center due to episodes of seizures. At admission her height was 147.5 cm, weight 30.5 kg, BMI 13.8 kg/m^2. She reported whole life weight and growth retardation, hearing loss since childhood but normal menses since 12 years old. The patient resembles her mother. Investigation at the time of admission revealed Chvostek's and Trousseau's symptoms, serum calcium 2.05 mmol/l (2.10–2.55), phosphate 1.54 mmol/l (0,74–1,52), parathyroid hormone 13.9 pg/ml (15–65), calcium in 24 h urine 0.63 mmol/24 h (2.5–8), HbA1c 5.5%, C-peptide 1.26 ng/ml (1.1–4.4), plasma lactate 3.21 mmol/l (0–2.4), TSH 0.278 mU/l (0.25–3.5). A month before she had been hospitalized unconscious with stroke like symptoms to a neurological department, where she was also diagnosed with diabetes. (hyperglycemia 20 mmol/l) and hypocalcemia (Ca^{2+} 0.96 mmol/l (1.03–1.29)). According to the results of CT scan, basal ganglia calcification was found. MELAS syndrome was confirmed by the presence of mutations in mitochondrial DNA: m. 3243A > G tRNA-Leu. All signs and symptoms were controlled on alfacalcidol 0.5 μg, 1000 mg of calcium carbonate, cholecalciferol 2000 IU daily and 6 IU of insulin glargine. Conclusion: hypoparathyroidism or diabetes at a young age due to MELAS syndrome seems to be more easily controlled than in sporadic cases or perhaps even partly reversible.

A case report of tumor-induced osteomalacia

Artem Zhukov[1], Ekaterina Pigarova[1], Alexandra Petrushkina[1], Liudmila Rozhinskaya[1], Dmitry Beltsevich[1], Konstantin Slashuk[1], Pavel Rumyantsev[1], Evgeniya Kogan[2], Yusif Osmanov[2] & Galina Melnichenko[1]
[1]Endocrinology Research Centre, Moscow, Russian Federation; [2]Federal State Autonomous Educational Institution of Higher Education I.M. Sechenov First Moscow State Medical University of the Ministry of Health of the Russian Federation (Sechenov University), Moscow, Russian Federation.

Objective
Tumor-induced osteomalacia is a rare paraneoplastic syndrome in which fibroblast growth factor 23 (FGF-23) hyperproduction by tumor causes renal phosphate wasting, severe hypophosphatemia and osteomalacia. Localization of the tumor can be a major diagnostic challenge.
Material and methods
We present a clinical case concerning a 62-year old woman previously diagnosed with hypophosphatemic osteomalacia, with a slight improvement of clinical and laboratory manifestations after initiation of medical treatment.
Results
The patient had 10-year history of pronounced lower back pain, decrease in height by 16 cm during life, multiple atraumatic fractures of the ribs and pelvic bones. 6 years earlier she underwent surgical treatment for the mass lesion of the proximal part of the left femur (histologic examination – osteoma). She was diagnosed with hypophosphatemic osteomalacia 4 years earlier and received treatment with alfacalcidol 3 mcg/day, cholecalciferol 15 000 IU/week, calcium 1000 mg/day. The examination showed low serum P level 0.6 mmol/l (0.74–1.52), elevated PTH 111 pg/ml (15–65), normal levels of total and albumin-adjusted serum Ca, a slight increase in alkaline phosphatase (ALP) 158 IU/l (50–150) and CTx 0.836 ng/ml (0.01–0.69), 25(OH)D 23.4 ng/ml. Low tubular maximum reabsorbtion of phosphate corrected for glomerular filtration rate (TmP/GFR) 0.45 indicated renal phosphate wasting. Considering likely ectopic hyperproduction of FGF-23, we performed whole body scintigraphy with somatostatin analogue, which revealed focal intensive radiotracer uptake in left inguinal region. CT scan of the pelvic area excluded the presence of a primary focus in the area of a previously removed osteoma. After tumor-removal surgery, follow-up blood test on the 3rd day showed normalization of serum P level. Four months after surgical procedure, P level remained within the normal range, TmP/GFR showed no renal phosphate wasting. Ca level also remained within the normal range, while elevation of ALP 209 IU/l (40–150) as well as PTH 99 pg/ml (15–65) was observed, 25(OH)D 20.4 ng/ml. Marked elevation of osteocalcin 153 ng/ml (11–43) and CTx 2.34 ng/ml (0.01–0.69) suggested intense bone remodeling. Therapy with alfacalcidol, cholecalciferol and calcium was continued with increase of calcium dose up to 2000 mg/day.
Conclusion
The diagnosis of tumor-induced osteomalacia is challenging and is commonly delayed for years. Attention to biochemical values (especially serum P level) and thorough use of imaging techniques are the key steps. Only surgical removal of causative tumor can provide complete cure.

Pregnancy-related osteoporosis: a series of cases

Alexandra Petrushkina, Ekaterina Pigarova, Larisa Dzeranova & Liudmila Rozhinskaya
Endocrinology Research Centre, Moscow, Russian Federation.

Objective
Pregnancy-related osteoporosis is a rare disorder with potentially severe complications. There is lack of clinical practice guidelines due to low incidence of this disease and few published cases.
Material and methods
We present eight cases of pregnancy-related osteoporosis in women aged between 28–42 years. Six of them were diagnosed between 1 month and 3 years postpartum and two were diagnosed in the third trimester of pregnancy. Most of them had otherwise healthy pregnancy, only one woman had risk factors promoting osteoporosis before pregnancy (heparin treatment).
Results
Blood tests showed normocalcemia and normophosphatemia in all patients. All patients except one had PTH level within normal range (one patient had secondary hyperparathyroidism due to vitamin D deficiency). Serum osteocalcin level was available in four patients, 3/4 had low levels of osteocalcin. Seven patients had multiple vertebral compression fractures at X-ray with a prominent decrease in BMD (spinal Z-score from −2.2 to −4.4) and one patient suffered bilateral femoral neck fracture. Treatment approaches included therapy with calcium (1000–2000 mg/day) and vitamin D (alfacalcidol 0.5–3 mcg/day or cholecalciferol 10,000–15,000 IU/week) in all patients; five patients had received specific treatment for osteoporosis (bisphosphonates in two patients, calcitonin spray in one patient, denosumab in one patient and sequential therapy with strontium ranelate, denosumab and teriparatide in one patient). Four women underwent surgery: three had vertebroplasty and one had bilateral hip replacement. Follow-up data was available in six patients with median 2 years, 5/6 had radiological improvement in lumbar spine.
Conclusion
Described cases confirm the severity of pregnancy-related osteoporosis and its challenging management. Necessity and regimen of specific treatment are the subject for further research. Women diagnosed with pregnancy-related osteoporosis should be advised to have appropriate calcium and vitamin D intake and counseled regarding the risk of potential detrimental effects on the bone health during breastfeeding and newborn care.

Bone mineral density, prevalence of fractures, antiosteoporotic drugs effectiveness and Ca/Vit D supplementations intake in elder patients with osteoporosis: a cross-sectional study on Moscow population

Lubov Machekhina, Yulia Onuchina, Ekaterina Dudinskaya, Natalia Brailova, Ksenia Eruslanova & Olga Tkacheva
Gerontology Research and Clinical Centre, Moscow, Russian Federation.

Aim of the study
To investigate osteoporosis features in elder patients in Moscow population.
Materials and Methods
It was a retrospective study, during which we analyzed the data of 192 outpatients (183 women and 9 men) admitted to Gerontology Research and Clinical Centre in 2018. In the focus of our attention was patients' past medical history, such as any antiosteoporotic treatment received, vitamin D and Ca supplementations, any fractures in previous 5 years and T-criteria values assessed by DEXA-scan. The statistical analysis was performed using Prism 8 Version 8.0.1 (145). Statistically significant were differences with $P < 0.05$.

Results
Median age of the patients was 77 [73; 87] years. 20% of the patients had history of taking oral glucocorticoids. The prevalence of fractures in PMH was 82% (157 patients). With more detailed analyzing we found out that the number of patients with three and more fractures was quite high and was 89, so more than a half of the group with fractures. The most frequent localization of fracture was lumbar vertebras (53%), meanwhile radius fractures and other localization fractures were found in 27% and 20% of the cases respectively. The values of T-criteria for hip and spine according to DEXA-scans showed significantly lower T-criteria ($P=0.04$) for lumbar vertebras vs hip: Me -3.1 [-2.6; -3.6]. 50% of the patients did not receive any antiosteoporotic treatment; treated patients received bisphosphonates in most cases (63%, $n=59$), followed then by denosumab (18%, $n=17$) and teriparatide (9%, $n=8$). The adverse effects were much higher in BF group (90% of all cases). Patients receiving only Ca supplementation had approximately the same prevalence of fractures compared to patients with no Ca/Vit D supplementation, meanwhile patients receiving only vitamin D had significantly lower prevalence of fractures [$P=0.045$], and patients receiving Ca + VitD did not differ from only Vit D-group.
Conclusion
Vitamin D and combined supplementation is extremely important in prevention of fractures, meanwhile Ca alone does not have any protective effect. In severe osteoporosis the preference should be given to anabolic treatment for better results.

Brown tumor of the palate as first manifestation of a primary hyperparathyroidism
Elena Roxana Novac
Emergency Hospital Moinesti, Moinesti, Romania.

Brown tumors represent a late-stage bone change caused by primary hyperparathyroidism, presenting in only 2–3 percent of the cases. Therefore as primary manifestations there is even a smaller percent. The common sites of brown tumor are the long bones, ribs, clavicle or pelvic girdle. The solitary palate brown tumor as initial presentation of a primary hyperparathyroidism is rare and often accompanied by tumors of other facial bones. We present the case of a 67 year old woman with initial presentation of a large tumor of the right palate, with no extension to the orbits. The first histological diagnosis was of a giant cell tumor, which delayed the diagnosis of the underlying cause for about 6 months, when the patient's relatives requested a second opinion on the initial histological findings, the second analysis revealed the same diagnosis but recommended that a primary or secondary hyperparathyroidism should be excluded as the brown tumor is very similar to the one with giant cells. We received the patient at this moment when we immediately diagnosed a primary hyperparathyroidism and sent the patient to surgery. Unfortunately in this case the long progression of high levels of PTH affected a lot the mineral density of the bones and now the patient is highly osteoporotic. The particularity of the case is the location of the brown tumor and the delayed diagnosis of a first primary hyperparathyroidism.

Difference in trabecular bone score according to spine-femur bone mineral density discordances in healthy postmenopausal women
Keunyoung Kim, Kyoungjune Pak, Bo Hyun Kim, Mijin Kim, Yun Kyung Jeon, In-Joo Kim, Sang Soo Kim & Tae Sik Goh
Pusan National University Hospital, Pusan, Republic of Korea.

Purpose
The purpose of this study was to evaluate the prevalence and characteristics of individuals with spine–femur bone mineral density (BMD) discordance and to examine whether trabecular bone score (TBS) is associated with major and minor BMD discordance in postmenopausal women.
Methods
This retrospective study included 533 healthy postmenopausal women (median age, 60 years; range, 55–82 years) who visited our hospital for a health check-up and performed dual X-ray absorptiometry for the evaluation of BMD between May 2013 and April 2017. Major discordance is defined when the T-score at one site indicates osteoporosis and at the other site indicates normal BMD. Minor discordance refers to one degree of difference in the diagnosis between two sites. The differences were analyzed using the Kruskal-Wallis test.
Results
Two hundred and forty-six participants (48.2%) exhibited spine-femur BMD discordance. Major discordance was noted in 4.5% ($n=24$) of the study population, and these patients were all diagnosed with osteoporosis in the lumbar spine. Minor discordance was noted in 41.7% ($n=222$) of the study population. In the group with normal BMD of the lumbar spine, the participants in the discordance group showed significantly lower TBS (median, 1.364; interquartile range [IQR], 1.328–1.398) than that in the concordance group (median, 1.406; IQR, 1.358–1.439). The participants with discordance who showed normal (median, 1.357; IQR, 1.326–1.399) or osteopenic (median, 1.352; IQR, 1.313–1.387, $P<0.001$) BMD in the femur had significantly lower TBS compared with that in the concordance group (for normal BMD; median, 1.406; IQR, 1.1.358–1.439; for osteopenic BMD, median, 1.364; IQR, 1.328–1.398, $P<0.001$). The major discordance group exhibited the lowest TBS in both groups with normal (median, 1.331; IQR, 1.275–1.384) and osteopenic (median, 1.307; IQR, 1.245–1.345) femoral BMD. The groups with osteoporotic femur or both osteopenic and osteoporotic lumbar spine did show a significant difference in TBS regardless of the presence of discordance.
Conclusions
The high prevalence of discordance between the spine and the femur in terms of BMD may be associated with degraded microarchitecture, especially in the presence of normal or osteopenic BMD, and suggests the need for further risk assessment and management in such patients.

P87

Heterogenous clinical presentation of primary hyperparathyroidism in Romania
Daniel Grigorie[1,2] & Alina Sucaliuc[1]
[1]National Institute of Endocrinology, Bucharest, Romania; [2]Carol Davila University of Medicine, Bucharest, Romania.

Introduction
In the last decades, primary hyperparathyroidism (PHPT) has changed in its clinical presentation, being mostly asymptomatic in western countries; in Romania is still common to see various clinical presentations.
Objective
To characterize a retrospective cohort of PHPT Romanian patients.
Patients and methods
271 patients were included: 88% women, ratio F/M 7.5/1, mean age 60.6 ± 12 yrs (15–83), mean BMI 26.3 ± 4.9 kg/m^2 (15.1–43). The biochemistries were measured by automated standard laboratory methods. Serum intact PTH, 25OH-vitamin D, C-telopeptide (CTX) and osteocalcin (OC) were measured by chemiluminescence immunoassay. Areal bone density was measured at the lumbar spine (LS), femoral neck (FN) and distal radius1/3 site (R). Site-matched spine TBS parameters were extracted from the DXA images using TBS iNsight software.
Results
Biochemistries (mean ± S.D.) (range): calcium 11.3 ± 1.1 mg/dl (10–18 mg/dl), PTH 266.5 ± 373.9 pg/ml (31–2812 pg/ml), 25OHD 15.2 ± 9.8 ng/ml (4–90.28 ng/ml), CTX 1.2 ± 1.6 ng/ml (0.1–15.8 ng/ml), OC 66.1 ± 19 ng/ml (8.9–609 ng/ml). Simptomatic hypercalcemia was noted in 15% and the prevalence of severe vitamin D deficiency (<10 ng/ml) was 34.7%. **Renal involvement** (51.7%)**:** nephrolithiasis 47.6% (7.7% had surgery), more likely in males and younger patients; nephrocalcinosis (ultrasound evidence 4.1%); hypercalciuria (30.2%); reduced renal function (13.3%). **Skeletal involvement:** fractures (26.3%; non-verterbral 17%, vertebral 8.1%, both 1.1%) in significantly older; osteitis fibrosa cystica 2.95%; LS- BMD (224 pts) mean T-score –2.3 S.D., FN-BMD (192 pts) mean T-score –1.8 S.D.; R- BMD (38 pts) mean T-score –2.6 S.D.. The prevalence of osteoporosis by a single site: 45.8% (LS), 20.1% (FN), 63% (R). Mean TBS was in the partially degraded range (1.258 ± 0.115); 32% had degraded microarchitecture (TBS ≤ 1.20), 51% had partially degraded microarchitecture (TBS > 1.20 and < 1.35) and 17% had normal TBS. **Etiology** (61.6% operated, 91 pts with available histology): adenoma (94.5%, 8 double), carcinoma (3.3%), hyperplastic (2.2%), probably selection bias in refferal to surgery. Mean adenoma weight (68 pts) 3.70 ± 7.78 g (range 0.05 – 48.6 g). Familial forms in 12 pts (4.5%): MEN (1,2) (8 pts), HPP-JT (3 pts), isolated (2 pts).
Conclusion
Currently in Romania there is a mixture of clinical presentations of all described phenotypes.

A case of primary hyperparathyroidism due to a giant parathyroid adenoma extending into the mediastinum

Monia Ghammem, Jihene Houas, Mouna Bellakhdhar, Abir Meherzi, Wassim Kermani & Mohamed Abdelkafi
ENT Department and Neck Surgery of Farhat Hached Hospital, Sousse, Tunisia.

Introduction
Primary hyperparathyroidism is a common disease. It is generally caused by a solitary parathyroid adenoma. Adenomas weighing more than 3.5 g are classified as giant. These giant parathyroid adenomas constitute a rare clinical entity.
Case report
A 54-year-old woman was referred to our ENT department for management of newly diagnosed hypercalcaemia. She had no significant medical history. She reported mild constipation, muscular weakness, nausea and intermittent abdominal pains since 1 month. There was no palpable mass on cervical examination. Biochemical evaluation revealed severe hypercalcemia (serum calcium: 5.54 mmol/l); the levels of serum parathormone were also elevated (2268 pg/ml). Cervical ultrasonography revealed a hypoechoic mass, measuring 3 cm, with augmented vascular Doppler signal at the periphery, which appeared to correspond to the right inferior parathyroid gland. There was no significant lymphadenopathy. A Tc99 m SestaMIBI scintigraphy showed an uptake compatible with an adenoma of the right inferior parathyroid gland extending into the mediastinum. Computed tomography of the neck and chest confirmed the presence of a lesion in the projection of the right inferior parathyroid gland extending to the anterior mediastinum measuring 5.94 cm $\times$ 2.71 $\times$ 2.05 cm. The severe hypercalcemia was temporarily controlled by hydration, forced diuresis and bisphosphonates. The parathyroid adenoma was successfully removed through a transcervical approach. Histopathological examination confirmed a benign giant parathyroid adenoma. The patient's postoperative course was uneventful. Her serum calcium and PTH levels normalized quickly. She is currently asymptomatic and normocalcaemic.
Conclusions
Diagnosis of a giant solitary parathyroid adenoma is based on clinical presentation, biochemical profile, and imaging studies. The parathyroid carcinoma is the principal differential diagnosis. The treatment is based on surgical excision combined with PTH levels measurement.

P89

Diagnostic and treatment delay in primary hyperparathyroidism (phpt): a pending issue

Miguel Paja, Adela L Martínez, Andoni Monzón, Cristina Arrizabalaga, Alba Zabalegui, Natalia C Iglesias, Laura A Calles, Eider M Etxeberría & Teresa Gutiérrez
Basurto University Hospital, Bilbao, Spain.

Background
PHPT is the leading cause of hypercalcemia in outpatients. Its clinical presentation varies from asymptomatic forms to renal or bone complications. The only curative treatment is surgical resection, and delayed diagnosis can lead to serious morbidity.
Objective
Identify the presence of PHPT at least one year prior to referral to endocrinology consultation. Secondly, determine whether diagnostic delay leads to increased complications.
Methods
Retrospective observational study. We analysed electronical records from a tertiary referral center in 116 patients with PHPT that underwent surgery between 2015 and 2018. Age, presence of nephrolithiasis, serum calcium, alkaline phosphatase, glomerular filtration rate and parathyroid hormone levels determined at least 12 months prior to referral were evaluated. In patients with [Ca] recorded more than one year earlier, the following four surgical criteria were assessed at the time of that determination: nephrolithiasis, age $<$50 years, [Ca] $>$ 11.4 g/dl and glomerular filtration rate $<$60 ml/min.
Results
Among the 116 operated patients, 81 (69.8%) had a previous measurement of serum calcium at a time interval $\geq$12 months. 65 of these 81 patients (56%) had a serum calcium$>$10.4 g/dl and presented an average delay of 57 months to receive a proper evaluation. Even more, 42 of these 65 patients with hypercalcemia (64.6%) had $\geq$1 inclusion criteria for surgery. The group of patients that met the surgical criteria were younger, had higher calcium serum values, a greater frequency of nephrolithiasis and a shorter Interval to undergo a parathyroidectomy than those patients who did not meet at least one surgical criterion. Conversely, the 35 patients that were not checked up $\geq$1 year before the endocrine evaluation was made, were older and had higher calcium serum values that those patients who had normal calcium values evaluated more than one year previously. No differences were found in the presence of kidney stones, surgical criteria or gender between both groups.
Conclusions
In our series of patients with PHPT, the referral to an endocrinologist is performed late, with an average delay of almost 5 years. A significant proportion of these patients have well documented hypercalcemia at least one year before evaluation and more than half of them met criteria for surgery. Despite increased early detection of the disease and avaibility of effective treatment, PHPT continues to be underdiagnosed and undertreated, with increased morbidity. System-level interventions that include proper management of hypercalcemia could improve outcomes.

Epidemiology of hypoparathyroidism in Korea

Eun Hyun Jee[1], Joon-Hyop Lee[2], So Young Park[3], Song Vogue Ahn[4] & Sihoon Lee[1]
[1]Department of Medicine, Gachon University College of Medicine, Incheon, Republic of Korea; [2]Department of Surgery, Gachon University College of Medicine, Incheon, Republic of Korea; [3]Department of Internal Medicine, Cheil General Hospital and Women's Healthcare Center, Seoul, Republic of Korea; [4]Department of Health Convergence, Ewha Womans University, Seoul, Republic of Korea.

Background
The National Health Insurance Service of South Korea is considered to be one of the most effective systems in the world with high accessibility to health care for all Koreans including foreign residents in the country as many as 50 M people. The accumulative information on the behaviors and the statistics of healthcare use based on the National Health Insurance Sharing Service Database has become important for medical research as a nationwide surveillance.
Methods
We, thereafter, performed analysis of the changes in the incidence and prevalence of hypoparathyroidism which is the common complication of thyroid surgery with the National Health Insurance Sharing Service Database in South Korea. From 2008 to 2015, we selected the postoperative hypoparathyroidism group who were prescribed with vitamin D over 6 months after the thyroid surgery with diagnosis of thyroid cancer.
Results
The incidence of postoperative hypoparathyroidism increased consistently from 2008 to 2013 and decreased in 2015. The number of cases of thyroid surgery reached its peak in 2012 and decreased after then, showing similar tendency. This trend is observed similarly with the incidence of thyroid cancer showing consistent increase from 2008 to 2012, and decrease in 2015. Percentage of hypoparathyroidism resulting from total thyroidectomy except slight increase in 2014 seems to be consistent, indicating at least surgical skill fluctuation.
Conclusion
Thereafter, the incidence of hypoparathyroidism, which is a common complication of thyroid surgery, has decreased with the effect of significant health care improvement.

Effectiveness of intramuscular Ergocalciferol treatment in a patient with o steomalaciadueto severe vitamin D deficiencyafterbariatric surgery

Labrini Papanastasiou[1], Christos Gravvanis[1], Symeon Tournis[2], Athina Markou[1], Athanasia Kalantzi[1], Manolis Zoulias[3], Georgia Georgakopoulou[3], Stamatina Pagoni[3] & Theodora Kounadi[1]
[1]Department of Endocrinology and Diabetes Center, General Hospital of Athens 'G. Gennimatas', Athens, Greece; [2]Laboratory for Research of the Musculoskeletal System 'Th. Garofalidis', Medical School, National and Kapodistrian University of Athens, KAT Hospital, Athens, Greece; [3]3rd Department of Internal Medicine, General Hospital of Athens 'G. Gennimatas', Athens, Greece.

Bariatric surgery is a common treatment for morbidly obese patients requiring weight loss and/or metabolic control. Vitamin D (VitD) deficiency and bone loss may occur post-operatively and supplementation with high oral doses of Vitamin D is required. Alternatively, intramuscular depot ergocalciferol (vitamin D2) which slowly releases VitD and overcomes the gastrointestinal tract, could be administrated in such patients.
Aim
To present a case of severe VitD deficiency–osteomalacia after gastric bypass operation for morbid obesity treated with ergocalciferol intramuscularly.
Case report
A 45-year-old woman (BMI 43 kg/m^2) was referred to the Endocrinology Department with a diagnosis of secondary hyperparathyroidism due to VitD deficiency. Two weeks earlier, she was admitted to the Department of Internal Medicine for pain at the upper third of left hip and pelvis and long-standing muscle weakness over the previous months. The last month she was immobilized in a wheelchair. Fifteen years ago she underwent roux-en-Y gastric by-pass for treatment of morbid obesity. Since then she was treated with multivitamin supplements (iron, VitB12, Calcium, VitD). In the last three months, after a neurological examination anti-epileptics and analgesics were also initiated. Despite this treatment, she complained for hips' pain and muscle weakness, which limited her ambulation. During her hospitalization, iron deficiency anaemia (Ht 23%, Hb 8g/dl Ferritine 3 μg/l) vitD deficiency (25OHD 3.7 ng/ml) and secondary hyperparathyroidism (PTH 334 pg/ml, Ca 8.3 mg/dl, Albumin 3 gr/dl, P 1.7 mg/dl, CaUr24h 30 mgr/24 h, PUr24h 200 mgr/24 h) were revealed. The indices of bone turnover (ALP 173IU/L, P1NP 196 ng/ml, βCTX 2.02 ng/ml) were elevated. Radiological evaluation demonstrated insufficiency fractures on the pubic and left femur and reduced lumbar spine (Tscore −2.8) and hip (Tscore −2.9) BMD. Osteomalacia due to vitD deficiency and calcium malabsorption was diagnosed. Calcium citrate 2000 mg daily and im ergocalciferol 600,000 IU every 20 days to correct vitD deficiency were initiated whereas anti-epileptics and analgesics were discontinued. One month after treatment initiation, musculoskeletal pain and weakness had resolved and the patient was mobilized almost completely. Within two months, hyperparathyroidism (PTH 175 pg/ml, Ca 8.7 mg/dl, *P* 3.5 mg/dl, Albumin 3.3 g/dl, ALP 206 IU/l, P1NP 668 ng/ml, βCTX 4.25 ng/ml) and vitD status (25(OH)D 8.1 ng/ml) had improved.
Conclusion
Regular monitoring and prompt correction of vitD and mineral deficiencies is necessary in patients that underwent bariatric surgery. Intramuscular ergocalciferol administration can improve the clinical and biochemical status and thus is suggested to prevent and/or treat osteomalacia in such patients.

A rare case of hypercalcemia associated with dysgerminoma with elevation of 1,25(OH)2 Vitamin D

Natsuko Hara, Hironori Abe, Hirotsugu Suwanai, Takuya Ishikawa, Fumiyoshi Yakou, Jumpei Shikuma, Hiroyuki Sakai, Ryo Suzuki, Takashi Miwa & Masato Odawara
Department of Diabetes, Metabolism, Endocrinology, Rheumatology and Collagen Diseases, Tokyo Medical University, Tokyo, Japan.

We hereby report a rare case of hypercalcemia-associated with dysgerminoma with elevation of 1,25(OH)2 Vitamin D. A 27-year-old nulliparous woman presented with hypercalcemia during examination of a right ovarian tumour. As the serum calcium level increased gradually, she started complaining of nausea and anorexia. The laboratory data at first-visit showed that serum calcium, LDH, ALP, 1,25(OH)2 Vitamin D and fractional excretion of calcium were elevated and intact PTH was suppressed. (serum calcium 13.3 mg/dl, albumin 4.4 g/dl, phosphorous 3.7 mg/dl, LDH 1411 U/l, ALP 399 U/l, intact PTH 6 pg/ml, PTHrP <=1.0 pmol/l, 25(OH) Vitamin D 15.2 ng/ml, 1,25(OH)2 Vitamin D 96.9 pg/ml, FECa 3.51%, BUN 16.6 ng/dl, Creatinine 0.93 mg/dl). Symptomatic hypercalcemia was treated by intravenous normal saline and elcatonin yet medical treatment had a marginal effect. On the 21st-day from the first visit, a right salpingo-oophorectomy was performed. The right ovary measured 13 cm× 12.5 cm×3.6 cm. Histopathology of the ovarian mass showed proliferation of large and homogeneous tumour cells with infiltration of small lymphocytes (two cell patterns). Immunohistochemical analysis revealed that tumour cell was PLAP (+, partly), CD117/c-kit(+, weak), D2-40(+), hCG(−), AFP(−). There was no evidence of metastasis, and cytology of the ascetic fluid showed no malignant tumour. Hence this patient was classified in stage pT1apNXpM0 (UICC, 2009) Therefore, she got a follow-up examination every 3-months in the first year without receiving chemotherapy. Postoperatively, serum calcium and 1,25(OH)2 vitamin D returned to normal range within a week. There are numerous causes of hypercalcemia. The case of hypercalcemia associated with dysgerminoma showing elevation of 1,25(OH)2 Vitamin D is still rare, whilst there are several previous reports. We would like to present the case series study of dysgerminoma with hypercalcemia of 15 cases including 14 previous reported ones of database from 1990 to 2018 at the day of the presentation.

Analysis of non-invasive DXA-derived bone structure parameters in patients with acromegaly with regards to vitamin D levels

Martin Kužma[1], Peter Vaňuga[2], Ivana Ságová[3], Dušan Pávai[2], Peter Jackuliak[1], Zdenko Killinger[1], Neil Binkley[4], Renaud Winzenrieth[5], Harry Genant[6] & Juraj Payer[1]
[1]Comenius University Faculty of Medicine, 5th department of Internal Medicine, University Hospital, Bratislava, Slovakia; [2]National institute of Endocrinology and Diabetology, Lubochna, Slovakia; [3]Comenius University Jessenius Faculty of Medicine, 1th department of Internal Medicine, University Hospital Martin, Martin, Slovakia; [4]Department of Medicine, University of Wisconsin, Madison, USA; [5]Galgo Medical, Barcelona, Spain; [6]University of California San Francisco, San Francisco, USA.

Introduction
Patients suffering from acromegaly, despite normal or even higher bone mineral density (BMD), have prevalent vertebral fractures (VFs). Impaired bone microarchitecture is involved fragility fracture development, but vitamin D status could be involved in this impairment.
Aim of the study
Comparison of bone parameters such as BMD, trabecular bone score (TBS) and 3D-SHAPER parameters in acromegaly patients according to level of 25(OH)D3.
Methods
A cross-sectional study recruited all acromegaly patients who came for visit from 6/2016 – 8/2017. In all subjects a single measurements of pituitary axis hormone levels, bone turnover markers (BTMs), BMD, (total hip [TH] and lumbar spine [LS]), TBS and 3D-SHAPER [volumetric BMD (vBMD), surface BMD (sBMD) and mean cortical thickness (mCth)] were performed. Levels of 25(OH)D3 were measured by measured in a chromatographic assay using a simple isocratic HPLC system with UV detection (Chromsystem®) (interassay variability CV, 0.8−3%). All patients were advised to use 800 IU of cholecalciferol and 1000 mg of Ca supplement daily.
Results
106 patients with acromegaly (mean age 56.6 years, BMI 30.2 kg/m^2) were included. Patients in lowest quartile (Q1vitD; mean 111.1 nnmol/) of 25(OH)D levels had lower LS BMD (0.99 vs. 1.06 g/cm^2; $P=0.02$); lower TBS (1.13 vs. 1.23; $P<0.0001$) and higher TH sBMD (183.2 vs. 172.4 g/cm^2; $P=0.05$) in comparison to patients in highest quartile (Q4vitD; mean 34.5 nnmol/l). There was no difference in TH BMD, FN BMD, mCth, vBMD, CTx and P1NP between Q1vitD vs. Q4vitD.
Conclusions
This study indicates that in patients with acromegaly low levels of vitamin D may contribute to significant impairment in trabecular bone at lumbar spine, as represented by TBS. Higher sBMD at TH could indicate increased amount of cortical bone caused by GH hypersecretion, but cortical porosity could be decreased, as showed by previous studies with bone biopsies. We recommend maintaining vitamin D levels in sufficient range in all patients with acromegaly.

Osteitis Fibrosa Cystica – A Forgotten Clinical And Radiological Feature Of Primary Hyperparathyroidism

Anna Katharina Flügel, Antonia Mondorf & Jörg Bojunga
Department of Internal Medicine 1, Endocrinology, Goethe University Medical School, Frankfurt/Main, Germany.

Introduction
Manifestations of primary hyperparathyroidism (PHPT) such as osteoporosis and stone diseases are common primary diagnostic findings beyond a hypercalcemia. Classical skeletal involvement can be the first sign of PHPT, but not recognized because osteitis fibrosa cystica (bone cysts, brown tumors of the long bones) is rarely seen today in Western Europe.
Case report
A 34-year old women from Afghanistan was presented to our out-patient-clinic with a history of chronic back and joint pain, as well as numbness and parasthesia in both arms and legs. Previously she was referred to orthopedic surgery,

neurosurgery and neurology for further investigations. MRI showed multiple intraosseous cystic lesions in the pelvis and multiple ribs. DXA confirmed osteoporosis (lumbar spine T-score: −4,6; total hip T-score −4,1). Biochemical evaluation revealed hypercalcemia of 2.81 mmol/l (ref. range 2.09–2.54), hyophosphatemia of 2.53 mg/dl (2.6–4.5), 25-OH Vitamin D of 26 ng/ml (20–70) under supplementation and elevated parathyroid hormone of 571 pg/ml (15–65). Blood and urine creatinine were normal. Ultrasound of the neck showed hyperplasia of all four parathyreoid glands. Multiple endocrine neoplasia 1 and malignancy of cystic pelvic lesions were excluded. By parathyreoidectomy two cranial parathyroid adenomas were removed. Caudal no adenoma could be identified during surgery. Immediately after surgery the parathyroid hormone decreased >50%. At the follow-up visits the patient showed a good improvement of her symptoms without developing a hungry-bone-syndrome.

Conclusion

The case shows the rare presence of osteitis fibrosa cystica as a clinical manifestation of a PHPT. It emphazises the importance of an early diagnosis of PHPT with a detailed diagnostic workup, including imaging and biochemical investigations of bone metabolism. When radiographic evidence of a lytic lesion and hypercalcemia are present, PHPT should always be considered in the differential diagnosis.

Clinical use of Cinacalcet in patients with complex primary hyperparathyroidism

Elaine Soong & Rahat Tauni
West Suffolk Hospital, NHS Foundation Trust, Suffolk, UK.

Background

Primary hyperparathyroidism is one of the most common disorders encountered in endocrine clinics and primarily affects women. The current recommendation for patients with primary hyperparathyroidism is to undergo parathyroidectomy which has a 97% success rate. However, there is a small group of patients where surgery is contraindicated, or patients who have a disease pattern not amenable to surgery or patients who refuse surgery. These patients would require an alternative treatment to manage hypercalcemia. Cinacalcet is an allosteric modulator of calcium sensing receptor and is currently commissioned by NHS England for patients with primary hyperparathyroidism who are not suitable for surgery and patients with secondary hyperparathyroidism with end stage kidney disease on dialysis. It is also indicated in treating hypercalcemia secondary to parathyroid carcinoma. European Medicines Agency and British National Formulary both endorse the use of Cinacalcet in these patients.

Method

We conducted a retrospective audit on the patients with primary hyperparathyroidism who were prescribed Cinacalcet against the NHS England Clinical Commissioning Policy (July 2016).

Results

A total of 17 patients were identified as suitable to be included in the audit. Majority of the patients are female ($n=16/17$) and only one male. The age range is between 54 to 91 years old (mean=78). Pre treatment calcium levels are between 2.59–3.3 mmol/L (mean=2.85 mmol/L) and PTH level between 8.92–57.65 pmol/L (mean=19.06). Vitamin D levels are between 9.99–99.26 nmol/L prior to treatment. Seven patients had low vitamin D levels (<50 nmol/L) and one patient did not have vitamin D levels prior to treatment. Calcium levels diminish after 1 month of treatment and were between 2.26–3.09 mmol/L (mean=2.5 mmol/L). Nine patients were started on Cinacalcet as a primary treatment when curative surgery was not an option, whereas only three patients were started with adjusted calcium levels greater than 2.85 mmol/l and significant cognitive impairment. Two patients were started as a secondary treatment where curative surgery had failed and further surgery was not possible.

Conclusion

We would need to continue to work on our practices to meet the criteria set out by NHS England Clinical Commisioning Policy.

We have identified that vitamin D is not consistently checked and replaced prior to starting Cinacalcet.

Majority of patients were started on Cinacalcet as a primary treatment when curative surgery was not an option.

A rare case of Graves' disease in a patient with type 1B pseudohypoparathyroidism and associated TSH resistance

Marta Morón-Díaz[1], Loida María García-Cruz[2] & Mauro Boronat[1,3]
[1]Section of Endocrinology and Nutrition, Complejo Hospitalario Universitario Insular-Materno Infantil, Las Palmas de Gran Canaria, Gran Canaria, Spain; [2]Service of Clinical Genetics, Complejo Hospitalario Universitario Insular-Materno Infantil, Las Palmas de Gran Canaria, Gran Canaria, Spain; [3]University Institute for Biomedical and Healthcare Research, University of Las Palmas de Gran Canaria, Gran Canaria, Spain.

Introduction

Pseudohypoparathyroidism (PHP) is a heterogeneous group of endocrine disorders characterized by target-organ resistance to the action of PTH, manifesting with hypocalcemia, hyperphosphatemia, and increased serum concentrations of PTH. PTH receptor couples with the stimulatory G protein (Gsα), leading to cAMP formation. Most cases of PHP are caused by heterozygous inactivating mutations in the *GNAS* gene, encoding Gs((PHP type 1A) or methylation defects within the imprinted *GNAS* locus (PHP type 1B). Resistance to other hormones signaling through G protein–coupled receptors, particularly TSH, is typical in type 1A PHP and can also occur in type 1B PHP.

Case report

In 2014, a 30-year-old woman sought medical attention because of fatigue. Laboratory tests showed: serum calcium 7.4 mg/dl, serum phosphate 5.2 mg/dl, PTH 916 pg/ml, 25OHD 19.8 ng/ml, TSH 5.78 mU/l and free T4 0.8 ng/dl. After 2 years without follow-up, the patient was referred to our hospital because of similar laboratory test results. Except for thigh muscle pains, she was asymptomatic. Clinical examination ruled out Albright hereditary osteodysthrophy, obesity or cognitive impairment. Laboratory examination included: serum calcium 7.2 mg/dl, albumin 3.9 g/dl, serum phosphate 5 mg/dl, magnesium 1.9 mg/dl, urine calcium 40.3 mg/24 h, urine phosphate 475.8 mg/24 h, PTH 948.3 pg/ml, 25OHD 20.8 ng/ml, $1.25(OH)_2D_3$ 66 pg/ml, TSH 6.2 mU/l, free T4 0.57 ng/dl, TPOAb 2 U/ml. Hands x-ray showed no brachydactyly. Thyroid ultrasonography was normal. The patient's genetic study revealed a methylation defect at *GNAS* exons *XL*, *AS* and *A/B*, and a gain of methylation at *NESP55*. DNA analyses from both parents showed normal methylation pattern at all differentially methylated regions, confirming the diagnosis of sporadic PHP type 1B. The patient was treated with oral calcium supplements, calcitriol and levothyroxine. Ten months later she begun with symptoms of severe hyperthyrodism and goiter. A new biochemical assessment showed normalization of serum calcium and phosphate, PTH 304.2 pg/ml, TSH <0.001 mU/l, free T4 3.77 ng/dl, free T3 17.93 pg/ml, TSI 11.2 mU/ml and TPOAb 10.4 U/ml. Since then, she is being treated with antithyroid drugs.

Conclusions

This case demonstrates that, although TSH and stimulating TSH receptor antibodies share signal transduction pathways for cell activation and growth, Graves' disease is possible even upon defective Gsα signalling and resistance to TSH, suggesting alternative effector mechanisms for TSH receptor antibodies.

Primary hyperparathyroidism: clinical manifistation in Russian population

Liubov Yanevskaya[1], Aluza Bakhtiyarova[2], Ekaterina Ivanova[2], Karina Pogosyan[1], Alena Andreeva[2], Marina Boriskova[1], Uliana Farafonova[1], Ilya Sleptsov[3], Tatiana Karonova[1,2] & Elena Grineva[1,2]
[1]Pavlov First Saint Petersburg State Medical University, Saint-Petersburg, Russian Federation; [2]Federal Almazov National Medical Research Centre, Saint-Petersburg, Russian Federation; [3]Saint-Peterburg State University Clinic of High Medical Technologies N.I. Pirogov, Saint-Petersburg, Russian Federation.

Hypothesis

The clinical presentation of primary hyperparathyroidism (PHPT) changed lately but we don't know if more patients in our population have asymptomatic form of PHPT.

Materials and methods

Medical records of 449 patients with PHPT who were operated in three Medical Centers (Saint-Petersburg, Russia) between Jan 2011– Jun 2018 were screened. We analyzed anthropometric data, laboratory tests (PTH, 25(OH)D, Ca, iCa, P, 24-h calciuria, ALP levels) and imaging tests (US, scintigraphy or CT/MRI scan, DXA).

Results

Most of the patients were women (93.1%), F:M ratio was 13.5:1. The age varied between 23 and 87 years (mean 59), men were younger than women (55 &

60, $P=0.02$). 310 patients had symptomatic PHPT (osteoporosis (41.9%), urolithiasis (25.5%) and GI lesions), and 139 patients were asymptomatic. Patients with clinical signs were older than asymptomatic ones ($P=0.025$) and often had cardiovascular pathology ($P=0.003$). 88% of men with symptomatic PHPT had urolithiasis compared to women who mainly had osteoporosis (64%). Of 449 patients 18 had MEN1, and one had MEN2a. Asymptomatic patients were younger (58 & 60 years, $P=0.002$) and had higher 25(OH)D level (32.2 & 18.6 ng/ml) compared to symptomatic PHPT patients. Vitamin D status was assessed only for 25% of pts and most of them did not receive supplements. Correlation analysis revealed associations between PTH and serum iCa ($r=0.464$, $P<0.000001$), total Ca ($r=0.258$, $P<0.000001$), phosphorus ($r=-0.313$, $P=0.000025$) and ALP ($r=0.334$, $P=0.02$). In addition, 25(OH)D was associated with iCa ($r=-0.352$, $P=0.0007$) and Ca ($r=-0.412$, $P=0.03$). Adenoma size was associated with the disease duration ($r=-0.183$, $P=0.002$), PTH ($r=0.367$, $P<0.000001$), iCa ($r=0.334$, $P=<0.000001$). Thirty-seven patients had normocalcemic PHPT form, including ten who were asymptomatic and 27 pts with certain manifestations of the disease. The size of adenoma was smaller ($P=0.01$) and PTH was lower ($P<0.0001$) than in hypercalciemic patients. In normocalcemic group there were no patients with hypophosphatemia ($P=0.04$).

Conclusion

Study results showed that in Russian patients PHPT continues to be a symptomatic disease and only 31% of cases are diagnosed using laboratory tests. PHPT is mainly a female disease often with osteoporosis. Half of PHPT men have urolithyasis. It seems that cardiovascular diseases associates with PHPT. Serum 25(OH)D level was rarely assessed and patients did not received vitamin D supplementation.

The effect of vitamin D supplementation on sarcopenia indices: a systematic review and meta-analysis of randomized controlled trials

Nifon K Gkekas[1,2], Panagiotis Anagnostis[2,3], Pavlos Siolos[2], Eustathios Kenanidis[1,2], Michael Potoupnis[1,2], Eleftherios Tsiridis[1,2] & Dimitrios G Goulis[2,3]

[1]Academic Orthopaedic Department, Papageorgiou General Hospital, Aristotle University Medical School, Thessaloniki, Greece; [2]Center of Orthopaedic and Regenerative Medicine (C.O.RE.) - Center for Interdisciplinary Research and Innovation (C.I.R.I) - Aristotle University Thessaloniki, Thessaloniki, Greece; [3]Unit of Reproductive Endocrinology 1st Department of Obstetrics and Gynaecology, Medical School, Aristotle University of Thessaloniki, Thessaloniki, Greece.

Objective

To systematically review and meta-analyze the best available evidence regarding the effect of vitamin D supplementation, either as monotherapy or in combination with protein and exercise, on sarcopenia indices (muscle strength, muscle mass, muscle performance).

Materials and methods

A comprehensive search was conducted in Medline, Cochrane Central, and Scopus databases, up to December 31st, 2018. Data were expressed as standardized mean difference (SMD) with 95% confidence intervals (CI). I^2 index was employed for heterogeneity.

Results

An initial search identified 768 studies, 12 of which met the eligibility criteria for qualitative and quantitative analysis ($n=1.470$, age 78.4 ± 7.6 years, follow-up 8–24 weeks). Vitamin D dosage was either 1,600 ($n=2$), 1,404 ($n=1$), 900 ($n=1$), 800 ($n=3$), 500 ($n=2$) or 100 IU/day ($n=1$), 10.000 IU thrice/week ($n=1$) or 300.000 IU, as a single dose ($n=1$). Concerning muscle strength, vitamin D supplementation was superior compared with placebo ($n=9$, SMD 0.41, 95% CI 0.133 to 0.689, $P=0.004$, I^2 71). This was also evident when vitamin D was co-administered with protein ($n=5$, SMD 0.559, 95% CI 0.102 to 1.017, $P=0.017$, I^2 84), whereas vitamin D monotherapy had no effect ($n=4$). Concerning muscle mass, vitamin D showed a marginal positive effect compared with placebo ($n=4$, SMD 0.23, 95% CI -0.003 to 0.472, $P=0.053$, I^2 0). When vitamin D was co-administered with protein, a significantly positive effect was evident compared with placebo ($n=2$, SMD 0.371, 95% CI 0.002 to 0.740, $P=0.049$, I^2 0). Concerning muscle performance, no effect was shown ($n=2$).

Conclusion

This is the first meta-analysis providing evidence that vitamin D supplementation increases muscle strength and mass in patients with sarcopenia, only when it is co-administrated with protein. Further well-designed studies are needed to clarify the effect of vitamin D supplementation on sarcopenia.

P99

The factors affecting balance function in patients with osteoporotic vertebral fractures

Larisa Marchenkova, Ekaterina Makarova, Mikhail Eryomushkin & Lilia Shakurova

National Medical Research Center of Rehabilitation and Balneology, Moscow, Russian Federation.

Aim

The aim of the study was to estimate the main factors influence on static and dynamic balance function in osteoporotic patient with vertebral fractures (VF).

Methods

90 patients aged 43-80 with primary osteoporosis were enrolled. Study group comprised of 56 women and 4 men (age 65.4 ± 7.1 years, BMI 26.7 ± 4.4 kg/m^2) with at least 1 VF confirmed by X-rays. Control group included 28 women and 2 men (age 62.0 ± 5.2 years, BMI 28.7 ± 5.9 kg/m^2) with the same BMD and without any osteoporotic fracture. The examination program included stabilometry, static and dynamic balance tests (Fukuda-Unterberger test, One-leg-standing test) and 25(OH)D level evaluation.

Results

Study group was characterized by change vs control group in balance coefficient (BC) (77.2 ± 7.6 vs 85.7 ± 9.4% with opened eyes, $P=0.002$, 67.1 ± 9.8 vs 73.4 ± 9.9% with closed eyes, $P=0.03$), pressure center of media-lateral (PCML) deviation in sagittal plane (1.2 [−1.1;1.5] vs −1.2 [−1.5;1.2] mm, $P=0.025$) and PCML displacement in sagittal plane (6.8 [3.1;37.7] vs to 4.8 [1.8;10.7] mm, $P=0.01$). BC correlated with age ($r=0.41$ with opened eyes, $r=0.40$ with closed eyes, $P=0<0.01$) and BMI ($r=0.16$ with opened eyes, $P=0<0.05$). PCML deviation in sagittal plane correlated with age ($r=-0.42$, $P=0<0.01$), number of VFs ($r=0.40$, $P=0<0.001$) and femoral neck BMD ($r=-0.43$, $P=0<0.05$), and in frontal plane only with age ($r=-0.27$, $P=0<0.05$). PCML displacement in sagittal plane correlated with age ($r=-0.29$, $P=0<0.01$), number of VFs ($r=0.22$, $P=0<0.01$) and femoral neck BMD ($r=-0.38$, $P=0<0.05$) and in frontal plane only with BMI ($r=-0.15$, $P=0<0.05$). PCML deviation in sagittal plane was higher in patients with vitamin D deficiency vs subjects with normal or suboptimal 25(OH)D level ($P=0.04$). Fukuda-Unterberger test showed greater side dislocation in patients with VF vs controls (40° [25.0;45.0] vs 30° [10.0;45.0], $P=0.02$). Side dislocation correlated with number of VFs ($r=-0.30$, $P<0.05$). Patients with VF lose their balance duting One-leg-standing test faster vs controls with open eyes (5.0 [1.0;10.0] vs 7.5 [5.0;10.5] sec, $P<0.05$) and with closed eyes (2.0 [0;3.0] vs 3.5 [3.0;5.0] sec, $P<0.05$). Balance time during One-leg-standing test correlated with age ($r=-0.35$, $P<0.001$ with open eyes, $r=-0.42$, $P<0.01$ with closed eyes) and with 25(OH)D level ($r=0.25$, $P=0.01$ with open eyes, $r=0.24$, $P=0.04$ with closed eyes).

Conclusions

VFs negatively affect static and dynamic balance function that may lead increasing risk of falls and new fractures in osteoporotic patients. Elderly age, high BMI, low BMD, multiple VFs and vitamin D deficiency are main factors of balance dysfunction in osteoporotic patients with VFs.

Evaluation of trabecular bone score in men with type 1 diabetes

Nadzeya Karytska[1], Yuliya Dydyshka[2], Alla Shepelkevich[2], Natallia Vasilyeva[3], Volha Vadzianava[4] & Volha Zhukouskaya[5]

[1]10th city clinical hospital, Minsk, Belarus; [2]Belarusian State Medical University, Department of Endocrinology, Minsk, Belarus; [3]Republic Center of Endocrinology and Medical Rehabilitation, Minsk, Belarus; [4]Belarusian Medical Academy of Post-graduate Education, Minsk, Belarus; [5]Department of Clinical Medicine and Surgery, Division of Endocrinology, University of Naples Federico II, Naples, Italy.

Background and aims

According to modern researchers, in patients with type 1 diabetes (T1D), the presence of diabetic osteopathy and an increasing fracture risk is evident. However, the determination of bone mineral density only is not enough to adequately assess the quality of the bone. Thus, the aim of the study was to study of the lumbar spine trabecular bone score as qualitative bone characteristic in T1DM men.

Materials and methods

52 males with T1DM (mean age: 32.4 (21.2–44.9) yrs, duration of DM: 13 (7–20) yrs, age of manifestation: 19 (14–23) yrs, BMI: 23.69 (19.38–27.96) kg/μ^2; HbA1c: 8.2 (7.6–8.9) %) and 31 controls, comparable in age and anthropometric data (mean age: 30.5 (23.5–41.3) yrs, U=687.5; $P=0.707$; BMI: 24.57 (21.46–28.39) kg/μ^2, U=571.5; $P=0.119$). The research involved general clinic

examination, dual energy X–ray absorptiometry (DXA) at lumbar spine regio performed on «PRODIGY LUNAR». Bone mineral density (BMD) was taken as a quantitative assessment and trabecular bone score (TBS) was used as qualitatively parameter.). Z–score of −2.0 or less was regarded as «low bone mineral density».
Results
Low BMD was detected in 19.2% of the surveyed patients with T1DM and 6.5% of control. Lower L1–L4 BMD and TBS were significantly found in patients with diabetes compared to controls: BMD 1.13 (0.92–1.22) vs 1.25 (1.07–1.43) g/cm^2; U=411; P=0.001; TBS 1.42 (1.23–1.46) vs 1.46 (1.32–1.57); U=266.5; P=0.028), and T-score TBS −0.30 (−1.90–0.50) vs 0.10 (−1.025–0.90); U=233; P=0.042). There were no significant differences in L1–L4 Z-score TBS in T1DM men compared with control: 0.40 (−0.70–1.25) vs. −0.70 (-0.90–0.50) g/sm^2; (U=97; P=0.077). There was a definite significant correlation between BMD (L1–L4) and TBS (L1–L4) – r^2=0.41, P=0.001. However, similar results were not obtained in subgroups of T1DM men (r^2=0.32, P=0.051) and controls (r^2=0.42, P=0.051).
Conclusions
The data confirmed low bone mineral density and trabecular bone in the lumbar spine in type T1DM men. Thus mechanisms responsible for the formation of healthy bones require further research.

Association between body mass index and the risk of falls: a nationwide population-based study

Se Hwa Kim[1], Soo Kyung Kim[2], Yoo Mee Kim[1] & Young Jun Won[1]
[1]Catholic Kwandong University College of Medicine, International St. Mary's Hospital, Incheon, Republic of Korea; [2]CHA Bundang Medical Center, CHA University, Seongnam, Republic of Korea.

Background
This study examined the associations between body mass index (BMI) and falls in Korean adults using data from a large population-based survey.
Methods
We analyzed 113,353 men and women (aged ≥50 years) who participated in Korean Community Health Survey in 2013. The BMI groups were classified as underweight (<18.5), normal weight (18.5≤ BMI< 24.9), overweight (25≤ BMI< 29.9), and obese (≥30). Logistic regression was used to assess the relationship between BMI and falls.
Results
The mean (± standard deviation) age and BMI of all the participants were 63.8± 9.6 years and 23.2±2.9 kg/m^2. Among 113,353 study participants (52,784 men and 60,569 women), 4.5% were underweight and 1.7% were obese. Fifteen percent of men and 22% of women had a history of falls. The association between BMI and falls was different according to sex. The normal weight group showed the lowest risk of falls in women, but not in men. The odd ratio (OR) for falls associated with BMI <18.5, 25–29.9, and ≥30 kg/m^2 were 0.99 (95% CI 0.87–1.14), 1.20 (95% CI 1.11–1.29), and 1.47 (95% CI 1.22–1.75) compared with women with BMI 18.5–24.9 kg/m^2 after adjusting for multiple variables. Underweight men had a higher risk of falls compared with normal weight men (OR 1.25, 95% CI 1.05–1.47). However, there was no difference of fall risk between normal weight, overweight, and obese men.
Conclusions
Overweight and obese women had an increased risk of falls than in normal weight women, whereas there was only a significant correlation between falls and underweight status in men.

Various clinical features of Digeorge syndrome

Natalia Mokrysheva, Svetlana Mirnaya, Anna Eremkina, Ekaterina Dobreva & Ekaterina Bibik
Endocrinology Research Centre, Moscow, Russian Federation.

Background
DiGeorge syndrome (DGS) is the rare genetic disorder caused by a 22q11.2 chromosome microdeletion. The main clinical features are associated with defective development of the pharyngeal pouch system and usually include congenital heart disease, hypoplasia of thymus resulting in immune deficiency and hypoparathyroidism. Also DGS patient has characteristic long face with narrow palpebral fissures, broad nasal bridge, micrognathia and small mouth, small dysmorphic ears.
Aim
To describe the 20 years old patient with delayed diagnosis of DGS due to unspecific disease manifestation.
Clinical case
Ventricular septal defect and patent foramen ovale were diagnosed at birth and repaired when the patient was 3 years old. Since childhood pediatrics have noted moderate delay in the cognitive function and rare episodes of febrile seizures up to 3–4 times a year. However, hypoparathyroidism was diagnosed only at the age of 17 years, when the low serum calcium levels were first determined. Despite the prescribed calcium supplementation the febrile convulsions have persisted. Upon admission to our center the patient presented with periodic muscle convulsions in the upper and lower extremities, recurrent headaches, stabbing pain in the heart, weakness, memory loss. Physical examination revealed mild facial dimorphism (wide and flat nose, small low-set ears), hyperkyphosis, obesity (BMI 30.0 kg/m^2). Pathological laboratory findings were as follows: corrected calcium 1.38 mmol/L (2.1–2.55), ionized calcium 0.68 mmol/l (1.03–1.29), phosphorus 3.0 mmol/l (0.74–1.52), PTH 9.13 pg/ml (16–65). CT-scan showed the calcifications in basal ganglia. No clinical and laboratory evidence of significant immunodeficiency was found in our patient. He had been managed by combined therapy with alfacalcidol (1 μg per day), cholecalciferol (7500 IU per week), calcium (6000–8000 mg per day) for one year. The follow-up examination demonstrated the significant improvement as persistent normocalcemia, absence of convulsions and paresthesia, posture straightening, muscle weakness reduction, weight loss and increased physical activity. A genetic study identified a large chromosome 22q11.2 deletion and the diagnosis was confirmed for DGS. Besides there were found the insertion in X-chromosomal Sox3 gene that can explained the mental retardation.
Conclusion
Clinical presentation of DGS can be variable and the severity of each organ involved is wide. Although the symptoms associated with hypocalcemia suggest a wide range of diseases, DGS should be considered in children and young adults with concomitant cardiac defects, development delays and other suspicious features.

About a case of familial hypocalciuric hypercalcemia (FHH) type 3 with neurological involvement

Hélène Hoth Guechot, Florence Kohler, Linda Humbert, Maxime Kwapich, Marie Françoise Odou & Marie Christine Vantyghem
CHRU, Service of Endocrinology, Diabetology and Metabolic Diseases, Lille, France.

Background
FHH is a genetically heterogeneous condition mimicking primary hyperparathyroidism at the difference of low urine calcium excretion. FHH types 1, 2, and 3 are due to loss-of-function mutations of the CASR, GNA11, or AP2S1 genes, respectively. FFH 3, the rarest of the 3, is usually associated to 3 recurrent mutations affecting the arginine residue in position 15. The clinical phenotype has not been well described. We report a new case striking by the neurological involvement. Case: A 26-year old man was referred for fortuitously found hypercalcemia (135 mg/l, 3.36 mmol/l). The family history was not well known. The personal history included bilateral inguinal hernia and testicular fixation. The patient had followed a special schoolchild course because of mild cognitive impairment but was able to work and no further investigations were done. Biological assessment revealed moderately high calcium (115 mg/l, 2.86 mmol/l), low 25OHvitD3 (22 ng/ml), but normal phosphate (29 mg/l; N:2–45), magnesium (22 mg/l; N:20–24), and PTH (54 ng/ml; N<68) blood levels, with low urine calcium excretion (63 mg/24 H; creatininuria: 0.7 g/24 H). Nevertheless, bilateral nephrocalcinosis was present on CTscan. The Tscore (DEXA) was −1.5 (vertebral) and −1 (femoral), and remained stable over time. The diagnosis of FHH1 was considered. Frequent intron 5 polymorphism and heterozygous variant of the CASR gene were identified that could not explain biological features. At 33 years old, the patient was re-referred after surgery of calcifying right hip tendonitis with very poor results confining the patient in a wheeling-chair. Besides physical inability, the patient had now overt cognitive impairment (MMS: 25/30) confirmed by a specialized neurological evaluation showing attentional and working memory disorders (MOCA 21/30) despite a normal brain MRI. He couldn't read or work anymore and couldn't remember the birth date of his 9-month old child. The NGS completion of the genetic work-up showed a AP2S1 gene heterozygous variation (exon2: c.43C>T (p.Arg15Cys) arguing for type 3 FHH.

Conclusion
Despite similar biological and genetic features (with the most frequent p.Arg15Cys mutation), the phenotype of this case was different from that one reported in one of the largest FHH3 cohort (Vargas-Poussou JCEM 2016) since our patient had nephrocalcinosis and no osteoporosis, with evolutive cognitive impairment, as reported in some other series (Szalat Endocrine 2017; 10 patients - Hannan Human Molecular genetic 2015; 17 patients). These findings suggest that AP2S1 could play a role in neural development. Cognitive impairment in FHH should orientate towards AP2S1 gene mutation.

Verified data on parathyroid hyperplasia incidence not related to primary hyperparathyroidism in persons exposed to ionizing radiation

Oleksii Kaminskyi[1], Olga Kopilova[1], Dmitrii Afanasyev[1], Konstantin Loganovskyi[1], Viktoria Talko[1], Irina Muravyova[1], Irina Chikalova[1], Olena Tepla[1] & Iryna Kiselova[2]
[1]State Institution National Research Centre for Radiation Medicine of NAMS of Ukraine, Kiev, Ukraine; [2]City Clinical Endocrinology Center, Kiev, Ukraine.

During the Chernobyl nuclear power plant accident (ChNPPA) a mixture of radioactive isotopes, mainly the iodine and cesium, were released, which through inhalation and food, and in some cases along with external exposure had affected the hormone-producing cells of endocrine system. Within days and months after the accident, the thyroid and parathyroids accumulated a significant amount of these isotopes with thyroid gland becoming a secondary emitter, which further increased the exposure of parathyroids. Therefore, we expect some significant disorders in parathyroid gland system in the late period of the ChNPPA. We have developed and improved the method of ultrasound screening of parathyroids, which increases the efficiency of their visualization. We have conducted a survey of 1,534 individuals attributed to the ChNPPA survivors exposed to ionizing radiation. Thirty-two years after irradiation the parathyroid hyperplasia not related to primary hyperparathyroidism was detected on average in 34.4% of cases, namely in 28.8% of the ChNPPA clean-up workers, 71.5% evacuees from the 30-kilometer contaminated zone around the Chernobyl nuclear power plant, 41.5% residents of areas under a radiological control, 45.5% residents of Kiev city and Kiev region, and 33.3% subjects irradiated in prenatal period of life. Thus, there is a high prevalence of parathyroid hyperplasia among the population of Ukraine exposed to a range of radiation doses from the tropic iodine, cesium and strontium isotopes, including the low-dose prolonged irradiation. In most cases there were no abnormalities in serum concentration of parathyroid hormone and ionized calcium. Deficiency or lack of vitamin D was an additional factor involved in this situation. Our immediate task is to study the incidence of functional disorders of parathyroid hormone secretion and relation of parathyroid hyperplasia on vitamin D deficiency, as well as to identify any comorbid disorders in the vulnerable population groups.

Parathyroid carcinoma: identity with diagnostic difficulties and therapeutic strategies

Cristina María Díaz Perdigones[1], Ana María Gómez Pérez[2], Isabel María Cornejo Pareja[2], Araceli Muñoz Garach[2], Miguel Damas Fuentes[2], María Molina Vega[2] & Silvia Maraver Selfa[2]
[1]Hospital Xanit, Málaga, Spain; [2]Hospital Virgen de la Victoria, Málaga, Spain.

Blackground
Parathyroid carcinoma is a malignant neoplasm affecting 0.5 to 5.0% of all patients suffering from primary hyperparathyroidism. This cancer continues to cause challenges for diagnosis and treatment because of its rarity, overlapping features with benign parathyroid disease.
Case report
50 years-old-woman, without relevant previous history. She begins to present asthenia, weakness of lower limbs, arthralgias, cramps and appearance of a painful tumor but with progressive upgrowth at the level of the left tibial tuberosity since one year ago. Physical examination: blood pressure 100/54 mm/Hg, 55 kg, 166 cm BMI 19.9 kg/m^2, nodule in left thyroid lobe and painful tumor of 5×3 cm on palpation in left anterior tuberosity, atrophy muscular and no presence of edema in lower limbs. The rest of the exploration without findings. Blood test: Hb 12.5 g/dl, Ca 14 mg/dl (VN < 10), P 1.8 mg/dl (VN > 2.7), Mg 2.3 mg/dl, albumin 3.9 dl/l, 15 OH calcitriol 22.8 ng/ml (VN > 30), PTH 1174 pg/ml (VN < 65). Urine test: calcium / creatinine index 0.3 mg/mg. In thyroid ultrasound we observed on the lower pole of the left thyroid lobe an hypoechogenic and heterogeneous nodule of lobulated foci, predominantly solid but with a superior cystic, vascularized component, appearing to present a plane of separation with the thyroid gland with size 16.5×15×38 mm. Suggestive of parathyroid injury and whose location it was also confirmed by Tc99 m MIBI scintigraphy. The biopsy of the tibial tumor presents pathological anatomy compatible with brown tumor. Densitometry with osteoporosis in the lumbar spine T −2,6. In the surgical treatment, a left hemithyroidectomy was performed, removal of the two left parathyroid glands and ipsilateral lymph node dissection. Pathological anatomy suggestive of 2.5 cm parathyroid carcinoma infiltrating thyroid and focally adjacent fat. Contact the surgical edge. Postoperative PTH level, performed on the second day of surgery, was 95 pg/mL and calcium levels within normal. At hospital discharge we left her calcium supplements and alendronic acid to avoid hungry bone syndrome and treat osteoporosis. Monitoring should be done every 3 months with clinical examination and calcium levels during the first 3 years.
Conclusion
We observed that patients with parathyroid carcinoma are more likely to have symptoms than adenomas: appearance of neck mass, bone and kidney disease, elevated levels of calcium and PTH. When we have an early diagnosis and an early surgery, the percentage of survival can reach 67% in 10 years.

Case Report of a large family with hyperparathyroidism- jaw tumor syndrome (HPT-JT) and a deletion of the third exon of *CDC73*

Lauriane Le Collen[1], Sara Barraud[2], Marie Francoise Odou[3], Marta Spodenkiewicz[1], Antoine Braconnier[1], Mohamad Zalzali[4], Céline Poirsier[1] & Brigitte Delemer[1]
[1]CHU, Reims, France; [2]CHU, Reims, France; [3]CHRU, Lille, France; [4]Institut Jean Godinot, Reims, France.

Heterozygote mutations of the gene *CDC73* are responsible for 3 types of parathyroid diseases: familial hyperparathyroidism, parathyroid carcinoma, hyperparathyroidism-jaw tumor syndrome (and uterine or kidney lesions). The goal of our study was to describe the phenotype associated with the deletion of the 3rd exon of *CDC73* found in a large family.
Patients
We have medical records for 25 patients of a large family composed of 44 individuals through 4 generations. 17 patients had a genetic analysis: the deletion was found in 11 individuals; was absent in 6 people. Additionally, 3 patients were assumed carriers of the deletion and 5 patients were children of non mutated patients. 4 patients were asymptomatic with among them, mostly children but also, one patient of 43 years. 8 mutated patients had primary hyperparathyroidism (HPT) with two acute hypercalcemic crisis (maximum calcium level 4.48 mmol/L, parathormone plasmatic level of 1100 pg/mL (N < 60 pg/mL). The median age of onset of hypercalcemia was 37 years (range from 14 to 59 years). We reported 2 patients with brown tumors (median age at onset was 37 years). Six patients had kidney diseases related to hypercalcemia: 5 urinary lithiasis (median age at onset was 41.5 years) 2 nephrocalcinosis, 3 chronic kidney failures with 1 chronic endstage kidney failure. Hypercalcemia was surgically resolved in the 8 patients and we found only a single parathyroid adenoma in each patient; no carcinoma or atypic lesion. Recurrence of moderate hypercalcemia occured in one patient after 7 years. In this family, the phenotype variability was emphasized by 2 cases: in 2 monozygotic twins, one patient is still asymptomatic at 43 years of age and the other presented with acute hypercalcemia and kidney failure. The youngest symptomatic patient was 13 years old (calcium level 3,4 mmol/L). The other lesions associated to this mutation in the family were: 1 ossifiying fibroma (surgically treated at 31 years of age, with a relapse at 36 years); and one kidney cyst. No gynecological lesions were described.
Conclusion
We report a new large family of HPT jaw tumor syndrome with deletion of the 3rd exon of *CDC73* which led mostly to HPT with a particularly severe impact on kidney. The presentation is highly variable highlighting the importance of a precocious genetic screening and a regular follow-up of the patients.

Pseudohypoparathyroidism- a tale of hypo- and hypercalcemia with a genetic solution

Rachel Chava Rosenblum[1], Yael Einbinder[2], Orit Twito[1], Giovanna Mantovani[3], Francesca Marta Elli[3] & Pnina Rotman-Pikielny[1]
[1]Endocrinology Unit, Meir Medical Center, Kfar Saba, Israel; [2]Nephrology Unit, Meir Medical Center, Kfar Saba, Israel; [3]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrinology Unit; Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy.

Introduction
Pseudohypoparathyroidism (PHP) is a rare genetic disease characterized by renal resistance to parathyroid hormone (PTH), presenting with hypocalcemia, hyperphosphatemia and elevated PTH levels. We describe a PHP patient who presented with clinically significant hypercalcemia.
Case description
A 46-year-old woman with a prior history of hypocalcemia presented to the emergency department with new-onset hypercalcemia, renal failure and anemia. Blood gases showed a mild metabolic alkalosis. She had suffered recurrent hypocalcemic episodes throughout her life with elevated PTH levels and hypocalciuria, suggestive of PHP. Chronic medications included calcium 1800 mg/day, alfacalcidol (1α-OHD3) 3 mcg/day and cholecalciferol (vitamin D3) intermittently. A previous PTH infusion test supported the diagnosis of PHP. There were no Albright Hereditary Osteodystrophy (AHO) features, other hormone resistances or family history of calcium homeostasis dysregulation. Bearing these characteristics in mind, PHP type 1B seemed most likely and was subsequently proven by genetic testing. As for the cause of hypercalcemia, intoxication of calcium or Vitamin D was suspected and all supplements were stopped with rapid normalization of calcium levels. Laboratory 25-OHD3 and 1α,25-OHD3 levels were low. There was no evidence of malignancy. The patient subsequently became hypocalcemic and supplements were recommenced at lower doses. The patient remains normocalcemic since.
Discussion
Treatment modalities in PHP include calcium and hydroxylated vitamin D supplements. Aims of treatment include maintaining normocalcemia and normalizing PTH levels in order to avoid potentially deleterious skeletal effects of chronically elevated PTH levels. Hypercalcemia has been reported rarely in PHP, but more frequently in hypoparathyroidism due to milk alkali syndrome or vitamin D intoxication. We speculate that our patient's hypercalcemia was caused by supplement overdose although vitamin D levels were not elevated and the patient denied increasing her regular calcium dose. The mild alkalosis and renal failure may allude to milk alkali syndrome. In conclusion, close surveillance is essential in PHP to prevent potentially life-threatening electrolyte disturbances.

Generalized skeletal hyperostosis mimicking acromegaly

Vlatka Pandzic Jaksic[1], Naranda Aljinovic Ratkovic[1], Rajko Kusec[1], Ozren Jaksic[1] & Mirko Korsic[2]
[1]Dubrava University Hospital, Zagreb, Croatia; [2]University Hospital Centre Zagreb, Zagreb, Croatia.

A female patient presented at the age of 30 years with an incidental radiological finding of hyperostosis after a traumatic knee ligament injury. Her large facial contours with wide hands and fingers reminded acromegalic features but without typical soft tissue changes. Hormone evaluation discovered an elevated IGF-1, growth hormone (GH) was non-suppressed on glucose load, but pituitary MRI was normal. The imaging revealed remarkable cortical thickening of long bones with prominent homogenous cranial hyperostosis, large and thick facial bones, sclerotic vertebral bodies and hypertrophic metatarsal and phalangeal bones. The bone mass density was extremely increased with Z-scores values between +10 and +13. An inborn flexion contracture of the left index, clubbing fingers and dysplastic nails were observed. The intracranial space was reduced, but without significant brain compression. Beside some occasional nonspecific headaches, she has been asymptomatic with no cranial nerves damage. After being lost for follow up, her condition was re-evaluated 8 years later. Her headaches did not deteriorate. She complained of progressive exophthalmos, torus palatinus and she had worsening nasal obstruction with pronounced sleep apnea due to the extreme narrowing of the nasal cavity. The thickness of her occipital bone reached 35 mm but no evident change in intracranial compression occurred. A surgical widening of the nasal airway was performed. The modelling of orbital rims and the floor of the orbit to reduce exophthalmos was done. The reduction of the mandible and the maxilla resulted in considerable clinical and facial contours improvement and the sleep apnea was significantly reduced. The predominant craniotubular hyperostosis and digit deformities in this patient are similar to skeletal alterations found in sclerosteosis. The DNA was sent for investigation, but no known high bone mass causative mutations have been confirmed yet. We are not aware of any other family member with such a phenotype. The patient had again a hormonal profile mimicking acromegaly without typical clinical sequelae of GH over-secretion. Pituitary, thorax and abdomen imaging did not reveal any process suspicious for neuroendocrine tumour. Due to technical reasons, we could not send her blood for GH-releasing hormone determination. The disorder of the GH axis is still unresolved, but clinical data make us believe that this is not a consequence of some autonomous secretion. Hyperostotic bone diseases are very heterogeneous, usually related with mutations in the complex Wnt signaling pathway and this case might suggest an unknown interaction with the GH secretion.

Evaluation of bone quality in acromegaly and thyrotoxicosis using trabecular bone score

Madalina Sorohan[1], Roxana Dusceac[1,2], Bogdan Sorohan[2,3] & Catalina Poiana[1,2]
[1]CI Parhon National Institute of Endocrinology, Bucuresti, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucuresti, Romania; [3]Fundeni Clinical Institute, Bucuresti, Romania.

Trabecular bone score (TBS) evaluates bone microarchitecture by measuring the grey-level variations from lumbar spine dual-energy X-ray absorbtiometry (DXA) images. Bone mineral density (BMD) in various endocrinopathies might not be sufficient in assessing bone fragility, especially in patients with acromegaly (ACM) but also in thyrotoxicosis. The aim of our study was to evaluate bone quality and quantity by BMD and TBS in patients with acromegaly and thyrotoxicosis.
Methods
We performed an observational, case-control study on 42 patients with acromegaly and thyrotoxicosis. Inclusion criteria were adult patients, with a positive diagnosis of acromegaly or thyrotoxicosis, with an active or residual disease, who performed DXA in our clinic. One analysis included 20 patients with acromegaly and 20 healthy controls mached 1:1 by age and gender. The second analysis was performed on 22 patients with thyrotoxicosis matched 1:1 with 22 healthy subjects, also according to age and gender. Anthropometric, biological, lumbar spine BMD, femoral neck BMD and lumber spine TBS were measured.
Results
When we compared TBS and BMD between patients with acromegaly and controls we found a non-statistically significant lower lumbar spine TBS (1.308 ± 0.140 vs 1.331 ± 0.118, $P=0.58$), femoral neck BMD (0.997 ± 0.152 vs 1.069 ± 0.319, $P=0.36$) and a higher lumber spine BMD (1.195 ± 0.170 vs 1.128 ± 0.203, $P=0.25$) in patients with acromegaly. In the second analysis, we found a lower but not statistically significant femoral neck BMD (0.774 ± 0.419 vs 0.858 ± 0.135, $P=0.37$) in the thyrotoxicosis group. Also, mean lumbar spine BMD and lumbar spine TBS did not show any difference between thyrotoxicosis and control group (0.997 ± 0.187 vs 0.999 ± 0.173, $P=0.97$ and 1.266 ± 0.164 vs 1.269 ± 0.124, $P=0.94$, respectively). In conclusion, in our study, TBS did not show superior results in evaluating bone quality alterations compared to BMD in patients with acromegaly and thyrotoxicosis.

Primary hyperparathyroidism and vitamin D

Najat Draoui, Imane Assarrar, Siham Rouf & Hanane Latrech
Department of Endocrinology-Diabetology-Nutrition, Mohammed VI University Hospital, Oujda, Morocco.

Introduction
Several studies suggest an association between primary hyperparathyroidism (HPTP) and vitamin D deficiency. Our goal is to study the clinical and biological consequences of vitamin D deficiency in patients with primary hyperparathyroidism, and to determine the impact of Vitamin D deficiency on bone, kidney and heart functions.
Materials and methods
It is a retrospective study of 17 cases with HPTP associated with a vitamin D deficiency. We collected clinical, paraclinical, management and evolution data.

All patients underwent a biological and radiological assessment of bone, cardiac and renal functions.
Results and discussion
The mean age was 57.17 years, with a sex ratio (F/M) of 0.23. The mean vitamin D value was 11.37 ng/mL, with a mean PTH value of 391 ng/L. Patients with vitamin D deficiency had a significantly higher PTH rate than patients with normal vitamin D levels ($P=0.04$). Mean serum calcium value was 117 mg/l, with no significant association with vitamin D level. Bone assessment showed an abnormal ODM in 70% of patients, radiological abnormalities were found in 29.4% of patients, these abnormalities didn't have any correlation to the rate of vitamin D. The assessment of renal function showed that 11% of patients had renal failure, while 35.6% had urolithiasis.
Conclusion
Our study suggests that vitamin D deficiency in patients with primary hyperparathyroidism is associated with a higher rate of PTH, and occurrence of bone complications.

The coincidence of primary hyperparathyroidism and primary hyperaldosteronism is not infrequent: a retrospective case analysis

Elvira Barrio[1], Elvira Ramos[1], Irene Crespo[2], Raquel Pallarés[1], Mario Pazos[1], Paz de Miguel[1], Martín Cuesta[1], María José Torrejón[1], Alfonso Calle[1] & Isabelle Runkle[1]
[1]Hospital Clínico San Carlos, Madrid, Spain; [2]Hospital Central de la Defensa Gómez Ulla, Madrid, Spain.

Introduction
Primary hyperparathyroidism (PHP) has been postulated to be a cause of primary hyperaldosteronism (PHA). In fact, PTH receptors have been detected in aldosteronoma tissue. Hyperaldosteronism can also induce elevation of PTH levels, as increased circulating volume increases calciuria, with secondary elevation of PTH levels as serum calcium levels rise. We studied the prevalence of PHP in a group of patients diagnosed with PHA either following or simultaneously with diagnosis of PHP.
Methods
A retrospective study was performed. In a single Endocrine outpatient clinic of a general hospital, 46 patients were diagnosed as having PHA over a 6-year period (2010–2016), with strict application of the Endocrine Society 2008/2016 guidelines. The 25 mg captopril test was considered diagnostic when either the 2-hour aldosterone level was $\geq$130 pg/ml and/or the 2-hour aldosterone/renin ratio (ARR) was $\geq$50. Patient histories were reviewed to detect cases in which PHP had been diagnosed prior to or simultaneously with PHA. We describe the characteristics of the patients presenting PHP. Direct renin and serum aldosterone were measured by RIA and expressed in pg/ml.
Results
10/46 (21.7%) patients were diagnosed as having both PHA and PHP. 7/10 were females. The mean age was 64.3 (SD 14.3). PHP was secondary to a parathyroid adenoma in 4/10 patients and secondary to hyperplasia in 3/10. In another 3/10 patients PHP responded to vitamin D therapy and localization tests were not undertaken. Adrenal vein sampling (AVS) was performed in 7/10 patients. 2/7 presented unilateral aldosterone secretion, whereas 5/7 presented bilateral secretion (Table 1). No correlation was found between maximum calcium levels and corresponding PTH values on the one hand, and basal or 2-hour post-captopril aldosteronemias on the other hand.
Conclusions
The coincidence of primary hyperparathyroidism and primary hyperaldosteronism is not infrequent, affecting over 20% of our primary hyperaldosteronism patients. Although hyperparathyroidism has been postulated to induce an aldosterone-secreting adrenal adenoma, in our small series of patients with primary hyperparathyroidism, primary hyperaldosteronism was found to be due more often to bilateral aldosterone secretion, as indicated by AVS. The relationship between the two entities has yet to be elucidated.

Table 1 Calcium, PTH, vitamin D, and serum aldosterone values in patients with PHP and PHA.

Maximum calcium (mg/dl)	PTH (pg/ml)	25-OH Vitamin D (ng/ml)	Basal (pre-captopril) serum aldosterone (pg/mL)	2-hour post-captopril serum aldosterone (pg/mL)
11,39 (SD 0.74)	122 [IQR 74-197]	21.4 (SD 13.2)	197.5 [IQR 169-293]	211 [IQR 201-352]

Bilateral hip fractures and osteoporosis in a 40-year old man – identification of a novel *TMEM38B* mutation causing osteogenesis imperfecta

Henna Cederberg-Tamminen[1], Frank V Bensch[2], Tuula Pekkarinen[1], Heikki Kröger[3] & Camilla Schalin-Jäntti[1]
[1]Department of Endocrinology, Abdominal Center, Helsinki University Hospital and University of Helsinki, Helsinki, Finland; [2]Department of Radiology, Töölö Trauma Center, Helsinki University Hospital, Helsinki, Finland; [3]Department of Orthopaedics, Traumatology and Hand Surgery, Kuopio University Hospital and Kuopio Musculoskeletal Research Unit, University of Eastern Finland, Kuopio, Finland.

Context
It is mandatory to rule out secondary causes of osteoporosis in young adult males presenting with osteoporotic fractures. If no such causes are identified, it is important to remember that an underlying genetic defect might explain the phenotype. This has implications for treatment, follow-up, as well as screening of family members.
Case
A 40-year old male (172 cm, 78 kg) with a past medical history of asthma and pollen allergies, initially presented to the orthopedic department with painful right groin. The pain had started 10 days after he fell on his back at work. The pain was provoked by weight-bearing and spread to both groins 1 month after the initial presentation - which on examination was pain on rotation of both hip joints. After the initial non-diagnostic pelvic radiograph and ultrasound, pelvic MRI showed bilateral stress fractures of the femoral necks. Previous history of fractures included high-energy fractures of right thumb and right fifth finger. The patient had a family history of osteoporosis (father and sister) and his father had had a femoral neck fracture at the age of 60. There was no history of fractures from the maternal side. On a DEXA scan, bone mineral density was osteopenic at the lumbar spine and right femoral neck and osteoporotic at the left femoral neck with a T score of -2.8. Primary hyperparathyroidism, and coelic disease were excluded. Serum 25-hydroxyvitamin D(3) was low at 33 nmol/L (reference range $>$ 40). Iliac crest bone biopsy showed low trabecular bone volume with a normal turnover rate, normal osteoblast and osteoclast surfaces, normal mineralising surface, but with a slightly low mineral apposition. Bone biopsy findings were consistent with normal-turnover osteoporosis. The patient was treated with calcium and vitamin D supplementation and alendronate for two years. The bilateral femoral neck fractures healed with conservative treatment but the patient continues to have bilateral hip pains and has early arthrosis of the left hip. Evaluation in Endocrine Department showed no features of Cushing's disease. Both hypercortisolism and hypogonadism were biochemically ruled out. However, genetic analysis revealed a novel mutation in *TMEM38B,* which to our knowledge is the first report of this specific mutation, which causes osteogenesis imperfecta type XIV.
Discussion
Genetic defects may underlie not only pediatric but also adult-onset fragility osteoporosis. Here, we report a novel mutation in *TMEM38B* causing type XIV osteogenesis imperfecta and bilateral femoral stress fractures in an adult male.

Hypomagnesemia induced disturbance of consciousness in alcoholic cirrhosis

Emir Muzurovic[1,2] & Olivera Boskovic[1]
[1]Clinical center of Montenegro, Podgorica, Montenegro; [2]Medical school University of Montenegro, Podgorica, Montenegro.

Introduction
Serum calcium (Ca) is a major regulator of PTH secretion, but serum magnesium (Mg)also can modulate PTH secretion. Intracellular Mg depletion impairs the ability of the parathyroid to secrete PTH,which subsequently cause fall in the serum Ca concentration.
Case report
A 67 year old male patient was admitted to intensive care unit because of disturbance of consciousness, due to suspected hepatic encephalopathy. In his previous history, he had only symptoms suspected on alcoholic polyneuropathy. His Glasgow coma scale was 5, with laboratory findings that indicated liver cirrhosis: hemoglobin 99 g/L, mean corpuscular volume 108 fL, platelets 78 $\times 10^9$,

glycemia 6.9 mmol/L, urea 24 mmol/L, creatinine 111 μmol/L, AST 99 IU/L, ALT 54 IU/L, GGT 267 IU/L, AP 212 IU/L, bilirubin 26 umol/l, LDH 312 IU/l, PV 20.6 s, APTT 44 s, fibrinogen 1.9 g/L, sodium 129 mmol/l, potassium 4.6 mmol/l and albumin 26 g/L. His total serum Ca was 1.12 mmol/L, and ionized Ca was 0.52 mmol/L. Ammonium was normal. Hepato-protective therapy was started with calcium replacement, but without improving the state of consciousness. Further evaluation revealed low PTH values with high phosphorus concentration, which confirmed hypoparathyroidism. By measuring magnesium, we realized hypomagnesemia (Mg 0.27 mmol/L) and add Mg supplementation. Two days after, a gradual increase in Ca, Mg and PTH concentrations lead to improved consciousness, and four days after he recovered completely. The patient developed alcoholic cirrhosis, still without elements of liver decompensation.

Conclusion

Usually hypocalcemic crisis presents with the classical symptomatology of tetany with extrapyramidal symptoms, accompanying with disturbance of consciousness leading to coma. In our patient, hypocalcemia appeared to result from transient hypoparathyroidism induced by magnesium deficiency due of prolonged alcohol abuse.

P114

Is any body composition parameter a risk factor for symptomatic hypocalcemia after thyroidectomy?

Suleyman Utku Celik[1,2], Tolga Akkan[3], Can Konca[1] & Volkan Genc[1]
[1]Ankara University School of Medicine, Ankara, Turkey; [2]University of Health Sciences, Gulhane Training and Research Hospital, Ankara, Turkey; [3]University of Health Sciences, Kecioren Training and Research Hospital, Ankara, Turkey.

Objective

Postoperative hypocalcemia is one of the major concerns following total thyroidectomy as well as the most frequent cause of prolonged hospital stay. The first purpose of this study was to evaluate the relationship between body composition parameters and symptomatic hypocalcemia following total thyroidectomy. In addition, the effects of disease- and patient-related factors on hypocalcemia were investigated.

Methods

In this cohort study, a total of 144 patients were included prospectively between March 2014 and September 2017. Demographics, preoperative biochemical parameters including serum calcium, albumin, parathyroid hormone (PTH), vitamin D, and thyroid function tests, ultrasonographic features of the dominant nodule, placement of the thyroid gland, and histopathological findings were recorded. The body composition measurements including weight, height, body mass index (BMI), total body water, free fat mass, fat mass, body fat range, muscle mass, bone mass, degree of obesity, and visceral fat rating were obtained using a bioelectrical impedance analyzer. Patients who underwent total thyroidectomy were divided into two groups according to the presence or absence of hypocalcemic symptoms. Subsequently, the relationship between body composition parameters and symptomatic hypocalcemia were evaluated.

Results

Postoperative symptomatic hypocalcemia occurred in 28 patients (19.4%). Permanent hypocalcemia was not encountered in any patient in the 12-month follow-up period. Patients with hypocalcemic symptoms were more likely to have a dominant nodule larger than 40 mm (39.3% vs. 17.2%, $P = .011$), retrosternal goiter (25.0% vs. 7.8%, $P = .017$), and parathyroid autotransplantation (28.6% vs. 3.4%, $P < .001$) compared with those without symptoms. However, no differences were observed for body composition parameters between symptomatic and non-symptomatic patients. In addition to these findings, when evaluated separately, patients with a BMI ≥ 25 kg/m^2 had a similar operative time (117.8 min vs. 117.4 min; $P = 0.693$) and length of hospital stay (32.7 h vs. 31.0 h; $P = 0.461$) to patients with a BMI < 25 kg/m^2. On multivariate analysis, lower preoperative PTH levels (OR 1.05, 95% CI 0.93−1.00, $P = .028$), presence of retrosternal goiter (OR 5.26, 95% CI 1.45−19.16, $P = .012$), and parathyroid autotransplantation (OR 16.85, 95% CI 3.68−77.11, $P < .001$) were the independent predictors of symptomatic hypocalcemia.

Conclusion

This study demonstrates that patients with lower preoperative PTH levels, retrosternal goiter, and parathyroid autotransplantation are at increased risk of developing postoperative hypocalcemia. Body composition parameters have no effect on the incidence of symptomatic hypocalcemia after total thyroidectomy.

Severe diffuse tissue calcifications in a patient with pseudohypoparathyroidism type 1 A due to a novel large deletion of GNAS gene

Alessandro Brancatella[1], Giovanna Mantovani[2], Claudio Marcocci[1] & Filomena Cetani[1]
[1]Department of Clinical and Experimental Medicine, Endocrine Unit, University of Pisa, Pisa, Italy; [2]Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, and Department of Clinical Sciences and Community Health, University of Milan, Milano, Italy.

Pseudohypoparathyroidism type 1 A (PHP-1A) is a rare genetic disorder characterized by hypocalcemia, hyperphosfatemia, multi hormones resistance (PTH, TSH, Calcitonin, GH) associated with Albright hereditary osteodystrophy (AHO) features. The disease is caused by GNAS haploinsufficiency due to inherited inactivating mutation of GNAS-gene that codes for the stimulatory alfa subunit of G protein. A positive genotype-phenotype correlation was recently hypothesized. The purpose of this work is to describe a new family affected by PHP-1A. The proband, a 18 years old man, came for the first time to our attention in 2017 for hypocalcemia diagnosed after a tetanic crisis. Physical examination showed the typical features of AHO: round face, stocky habitus with short stature, brachydactyly and ectopic-severe ossification in the back and in the legs. Laboratory tests showed low levels of calcium, high levels of phosphate and high levels of PTH, TSH and calcitonin despite therapy with calcium carbonate, calcitriol and levothyroxine. Computed tomography showed diffuse calcifications 'rosary-like' in the cortex and scalp. Bone radiography showed diffuse soft tissue and costal cartilage calcifications and marked brachydactyly and brachimetacarpy. Family history was remarkable for hypocalcemic crisis associated with neurocognitive impairment and cerebral calcification in the brother. The genetic analysis of the GNAS gene showed a novel large deletion (encompassing exons 1–7), in the proband, in the brother and in the mother. The daily dose of calcitriol, calcium carbonate and L-thyroxine was increased with good control of hypocalcemia thereafter. At the latest evaluation, serum calcium and TSH levels were normal with a reduction of PTH levels. In conclusion, we have identified an additional PHP-1A family with severe phenotype that supports the hypothesis of a positive genotype-phenotype correlation.

Successful removal of parathyroid cancer metastasis from VI thoracic vertebra

Natalia Mokrysheva[1], Julia Krupinova[1], Anna Gorbacheva[1], Valeriy Teplyakov[2] & Pavel Rumyantsev[1]
[1]Endocrinology Research Centre, Moscow, Russian Federation; [2]Russian Scientific Center of X-Radiology, Moscow, Russian Federation.

Background

Approximately 25% of patients with parathyroid carcinoma (PC) have metastases; the most frequent sites include cervical lymph nodes (30%) and lungs (40%). Less common are liver, bones and brain. Surgical resection of local or distant metastases (if possible) provides the best control of hypercalcemia and enhances long-term survival.

Case description

A 70-year old patient was admitted to hospital with a primary hyperparathyroidism (PH). He did not display disease specific signs or symptoms. Blood biochemistry resulted: severe hypercalcemia (total calcium – 3.21 (2.15–2.55)), elevated PTH level - 543 pg/mL (15–65). Ultrasound (US) examination and 99 mTc-Sestamibi (99 mTc-MIBI) scintigraphy detected a tumor of right lower parathyroid gland (PG) – 19 × 22 × 35 mm. A surgical treatment did not lead to remission of the PH, the parameters of phosphorus-calcium metabolism remained on the same levels. The histological examination demonstrated vascular, adipose tissue and capsular invasion regarded as PC. CT-scan showed no evidence of metastatic lesions in lungs, mediastinum, liver, kidneys and adrenal glands. However, PET/CT with 18F-fluorocholine revealed a pathological accumulation focus of 18F-fluorocholine (SUV 8.42) in the arch of VI thoracic vertebra (ThVI). The focus measured up to 20 × 12 × 25 mm. with a displacement of the structural-dural sac at this level. Normal bone tissue in this lesion was replaced by pathological soft tissue. 99 mTc-MIBI full-body scintigraphy showed a high MIBI uptake only in the ThVI. Thus, a decompression laminectomy of ThVI with transpedicular fixation of ThV-ThVII was successfully performed with normalization of PTH and Ca levels (48 pg/ml (15–65) and 2.48 mmol/l (2.10–2.55) respectively). The histological and immunohistochemical examination confirmed the parathyroid metastasis. Another 99 mTc-MIBI scan showed no pathological

uptake in the whole body. The last follow-up in a year after the surgery confirmed the disease remission (PTH 35 pg/ml, Ca 2.3 mmol/l). The patient continues regular monitoring in our center.
Conclusion
Distant local PC metastases could be successfully surgically removed to achieve laboratory remission of the disease.

Primary Hyperparathyroidism: about 34 observations

Asma Zargni, Chadia Zouaoui, Kawthar El Arbi, Amel Jaïdane & Haroun Ouertani
Departement of Endocrinology and Diabetology, The Principal Training Military Hospital, Tunis, Tunisia.

Introduction
Primary hyperparathyroidism (PHP) is the result of excessive, independent, and inappropriate production of parathyroid hormone (PTH). The aim of this work is to study the epidemiological, clinico-biological and therapeutic aspects of PHP.
Materials and methods
This is a retrospective study of 34 patients hospitalized for the management of PHP in the Endocrinology Department of the Military Hospital of Tunis between March 1999 and July 2018.
Results
The average age of our patients was 59 years old with female predominance (sex ratio = 0.37). PHP was asymptomatic in 57% of patients and fortuitously discovered by systematic measurement of serum calcium. The diagnosis was biological: elevated PTH with hypercalcemia or normo-calcemia. Parathyroid ultrasonography/scintigraphy, performed in 90% and 83% of patients respectively, made it possible to locate the pathological parathyroid(s), with a concordant result in 65% of cases. CT/MRI imaging was used in 23.5% of cases, with 6% of patients found to have ectopic mediastinal parathyroid adenoma. Complications were mainly found in kidneys and bone: kidney stones (37%) and osteoporosis (40%). The treatment was in all cases surgical, essentially a subtotal adenomectomy or parathyroidectomy except for cases of ectopic parathyroid nodule, which were addressed in Cardio Thoracic Surgery.
Discussion and conclusion
The signs of hypercalcemia are rarely indicative of PHP but rather sought after positive biological diagnosis. Imaging plays a key role in preoperative diagnosis and surgical approach.

The clinical spectrum and endocrine profile of pseudohypoparathyroidism: ACTH resistance should not be ignored

Eleni Magdalini Kyritsi & Christina Kanaka-Gantenbein
Division of Endocrinology, Metabolism and Diabetes, First Department of Pediatrics, National and Kapodistrian University of Athens Medical School, 'Aghia Sophia' Children's Hospital, Athens, Greece.

Backround
Pseudohypoparathyroidism (PHP) type 1A is a rare disorder characterized by end-organ resistance to the action of parathyroid hormone (PTH), resistance to other hormones that activate Gs-coupled receptors, such as TSH and gonadotropins and phenotypic features of Albright hereditary osteodystrophy (AHO), including short stature, obesity, round face, brachydactyly and subcutaneous ossifications. PHP type 1A is caused by heterozygous loss-of-function mutations in the gene encoding the α-subunit of Gs (GNAS), inherited from the mother or de novo. The clinical features and disease severity may vary considerably among affected individuals.
Objective
To describe the diversity of the clinical and endocrine features in 11 children with PHP seen in our Division between 2007 and 2018.
Methods
In the present retrospective study, the medical records of 11 PHP children were reviewed. Data collected included: a) clinical parameters: age at diagnosis, growth pattern, AHO features, abnormalities of male genitalia b) biochemical parameters: PTH, TSH, LH, FSH, PRL, ACTH, cortisol, calcium and phosphate levels, growth hormone (GH) response following GH stimulation tests, when performed c) bone age d) molecular analysis of the GNAS gene.
Results
The median age at diagnosis was 8.5 months (range: 40 days–9 years). Among 11 PHP patients ($n = 7$ males), 9 were obese (81.8%). 8 out of 9 patients manifested early onset obesity (< 2 years of age). Round face, brachydactyly and ectopic ossifications were present in 90.9%, 81.8% and 72.7% of patients, respectively. During follow-up, growth rate retardation was noted in 45.5% and adult short stature in another 18.2% of our PHP patients. 42.9% of male patients displayed abnormalities of external genitalia. Endocrine features included: increased PTH and TSH in all cases, low PRL in 80% ($n = 8/10$), increased FSH in 10% ($n = 1/10$), and elevated phosphate levels in 81.8%. Only three cases developed hypocalcemia. GH deficiency was diagnosed in 45.5% of patients. Increased ACTH levels were observed in 3 patients (27.3%). Two of them had normal cortisol concentrations. The third case, a 2-year old girl was diagnosed with adrenal insufficiency, first manifested as full-blown adrenal crisis, while undergoing adenoidectomy. Molecular analysis of GNAS gene was performed in 9 cases. Heterozygous mutations were identified in 8 patients (88.9%), one de novo and three inherited from the mother.
Conclusions
PHP disorders may exhibit wide phenotypic variability. Measurement of ACTH and cortisol levels should be always included in the assessment of PHP patients in order to promptly diagnose an associated adrenal insufficiency that can be fatal.

Biochemical and clinical features of a family with a novel mutation of CYP24A1

Alessandro Brancatella[1], Daniele Cappellani[1], Martin Kaufmann[2], Simona Borsari[1], Glenville Jones[2], Claudio Marcocci[1] & Filomena Cetani[1]
[1]Department of Clinical and Experimental Medicine, Endocrine Unit, University of Pisa, Pisa, Italy; [2]Department of Biomedical & Molecular Sciences, Queen's University, Kingston, Canada.

Context
Mutations of cytochrome P450 24 subfamily A member 1 (*CYP24A1*) gene are associated with Idiopathic Infantile Hypercalcemia (IIH), a disease recently related to vitamin D catabolism impairment.
Aim of the study
Report of clinical and biochemical features of a large family with a novel mutation of CYP24A1.
Methods
We performed dosage of total calcium, ionized calcium, 24 h urinary calcium, PTH, 25-OH-Vitamin D (25-OH-D), and 24–25 Vitamin D, genetic analysis of CYP24A1 and abdomen ultrasound in the proband, a 44 year old man, and in first-degree relatives (Mother, Father, Sister and Two sons). Vitamin D metabolites were analyzed using liquid chromatography mass spectrometry at Queen's University Laboratory (Kingston, Canada).
Results
The proband showed high levels of total calcium, 25-OH-D, 1,25-(OH)2-D and low levels of PTH, 24,25-(OH)2D3 and 1,24,25-(OH)3D3. 25-OH-D/24-25-OH-D ratio was high (500.5). Abdomen ultrasound showed bilateral nefrolitiasis. Genetic analysis revealed a novel homozygous mutation. In first-degree relatives, serum calcium and 25-OH-vitamin D were in the upper limit of normal range and PTH low. The 25-OH-D/24-25-OH-D ratio was normal. Abdomen ultrasound showed nefrolitiasis only in the sister. Genetic analysis confirmed the mutation in heterozygosity in each member.

Family members	CYP24A1 Mutation	*Ca^{2+} (mmol/L)	*PTH (ng/L)	25-OH-D (ng/mL)	24,25-$(OH)_2$D3 (ng/mL)	*25D3/ 24,25D3	1,24,25-$(OH)_3$D3 (pg/mL)	1,25-$(OH)_2$D3 (pg/mL)	Nephro-lithiasis
Proband (M 44 yr)	c.667 A>T p.Arg223 Homozygous	1.34	6	71.89	0.14	500.5	<2	68.2	yes
Sister (54 yr)	c.667 A>T p.Arg223 Eterozygous	1.26	14	32.26	1.54	20.6	19.7	56.6	yes
Son (13 yr)	c.667 A>T p.Arg223 Eterozygous	1.33	12	37.55	1.83	20.4	15.6	97.2	no
Son 2 (11 yr)	c.667 A>T p.Arg223 Eterozygous	1.37	20	40.59	1.53	26.3	10	70.4	no
Father (85 yr)	c.667 A>T p.Arg223 Eterozygous	n.a.	n.a	38.95	1.15	33.6	10.8	41.6	no
Mother (82 yr)	c.667 A>T p.Arg223 Eterozygous	n.a.	n.a	48.93	2.37	20.5	17.2	38.3	no

n.a.: not available*Ca2+: normal range 1,12–1,32 mmol/L * PTH: normal range 8-40 ng/L *25D3/24,25D3: normal range < 30.

Conclusions
We report the biochemical and clinical features of a family with a novel CYP24 A1 mutation. Preliminary data suggest that the new mutation is associated with a mild phenotype. However, genetic and environmental factors could contribute in the clinical outcome.

DOI: 10.1530/endoabs.63.P119

A case of primary hyperparathyroidism in a patient with Lobstein's disease

Sabrine Mekni, Ibtissem Oueslati, Wafa Grira, Ons Rejeb, Meriem Yazidi, Fatma Chaker & Melika Chihaoui
Department of endocrinology, La Rabta hospital, Tunis, Tunisia.

Introduction
Osteogenesis imperfecta also known as Lobstein's disease (LD) is a rare disorder of type 1 collagen characterized by an increased susceptibility to bone fractures. Its coexistencewith primary hyperparathyroidism (PHP) was rarely described. Herein we report a new case of a primary hyperparathyroidismin a patient with a history of Lobstein's disease.
Observation
A 35-year-old woman was referred to our departmentfor hypercalcemia. Her past medical history included osteogenesis imperfecta type I diagnosed at the age of 8 years and recurrent urinary tract infections due to a vesicoureteral reflux. She presented with nausea, vomiting, constipation, bone pain, muscle weakness and depression. On examination, she had a body weight of 70 kg, a short stature, a body mass index of 28.39 kg/m^2, a blue sclera, a blood pressure of 100/60 mmHg and a regular pulse of 75 beats/min. The laboratory investigations showed a serum calcium level of 114 mg /L(normal range: 85–105), a urinary calcium level of 330 mg/24 h, a phosphate level of 17 mg/l (normal range: 25–45), a creatinine level of 7 mg/l, a magnesium level of 21 mg/l (normal range:16–26 mg/l) , a serum albumin of 34 g/L (normal range: 38–56), a Vitamin D deficiency (25 OH Vitamin D level of 5,5 µg/L, normal range: 30–80 µg/L) and an elevated parathormone level of 626 pg/ml (normal range: 10–65 pg/ml). Radiographs of long bones showed cortical bone thinning and excessive trabecular bone transparency. Bone densitometry revealed osteoporosis. Cervical ultrasound and parathyroid scintigraphy were normal. Cervical computed tomography disclosed a left superior parathyroid adenoma. Parathyroid adenomectomy was performed to the patient. After surgery, serum calcium and PTH level were normal (91 mg/l, 29 pg/ml, respectively).
Conclusion
PHP and LD are two disorders affecting the skeletal system and the calcium metabolism. Their coexistence seems to be a chance occurrence. However, it has been suggested that LD may predispose to PHP. In fact, the lifelong disorder of skeletal homeostasis in LD may lead to a secondary hyperparathyroidism and then to autonomous parathyroid tumor formation.

Lifestyle modification strategies to prevent diabetes in individuals who participated in a medical health check

Toshihiro Takao[1], Fumiaki Mikami[2], Yoshiyuki Yamanaka[1], Sohachi Fujimoto[1], Tomoari Kamada[1], Hiromi Kataoka[2] & Mihoko Okada[2]
[1]Kawasaki Medical School, Kurashiki, Japan; [2]Kawasaki University of Medical Welfare, Kurashiki, Japan.

Several lifestyle modification strategies have been suggested to prevent lifestyle-related diseases. However, the situation may be different for health check participants and outpatients. This study aimed to determine suitable lifestyle modification strategies to prevent diabetes in individuals who participated in a medical health check using retrospective cohort study. Individuals who participated in a medical health check in Fukuyama, Japan every year from 2011–2015 were investigated. Laboratory data between 2011 and 2015 were compared and the association between current lifestyle and onset of diabetes in the next 5 years was assessed via Cox proportional hazard model, controlling for age, sex, and body mass index (BMI). Disease onset was defined as the year of starting relevant medications. BMI was not different between 2011 and 2015. By contrast, waist circumference, systolic blood pressure, diastolic blood pressure, plasma glucose, and hemoglobin A1c levels were significantly higher in 2015 compared with those of 2011. Onset of diabetes was related to current smoking. In addition, 'eating quickly' was relevant to the onset of diabetes in the next 5 years. Medical professionals generally use 'less calories and more exercise' as advise to patients with lifestyle-related diseases. However, recommended lifestyle modification for those undergoing health checks and those in an outpatient-setting should be modified as appropriate, as they may have different characteristics from those who already have lifestyle-related diseases.

Effects of ginger powder supplementation on glycemic status and lipid profile in newly diagnosed obese patients with type 2 diabetes mellitus

Maram M Aboromia[1], Hesham Elgayar[1], Nesma Aly[1] & Mostafa Hussein[2]
[1]Ain Shams University, Cairo, Egypt; [2]Diabetes Institute, Cairo, Egypt.

Diabetes is a huge problem affecting 387 million adults by a global prevalence of (8.3%) which is expected to rise to (10.1%) by 2035. Type 2 diabetes, a growing public health problem, is associated with increased morbidity and mortality.
Aim
To evaluate the effects of ginger powder supplementation on glycemic status, lipid profile and beta-cell function in obese Egyptian patients with new-onset type 2 Diabetes Mellitus.
Design
A randomized, single blind, placebo-controlled clinical trial, was performed on 80 subjects newly diagnosed with T2DM conducted at the National Institute of Diabetes and Endocrinology. Subjects were randomly divided into: Group 1: Ginger Group (GG), consumed three capsules daily, each capsule containing: 600-mg of ginger powder (total daily dose was 1.8 g), they also underwent certain diet and physical activity changes, and also received metformin as one 850-mg tablet twice a day with meals for a duration of 8 weeks. Group 2: Placebo Group (PG), which received capsules of the same color, size, and number as (Group 1) but containing wheat flour, they also underwent the same diet, physical activity, and metformin dosage as (Group 1) during the 8 weeks of the study.
Results
Ginger powder supplementation significantly reduced body mass index, fasting blood glucose, 2-hour postprandial blood glucose, glycated hemoglobin, total cholesterol, low density lipoprotein cholesterol, triglycerides, fasting insulin levels, and homeostasis model assessment-insulin resistance index(HOMA2-IR). Ginger also significantly increased high density lipoprotein cholesterol levels, beta cell function index (HOMA2-%β) & insulin sensitivity index (HOMA2-%S) in comparison to the placebo group.
Conclusion
Ginger supplementation could be an effective adjuvant therapy for patients with T2DM.

Effects of lemon and cumin on premature atherosclerosis in obese patients

Randa Salam[1], Mary Fawzy[1], Rehab Gab Alla[2], Samah Sayed[3], Seham Mahmoud[3] & Ashraf Abd El Megid[3]
[1]Cairo Unversity, Cairo, Egypt; [2]Agriculture Research Center, Cairo, Egypt; [3]Helwan, Cairo, Egypt.

Background
Obesity is a multifactorial chronic disease that leads to a cardio-metabolic disease, with increased incidence of atherosclerosis.
Aim
Our aim to evaluate premature atherosclerosis in those patient and the impact of different diet on ameliorating its course.
Methodology
100 obese patients were subjected to Hb A1c, Fasting blood glucose, lipid profile, carotid artery duplex, and Brachial artery flow media dilation divided into five groups each group includes 20 patients, mean age 30–45y. group 1 without regimen diet considered as a control group, group 2 on diet regimen, group 3 diet plus cumin, group 4 diet plus lemon, group 5 diet plus cumin and lemon.

Results
There was statistically significant difference in flow mediated dilation of the brachial artery between all groups and group 1 with better values in group 3 yogurt with lemon and cumin group, however there was no differences between other groups. There was statistically significant difference between all groups and group 1 in intima media thickness, LDL, cholesterol, triglycerids, BMI, glucose level, HA1C, serum creatinine with higher values in group 1, and between all groups and group 1 in HDL with lower values in group 1. There was statistically significant difference in those use lemon and cumin and all other groups in HDL with higher values in first group.
Conclusion
Combination of lemon and cumin raise the protective effect of either component alone in preventing premature atherosclerosis in obese patients.

Management of acute charcot arthropathy

F Ahmad, S Yehia, F Devaka, V Muraleedharan, S Sihota, H Abdulla, E Higgins, A Fisher & J Thompson
Kings Mill Hospital, Mansfield, UK.

Aims/objectives
The aim of this retrospective audit on MANAGEMENT OF ACUTE CHARCOT ARTHROPATHY was to assess the current practice at King's Mill hospital against the latest National institute of clinical excellence guidelines.
Methods
A retrospective audit of 22 patients with diabetes presented with acute Charcot neuro-arthropathy, between January 2016 and August 2018 to the specialist diabetes foot team at KMH. The data was collected from the hospital software systems ICE, ORION, EPRO and patients' files.
Results
Of These 22 patients 16 were males, 18 patients (31.82%) were type 2 diabetics. 31.82% patients had diabetes duration >20 years, 27.28% for 10 to 19 years, 31.82% patients 5 to 10 years whereas 9.09% patients had less than 5 years. 59.09% patients had associated ulcer on foot. 27.27% patients had history of fracture of the affected foot in the past, whereas 36.36% patients had history of previous amputation. 81.82% patients were known to have peripheral neuropathy and 40.91% had history of CKD. 72.27% patients were known to have hypertension, 45.45% hyperlipidemia and 40.91% patients had history of cardiovascular disease. Charcot was on right side in 72.73%. All the patients had clinical suspicion which was later confirmed on MRI in 54.55%, whereas 22.73% had single X-ray. Temperature difference was not documented in 4.55%. 54.55% had less than 3 degrees difference whereas remaining had more than 3 degrees difference. 90.91% patients had documented advice of weight off-loading. 50% had removable cast and 50% had non-removable ones. 90.91% patients had serial temperatures documented and 4.55% patients had serial x-rays done. 50% patients had complete resolution of acute arthropathy, whereas others had partial resolution so far.
Conclusions
The audit demonstrated that all the patients were given cast (removable or non-removable) and were followed up in MDS Diabetes Foot Clinic. Temperature difference on presentation was documented in 95.45%. However the two key concerns were that only 4.55% patients had serial X-rays done for monitoring and 09.09% patients did not have documented advice of weight off-loading. It is really important to check and document temperature difference and do serial X-rays during follow up of these patients in order to bridge the gap between current recommendations and clinical practice.

Non-Governmental Organizations (NGO's) & Diabetes – advocacy for support services in resource-poor nations

S Pal, T Roy, V Shastri & Pande R
SFCCP, Meerut, India.

Background
Diabetes-support services facilities available only in few city hospitals. Especially diabetics in rural India lack comprehensive diabetes care plan. NGO's play key role in psychosocial-support/Counseling/rehabilitation in remote towns of India. Our Project aimed to formulate policy for trained personals to give better & cost-effective Diabetes-support services.
Methods
We mobilized training resources from local primary Health-centers. Training in Counseling & diabetes care imparted to nurses. Team consisted 2 social worker, 4 nurse & one physician. Local traditional faith-healers & community leaders involved for more effective diabetes awareness/education programs. Aim was to provide physical-comfort to patient, improve relationship with diabetics family members, gradually we prepared patient/family for long term diabetes care needed by patients. Discomfort/anxiety decreases overall treatment efficacy. 51 Patients enrolled during community out-reach-programs. Data collected on feedback-questionnaire. Most difficult tasks is discussing cost of long term therapy & non-availability of newer insulin preparations in rural/tribal areas.
Results
Diabetes Counseling/ support services must be made more accessible in rural-areas. Our NGO's approach is also very cost-effective. Due to non-availability of trained-personal in rural areas this approach crucial in resource poor nations. We noted 86% responded favorably to counseling/nursing care programs, 79% showed willingness to motivate fellow patients to facilitate supportive-care-program of NGO-volunteers. Infact 17 patients themselves became regular active facilitators in our NGO's Diabetes-care workshops. Our Holistic approach helped overcome hopelessness/fear depression. supportive care emerged very serious issue affecting QOL in diabetics. NGO's need to Improve access to drugs by collaboration with national diabetes societies.
Conclusion
In no extra cost our NGO's performed good job of Counseling/rehabilitation for diabetics. Restricted resource-limitations didnot permit us to take study large-sample-size, but we can collaborate with other NGO's & diabetic associations for larger effort.

Microvascular and macrovascular complications in a cohort of patients with type 2 diabetes mellitus

Sandra Herranz-Antolín, Visitación Álvarez-de Frutos, Miguel Torralba & Andrea Biedma-Méndez
University Hospital of Guadalajara, Guadalajara, Spain.

Objective
To assess the prevalence of complications In a cohort of patients with type 2 diabetes mellitus (T2DM).
Material and methods
Prospective cohort study. 465 patients with T2DM who were not followed-up at an endocrinology clinic were included. The follow-up was carried out during 26 weeks. The prevalence of complications was evaluated throughout the study. This

Table 1 Associated factors with DN, OD and MD in the multivariate logistic regression analysis.

	OR			95% CI			P		
	DN	OD	MD	DN	OD	MD	DN	OD	MD
Age (years)	1	1.1	1.1	0.9–1.1	0.9–1.2	1–1.2	0.104	0.074	0.002
Male	2.8	1.1	4.1	1.4–5.8	0.5–2.2	1.9–8.8	0.0004	0.809	<0.0001
Time of evolution ≥ 5 years	1.7	3.7	0.9	0.8–3.7	1.4–9.7	0.4–2.2	0.208	0.008	0.883
Initial HbA1c (%)	1.7	0.7	1.2	1.1–2.7	0.4–1.1	0.8–1.7	0.029	0.124	0.474
HbA1c in the previous two years (%)	2	1.9	0.9	1.2–3.4	1.1–3.1	0.6–1.4	0.006	0.014	0.568

study was approved by the Ethics and Clinical Research Committee of the University Hospital of Guadalajara (Spain).
Results
Mean age was 63.4 ± 12.5 years and 61.5% were males. Time of evolution of T2DM was ≥5 years in the 69.9%. Initial HbA1c was 8.3% ± 1.8 and the HbA1c at the 26th week of the follow-up was 6.6% ± 0.9 (difference of mean 1.7; 95% CI 1.4–1.9; $P < 0.0001$). The 80.6% of patients had hypertension (HT), 83.1% had dyslipidemia (DL), 61.5% had obesity and the 16.8% were smokers. 25.1% of patients had diabetic nephropathy (DN), 21.9% had ocular disease (OD) (retinopathy and/or macular edema) and the 6.9% had diabetic foot or amputation. Regarding to macrovascular disease (MD), the 4.9% had cerebral vasculopathy, 7.7% had peripheral arterial disease and 19.8% had coronary disease. The factors that were independently associated with the presence of complications are shown in Table 1.
Conclusions
• The prevalence of cardiovascular risk factors is high in the cohort of patients and microvascular complications are more frequent than macrovascular ones.
• Poor metabolic control of T2DM is associated with the presence of microvascular complications among other factors. However, it is not associated with the presence of macrovascular disease.

Calbindin-D9k ablation cause endoplasmic reticulum stress induced β cell death

Eui-Bae Jeung, Changhwan Ahn & Dinh Nam Tran
Chungbuk National University, Cheongju, Republic of Korea.

Cellular Ca^{2+} signals have been proposed to activate signal for hormone secretion. In pancreatic β cell which produce insulin, Ca^{2+} signals have been known contributing insulin secretion. Prior to conduct this study, we confirmed Calbindin-D9k (CaBP-9k) which responsible for regulation of the distribution of free calcium in the cytoplasm. We confirmed Insulin-secreting β cell express CaBP-9k and assumed that CaBP-9k play a certain role in β cell insulin synthesis or secretion. Using CaBP-9k knock out (CaBP-9k KO) mice, we demonstrate ablation of CaBP-9k induces reduction of insulin secretion and hyperglycemia. Furthermore, to find the role of CaBP-9k in pathophysiologic condition, we evaluate the pathophysiology of aged wild-type and CaBP-9k KO mice. Compare to the aged wild-type mice accumulates abdominal fat, CaBP-9k KO mice does not. CaBP-9k mice showed decreased expression of PPARγ in liver, results in decreased lipid synthesis. Furthermore, CaBP-9k KO ablation induces endoplasmic reticulum (ER) stress, which increase insulin resistance. CaBP-9k KO mice showed more increased level of ER stress marker protein than wild type mice. Taken together, we assumed that CaBP-9k play a certain role in glucose homeostasis accompanying decreased lipid metabolism.

Serum 25-hydroxycholecalciferol and the A allele of rs2228570 of the vitamin D receptor locus reduce the risk of type 2 diabetes mellitus in Jordan

Mahmoud Alfaqih & Abdullah Araidah
Jordan University of Science and Technology, Irbid, Jordan.

Diabetes mellitus (DM) is a disease of epidemic proportions. Most of DM patients are classified as type 2 diabetes mellitus (T2DM) that is linked with resistance to insulin action on target tissues. In 2015, 415 million people were living with DM worldwide with the highest prevalence rates recorded in the Oceania and the Middle East and North Africa (MENA) regions. In Jordan, a MENA country, the prevalence of DM has increased from 13% to 17% over a 10-year period (1994–2014). This highlights the need to identify risk factors associated with the current DM epidemic. This will better inform the public health policy of potential preventive measures to control the disease. Vitamin D, cholecalciferol, is a fat-soluble vitamin and a hormone. Vitamin D traditional role is to maintain calcium homeostasis and bone health. Vitamin D is increasingly recognized for its' 'extra-skeletal' activities including a role in regulating insulin action on target tissues. Vitamin D elicits its action via binding to the vitamin D receptor (VDR). VDR, a nuclear receptor, mediates its action through transcriptional regulation of target genes. Vitamin D deficiency was reported in T2DM patients in several populations but not in Jordan. Herein, we recruited 125 T2DM patients and 125 healthy controls matched by gender and body mass index (BMI). We found that 25-hydroxycholecalciferol (25(OH)D) levels were lower in T2DM patients ($P = 0.0306$). We also genotyped subjects for the following VDR SNPs (rs2228570, rs1544410, rs7975232 and rs731236). We showed that under a dominant inheritance model, the A allele of rs2228570 reduces the risk of DM ($P = 0.0432$; OR 0.597; 95% CI 0.362-0.984). This effect was independent of age and 25(OH)D levels. Haplotype analysis of VDR rs2228570, rs1544410, rs7975232 and rs731236 showed that the ACAA and GAAG haplotypes both reduced the risk of DM in our population ($P < 0.05$). Our findings indicate that vitamin D deficiency/insufficiency may be a risk factor of T2DM in Jordan. Normalizing 25(OH)D levels in the general population may be a feasible and well-tolerated approach to reduce T2DM burden in Jordan.

Long term functional prognosis is worse in patients with chronic hyperglycemia

Julia Silva-Fernández[1], Rafael García-Ruiz[2], Francisco Javier Gómez-Alfonso[1], Florentino Del Val-Zaballos[1], Belvis Torres-Arroyo[1], Paloma González-Lázaro[1], Cristina Contreras-Pascual[1], Critina Montalbán-Méndez[1] & Inés Gómez-García[1]
[1]Endocrinology Department, Mancha Centro General Hospital, Alcázar de San Juan, Spain; [2]Neurology Department, Mancha Centro General Hospital, Alcázar de San Juan, Spain.

Diabetes and acute hyperglycemia are known to increase stroke volume and disability in stroke patients, and deliver worse outcomes after reperfusion therapies. Chronic glycemic status has recently been linked to stroke functional outcome, but its impact on long term prognosis of stroke has rarely been studied. We conducted a study to investigate the impact of glycosylated hemoglobin (HbA1c) levels on functional outcome 1 year after stroke.
Methods
Patients with acute stroke or TIA were prospectively included. Sociodemographic factors, premorbid conditions, and clinical, biochemical and hematological parameters that were considered as possible prognostic factors in previous studies were collected, as well as modified Rankin Scales (mRS) scores at different times. Multivariate logistic regression analyses were conducted to identify factors related to achieving functional independency 12 months after stroke. HbA1c levels higher than 6.4% were considered as pathologic.
Results
382 patients were included. In 217 of them (56.81%) mRS was 2 or less 12 months after stroke, while 167 (43.19%) had a mRS ≥ 3. Medium HbA1c on admission was 6.6 ± 1.55% (6.29 ± 1.43% vs 6.76 ± 1.70%; $P = 0.032$). Additionally, 130 patients (34.03%) had HbA1c levels higher than 6.4% (23.08% vs 44.76%; $P < 0.001$). In multivariate analysis for functional independency, elevated HbA1c level was an independent predictor of functional dependency 1 year after stroke (OR 0.190; CI 95% 0.064–0.568; $P = 0.003$).
Conclusions
Chronic glycemic status is an independent prognostic factor for long term outcome after stroke, as patients with higher HbA1c are more frequently disabled one year after the event. We propose that HbA1c levels should be determined in all stroke patients to help physicians predict functional status after stroke.

Role of blood catecholamine in cases with dysmetablolic iron overload syndrome (DIOS) in patients of Metabolic Syndrome

Hany William Z Hanna[1], F El-Mougy[1], Heba N Baz[1] & Hemmat E El Haddad[2]
[1]Chemical Pathology, Faculty of Medicine, Cairo University, Cairo, Egypt; [2]Internal Medicine Department, Faculty of Medicine, Cairo University, Cairo, Egypt.

Background
Dysmetabolic iron overload syndrome (DIOS) is characterized by elevated ferritin and normal transferrin saturation level. Iron metabolism may be linked to the sympathetic overactity. DIOS is seen in 15–20% of the metabolic syndrome cases.
Aim
This study aimed to test the hypothesis linking the increased baseline sympathetic drive to the hypertension seen in dysmetablolic iron overload syndrome in cases of metabolic syndrome.
Subjects
64 hypertensive patients with metabolic syndrome diagnosed based on the criteria of National Cholesterol Education Program (NCEP)compared to 37 hypertensive controls without metabolic syndrome.
Methods
History and general examination including height, weight, BMI and waist circumference measurements were done for both cases and controls. Panel of assay (CRP, cholesterol, triglycerides, uric acid, glucose, creatinine, ALT and GGT). Iron, transferrin, ferritin, insulin and catecholamines (adrenaline, noradrenaline and dopamine) were measuredfor both groups. Transferrin saturation and HOMA-IR were calculated as well.
Results
Six patients were found fulfilling criteria of DIOS represented 9.3% of metabolic syndrome patients. Demographically DIOS patients were shown to be statistically older when compared to non-DIOS patients (P value$=0.026$). BMI of DIOS patients (mean$=28.2$, SD$=2.5$) was found to be statistically lower than non DIOS patients (mean$=33.7$, SD$=6.2$) (P value $=0.033$). 4 out of 6 DIOS cases were females. No significant difference was found between the cases presenting with DIOS versus the Non DIOScases as regard to assayed catecholamines (adrenaline P value $=0.4$, noradrenaline P value $=0.68$, dopamine$=0.516$).
Conclusion
9.3% of metabolic syndrome cases were diagnosed as dysmetabolic iron overload syndrome. Thus, iron profile and liver MRI should be done routinely in these cases for early diagnosis of liver cirrhosis and hepatocellular carcinomas. Further research on more mass population should be continued to assess the role of age, gender and BMI in the pathogenesis of DIOS.

Incidence of obesity, overweight and hypertension in children and adolescents in Ahvaz southwest of Iran

Homeira Rashidi[1], Azam Erfanifar[2], Seyed Mahmoud Latifi[1], Seyed Peyman Payami[1] & Armaghan Moravej Aleali[1]
[1]Diabetes Research Center, Health Research Institute, Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran, Republic of Islamic; [2]Diabetes Research Center, Health Research Institute, Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran, Republic of Islamic.

Objective
The purpose of this study was to investigate the incidence of obesity, overweight and Hypertension in children and adolescents aged 10–15 in Ahvaz.
Methods
This is a epidemiologic study performed on 176 people aged 10–15 in Ahvaz. In 2009, 300 people underwent weight, height and blood pressure measurements. Five years later, the same people were reassessed for obesity, overweight and hypertension, of whom a total of 176 people agreed to repeat the procedure.
Results
The study included 100 (57%) males and 76 (43%) females. Mean BMI was 22.1 ± 4.3 kg/m^2 in year 2014, without any significant difference between the two sexes ($P=0.518$). In the same year, the prevalence of obesity and overweight was 26 (14.8%) and 13 (7.4%), respectively. After 5 years, BMI increased significantly ($P<0.001$). Of the 150 norma participants with normal BMI in 2009, 15 (10%) and 6 (4%) became overweight and obese in 2014 respectively. The mean systolic and diastolic blood pressures increased significantly over 5 years $P=0.042$ and $P<0.001$.
Conclusions
This study shows an increase in mean BMI and mean systolic and diastolic blood pressures after 5 years among people aged 10–15 in Ahvaz.

DOI: 10.1530/endoabs.63.P131

Association of serum lipid profile and insulin resistance in polycystic ovary syndrome (PCOs) women in Ahvaz, Iran

Homeira Rashidi, Mina Tafazoli, Mohammad Taha Jalali & Armaghan Moravej Aleali
Diabetes Research Center, Health Research Institute, Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran, Republic of Islamic.

Polycystic ovary syndrome is a common endocrine disorder in women was associated with lipid disorders with increased risk of cardiovascular disease and obesity are associated. This study aimed to compare the lipid profile and fasting plasma glucose levels, insulin resistance in women with polycystic ovary syndrome is done with the control group.
Methods
This case–control study on 153 women with PCOS and 449 healthy control subjects from 4 cities in the province of Khuzestan) was performed. Serum lipids, fasting plasma glucose and serum insulin levels associated with BMI, HOMA IR, Lipid Accumulation Product Index and Body Adiposity Index in the two groups were compared using appropriate statistical tests.
Results
Prevalence of low HDL and total cholesterol$>$ 200 in women with polycystic ovary higher than the control group (respectively $P=0.032$ and $P=0.001$). Average levels of total cholesterol, triglycerides, HDL, LDL, glucose and indicators HOMA IR, LAP and BA in between the two groups showed no significant difference. In PCOs women with BMI <25 and BMI between 25 and 30, mean total cholesterol was higher than the control group, the PCOs subjects with BMI$>$ 30 had average triglycerides and glucose higher than women in the control group respectively $P=0.029$, $P=0.010$.
Conclusion
The level of triglycerides and glucose in obese women with polycystic ovary syndrome were more than healthy women. PCOs non-obese women had a total cholesterol level higher than healthy women.

A1c level in people with newly diagnosed type 2 diabetes during screening

Anna Alieva[1], Saydiganikhodja Ismailov[2] & Gulnara Rakhimova[3]
[1]Republican Specialized Scientific-Practical Medical Centre of Endocrinology named after academician Ya.Kh.Turakulov, Tashkent, Uzbekistan; [2]Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan; [3]Tashkent Institute of Postgraduate Medical Education, Tashkent, Uzbekistan.

Background
There are about 50% of people living with undiagnosed diabetes worldwide. Moreover, by the time of diabetes diagnosis, chronic disabling complications are already present.
Aim
To assess level of A1c by the time of type 2 diabetes diagnosis.
Material and methods
We analyzed results of type 2 diabetes screening in three regions of the Republic of Uzbekistan among 2521 people aged 35 or older without known carbohydrates metabolism disorders. A1c was tested using method of immune precipitation with anti-human and anti-mouse A1c antibodies (Human), oral glucose tolerance test was performed with 75 g glucose. Diabetes was diagnosed according to IDF recommendations.
Results
Average fasting glycemia in people with newly diagnosed diabetes was 9.6 ± 0.3 mmol/l ($P<0.001$ comparing to people without carbohydrate metabolism disorders), average 2h post-load glycemia was 13.7 ± 0.5 mmol/l ($P<0.001$). Average A1c level was $9.4 \pm 0.24\%$ ($P<0.001$). 49% of people with newly diagnosed diabetes had A1c level $\geq 9\%$, and 33% had A1c $\geq 10\%$.
Conclusion
By the time of type 2 diabetes diagnosis, average A1c level is very high, and almost in half of patients demand as a minimum double (16%) or triple (33%)

combination therapy (according to international algorithms), including injectable medicines. Informational campaign in population about first clinical symptoms and signs of diabetes is essential as well as regular screening in high diabetes risk groups.

Metabolic syndrome is associated with peripheral endothelial dysfunction amongst men

Riad Taher[1,2], Jaskanwal D Sara[1], Behnam Heidari[1], Lilach O Lerman[1] & Amir Lerman[1]
Clinic College of Medicine and Science, Rochester, MN, USA; [2]Rambam Health Care Campus, Haifa, Israel.

Background
Metabolic syndrome (MetS) and peripheral endothelial dysfunction (PED) are both independently associated with an increased risk of cardiovascular disease (CVD). PED provides prognostic information beyond that provided by conventional risk factors. However, the association between MetS and PED remains uncertain. We evaluated the association between MetS and PED.
Methods
We performed a retrospective analysis of patients who were referred to Mayo Clinic between 2006 and 2014 for evaluation of chest pain and/or an assessment of CVD risk that included an assessment of PED measured with reactive hyperemia peripheral arterial tonometry (index <2.0 defines PED). MetS was defined as the presence of at least 3 of the following: body mass index $\geq 25\ kg/m^2$, impaired fasting glucose or diabetes, high blood pressure, hypertriglyceridemia, or low high-density lipoprotein cholesterol.
Results
Six hundred seventy eight patients were included (mean age 51.9 ± 13.5 years, 418 (61.6%) women), of which 293 (43.2%) had PED, and 249 (36.7%) had MetS. In multivariable analyses adjusted for age, sex, presence of obstructive CVD, smoking status and elevated low-density lipoprotein, MetS was significantly associated with PED (Odds Ratio (OR) 2.06; $P=0.0090$). Of the individual MetS components, only being overweight and MetS range high density lipoprotein had a similar association. After stratifying by sex with adjustment for the same confounding variables except sex, the association between MetS and PED persisted only in men (OR 3.16, $P=0.0094$).
Conclusions
MetS is associated with PED in men undergoing an assessment of chest pain and/or CVD risk. Identifying PED in individuals with MetS could provide an abridged assessment of risk, potentially allowing for earlier and more intensive management of risk factors.

The frequency of Cushing's disease, ACTH independent Cushing's syndrome, and autonomous cortisol secretion among turkish patients with obesity

Resit Volkan Atar[1], Ismail Yildiz[2], Birol Topcu[3], Gulsah Elbuken[2] & Sayid Zuhur[2]
[1]Namik Kemal University, Faculty of Medicine, Department of Internal Medicine, Tekirdag, Turkey; [2]Namik Kemal University, Faculty of Medicine, Department of Endocrinology and Metabolism, Tekirdag, Turkey; [3]Namik Kemal University, Faculty of Medicine, Department of Bioistatistic, Tekirdag, Turkey.

Objectives
The frequency of Cushing's disease (CD), ACTH independent Cushing's syndrome (CS) and autonomous cortisol secretion (ACS) in patients with obesity is not well known and the results of the studies are heterogeneous. Therefore, in the present study, we aimed to assess the frequency of CD, CS, and ACS among patients with obesity.
Methods
In this study, 813 consecutive patients [683 female, mean age 46.47 ± 14.23-year-old, mean BMI $37.31 \pm 6.50\ kg/m^2$] who were admitted due to obesity between January 2010–December 2015, were retrospectively analyzed. All patients who admit due to obesity to our institution are evaluated for Cushing's syndrome by clinical and laboratory evaluations. The diagnosis of obesity was made according to BMI and the obesity was classified further to grade 1, 2 and 3, according to the BMI. Serum cortisol levels failed to suppress to $< 1.8\ \mu g/dl$ after overnight 1 mg dexamethasone suppression test (DST) in 44 (5.4%) patients. These patients were evaluated further by 2 days 2 mg DST, 24 hours urinary free cortisol excretion, late-night salivary cortisol, and plasma ACTH levels. The patients with CD, CS and ACS and those without these conditions were compared in terms of gender, age, diabetes, hypertension, and hyperlipidemia.
Results
Forty-four (% 5.4) out of 813 patients were diagnosed as CD, CS or ACS. Five (0.6%) of the patients were lost to follow-up. According to the laboratory, pituitary and upper abdominal MRI results, CD, CS, and ACS were diagnosed in 4 (0.4%), 2 (%0.2) and 33 (4%) out of 39 patients, respectively. Among patients diagnosed as CD, CS and ACS, 4, 2 and 2 patients underwent transsphenoidal surgery and unilateral adrenalectomy, respectively. When patients with CD, CS, and ACS were compared to those without these conditions, older age at diagnosis, and the presence of stage-1 obesity, hypertension, diabetes and uncontrolled DM (Hgb A1c $>$ 7%) were significantly higher in patients with CD, CS and ACS ($P=0.001$, $P=0.007$, $P=0.004$, $P=0.038$ and $P=0.026$, respectively).
Conclusions
According to the results of this study, the frequency of CD, CS, and ACS are high among patients with obesity. Therefore, all patients with obesity, particularly patients older than 50 years of age with grade-1 obesity, who also have type-2 diabetes and hypertension, as well as those with uncontrolled diabetes, should be evaluated in terms of CD, CS or ACS.

Higher level of astrocyte elevated gene 1 expression in peripheral blood monocytes in adults with newly diagnosed type 2

Shahjada Selim[1], SK. Md. Khorshed Alam[1], Mohammad Shahnoor Hossain[2] & Sahadat Hossain Riyad[2]
[1]Bangabandhu Sheikh Mujib Medical University, Dhaka, Bangladesh; [2]Dhaka University, Dhaka, Bangladesh.

Background
Diabetes mellitus or more appropriately type 2 diabetes mellitus (T2DM) is the most heterogeneous form of diabetes which is caused by complex interactions between genetic and environmental factors. Although genome-wide analysis has found several single nucleotide polymorphisms (SNPs) in association with T2DM, their documented role is ambiguous and very few studies have reported about the correlation of particular gene expression with T2DM. In this study, we aimed to examine the correlation of AEG-1 gene expression in peripheral blood monocytes with type II diabetes.
Methods
This cross sectional study includes 17 newly diagnosed T2DM patients and 16 healthy nonglycemic control subjects of Bangladeshi origin without any current treatment regimen. Peripheral blood monocytes (PBMCs) were sorted from the whole blood and RNA was extracted followed by Q-RT PCR analysis to study the gene expression patterns.
Results
Our study suggests that Aeg-1 gene expression in peripheral blood monocytes of newly diagnosed patients with type II diabetes is significantly higher than control subjects. Aeg-1 gene expression is positively correlated with BMI index and increased level was observed in patients with BMI index of 30 or more.
Conclusion
Our study indicates that elevated expression of AEG-1 gene is a novel risk factors for type II diabetes.

The EMPA-REG OUTCOME, a real cardiovascular benefit or a play on words?

Ismail Nasri
Libera Medical Practice, Chlef, Algeria.

Introduction
The EMPA-REG OUTCOME is a cardiovascular safety study with empaglifozin that has shown a reduction in cardiovascular mortality and a decrease in hospitalization for heart failure. Our work is based on the analysis of the protocol

that recognized five changes, the last, 3 years after the start of the study and which affects the definitions of the elements of the primary composite, and following these modifications, we find that the mortality Cardiovascular was increased by 67% in favor of empaglifozin, and myocardial infarction was underestimated, which leaves some doubt about the reality of cardiovascular benefit in this study.
Method
Our work is based on the analysis of the protocol that recognized 5 changes, these changes affect the definitions of the elements of the primary composite
1) Cardiovascular mortality: undetermined cause mortality is considered as a presumed cardiovascular death.
2) myocardial infarction: silent myocardial infarction is excluded from myocardial infarction.
Results
1) cardiovascular mortality: this is the only cardiovascular safety study that has considered undetermined cause mortality to be presumed cardiovascular mortality, which has increased cardiovascular mortality by 67%, and this increase is 53% higher in the placebo arm compared with the empagliflozin arm.
2) myocardial infarction: in this study silent myocardial infarction is excluded from myocardial infarction, but the problem, we can not evaluate the impact of this change, because the results of silent myocardial infarction reported, only affects 53% of the population studied.
Conclusion
The play on words used to define cardiovascular mortality for the benefit of empagliflozin, and the retention of information about the number of the silent myocardial infarction, leave some doubt about the real cardiovascular benefit of this study, whose results have been taken into consideration to make cardiovascular safety a criterion in the therapeutic choice in the latest recommendations of ADA EASD 2018.

Diabetic nephropathy and arterial stiffness in patients with type 1 diabetes mellitus

Karina Sarkisova[1], Iwona-Renata Jarek-Martynowa[2], Marina Shestakova[2], Minara Shamkhalova[2] & Alexander Parfenov[3]
[1]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation; [2]Endocrinology Research Centre, Moscow, Russian Federation; [3]LTD Angioskan, Moscow, Russian Federation.

Background and aims
In 2005, experts from the IDF assigned the risk of developing coronary heart disease in patients with type 1 diabetes mellitus (DM1) at age of 30 and over or patients with DM1 with kidney damage equal to the patients with type 2 diabetes mellitus. The need for a non-invasive preclinical marker for identifying patients with the increased risk of cardiovascular disease is obvious. The assessment of arterial stiffness can play a role of such marker. The aim of this study was to assess the effect of microvascular complications of DM1 on arterial stiffness in patients with DM1.
Materials and methods
We examined 73 patients with DM1 (age 28.1 ± 6.4; HbA_1c $8.9 \pm 1.8\%$) with normoalbuminuria AER in the morning urine <20 mg/l ($n=40$); microalbuminuria AER <199 mg/l ($n=24$); macroalbuminuria AER ≥ 200 mg/l ($n=9$). The decrease of glomerular filtration rate (GFR) <60 ml/min/1.73 m^2 was noted in eight patients, and GFR ≥ 60 ml/min/1.73 m^2 was registered in 65 patients. Control group included 25 healthy subjects (age 26.3 ± 4.2). The study included an evaluation of the contour pulse wave analysis with the determination of the stiffness index of the arterial wall-the augmentation index (Alx75) on the unit. Additionally, all patients were assessed the thickness of the intima-media complex (TIM) and general clinical studies. Statistical analysis was performed with SPSS22.0, $P<0.05$.
Results
There was no statistical significant differences Alx75 between the DM1 group and the control group. Alx75 was significantly higher in patients with DM1 and diabetic nephropathy compared to patients without nephropathy ($P=0.000$). In the group of patients with GFR <60 ml/min/1.73 m^2, Alx75 was higher in comparison with the group with GFR ≥ 60 ml/min/1.73 m^2 ($P=0.009$). An increase of Alx75 was noted in patients with microalbuminuria compared to patients with normoalbuminuria ($P=0.006$), however, there were no significant difference during comparison of patients with DM1 without nephropathy with the control group. Alx75 was higher in patients with diabetic retinopathy compared to the patients without retinopathy($P=0.000$), while no statistically significant difference was found during comparison the patients with type 1 diabetes without retinopathy and the control group ($P=0.093$). Alx75 was correlated positively with TIM ($R=0.490$; $P=0.000$); age ($R=0.326$; $P=0.007$); duration of DM1 ($R=0.441$; $P=0.000$); and albumin/creatinine ratio ($R=0.369$; $P=0.004$), Alx75 was correlated negatively with GFR ($R=-0.301$; $P=0.015$). Smoking status and arterial hypertension was not independently associated with increased arterial stiffness in patients with DM1.
Conclusion
An increase of the arterial stiffness index in the early stages of microvascular complications may be an early marker of macrovascular lesions even in patients without arterial hypertension.

Evaluation of perior-operational safety and efficiency of the laparoscopic gastroplication procedure compared to laparoscopic handle gasstroektomia in patients with overweight and metabolic syndrome

Kostyantyn Mylytsya & Yuliia Klitsunova
State Institution 'Zaporizhia Medical Academy of Post-Graduate Education Ministry of Health of Ukraine', Zaporizhia, Ukraine.

The aim of the study
Laparoscopic sleeve gastroectomy is now the gold standard for bariatric surgery for the treatment of obesity and metabolic syndrome. Laparoscopic gastroplasty is a relatively innovative procedure that has recently been used throughout the world. The purpose of the study was to assess the perioperative safety and outcome of procedures in 2 years.
Materials and methods
Sixty two patients with a body mass index of 35 kg/m^2 to 50 kg/m^2 who were undergoing surgical barrier intervention. Laparoscopic gastroplasty was performed for thirty-eight patients, and 24 patients chose gastro-enteromatous sleeve. Patients were monitored for 2 years after surgery. During this period, both groups studied the percentage of loss of overweight, early and late complications, and improved comorbid conditions associated with obesity and nutritional disorders.
Results
Both groups did not have fatalities, and there was no significant difference in the results of early and late morbidity in both groups (11% after laparoscopic gastroplasty and 12.5% after sleeve gastroectomy). Losing weight was much better after sleeve gastroectomy. During 2 years of observation, the percentage of loss of overweight reached 46% after laparoscopic gastroplasty and 62% after sleeve gastroectomy. There was no significant difference in the overall improvement of concomitant diseases. Nutrient deficits were similar in both groups, with the exception of vitamin B12 deficiency, which was more common after sleeve gastroectomy.
Conclusions
Sleeve gastroectomy and laparoscopic gastroplasty are equally safe and effective for the improvement of concomitant diseases. Sleeve gastrectomy has a better result of overweight loss, whereas laparoscopic gastroplasty is associated with fewer postoperative metabolic deficiencies, without correction. The use of laparoscopic gastroplasty requires additional research to prove the reliability and metabolic efficiency of the new procedure.

Predictors of incident hypertension in healthy, non-diabetic postmenopausal women with normal renal function

Kimon Stamatelopoulos[1], Michael Apostolakis[2], Areti Augoulea[2], Stavroula A Paschou[2], Eleni Armeni[2], Konstantinos Panoulis[2], Panagiotis Bakas[2], Georgios Georgiopoulos[1], George Kaparos[3], Dimitrios Rizos[3] & Irene Lambrinoudaki[2]
[1]Vascular Laboratory, Department of Clinical Therapeutics, Alexandra Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece; [2]Second Department of Obstetrics and Gynecology, Aretaieio Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece; [3]Biochemical Laboratory, Aretaieio Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece.

Introduction
The aim of this study was to investigate the incidence of hypertension and to identify potential risk factors in healthy, non-diabetic recently postmenopausal Greek women with normal renal function.

Patients and methods
In this retrospective cohort study, we evaluated 141 recently postmenopausal women at baseline and annually thereafter (follow-up time: 1 to 8 years). Blood samples were obtained and ultrasound evaluations were performed at baseline. A detailed medical history, anthropometric parameters, blood pressure and cardiovascular risk factors were recorded for every woman at each visit. Incident hypertension was defined as first occurrence of systolic or diastolic hypertension, measured at 2 different visits within 2 months, or initiation of antihypertensive medication.
Results
Incident hypertension was diagnosed in 30 out of 141 women (21.3%). Median time to incident hypertension was 3.5 years after menopause. Obesity, elevated cholesterol and triglyceride levels, insulin resistance and parity were positively associated with incident hypertension. In multivariate analysis, however, obesity and insulin resistance were the only statistically significant variables associated with more than 3fold and 2fold respectively increased risk of incident hypertension (obesity: OR = 3.746, P value = 0.019, HOMA-IR: OR = 1.988, P-value = 0.043).
Conclusions
A large proportion of women entering the menopause present incident hypertension and this is mostly associated with obesity and insulin resistance.

The role of sodium glucose co-transporter inhibitors in patients with acromegaly and diabetes: is there an additive effect beyond glucose control? A clinical hypothesis

Adnan Zaina
Clalit-Zvulon Medical Center, Kiryat Bialik, Israel.

Acromegaly represents a rare chronic disease mainly caused by GH pituitary adenoma with increased levels of GH and IGF-I. Diabetes mellitus was shown to increase cardiovascular morbidity and mortality in patients with acromegaly. Management of diabetes in acromegaly represents a challenging matter and deserves special considerations due to multiple factors that might be implicated in hyperglycemia including: i) the etiology of diabetes, which could be related to acromegaly per se. ii) the treatment modality applied for controlling disease activity, such as pasireotide long acting release (PAS-LAR) with remarkable increase rate of hyperglycemia and worsening of preexisting diabetes. iii) the disease activity and the tumor burden taking into consideration the negative effects of GH excess other than hyperglycemia such as weight gain, water retention. Sodium glucose cotransporter inhibitors (SGLT2is) are vastly administrated in patients with T2DM. Despite their cardiovascular safety and superiority this class is not recommended for patients with acromegaly and diabetes. Taking into consideration at least three positive aspects of this class: i) cardiovascular superiority beyond glucose control, ii) weight reduction and osmotic diuresis and iii) decreased insulin levels which might play an important role in GH receptor (GHR) expression and as a result decreased IGF-I levels. The aim of this paper is to focus on the role of SGLT2is in this group of patients and the potential‘ additive effect’ of this novel class beyond glucose control.

Irisin level in type 2 diabetic patients and its relation to glycemic control and diabetic complications

Hemmat EL Haddad[1], Heba Sedrak[1], Mervat Hussin[1], Elham Yousief[1], Dalia Ibrahim[2], Rasha Abdel Samie[1] & Ahmed Ramadan[1]
[1]Cairo University, Cairo, Egypt; [2]Nuclear Research Center, Atomic Energy Authority, Cairo, Egypt.

Background
Irisin is a new myokin and adipokine related to human obesity and insulin resistance status.
Aim
To assess serum irisin level as well as to investigate whether serum irisin is related to glycemic indicators, and micro and macrovascular complications in patients with T2DM.
Methods
The study included 60 T2DM patients and 30 healthy controls. Anthropometric measures, neurological assessment and fundus examination were done to all patients. Correlations of serum irisin and blood glucose, glycosylated hemoglobin (HbA_{1C}), urinary albumin, estimated glomerular filtration rat (eGFR), C-reactive protein (CRP), and carotid intima media thickness (CIMT) were analyzed using Spearman's correlation coefficient.
Results
There was no significant difference of irisin level between T2DM patients and healthy controls (0.18 ± 0.10 vs. 0.16 ± 0.05 ng/ml, $P = 0.940$). In diabetic patients, there was negative correlation between irisin level and duration of diabetes ($r = -0.302$, $P = 0.023$), BMI ($r = -0.663$, $P < 0.001$), HbA_{1C} ($r = -0.528$, $P < 0.001$), urinary albumin ($r = -0.439$, $P < 0.001$), CRP ($r = -0.692$, $P < 0.001$), and CIMT ($r = -0.807$, $P < 0.001$). Levels of irisin were significantly lower in patients with peripheral diabetic neuropathy (PDN) compared to those without PDN (0.11 ± 0.05 vs. 0.22 ± 0.11 ng/ml, $P < 0.001$). Levels of irisin was not significantly different between patients with diabetic retinopathy and those with normal fundi.
Conclusions
Serum irisin levels were not different between T2DM subjects and controls. In T2DM patients, negative correlations between irisin and $HbA_{1C,}$ urinary albumin, CIMT were found. Patients with diabetic neuropathy had lower irisin levels.

Clinical importance of determination of glytoxic methylglyoxal in nafld and type 2 type

Zvenigorodskaya Larisa, Shinkin Michael, Petrakov Alexander & Nilova Tamara
MCSC, Moscow, Russian Federation.

Introduction
The formation of oxidative stress in the biological reaction of inflammation is accompanied by the formation of methylglyoxal (MG), which initiates the glycosylation reaction of proteins. When hyperglycemia MG content significantly increased. MG interacts with the amino groups of lysine and arginine to form further glycation end products (CNG). Glycation is due to the ability of glucose to form irreversible chemical compounds of CNG with amino groups of proteins. During inflammation, MG covalently binds to proteins, enzymes, lipids, and DNA, in violation of their physiological functions. CNG causes complications of diabetes, damaged proteins in the glomeruli of the kidneys, retina and peripheral nerves. The formation of covalent bonds with the amino groups of collagen is the cause of the loss of vascular elasticity.
Purpose of the study
To determine the level of MG in serum by the method of high performance liquid chromatography according to Titov V.N. 2014 in our modification in patients with NAFLD and type 2 diabetes.
Materials and methods
Surveyed 98 patients with NAFLD and 52 patients with type 2 diabetes and 22 healthy volunteers. Age 57.3 ± 5.2 years. IMT 34.85 ± 1.79. The diagnosis was established on the basis of clinical laboratory data and examination results. The level of POL was determined by the content of malonic dialdehyde (MDA).
The results
In patients with NAFLD, the MG content in the serum was 520.75 ± 114.35 in the control 69.02 ± 6.67 nM/l $P = 0.001$. For T2DM, the content of MG292 is 11 ± 16.34 nM/l. With hyperglycemia and excessive accumulation of lipids, the processes of lipid peroxidation enhance, which leads to an increase in the activity of PLA2. In apoptosis, the function of cellular membrane phospholipids is impaired, the function of mitochondria is disturbed, fibrosis develops and steatohepatitis is formed. The correlation of MDA and PLA2 in the serum $r = -0.578$ $P = 0.001$ was noted. MG and MDA are in the correlation dependence $r = 0.495$. The content of PLA2 correlates with the level of nitric oxide $r = 0.625$ $P = 0.001$.
Conclusion
In patients with NAFLD there is a significant increase in MG in serum by 7 times compared with the control. MG damages arginine residues of proteins, the insulin signaling is disturbed, and enzymes are inhibited. MG plays a key role in the development of IR and hyperglycemia. Quantitative determination of MG in serum by HPLC is a prognostic and diagnostic test.

The psychometric adaptation of the Russian version of the Diabetes Eating Problem Survey–Revised (DEPS-R)

Veranika Labashova[1], Alla Shepelkevich[2] & Yulia Dydyshka[2]
[1]Republic Centre of Medical Rehabilitation and Balneotherapy, Minsk, Belarus; [2]Belarusian State Medical University, Minsk, Belarus.

Objectives
Eating disorders often co-occur with diabetes, and this comorbidity is associated with severe medical complications. The DEPS-R is a 16-item diabetes-specific self-report measure of disordered eating that can be completed in <10 min. The purpose of the study was to translate and validate the Russian version of the Diabetes Eating Problem Survey–Revised (DEPS-R).
Methods
372 patients with diabetes mellitus using insulin injections participated in the research (109 patients with type 1 diabetes mellitus and 273 patients with type 2 diabetes mellitus). The participants completed the DEPS-R and EAT 26 questionnaires. Clinicians provided data on height, weight, A1C, and insulin dosing.
Results
The factor analyses of the Russian version of the Diabetes Eating Problem Survey–Revised (DEPS-R) identified 3 subscales 'disordered eating behavior', 'preoccupation with thinness or weight', 'concept of maintaining high blood glucose values to lose weight'. The reliability was confirmed by the Cronbach's Alpha $=0.74$. Analysis of internal consistency of the responses pointed out a good homogeneity for the scale DEPS-R. It correlates positively with the EAT-26 ($r=0.524$; $P\leq0.01$).
Conclusion
The data confirmed the good reliability and validity of the Russian version of the Diabetes Eating Problem Survey–Revised. Although it cannot be used alone to establish a diagnosis of eating disorders, the scale is a reliable instrument for assessing the risk of eating disorders among patients with either type of diabetes.

Retinol binding protein 4-marker insulin resistance in patients with diabetes mellitus 2 types and NAFLD

Zvenigorodskaya Larisa, Shinkin Michael, Nilova Tamara, Petrakov Alexander & Varvanina Galina
Moscow Clinical Scientific Center named after A.S. Loginov, Moscow, Russian Federation.

Introduction
Retinol binding protein (RSP) is a member of the adipokine family associated with insulin resistance (IR). With an excess of free fatty acids, the binding of insulin by hepatocyte receptors decreases and hyperinsulinemia develops. RSP is a transport protein for retinol, synthesized in hepatocytes and adipocytes. The level of RSP increased in patients with obesity, diabetes mellitus and non-alcoholic fatty liver disease (NAFLD) correlated positively with the severity of the inflammatory process and fibrosis. RSP regulates the action of insulin in tissues, skeletal muscle and liver.
Purpose of the study
To determine the CPR in patients with NAFLD and type 2 diabetes. To compare the results of CPR with inflammatory markers of lipoprotein associated phospholipase (PLA2) and nitrogen oxide (NO), which inhibits the proliferation of collagen and regulates hepatic blood flow.
Material and methods
A total of 208 patients with NAFLD and T2DM (120zh/88m) were examined. The average age is 57.3 ± 5.2. Of these, patients with type 2 diabetes are type 76 patients and 132 have impaired glucose tolerance (IGT). BMI over 30 kg/m^2 (34.85 ± 1.79). Patients underwent clinical, biochemical, and instrumental research methods. RSP was determined in 89 patients with type 2 diabetes using the ELISA method in blood serum. The control group consisted of 15 healthy individuals. FLA was determined by ELISA. NO metabolites were determined by the express method.
The results of the study
The RSP content in the control group was 26.15 ± 1.31 μg/L. In patients with type 2 diabetes without NAFLD (group 1), it was reduced by 12.8% and amounted to 20.34 ± 3.8 μg/l. In 49 patients with NAFLD and type 2 diabetes (group 2), the RSP content was significantly increased by 48.9% and amounted to $38,96\pm11.47$ μg/l. The content of PLA2 was increased by 4.78 times compared to the control in group 2 and the level of stable metabolites of nitric oxide increased parallel to the activity of hepatic enzymes. A direct positive correlation between PLA2 and NO is noted. The correlation coefficient was $r=0.625$ $P=0.001$.
Conclusion
The level of CPR was significantly increased in patients with type 2 diabetes and NAFLD compared with controls and group 1. An increase in the content of inflammatory markers was accompanied by an inflammatory process in the liver with an increased activity of liver enzymes and severity of morphological changes.

Metabolic profile and diabetes in prison

Sara Askaoui, Loubna Oukit, Guizlane Lmghari & Nawal El Ansari
Endocrinology Departement, Marrakech, Morocco.

Introduction
The prison environment is a space that involves certain restrictions on prisoners. The diabetic subject requires, however, special attention. The aim of this work is to evaluate the impact of this medium on the glycemic balance and the metabolic profile.
Patients and method
Descriptive cross-sectional study carried out on a health campaign day in a penitentiary center, in the men's sector, and concerned patients with known diabetes from the institution.
Results
The prevalence of diabetes was 12%, diagnosed in a penitentiary environment in 3 cases. The average age was 42.3 years and type 2 diabetes was found in 93.1% of cases. The average duration of diabetes was 6.15 years, 76.4% of patients were on oral treatment. Mean HbA1c was 8.2%. The mean capillary blood glucose level on examination was 1.92 g/L and pathological waist circumference in 32% of cases. Hypertension and dyslipidemia were associated in 26% of cases. Patients complied with the rules of hygiene and diet (physical activity and diet) in 36% of cases.
Discussion
In prison, the health care system deals with a vulnerable population. In our study, diabetes was more common than in the general population. The exclusive male sex is a cardiovascular risk factor in its own right. The detention environment involves limited physical activity and imposed nutrition. However, the institution tries to encourage a healthy lifestyle. Also, access to care and treatment is available and provided by the penitentiary pharmacy.

DOI: 10.1530/endoabs.63.P146

P147

The treatment of fertile age women with obesity

Yulduz Urmanova, Nazira Rikhsieva, Feruza Khodgaeva & Ortikali Tursunkulov
Tashkent Pediatric Medical Institute, Department of Endocrinology, Pediatric Endocrinology, Tashkent, Uzbekistan.

The aim of investigation to study of optimization of treatment of women of childbearing age with metabolic syndrome.
Material and methods
Under supervision were 20 women with a metabolic syndrome who applied for infertility in Center of Endocrinology from 2014–2015. The control group consisted of 20 women without obesity and without disturbances of the menstrual cycle. The age of patients ranged from 20 to 39 years and averaged 28.3 ± 0.64 years. All patients underwent a set of studies, including General clinical (General blood and urine analysis), biochemical (blood glucose, glucose tolerance test), hormonal (LH, FSH, prolactin, estradiol, progesterone, free testosterone,

dehydroepiandrostenedione (DHEA), 17-oxyprogesterone (17 OKS), antimuller hormone (AMG), insulin on day 14 of the cycle), determination of cortisol in the blood and free cortisol in the daily urine. Patients to decrease body mass was appointed non-pharmacological and etiopathogenetic therapy. Etiopathogenetic therapy included therapy for 6 months: was assigned to a combination Metformin 1000 mg per day + veroshpiron 50 mg twice a week + lodmarin 100 mg in the morning + levothyroxine 50 mg in the morning + antiandrogens (Yarina, Jess, dexamethasone, etc.)+ antidepressants courses (amitriptillin, rexetin, etc.).
Results
It was found that after 6 months after treatment, patients had a significant decrease in BMI of 1 and 2 degrees after 6 months of treatment. In addition, fertility recovery and pregnancy were achieved in patients in 19.5% of cases (10 patients).
Summary
Thus, the inclusion of the drug 'Siofor' (Metformin) in the traditional treatment of patients with obesity of different groups contributes to a significant improvement in clinical indicators - a decrease in BMI, which indirectly indicates that in the study groups of women obesity is one of the manifestations of the metabolic syndrome.

P148

Prevalence and risk factors of hepatic steatosis among patients with chronic hepatitis B

Myriam Ayari, Hella Kchir, Dhouha Cherif, Dhilel Issaoui & Nadia Maamouri
La Rabta Hospital, Tunis, Tunisia.

Introduction
Chronic hepatitis and NAFLD represent a global public health problem since they are two common cause of chronic liver disease. Hepatic steatosis (HS) is becoming highly prevalent worldwide and its association with hepatitis B, although controversial previously, is increasingly encountered and thought to be related to host factors.
Aim and methods
The aim of this retrospective study is to determine the prevalence of HS in chronic hepatitis B (CHB) patients and to investigate causes of fatty liver. This study included 80 patients diagnosed with CHB between 2010 and 2018. Liver Biopsy was performed in each patients. Clinical, biochemical, and histological characteristics were examined. Patients with alcohol intake were excluded. Pathological data that were collected from biopsy reports included presence of steatosis (>5% of hepatocytes), presence of fibrosis according to Metavir staging, steatosis type and area.
Results
Thirty-eight men (48%) and 42 women (52%) were enrolled. The average age was 49 years. Most of patients (80%) was infected by mutant virus B, common type in Tunisia. the average level of viral DNA was 10881 IU/ml. 57% of patients had Metavir score >=F2 and 25% were cirrhotic. HS was present in 18% of patients ($N=15$). Their mean age was 47 years. 58% of patients with SH had Metavir score >=F2 but none was cirrhotic. Diffuse steatosis was found in 25% of cases. Our data showed that HS was not associated with age, sex, HBeAg, viral load, amount of fibrosis, transaminase levels, or alkaline phosphatase. Conversely, HS was significantly associated with type 2 diabetes ($P<0.001$), hypercholesterolemia ($P=0.01$) and body mass index BMI ($P=0.02$).
Conclusion
Concomitant hepatic steatosis and hepatitis B is relatively common in daily practice, although this association remains less frequent than observed in chronic hepatitis C. In our study overall HS prevalence was 18%. HS was significantly associated with metabolic factors, such as obesity, dyslipidemia and does not seem to influence the progression of liver fibrosis.

Negative regulation of AMPK-related kinase MPK38/MELK activity by protein phosphatase 5 (PP5)

Hyun A Seong & Hyunjung Ha
Department of Biochemistry, School of Biological Sciences, Chungbuk National University, Cheongju 28644, Republic of Korea.

Murine protein serine-threonine kinase 38 (MPK38), also known as maternal embryonic leucine zipper kinase (Melk), is a member of the AMP-activated protein kinase (AMPK)-related kinase family and regulates multiple cellular processes, including cell cycle, stem cell self-renewal, apoptosis, carcinogenesis, and metabolism, and is activated in response to apoptosis signal-regulating kinase 1 (ASK1)/TGF-β/p53 signals. A serine/threonine protein phosphatase PP5 has been suggested to negatively regulate the functions of ASK1 and p53. Here, PP5 is found to be a binding partner of MPK38 in cells. The association of PP5 and MPK38 is mediated via the N-terminal domain of PP5 and the C-terminal domain of MPK38. PP5 dose-dependently suppressed the kinase activity and functions of MPK38, as determined by *in vitro* kinase assays, reporter assays, and apoptosis assays, by destabilizing MPK38. The inhibitory effect of PP5 on MPK38-dependent ASK1/TGF-β/p53 signaling is also confirmed in MEF cells that were null (-/-) for PP5. Consistently, PP5 overexpression by an adenoviral delivery worsens obesity-associated metabolic disturbances in high fat diet (HFD)-fed C57/BL6 mice. However, such adverse effects are not observed in MPK38-deficient obese mice. These findings suggest that PP5 physiologically functions as a specific inhibitor of MPK38 that may participate in obesity metabolism.

Effects of diabetes mellitus and autoimmune thyroiditis on features of rheumatoid arthritis

Anton Dvorovkin, Vitaly Odin, Vadim Tyrenko & Michael Toporkov
Military Medical Academy named after S.M. Kirov, Saint Petersburg, Russian Federation.

Background
It is known that rheumatoid arthritis (RA) can be a part of autoimmune polyglandular syndrome and be combined with endocrine diseases.
Objectives
To study the effects of autoimmune thyroiditis (AIT) and diabetes mellitus (DM) on the clinical and laboratory manifestations of RA.
Methods
The study included two groups of patients. The first group of patients included 24 patients (20 women and 4 men, mean age - 68.37±1.75 years) with a combination of RA and DM. The second group included 24 patients (20 women and 4 men, mean age - 59.1±2.13 years) with a combination of RA and AIT. In the group of patients with a combination of RA and DM 2 patients were with type 1 diabetes, 22 with type 2 diabetes. In a group of patients with RA and AIT 15 patients had euthyroidism, 8 had hypothyroidism, and 1 had hyperthyroidism. Patient groups were compared by statistical treatment and correlation analysis method for the following indices of rheumatoid arthritis: detection of rheumatoid factor in blood serum, presence of erosion on radiographs of the hands/feet, radiographic stage and on a scale of activity DAS-28.
Results
In both groups of patients similar data were obtained on the average results for the studied parameters (detection in the serum of the rheumatoid factor was noted in 75% and 87.5% of patients, erosion in 87.5% and 83% of patients, in 50% and 54% identified III X-ray stage of rheumatoid arthritis, a high degree of activity of rheumatoid arthritis was detected in 67% and 50% patients). However, using the Spearman correlation analysis in the first group of patients (combination of RA and DM), a direct relationship between the presence of erosion and the degree of activity of rheumatoid arthritis (DAS-28, $R=0.39$, $P<0.05$), as well as between the detection of rheumatoid factor in the blood and the degree of disease activity ($R=-0.63$, $P<0.05$). In the second group of patients (a combination of RA and AIT), a direct relationship was found between the detection of rheumatoid factor and the degree of disease activity ($R=0.39$, $P<0.05$).
Conclusions
Thus, in the first group of patients there is a stronger correlation between the clinical and laboratory indicators of RA, including the severity of bone destruction, than in patients with a combination of RA and AIT. This fact can speak about synergistic enhancement of damage to the joint tissue pathogenetic mechanisms inherent in both diabetes and RA.

'Killing two birds with one stone' treating porphyria patient with diabetes with SGLT2 inhibitors - a case report

Milan Bogojevic & Olivera Boskovic
Clinical Center of Montenegro, Podgorica, Montenegro.

Background
Acute intermittent porphyria (AIP) is characterized by attacks of abdominal pain and neuropsychiatric symptoms. This disease is more frequently and more severely affecting women. Hem deficiency in the liver of AIP patients stimulates an increase in ALA-synthase which triggers an escalating metabolic chain reaction, leading to an increase in the porphyrin content. Treatment of AIP is carbohydrate-rich diet and by treating the attacks with intravenous infusions of glucose or hem. This presents difficulty in treating patients with diabetes mellitus. SGLT2 inhibitors drugs are a class of medications that inhibit *reabsorption of glucose in the kidney* and therefore lower *blood sugar*.
Method
A case report
Result
We present a 60 years old female diagnosed with porphyry seven years ago, which presented with acute abdominal pain and positive porphyrin in urine. She was treated with carbohydrate-rich diet and was symptom free for three years. She complained polydipsia and polyuria, her blood sugar lever were over 11 mmol/L in her profile and HbA1c 6.5%. Diagnosis of diabetes mellitus was made and she started using metformin. For the last year her abdominal pain attacks are more often, Other reasons for chronic abdominal pain were examined. Her ultrasound of abdomen, MR enterography and MR colonography were normal. Antibodies for celiac disease and calprotectin were in referent range. As we don't have hem treatment in our country and its used for only attacks she started using carbohydrate rich diet which caused bad regulation of her diabetes (HbA1c 7.5…8.3%). We decided to start treatment of diabetes mellitus with SGLT2 inhibitors. Blood sugar profiles values range from 5.1 to 6.4, and her HbA1c on the last control was 6.1, as far as her abdominal pain attacks, frequency of attacks reduces almost double and intensity of pain is lower.
Conclusion
Treating porphyria patients with diabetes is a two-edged sword, while carbohydrate help a lot patient with porphyria, they cause bad regulation of diabetes. With using SGLT2 inhibitors and their mechanism it is possible to keep both diseases under control.

Effect of glucocorticoid on agouti-related protein deficient mice

Mitsuru Nishiyama[1], Shuichi Nakayama[1], Yasumasa Iwasaki[2], Shinpei Fujimoto[1] & Yoshio Terada[1]
[1]Department of Endocrinology, Metabolism & Nephrology, Kochi Medical School, Nankoku, Japan; [2]Health Care Center, Kochi Medical School, Nankoku, Japan.

Purpose
Agouti-related protein (AgRP) is known as an orexigenic neuropeptide which is expressed in the hypothalamic arcuate nucleus. It's possible AgRP is an important molecule in glucocorticoid (GC) induced obesity (e.g. Cushing syndrome), because GC positively regulate hypothalamic AgRP. To clarify the role of AgRP in GC-induced obesity, we investigate here the effect of GC on AgRP deficient mice.
Methods
Male wild-type littermates ($n=20$) and AgRP deficient mice (AgRP-KO, $n=20$) were randomly divided into two groups, and were implanted subcutaneously with either placebo or corticosterone (CORT) pellet. Their body weight and food consumption were measured every day. They were decapitated on day 14, and trunk blood, hypothalamus and fat tissue were collected for further examination.
Results
There were no differences in body weight between WT and AgRP-KO before treatment (WT 21.5 ± 0.3, AgRP-KO 21.9 ± 0.5 g), and CORT treatment increased circulating CORT levels compared with placebo in both groups. In WT group, CORT administration increased epididymal fat weight compared with placebo (Placebo 271 ± 22, CORT 486 ± 42 mg, $P<0.05$), but not their body weight (Placebo 25.2 ± 0.7, CORT 24.9 ± 0.6 g). In AgRP-KO group, CORT administration increased epididymal fat weight (Placebo 310 ± 20, CORT 727 ± 63 mg, $P<0.05$) and body weight (Placebo 25.2 ± 0.4, CORT 29.4 ± 0.5 g, $P<0.05$) compared with placebo.
Conclusion
These results suggest that AgRP is not necessary in GC-induced obesity. On the other hand, accumulated evidences support GC clearly increase AgRP, and it's reported GR (GC receptor) deficient in AgRP neuron shows obesity resistant phenotype. Therefore, the role of AgRP in GC-induced obesity should be further examined.

DOI: 10.1530/endoabs.63.P152

P153

Insulin content and activity of inflammatory markers in patients with nonalcoholic fatial liver disease and diabetes of the second type

Zvenigorodskaya Larisa, Shinkin Mikhail, Nilova Tamara, Varvanina Galina & Petrakov Alexander
Moscow Clinical Scientific Center named after A.S. Loginov, Moscow, Russian Federation.

Pathogenesis of Non-alcoholic fatty liver disease in 90% combined with diabetes mellitus (DM) of the second type. Factors cutting: abdominal obesity, excessive content of free fatty acids. Development of insulin resistance through protein kinase. Violation of the transmission of insulin signal leads to damage to the endothelium. Glycation of nitric oxide synthase leads to the development of diabetic complications and violates the sensitivity of the insulin receptors.
Purpose of the study
To determine the level of insulin, metabolites of nitric oxide, malonic dialdehyde, activity of lipoprotein-associated phospholipase A2 (PLA2), in the serum of patients with NAFLD and type 2 diabetes and impaired glucose tolerance.
Material and methods
74 patients with NAFLD and type 2 diabetes were examined; 30 with NAFLD and impaired glucose tolerance. The age of patients is 55.6 ± 2.2 years. The body mass index is 34.85 ± 1.79 kg/m^2. Phospholipase A2 was determined by the method of chemiluminescent immunological analysis on a Siemens device. Fatty acids were determined by the enzyme method using test systems (England). Nitric oxide metabolites were determined by the method of Metelskoy VA, Malondiy aldehyde was determined by the Andreeva method.
Results
Insulin was determined in 74 patients. Hyperinsulinemia was observed in 30 patients with low glucose tolerance. 34.65 ± 4.16 μIU/ml. Control group: 8.3 ± 1 μIU/ml. In patients with diabetes, insulin content: 6.28 ± 0.4 ($P=0.001$), which caused the expression of phospholipase A2 3 times in diabetes and twice in violation of glucose tolerance. With NAFLD, the content of nitric oxide is increased: the level of metabolites increased in parallel with the activity of hepatic enzymes. The content of malondialdehyde in diabetes in patients with diabetes increased and amounted to 24.12 ± 1.64 μmol/l. In case of violation of glucose tolerance: amounted to 16.91 ± 3.87. (the norm is 9.94 ± 1.62 μmol/l). $P=0.001$. A negative correlation between insulin and malonic dialdehyde was detected. ($R=-0.31$). The interrelation of the peroxide and phospholipase mechanism of lipid damage to the membranes of hepatocytes FLA2 and MDA $r=-0.53$; $P=0.001$; between NO and FLA2 $=0.625$. $P=0.001$.
Conclusions
High activity of inflammatory markers in patients with NAFD with diabetes mellitus is an early diagnostic criterion for the activity of non-alcoholic steatohepatitis (NASH).

DOI: 10.1530/endoabs.63.P153

P154

The role of bile acids in the pathogenesis of NAFLD

Zvenigorodskaya Larusa, Nilova Tamara, Petrakov Alexander, Varvanina Galina & Shinkin Mikhail
Moscow Clinical Scientific Center named after A.S. Loginov, Moscow, Russian Federation.

Obesity affects on the composition of bile: the lithogenicity of bile increases, biliary sludge and cholelithiasis are developing. Under the influence of the active form of oxygen, abnormal forms of bile acids are formed, which negatively affects the development and progression of the pathological process. With the development of inflammation in the liver and pancreas, disturbances in the membrane proteins of glucose transporters occur, the activity of nuclear receptors for the synthesis and conjugation of bile acids decreases. Ursodeoxycholic acid activates nuclear receptors, improves sensitivity to insulin, leptin, ghrelin, adiponectin, increases the activity of glucose transporters, lipoproteinlipase and other enzymes.

Objective
To determine the effect of inflammation markers (NO, LPS, FLA2, MDA) on the synthesis and transport of bile acids in patients with NAFLD and diabetes.
Materials and methods
158 patients with NAFLD: 46 patients with DM2 and 112 patients with IGT were examined. Activation of LPO stimulates fibrogenesis and progression of the pathological process in the liver. The level of LPO was determined by the content of MDA. NO metabolites- by screening FLA2, LPS- by chromogenic end point method using LAL test. Pharmacotherapy with Ursosan in 50 patients with NAFLD.
Results
Group I included 59 patients with NAFLD and DM in which the content of bile acids was lower by 45% compared with the control group was 2.97 ± 1.02 μmol\l the control group consisted of practically healthy persons without disorders of carbohydrate metabolism of 56 patients with the LCD level of 5.4 ± 1.8 mmol\l. group II: NAFLD patients with IGT, $n = 21$;LCD 8.88 ± 4.94 mmol/l, $P = 0.0001$. MDA in group I (24.12 ± 1.64 μmol\l) was increased compared to the control (9.94 ± 1.62 μmol\l). NO metabolites in group I was increased (137.7 ± 35.96 μmol\l). The activity of FLA2 at CD2 median 605 (504–826) ng\ml and LPS = 3.69 EE\ml, at NTG median 430 (324–497) ng\ml ($P = 0.001$), LPS = 1.43 EE\ml. A negative correlation $r = -578$ (FLA2/MDA). After 12 weeks treatment with Ursosan, inflammation markers decreased, biochemical parameters improved.
Conclusions
In patients with NAFLD with DM there is a decrease in the synthesis of bile acids and a violation of bile acid transport, which is associated with damage to cell membranes, inhibition of enzyme systems and inflammation. Accumulation of products of lipid peroxidation leads to the damage of hepatocyte membranes, impaired synthesis of bile acids in the liver, it inhibits the transporters of bile acids. Replacement therapy with Ursosan is recommended in NAFLD.

Improvement of human pancreatic islet quality after co-culture with human adipose-derived stem cells

Bianca de Souza[1,2], Michelle Rodrigues[1], Fernanda de Oliveira[1], Liana da Silva[1], Ana Paula Bouças[1,2], Ciro Portinho[1], Bruno dos Santos[3], Melissa Camassola[3], Juliano Martini[4], Cristiane Leitão[1,2], Nance Nardi[3], Andrea Carla Bauer[1,2] & Daisy Crispim[1,2]
[1]Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil; [2]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil; [3]Universidade Luterana do Brasil, Canoas, Brazil; [4]Santa Casa de Misericórdia de Porto Alegre, Porto Alegre, Brazil.

Introduction
Pancreatic islet transplantation is an effective treatment for patients with type 1 diabetes mellitus (T1DM) with unstable metabolic control. However, the quality of islets isolated from a donor is negatively affected by the inflammatory environment related to the donor's brain death and by the stress related to islet isolation and culture. To overcome islet quality loss, some studies have co-cultured islets with mesenchymal stromal cells (MSCs). Considering that MSCs release growth factors, cytokines and chemokines that support cell survival and function, we therefore hypothesized that MSC-secreted molecules would induce a trophic effect in islets during culture conditions, attenuating inflammation and decreasing apoptosis of islets. To date, no study has co-cultured human islets with human adipose-derived stem cells (ASCs) in an indirect contact environment. Thus, the aims of this study were to investigate whether co-culture of human islets with human ASCs can improve islet viability and function *in vitro*, and to evaluate which factors are related to the protective effect of ASCs against islet dysfunction.
Methods
Human islets were isolated according to the well-stablished method described by Ricordi *et al*. (1989), while human ASCs were isolated from lipoaspirates using the protocol established by Zuk *et al*. (2001). Islets and ASCs were cultured in three experimental groups for 24, 48 and 72 h: i) indirect co-culture of islets with an ASC monolayer (Islets/ASCs); ii) islets cultured alone; and iii) ASCs cultured alone. Islet viability was evaluated using fluorescein diacetate/propidium iodide staining, and function was assessed by glucose stimulated-insulin secretion. Growth factors, cytokines and chemokines in supernatant of all conditions were quantified using an ELISA multiplex kit. Expressions of inflammation-, oxidative-stress-, apoptosis- and endoplasmic reticulum stress-related genes in islets were quantified using qPCR.
Results
The percentage of viable islets was higher in islet/ASC group compared to islet alone in all times analyzed ($P < 0.001$). In the same way, islets from islet/ASC group showed improved beta-cell function ($P = 0.001$). VEGF, HFG, IL-6, IL-8, IL-10, MCP-1, IL-1β and TNF levels were increased in the supernatants of islet/ASC group compared to islet alone, mainly after 24 h of culture. Moreover, *VEGF*, *IL-6*, *MCP-1*, *HIF-1a*, *CHOP*, and *NFKBIa* genes were differentially expressed in islets from the co-culture condition compared to islet alone.
Conclusion
Co-culture of islets with ASCs seems to promote an improvement in islet viability and function, probably due to protective trophic factors secreted by ASCs.

The association between lipoprotein (a) and metabolic syndrome

Ji Eun Jun[1], You-Cheol Hwang[1], Kyu Jeung Ahn[1], Ho Yeon Chung[1], In-Kyung Jeong[1], Ji Cheol Bae[2] & Jae Hyeon Kim[3]
[1]Kyung Hee University Hospital at Gangdong, Seoul, Republic of Korea; [2]Samsung Changwon Hospital, Changwon, Republic of Korea; [3]Samsung Medical Center, Seoul, Republic of Korea.

Background
Lipoprotein (a) (Lp(a)) is a low-density lipoprotein like particle which has proatherogenic and a prothrombotic properties. Therefore, increased Lp(a) levels have been reported to be associated with a higher cardiovascular risk in numerous studies. However, the association between Lp(a) and metabolic disorders such as diabetes or metabolic syndrome (MetS) is still controversial. This study aimed to examine the association between Lp(a) levels and presence of MetS in a large cohort.
Methods
A total of 10,150 Korean participants (men: 60.5%, mean 51.6 years) who underwent the health checkup in 2006–2013 were included in this cross-sectional study. MetS was defined using a revised National Cholesterol Education Program definition, which adopted an Asian-specific waist circumference threshold suggested by the International Diabetes Foundation. Logistic regression analyses were performed to determine the significance of the association between baseline Lp(a) levels and presence of MetS.
Results
The overall prevalence of MetS was 7.1% and the proportion of the participants with MetS decreased across the Lp(a) quartiles (P for trend < 0.001). In a multivariate model, the highest quartile of Lp(a) levels (> 37.0 mg/dl) was significantly associated with a reduced risk of MetS (odds ratio (OR) 0.63, 95% CI: 0.49–0.80; P for trend < 0.001) compared with the lowest quartile (< 12.2 mg/dl). When we analyzed log-transformed Lp(a) level as continuous variables, elevated Lp(a) level was also associated with a lower MetS risk. Serum Lp(a) levels inversely correlated with waist circumference, body mass index, blood pressure, fasting glucose, insulin, index of insulin resistance, and the number of MetS components, while it correlated positively with C-reactive protein.
Conclusions
Serum Lp(a) level showed a significant inverse correlation with MetS prevalence and individual components of MetS.

Relationship study between blood groups, rhesus factor and the risk of diabetes type 2 in a population of the Sidi Othmane district, Casablanca

Fatima Zahra Kehailou[1], Houriya Mestaghanmi[1], Mohammed Jabari[2], Ali Labriji[3], Souad Amrani[4] & Ahmed Dibane[5]
[1]Laboratory of Pathophysiology and Molecular Genetics, Team of Metabolism Nutrition Toxicologie, Ben M'Sik Faculty of Sciences, Hassan II University of Casablanca, Casablanca, Morocco; [2]Hygiene Service of the District of Sidi-Athmane, Casablanca, Morocco; [3]Laboratory Modelisation Analysis and Simulation, Department of Computer Mathematics, Ben M'Sik Faculty of Sciences, Hassan II University of Casablanca, Casablanca, Morocco; [4]Laboratory of Ecology and Environment, Faculty of Sciences Ben M'Sik, University Hassan II-Casablanca, Casablanca, Morocco; [5]Sidi Othmane Hospital, Casablanca, Morocco.

Introduction
Blood groups and the Rh factor are involved in several pathologies. Some studies have also identified them as risk factors for diabetes. The objective of this work is to evaluate the possible association between ABO blood groups, rhesus (Positive, Negative) and the risk of diabetes.

Patients and methods
This is a case-control study involving 257 diabetic patients followed in the hygiene department and 266 controls followed at Sidi Othmane Hospital. Blood groups were taken from medical records and blood glucose was determined. Statistical analysis is performed using SPSS software 23.
Results
523 subjects were included in this study, of whom 71.2% are women and 28.8% are men with an average age of 50.62 ± 14.93. The mean fasting blood glucose level was 1.57 ± 0.78 in diabetic subjects and 1.01 ± 0.11 g/l in controls. The distribution frequency of group O in the population is 45.5%, while that of non-O (A, B and AB) is 54.5% with (31.4% of group A, 5% of the AB group and 16.6% of the B group). The distribution of ABO blood groups in diabetics by sex (women vs men) is respectively A (73.3% vs 26.7%), AB (81.2% vs 18.8%), B (83, 8% vs. 16.2%) and O (82.2% and 17.8%). On the other hand, among controls, it is 65.2% vs 34.8% for group A, 77.8% vs 22.2% for AB, 78% vs 22% for B and 51.4% and 48.8%, 6%) for O. 94.4% of the control population and 91.1% of the diabetic population consisted of Rh+. Analysis of the association between diabetes and blood group O and non-O revealed a low but significant correlation ($r = 0.093$, $P = 0.034$, OR = 1.452, CI = 1.027–2.051), with an effect protective agent for blood group O (OR = 0.861, CI = 0.676–0.986) and a pejorative effect for non-O blood groups (OR = 1.185, CI = 1.185–1.388) and with a significant difference by female gender. In addition, no association was observed between diabetes and Rhesus factor ($P = 0.098$).
Conclusion
Our study showed a slight association between blood group O and the risk of diabetes probably related to the female sex. Further studies are needed to support it.

Case-control study on the obesity prevalence in a population of diabetic's consultant at the health department of Sidi-Othmane district, Casablanca: Morocco

Fatima Zahra Kehailou[1], Houriya Mestaghanmi[1], Mohammed Jabari[2], Ali Labriji[3] & Souad Amrani[4]
[1]Laboratory of Pathophysiology and Molecular Genetics, Team of Metabolism Nutrition Toxicologie, Ben M'Sik Faculty of Sciences, Hassan II University of Casablanca, Casablanca, Morocco; [2]Hygiene Service of the District of Sidi-Athmane, Casablanca, Morocco; [3]Laboratory Modelisation Analysis and Simulation, Department of Computer Mathematics, Ben M'Sik Faculty of Sciences, Hassan II University of Casablanca, Casablanca, Morocco; [4]Laboratory of Ecology and Environment, Faculty of Sciences Ben M'Sik, University Hassan II-Casablanca, Casablanca, Morocco.

Introduction
Obesity is a risk factor for cardiovascular disease and diabetes. The objective of this work is to study the prevalence of obesity among a consultant population at the Hygiene Service of the Sidi-Othman District (ASO) in Casablanca.
Patients and methods
This is a case-control study of subjects consulting the Sidi Othmane hygiene service. Socio demographic, anthropometric data (weight, height, waist circumference, hip circumference, body mass index (BMI)) blood pressure and pulse were collected. Capillary blood glucose and a lipid profile were performed. Arterial age and cardiovascular risk were estimated by the Framingham score. The data was analyzed by the SPSS software 23.
Results
1281 subjects were included in this study, of which 236 are diabetics. The average age is 49.11 ± 15.46 years. The mean fasting blood glucose level is 1.89 ± 0.68 in diabetic subjects and 0.90 ± 0.15 g/l in controls. Compared to controls, the prevalence of hypertension and dyslipidemia was 40.7%–66.5% for diabetics and 23%–56.2% for controls, respectively. In addition, the mean arterial age is higher in diabetics (66.26 ± 14.47 years) than in controls (54.02 ± 16.67 years). Diabetics were more likely to have cardiovascular risk (14.15%) than controls (8.2%). The average BMI of the population is 28.92 ± 5.95 kg/m^2. The distribution of BMI classes in diabetics vs controls is as follows: overweight (36% vs. 33%), class I obesity (28.4% vs. 25.2%), class II obesity (10.6%) % vs. 11.5%), class III obesity (6.4% vs 3.3). Obesity is slightly higher in diabetics than in controls (45% vs. 40%); especially the distribution of abdominal fat (Obesity android) (61.8% vs 43.3). The correlation coefficients of Pearson are significant, on the one hand, between classes of BMI and diabetes ($P = 0.001$); and on the other hand between diabetes and dyslipidemia ($P = 0.0001$).
Conclusion
The correlation observed in this study between diabetes and BMI classes makes it possible to understand that the primary prevention of diabetes in this population goes, for the most part, by the fight against obesity and even against overweight. The distribution of obesity/overweight for both populations follows the same pattern with higher values for diabetics. We can expect today's witnesses to be the diabetics of tomorrow.

Vitamin D: cardiovascular risk marking? About 290 patients

Samir Abderrahmane[1], Kemali Zahra[2] & Oudjit Brahim[1]
[1]Hopital Kouba, Alger, Algeria; [2]Medical Office, Alger, Algeria.

Introduction
The question of the relationship between vitamin D and cardiovascular disease is still open to debate. Recent, exciting and preliminary evidence suggests that vitamin D may play a role in the occurrence of cardiovascular events.
Materials and methods
Patients of both sexes, involving 290 patients recruited between September and March, aged between 40 and 80 years, with type 2 diabetes mellitus after informed consent. We excluded patients with pathologies responsible for hypovitaminosis D. We studied the relationship between cardiovascular risk factors and vitamin D level, then an experimental therapeutic test over a period of 24 weeks was performed in 42 patients divided at random in two groups: a group under vitamin D 3 and a control group without treatment. The purpose of this test is to determine the effect of vitamin D 3 supplementation on risk factors for cardiovascular risks; Diastolic systolic blood pressure, lipid profile (HDL, LDL, TG, and cholesterol).
Results
We found no significant relationship between vitamin D levels and cardiovascular risk factors.
Conclusion
Numerous studies have demonstrated the link between hypovitaminosis D and cardiovascular risk. Until the role of vitamin D is explored at the cardiovascular level, it is possible that more emphasis is placed on vitamin D levels, especially in people at risk, including the elderly, obese and those with diabetes.

Complementary-alternative medicine & diabetes treatment adherence

Manju Chaturvedi
SFHCP, Nashik, India.

Issues
In resource-poor-settings, Unlike Western nations monitoring DIABETES-treatment Adherence is low priority due to lack of training modules/funds/expertise. we analyzed experiences in using locally available Complementary Alternative Medicines [CAM] in rural/tribal areas.
Aims
Facilities for diagnosis/treatment located in major cities &are unaffordable to >85%. ADR's & social stigma worsened situation. CAM must be incorporated along with standard ARV's to reduce ADR's & control symptoms to get better DIABETES-Treatment-Adherence. Provide CAM to Traditional-faith-hearers. To assess CAM response to pain, fatigue, Mayalgia, wt loss, feeling of hopelessness. Hence combine CAM with ARV's.
Methods
80 subjects aged 40–65 years enrolled. 40% females, 60% males. 20% returned to villages after incomplete therapy in city hospitals on allopathic drugs. 10% has severe ADR's. Mud therapy 10%, Bach-flower 30%, Acupressure/Acupuncture 40%, Hydrotherapy 10%, Hypnotherapy 40%, ayurvedic therapy 80%, 20% on Unani, 60% Homeopathic.
Results
Patients treated in 11 CAM sessions. responses evaluated by feedback Performa periodically to modify treatment. Our NGO functioning shown graphically [pictorial display]. Symptom relief 60%, Psychosocial mood elevation 70%, willingness to shift back to ARV therapy 80%. CAM 50% cheaper compared to drugs. CAM available locally & high acceptance in patients.
Conclusion
62 patients used & preferred CAMs. Hence CAM effectively compliments DIABETES-treatment-adherence. Community NGO's must be part of such efforts to evolve newer concepts in Adherence. Realizing divergent versions of

CAM multicentre study needed. We shall form group with researchers to substantially improve DIABETES care policy.

Diabetes and QOL: strategies we need to work on

Manju Chaturvedi
SFHCP, Nashik, India.

Background
Cultural/psychological/spiritual/social factors influence quality-of-life (QOL) of population with diabetes [PWD]. We correlated spiritual well-being, religiosity, QOL, depression, and end-of-life despair in terminally ill PWD. We also explored stigmatized-issue of sexual-desire of PWD.
Aim
Evaluate spirituality and its relation to depression and the QOL. Analyze impact of anxiety/mental-fatigue due to DIABETIES-diagnosis on sexuality/desire.
Patients and methods
We surveyed 62 PWD through questionnaires. [FACIT-Sp QOL questionnaire & Beck-Depression-Inventory, Hamilton-Depression-Rating-Scale (HDRS), Memorial-Symptom-Assessment-Scale, Duke-UNC Functional-Social-Support-Questionnaire]. Evaluated correlations between variables with Chi-square-Fisher and ANOVA-tests. Multiple regressionanalysis to evaluate if depression and spirituality would independently correlate with QOL.
Results
$n=62$. 56 participants completed-study. [4-died, 2-dropouts]. Mean-age 50-65years. 45-males, 11-female. 37-married. 82% felt religious-faith/spirituality most-important-factor to cope with HIV. no statistical-correlations between FACIT-Sp-scores & demographic-variables. significant correlations between higher-scores of spirituality (ANOVA $P<0.001$) with absence-of-depression. By multiple-regression-analysis both spirituality-dominion of FACIT-Sp and Beck-depression-inventory-score correlated independently and significantly with general-QOL measured by FACT-G-questionnaire's score ($P=0.023$ and $P=0.003$, respectively).Strong-negative-association observed between FACIT-Spiritual-Well-Being-Scale and HDRS.
Conclusion
QOL/Mental[wellbeing of PWD enhanced by spirituality/psycho-social-support. religion provide solace reducing depression. spirituality/psycho-social-support emerging new hope for PWD. Spiritual well-being prevents end-of-life-despair. Effect of spiritual/psycho-social-community support fertile ground for further investigations. We need to work-together/share-experiences to further ground work on this issue among patients community with a larger sample size. We aim at improving spiritual-health and general-QOL among PWD.

The relationship between glycated hemoglobin, postload blood glucose levels and non-hdl cholesterol among 75 gram oral glucose tolerance test applied women

Hilal Yönet Aslan[1], Özlem Polat[1], Ayşe Esen[2], Evin Bozkur[2], Betül Öndes Denizli[1], Medine Şişman[1], Hamide Pişkinpaşa[2], Yasemin Şefika Akdeniz[2], Sami Hatipoğlu[3] & Meral Mert[2]
[1]Family Medicine, University of Health Science, Bakirkoy Dr. Sadi Konuk Education and Research Hospital, Istanbul, Turkey; [2]Endocrinology and Metabolism, University of Health Science, Bakirkoy Dr. Sadi Konuk Education and Research Hospital, Istanbul, Turkey; [3]Pediatry, University of Health Science, Bakirkoy Dr. Sadi Konuk Education and Research Hospital, Istanbul, Turkey.

Aim
Diabetes and prediabetes become prevalent day by day, likewise their complications are also as important as they are. Lipid profile is also evaluated for cardiovascular diseases which are the major complications of diabetes and prediabetes. Non-HDL cholesterol has begun to be taken as one of the treatment goals, especially in diabetics, with respect to the recent dyslipidemia guidelines. The aim of this study is to compare non-HDL values in women with normal or impaired glucose tolerance or diabetes mellitus according to the results of 75 g oral glucose tolerance test (OGTT) and to analyse the relationship between 0- and 2- hour blood glucose values with HbA1c and non-HDL.
Materials and methods
Glucose, OGTT 0- and 2-hour blood glucose values, HbA1c, total cholesterol, triglyceride, HDL, LDL and non-HDL cholesterol results of 75 g OGTT applied women in Bakırköy Dr. Sadi Konuk Education and Research Hospital, were evaluated retrospectively. Patients were grouped according to OGTT results. The relationship of the parameters in each other for each group and the differences between groups were examined. Pearson correlation coefficient and, for ANOVA and Post-Hoc information Bonferroni test were applied as statistical methods.
Results
34, 85 and 14 of 133 women were determined as normal, prediabetic and diabetic in our study group, respectively. For whole group, OGTT 0-hour variable was determined as 41% and 38.6% correlated with OGTT 2-hour and HbA1c, respectively; OGTT 2-hour variable was 36.5% correlated with HbA1c; HbA1c was 17.2% correlated with non-HDL positively and these were statistically significant. In diabetic group, non-HDL averages were found as significantly higher when compared to impaired glucose tolerance, statistically. In whole group, proportion of individuals who reached to target LDL values and non-HDL targets were 34.6% and 47.4%, respectively.
Conclusion
Glucose metabolism states of individuals should be determined and precautions should be taken to avert complications within the context of preventive medicine. The risk should be identified by evaluating lipid profile in the scope of cardiovascular diseases. Non-HDL cholesterol should be considered as secondary treatment target, especially for diabetics.

Diabetes-, sex-, and BMI specific associations of genetic variants in PRRG1 with cardiovascular surrogates in a large cohort at CV risk

Natascha Schweighofer[1,2], Christoph W Haudum[1,2], Albrecht Schmidt[3], Ewald Kolesnik[3], Caterina R Colantonio[3], Burkert Pieske[3], Thomas R Pieber[1,2] & Barbara Obermayer-Pietsch[1]
[1]Department of Internal Medicine, Division of Endocrinology and Diabetology, Medical University of Graz, Graz, Austria; [2]CBmed GmbH, Center for Biomarker Research in Medicine, Graz, Austria; [3]Department of Internal Medicine, Division of Cardiology, Medical University of Graz, Graz, Austria.

The proline rich and Gla domain genes PRRG1-4 encode for short transmembrane proteins. PRRG proteins contain a Gla domain with glutamic acid residues which are gamma-carboxylated in a vitamin-K-depend manner. In a previous study, we were able to show a decrease in PRRG1 gene expression during intima thickening in atherosclerosis. In this study, we investigated the association of single nucleotide polymorphisms (SNPs) in the vitamin-K-dependent protein PRRG1 with cardiovascular parameters (pathologic intima media thickness (IMT), left atrial volume index (LAVI), left ventricular mass index (LVMI) or pulse wave velocity (PWV), and relative wall thickness (RWT) groups) in three diabetes stages (no diabetes, prediabetes and type 2 diabetes), in lean and overweight persons and males vs. females. We investigated the BioPersMed cohort ($n=1025$), a prospective cohort study of asymptomatic patients with one cardiovascular risk factor. Determination of PRRG genotypes was done by GSA array (Illumina Inc., USA). Pulse wave analysis was done using a SphygmoCor device (Atcor Medical, Australia) and echocardiographic measurements were performed using the Vivid 9 device (GE Healthcare Austria GmbH & Co OG, Austria). Type 2 diabetes (T2DM) and prediabetes were defined according to ADA criteria. Persons with a BMI <25 were defined as lean. RWT groups showed concentric (>0.42) or eccentric (≤ 0.42) hypertrophy. A LAVI <29 ml/m^2, a LVMI ≥ 96 (females) or 116 (males) g/m^2, an IMT >0.9 mm and a PWV <10 m/s (end organ damage) were considered pathologic. No associations were seen with these SNPs and parameters in the other patients' groups (data not

shown). Chi-square analysis revealed significant associations of PRRG1 SNPs in females and males with RWT groups. These associations might implicate a possible role of PRRG1 and vitamin K-dependent proteins in the modulation of important cardiovascular parameters and thus contribute to cardiovascular risk.

Table 1 Significant associations of PRRG1 with cardiovascular parameters in various patients' groups.

ID of genetic variation	no diabetes		pre-diabetes		T2DM	lean			overweight

CGI-58 gene expression is decreased in the subcutaneous adipose tissue of patients with obesity

Denise Sortica[1], Jakeline Rheinheimer[2], Bianca de Souza[1,2], Mayara de Oliveira[1,2], Milene Moehlecke[3], Cristiane Leitao[1,2], Andrea Carla Bauer[1,2] & Daisy Crispim[1,2]
[1]Hospital de Clinicas de Porto Alegre, Porto Alegre, Brazil; [2]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil; [3]Universidade Luterana do Brasil, Canoas, Brazil.

Background and aims
In adipose tissue, excess of energy is stored inside cytosolic lipid droplets as triglycerides. During fasting or exercise, the stored fat is mobilized for utilization as free fatty acids and glycerol via lipolysis. The complete lipolysis of triglycerides is mediated by the orchestrated activation of adipose triglyceride lipase (ATGL) and hormone-sensitive lipase, which have been associated with obesity. There is compelling evidence that the protein comparative gene identification 58 (CGI-58) markedly enhances ATGL-mediated lipolysis. However, to date, only few studies have evaluated the association between CGI-58 and obesity, with inconclusive results. Thus, here, we compared *CGI-58* expression in subcutaneous adipose tissue (SAT) of subjects with different body mass index (BMI) categories. We also evaluated if *CGI-58* correlates with body composition parameters, resting energy expenditure (REE), insulin resistance (IR), and lipid and glycemic profiles.
Methods
SAT biopsies were obtained from 59 individuals who underwent bariatric surgery or elective abdominal surgery. Patients were divided in Group 1 ($n=8$; BMI <25.0 kg/m^2), Group 2 ($n=22$; BMI 30.0 – 39.9 kg/m^2) and Group 3 ($n=29$; BMI ≥ 40.0 kg/m^2). *CGI-58* expression in SAT was quantified using real-time PCR (qPCR).
Results
CGI-58 expression was decreased in Group 3 [median 0.60 (0.56 – 0.82, 25th–75th percentiles)] and Group 2 [0.89 (0.70 – 1.10)] compared to Group 1 patients [2.48 (1.64 – 3.23)] ($P<0.00001$). Accordingly, *CGI-58* expression was negatively correlated with BMI values ($r=-0.424$, $P<0.001$). Moreover, after BMI adjustment, *CGI-58* expression was negatively correlated with waist circumference ($r=-0.525$, $P<0.001$), fat-free mass ($r=-0.290$, $P=0.030$), insulin ($r=-0.266$, $P=0.047$), HbA1c ($r=-0.379$, $P=0.003$), and triglycerides ($r=-0.521$, $P<0.001$), while it was positively correlated with adiponectin levels ($r=-0.277$, $P=0.044$).
Conclusion
CGI-58 expression is decreased in patients with obesity, being associated with worse metabolic profile.

Results at 2 years of bariatric surgery in patients with type 2 diabetes mellitus

Daniel Medina Rivero[1], Isabel María Mateo Gavira[1], Almudena Lara Barea[1], María Ángeles Mayo Ossorio[2] & Manuel Aguilar Diosdado[1]
[1]UGC Endocrinología y Nutrición Hospital U. Puerta del Mar, Cádiz, Spain. [2]UGC Cirugía General y del Aparato Digestivo Hospital U. Puerta del Mar, Cádiz, Spain.

Objectives
1. To evaluate the effect after two years of bariatric surgery on comorbidities in patients with diabetes mellitus type 2 (DMT2) and obesity grade II or higher.
2. Analyze the surgical complications in these patients.
Material and methods
Cohort study with intrasubject measures (before-after) in patients with grade II or higher obesity and T2DM, who underwent bariatric surgery (gastric bypass or vertical gastrectomy) at the Puerta del Mar Hospital in Cádiz during the period from 2005 to 2015. We analyzed anthropometric parameters, cardiovascular risk factors and complications related to surgery at baseline and 2 years after the intervention.
Results
Of the 333 patients who underwent bariatric surgery in that period, 87 had T2DM prior to surgery. 63.2% ($n=55$) women, with a mean age of 44.20 ± 10.24 years and a BMI prior to surgery of 50.72 ± 7.81 Kg/m^2 and 32.67 ± 6.12 Kg/m^2 after surgery. The percentage of overweight lost was $63.51\pm18.61\%$. 54% ($n=47$) were operated on by gastric bypass and 46% ($n=40$) by vertical gastrectomy. The resolution rate of diabetes was 77.6% ($n=66$). In most cases, the duration of diabetes was less than 10 years and there were no known chronic complications. The average HbA1c prior to surgery was $7.48\pm1.52\%$ and $5.66\pm0.98\%$ at two years. 29.1% ($n=25$) are smokers, 71.3% ($n=62$) have high blood pressure and 69% ($n=60$) have dyslipidemia. The resolution of these comorbidities occurred in 61.7% and 71.7% of the cases respectively ($P<0.001$). 12% ($n=10$) of the patients presented early surgical complications and 14.8% ($n=12$) developed late complications.
Conclusions
In patients with obesity grade II or higher and T2DM, bariatric surgery is shown in our environment as an effective tool in the early resolution of diabetes, in addition to its beneficial effects on the rest of associated metabolic comorbidities and with a rate of surgical complications similar to other series.

Assessment of the functional activity of neutrophilic granulocytes in patients with metabolic syndrome

Olga Smirnova, Eduard Kasparov & Olga Moskalenko
Research Institute of Medical Problems of the North FIC KSC SB RAS, Krasnoyarsk, Russian Federation.

Introduction
Metabolic syndrome (MS) is a common disease with up to 25% of the total adult population and more than 45% of those over 60 years of age. When MS develops a complex of metabolic disorders that contribute to the development of vascular atherosclerotic diseases, such as abdominal obesity, hypertension, insulin resistance, dyslipidemia. Exchange disorders in MS are associated with the development of inflammation in organs and vessels, while the role of neutrophils in MS cellular reactivity is not fully understood.
Aim
To study the characteristics of neutrophil chemiluminescent activity in patients with MS in dynamics.
Materials and methods
We studied 30 patients with MS and 30 practically healthy individuals. The groups did not differ in age and sex. The intensity of the synthesis of reactive oxygen forms NG was determined by chemiluminescence analysis.
Results
The study of luminol-dependent chemiluminescence showed a significant increase in the intensity of spontaneous and induced luminescence in patients with MS, regardless of the degree of obesity. The area under the spontaneous chemiluminescence curve in patients with MS was significantly increased. In the study of zymosan-induced chemiluminescence, the area under the curve is increased in all groups of patients, while in patients with grade III obesity, the total production of reactive oxygen species is significantly higher than in grades I and II. After undergoing a course of treatment, the chemiluminescent activity of neutrophils in MS patients tended to decrease, not reaching the indicators of the control group.
Conclusion
In patients with MS before treatment, there was an increase in neutrophil chemiluminescent activity regardless of the degree of obesity, and after treatment, there was a tendency to decrease, which indicated the effectiveness of the therapy.

Hygienic-dietetic habits in a group of patients with morbid obesity waiting for bariatric surgery and in a group already intervened

Daniel Medina Rivero[1], Isabel María Mateo Gavira[1], Laura Larrán Escandón[1], Amelia Rodríguez Martín[2] & Manuel Aguilar Diosdado[1]
[1]UGC Endocrinología y Nutrición, Hospital U. Puerta del Mar, Cádiz, Spain; [2]Department of Biomedicine, Biotechnology and Public Health. Universidad de Cádiz, Cádiz, Spain.

Objectives
To determine the lifestyle in patients with morbid obesity in a previous group and in a group after performing bariatric surgery.
Material and methods
Cross-sectional study in two groups of patients with morbid obesity one before and one after bariatric surgery attended in the Clinical Management Unit of Endocrinology and Nutrition of the Puerta del Mar Hospital in Cádiz. The clinical and analytical data of the patients, the sociodemographic characteristics and lifestyles are collected.
Results and conclusions
Some 111 patients with morbid obesity were collected before and after the surgical intervention: (31.5% males, 68.5% females) and operated patients (29.9% males and 70.1% females). Before surgery, the average weight was 133.4 kg (SD 24.4) and the BMI 48.6 kg/m^2 (SD 7.0), and in the patients treated, it was 94.9 kg (SD 19.8) and BMI 34.5 kg/m^2 (6.5). There are statistically significant differences between both groups in terms of habits and lifestyle: tobacco consumption (21.1% vs 7.1%), alcohol consumption (21.1% vs 17.4%), physical exercise (55.0% vs 82.6%), hours of physical exercise (4.75 h/week vs 5.9), eating habits such as snacking (35.5 vs 19.8%), fast food consumption (56.5% vs 11.9%), and increase in meals/day from 3 to 5. We observed statistically significant differences in lifestyle both before and after bariatric surgery, which could contribute to maintenance, improved prognosis and good patient evolution.

Challenges in managing patients with type 1 diabetes and hypersensitivity reaction to insulin

Rahat Tauni[1,2] & Rajna Golubic[2]
[1]West Suffolk Hospital NHS Foundation Trust, Bury St Edmunds, United Kingdom; [2]Cambridge University Hospitals, Cambridge, United Kingdom.

Patients with type 1 diabetes (T1DM) and insulin hypersensitivity reaction of any type are at high risk of acute and chronic long term complications of hyperglycaemia and glycaemic variability. Such patients are challenging to manage. We present a case report. A 57 year old lady with T1DM for 21 years managed with insulin pump for 7 years reported new onset intermittent skin reaction at the pump infusion site over the last two years. She described her skin becoming swollen and hard and sometimes itchy and red within 4–12 hours of starting NovoRapid insulin via a new cannula. The reaction persisted up to a week and swelling subsided without any intervention. The reaction continued with the new types of cannula or with Humalog or Apidra in the pump. The reaction also happened with subcutaneous injections of quick, intermediate and long acting insulin. The reactions seemed to be more pronounced during infections. Skin prick and intradermal testing to all human, bovine and porcine insulins were negative. Specific IgE to insulins were negative and mast cell tryptase was normal. She was diagnosed to have type 3 hypersensitivity reaction to insulin molecule. Antihistamines would help minimise itching but no other treatments were deemed suitable as reactions were intermittent and satisfactory glycaemic control was maintained. She will be considered for trial of DiaPort, peritoneal insulin delivery system in future if reactions become more persistent and/or glycaemic control is affected. Insulin hypersensitivity presents a management challenge for patients with insulin dependent diabetes. Its incidence has reduced since the invention of human insulin. Most common type is immediate or less commonly biphasic IgE medicated type 1 local or systemic reaction. Type 3 hypersensitivity is less common and usually presents with a slightly delayed local reaction. Management of hypersensitivity reactions involves switching to different insulin, antihistamines, glucocorticoids or desensitisation although type 3 hypersensitivity is more difficult to treat. It is important to note that the hypersensitivity could either be due to insulin itself or other substances in the insulin injections therefore it is critical to recognise the exact allergen. DiaPort system of insulin delivery through peritoneum is a promising option for such patients if other treatments fail or are deemed unsuitable.

Relationship between liver fibrosis and diabetes-related complications in type 2 diabetic patients

Soo Min Hong[1], Sejeong Park[2] & Ho Seok Koo[1]
[1]Seoul Paik Hospital, Seoul, Republic of Korea; [2]Samyook Medical Center, Seoul, Korea.

Introduction
Type 2 diabetes has a relationship with fatty liver. Fatty liver can progress to liver fibrosis. This study examined relationship between liver fibrosis and diabetes-related complications in type 2 diabetic patients.
Methods
This study analyzed data from the 2007 to 2015 the Korea National Health and Nutrition Examination Survey (KNHANES) in South Korea. Which included values of c-peptide, fasting blood sugar, AST, ALT, and platelet to calculate parameter of homeostasis model assessment (HOMA) and fibrosis-4 scores (FIB-4). We compared FIB-4 scores by groups of normal glucose tolerance (NGT), impaired glucose tolerance (IGT) and diabetes. We also compared frequencies of diabete-related complications depending on the presence of liver fibrosis among diabetic patients.
Results
A total of 16,420 subjects were analyzed. Diabetes group showed higher FIB-4 scores than NGT or IGT groups (1.4 ± 0.9 vs 0.9 ± 0.6 vs 1.1 ± 0.8). Among diabetes patients, liver fibrosis group (Fib-4 ≥ 1.45) had more hypertension (40.9% vs 17.8%), hypercholesterolemia (13.3% vs 6.5%), stroke (3.2% vs 1.4%), cardiovascular diseases (5.1% vs 1.4%), cataract (11.6% vs 4.5%) and glaucoma (1.5% vs 0.7%) than non-fibrosis group. Particularly, liver fibrosis increased risk of cardiovascular diseases such as myocardial infarction or angina (OR 11.01, 95% CI 1.64–73.94) by multivariate regression analysis.
Conclusion
Diabetes patients are more accompanied by liver fibrosis. Liver fibrosis increased risk of diabetes-related complications. Thus, early screening of liver fibrosis and fatty liver in diabetic patients is needed. And appropriate treatment would be helpful to prevent progression of diabetes-related complications.

Study on compositions of lipids in tissues of rats with alimentary obesity

Sanobarkhon Irgasheva, Bakhodyr Zainutdinov, Tokhir Ishankhodjaev, Elvira Ibragimova, Mukhammadjon Mustafakulov & Talat Saatov
Institute of biophysics and biochemistry, Mirzo Ulugbek National University of Uzbekistan, Tashkent, Uzbekistan.

Obesity is considered as a major factor of insulin resistance and diabetes mellitus risk. Study on lipid composition of tissues in obesity is relevant in understanding of mechanisms underlying insulin resistance.
Aim
The work was initiated to study lipid composition of liver and skeletal muscles tissues in rats with alimentary obesity.
Materials and methods
Obesity was induced in rats leading an inactive lifestyle with prolonged high calorie diet (standard diet + fat, sugar and margarine). After the animals' weight of 400–500g was achieved they were sacrificed; their liver and skeletal muscles were removed for study. Lipids were extracted by Kates (1975) and fractionated by thin layer chromatography.

Results
In livers of rats with induced alimentary obesity cholesterol and triglycerides were found to increase by 23% and 48%, respectively, total phospholipids were found to decrease from 1039 ± 37.2 μg of phosphorus per gram of tissue to 878.6 ± 32.1 μg of phosphorus per gram of tissue documented in the control animals. Changes in the fraction composition of liver phospholipids were found in rats with the induced alimentary obesity too. Thus, lysophospholipids, cardiolipin and phosphatidic acid were found increased by 280%, 7.1% and 29%, respectively, while phosphatidylcholines, phosphatidylethanolamines and sphingomyelins were found to decrease by 9%, 34% and 31%, respectively. In the skeletal muscles of rats with alimentary obesity cholesterol and triglycerides were found to increase, while total phospholipids decreased; changes in some phospholipid fractions were oppositely directed.
Conclusions
Changes in concentrations of neutral lipids, total phospholipids and some of their fractions registered in rats with the induced alimentary obesity are thought to be caused by fluctuations in lipid metabolism and activation of lipolytic enzymes. The changes in lipid composition of tissues under study could underlie insulin resistance in alimentary obesity.

Dopamine Receptor and Dopamine Transporter in Obesity: A Meta-analysis

Kyoungjune Pak, Bo hyun Kim, Mijin Kim & Keunyoung Kim
Pusan National University Hospital, Busan, Republic of Korea.

Objectives
The brain plays a major role in controlling the desire to eat. We performed a meta-analysis to assess the association of dopamine transporter (DAT)/dopamine receptor (DR) availabilities from neuroimaging studies with obesity.
Methods
We performed a systematic search of MEDLINE and EMBASE for English-language publications. Data were extracted from the publications independently by two reviewers. Effect sizes were correlation coefficient between BMI and the availabilities of DR or DAT from both controls and obese subjects. To investigate DR availability ratio of obese subjects to controls, mean DR availabilities and mean BMI of each group were extracted.
Results
8 (DR) and 3 (DAT) studies including 332 (DR), and 358 (DAT) subjects were eligible for inclusion in this study. DR availabilities were weakly correlated with BMI (correlation coefficient 0.239, 95% confidence interval 0.164 ~ 0.311, $P < 0.001$, $I^2 = 26.7\%$). DR availability ratios decrease as the BMI increases in subjects with BMI more than 40kg/m^2. However, the pooled data did not show the significant association between DAT availabilities and BMI (correlation coefficient 0.0277, 95% confidence interval −0.130 ~ 0.184, $P = 0.732$, $I^2 = 74.9\%$).
Conclusions
DR availability was positively correlated with BMI, however, DAT availability was not associated with BMI. DR availability from subjects with BMI of approximately 35 kg/m^2 was higher than that from controls, however, DR availability from subjects with BMI more than 40 kg/m^2 was lower than that from controls, which is consistent with the hypothesis of reward deficiency syndrome in severe obesity.

Cerebral glucose metabolism and Cerebral blood flow in Hypothyroidism and Hyperthyroidism: An activation likelihood estimation Meta-analysis

Kyoungjune Pak, Bo hyun Kim, Mijin Kim & Keunyoung Kim
Pusan National University Hospital, Busan, Republic of Korea.

Objective
Thyroid dysfunction is frequently associated with functional disturbances of the brain. We performed a meta-analysis of previous positron emission tomography and single-photon emission computed tomography studies using a coordinate-based technique of activation-likelihood estimation (ALE) to investigate the potential background of neuropsychiatric complications in patients with hypo- and hyperthyroidism.
Methods
We performed a systematic search of MEDLINE and EMBASE for English-language publications using the keywords of 'positron emission tomography', 'single-photon emission computed tomography', and 'thyroid'. The software GingerALE ver 2.3.6 was used to transform all reported coordinates into stereotactic Montreal Neurological Institute space. A threshold of uncorrected $P < 0.001$ (minimum volume of 200 mm^3) was applied to the resulting ALE map.
Results
Six studies were eligible for inclusion in the study; 4 studies of cerebral metabolic rate of CMRglu, and 2 studies of CBF. In hypothyroidism, significant decreases in CMRglu were identified in 3 clusters including left anterior cingulate, right inferior occipital gyrus, and right cuneus. In hyperthyroidism, a significant decrease in CMRglu was identified in right superior frontal gyrus. In hypothyroidism, a significant decrease in CBF was observed in left postcentral gyrus.
Conclusions
Several brain regions showed altered CMRglu and CBF in patients with thyroid dysfunction compared with euthyroid controls. These findings might account for underlying mechanisms of thyroid hormones on psychological and physiological effects on brain.

Biomarkers of myocardial fibrosis at coronary heart disease in the presence and absence of diabetes mellitus type 2

Alexey Korotaev, Andrey Prystrom, Lyudmila Korotaeva, Maria Rusalenko & Elena Naumenko
Repablican Scientific Center for Radiation Medicine and Human Ecology, Gomel, Belarus.

Combination of coronary heart disease (CHD) with diabetes mellitus type 2 significantly increases the risk of left ventricular remodeling. The objective of the study was to determine the association of biomarkers of myocardial fibrosis with the level of glycaemia at CHD in patients with and without DM type 2.
Methods
We have examined 104 patients with CHD of average age 64.9 ± 0.3 years old, 27 of them were with DM type 2; 77 patients were without DM type 2.
Results
The levels of glycaemia and HbA1c differed depending on the presence of DM type 2: 5.16 [4.7; 5.48] vs 6.70 [5.39; 7.40] mmol/l ($P < 0.001$) and 5.70 [5.40; 5.93] vs 6.60 [5.80; 7.50]% ($P < 0.001$). In the case if the CHD wasn't combined with DM type 2, a correlation was found between the level of glycaemia and IL-1β ($r = -0.30$; $P = 0.007$); IL-2 ($r = -0.26$; $P = 0.024$); HbA1c with BNP ($r = -0.42$; $P < 0.001$), galectin-3 ($r = -0.30$; $P = 0.008$), IL-6 ($r = -0.24$; $P = 0.032$), IL-12 ($r = -0.26$; $P = 0.023$). When CHD was combined with T2DM, a correlation was found between the level of glycaemia and aldosterone ($r = 0.57$; $P = 0.002$); HbA1c with IL-1β ($r = 0.42$; $P = 0.027$), IL-6 ($r = 0.55$; $P = 0.003$) with aldosterone ($r = 0.56$; $P = 0.002$).
Conclusion
Patients with CHD showed a correlation between glycaemia and HbA1c levels with a number of biomarkers of myocardial fibrosis, regardless of the presence of DM type 2, which indicates the necessity to determine critical points of glycaemia and HbA1c, and perhaps of glycemia variability, which influence the myocardial fibrosis development.

Prevalence of vitamin D deficiency in a population of patients with prediabetes and type 2 diabetes mellitus

Beatriz Lardiés Sánchez[1], Guayente Verdes Sanz[2], Maria José Camallonga[1] & Luis Cipres Casasnovas[1]
[1]Polanco Hospital, Teruel, Spain; [2]Alcañiz Hospital, Teruel, Spain.

Objective
Vitamin D deficiency has been related to extraskeletal manifestations such as insulin resistance, type 2 diabetes mellitus (DM) and obesity. The objective of this study was to assess the prevalence of vitamin D insufficiency and deficiency in a population of patients with prediabetes and with type 2 DM already established, and to see if there were differences according to different parameters.
Material and methods
Cross-sectional study, in which a total of 460 patients were selected, 230 of them with prediabetes and another 230 patients with type 2 DM, controlled in Endocrinology consultations. 50% of each group were women. The main variables determined were: weight, body mass index (BMI), abdominal perimeter, fasting glucose levels, and 25-OH vitamin D levels. Serum 25-OH vitamin D levels considered as sufficiency were >30 ng/ml; insufficiency was considered between 20–30 ng/ml, and deficiency <20 ng/ml.
Results
The prevalence of vitamin D deficiency was 85.7%, being higher in women (92.8%) than in men (79.3%) ($P<0.05$). In patients with type 2 DM, the prevalence of vitamin D insufficiency was 7.1% and the prevalence of deficiency was 84.2%; while in patients with pre-DM, 5.7% had vitamin D insufficiency and 64.3% had deficiency of this vitamin ($P<0.05$). A greater deficiency was also observed in patients older than 65 years (88.3% vs. 76.1%, $P<0.05$); in patients with a higher BMI (91.2% of patients with BMI >30 kg/m^2 had deficiency compared to 78.1% of those with BMI <30 kg/m^2), and a greater abdominal perimeter (90.1% if abdominal circumference was >110 cm, compared to 81.3% in those with abdomen perimeter <110 cm).
Conclusions
There is a high prevalence of vitamin D deficiency in population with type 2 diabetes mellitus, being higher in women, in patients with higher BMI and greater abdominal perimeter, and in those with established type 2 DM compared to patients with prediabetes.

Table 1 Studied variables in patients with pre-DM and established type 2 DM.

	Prediabetes	Type 2 Diabetes Mellitus	*P*
Age (years)	59.1 (+*4.1*)	60.3 (+*5.5*)	>0.05
BMI (kg/m^2)	31.4 (+*4.9*)	33.5 (+*4.3*)	>0.05
Abdominal perimeter (cm)	103.8 (+*12.4*)	123.1 (+*11.1*)	0.01
25-OH vitamin D levels (ng/dl)	19.3 (+*4.2*)	14.1 (+*3.6*)	0.02
Fasting glucose levels (mg)	115 (+*12.6*)	132 (+*13.8*)	0.01
Glycated hemoglobin (%)	5.8 (+*0.6*)	6.9 (+*0.9*)	0.01

Genealogical analysis in diabetes mellitus risk assessment

Talat Saatov[1], Elvira Ibragimova[2], Tokhir Ishankhodjaev[2], Anvar Abduvaliev[1], Nasiba Alimova[1,3] & Zafar Ibragimov[1]
[1]Institute of Biophysics and Biochemistry, Mirzo Ulugbek National University of Uzbekistan, Tashkent, Uzbekistan; [2]Institute of Biophysics and Biochemistry, Mirzo Ulugbek National University of Uzbekistan, Tashkent, Uzbekistan; [3]Center for the Scientific and Clinical Study of Endocrinology, Tashkent, Uzbekistan.

Prevention of familial diabetes mellitus is a most urgent problem in diabetology. Genetic susceptibility is a leading factor in diabetes mellitus onset.
Aim
The work was initiated to assess potentiality of diabetes mellitus risk prediction based on genealogical analysis.
Materials and methods
For the purpose of the study, 53 patients with diabetes mellitus were examined. The probands' mean age was 14.4 years. Genealogical medical history was assessed by establishing breeding background with number of generations not less than 3. Index of hereditary burden was calculated as the quotient from total number of diabetes mellitus cases and total number of a proband's relatives to establish orientation of family medical history by diabetes mellitus. The index of hereditary burden less than 0.4 meant the absence of the hereditary burden by diabetes mellitus.
Results
Clinical-genealogical analysis of breeding background showed hereditary burden by diabetes mellitus in 74.2% of patients examined in the study with index of hereditary burden 0.5. The onset of diabetes mellitus in a proband was determined by the number of his affected relatives. If parents are healthy, the probability ranges from 5 to 10%. Diabetes mellitus in one parent implies its risk in 10–20%. If both parents are diabetic, the risk can increase up to 40%. The disease risk in children of the proband may range by the affection of his parents ranging from 10 to 20%.
Conclusions
Analysis of genealogical tree for patients with diabetes mellitus demonstrated multifactor character of the pathology confirmed by mode inheritance non-conformity with Mendelian laws which are general for the monogenic characters. Type I diabetes mellitus was demonstrated to develop in the offsprings of patients with type II diabetes mellitus which is an activating factor to a mutant gene capable of triggering mechanism for the hereditarily associated diabetes. Thus, clinical genealogical analysis allows identifying groups at higher risk of diabetes mellitus and performing timely interventions.

The waist-to-hip ratio is a better obesity index than body mass index and waist circumference for screening for nonalcoholic fatty liver disease in postmenopausal women

Hye Jin Yoo, So-hyeon Hong, Jung A Kim, You-Bin Lee, Eun Roh, Kyung Mook Choi & Sei Hyun Baik
Korea University College of Medicine, Seoul, Republic of Korea.

Background/Objectives
Although it has been well-established that menopause causes a shift in body fat, thereby eliciting metabolic disturbances in women, there has been no study conducted yet to examine the best obesity parameters to predict the risk of nonalcoholic fatty liver disease (NAFLD) in this population. Thus, the aim of this study was to compare the efficacy of body mass index (BMI), waist circumference (WC), and waist-to-hip ratio (WHR) for screening NAFLD according to menopausal status.
Subjects/Methods
This cross-sectional analysis included 620 healthy women between 20 years and 80 years of age recruited from the Health Promotion Center of Korea University Guro Hospital. NAFLD was diagnosed by abdominal ultrasonography.
Results
All receiver operating characteristic curves of BMI, WC, and WHR for NAFLD were established statistically above the diagonal nondiscrimination line. In premenopausal women, there were no statistical differences in area under the curve (AUC) values among the three obesity indices, whereas, in postmenopausal women, the AUC value of WHR was significantly larger than those of either BMI ($P=0.005$) or WC ($P=0.007$). Furthermore, in postmenopausal women, the combination of WHR with BMI or WC significantly increased predictive power of NAFLD when compared to using BMI or WC alone. The optimal cutoff values for BMI, WC, and WHR for detecting NAFLD were 23.9 kg/m^2, 69 cm, and 0.81 in premenopausal women and 22.9 kg/m^2, 74 cm, and 0.86 in postmenopausal women, respectively.
Conclusion
In premenopausal women, BMI, WC, and WHR hold similar potential in predicting the risk of NAFLD, whereas, in postmenopausal women, WHR is the most useful discriminative indicator for NAFLD. Women's optimal cutoff values for NAFLD were different according to menopausal status.

The severity of different components of metabolic syndrome in hypertensive patients depending on IRS-1 gene polymorphism

Anna Shalimova[1,2], Galyna Fadieienko[1], Olena Kolesnikova[1], Vira Zlatkina[2] & Maryna Kochuieva[3]
[1]L.T. Malaya Therapy National Institute of the National Academy of Medical Sciences of Ukraine, Kharkiv, Ukraine; [2]Kharkiv National Medical University, Kharkiv, Ukraine; [3]Kharkiv Medical Academy of Postgraduate Education, Kharkiv, Ukraine.

Objective
To establish possible associations of the polymorphism of the insulin receptor substrate−1 (IRS-1) gene with the severity of various components of metabolic syndrome in patients with arterial hypertension (AH). We examined 187 patients with AH aged 45–55 years (with history of hypertension less than 5 years, unsystematic administration of antihypertensive drugs and/or failure to achieve target blood pressure (BP) levels when prescribing drug therapy). The control group consisted of 30 individuals matched for age and sex.
Methods
Anthropometry, reactive hyperemia, color Doppler mapping, biochemical blood analysis, HOMA-insulin resistance (IR), glucose tolerance test, enzyme immunoassay (determined levels of adiponectin, interleukin-6 (IL-6), C-reactive protein (CRP)) and molecular genetic method (genotyping of polymorphic marker Gly972Arg of IRS-1gene).
Results
It was found that among the hypertensive patients, 103 had abdominal obesity, 43 – type 2 diabetes mellitus (established less than 2 years ago), 131 – increased blood triglycerides ($\geq$150 mg/dL), 19 – decreased high density lipoproteins (HDL, $<$40 mg/dL in men and $<$50 mg/dL in women), 59 – prediabetes (33 – fasting hyperglycemia and 26 – impaired glucose tolerance), 126 had IR, assessed by the HOMA-IR. At the same time, hypertensive patients had the following distribution of IRS-1 genotypes: Gly/Gly −47.9%, Gly/Arg −42.2% and Arg/Arg −10.7%, whereas in practically healthy individuals the distribution of genotypes was significantly different: Gly/Gly −86.8% ($P<0.01$), Gly/Arg −9.9% ($P<0.01$) and Arg/Arg −3.3% ($P<0.05$). At the next stage, associations of the IRS-1 gene polymorphism with anthropometric, metabolic and hemodynamic parameters in hypertensive patients were evaluated. It was found that hypertensive patients with Arg/Arg and Gly/Arg genotypes had significantly higher levels of glucose ($P<0.05$), insulin ($P<0.05$), HOMA-IR ($P<0.01$), triglycerides ($P<0.05$) than patients with the Gly/Gly genotype. At the same time, body mass index, waist circumference, levels of BP, adiponectin, HDL, IL-6, CRP, total antioxidant activity, degree of endothelium-dependent vasodilation, as well as the frequency of occurrence of impaired glucose tolerance did not differ significantly with various IRS-1 genotypes.
Conclusions
In hypertensive patients, the genetic polymorphism of IRS-1 gene is associated with such components of metabolic syndrome as hypertriglyceridemia and fasting hyperglycemia; this polymorphism is not associated with proinflammatory state, endothelial dysfunction, dysglycemia, an increase in waist circumference and decrease in HDL.

The association of fibroblast growth factor 23 with other factorsof mineral and bone disorder in chronic kidney disease

Snjezana Popovic-Pejicic[1,2] & Andreja Figurek[1,2]
[1]University Clinical Centre of the Republic of Srpska; [2]Medical Faculty, University of Banja Luka, Banja Luka, Bosnia and Herzegovina, Banjaluka, Bosnia and Herzegovina.

Introduction
Chronic kidney disease (CKD) is growing problem nowadays. Disorder of mineral metabolism occurs in initialCKD and includes the changes of bone metabolism. Fibroblast growth factor 23 (FGF23) plays an important role in phosphate metabolism. Bearing in mind this physiological role of FGF23, but also it's role in pathophysiology of mineral and bone metabolism, there is a growing interest in conducting clinical studies in patients affected by CKD. Our aim was to investigate the potential relationship among FGF23 and other chronic kidney disease-mineral and bone disorder (CKD-MBD) participants in the clinical setting.
Methods
Eighty-seven CKD patients were involvedin our cross-sectional study, including all causes of the disease. The mean estimated glomerular filtration rate (eGFR) was 40.1 (3–110) mL/min/1.73 m^2. Evaluation of renal function and mineral methabolism condition were perfomed by using standard biochemical protocols. Serum intact FGF23 (iFGF23) level determination was accomplished by utilizing ELISAtechnique. The concentration of iFGF23 in serum greater than 50 ng/L was defined as elevated levels. Descriptive and analytical statistics were used to analyze the data acquired from the study.
Results
The mean iFGF23 level was 80.53$\pm$43.59 ng/L and was increased from CKD stage 1. Serum iFGF23 correlated negatively with eGFR ($P<0.05$) and positively with the levels of serum creatinine ($P<0.05$). Increased level of PTH was seen in stage 3 CKD. Hyperphosphatemia was present from stage 4 CKD, while serum calcium levels remained mostly in reference range. No correlation was seen between iFGF23 with serum calcium, phosphate and parathyroid hormone (PTH) levels.
Conclusion
Initial CKD shows elevated serum iFGF23 levels, whereas other CKD-MBD parameters are mostly within reference range. No significant association was seen between iFGF23 with other markers of CKD-MBD.

Delivery in the diabetic women

Haifa Bergaoui
Gynecology, Monastir, Tunisia.

Purpose
To determine the frequency of *trial of labor* after *caesarean delivery* and the success rate of this trial in women with diabetes as well as in a *control population*.
Materials and methods
This is a retrospective *case-control study* involving 400 cases: 200 diabetic women compared to 200 non-diabetic women conducted in obstetrics and *gynecology* department of the university hospital center of Monastir over 5 years.
Results
The rate of patients with a scarred uterus was 29% (53 cases) in diabetes group against 15% (30 cases) in the control group. The trial of labor is accepted in 24 women in the diabetes group against 26 women in the control group. The failure of the trial of labor was noted in 17% of cases (4 cases) in diabetic women and 38% of cases in non-diabetic women (10 cases).
Conclusion
The rate of elective *cesarean* in case of scarred uterus can be decreased among women with diabetes and expanding indications for the trial of labor. The success rate of trial of labor is high among diabetic, this is explained by the fact that those women with *high-risk pregnancies* are better selected before passing this test.

Peripheral arterial disease in Asian Type 2 diabetes mellitus under 65 years old and its risk factors

Sheng-Fong Kuo[1], Kun-Chun Chiang[2] & Jen-Der Lin[3]
[1]Department of Endocrinology and Metabolism, Chang Gung Memorial Hospital, Keelung, Taiwan; [2]Chang Gung Memorial Hospital, Keelung, Taiwan; [3]Chang Gung Memorial Hospital, LinKo, Taiwan.

Objectives
Peripheral arterial disease (PAD) is the macrovascular complications of type 2 diabetes mellitus, and type 2 diabetic patients with PAD may have higher incidence of foot amputation and coronary heart disease. We conducted a clinical-based cohort study in northern Taiwan in order to assess PAD in diabetes and its associated risk factors.
Methods
This study enrolled type 2 DM patients not older than 65 years old who were seen in diabetes clinics in Chang Gung Memorial Hospital (Keelung, Taiwan). Body mass index (BMI) was measured and relevant laboratory investigations were performed. We also checked serum Vitamin D level in each patient. Ankle brachial index (ABI) was obtained for each leg. The lower value obtained for the two legs was taken as the ABI value. A cut off of $<$ 0.9 was used to define PAD. Brachial-ankle pulse wave velocity (baPWV) was measured to assess arterial stiffness.
Results
We studied 182 patients (85 men and 97 women; mean age 55.5$\pm$7.6 years ranging from 30 to 65 years old; mean duration of diabetes 9.4$\pm$6.1 years). The prevalence of PAD was 6.6%. PAD subjects had a significantly higher prevalence of proteinuria (33.3% vs 12.4%), and a lower baPWV values than those without PAD (R:1617.5$\pm$184.2, L:1575.5$\pm$219.8 vs R:1631.8$\pm$315.7, L:1634.5$\pm$321.9). Otherwise, we did not find a correlation between age, serum vitamin D levels, A1c, duration of diabetes, BMI and PAD.
Conclusion
The low prevalence of PAD in these diabetes patients was due to relatively young age. Our data shows type 2 diabetes patients with proteinuria are at higher risk of PAD. Type 2 diabetes patients with PAD had lower baPWV values than those without PAD. However, more study subjects are needed in the future to enhance the significance of the study.

Gestational diabetes mellitus and continuous glucose monitoring: glycemic patterns and pregnancy outcomes

Márquez-Pardo Rosa[1], Torres-Barea Isabel[2], García-García Doncel Lourdes[1], Cruzado-Begines Concepción[1] & Baena-Nieto Maria-Gloria[1]
[1]Hospital de Jerez, Jerez de la Frontera, Spain; [2]Hospital Puerta del Mar, Cádiz, Spain.

Introduction
Gestational diabetes mellitus (GDM) is associated with an increase risk of neonatal and maternal complications. Continuous glucose monitoring (CGM) detects glycemic patterns, which could help predict the development of maternal-fetal complications.
Objective
To analyze the different glycemic patterns obtained with CGM and to correlate them with the appearance of maternal-fetal complications in GDM.
Methods
Women with GDM at 26–32 gestational weeks were allocated a 6-day CGM system (Ipro^{TM}2) right after diagnosis in an observational prospective study. The following parameters were analyzed by CGM: percentage of time that glucose is above or below range before and after breakfast, lunch, dinner and night. Glucose targets: before meals 70–95 mg/dL, after meals 70–140 mg/dL and night 70–120 mg/dL. Multivariable binary logistic regression was performed to identify independent risk factors associated with both neonatal and maternal outcomes. Value of P 0.05 were considered statistically significant.
Results
$n=87$. Maternal age 33 ± 4.26 years (>35 years$=39\%$). Pregestational body mass index 26.2 ± 4.7kg/m^2 (>30 kg/m$^2=22.1\%$). Insulin treatment 23.4%. *Maternal and neonatal outcomes*: caesarean 28.6%, macrosomia13%, large gestational age (LGA) 8.2%, small gestational age 6.5%, neonatal hypoglycemia 22.1%, neonatal hyperbilirubinemia 7.8%, need for supplemental oxygen in the neonate 7.8%. *Glucose time above and below range (%):* before breakfast: $>95=25.75\%$, 70–95$=66.79\%$ and $<70=7.36\%$; after breakfast:$>140=18.49\%$, 70–140$=80.71\%$ and $<70=0.77\%$; before lunch: $>95=20.43\%$, 70–95$=70.16\%$ and $<70=90.48\%$; after lunch: $>140=11.08\%$, 70–140$=85.87\%$ and $<70=3.18\%$; before dinner:$>95=35.81\%$, 70–95$=58.55\%$ and $<70=5.47\%$; after dinner: $>140=8.18\%$, 70–140$=88.89$ and $<70=2.94\%$; night: $>120=7.84\%$, 71–120$=81.79\%$ and $<70=90.40\%$. *Multivariate binary logistic regression:* Glucose time above range after lunch was an independent factor for macrosomia (Odds ratio 1.041, 95% confidence interval [1.002–1.081]; P value 0.035) and LGA (Odds ratio 1052, 95% confidence interval [1.012–1.094]; P value 0.010). It was not found another independent risk factor for maternal or neonatal outcomes.
Conclusions
There is a correlation between hyperglycemia after lunch at diagnosis of GDM and macrosomia and LGA, although a predominance of preprandial hyperglycemia is observed, especially before dinner. The use of CGM could help identify those patients with higher risk of maternal-fetal complications. However, further studies with a larger number of patients are required.

Evaluation of leptin levels in diabetic and nondiabetic patients with increased BMI

Veranika Labashova[1] & Alla Shepelkevich[2]
[1]Republic Center of Medical Rehabilitation and Balneotherapy, Minsk, Belarus; [2]Belarusian State Medical University, Minsk, Belarus.

Objectives
Leptin is an adipokine responsible for controlling appetite and fat accumulation. The role of leptin in pathophysiology of obesity and diabetes mellitus is an area of active investigation.The aim was to study leptin levels in diabetic and nondiabetic patients with increased body mass index (BMI).
Methods
A sample of 246 patients with type 2 diabetic mellitus and 86 age and BMI-matched controls were examined. The mean age of the participants with diabetes mellitus was 58.24 (53–66) years, healthy adults 51.23 (40–63) years. The mean BMI of diabetic patients was 31.26 (28.08–34.68) kg/m^2 vs controls 30.4 (27.28–34.92) kg/m^2. Blood samples were taken from participants after fasting for 12 hours. For diabetic patients antidiabetic drugs were given 12 hours before.
Results
We found no statistical differences in serum leptin levels in the examined groups. Leptin levels in diabetic patients were 32.37 (14.93–43.67) ng/ml, in healthy adults 27.05 (12.42–38.2) ng/ml, $P=0.109$. These may be the result of increased levels of BMI in diabetic and nondiabetic patients and the absence of significant differences in BMI between two groups. Study of gender differences in fasting serum leptin concentrations revealed statistically higher concentrations of leptin in diabetic females 38.22 (19.61–40.62),ng/ml than in diabetic males 16.09 (9.24–20.3) ng/ml, $P=0000.1$ and in healthy females 31.02 (17.4–42.98) ng/ml vs healthy males 14.74 (8.19–17.6) ng/ml; $P=0.001$.
Conclusion
The data revealed no statistical differences in leptin levels in diabetic and non diabetic patients with increased BMI, but suggest gender dichotomy in both groups.

DOI: 10.1530/endoabs.63.P182

Adiponectin concentrations in type 2 diabetes mellitus patients compared with healthy controls

Veranika Labashova[1] & Alla Shepelkevich[2]
[1]Republic Center of Medical Rehabilitation and Balneotherapy, Minsk, Belarus; [2]Belarusian State Medical University, Minsk, Belarus.

Objectives
Adiponectin is an adipokine that play an important role in glucose metabolism and energy homeostasis. The aim of our study was to evaluate adiponectin levels in type 2 diabetes mellitus patients compared with healthy controls.
Methods
A sample of 246 patients with type 2 diabetic mellitus and 86 age and BMI-matched controls were included. The mean duration of diabetes was 9.54 (5–13) years. The mean glucose level was 8.14 (5.56–9.9) mmol/l in diabetic patients, 5.48 (4.9–5.78) mmol/l in healthy controls.
Results
No statistical differences were revealed in adiponectin levels of the examined groups. Fasting concentration of adiponectin in diabetic patients was 3.44 (1.6–4.44) ng/ml vs 4.03 (1.62–6.28), ng/ml in healthy adults, $P=0.25$. However the study identified gender differences in serum adiponectin concentrations. The level of adiponectin in women with type 2 diabetes mellitus was 3.74 (1.84–4.72), ng/ml, in male 2.61 (1.32–3.17) ng/ml; $P=0.001$. In the group of healthy women adiponectin concentration was 4.47 (1.92–6.72), ng/ml; in healthy men 2.65 (1.54–3.77) ng/ml; $P=0.039$.
Conclusion
The study did not found statistical differences in adiponectin levels in diabetic and nondiabetic patients. The level of adiponectin was higher in female than in male regardless of the presence of the disease.

Diagnosis of type 1 DM in a patient with Hydroxymethylglutaric aciduria: Case report

Viyey Kishore Doulatram Gamgaram, Montserrat Gonzalo Marin, Inmaculada González Molero, José Abuín Fernández, Francisco José Sanchez Torralvo, Marisol Ruiz de Adana & Gabriel Olveira Fuster
Hospital Regional Universitario, Málaga, Spain.

Introduction
Hydroxymethylglutaric aciduria is a rare metabolic disease that is caused by the deficiency of the enzyme 3-hydroxy-3-methylglutaryl-CoA lyase, which participates in the metabolism of leucine and in the formation of ketone bodies. The symptomatology usually occurs in the first two years of life and consists of nausea, vomiting, diarrhea, hypotoniaanddepressed level of consciousness. Metabolic acidosis occurs during crises as a result of the accumulation of metabolites and hypoglycaemia.The crises are triggered by infections or prolonged fasting.

Case report
A 18-month-old female who comes to the hospital due to seizures andhypotonia, with the suspicion of encephalitis. The blood test shows hypoglycaemia (19 mg/dL) and non-ketotic metabolic acidosis with high anion GAP. A study of hypoglycaemia in children is performed with the following results: marked increase of the excretion of leucine metabolites, decreased levels of free carnitine and normal levels of total and esterified carnitine. The diagnostic suspicion is Hydroxymethylglutaric aciduria, which is confirmed by a skin biopsy. Treatment is started with a diet low in proteins of high biological value, carnitine, and a leucine-free nutritional supplement. We also indicate to avoid prolonged fasting. With the adjustments, the patient showed a good evolution having only one admission due to a hypoglycaemia associated with a rotavirus gastroenteritis. In the follow-upthe genetic testindicates alikely pathogenic variant in apparent homozygotes: c.575T>C (p.Phe192Ser) in the HMGCL gene. At the age of 21, the patient debuted with diabetes with associated cardinal symptoms, which led to the initiation of insulin in basal-bolus therapy. Blood test results: GAD65-Ab >250 IU/mL, C-peptide 0.54 ng/mL and negative anti-IA2 and anti-Insulin antibodies. Currently the patient has good metabolic control with glycosylated hemoglobin of 6.1%.
Conclusions
We present a patient with type 1 DM who cannot present with metabolic ketoacidosis due to the deficit of the HMGCL enzyme. The association of both diseases is not previously described in the literature. Could an SGLT2i be used safely in this case? Is it beneficial that she cannot have ketoacidosis?

Novel clusters of adult-onset Diabetes: Casuistic from an Endocrinology Department

Vitoria Duarte, Catarina Ivo, David Veríssimo, João Silva, Luís Lopes, Dolores Passos, J Jácome de Castro & Mafalda Marcelino
Hospital das Forças Armadas, Lisboa, Portugal.

Introduction
Type 2 diabetes (T2D) is a heterogeneous disease for which causal mechanisms are incompletely understood and subclassification may improve patient management. In the latest assessment of patients with adult-onset diabetes, *Ahlqvist and colleagues (2018)* defined five new subgroups: an autoimmune form, two severe forms (insulin-deficient and insulin-resistant diabetes) and two mild forms (obesity and age-related diabetes).
Objectives
To stratify patients with T2D into subgroups and assess the impact of the clusters on outcomes and therapeutics.
Material and Methods
We conducted a cluster analysis of patients with T2D ($n=1280$) in an Endocrinology department. Clusters were based on three variables (presence of antibodies, age at diagnosis and BMI) and data from patient records was collected on development of complications and therapeutics.
Results
We identified 4 clusters of T2D, with significantly different patient characteristics. Cluster 1 (autoimmune) consisted of 2% of patients, Cluster 3 (obesity-related diabetes) of 63%, Cluster 4 (age-related diabetes) of 13% and Cluster 2 the remaining 22%. Clusters 1 to 4 presented a mean age at diagnosis of 46, 52, 54 and 72, respectively. The remaining clusters presented a mean BMI of 24.4 kg/m^2. Cluster 3 presented the highest mean BMI value (31.7 kg/m^2). Cluster 1 had the highest mean HbA1c (7.3%), while Cluster 4 the lowest (6.6%) (*P*-value 0.033). Nephropathy was the most common complication in this population. Retinopathy was most frequent in Clusters 1 (18%) and 2 (16%) (*P*-value 0,001). Insulin was prescribed to most patients in Cluster 1. Monotherapy was the trend in Cluster 4. Combination therapy was required more often in clusters 2 and 3 (*P*-value <0.001). The majority of patients in Clusters 2 and 3 (60%) presented family history of diabetes.
Discussion and Conclusions
Clusters 1 and 2 were characterized by early-onset disease, higher HbA1C and low BMI. Furthermore, they presented the highest prevalence of retinopathy. Cluster 3 presented the highest BMI. Combination therapies were more common in clusters 2 and 3. Cluster 4 was characterized by late-onset disease, low HbA1c and low BMI. Also, monotherapy was the treatment of choice. Nephropathy was the most common complication. This new classification is easily replicable in a real word setting, especially amid general practioners. It will be exciting to explore whether individuals respond differently to medications based on the pathway predominantly disrupted or whether they have a variable rate of progression and diabetic complications.

Relationship between cortisoluria and the presence of metabolic syndrome among HIV-infected patients

Vanessa Guerreiro[1,2], João Sérgio[1,2], Rosário Serrão[2,3], António Sarmento[3], Davide Carvalho[1,2] & Paula Freitas[1,2]
[1]Department of Endocrinology, Diabetes and Metabolism, São João Hospital Center, Porto, Portugal; [2]University of Porto, Porto, Portugal; [3]Infectious Diseases Department, São João Hospital Center, Porto, Portugal.

Introduction
People living with human immunodeficiency virus (HIV) are at increased risk of developing metabolic disorders, such as obesity, dyslipidemia, insulin resistance, diabetes and hypertension; which may also be associated with hypercortisolism. Due to the similarity between the metabolic changes present in these two clinical situations, several studies have evaluated whether HIV-infected patients have increased levels of cortisol, but the results are not consensual. Urine free cortisol (UFC) is a screening test for hypercortisolism.
Purpose
We aims to determine the relationship between cortisoluria and the presence of metabolic syndrome (MetS) and assess the relationship between the UFC and each components of MetS in HIV-infected patients.
Methods
As part of a cross-sectional study, 219 Caucasian, non-institutionalized, HIV-1 infected adults under cART (combined antiretroviral therapy) were evaluated. For each patient the following data were collected at baseline: demographic data (age, gender), weight, height, waist and hip circumferences and UFC levels. For non-normally distributed continuous variables, we used Mann–Whitney U tests for comparison between two groups. To evaluate the association of anthropometric parameters with UFC we performed adjusted logistic regression models for the confounding variables (sex, age, duration of disease and cART. We excluded the patients without UFC and with the diagnosis of Cushing's syndrome or under corticotherapy. The presence of MetS was defined according to the harmonized International Diabetes Federation criteria of 2009.
Results
Of the 219 patients observed, 61.4% were males, with a mean age of 46.33 ± 11.46 years, BMI of 25.41 ± 5.00 kg/m2, waist circumference of 92.12 ± 12.59 cm and the hip circumference of 95.45 ± 9.66 cm. The median disease duration was 8.11 ± 4.01 years and the cART median duration was 6.67 ± 3.90 years. The median UFC values in patients with SMet were 38.4 μg/day [7–127.3] and in those without SMet of 50.1 μg/day [8.9 – 208.6]. No significant difference in UFC levels in HIV-infected patients with and without MetS ($P=0.147$), even after adjusting for confounding variables, was observed. The presence of obesity, diabetes, hypertension or dyslipidemia wasn't associated with UFC levels ($P=$ 0.509, 0.611, 0.675 and 0.778, respectively).
Conclusion
In our population of HIV-infected patients, MetS was not associated with higher levels of UFC, contrary to previous data in the general population. These findings suggest that the pathophysiological mechanisms of the metabolic syndrome in HIV patients could be different of uninfected population, where the MetS is associated with higher cortisol levels.

Complication of bariatric surgery as a reason of unsuccessful hypothyroidism and hypoparathyrosis treatment

Natalya Volkova[1], Ilya Davidenko[1], Alexey Harlamov[1], Alexander Zibarev[1], Anastasia Chernova[2] & Andrey Korovyanskiy[1]
[1]Rostov State Medical University, Rostov-on-Don, Russian Federation; [2]Rostov State Medical University, Rostov-on-Don, Russian Federation.

Background
Bariatric surgery remains the most effective method of weight loss and can result in partial or complete resolution of multiple obesity-related comorbidities. Bariatric surgery should be performed in conjunction with a comprehensive preoperative assessment and a follow-up plan consisting of nutritional, behavioral, and medical programs. The bariatric surgical procedures are associated with significant long-term complications, primarily malnutrition.
Clinical case
A 56-year-old woman was presented with complaints about tingling in her fingertips, painful muscle cramps, and difficulties with finger extension. It was found out from medical history that total thyroidectomy with parathyroidectomy because of papillary thyroid cancer was performed in 2007 and oral levothyroxine was prescribed. Bariatric surgery SADI-S (sleeve gastrectomy, duodeno–ileal anastomosis) was performed because of morbid obesity in September 2018. On

physical examination Chvostek and Trousseau signs were noted. BMI was 39 kg/m^2. Laboratory examination was carried out. Increased level of TSH and decreased value of calcium and 25-OH vitamin D were revealed. Laboratory results demonstrated postoperative hypothyroidism decompensation due to abnormal gastric acid secretion because of sleeve gastrectomy and postoperative hypoparathyrosis decompensation due to reduced calcium absorption because of duodeno–ileal anastomosis. So, the dosage of calcium, vitamin D and levothyroxine was increased. Also 10% calcium gluconate was prescribed. But compensation of postoperative hypothyroidism and hypoparathyrosis was not achieved. Thus, reconstructive operation was recommended due to ineffective medical treatment of hypothyroidism and hypoparathyrosis.

Conclusion

This clinical case demonstrates that lack of comprehensive preoperative assessment indications to bariatric surgery leads to complication in compensation of comorbid states, such as postoperative hypothyroidism and hypoparathyrosis.

Assessment of asymptomatic coronary aretry disease using myocardial perfusion scan in diabetic patients

Ali Sellem[1,2], Wassim El Ajmi[1,2] & Hatem Hammami[1,2]
[1]Military Hospital, Tunis, Tunisia; [2]Medicine Faculty, Tunis, Tunisia.

Purpose

Coronary artery disease (CAD) is more common and severe in diabetic patients. The aim of this study is to assess the frequency of silent myocardial ischemia in asymptomatic diabetitics by myocardial perfusion scintigraphy and to correlate the results with risk fators.

Methods

We prospectively studied 50 (25 men and 25 women) diabetic patients asymptomatic and without known history of CAD. The minimum duration of diabetes was 15 years for the type 1, 10 years for type 2. The average age was 61.4 years ranging from 43 to 80 years. All these patients had a first stress Myocardial Tomoscintigraphy (MTS) 99mTc-MIBI. MTS has enabled a study of myocardial perfusion, wall motion abnormalities and LV function. If MTS showed severe ischemia, further exploration was carried out by coronary angiography. It was performed in 5 patients in our study. These patients were recruited over a period of 8 months and have received specialized follow-up of 12 months post MTS.

Results

Positive MTS screening results were obtained in 20 patients (40% of cases) and showed ischemia in 65%, necrosis in 20% and mixed abnormalities in 15% of cases. lschemia is minimal in 8 patients (40%), moderate in 4 patients (20%) and severe in 8 patients. In the latter two cases there were at least 4 factors of cardiovascular risks. For the 8 patients with severe ischemia, the stress test (ST) was positive in only 10% of cases. Perfusion abnormalities sit at the inferior wall in 43%, concern the right coronary artery in 53%, and reach a single territory in 55% of cases. Coronary angiography was normal in one case, while the MTS objectified hypo perfusion. Moreover, the MTS abnormalities observed were consistent with coronary angiography. For six negative MTS, ST was negative in 80% of cases and doubtful in 20% of cases. Positive MTS patients have had therapy reinforcement or revascularization procedures. The SMI was more frequent in the group of male subjects, aged over 60 years for type 2 diabetes and over 45 years for the type 1, unbalanced, smoking, dyslipidemic.

Conclusions

MTS is a reliable tool for diabetic SMI screening. Its prognostic value can stratify the cardiac risk and guide therapeutic strategy. Improving this prognosis is based more on the intensive correction of risk factors than on possible revascularization procedure. Through better management of radiation risks, MTS is most appropriate.

HbA1c as a marker of glycemic control in patients with thalessemia HbH disease

Melvin Kok Seng Lee & Pei Shan Yeo
Tan Tock Seng Hospital, Singapore, Singapore.

Hemoglobin A1c (HbA1c) is formed from the addition of a glucose residue to the N terminus of the Beta chain of a hemoglobin molecule via a non-enzymatic glycation pathway. Its levels correlate with the ambient plasma glucose concentration. The 120-day life span of red blood cells makes HbA1c a useful tool to approximate the diabetic control of patients over three to four months. It has also been found to be an accurate predictor of the microvascular and macrovascular complications of DM. The measurement of HbA1c works on the principle of separating and quantifying glycated hemoglobin chains. Several techniques have been developed for daily clinical use including High Pressure Liquid Chromatography (HPLC) via ion exchange and immunoassay techniques. However, there are caveats to their uses with some limitations. Several factors can cause assay interference including hemoglobinopathies. Hemoglobinopathies such as Thalessemia (HbH) disease can affect HbA1c results through both HPLC and immunoassay methods. We report a case of a patient with a falsely low HbA1c in a patient with known Thalessemia (HbH disease) and DM. The error occurred on both HbA1c assays available in our local hospital. His HbA1c was discordant with his home serial blood glucose monitoring (SBGM) and real-time interstitial glucose monitoring. This posed an important clinical management challenge. Further evaluation and analysis of the HPLC chromatogram revealed an inaccurate estimation of HbA1c via the HPLC method. It is important to recognise such pitfalls. While HbA1c may be a popular marker to assess patients' long-term glycemic control, clinical judgement needs to be exercised in situations where serial blood glucose monitoring does not correlate. In patients with Thalessemia HbH disease, other markers of glycemic control such as fructosamine should be considered.

HbA1C as a marker of retrograde glycemic control in diabetes patient with co-existed beta thalassemia: Case report

Zoran Gluvic[1], Milena Lackovic[1], Vladimir Samardzic[1], Jelena Tica Jevtic[1], Marina Vujovic[1], Bojan Mitrovic[1], Anita Vasic-Vlaisavljevic[2], Marija Popin Taric[2], Violeta Mladenovic[3], Sasa Radenkovic[4], Milan Obradovic[5] & Esma R Isenovic[5]
[1]Zemun Clinical Hospital, Department of Endocrinology and mITU, School of Medicine, University of Belgrade, Belgrade, Serbia; [2]Zemun Clinical Hospital, Department of Geriatrics, School of Medicine, University of Belgrade, Belgrade, Serbia; [3]Clinical Centre Kragujevac, Clinic for Endocrinology and Diabetes, School of medicine, University of Kragujevac, Kragujevac, Serbia; [4]Clinical Centre Nis, Clinic for Endocrinology and Diabetes, School of medicine, University of Nis, Nis, Serbia; [5]Laboratory of radiobiology and molecular genetics, Institute for nuclear sciences 'Vinca', University of Belgrade, Belgrade, Serbia.

Introduction

A number of studies reported that almost every fifth patient with thalassemia hav e diabetes. Various factors could contribute to inadequate retrograde glycemic control in thalassemia patients co-existed with diabetes. According to published data, HbA1C seems to be an insufficient marker of the quality of diabetes control in thalassemia patients.

Case report

We present a male 67 years old type 2 diabetes patient with disease history for 15 years, who is under oral treatment and has microvascular diabetes complications on peripheral nerves and small distal arterial vessels. A retrograde glycemic control determined by HbA1C measurement was unexpectedly satisfied. The patient has been admitted to the hospital because of chronic distal neuropathic pain, right toe trophic ulcer, and electromyography (EMG) finding of distal sensorimotor polyneuropathy. In past medical history, the patient reported a

discus hernia (L1-5) surgery and later on noticed the presence of blood transfusions-independent thalassemia. Additionally, his daughter is also a beta thalassemia-heterozygous carrier. Five-point glycemic profile revealed moderate postprandial hyperglycemia and no hypoglycemic episodes. Despite the fact of already EMG confirmed distal polyneuropathy, retrograde glycemic control was optimal (HbA1C 6.5%). The thorough patient examination did not reveal any other chronic micro- or macrovascular diabetes complication. Laboratory analyses show microcytic anemia, mild biochemical syndrome of liver necrosis and remodeling and moderate hepatosplenomegaly detected by abdominal ultrasound. After the introduction of insulin and treatment by hyperbaric oxygen, the patient was discharged slightly improved in regard to actual glycemic control and right toe trophic ulcer healing. Some neuropathic complaints alleviation was achieved by use of alpha lipoic acid, pregabalin and amitriptyline.
Discussion and conclusion
When different factors can interfere with HbA1C measurements in diseases such as thalassemia and hemoglobinopathies, the discrepant findings of profile glycemic control and HbA1C values could be expected. In such patients, it is necessary to measure HbA1C with another method or to use fructosamine as a more reliable marker of retrograde glycemic control. When the 5-point glycemic profile is acceptable, HbA1C can be cautiously used in the estimation of retrograde glycemic control, preferably accompanied by fructosamine.

Clinical determinants of mean platelet volume in patients with abdominal obesity from different age groups

Ivan Pchelin[1], Alexander Shishkin[1] & Volha Vasilkova[2]
[1]Saint Petersburg State University, Saint Petersburg, Russian Federation; [2]Gomel State Medical University, Gomel, Belarus.

There is growing evidence that platelet indices correlate with functional status of platelets and with the risk of cardiovascular events. In this study we aimed to assess clinical correlates of mean platelet volume (MPV) in patients with abdominal obesity from different age groups. We investigated 111 adults with abdominal obesity, not receiving antiplatelet therapy. Abdominal obesity was defined in accordance with IDF criteria (2006). Group 1 included 44 patients aged 26–45, group 2–67 patients aged 46–65. We evaluated clinical history, serum levels of lipid fractions, homocysteine, creatinine, eGFR, C-reactive protein, total and free testosterone (in men only), insulin, HOMA-IR index, and 25-hydroxyvitamin D. Mann-Whitney U-test and Spearmen's correlation coefficient (rs) were used for statistical analysis. Groups were found to have no significant differences when compared on the basis of sex composition, BMI, waist-to-hip ratio, HOMA-IR index, platelet level, and MPV. In both groups MPV was not interconnected with age, BMI and eGFR. In group 1, MPV correlated positively with the level of C-reactive protein ($rs = 0.390$, $P = 0.009$) and negatively – with total testosterone ($rs = -0.387$, $P = 0.042$) and free testosterone ($rs = -0.637$, $P = 0.001$) in men. In group 2, MPV had the only negative correlation with the level of 25-hydroxyvitamin D ($rs = -0.299$, $P = 0.015$). The results of the study suggest that different age groups of patients with abdominal obesity are characterized by different clinical determinants of MPV. In younger adults MPV is interconnected with C-reactive protein and testosterone levels (in men), while in people aged 46-65 it is significantly related to the level of 25-hydroxyvitamin D.

Large phenotypic variability of diabetes due to *ABCC8* gene mutation illustrated by the paradigm of a family

Theocharis Koufakis[1], Amalia Sertedaki[2], Elizabeth-Barbara Tatsi[2], Christina-Maria Trakatelli[1], Spyridon Karras[1], Christina Kanaka-Gantenbein[2] & Kalliopi Kotsa[1]
[1]Division of Endocrinology and Metabolism and Diabetes Center, First Department of Internal Medicine, Medical School, Aristotle University of Thessaloniki, AHEPA University Hospital, Thessaloniki, Greece; [2]Division of Endocrinology, Metabolism and Diabetes, First Department of Pediatrics, Medical School, National and Kapodistrian University of Athens, 'Aghia Sophia' Children's Hospital, Athens, Greece.

Background
Monogenic Diabetes is relatively rare, representing only 1–2% of total diabetes cases; nevertheless, it is often misdiagnosed primarily as Type 1 Diabetes, leading to unnecessary insulin therapy and delayed recognition of affected family members.
Methods
Case report.
Results
We describe a case of a young patient who presented with hyperglycemia in the absence of ketosis and following genetic testing, he proved to harbor the R1352H mutation in the *ABCC8* gene, inherited from his mother. This mutation has been previously described in patients with Congenital Hyperinsulinism. Furthermore, different mutations in the *ABCC8* gene have been linked with MODY 12, Type 2 and Gestational Diabetes; however, to the best of our knowledge, this is the first report that associates this specific mutation with diabetes phenotype. We present our diagnostic and therapeutic approach and suggest a theoretical framework to explain the association between the cellular alterations resulting from genetic variation and the clinical presentation of the described case.
Conclusions
Given that there is no definite consensus regarding the management of such cases and that relative clinical data are still inadequate, close clinical follow-up and individualized treatment are required, in order for these patients to achieve metabolic targets and avoid long-term diabetic complications.

Find prevalence of type 2 diabetes mellitus (DM) in age, BMI, symptoms and comorbidities (hypertension, dyslipidimia) in Indian scenario

Viralsinh Raj & Banshi Saboo
DIA CARE (Complete Hormone Clinic), Ahmedabad, India.

Objective
To Find Prevalence of type 2 diabetes mellitus (DM) in Age, BMI, Symptoms And Comorbidities (Hypertension, Dyslipidimia) in Indian Scenario.
Methods and plan
This is retrospective observational multicentric Study carried out in our four (4) centres of DIA CARE, Ahmedabad during September to December 2018, We divided patients with newly-diagnosed DM in BMI, Age,Symptoms, Comorbidities(Hypertension, Dyslipidimia). We studied consecutive patients with newly-diagnosed DM during September 2018 -December 2018. We recorded data regarding BMI and Age of newly diagnose patients and recorded symptomatic or Asymptomatic and Comorbidities, We recorded data newly diagnosed DM with blood pressure (BP) and Cardiovascular risk factor like dyslipidimia. Data are presented as mean ± S.D. or median (interquartile range).
Results
We studied total 150 newly diagnosis diabetes patients 4 centres at Dia Care, Ahmedabad, Gujarat, India (Tables 1–5).

Table 1 Data Recorded between Age – 50 ± 15.

Male	88
Female	62
Age	Patients
Above 55	
45-55	(55%)83
30-45	(25%)-37
Less than 30	(20%)-30

Table 2 Data Recorded Symptomatic or Asymptomatic. Symptoms (Polyuria, Polydipsia, Polyphagia, Weight loose, etc).

Symptomatic	Asymptomatic
93 (62%)	57 (38%)

Table 3 Data recorded According to BMI.

BMI	
Overweight	57 (38%)
Obese class 1	23 (15%)
Obese class 2	12 (8%)
normal	58 (39%)

Table 4 Data Recorded of Hypertensive/Non Hypertensive.

Hypertension	Hypertension Simultaneously	Normotensive
52 (35%)	30 (20%)	68 (45%)

Table 5 Dyslipidimia (High LDL, Low HDL, High TG).

Dyslipidimia	Normal
97 (65%)	53 (35%)

Conclusions
Study Indicates High Prevalence in Age between 45–55 age. In BMI high prevalence seen in Over Weight People. We found 35% hypertensive, 20%. Simultaneously, 45% Normotensive and 65% Dyslipidemic and 35% Normal in Newly Diagnosed Diabetes type 2 Patients.

P194

Clinical case of insulin autoimmune syndrome

Marina Yukina, Nurana Nuralieva & Ekaterina Troshina
Endocrinology Research Centre, Moscow, Russian Federation.

Introduction
Insulin autoimmune syndrome (IAS) is characterized by the development of hypoglycemia due to insulin and insulin autoantibodies (IAA) interaction. The disease has a strong association with certain alleles of *HLA* gene. In most cases the disease affects predisposed persons who take drugs containing the sulfhydryl groups. The IAA are also noticed in patients with other autoimmune pathology and in patients with multiple myeloma or monoclonal gammopathy. In case of mild course of disease the treatment is not necessary, but in some cases the glucocorticoids may be prescribed.
Clinical case
A 46-year-old female patient with obesity (BMI 36.0 kg/m^2) received the Thioctic acid since November 2017. Since December 2017 the patient had the episodes of dizziness and feelings of fear which occurred 2–3 hours after meals and accompanied by hypoglycemia to 2.1 mmol/l. The drug was discontinued. The results of examination in a non-specialized clinic: HbA1c 5.4%, insulin $>$600 mIU/l. Abdominal ultrasound and MRI did not reveal insulinoma. Since February 2018 no hypoglycemic episode appeared. In April 2018 the patient was firstly examined in Endocrinology Research Centre. During the 72-hour fast, mixed meal test and oral glucose tolerance test the normoglycemia was recorded according to the continuous glucose monitoring system. The results of examination: insulin 330.7 mIU/l, C-peptide 4.96 ng/ml, glucose 5.2 mmol/l, HOMA-IR 76, IAA 102.4 U/ml, antibodies (AB) to insulin receptor 4.156 ng/ml, AB to 21-hydroxylase, thyroid peroxidase, thyroglobulin, receptor for thyroid-stimulating hormone, glutamate decarboxylase, islet cell AB, islet antigen 2 AB, zinc transporter 8 AB were not increased. The electrophoresis and immuno-chemical study of serum and urine proteins did not reveal any pathologic findings. HLA-typing was carried out: *DRB1*: *03, 04*; *DQA1*: *0301, 0501*; *DQB1*: *02, 0302*. There were no other autoimmune pathology in patient or any autoimmune pathology in her relatives. We diagnosed the IAS, induced by Thioctic acid. The examination in November 2018 revealed: insulin 143.1 mIU/l, C-peptide 4.91 ng/ml, glucose 4.87 mmol/l, IAA 35.26 U/ml, AB to insulin receptor 3.821 ng/ml. Thus, after discontinuation of Thioctic acid the levels of insulin and IAA gradually decreased, hypoglycemia was not recorded.
Conclusion
IAS should be excluded in any patient with hyperinsulinemic hypoglycemia to determine the appropriate tactics for subsequent examination and treatment. Imaging study of the pancreas is not required for patients with IAS. The detailed survey on the use of drugs and a thorough analysis of laboratory examination data are necessary.

Evaluation of distance learning activities for healthcare professionals in diabetes management in Albania

Edmond Pistja[1], Alba Themeli[1], Mirela Rexhepi[2] & Zvjetllana Skorovoti[2]
[1]Medical Training Center Santa Maria, Lezhe, Albania; [2]University Hospital Mother Teresa, Tirana, Albania.

Background and purpose
The rising incidence of diabetes mellitus in Albania intensifies the need for effective health education for DM risk reduction among pharmacists, nurses and other health care practitioners. As a result, continuing diabetes education is pivotal in improving the performance of these professionals and thus providing better health care services.
Objective
Our goal was to develop an e-learning course on the management of Diabetes mellitus for community pharmacists, primary care nurses and other primary care healthcare professionals and assessing its efficacy, effectiveness, and user satisfaction.
Methodology
This was a self-paced distance learning course on Diabetes Management for pharmacists and other healthcare professionals was developed and evaluated for its efficacy, effectiveness, and satisfaction. We performed a stratified randomized controlled trial with these healthcare professionals which have at least 1 year working experience, using pre- and post-knowledge tests, and satisfaction questionnaires. We wanted to identify the possible improvement in test results (percentage of correct answers), using intention-to-treat and per-protocol analysis.
Results
A total of 72 participants were assigned to the intervention (22 nurses, 42 pharmacists, 8 GPs) with 65 participants in the control group (20 nurses $+$39 pharmacists, 6 GPs). The intervention was completed by 60 participants (17 nurses$+$39 pharmacists $+$4 GPs), with 4 (2 nurses$+$2 pharmacists) discontinued interventions, and 8 (3 nurses$+$3 pharmacists $+$2 GPs) lost to follow-up. Substantial differences were found between intervention and control: 21 versus 4 percentage points (pp) in the primary outcome results.
Discussion and conclusions
This e-learning course is effective, especially for community pharmacists and primary care nurses, which highlights the need for continuing education in Diabetes Management.
Keywords: diabetes mellitus, continuing education, distance learning, evaluation studies, community pharmacists, primary care

Type 1 diabetic patients with more than five years of disease have increased global methylation levels

Guilherme CK Duarte[1,2], Tais S Assmann[3], Melissa D Alves[1], Elis A Rossoni[1], Nathalia RF Corrêa[1], Andrea C Bauer[1,2], Ramon Bossardi[2,4] & Daisy Crispim[1,2]
[1]Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil; [2]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil; [3]University of Navarra, Pamplona, Spain; [4]Anhembi Morumbi University, São Paulo, Brazil.

Background and aims
Type 1 diabetes mellitus (T1DM) results from a severe autoimmune destruction of pancreatic beta cells, which renders patients insulin-dependent for life. The triggering of autoimmunity against beta cells is caused by a complex interaction

between environmental, genetic and epigenetic risk factors. Although significant progress has been made in elucidating the genetic factors associated with T1DM, the non-genetic components have remained poorly understood. Recent evidence has suggested that epigenetic regulation is a key mechanism by which environmental factors interact with genetic factors to trigger T1DM. DNA methylation is an epigenetic modification that results in the addition of methyl groups to the cytosine residues of CpG dinucleotides, leading to repression of gene expression. Even though some studies have suggested that T1DM patients have global alterations in DNA methylation levels, little is known about the contribution of methylation to the etiology of T1DM. Therefore, the aim of this study was to investigate the global DNA methylation levels in T1DM patients and non-diabetic subjects from Southern Brazil.
Material and methods
This case-control study was carried out in 55 T1DM patients (cases) and 55 non-diabetic subjects (controls). Subjects were divided into two groups: Group 1: 39 patients with >5 years of T1DM paired to 39 controls, and Group 2: 16 patients with ≤ 5 years of T1DM paired to 16 controls. Case and control subjects from both groups were paired according to body mass index, age and sex. DNA was extracted from peripheral leukocytes, and global DNA methylation levels were quantified using a colorimetric kit (MDQ1, Imprint Methylated DNA Quantification Kit, Sigma-Aldrich). Percentages of global methylation were compared between paired case and control groups using generalized estimating Default (GEE), and are shown as estimated means (95% confidence interval).
Results
Global DNA methylation levels were higher in T1DM cases compared to non-diabetic controls from Group 1: 117.2% (95.9–138.5) vs 74.7% (65.3–84.1); $P=0.001$. In contrast, in Group 2, global methylation levels did not differ between cases and controls 93.7% (57.9–129.5) vs 99.6% (85.2–113.9); $P=0.753$). Moreover, glycated hemoglobin levels were positively correlated with methylation levels in cases and controls from Group 1 ($r=0.369$; $P=0{,}001$), but not Group 2 ($r=-0.335$; $P=0.065$).
Conclusion
Our results indicate that global DNA methylation levels are associated with T1DM, which is dependent on the duration of this disease.

Results of application intensive weight management program in overweight (obese) patients with type 2 diabetes in real clinical practice

Svetlana Motkova[1], Larisa Rudina[2], Larisa Savelyeva[1], Maria Gurkina[3], Elena Surkova[1], Farida Valeeva[4], Gagik Galstyan[1] & Marina Shestakova[1]
[1]Endocrinology Research Centre, Moscow, Russian Federation; [2]The Russian Presidential Academy Of National Economy And Public Administration, Moscow, Russian Federation; [3]Medical and Rehabilitation Center, Moscow, Russian Federation; [4]Kazan State Medical University, Kazan, Russian Federation.

Aim
To estimate the efficacy of structured lifestyle modification program on clinical and metabolic status in overweight/obese patients with type 2 diabetes (T2DM).
Materials and methods
The program was implemented in 2 centers (Moscow, Kazan) and 130 participants were recruited (100-active group, 30-control group). The patients' characteristics in active group: mean age was 54.6 ± 10.2 years, diabetes duration 6.6 ± 5.6 years, BMI 34.4 ± 3.5 kg/m^2, HbA_{1C} 7.4 ± 1.7%. The patients' characteristics in control group: mean age was 60.6 ± 8.9 years, diabetes duration 11.2 ± 8.5 years, BMI 33.5 ± 3.5 kg/m^2, HbA_{1C} 7.8 ± 1.9%. This program consisted of five components: dietary intervention; individualized exercise intervention; specific model of psychotherapeutic intervention (team coaching); group education and antidiabetic drug adjustment. Before the program patients underwent a comprehensive evaluation. Patients of active group attended the clinic once weekly for 3 hours (12 weeks). Group sessions were conducted each week by the endocrinologist, dietitian, psychologist and exercise physiologist (EP). The exercise plan included weekly 60-minute exercise session (in the 1-st month 30-minute) of aerobic, resistance and flexibility exercises under the supervision of EP. The components of team coaching were: goal setting, self-monitoring, stimulus control, attributive style modification, stress management and relapse prevention. During another 9 months, medical monitoring was carried out monthly. Medical parameters were measured at baseline, after 3 and 12 months.
Results
90 participants of active group and 29 participants of control group completed the study. After 1 year 50% of active group and 13.3% of control group achieved the primary goal ≥ 5% of weight reduction from baseline (OR 6.54 (95% CI [2.01; 21.33], $P=0.002$). The weight loss ≥ 10% was achieved in 26 patients of active group and in two patients of control group (OR 12.09 (95% CI [1.41; 103.39], $P=0.023$). Mean weight loss was 5.6 kg (95% CI [-6.7; -4.4]) and 0.8 kg (95% CI [-2.1; 0.4]) in the active and control groups respectively. The reduction of waist-hip ratio (WHR) was 0.016 (95% CI [-0.023; -0.008]) in active group; WHR increased by 0.017 (95% CI [0.0076; 0.026]) in control group. HbA_{1C} decreased by 0.8% (95% CI [-1.1; -0.5]) and by 0.1% (95% CI [-0.5; 0.2]) in active and control groups respectively. 58.3% of active group achieved HbA_{1C} ≤ 7%. The mean difference of patients' achieved HbA_{1C} ≤ 7% between groups was 58.3% (95% CI [30.2;80.6], $P<0.001$).
Conclusion
Structured weight management program in overweight/obese patients with T2DM showed high effectiveness in both the weight reduction and the improvement of glycemic control.

Structural changes of bone tissue in patients with type 1 diabetes mellitus

Volha Vadzianava[1], Yuliya Dydyshka[2], Nadzeya Karytska[3], Alla Shepelkevich[2] & Natalya Vasilyeva[4]
[1]Belarusian Medical Academy of Post-Graduate Education, Minsk, Belarus; [2]Belarusian State Medical University, Minsk, Belarus; [3]10th City Clinical Hospital, Minsk, Belarus; [4]Republican Medical Rehabilitation and Balneotherapy Centre, Minsk, Belarus.

Objective
The aim of this study is to evaluate the bone mineral density, hip geometry parameters and bone quality, measured by trabecular bone score (TBS) in patients with type 1 diabetes mellitus (T1DM).
Materials and methods
We examined 97 patients with T1DM (28 males, 69 females, age: 31 (24.9 – 37.7) yrs., duration of DM: 11 (7 – 19.5) yrs., HbA1c: 8.6 (7.1 – 10) %, BMI: 23.1 (21.9 – 25.7) kg/m^2). The control group consisted of 77 health age- and BMI-matched persons (20 males, 57 females). Bone mineral density (BMD) and the TBS were measured with dual X-ray absorptiometry. Geometric parameters were determined using Advanced Hip Analysis program including hip axis length (HAL), cross-sectional moment of inertia (CSMI) and cross-sectional area CSA.
Results
T1DM patients had lower BMD both at spine (T1DM: $-0.4(-1.6$–$0.4)$ vs. controls: $0.3(-0.7$–$0.8)$, $P=0.001$, respectively) and at femoral neck (T1DM: $-0.6(-1.5$–$0)$ vs. controls: $0.1(-0.5$–$0.7)$, $P<0.001$, respectively), higher frequency of fragility Fx (T1D: $n=21$ vs controls: $n=6$, $P=0.012$, respectively), lower level of osteocalcin (T1D: 15.14(11.8–24.2) vs controls: 24.5(22.2–28.2) pg/ml, $P<0.001$, respectively) compared with controls. T1D patients had shorter hip axis length (HAL) than in control group (T1D: HAL 107(102–113) vs. controls: 109(106–116) mm, $P=0.010$, respectively). T1D patients had lower CSA (T1D: 145(127–166) vs. controls: 160(139–178) mm^2, $P=0.002$, respectively) and TBS L1–L4 (T1D: 1.382(1.277–1.414) vs. controls: 1.428(1.368–1.470) $P=0.016$, respectively) compared with controls.
Conclusions
BMD, TBS and CSA in patients with type 1 DM were lower in comparison to the control group. Structural changes of bone tissue may indicate the poor bone quality and might potentially predispose to higher fracture risk in T1DM patients.

Early morphofunctional changes in the myocardium in young people with type 1 diabetes can be detected by magnetic resonance imaging

Kirill Popov[1,2], Elena Biryukova[2], Irina Bondarenko[1], Elena Averkieva[1] & Alexander Vorontsov[1]
[1]Endocrinology Research Center of the Ministry of Health of the Russian Federation, Moscow, Russian Federation; [2]A.I.Evdokimov Moscow State University of Medicine and Dentistry of the Ministry of Health of the Russian Federation, Moscow, Russian Federation.

Aim
To study the morphofunctional state of the myocardium in young people with diabetes mellitus 1 using magnetic resonance imaging (MRI) technology.
Material and methods
38 patients (14 men, 24 women), aged 18–36 years old, with an experience of type 1 diabetes from 5 to 16 years old were underwent contrastive mri of the heart. The exclusion criteria were: pronounced electrolyte disorders in the blood, dysproteinemia, chronic liver and kidney failure – glomerular filtration rate (EPI) −60 ml/min/1.73 m^2, thyroid dysfunction, obesity (body mass index −30 kg/m^2), diagnosed cardiovascular diseases, contraindications for mri. The indicators of functional changes in the left ventricle (circular strain, strain relaxation index – SRI), peak early diastolic strain (PSRDS) were obtained and the accumulation of the contrast agent in the delayed period were assessed.
Results
The obtained results of strain, SRI, PSRDS do not allow to exclude the presence of functional changes in the myocardium of the left ventricle. In 42.11%, zones of accumulation of the contrast agent were visualized in the delayed period (insignificant – 28.95% and moderate accumulation – 13.16%), mainly by the endocardium of the cardiac apparatus (mitral and tricuspid), and in one observation (2.9%) – in combination with unexpressed diffuse heterogeneity of the myocardium of the left ventricle.
Conclusion
MRI of the heart is a promising direction in the assessment of early morphofunctional changes in the structure of the myocardium, which will probably make it possible to predict life-threatening changes in the heart muscle in young patients with type 1 diabetes.

PCSK9 inhibitors effects after 2 years in real life

Inmaculada González Molero, Montserrat Gonzalo Marin, Viyey Kishore Doulatram Gamgaram, José Abuín Fernández, Ignacio Ruíz García, Maria José Vallejo Herrera & Gabriel Olveira Fuster
Hospital Regional Universitario, Málaga, Spain.

Introduction
Recently, PCSK9 inhibitors have been approved in our country for familial hypercholesterolemia and for patients with cardiovascular diseases. They are still scarce data in real life patients effects.
Objective
Analyse the features of first patients treated with PCSK9 inhibitors in a specific unit of familial dyslipidemia and the effect on lipid profile and other clinical variables.
Material and methods
Data from patients with familial hypercholesterolemia treated with PCSK9 inhibitors were collected. Clinical data, physical examination and blood test data were collected at baseline, 3 months, 1 and 2 years.
Results
Data were obtained from 35 patients, 50% male. Mean age: 49.5 years (26–74). Mean follow-up: 12 years. Diagnosis: 11.4% combined familial hyperlipemia and 82.9% heterocigous familial hypercholesterolemia, 43% cases with mutation detected in LDL-R. 71% had a family history of premature CVD, 28.6% with obesity, diabetes 19.2%, smokers 2.9%, HTA 43,8%, 71.4% with high lipoprotein(a), 42.4% with early CVD (71% AMI). 69.6% treated with statins (54.3% rosuvastatin, 2.9% atorvastatin, 5.7% Fluvastatina), 66.7% ezetimibe, 20% resincolestiramina. 23% had elevated transaminases with at least two statins and 54.3% did not tolerate adequate dose of statin/ezetimibe because of secondary effects. The mean pre and postreatment levels (3–6 months) were: TC: 246.5 ± 51.6 vs 147.5 ± 39.4 mg/dl (*P* 0.001), LDL-C: 160.2 ± 42.5 vs 70.3 ± 28.6 (*P* 0.001), 60% achieved therapeutic objective, HDL-C: 55.4 ± 17.9 vs 51.1 ± 14.5 (*P* 0.16), non HDL-C:194.3 ± 31.5 vs 97.8 ± 30.7 (*P* 0.001), TG:158.1 ± 46.2 vs 128 ± 56.8 (*P* 0.25), Apo B 135.8 ± 22.9 vs 78.3 ± 17.7 (*P* 0.01), lipoprotein (a) 98.2 ± 54.9 vs 77.5 ± 40.1 (*P* 0.006). There were no significant changes in: Blood pressure, heart rate, HbA1c, thyroid hormones, cortisol, Vitamin D, creatinine, transaminases and cell blood counts. Weight was 75.4 ± 14.2 vs 73.6 ± 13.4 (*P* 0.039) and testosterone 5.06 ± 0.93 vs 4.2 ± 1.1 (0.043) After 2 years of treatment: mean TC was 149.5 ± 49.4, LDL: 75.3 ± 34.6, HDL 54.1 ± 17.5, nonHDL 96.3 ± 38.2, TG 118.1 ± 41.1, Apo B:47 ± 10.6, Lipoprotein (a): 85.8 ± 59.09 (non stadistical differences with effects at 3–6 months) There were no stadistical differences between alirocumab and evolocumab effects. Only four patients had mild side effect: 3 patients with pseudogripal syndrome and another patient with injection site reaction.
Conclusion
PCSK9 inhibitors were well tolerated and significantly reduced levels of TC, LDL-C, ApoB, non-HDL C and lipoprotein (a) after 2 years of treatment, with 60% of patients achieving therapeutic goals on LDL.

Acquired generalized lipodystrophy: a new cause of Anti-PD-1 immune-related diabetes

Christine Cugnet Anceau[1,2], Alexandre Jehl[1,3], Corinne Vigouroux[4,5], Stephane Dalle[2,6], Olivier Harou[2,7], Lucien Marchand[8], Olivier Lascols[4,5], Cyrielle Caussy[1,3], Charles Thivolet[1,2,3], Martine Laville[1,3] & Emmanuel Disse[1,2,3]
[1]Hospices Civils de Lyon, Lyon Sud Hospital, Endocrinology Diabetology and Nutrition Department, Pierre Benite, France; [2]ImmuCare, Cancer Institute of Hospices Civils de Lyon, Lyon, France; [3]Lyon University, Université Claude Bernard Lyon 1, Lyon, France; [4]Assistance Publique-Hôpital de Paris, Saint Antoine Hospital, Biology and Molecular Genetics and Endocrinology Departments, Paris, France; [5]Sorbonne University, INSERM UMR S938, Saint Antoine REsearch Center (CRSA), Paris, France; [6]Hospices Civils de Lyon, Lyon Sud Hospital, Dermatology Department, Pierre Benite, France; [7]Hospices Civils de Lyon, Lyon Sud Hospital, Anatomopathology Department, Pierre Benite, France; [8]Saint Luc Saint Joseph Hospital, Endocrinology Department, Lyon, France.

Context
Anti-programmed cell death-1 (Anti-PD-1) antibodies have revolutionized advanced cancer therapy. Anti-PD1 therapy is responsible for immune-related adverse events, with frequent endocrine manifestations. Acquired generalized lipodystrophy (AGL), is a rare disease, thought to be immune-mediated, characterized by loss of adipose tissue and insulin resistance-associated complications. We describe the first case of AGL induced by immune checkpoint therapy.
Case description
A 62-year-old woman is treated with nivolumab for metastatic melanoma. After 18 months of treatment (34 courses), the patient developed a severe and rapidly progressive weight loss. The computed tomography revealed a major liver steatosis hitherto unknown, which was associated with hepatic cytolysis. Autoimmune and viral hepatitis were ruled out, and the liver biopsy showed a nonalcoholic steatohepatitis. One month later, the patient presented with a severe nonketotic hyperglycemia (24.9 mmol/L) and HbA1c 11.4% (97 mmol/mol). Aniti-GAD, IA2 and ZNT8 autoantibodies were negative although the patient exhibited a DR4 haplotype for class II HLA genes (DRB1*04 DQA1*03 DQB1*03:02) conferring a high risk of type 1 diabetes. Her pancreas was morphologically normal at abdominal CT and serum lipases were in a normal range. Fasting plasma insulin and HOMA-IR were strongly increased (40 mUI/L and 44.5, respectively). Diabetes was associated with severe insulin resistance and undetectable plasma leptin. She had presented with a rapidly progressive generalized loss of subcutaneous adipose tissue. The search for serum autoantibodies against insulin and insulin receptor was negative. The pathogenic variant in 23 genes of associated with lipodystrophy was absent. The complement system was unaffected and non-organ-specific autoantibodies were negative. The initiated treatment was composed with high-dose basal-bolus insulin regimen (1.6 U/kg/d) and metformin. Subcutaneous biopsy showed that atrophic adipose tissue was extensively infiltrated with cytotoxic CD8+T lymphocytes and fibrosis.
Conclusions
AGL should be added to the list of immune-related adverse events associated with anti-PD-1 treatment for malignancies. It is associated to a new pathophysiological mechanism of anti-PD-1 related diabetes that should be suspected from recent modification of body appearance with unusual fat loss. The benefit/risk ratio of leptin replacement on metabolic improvement, tumor progression and responsiveness to immunotherapy, needs to be evaluated in that setting.

Necrotizing external otitis: a severe form of otitis in diabetic patients

Monia Ghammem, Jihene Houas, Mouna Bellakhdher, Abir Meherzi, Wassim Kermani & Mohamed Abdelkafi
ENT Department and Neck Surgery of Farhat Hached Hospital, Sousse, Tunisia.

Introduction
Necrotizing external otitis (NEO) is a serious life-threatening infection of the external ear and skull base condition. The precise etiology of this condition is unknown. Diabetes mellitus is well known to be one of the most tightly associated characteristics seen in NEO patients. It is documented that diabetes causes endarteritis and microangiopathy, leading to poor microcirculation and impaired polymorphonuclear cell function.
Patients and methods
A retrospective chart review was performed in the ENT Department and neck surgery of Farhat Hached hospital Tunisia between 2000 and 2018. 94 patients with a diagnosis of NEO were identified in the medical records within this period.
Results
Seventy-seven patients were diabetic within the period of study, which represent 82% of cases. The average duration of diabetes follow up was 8 years. The mean age was of 67 years and the male:female ratio was of 43:33. Four patients had associated chronic renal failure. All patients have received oral and local antibiotics before hospitalization. Symptoms were made of otalgia in all patients, otorrhea in 48 patients. Headache and temporo-mandibular joint pain were reported in six cases. Fever was observed in three patients. Four patients noted ipsilateral facial palsy. Stenosis of external auditory canal was observed in all patients. On admission, the fasting blood sugars levels ranged between 1.8 and 4.8 g/l. The erythrocyte *sedimentation rate* ranged from 33 to 110 mm/h. Computed tomography confirmed the NEO in all cases. Pseudomonas aeruginosa was the most commonly isolated organism in 84% of cases. Patients have primary received intravenous anti-pseudomonal medications. Antifungual therapy was conducted in 16% of cases. Diabetic control worsened with the onset of invasive external otitis in all cases. One patient received hyperbaric oxygen therapy as adjuvant treatment. A regression of symptoms was observed in 88% of cases. Patients were discharged after a mean duration of hospitalization of 34 days.
Conclusion
Successful management of NEO frequently requires a multidisciplinary approach with treatment discussed with an endocrinologist, radiologist, and infectious disease specialist. Adequate control of diabetes, the correction of electrolyte imbalance must be instituted at the earliest opportunity in association with antibiotic therapy. A quick and proper diagnosis is needed to start treatment and reduce morbidity and mortality.

Does osteocalcin have a role in Turkish gestational diabetes mellitus and its subgroups

Gonul Koc[1], Gul Gursoy[2], Besime Halis[3], Hanife Copur Eksiler[4], Ahmet Yıldırım[5], Suheyla Gorar[6], Cavit Culha[1] & Yalcın Aral[7]
[1]Ankara Training and Research Hospital, Deparment of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Training and Research Hospital, Department of Internal Medicine, Ankara, Turkey; [3]Turkish High Speciality Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey; [4]One Breath Hospital, Department of Gynecology, Ankara, Turkey; [5]Balıkesir Public Hospital, Department of Endocrinology and Metabolism, Balıkesir, Turkey; [6]Antalya Training and Research Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey; [7]Bozok University, Department of Endocrinology and Metabolism, Ankara, Turkey.

Background
Osteocalcin (Ost) is an osteoblast derived protein locally acting on bone formation. Ost could also have a role in regulation of glucose and fat metabolism. It has been shown that Ost can directly stimulate proliferation of β cells and have effect on secreting insulin, and can act on insulin sensitivity by cytokines. It was not fully investigated in gestational diabetes mellitus. The aim of our study was to investigate osteocalcin in Turkish gestational diabetes mellitus and its subgroups.
Methods
We performed a case–control cross sectional study and evaluated all the demographic and anthropometric parameters of 80, age and body mass indices similar pregnant women, half of them having normal glucose metabolism (NGT) and the other half having gestational diabetes mellitus (GDM). We classified the women according to age, parity, body mass index, and vitamin D levels and compared Ost levels, calcium metabolism, glucose, lipid and insulin resistance parameters and correlation of all the parameters in NGT, GDM and in GDM subgroups.
Results
Osteocalcin levels were high, but not-significant, in gestational diabetes group and also in old, multiparous, having low Vitamin D and high BMI gestational diabetes subgroups. There was a positive correlation between Osteocalcin and C peptide in GDM and GDM subgroups having age >30, multiparous, Vitamin D >20 ng/ml, BMI >30 kg/m^2 ($r=0.424$, $P<0.01$; $r=0.466$, $P<0.05$; $r=0.408$, $P<0.05$; $r=0.520$, $P<0.05$; $r=0.603$, $P<0.01$; respectively) and a negative correlation between Osteocalcin and HDL-Cholesterol in GDM subgroups having multiparous, Vitamin D >20 ng/ml and BMI <30 kg/m^2 ($r=-0.334$, $P<0.05$; $r=-0.352$, $P<0.05$; $r=-0.430$, $P<0.05$; $r=-0.442$, $P<0.05$; respectively).
Conclusion
We concluded that Ost may play a role in Turkish GDM and it increases in order to cope with beta cell dysfunction and insulin resistance which are important in GDM etiopathogenesis. Although we could not demonstrate statistically significant high levels of Ost in our GDM patients and in all subgroups, probably due to our relatively small group and subgroup sizes we think that multiparity, high BMI, low Vitamin D levels provide negative conditions for especially insulin resistance was concerned.

False memory is very common by elderly diabetics and could be a big problem in patients education and diabetes outcome

Anna Gołda[1], Agnieszka Jarosz[2], Marek Maciejewski[3] & Krzysztof Marczewski[4,5]
[1]Department of Nephrology and Endocrinology Pope John Paul II Regional Hospital, Zamość, Poland; [2]Department of Nephrology and Edocrinolgy Pope John Paul II Regional Hospital, Zamość, Poland; [3]Department of Nephrology and Edocrinolgy Pope John Paul II Regional Hospital, Zamość, Poland; [4]Faculty of Human Sciences Lublin University of Economics and Innovations, Lublin, Poland; [5]Deparment of Nephrology and Edocrinolgy Pope John Paul II Regional Hospital, Zamość, Poland.

Introduction
False memory, that is, remembering events, prohibitions and recommendations that did not happen. This phenomenon has long been known in forensics as it seems to be much more recognized in everyday life. This also applies to patients who could significantly interfere with communication with the doctor and education opportunities. In the face of surprisingly few papers on this subject regarding diabetes, we would like to present our observation.
Method
Participation in the study was proposed to subsequent patients hospitalized in the internal ward, whose condition allowed them to complete the questionnaire. False memory was investigated according DRM paradigm.
Results
In a group of 159 patients, aged >60 years, [[x +/−]y hospitalised in our internal ward 61 patients were diagnosed with diabetes. Fa; False memory wa every frequent both in the group of patients with diabetes 89% and hospitalised for another reason 90%. We could not find a relationship between the risk of false memory and gender, age, and the results of scales and tests like ADL IADL, GDS TYM MMSEi, Barthel, Berg Tinetti.
Conclusion
False memory is almost common among older patients. The presence of diabetes does not increase the risk of its occurrence. Practical importance for diabetes education and diabetes outcome requires further research.

GLP-1 secretion after oral glucose load is greater as eGFR is lower

Makoto Murata & Hitoshi Adachi
Gunma Prefectural Cardiovascular Center, Maebashi, Japan.

Background
Glucagon-like peptide-1 (GLP-1) is secreted from L cell at a small intestine and decreases blood glucose by stimulating insulin secretion. Therefore, GLP-1 receptor antagonists (GLP1-RA) is used to treat type 2 diabetes mellitus. In addition to the hypoglycemic effect, GLP-1 has been reported to reduce heart disease and renal dysfunctions. GLP-1 action on the kidneys is a natriuretic effect. Therefore, it may have a renoprotection effect. However, it is unknown whether

there is any correlation between kidney function and GLP-1 secretion. Long oral glucose tolerance test (OGTT) can detects glucose metabolism (i.e.: reactive hypoglycemia) more precisely than 2-h OGTT. In this study, we investigated the relationship between GLP-1 levels and estimated glomerular filtration rate (eGFR) in patients with heart disease, using long OGTT.
Methods
In this prospective observational study, we enrolled 30 non-diabetic patients (age 69 ± 10 years, 70% males, HbA1c 43 mmol/mol). A 4-h OGTT was performed, and glucose, insulin, glucagon (radioimmunoassay [RIA] and sandwich ELISA [S-W] methods) and active GLP-1 were evaluated during 4-h. We compared these factors and eGFR.
Results
HbA1c and area under the curve (AUC) of the glucose, insulin and glucagon during long OGTT are not correlated with eGFR. Although fasting activated GLP-1 is not correlated with eGFR, AUC of the activate GLP-1 after long OGTT is significantly negatively correlated with eGFR ($R = -0.385$ $P = 0.043$). Divided into 3 tertials, although HbA1c (Lowest eGFR group: 42 ± 4 vs. the other eGFR group: 43 ± 3 mmol·min/l, $P = 0.43$), fasting active GLP-1 (Lowest eGFR group: 2.00 [2.00–2.00] vs. the other eGFR group: 2.00 [2.00–2.40] pmol·min/l, $P = 0.59$) and AUC of the glucose (Lowest eGFR group: 1789.2 ± 261.0 vs. the other eGFR group: 1864.4 ± 353.5 mmol·min/l, $P = 0.57$), insulin and glucagon after long OGTT were not different, AUC of the active GLP-1 after long OGTT was significantly greater in the lowest eGFR group (38 ± 10 ml/min/1.73 m^2), than that in the other group (70 ± 12 ml/min/1.73 m^2) (Lowest eGFR group: 1773.0 [1000.5–2958.0] vs. the other group: 982.5 [825.8–1551.0] pmol·min/l, $P \leq 0.05$).
Conclusion
In non-diabetes patients with heart disease, fasting GLP-1 secretion and other glucometabolic factors were not correlated with eGRF. However, GLP-1 secretion after oral glucose load was negatively correlated with eGFR. Greater GLP-1 secretion was observed as eGFR was lower. These data suggest that GLP-1is assumed have renoprotective effect besides glycemic control.

Lessons from studying the characteristics of type 1 diabetes mellitus patients in a tertiary hospital in Singapore

Nicholas Teo[1] & Cherng Jye Seow[2]
[1]Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore; [2]Tan Tock Seng Hospital, Singapore, Singapore.

Background
To identify areas of improvement in the management of Type 1 Diabetes Mellitus patients by analysing their clinical data.
Methods
Computer records of 333 T1DM patients on follow-up at Tan Tock Seng Hospital from May to October 2017 were reviewed and analysed retrospectively.
Results
The average age of diagnosis is 29.75 years-old, and average BMI was 22.59 kg/m^2. 18% of patients had concomitant thyroid disease. 44.7% of patients had positive anti-GAD and 9.9% had positive serum ICAb. 20.7% of patients were misdiagnosed as having T2DM initially. Complications: 39.9% had DKA, 15.9% had hypoglycemia, 39.3% had microvascular and 13.8% had macrovascular complications. 52% of patients achieved the LDL target of 2.6 mmol/l and below. However, only 15.3% of patients have an established insulin-carbohydrate ratio and insulin correction factor that they use when administering their prandial insulin. While patients with established ICR/ICF do not have lower rates of DKA, (31.4% vs 41.5%, $P = 0.175$), they experienced significantly lower rates of microvascular (42.2% vs 23.5%, $P = 0.012$) and macrovascular (15.6% vs 3.9%, $P = 0.026$) complications. It is also observed that patients going for DM classes experienced significantly lower rates of DKA (18.2% vs 44.2% $P < 0.001$), and experienced lower rates of microvascular (20% vs 43.2%, $P = 0.001$) and macrovascular (5.5% vs 15.5%, $P = 0.049$) complications. Only 2.4% of patients are recorded to have been administered influenza or pneumococcus vaccines.
Discussion
There is little variation from the general population statistics in distribution of gender and ethnicity. However, it is noted that the average age of diagnosis is older, with average BMI that nears the upper limit of normal in Asians, rather than a lower BMI. As 18% of patients had thyroid disease, it is worthwhile screening patients for thyroid disease, even if they are asymptomatic, especially if serum antibodies are positive. Although it could be due to a lack of records, vaccination against common infections is still an important aspect of management which must be reinforced to physicians managing T1DM patients.
Conclusion
These findings break the preconceived notions that T1DM is a disease of only the young and/or lean. Vaccinations for common infections need to be encouraged, thyroid function should be screened regularly, and above all, patient education should be the forefront of management to reduce complication rates. These new insights may pave the way to a more holistic and effective management of T1 diabetic patients.

An assessment of physician reasons for prescribing insulin lispro 200 units/ml in a prefilled pen in Germany

Jieling Chen[1], Magaly Perez-Nieves[1], Carolina Piras De Oliveira[1], Erik Spaepen[2], Beatrice Osumili[3], Jiat Ling Poon[1], Nanette Schloot[2], Nuria Lara[4], Laura Garcia Alvarez[4], Montserrat Roset[4] & Dirk Lennartz[5]
[1]Lilly and Company, Indianapolis, USA; [2]Eli Lilly and Company Deutschland GmbH, Bad Homburg, Germany; [3]Eli Lilly and Company, Surrey, United Kingdom; [4]IQVIA, Real-World Evidence Solutions, Barcelona, Spain; [5]IQVIA, Real-World Evidence Solutions, Munich, Germany.

Background
Insulin Lispro 200 units/ml is a concentrated rapid-acting mealtime insulin (MTI) available as a prefilled, disposable pen (IL200) indicated for adults who require >20 units/day of prandial insulin. In comparison with Insulin Lispro 100 unit/ml prefilled pen, IL200 permits the delivery of an insulin dose in half the injection volume [1] and a lower glide force [2]. This study aims to understand physicians' reasons to prescribe IL200, as well as characterize patients treated with IL200 in Germany.
Methods
Physicians surveyed were diabetologists, endocrinologists or internal medicine specialists selected through screener questions from IQVIA's Primary Intelligence platform. Only physicians treating at least 20 patients per month with IL200 were invited to participate to gain experienced and specialized physicians. The physician survey comprised questions related to physician rationale for prescribing IL200 and patient characteristics.
Results
A total of 98 physicians were included in the survey. The majority were men (75.5%), above 50 years (51.0%), with a mean 18.1 years (SD:7.0) experience treating patients with diabetes (PwD), and mainly working in an office setting (65.3%). Responders reported that an average of 227 PwD were consulted per month, 39.8% of PwD consulted were treated with MTI therapy, and out of these, 52.0% were prescribed IL200. On average, physicians reported that, for patients treated with IL200, 78.6% had Type 2 diabetes, 50.0% were female, 51.9% were aged 21–64 years old at diagnosis, and 45.1% had a BMI above or equal 30.0 kg/m^2. Physicians reported that 77.9% of patients received an IL200 total daily dose higher than 20 units/day, and 48.3% of patients had an A1c level >7.5%. When asked the rationale for prescribing IL200, physicians rated as 'very' or 'absolutely important' the following objective clinical factors: insulin dose (88.8%); pattern of self-measured glucose levels (80.6%); and A1c level (80.6%). Regarding patient behaviour, the most important reasons for prescribing IL200 were the following patient characteristics: adherence behaviour (88.8%); knowledge about hypoglycaemia (88.8%); motivation to improve lifestyle (80.6%); and desire to reduce insulin injection volume (72.4%).
Conclusions
Physicians are mainly prescribing IL200 to people with T2D that are using more than 20 units of MTI/day. The top reasons of the physicians to prescribe IL200 were the required daily insulin dose, the ability to self-monitor glucose levels, and the desire to achieve better glucose control.

P208

Lipoprotein apheresis during pregnancy in severe familial hypercholesterolemia – How and when should we switch treatment in the era of PCSK9 monoclonal antibodies?

Tinh-Hai Collet, Floriane Beaud, Christophe Kosinski, Alice Panchaud Monnat, David Baud & Sébastien Kissling
Lausanne University Hospital, Lausanne, Switzerland.

Introduction
Familial hypercholesterolemia (FH) is a genetic condition associated with elevated cholesterol levels and increased risk of atherosclerotic cardiovascular

diseases. Lipid-lowering drugs, i.e. statins, ezetimibe and PCSK9 inhibitors (PCSK9inh) are most often combined for effective treatment of FH. While statins may be continued during pregnancy if deemed necessary, other lipid-lowering drugs lack safety data leaving little pharmacological therapeutic options in pregnancies with FH. Thus, guidelines recommend withdrawing lipid-lowering drugs, ideally pre-conception, followed by lipid apheresis.
Clinical case
A 28-year old female patient was diagnosed with FH in the face of total cholesterol level of 17.0 mmol/L (657 mg/dL), HDL-cholesterol 2.6 mmol/L (101 mg/dL), triglycerides 1.2 mmol/L (106 mg/dL) and LDL-cholesterol 14.6 mmol/L (14.6 mg/dL). The three-vessel coronary heart disease was treated by coronary artery bypass graft (CABG) and drug-eluting stents, with a sequential introduction of rosuvastatin, ezetimibe and alirocumab at maximal dosage. Genetic testing confirmed compound heterozygous *LDLR*mutation, in addition to elevated Lp(a) at 1150 mg/L. While the patient was planning a future pregnancy, she was advised to use contraceptives for at least 12 months post-CABG. Pre-conception drug withdrawal was planned, followed by a bridge to lipid apheresis, such as the Direct Adsorption of Lipoproteins (DALI) technique. Meanwhile, an unplanned pregnancy led us to stop all medications abruptly at 6 gestational weeks, except for aspirin. DALI allowed the control of LDL-cholesterol in the range of 4.9–7.9 mmol/L (189–305 mg/dL, before DALI session) to 1.2–3.2 mmol/L (46–124 mg/dL, after DALI session). This first required weekly sessions, then the frequency was increased to twice weekly for the third trimester. The regular pregnancy ultrasounds highlighted an isolated agenesis of the corpus callosum with a normal CGH array and confirmed by fetal magnetic resonance imaging. No first trimester exposure to PCSK9inh has been reported so far. At the time of the ECE meeting, we will be able to report the outcome of the pregnancy, the DALI efficacy and the first neonatal evaluation of this at-risk pregnancy, with an assessment of the accountability of the reported treatment in the observed malformation.
Discussion
Lipid apheresis should be discussed with all female patients of childbearing age with FH. Guidelines do not specifically recommend preconception measures to optimize the fetal development and lower maternal risks. Pharmacovigilance in the era of PCSK9inh for FH requires more data on their potential fetal effects in humans.

Insulin sensitivity and counter regulatory responses following hypoglycemia in healthy and type 1 diabetes patients

Mads Bisgaard Bengtsen[1], Julie Støy[1], Nikolaj Fibiger Rittig[2], Thomas Schmidt Voss[2], Mads Vandsted Svart[1], Niels Jessen[2] & Niels Møller[1]
[1]Department of Endocrinology and Internal Medicine, Aarhus, Denmark; [2]STENO Diabetes Center Aarhus, Aarhus, Denmark.

Background and aim
Insulin resistance is associated with type 2 diabetes and obesity but recent studies suggest that it may also be associated with type 1 diabetes (T1D), which may affect glycemic control. Hypoglycemia is a dreaded condition among patients with T1D and may also limit optimal glycemic management. We aimed to investigate insulin sensitivity and metabolic adaptions in healthy control subjects and T1D subjects.
Material and methods
We used a randomized crossover design to investigate nine normal weight men with T1D and nine age, BMI and gender comparable healthy control subjects. All subjects were investigated on two separate occasions only differing in regards to the intervention: 1) one episode of hypoglycemia (Single hypo-day) and 2) two consecutive episodes of hypoglycaemia (Dual hypo-day). Both study days included ahyperinsulinemic euglycemic glucose clamp and blood samples were obtained consecutively throughout the day.
Results
Glucose infusion rate (GIR) was significantly ($P=0.001$) lower in the T1D subjects ($\approx$ 5.7 mg/kg per min) compared to the control subjects ($\approx$ 7.6 mg/kg per min) with no significant effect of single/dual hypoglycemia events ($P>0.05$). During hypoglycemia, plasma glucose levels reached a comparable nadir of $\sim$2.55 mmol/L within interventions and groups. The T1D subjects had lower increments in glucagon and adrenaline compared with healthy controls ($P<0.05$) without any difference as regards to the interventions ($P>0.05$).
Conclusion
Subjects with T1D were more insulin resistant and had inferior increments in counter regulatory hormones during hypoglycemia compared with control subjects. A preceding hypoglycemic event the day before did not affect these findings. These results indicate that insulin resistance in present in normal weight T1D subjects and confirm that T1D subjects have defective counter regulatory response to hypoglycemia

Cardiovascular complications in metabolic syndrome in the Chernobyl NPP accident clean-up workers of in a late period upon exposure to ionizing radiation

Irina Muraviova, Iryna Chikalova, Dmitriy Afanasyev & Alexey Kaminskyi State Institution 'National Research Center for Radiation Medicine of the National Academy of Medical Sciences of Ukraine', Kiev, Ukraine.

Objective
Evaluation of the role of collagen I type turnover in presentation of metabolic syndrome (MS) key components among the Chernobyl nuclear power plant (ChNPP) accident survivors three decades upon.
Results
The study involved 100 clean-up workers of the ChNPP accident of the with MS divided into 2 subgroups: 50 patients with acute radiation sickness (ARS) exposed to doses over 1.0 Gy, 50 patients exposed to doses 0.3–0.9 Sv; 37 patients with MS in the control group not exposed to ionizing radiation. Serum amino-terminal propeptide (PINP) and carboxy-terminal telopeptide of collagen type I (ICTP) levels were greater in exposed patients with ARS having doses over 1.0 Gy than in those with no radiation exposure in a history ($F=3.28$, $P=0.043$ and $F=3.65$, $P=0.041$). Linear dependence was found between the radiation dose and serum PINP and ICTP level in a first subgroup ($R=0.338$, $P=0.041$ and $R=0.689$, $P=0.0001$). This observation may help explain the complex changes in extracellular matrix after radiation impact and may suggest the new ways for diagnostic and therapeutic interventions. Systematic Coronary Risk Evaluation (SCORE) was elevated in the ChNPP accident clean-up workers having a left ventricular hypertrophy (LVH) and correlated with PINP in ARS patients having a concentric LVH ($F=5.46$, $P=0.001$ and $R=0.445$, $P=0.015$).
Conclusions
These findings suggest that abnormalities of collagen I type turnover in exposed persons having metabolic syndrome may be involved in the enhancement of myocardial fibrosis that accompanies the development of systematic coronary risk.

Pattern of C-peptide response to oral glucose tolerance test: interest and reference values

Fidéline Bonnet-Serrano[1,2], Amina Bouzerara[1], Mathieu Abou Jaoude[1], Camille Gobeaux[3], Helen Mosnier-Pudar[4] & Jean Guibourdenche[1,5]
[1]Hormonology Department, Cochin Hospital, Paris, France; [2]Inserm U1016-CNRS UMR8104-Université Paris Descartes, Cochin Institute, Paris, France; [3]Automatized biological diagnosis department, Cochin Hospital, Paris, France; [4]Endocrinology Department, Cochin Hospital, Paris, France; [5]INSERM U1139, Université Paris Descartes, Paris, France.

Introduction
Oral glucose tolerance test (OGTT) allows classification of subjects in 3 groups, depending on glycaemia 120 minutes after 75 g glucose ingestion: normal (glycaemia $<$ 1.4 g/L), glucose intolerant (1.4–2 g/L) and diabetic ($>$2 g/L). Five insulin profiles associated with different incidence rates of diabetes over 10 years of follow-up have also previously been described. Insulin measurement is very sensible to hemolysis and can advantageously be replaced by C-peptide determination. However, little is known about C-peptide response to OGTT.
Material and methods
128 patients were included to evaluate glyceamia (COBASE801® ROCHE Diagnostics, France), insulin and C-peptide (LiaisonXL®, Diasorin, France) responses to OGTT.
Results
According to Hitashi classification, 23 (18%) patients of the whole cohort harbored a physiological insulin response corresponding to profile I (peak of insulin during OGTT at 30 min and higher insulin level at 60 vs 120 min), 14 (11%) patients were classified in profile II (peak of insulin at 30 min and lower or equal insulin level at 60 vs 120 min), 56 (44%) in profile III (peak of insulin at 60 min), 26 (20%) in profile IV (peak of insulin at 120 min and lower insulin level at 30 vs 60 min), and finally 9 (7%) in profile V (peak of insulin at 120 min and

higher or equal insulin level at 30 vs 60 min). Only 4 different mean C-peptide profiles emerged from the 5 subgroups previously defined by insulin profile, mean C-peptide profile being globally similar to mean insulin profile. The only difference relied on a similar C-peptide profile corresponding to a growing curve from T0 to T120 in both patients with insulin profile IV and V. Mean and 95% confidence interval of C-peptide value at the different times of OGTT were also calculated in the subgroup of patients with both normal glycemic and insulin (pattern I) responses to propose reference values: respectively T0: 0.53 (0.26–0.77); T30: 2.2 (1.24–3.29); T60: 2.26 (1.36–3.68); T120: 1.88 (0.84–2.62) nmol/L.
Conclusion
C-peptide response to OGTT profile seems to give globally the same information as insulin profile and should therefore also be predictive of the risk type 2 diabetes. The slight differences observed between the 2 parameters can be explained by different metabolism kinetics. This work also allows us to propose for the first time reference values for C-peptide at the different times of OGTT using Liaison XL® (Diasorin, France).

Microalbuminuria and its relation to other factors of cardiovascular risk in type 2 diabetic patients

Ergita Nelaj, Margarita Gjata, Irida Kecaj & Mihal Tase
Department of Internal Medicine, Univerity Hospital Center 'Mother Teresa', Tirane, Albania.

Background
Microalbuminuria was originally established as a predictor of renal failure in patients with diabetes mellitus and an indipendent risk factor for cardiovascular disease. The aim of our study is to assess the relationship between microalbuminuria and the other risk factors in diabetics and their prevalence.
Methods
120 patients with type 2 diabetes, were hospitalized at the Internal Medicine in the University Hospital Center 'Mother Teresa' in Tirana. Patients were divided in two groups: with and without microalbuminuria and for each group we evaluated cardiovascular risk factors such as: left ventricular mass index (LVMI), body mass index (BMI), glycosylated hemoglobin (HbA1C), lipidic profile, intima media thickness (IMT).
Results
Prevalence of microalbuminuria in our study is 32.3%. Prevalence of microalbuminuria among males was 37.5% and among females 62.5%. The microalbuminuric patients were older and had a longer duration of diabetes compared with normoalbuminuric patients ($P=0.01$). The microalbuminuric patients had significantly increased LVMI compared with normoalbuminuric group ($P=0.02$). Prevalence of obesity (BMI >30 kg/m^2) in type 2 diabetics patients was high. In our study this prevalence is 44.6%. In microalbuminuric group the mean value of BMI (30.13) was higher than the other group (28.00) ($P=0.04$). Presence of retinopathy was significantly higher in patients with microalbuminuri. (33.3% vs 14.6%) ($P=0.05$). In patients with microalbuminuria the mean value of IMT was higher than the other group (1.28 vs 1.09) ($P=0.03$)
Conclusion
The prevalence of microalbuminuria in patients with diabetes is high. In microalbuminuric group LVMI, IMT, BMI, duration of diabetes is significantly higher than normoalbuminuric group.

Pecularites of psychoemotional state at diabetes mellitus

Anastasiya Sachkouskaya[1], Marya Rusalenko[2], Tamara Sharshakova[1] & Irina Savasteeva[2]
[1]State Medical University, Gomel, Belarus; [2]The Republican Research Center for Radiation Medicine and Human Ecology, Gomel, Belarus.

We have interviewed 246 people aged 18–55 years: 126 with DM type 2 with a duration of more than 5 years; 120 – without DM. The median body mass index (BMI) was 28.81 (23.51; 32.65) kg/m^2: at DM – 29.12 (24.48; 33.35); without DM – 27.92 (22.85; 31.26). The presence of DM didn't show any differences in eating behavior (DEBQ questionnaire) in contrast to BMI and gender. The emotiogenic style has become the leading one, the incentive for food intake is not hunger, but emotional discomfort in people with BMI $\geq$ 25 kg/m^2 – 48.6%; in women, in contrast to men ($\chi^2=16.71$; $P<0.0001$). The results of HADS scales indicate the same frequency of occurrence of depression in individuals with and without DM, in contrast to the manifestations of anxiety, which are more often recorded in diabetes ($\chi^2=3.96$; $P<0.05$). We have determined a direct correlation between the frequency of occurrence of clinically significant anxiety with the emotiogenic type of eating behavior in women with overweight or obesity (rS $=0.49$; $P<0.05$) Also there has been determined the absence of correlation between the psychoemotional status of men and types of eating behavior according to BMI and presence of DM type 2. Both individuals with DM (84.62%) and without DM (83.17%) demonstrated high stress tolerance (scales of assessment of social adaptation by T. Holmes, R. Reich), but more often it was noted in individuals with DM ($\chi^2=4.20$; $P=0.04$), which indicates psycho-emotional stress and difficulties in overcoming negative psychological situations. The non-alexithymic type of personality (Toronto alexithymia scale) was noted in 81.58% of cases in persons without DM and in 79.23% with DM ($P>0.05$). The alexitimic personality type was more often noted at BMI $\geq$ 25 kg/m^2 ($\chi^2=6.28$; $P=0.01$) and showed a direct correlation with the clinical manifestations of anxiety (rS $=0.34$; $P<0.042$). The study demonstrated that overweight people, even without DM, are in a state of disadaptation and psychoemotional stress, which may be a risk factor for the development of psychosomatic diseases and DM.

Peroxisome proliferator activated receptor gamma mutation responsible for partial lipodystrophy with end stage renal disease: pharmacokinetics of metreleptine during hemodialysis: Clinical case report

Françoise Archambeaud[1], Pauline Vital[1], Sophie Galinat[1], Anne Drutel[1], Camille Plas[1], Marie Christine Vantyghem[2] & Corinne Vigouroux[3]
[1]de Medecine B Endocrinologie CHU Dupuytren 87042, Limoges, France; [2]Service Endocrinologie Metabolisme Hopital C Huriez CHU Lille 59037, Lille, France; [3]Hopital Saint Antoine 75571, Paris, France.

Lipodystrophy is a rare disorder characterised by loss of adipose tissue, severe insulin resistance, diabetes, hypertriglyceridemia, hepatic steatosis with hypoleptinemia. Renal complications are also present but end stage renal disease is less frequent in partial lipodystrophy. We report efficacy and pharmacokinetics of metreleptine during hemodialysis in one case of partial lipodystrophy. A caucasian female presented with acute pancreatitis, major hypertriglyceridemia (25 g/l), and diabetes at the age of 21 years. She was non- obese (body mass index BMI:26) but has hirsutism, acanthosis nigricans, muscle hypertrophy and absence of subcutaneous fat on the limbs with facial sparing. She has severe hypertension, hepatosplenomegaly and renal failure (creatinin clearance 25 ml/min). 15 years later, patient developped proteinuria (10 g/l) with end stage renal disease requiring hemodialysis. She was treated by insulin delivered by external pump (300 ui/day). Diagnosis of partial lipodystrophy was made: plasma leptine level (immunoassay ELISA) was 6.89 µg/l. (for BMI 27, Normal: 37.5) A mutation of peroxisome proliferator activated receptor was identified (G 211E). Metreleptine was started at the dose of 0.04 mg/kg three time per week, after every hemodialysis achievement. Leptin plasma level were mesured at time 0 before injection of metreleptine and +1h, +2h, +3h, +4h, +5h, +6h, +8h, +10h, +12h, +24h+36 hafter. Result showed a rise with normalisation of leptine and return to baseline values by 36 h after the injection. Although, the regimen of metreleptine was increased at 0.08 mg/kg three times per week then plasma leptine level stayed in the normal range during 48 h. In addition patient developped for the first time hypoglycemias and the regimen of insulin was dramatically reduced to 90 ui/day, triglycerides were 3.6 g/l and proteinuria g/l (urinary sample).
This case report confirm the efficacy of metreleptine in partial lipodystrophy. We agree that in case of renal failure, plasma leptine level are modified.We analysed for the first time phamacokinetic profils of metreleptine in case of end renal stage disease and after hemodialysis: our results show a prolonged half life of metreleptine. We suggest in this condition, the delivrance of metreleptine at normal regimen but only three time/week after hemodialysis achievement.

Lipodistrophy, a rare disease: 'If you don't think about it, you doesn't diagnose it'

Rodriguez Pilar Ortega[1], Lopez ME Valverde[2], Martin M Lopez[1], Roldan E Mayorga[1], Rebollo I Perez[1], Carrasco Pilar Salas[3] & Araujo D Vilar[4]
[1]Juan Ramon Jiménez, Department Endocrinolgy, Huelva, Huelva, Spain; [2]Hospital Juan Ramón Jiménez, Department Endocrinology, Huelva, Spain; [3]Hospital Juan Ramon Jiménez, Genetics, Huelva, Spain; [4]Asocciated professor University of medicine Santiago de Compostela, Santiago de Compostela, Spain.

Introduction
In the geographical area of southern Spain, in the province of Huelva, we have detected prevalent cases of Dunnigan's partial hereditary lipodystrophy. The genealogy, the suspicion phenotype and the coordination with the Genetics Service and Reference center, have borne fruit, and more and more families are detected in Our Area. The lipodystrophies, in general, are rare diseases that affect the adipose tissue, disappearance of it in different parts of the body together with metabolic alterations: Insulin resistance and hypertriglyceridemia. Traditionally they have been classified as congenital and acquired. We present a clinical case, in which the suspicion of acquired lipodystrophy in relation to AIDS and TARGA therapy coincides, to which is added the clinical suspicion of genetic lipodystrophy. We request genetic study.
Clinical case
62 year old woman HIV infection stage 2 in virological response, on antiretroviral treatment. DM2 bad control of 20 years of evolution. Severe diabetic retinopathy. Ischemic cardiopathy revascularized. Referred to Endocrinology, for treatment optimization, after family history and confirm the inspection, lipodystrophic phenotype, not located on the face and nasolabial fold, loss of the adipose panniculus in MMII, with increase of the adipose panniculus neck and cervical region, and increase of the abdominal perimeter. In treatment with Insulin in basal bolus pattern very poorly controlled Hba10%, Triglycerides> 600, HDL 15. LDL <100. After intensification with insulin therapy Degludec and Rapid Analogs (DTI 220), high potency statins and fibrates in association, the parameters at present Hba1c 7.5%. LDL 30, Tg 223, with stability of their underlying disease and maintenance of their TARGA therapy. Mutation C.1444> T (p.Arg 482 Trp) LMNA gene (Laminin A), compatible with Dunningan lipodystrophy, is confirmed.
Conclusion
The family history, the phenotype and the serious metabolic alterations should make us think about secondary etiologies, suspicion of pathology of less prevalent diseases. We have not found any association of LPD acquired by HAART therapy and basic genetic lipodystrophy, the coincidences exist, we must reflect: 'not everything is what it seems.'

Please Don't Sugarcoat it: An avoidable case of Euglycaemic DKA in the setting of a SGLT-2 Inhibitor

David J Tansey[1] & Agnieska Pazderska[2]
[1]St. James's Hospital, Dublin 8, Ireland; [2]St. James's Hospital, Dublin 8, Ireland.

Intro
Diabetic Ketoacidosis (DKA) is a medical emergency characterised by hyperglycemia, ketosis and acidosis. If left untreated it can lead to cerebral oedema, acute kidney injury, Adult Respiratory Distress Syndrome andeven death. Euglycaemic DKA (EuDKA) without hyperglycaemia is rare but increasing cases of EuDKAbeing reported in patients taking SGLT2 inhibitors.
Case report
A 53 year old, Type 2 Diabetic was admitted for an elective cholecystecomy. He had a background history of Oesphageal cancer, previous trans-hiatel oesphagecomy, hypertension, and high cholesterol. His diabetic medications included Metformin 1 g BD, Linagliptan 5 mg OD and Empagliflozin 25 mg OD PO. He Smoked 20 cigarettes a day, drank 10 units per week. He was a retired chef and lived with his wife and daughter. He had no family history of type 1 or 2 diabetes. The patient successfully had his gallbladder removed however he had still not recovered on day 3 post-op. He reported to his surgical team that since the surgery he was very Nauseous and was 'feeling dreadful'. He had not been eating or drinking but had still taking all his medications. His surgical site looked clean and he had a CT Abdomen, which was normal. The patient was then seen by the Medical Registrar who did a Venous Blood Gas which showed a severe metabolic acidosis (Ph: 7.04, HCO3: 4.3, pCO2: 2.16, Lactate: 1.93) with a raised anion gap of 18. His Blood Glucose was only 13mmol/lhowever his blood ketones were 4.5. The patient was promptly diagnosed as having a severe euDKA and started urgently on the DKA treatment protocol, his SGLT-2 inhibitor was held and he was transferred to a High Dependency Unit for close monitoring. The patient made a full recovery and was discharged a week later.
Conclusions
SGLT-2 Inhibitors are very popular and effective drugs for use in Type 2 Diabetics. They promote HbA1c reductions, weight loss as well as improved cardiovascular and renal outcomes. There are an increasingly wide range of SGLT-2 Inhibitors available. This case demonstrates the dangers posed by poor education about these drugs among our Diabetic patientsand non-diabetologist colleagues. Poor education aboutthe importance of stopping SGLT-2 Inbibitors when patients are unwell, fasting or going for surgery can lead to repeat hospitals admissions, prolonged hospital stays and potential morbidity and mortality.

Metabolic health is strongly predicted by free Testosterone and SHBG levels in non-obese postmenopausal women

Eleni Armeni[1], Stavroula A Paschou[1], Areti Augoulea[1], Dimitrios Rizos[2], George Kaparos[3], Anastasia Soureti[1], Iliana Karagouni[1], Georgios Georgiopoulos[2], Kimon Stamatelopoulos[2], Nikolaos Syggelos[1] & Irene Lambrinoudaki[1]
[1]Second Department of Obstetrics and Gynecology, Aretaieio Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece; [2]Vascular Laboratory, Department of Clinical Therapeutics, Alexandra Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece; [3]Biochemical Laboratory, Aretaieio Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece.

Introduction
Ovarian senescence and fluctuating levels of sex hormones is associated with metabolic derangement and central obesity. The aim of this study was to explore the association between serum levels of sex hormones and metabolic health in non-obese postmenopausal women.
Patients and methods
This cross-sectional study included a total of 457 non-obese postmenopausal (BMI $<30\ kg/m^2$) women, retrieved from the Menopause Clinic of Aretaieio Hospital, Medical School, National and Kapodistrian University of Athens. Participating women were classified into metabolically obese, if they fulfilled at least 3 diagnostic criteria of the International Diabetes Federation, used for the definition of Metabolic Syndrome (MONW), while women with less than 3 criteria were defined as metabolically healthy (MHNW).
Results
The prevalence of metabolic health was evident in 80.8% of non-obese women, while metabolic obesity was evident in 19.2% of women. We observed a significant difference in levels of sex hormones between obesity phenotypes (MONW vs MHNW: SHBG 55.8 ± 30.4 vs. 76.7 ± 32.8, P-value <0.001; FAI 3.14 ± 1.82 vs 2.29 ± 1.54, P-value <0.001; FEI 0.157 ± 0.153 vs 0.119 ± 0.127, P-value $=0.036$; E2 17.9 ± 13.7 vs 27.8 ± 44.4, P-value $=0.047$). Levels of testosterone were not associated with phenotypes of metabolic health. Multivariate logistic regression analysis showed significant predictors of the MONW phenotype, in models adjusted for age and YSM (years since menopause): i) SHBG levels (OR 0.979, 95% CI: 0.967 to 0.990); ii) FAI levels (OR 1.339, 95% CI: 1.121 to 1.599, P-value $=0.001$). The multivariate analysis showed that the association between FEI, E2 and the MONW phenotype was lost following adjustment for age and YSM.
Conclusions
This study provided evidence that metabolic obesity is associated with higher levels of free testosterone and lower levels of SHBG, irrespectively of age and time since menopause, in non-obese postmenopausal women.

The presence of polymorphic variant A1298C of the MTHFR (methylenetetrahydrofolate reductase) gene is associated with lower body mass index in girls with anorexia nervosa

Stavroula A Paschou[1], Evangelia Deligeoroglou[1], Emmanuel Economou[1], Eleni Armeni[1], Georgios Papadimitriou[1], Evgenia Stergioti[1], Vassilios Karountzos[1], Artemis K Tsitsika[2], Areti Augoulea[1], Konstantinos Panoulis[1] & Irene Lambrinoudaki[1]
[1]Second Department of Obstetrics and Gynecology, Aretaieio Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece; [2]Adolescent Health Unit, Second Department of Pediatrics, P & A Kyriakou Children's Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece.

Introduction
Single nucleotide polymorphic variants of the methylenetetrahydrofolate reductase (MTHFR) gene have been related with a tendency to gain weight according to recent studies. The aetiology of atypical anorexia nervosa remains under investigation and might be associated with the genetic background. The aim of this study was to evaluate the association between the presence of A1298C or C677T polymorphisms of the MTHFR gene and weight status in a sample of adolescent girls diagnosed with anorexia nervosa.
Patients and methods
This cross-sectional study evaluated a total of 40 adolescent girls diagnosed with anorexia nervosa aged 13–19 years. We recorded anthropometric parameters and calculated BMI z-scores adjusted for age, as well as duration of amenorrhea. Blood samples were obtained for genotyping and hormonal assessment.
Results
Mean values of BMI were 16.25 ± 1.41 kg/m^2, while the mean BMI adjusted for age was -2.10 ± 1.31. The prevalence of the MTHFR A1298C polymorphic variant differed, almost significantly, between quartiles of BMI z-scores (CA + CC vs AA genotype, Q1 vs Q2 vs Q3 vs Q4: 70% vs 50% vs 25% vs 20%, Chi-square P-value = 0.092). Multivariate regression analysis showed that girls with BMI z-scores within the top quartile had significantly lower risk of carrying the MTHFR A1298C polymorphic variant compared to the lowest quartile (CA + CC genotype vs AA genotype: OR 0.047, P-value = 0.032), adjusted for age, estrogen levels and duration of amenorrhea. The prevalence of MTHFR C677T polymorphic variant or the combined prevalence of either MTHFR polymorphic variant (C677T or A1298C) did not differ between quartiles of BMI z-score adjusted for age.
Conclusions
We observed a significantly lower prevalence of the polymorphic variant A1298C of the MTHFR gene in adolescent girls with BMI z-score in the highest quartile compared to the lowest quartile, indicating a possible association between the presence of MTHFR wild type genotype and the tendency to lose weight.

The inverted U-shaped curvilinear effect of fat mass on bone mineral density in Korean adolescent teenagers

Bom Lee & Ohk-Hyun Ryu
Hallym University College of Medicine, Chuncheon, Republic of Korea.

Background
Higher body weight is associated with greater bone mineral density (BMD). Lean mass (LM) is positively related with bone parameters in adolescence. However, a number of controversial studies have suggested that fat mass (FM) has beneficial effect or has detrimental effect on BMD in adolescence. These contradictory results of FM on bone parameters might be developed by the non-linear relationship in the adolescent population.
Objective
We evaluated the effect of FM on BMD in Korean adolescent teenagers according to gender and menarcheal status in female.
Methods
We analyzed the data of 2,060 Korean adolescent teenagers (male = 1,114; female = 946) aged 10 to 19 years from the Korea National Health and Nutrition Examination Survey (2008–2011).The whole body bone mineral content (BMC), bone area (BA), and soft tissue composition (LM and FM) excluding head (total body less head) were measured by dual-energy X-ray absorptiometry. Bone parameters were compared among groups according to age-specific quartiles of total body FM. The effect of FM on BMD was evaluated by multiple regression models (age, menarcheal status, LM, and FM) with second-order polynomial terms for FM.
Results
Bone parameters (BMC, BA, and BMD) were greater in the group of higher quartiles of FM than that of lower quartiles. In a multiple regression result, FM was negatively related to BMD in male adolescents. Furthermore, in a model with second-order polynomial terms for FM, it was in an inverted U-shaped curvilinear relationship with BMD in female adolescents, especially in premenarcheal state.
Conclusions
Our study shows that the relationship between BMD and FM is depended on gender and menarcheal state. The relationship is an inverted U-shaped curve in Korean premenarcheal adolescent teenagers and negative in male adolescents. FM may be beneficial in premenarcheal adolescent. However, FM might have a detrimental effect on BMD in adolescent period with excess FM.

The effect of dapagliflozin add on to triple combination therapy in Type 2 diabetes

Yonghyun Kim, Donghyun Shin & Seongkyeong Lee
Endocrinology, Jesaeng Hospital, Deajin Medical Center, Seongnam, Republic of Korea.

Before releasing of SGLT-2 inhibitor, triple combination of metformin, DPP-4 inhibitor and TZD except sulfonylurea was commonly used in our center because it could be best option for delaying progression of diabetes by improving both insulin resistance and secretory dysfunction. SGLT-2 inhibitor is commonly used and recommended as initial combination with metformin in most guidelines because of cardiovascular risk and weight reduction, but theoretically add on to above combination can be more effective because of less pancreatic beta cell reserve and relatively high risk of cardiovascular event in long duration of diabetes. But there are few studies about multiple combination therapy with SGLT-2 inhibitor. And triple combination therapy of metfomin, SGLT-2 inhibitor with DPP-4 inhibitor or TZD is not covered by insurance in this country, so we tried to know the effect of that. We recruited 36 patients of triple combination therapy with metformin, DPP-4 inhibitor and TZD and dapagliflozin was added without changing previous dose of triple combination. The difference in HbA1c was compared between mean of 3 months and just before and mean of 3 and 6 months after add on. Weight change was also assessed after 6 months. The mean age was 53.3 years old and duration of diabetes was 11.6 years. 69% of patients have dyslipidemia and 52% have hypertension or proteinuria. The initial mean HbA1c before add on was 8.28 ± 0.76 and it was decreased to 7.33 ± 0.55. The mean decrement was 0.95 ± 0.69. The initial BMI was 26.2 ± 4.2 and body weight was decreased by 2.10 ± 2.28 kg. Add on therapy of dapagliflozin to previous anti-diabetic medication with triple combination therapy was effective both in both glucose control and weight reduction, so it could be more effective than initial combination with metformin in longer duration of diabetes with relatively high cardiovascular risk.

The correlation between overweight and beta-cell function in a healthy young population: a cross-sectional study in Korea

Hannah Seok, Tae Seo Sohn & Hyun Shik Son
Department of Internal Medicine, Uijeongbu St. Mary's Hospital, The Catholic University of Korea College of Medicine, Seoul, Republic of Korea.

Aims
The introduction of Western diet has changed the prevalence of overweight and obesity in Korean young population. The aim of this study was to evaluate the obesity status and its effect on β-cell function and insulin resistance in a healthy young population in Korea.
Methods
This was a large-scale, community-based study conducted from January 2007 to December 2010. A total of 2,587 subjects (1,066 men and 1,521 women) aged 19–29 years who showed normal fasting glucose were enrolled. BMI was categorized into underweight (<18.5), normal weight (18.5–22.9), overweight (23.0–24.9), and obese (≥ 25.0 kg/m^2) according to Asian-specific WHO criteria.
Results
Overweight and obese subjects were 22% and 28% in men, and 13% and 13% in women, respectively. HOMA-β was increased in obese men (189.4 ± 97.6 vs. 152.8 ± 84.4, $P < 0.001$), and overweight and obese women (183.9 ± 90.4 and

212.5±112.2 vs. 161.3±77.1, respectively, P <0.001), compared to normal-weight subjects. HOMA-IR was increased in overweight and obese men (2.25±0.91 and 2.76±1.40 vs. 1.92±0.75, respectively, P <0.001), and overweight and obese women (2.38±1.03 and 3.00±1.42 vs. 2.01±0.85, P <0.001), compared to normal-weight subjects. HOMA-β and HOMA-IR were significantly correlated with BMI in men (r=0.246 and 0.400, respectively, P <0.001), and women (r=0.245 and 0.395, respectively, P <0.001).

Conclusion

Not only obesity, but also overweight was significantly correlated with hyperinsulinemia and insulin resistance, even if in cases of normoglycemic young adults. Overweight should be taken more attention in a healthy young population.

Vitamin B12 deficiency prevalence and associated biomarkers in type 2 Diabetes (T2DM) treated with metformin: biochemical assessment in a series of 106 patients

Hernan Valdes-Socin, Laura Vranken, Lauranne Schoneveld, Pauline Delannoy, Caroline Le Goff, Albert Beckers & Etienne Cavalier
University of Liege, Liège, Belgium.

Introduction

Increased B12 deficiency among T2DM patients using metformin has been reported. Holotranscobalamin (HoloTc), the bioactive form of B12, is proposed as a specific and sensitive marker of B12 deficiency. Methods to evaluate vitamin B12 deficiency in these patients remain controversial.

Methods

First, we studied the prevalence of vitamin B12 deficiency in a group of 106 T2DM patients treated by Metformin, not supplemented by B12. Antacids were taken by 29/106 patients. Second, we assessed associated biomarkers of vitamin B12 supply. All venous blood samples were analyzed for total VB12, HTc and Hcy on Abbott Architect. MMA was measured with a LCMS/MS method with the Chromsystems kit. Cut-off values defining VB12 deficiency were total VB12 < 200 ng/l, HoloTc < 35 pmol/l, Hcy > 15 µmol/l and MMA >300 nmol/l.

Results

Metformin dose ranged from 425 to 3400 mg/day (1 to 21 years). Mean age of the cohort was 60.9 years (range: 36–90). Patients under antacid presented lower B12, HTc, MMA and Hcy concentrations (P=0.007, P=0.0008, P<0.0001 and P<0.0001). A total of 18/106 patients (17%) were considered as deficient with total B12 assay but only 9/106 patients (8.5%) with HTc, 29/106 (27%) with Hcy and 21.6% with MMA. Four patients presented B12 <200 ng/l and HTc <35 pmol/l. The mean B12 values observed in patients with HTc <35 pmol/l was 208±83 pmol/l whereas the mean HTc in patients with B12<200 ng/l was 46.0±15.5 pmol/l. 33.3 vs. 55.5% of the patients with B12<200 and HTc <35 had HcY levels >15 µmol/l whereas they were 35% vs. 75% to have MMA>300 nmol/l, respectively (P=0.06). There was a significant correlation (P<0.0001) between B12 and HTC and HCy and between HTC and B12, MMA and HCY. For B12, multiple regression analysis using BMI, age, creatinine, folate, MMA, Hcy, antacid consumption and metformin intakes per day did not show any interrelated variable. Using Htc, as dependent variable and the same independent factors showed that creatinine (P<0.0001), MMA (P=0.0008) and Hcy (P=0.0010) were significantly associated.

Conclusions

The 2018 ADA Clinical Practice Recommendations endorse screening Metformin users for vitamin B12 deficiency. In our series, diabetic patients treated by metformin had B12 deficiency in 17% of cases (total B12) and only in 8.5% (HTC). HTC seems more specific than total B12 to assess vitamin B12 deficiency. Antacids seem to have an impact of vitamin B12 absorption.

The association between serum cystatin C and carotid artery intima-media thickness in Korean type 2 diabetic patients

Soo-Kyung Kim[1], Se-Hwa Kim[2], Kyung-Soo Kim[1], Seok-Won Park[1] & Yong-Wook Cho[1]
[1]CHA Bundang Medical Center, Seongnam, Republic of Korea; [2]Catholic Kwandong University, Incheon, Republic of Korea.

Background

There are several markers of renal function such as estimated glomerular filtration rate (GFR) calculated by serum creatinine and cystatin C and urinary albumin-creatinine excretion ratio (ACR). Recently, a few studies showed relationships between markers of renal function and carotid arterty intima-media thickness (IMT), but the results were inconsistent. The aim of this study is to compare serum cystatin C as risk factors for atherosclerosis in Korean type 2 diabetic patients.

Methods

This study was performed in 450 type 2 diabetic patients, who were evaluated by serum cystatin C, urinary ACR (both divided into tertiles) and carotid artery IMT. Estimated GFR was calculated using the modification of diet in renal disease (MDRD) equation. The carotid artery IMT was assessed by B-mode ultrasonography.

Results

There were no differences in the proportion of gender, obesity, smoking status and dyslipidemia according to serum cystatin C tertiles. Higher level of serum cystatin C was associated with older age, longer duration of diabetes, lower HDL-cholesterol level and increased carotid artery mean IMT (P for trend <0.05, respectively). In multivariate analyses adjusted for traditional atherosclerotic risk factors, carotid artery mean IMT was strongly associated with urinary ACR and serum cystatin C (P for trend 0.025 and 0.032, respectively), but not with estimated GFR (P=0.954).

Conclusion

The level of serum cystatin C beyond traditional risk factors was related with carotid atherosclerotic burden in Korean type 2 diabetic patients. Measurement of these renal parameters might be important for early detection of atherosclerosis as well as renal insufficiency in type 2 diabetic patients.

Prevalence of psychiatric comorbidities in diabetic patients who are candidates for therapy with SGLT2 inhibitors: clinical and metabolic characteristics

Maria Concepcion Terroba Larumbe, Cristina Crespo Soto, Jose Maria Palacio Mures, Manuel Gonzalez Sagrado, Marta Ventosa Viña, Silvia Peña Lozano, Ainara Portela Martin, Mar Calleja Baranda, Rosa Conde Vicente & Luis Cuellar Olmedo
Hospital Rio Hortega, Valladolid, Spain.

Introduction

Depression, anxiety and eating disorders appear more frequently in patients with type 2 diabetes and are associated with worse metabolic control and higher risk of developing micro and macrovascular complications. The aim of this study was to determine the prevalence of psychiatric comorbidities in diabetic patients, candidates for therapy with SGLT2 inhibitors (SGLT2i) and to evaluate their clinical profile and degree of metabolic control before beginning the treatment.

Methods

225 diabetic patients included in a therapy protocol with SGLT2i were evaluated analyzing clinical characteristics, biochemical parameters, lifestyle and pharmacological therapy. The analysis was performed separating patients in two groups according to the presence of psychiatric comorbidity. Quantitative variables are expressed by mean (standard deviations). Qualitative variables are expressed by frequencies and percentages. We consider significant P<0.05.

Results

55 patients (24.4%) of the total, 25 (54.5%) women, mean age 63 (S.D. 10.5), had psychiatric comorbidities and the most frequent diagnoses were anxiety (34.5%), depression (32.7%) and anxiety-depressive syndrome (16.4%); time of evolution of diabetes 11.1 years (S.D. 9.4), BMI 35 kg/m^2 (S.D. 6.2), systolic blood pressure 146.3 mmHg (S.D. 18.9), plasma glucose 173.3 mg/dl (S.D. 50.5), glycated hemoglobin (HbA1c) 8.2% (S.D. 1.02) cholesterol 186 mg/dl (S.D. 45.3), low-density lipoprotein cholesterol (LDL-C) 106 mg/dl (S.D. 40), high-density lipoprotein cholesterol (HDL-C) 48.9 mg/dl (S.D. 15.5), triglycerides 189.2 mg/dl (S.D. 89.2); 9.8% smoked; 41.8% met dietary recommendations; 34.5% performed physical exercise; 9% did not receive antihyperglycemic drugs; 16.4% received one, 47.3% two and 27.3% triple therapy; 41.8% of patients were treated with Insulin; 76.4% took lipid-lowering drugs; 36.4% had presented a cardiovascular event (ischemic cardiopathy, stroke, peripheral vasculopathy). The HDL-C was significantly higher in patients with psychiatric comorbidity (P=0.007), but there were no significant differences neither in the prescription of lipid-lowering drugs nor in the rest of parameters evaluated compared with diabetics without psychiatric pathology.

Conclusions

The prevalence of psychiatric comorbidities in diabetic patients included in this study agrees with that described in literature. However, we found no association with a higher BMI, lower adherence to changes in lifestyle, worse metabolic control, a greater prescription of antihyperglycemic drugs and Insulin or a higher prevalence of cardiovascular events compared with diabetics without psychiatric

pathology. According to some authors, this could be due to depression and anxiety oriented treatment.

Efficacy and safety of multimodal therapy in the management of aggresive prolactinoma

Pedro Iglesias[1,2], Alberto Acitores[3], Víctor Rodríguez Berrocal[3], Héctor Pian[4], Teresa Navarro[5], Teresa Alonso[6] & Juan José Díez[1,2]
[1]Department of Endocrinology, Hospital Universitario Ramón y Cajal, Madrid, Spain; [2]Department of Endocrinology, Hospital Universitario Puerta de Hierro Majadahonda, Madrid, Spain; [3]Department of Neurosurgery, Hospital Universitario Ramón y Cajal, Madrid, Spain; [4]Department of Pathology, Hospital Universitario Ramón y Cajal, Madrid, Spain; [5]Department of Nuclear Medicine, Hospital Universitario Ramón y Cajal, Madrid, Spain; [6]Department of Medical Oncology, Hospital Universitario Ramón y Cajal, Madrid, Spain.

Background
Aggressive prolactinomas are rare neoplasms that are characterized by rapid growth and usually large tumor size, invasion of adjacent structures, an aggressive clinical behavior with little response to conventional treatment, high rate of recurrence, and elevated morbidity and mortality.
Case Report
48-year-old woman diagnosed with life-threatening aggressive prolactinoma was referred to us for evaluation of complementary therapy after therapeutic failure to dopamine agonists (DA), several surgical interventions and radiotherapy. A clinical assessment by our multidisciplinary team recommended completing treatment with palliative surgery, DA, somatostatin analogues (SSA), temozolomide (TMZ), and re-irradiation. Two years after the last surgery the patient was well, without headaches showing postoperative changes in pituitary MRI, with normoprolactinemia and a partially empty sella without signs of tumor recurrence.
Conclusion
The present case demonstrates how multimodal treatment is effective and safe in the management of life-threatening aggressive prolactinoma.

Metabolic fingerprint of acromegaly and its potential usefulness in clinical practice

Betina Biagetti[1], JR Herance[2], Roser Ferrer[3], Anna Aulinas[4], Jordi Mesa[1] & Rafael Simó[5]
[1]Diabetes and Metabolism Research Unit, Vall d'Hebron Research Institute, UAB, Barcelona, Spain; [2]Medical Molecular Imaging Research Group, Vall d'Hebron Research Institute, CIBBIMNanomedicine, CIBERbbn, Barcelona, Spain; [3]Department of Biochemistry, Vall d'Hebron Research Institute, Barcelona, Spain; [4]Endocrinology Department. Hospital Universitari de Vic, Barcelona, Spain; [5]CIBERDEM (Instituto de Salud Carlos III), Madrid, Spain.

Background
Acromegaly is a rare chronic and debilitating disease. More than half of patients are not well controlled and most of them require chronic surveillance. Although IGF1 and GH circulating levels are the main targets, they are not in close relationship with the behaviour of the tumour, the clinical course of the disease, the therapy response and the associated comorbidities. Metabolomics is an emergent research tool that we have used to examine in a massive manner the metabolic fingerprint of the chronic exposure to GH and its change after receiving treatment.
Objective
1) To identify metabolites and pathways which could be used as biomarkers of the disease. 2) To explore whether metabolomics could be useful to identify those patients with active disease form those under control by using pharmacological treatment or already cured.
Methods
We compared the serum metabolic fingerprint of 30 patients with acromegaly (16 males and 14 females) and 30 controls matched by age, gender, body mass index (BMI) and smoking habit. Regarding the status of the disease, 5 presented active disease defined by elevated IGF-1 and, 25 had IGF1 concentrations within the specific age-adjusted normal values (14 under medical treatment and 11 in remission or cured).
Results
Patients with acromegaly presented less BCAAs, valine and isoleucine, compared to the control group (valine: 4.50 ± 0.21 AU vs 5.26 ± 0.17 AU, $P < 0.05$; isoleucine: 2.48 ± 0.02 AU vs. 2.80 ± 0.08 AU, $P < 0.05$). BCAAs were lower in those patients with active disease in comparison with patients with normal serum IGF-1 (valine 4.35 ± 0.23 AU vs. 5.01 ± 0.12 AU; isoleucine 5.10 0.32 vs 5.62 ± 0.28 AU; respectively, $P < 0.05$).
Conclusions
The main metabolic fingerprint of acromegaly is a decrease in BCAAs (i.e. valine and isoleucine). The metabolic abnormalities could help to identify active disease and to monitoring the response to several therapeutic strategies. These findings could also open up a new research area in adjuvant nutritional support in patients with active acromegaly. However, further studies to confirm this preliminary results are needed.

NCKX3 knockout mice showed abnormal motor function and social behavior

Dinh Nam Tran, Jae-Hwan Lee, Bo Hui Jeon & Eui-Bae Jeung
College of Veterinary Medicine, Chungbuk National University, Cheongju, Republic of Korea.

NCKX3 (Sodium/potassium/calcium exchanger 3), a novel member of the family of K^+-dependent Na^+/Ca^{2+} exchangers, is an important component of intracellular Ca^{2+} homeostasis. Ca^{2+} homeostasis has been extensively studied in various cell systems. Dysregulation of Ca^{2+} homeostasis can induce the excitotoxic and neurodegeneration in central nervous system. NCKX3 gene is highly expressed in thalamic nuclei, in hippocampal CA1 neurons, and in layer IV of the cerebral cortex in the mouse brain. Here, we examined the effects of NCKX3 deletion in mice. NCKX3 knockout (KO) mice at 6 week-age were used for behavior assays. NCKX3 KO mice show increased moving distances in the open field test. In the sociability test, NCKX3 KO mice have reduced time spent on general sniffing, anogenital sniffing, and following behavior but increased in fighting. Additionally, the rotarod test revealed motor learning defects in NCKX3 KO mice. However, NCKX3 KO mice showed no change in recognition memory in the novel object recognition test. During acquisition phase in the Morris water maze test, there was no different in escape latency time between wild-type and NCKX3 KO mice. This indicated NCKX3 mutation did not impair to spatial learning in mice. These results suggest that NCKX3 mutation causes abnormal motor functions and social behaviors in mice.

Long terms effects of cranial irradiation for nasopharyngeal carcinoma on hypothalamic-pituitary function – a 5-years longitudinal study

Ach Taieb, Barka Ines, Ben Abdelkrim Asma, Hasni Yosra, Maaroufi Amel, Kacem Maha, Chaieb Molka & Ach Koussay
Department of Endocrinology, University Hospital of Farhat Hached, Sousse, Tunisia.

Introduction
Pituitary insufficiency is a late-onset sequel of cranial irradiation for nasopharyngeal tumors. In a Cancer Survivor Study, 43% of patients treated for nasopharyngeal tumors had one or more endocrinopathies. We aim to characterize the pituitary-related outcomes following cranial radiotherapy for nasopharyngeal tumors over a period of 5 years.
Material and methods
The effects of cranial irradiation on hypothalamic-pituitary function were studied first after a mean time post-radiation of 3.66 ± 2.91 years than controlled after 3-year period in 13 patients (7 men and 5 women) with nasopharyngeal carcinoma of a mean age 31.08 ± 14.40 yo. No preradiation endocrinopathies were noted. The estimated radiotherapy doses were 68.91 ± 7.26 Gray. The diagnosis of pituitary hormone dysfunction was based on standard criteria. Specifically, GH

deficiency if a peak stimulated GH level was <10 ng/ml after the sequential administration of 2 secretagogues. Central hypothyroidism was diagnosed if the patient had a low free thyroxine value in the setting of a normal level of thyroid-stimulating hormone (TSH). Central adrenal insufficiency was diagnosed if a patient had a peak stimulated cortisol level of <18 µg/dl after low-dose (1 µg) adrenocorticotropic hormone (ACTH) stimulation testing. Hypogonadotropic hypogonadism was diagnosed if patients had absence of puberty by age 13 years in girls and age 14 years in boys with low serum gonadotropin levels. Data are reported as means $\pm$ S.D.

Results

Of the 13 patients who had received radiation therapy after 3.66 ± 2.91 years of radiotherapy treatment, 38.46% have at least one central endocrinological impairment. Significant impairment in the secretion of growth hormone (23.07%), gonadotrophins (15.38%), corticotrophin (7.6%) and thyrotropin (7.6%) were evident and 30.7% of patients developed hyperprolactinemia. Growth hormone deficiency was the earliest endocrine dysfunction observed. The cumulative probability of endocrine dysfunction was estimated to be 62% after a mean of 5 years with deficiencies in growth hormone, gonadotrophins, corticotrophin and thyrotropin found in 84.6%, 61.53%, 53.8%, and 38.46% of patients. Hyperprolactinemia was uncommon in the male patients (23.07%) but occurred significantly more in four of five women within 5 years of cranial irradiation.

Conclusion

Thus, in these patients with no pre-existing disease in the hypothalamic-pituitary region, progressive impairment in hypothalamic pituitary function leading to endocrine dysfunction requiring treatment occurs in 62 per cent of patients 5 years after cranial irradiation. Regular endocrine assessment should be performed in all patients following cranial irradiation.

A rare case of recurrent granulomatous hypophysitis treated with a trial of oral glucocorticoids

Katrina Asuncion & Thelma Crisostomo
Makati Medical Center, Makati, Philippines.

Background

Granulomatous hypophysitis is an extremely rare condition, therefore, a number of these cases were initially diagnosed as adenoma and inappropriately underwent surgery. Definitive management is not yet established for granulomatous hypophysitis however improvement and resolution of symptoms were noted using oral glucocorticoids.

Clinical case

A 70 year old, Filipino, female, a diagnosed case granulomatous hypophysitis in 2012. At that time she was initially managed as a case non-functioning pituitary macroadenoma (cortisol 13.4 ug/dL (6.2–19.4 ug/dL), prolactin 11.265 ng/ml (3.6–18.9 ng/ml), TSH 0.665 uIU/ml (0.27–3.75 uIU/ml), FT4 12.900 pmol/l (8.8–33 pmol/l), LH 1.876 mIu/ml (5–20 mIU/ml), FSH 15.144 mIu/ml (5–20 mIU/ml)), until the patient underwent transphenoidal surgery and histopathological results showed presence of chronic, non-caseating granulomatous inflammation of the pituitary gland. Tests for the presence of Mycobacterium tuberculosis such as AFB stain, Mycobacterium Tuberculosis PCR/nucleic acid amplification and Silver Methenamine stain were all negative. Patient does not require hormonal therapy and was lost to follow up due to resolution of symptoms. Five years after the surgery, the patient complained recurrent headaches. Cranial MRI, showed presence of an enhancing left sellar nodule measuring $1.2 \times 1.3 \times 1.5$ cm which is superiorly deviating the pituitary infundibulum to the right and abutting the optic chiasm. No visual field defects were noted. Hormonal tests only showed central hypothyroidism and low LH and FSH. The patient was started on oral glucocorticoids (prednisone 30 mg per day and was tapered accordingly). Symptoms completely disappeared after the medication was started. After three months of steroid therapy, cranial MRI showed complete resolution of the sellar mass.

Conclusion

Granulomatous hyophysistis is a rare chronic inflammatory disorder of the pituitary that usually imitates pituitary adenoma. Diagnosis can only be made histopathologically after biopsy or surgery. Glucocorticoids in tapering doses in this case showed complete resolution of the symptoms and the pituitary lesion as well.

DOI: 10.1530/endoabs.63.P229

The role of interleukin-1 in the dynamics of exercise-induced copeptin

Milica Popovic[1,2], Katharina Timper[1,2], Eleonora Seelig[1,2], Thierry Nordmann[1,2], Tobias Erlanger[2,3], Marc Donath[1,2] & Mirjam Christ-Crain[1,2]
[1]University Hospital Basel, Endocrinology, Diabetology and Metabolism, Basel, Switzerland; [2]University of Basel, Basel, Switzerland; [3]University Hospital Basel, Clinical Trial Unit, Basel, Switzerland.

Background

The goal of this project was to identify non-osmotic stimuli of arginine vasopressin (AVP) release during exercise. Non-osmotic AVP release can lead to severe hyponatremia in otherwise healthy marathon runners.Interleukin-1 (IL-1) increases during exercise and was shown to induce AVP in animal models. We here therefore investigated whether copeptin (a surrogate marker for AVP) increases upon exercise in young and healthy males, and whether this increase is regulated by IL-1. The effect of the IL-1 receptor antagonist anakinra on exercise-induced copeptin was assessed.

Methods

Data from a randomized, placebo-controlled, double-blind crossover trial were analyzed where 17 healthy male volunteers exercised for one hour at 75% of VO_{2max} and were not allowed to drink/eat 6 hours before and during the study. Participants received either 100 mg of anakinra or placebo one hour before exercise. Blood was drawn at certain time intervals before, during, and after exercise. Statistical analysis: To test for change in copeptin levels over time and for differences between the placebo and the anakinra group, linear mixed-effects models were fit. Fixed-effect explanatory variables were time of measurement (0, 60, 120 min), treatment allocation, and sodium levels. Furthermore, differences in the area under the curve (AUC) for the anakinra and placebo group were analyzed using a Wilcoxon signed rank test.

Findings

In both groups, copeptin levels were induced by 2.5-fold upon exercise ($P<0.001$), from 4.5–10.6 pmol/l in the placebo, and 4.3–11.3 pmol/l in the anakinra group, with no difference between the groups ($P=0.4$). One hour after exercise, copeptin levels dropped to 7.7 and 7.9 pmol/l in the placebo and anakinra group, respectively ($P=0.6$). The increase of copeptin levels was not explained by sodium concentrations ($P=0.1$). The AUCs of copeptin values for the time during and after exercise were not significantly different when participants were treated either with placebo or anakinra ($P=0.7$).

Interpretation

Exercise induces a continuous rise of plasma copeptin levels in healthy male volunteers independently of sodium levels and fluid intake. This increase is not regulated by the IL-1 pathway.

Growth hormone deficiency, which etiologies?

Sara Askaoui, Guizlane Elmghari & Nawal El Ansari
Departement of Endocrinology, Med vi Hospital, Marrakech, Morocco.

Introduction

Growth hormone deficiency is a rare cause of stunting; its diagnosis is often delayed by severe growth retardation; confirmed by non-response to GH stimulation tests (insulin and glucagon-propranolol test). The absence of early diagnosis and treatment can lead to severe growth retardation. We propose to determine the prevalence of different etiologies of growth hormone deficiency in patients followed for a saturo-weight delay at the Arrazi Hospital, Medical University Hospital VI of Marrakech.

Materials and methods

A prospective study was conducted over a period of 4 years [January 2013-January 2017]. 65 files were identified. The clinical symptomatology was varied, ranging from signs of hypopituitarism, polymalformative syndrome to intracranial hypertension. Biological exploration was oriented by clinical symptomatology, based on stimulation tests and reinforced by radiological exploration (hypothalamic-pituitary MRI).

Results

The average age of these patients is 15.6 years with a H-F sex ratio of 3.7. Severe growth retardation was observed in 89.3% of cases. Of the 65 cases with a GHG deficiency, 38 cases of congenital deficiency were found. 58.4% of cases (26.2% of which were due to malformation of the hypothalamic-pituitary area), 13 cases of acquired deficit -tumors- (20%) and 14 cases integrating into polymalformative syndromes (21.6% of cases). Ante-pituitary deficits were associated: 33.9% of cases of gonadotropic deficiency, 23.8% of thyrotropic cases and 8.4% of adrenocorticotropic cases.

Discussion
The plasma IGF-1 assay allows in the majority of cases to detect the severe deficits in growth hormone. Confirmed by the couple, dynamic stimulation tests and hypothalamic-pituitary MRI. Some are currently based on IGF-1 and IGFBP3 assays in combination with imaging of the pituitary region, given the very poor reliability and reproducibility of the tests.
Conclusion
The staggered delay can be the gateway to a large number of serious diseases of the child and that the diagnostic priority is not to ignore a tumor: cranipharyngioma, glioma.

Mammosomatotropic adenoma and acromegaly: about 3 cases

Sara Askaoui[1], Guizlane El Mghari[1], Hanane Raiss[2] & Nawal El Ansari[1]
[1]Department of Endocrinology, MEd VI, Marrakech, Morocco; [2]Department of Pathology, Med VI, Marrakech, Morocco.

Introduction
Somatotropic adenomas are clinically expressed either by acromegaly or by gigantism according to age of onset. Several histological types are involved. Immunohistochemistry provides conclusive evidence that significant diversity exists between growth hormone secreting (GH) tumors in excess. We report three observations of a particular histological type: mammosomatotropic adenoma.
Observation 1
Mrs. M.H., aged 56, hypertensive for 10 years, followed for acromegaly with a pituitary macro-adenoma for 4 years, operated 3 times. The interrogation found a dysmorphic acromegaloid syndrome evolving for 11 years. The patient was put on cabergoline for 3 years. The hypothalamic-pituitary MRI of control is in favor of a sellar arachnoidocele without visible adenoma, the anatomopathological study speaks of aspect in favor of a mixed pituitary adenoma and immunohistochemistry, an aspect in favor of an adenoma mammosomatotrope.
Observation 2
Mrs. L.F., aged 45 years, hypertensive for 1 year, who presents for a dysmorphic acromegaloid syndrome noted for 5 months. The MRI showed a pituitary macro-adenoma, a surgical procedure was performed and the patient was put on cabergoline. The anatomopathological and immunohistochemical studies have objectified an aspect in favor of a mammosomatotropic adenoma.
Observation 3
Mrs. L.B, aged 43, presenting for an acromegaloid dysmorphic syndrome observed for 7 years. The MRI showed a pituitary macro-adenoma, a surgical procedure was performed and the patient was put on cabergoline. The anatomopathological and immunohistochemical studies have objectified an aspect in favor of a mammosomatotropic adenoma.
Discussion
Mammosomatotropic adenoma is characterized by intense immunohistochemistry antiGH and immunopositivity antiprolactin less, but within the same cell. Electron microscopy confirms this granular colocalization of the two hormones. The diagnosis of multi-hormonal somatotropic adenomas requires the routine practice of immunohistochemical tests because there is no specific clinical presentation.

Silent somatotropic adenoma: about a case

Sara Askaoui, Guizlane Lmghari, Sana Rafi & Nawal El Ansari
Departement of Endocrinology, Med VI, Marrakech, Morocco.

Introduction
Somatotropic adenomas are classically a source of hypersecretion of GH and consequently of IGF1 responsible for the clinical signs of acromegaly. Rarely, these adenomas remain 'silent', without any obvious clinical manifestation. They can then be detected on the basis of a routine determination of growth hormone under oral glucose tolerance test (GH/OGTT) and insulin growth factor 1 (IGF1) or be diagnosed only to immunohistochemical study as is the case of a patient we report.
Observation
Patient of 33-year-old, consult for secondary amenorrhea with galactorrhea. Clinical examination did not indicate a dysmorphic syndrome. A pituitogram was performed showing the presence of thyrotropic and corticotropic insufficiency, with a prolactin level of 153 ng/ml. The somatotropic axis has not been explored. A pituitary MRI revealed a hypophysary macroadenoma treated as prolactinoma by cabergoline with substitution of both deficits. The evolution at one year was marked by the increase (by 17%) of the tumor volume with a prolactin control at 0, 22 ng/with an altered visual field. An echo-heart was requested, revealing the presence of an average tricuspid insufficiency, the surgical indication was raised. Immunohistochemical analysis favors a somatotropic adenoma. A postoperative 3-month postoperative pituitary MRI showed constant tumor volume with some necrosis areas with IGF1 at 131 ug/l (112–300).
Discussion
Somatotropic adenomas are often identified because of their clinical consequences (dysmorphism); some cases of subclinical adenomas have been described in the literature, where only histopathological examination reveals a positive immuno-marking for GH. Their frequency is poorly studied: in the absence of an immunohistochemical study, a non-functional adenoma is concluded and IGF1 is not carried out as part of the follow-up; all this leads to a diagnostic delay giving later dysmorphism with the various complications of hypersecretion of GH. Treatment of this type of adenoma is initially based on surgery, then somatostatin analogues and lastly time on temozolamide and radiotherapy if signs of aggression.
Conclusion
Silent somatotropic adenoma is a distinct entity with respect to the usual cases of acromegaly, as it may be an onset of the disease, or a benign aspect of the disease?

Posterior pituitary spindle-cell oncocytoma: case presentation and literature review

Elia-Belle Touati[1], Naomi Even-Zohar[1], Naftali Stern[1,2] & Yona Greenman[1,2]
[1]Institute of Endocrinology, Metabolism and Hypertension, Tel Aviv Sourasky Medical Center, Tel-Aviv, Israel; [2]Sackler School of Medicine, Tel Aviv University, Tel-Aviv, Israel.

Introduction
Spindle cell oncocytoma (SCO), pituicytoma, granular cell tumor, and sellar ependymoma are rare TTF-1 positive posterior pituitary tumors classified as WHO Grade I, indicating low proliferative potential and high rates of surgical cure.
Aims
To report a case of SCO and review the pertinent literature.
Methods
English and non-English literature was searched, clinical, data were retrieved and summarized.
Results
A 39 years old male presented with complaints of headaches. MRI identified a suprasellar tumor that was initially followed conservatively. Vision and pituitary function were preserved. Symptom exacerbation and evidence of tumor growth led to transsphenoidal surgery. Tumor resection was compromised by profuse bleeding. He developed post-surgical pan-hypopituitarism. 42 publications describing 54 cases of SCO were identified (median age 60 y, 57% males). Presenting symptoms were mostly secondary to mass effect. 67% of tumors were sellar with suprasellar extension, 23% and 9.6% were exclusively intra or suprasellar respectively. All patients underwent surgery, 83% of which was transsphenoidal. Mean Ki-67 was 3.4%. Gross total resection was achieved in only 47.8% of cases, with recurrence-free survival time of 116 months (95% CI, 65–167). After partial resection, event-free survival time was 23 months (95% CI, 12–34). Nine patients received radiation therapy with mixed results.
Conclusions
Surgical resection of these rare tumors is challenging; surgical cure is infrequent and recurrence rates are high. Based on this literature review, we suggest that WHO classification of these tumors as grade 1 is not accurate, and that a revision should be considered.

No central adrenal insufficiency found in adults with prader-willi syndrome tested by multiple dose metyrapone test

Anna Rosenberg[1], Karlijn Pellikaan[1], Kirsten Davidse[1], Stephany Donze[2], Anita Hokken-Koelega[2] & Laura de Graaff[1]
[1]Department of Internal Medicine – Endocrinology, Erasmus Medical Centre, Rotterdam, The Netherlands; [2]Department of Pediatric Endocrinology, Erasmus Medical Centre, Rotterdam, The Netherlands.

Introduction
Individuals with Prader-Willi syndrome (PWS) have hypothalamic dysfunction, with deficiencies of several hypothalamic-pituitary axes. Prevalence of central hypogonadism, hypothyroidism and growth hormone deficiency are increased in comparison with non-PWS individuals. Central adrenal insufficiency (CAI) has also been reported in PWS. Several studies, using different testing modalities, have reported strikingly differing prevalences of CAI in PWS, ranging from 0% to 60%. It is speculated that CAI may be responsible, in part, for high mortality (3%) in patients with PWS. If CAI is present, timely diagnosis and treatment is needed in order to prevent avoidable mortality. Due to the lack of consensus, there are no guidelines or recommendations on the appropriate evaluation and management of CAI in the adult PWS population. Many adults patients with PWS receive standard hydrocortisone (HC) stress dose during physical and/or psychological stress. Frequent administration of HC increases the risk of obesity, hypertension, osteoporosis and diabetes, already a major problem in adults with PWS. It is therefore of utmost importance to assess the prevalence of CAI in order to prevent overtreatment with HC.
Methods
We screened medical histories of all patients for symptoms of CAI. We performed multiple dose metyrapone (MTP) test in 47 adults with genetically confirmed PWS. At day one, oral MTP 750 mg (Laboratoire HRA Pharma, Paris, France) was administered orally every 4 hours, starting from 0800 h. At 0800 h on day two, blood was drawn for determining 11-deoxycortisol (11-DOC) levels. At both days, blood was drawn after 8 hours fasting. Levels of 11-DOC greater than 7.6 g/dl (230 nmol/l) were classified as adrenal sufficiency.
Results
Median (IQR) age of participants was 28.8 (22.8–35.5). Twenty were using GH treatment since childhood. Male/female ratio was 28/19. Revision of medical histories revealed that a substantial part of patients had undergone operations or had infections without receiving HC stress dose, without any negative consequences. All 47 patients had 11-DOC greater than 7.6 g/dl during MTP test and therefore CAI was excluded in all patients. MTP test was tolerated well by all individuals.
Conclusion
Central adrenal insufficiency was absent in 47 adults with Prader-Willi syndrome assessed by a multiple dose metyrapone test. This indicates that CAI is rare, or even absent, in adults with PWS. Based on these results, we recommend to perform MTP test instead of routinely prescribing HC stress dose in adults with PWS.

Serum aryl hydrocarbon receptor-interacting protein (AIP) levels are independent of serum GH levels both at baseline and in dynamic tests of GH stimulation and suppression

Marko Stojanovic[1,2], Zida Wu[3], Craig Stiles[4], Dragana Miljic[1,2], Ivan Soldatovic[2,5], Sandra Pekic[1,2], Mirjana Doknic[1,2], Milan Petakov[1,2], Vera Popovic[2], Christian Strasburger[3] & Marta Korbonits[4]
[1]Neuroendocrinology Department, Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Centre of Serbia, Belgrade, Serbia; [2]University of Belgrade, Medical Faculty, Belgrade, Serbia; [3]Department of Medicine for Endocrinology, Diabetes and Nutritional Medicine, Charité Universitätsmedizin, Campus Mitte, Berlin, Germany; [4]Centre for Endocrinology, William Harvey Research Institute, Barts and the London School of Medicine and Dentistry, Queen Mary University of London, London, UK; [5]Insitute of Medical Statistics and Informatics, Belgrade, Serbia.

Background and aim
Aryl hydrocarbon receptor-interacting protein (AIP) is evolutionary conserved and widely distributed throughout organism. Broad interest for AIP comes from involvement of loss-of-function AIP mutations in pituitary adenoma pathogenesis. The role of AIP in normal pituitary function is largely unknown. AIP is co-localized with GH in somatotroph secretory vesicles. Serum AIP protein was proteomically identified. We aimed at investigating whether AIP and GH are co-secreted by measuring serum AIP and GH levels at baseline and after GH stimulation and suppression tests using *in vivo* human models of normal GH secretion, patients with GH deficiency (GHD) and patients with GH hypersecretion - acromegaly.
Subjects and methods
ITT was performed in GHD patients ($n=13$) and age-BMI-matched non-GHD controls ($n=31$). OGTT was performed in patients with active acromegaly ($n=26$) and age-BMI-matched controls ($n=18$) with normal GH suppressibility. In-house immunometric AIP assay was developed and employed.
Results
Serum AIP was independent of gender, age or BMI. Baseline AIP levels did not differ in GHD and non-GHD subjects nor did AIPmax, AIP-AUC or AIP-Delta in ITT. AIP levels did not correlate with GH, PRL or cortisol levels in ITT. Baseline AIP, AIPmax, AIP-AUC or AIP-Delta did not differ between patients with active acromegaly versus control subjects at baseline and during GH suppression test (OGTT). Serum AIP values did not significantly change during ITT or OGTT.
Conclusions
A novel immunometric assay was employed for the first time to assess human circulating serum AIP in vivo. Serum AIP levels were independent of age, sex or BMI, and were unaffected by hypoglycemia or hyperglycemia. Contrary to expectations based on secretory vesicles co-localization of AIP and GH, no correlation was found between serum AIP and GH secretion at baseline nor during GH stimulation (ITT) and GH suppression tests (OGTT). A platform of reliable serum AIP measurement is established for further research of the circulatory source, role and impact for this highly conserved protein essential for survival.

Some risk factors of re-growth of non-functional pituitary adenomas in patients with growth hormone deficiency

Yulduz Urmanova[1,2], Ashley Grossman[3,4], Zamira Khalimova[1,2], Michael Powell[5], Marta Korbonits[4], Mukhlisa Shakirova[6], Vladimir Pankiv[7], Dinara Alieva[2] & Ortikali Tursunkulov[1]
[1]Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan; [2]Republican Specialized Scientific Practical Medical Center of Endocrinology of Republic of Uzbekistan named by Ya.Kh.Turakulov, Tashkent, Uzbekistan; [3]University of Oxford Research Fellow, Green Templeton College, London, UK; [4]Saint Bartholomew's Hospital, London, UK; [5]National Center of Neurosurgery and Neurology, London, UK; [6]Liv Hospital, Istanbul, Turkey; [7]Ukraine State Medical Institute, Kiev, Ukraine.

Aim
The aim of investigation to determine clinical aggressiveness diagnostic markers in patients with non-functional pituitary adenomas (NFPA), and growth hormone deficiency (GHD) in the formation of gravity neuroendocrine disease symptoms.
Material and methods
We observed in 87 patients (including man – 44 women – 43) of which have a verified diagnosis of NFPA after surgery – 31 which were subjected transnasal adenomectomy of the pituiatary (TAG). Further analysis was performed on these patients, who were followed from 1 to 3 years.
Results
After the analysis of the frequency of remission and relapse NFPA data selectively in patients we studied the correlation between various parameters and the frequency of relapses. NFPA developed the scale of aggressiveness allowed to identify the risk factors of markers on the 3rd degrees, allowing to create a set of measures of tumor growth relapse prevention.
Conclusions
Comparative analysis of the results of our research showed that there was a direct correlation with these markers of aggressiveness flow NFPA as the young age of the patient, the first symptoms of a manifest disease, large tumor size, asymmetry, and the pituitary gland deformation, signs of tumor invasion into surrounding tissue/artery/cavernous sinus, the presence of small-cell and/or dark cell chromophobe adenomas panhypopituitarism.

The frequency of growth retardation among children and adolescents from orphanages in Tashkent city

Saidganikhoja Ismailov, Yulduz Urmanova, Nazira Rikhsieva, Maftuna Kulmirzaeva & Maryam Abduvakhobova
Tashkent Pediatric Medical Institute, Department of Endocrinology Children Endocrinology, Tashkent, Uzbekistan.

The aim of investigation to study the frequency of growth retardation in children and adolescents from orphanages in Tashkent city.

Material and methods

We observed 595 children and adolescents (including boys – 342, girls – 253) as part of the special program 'You are not alone' from November 12 to November 17, 2018 in the admission department of the clinic of the Tashkent Pediatric Medical Institute. During the week, children and teenagers from 6 orphanages were examined. The patients were examined by all specialists – endocrinologists, pediatricians, neurologists, urologists, orthopedic surgeons, ophthalmologists, etc. Patients were measured height, weight, considered a lack of growth, weight, performed a palpation of the thyroid gland and an objective examination of sexual development's stages by Tanner. If necessary, performed ultrasound investigation of endocrine organs.

Results

It was established that growth retardation occurred in 36 (6%) patients examined, in 1 (0.16%) case - dwarfism, in 2 (0.32%) cases - puberty delay, in 1 (0.16%) case – varicocele and 1(0.16%) -cryptorchidism. After the analysis of the frequency of growth retardation among 595 children and adolescents we found that in 3 (0.5%) cases patients with growth retardation have diffuse goiter. Total diffuse goiter 1 degree was found in 164 (27.5%) examined.

Conclusions

Comparative analysis of the results of our research showed that there was growth retardation in 36 (6%) patients.

Supraselar tumor as cause of amaurosis – the unusual suspects-case series

Olivera Boskovic, Predrag Bulajic & Milan Bogojevic
Clinical Center of Montenegro, Podgorica, Montenegro.

Background

Most common tumors in the suprasellar region are adenomas of the pituitary gland, craniopharyngiomas, cystic lesions (Rathke's cleft cysts). Supraselar meningiomas are rare and slow-growing tumors that usually arise from the tuberculum sellae or the chiasmatic sulcus. These tumors frequently invade the sella turcica because that they are mistaken for a pituitary tumor.

Methods

A case series

Results

We present a two cases of patients complaning about one side vision loss. First case is a 40 years old female, that was sent to endocrinologist because of infertility. She was diagnosed with PCOS and glucose intolernce. Due to losing eye sight and PCOS we ordered MR of pituirary gland and full hormonal blood work. Her leverls of prolactin, TSH, fT4, FSH, LH, ACTH, GH and IgF 1 were within normal range. MR of showed expansive mass in left supraselar region that compresses optical chiasma and left optic nerv. Surgical treatment was preformed and patohystological examination of tumor showed Meningeoma transitionale WHO gradus I. After surgery vision was restored with preserved pituitary function. Second case is 61 years old male, that was send to endocirnologist due to acute blury sight on right eye and headache. Full hormonal blood work up was done and was withing normal range. On the MR of pituitary gland showed meningeoma in supraselar region. Patient is scheduled for surgical treatment.

Conclusion

Supraselar meningiomas are rare and can be hard to differentiate from pituitary adenomas, and they are often sent to endocrinologist for that reason. It is really important to diferentiate appropriated surgical approach. Follow ups reqiered because of recurrence of the meningeoma.

Pituitary stalk interruption syndrome: an uncommon presentation

María Eugenia López Valverde, Luna Florencio Ojeda, Manuel Martín López & María Isabel Rebollo Pérez
Endocrinology and Nutrition department, Hospital Juan Ramón Jiménez, Huelva, Spain.

Pituitary stalk interruption syndrome (PSIS) is a rare clinical entity characterised by an absent or thin pituitary stalk, hypoplasia of the anterior pituitary gland, and ectopic location of the posterior pituitary on magnetic resonance imaging (MRI). Presentation is on early childhood or puberty and the most common hormonal deficiencies are growth hormone (GH) and gonadotropines. We present the case of a 28-year-old female patient who consulted after 2 years in secondary amenorrhea with menarche at 13 years old and previous regular menses; her family doctor prescribed oral contraceptives (restoring regular menses) and patient was referred to endocrinology consultation. She was as well in treatment with Levetiracetam for epilepsy. She didnt have any other familiar or personal pathological antecedents. The anamnesis showed 6–7 liter/day polidipsia, polyuria and nighttime thirst in the last 3 years, with no other symptoms. At physical exploration, her weight was 58.6 kg, height 160 cm (mid parental height: 158 cm) and had a Tanner stage V phenotype; she didnt have any midline craniofacial malformation. One month after contraceptives withdrawal, analysis revealed: glucose 86 mg/dl, creatinine 0.72 mg/dl, sodium 140 mmol/L, potassium 4.6 mmol/L, serum osmolality 290 mOsm/kg (N 275–295), thyrotropin 1.9 μUI/mL (N 0.4–4.2), free T4 0.91 ng/dl (N 0.93–1.7), GH 3.29 ng/mL (N 0.3–9.8), IGF-1 171 ng/ml (N 100–310), prolactin 7.65 ng/Ml (N 6–30), follistatin 3.6 mUI/mL, luteinizing hormone 0.47 mUI/mL, progesterone 0.05 ng/mL, estradiol 37 pg/mL, total testosterone 0.08 ng/mL, corticotropin 13.9 pg/mL, basal cortisol 14.6 μg/dL. Urine test: 6000 ml diuresis, urine osmolality 137 mOsm/kg. Water deprivation test: serum osmolality 273 mOsm/kg and urine osmolality 281 mOsm/kg, after 11 hours of fluid deprivation. Urine osmolality 719 and 756 mOsm/kg, before and after 1 subcutaneous μg desmopressin respectively. Synacthen test: cortisol basal levels 17.1 μg/dl, at 30 minutes 21.1 μg/dl and 25.3 μg/dl at 60 minutes. Propanolol-exercise provocative test: basal GH 4.91 ng/ml, 4.4 ng/ml at 30 minutes. MRI was performed: hypoplastic adenohypophysis (image). Patient was diagnosis with partial central diabetes insipidus (CDI), hypothyroidism, GH deficit and hypogonadism. Nowadays our patient is receiving treatment with 100 μg/day levothyroxine, 0.1 mg/24 hours oral desmopressin and contraceptives. Our case is uncommon due to SPIS presentation at adult age, normal sexual development and initial normal somatotropic axis, as well as partial CDI.

Long-term results of bilateral adrenalectomy in a patient with cyclic Cushing's syndrome

Maria Concepcion Terroba Larumbe, Jose Maria Palacio Mures, Cristina Crespo Soto, Miguel Angel Citores Pascual, Cesar Benito Fernandez, Hermogenes Calero Aguilar, Itciar Anacabe Goyogana, Marta Ventosa Viña & Luis Cuellar Olmedo
Hospital Rio Hortega, Valladolid, Spain.

Introduction

Cyclic Cushing's Syndrome (CCS) is a rare disorder in which rhythmic fluctuations in the secretion of ACTH trigger cyclic variations in the production of adrenal steroids and an extremely variable clinical presentation. It should be considered when clinical hypercortisolism coexists with normal cortisol levels and a paradoxical response to the dexamethasone test, and when selective transsphenoidal adenomectomy fails after an uncomplicated intervention.

Clinical case

A 34-year-old woman was evaluated from 2000 to 2005 in another hospital and diagnosed with cyclic Cushing's syndrome without evidence of primary adrenal pathology or ectopic ACTH production. In December 2004 and February 2005 hypercortisolism was confirmed, but previous studies were not conclusive because the hormonal determinations were normal in most cases although the patient presented Cushingoid features, and dexamethasone suppression tests were starting from practically normal values of cortisol. Pituitary magnetic resonance (MR), performed in 2000, revealed a possible microadenoma in the left half of the pituitary, not confirmed in subsequent studies. Computed tomography thoracoabdominal and catecholamines, 5-OH-indole acetic acid, histamine in 24-hour urine were normal. For years she followed therapy with ketoconazole, suspended in January 2004 for inoperability. In 2006 the patient was sent to our hospital to perform petrosal sinus catheterization with stimulation of CRH showing these

results: central/peripheral ACTH ratio <2:1 (basal) and >3:1 after stimulation. Further tests included: basal ACTH (with hypercortisolism): 32.9 pg/ml; In-111 Octreoscan and all the biochemical tests repeatedly performed did not show significant alterations; bone densitometry showed very mild osteopenia in the spine; adrenal MR bilateral hypertrophy without nodular images and pituitary MR repletion defects inside the adenohypophysis, of right and left location, in possible relation to microadenomas. Given the impossibility of controlling the episodes of hypercortisolism with cabergoline and ketoconazole, in March 2010 a bilateral adrenalectomy was performed. Histopathological diagnosis corresponded to a combined bilateral adrenal cortical hyperplasia, diffuse and micronodular with several nodules, the largest one being 1 cm, in the right adrenal. Clinical and biochemical hypercortisolism disappeared in the postoperative period and is still the case >8 years later. In September 2018, basal ACTH was 376 pg/ml (0–46). In control pituitary MR a pituitary gland with normal characteristics is observed.
Discussion
The high degree of recurrence of CCS after pituitary surgery often conditions new interventions and/or combined pharmacological therapy. Despite the risk of developing Nelson syndrome, bilateral adrenalectomy could be the best initial surgical option

Pituitary tumors diagnosed in octogenarians – clinical implications

Nelson Cunha[1,2], Leonor Gomes[1,2], Isabel Paiva[1], Lúcia Fadiga[1], Diana Catarino[1], Diana Silva[1], Joana Guiomar[1], Inês Vieira[1], Mariana Lavrador[1] & Margarida Bastos[1,2]
[1]Department of Endocrinology, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal; [2]Faculdade de Medicina da Universidade de Coimbra, Coimbra, Portugal.

Introduction
The aging population brought new challenges in several diseases. Pituitary tumors are usually not related with elderly, although the rise in life expectancy has allowed its diagnosis in unusual age groups.
Aim
To describe the pituitary tumors diagnosed in patients with age $\geq$ 80 years
Methods
Retrospective observational study which included 23 patients with pituitary tumors with age $\geq$ 80 years observed in consultation between October of 2017 and October of 2018. Data were collected from clinical registry.
Results
57% were female ($n=13$), with a mean age at diagnosis of 83.3 ± 2.2 years. 78% were considered incidentalomas ($n=18$) and the clinical diagnosis were: 78% clinically non-functional tumors (CNFT) ($n=18$), 17% prolactinomas (PRLoma) ($n=4$), 4% acromegaly (ACRO) ($n=1$). 91% were macroadenomas ($n=21$) with mean length of 2.7 ± 1.1 cm, 95% with suprasselar extension, 45% with extension to cavernous sinus and 15% with infrasselar extension. 60% of patients presented neurological symptoms, 50% ophthalmological symptoms and 10% endocrinological symptoms. 70% of patients were diagnosed with some degree of hypopituitarism, wherein 13% presented panhypopituitarism ($n=3$). Visual field evaluation was performed in only 44% of patients due to limitations related with age and, in these, visual field defects were observed in 90% of patients ($n=9$). Transsphenoidal surgery was performed in four patients (13%) with CNFT and the immunochemistry was consistent with gonadotroph adenomas. Three patients presented improvement of visual evaluation and no improvement was seen in endocrinological function. Thirteen patients (57%) were treated with dopamine agonists (8 CNFT, 4 PRLomas, 1 ACRO), 54% with bromocriptine with a mean dose of 2.5 mg/day and 46% with cabergoline with a mean dose of 1mg/week, with improvement of hypogonadism in two patients (1 PRLoma, 1 CNFT). Acromegaly patient was also treated with lanreotide. During follow-up two patients developed corticotroph insufficiency and four patients deceased.
Conclusion
These data show that majority of pituitary tumors diagnosed in octogenarians were clinically non-functional macroadenomas, identified in imaging exams performed due to other clinical reasons. Despite the incidental diagnosis, 80% of patients presented some kind of neurological, ophthalmological or endocrinological symptoms. Just five patients (22%) had clinically functional tumors (4 prolactinomas and 1 acromegaly) and no Cushing disease was diagnosed. The presence of non-specific symptoms and its difficult appreciation associated with high prevalence of some degree of hypopituitarism shows the relevance of the diagnosis of pituitary tumors in this age group to do the prompt start of substitutive treatment in order to avoid potentially fatal outcomes.

Papillary thyroid carcinoma in acromegalic patient diagnosed with McCune Albright syndrome (MAS)

Maria Concepcion Terroba Larumbe, Cristina Crespo Soto, Jose Maria Palacio Mures, Manuel Acuña Garcia, Marcelino Mendo Gonzalez, Marta Ventosa Viña, Luis Cuellar Olmedo, Paula De las Heras Florez & Itciar Anacabe Goyogana
Hospital Rio Hortega, Valladolid, Spain.

Introduction
McCune Albright syndrome (MAS) is a rare, sporadic disease that affects the skin, skeleton and several endocrine systems, caused by an activating mutation in the GNAS gene that leads to endocrine cell hyperfunction and increased cell proliferation. The development of thyroid carcinoma in MAS is considered an uncommon event and, on the other hand, it is well established that acromegaly is associated with an increased prevalence of malignant tumors including thyroid cancer.
Clínical case
A 53-year-old female without family history of endocrine disease, surgically treated for facial asymmetry, was diagnosed in 1992 with polyostotic fibrous dysplasia, GH/prolactin producing pituitary macroadenoma and toxic multinodular goiter. Hyperprolactinemia and hyperthyroidism were controlled from the diagnosis with dopamine agonists and methimazole, but acromegaly remained active until 1999 because the patient refused treatment with subcutaneous octreotide. In January 2000 intramuscular Sandostatin LAR 30 mg/month was included in the treatment. In 2007 Sandostatin was replaced by subcutaneous GH receptor antagonist Pegvisomant, 20 mg/day because the control objective for IGF-1 was not achieved. Later, after confirming a significant increase in the size of the pituitary adenoma in magnetic resonance, we opted for combined therapy with Sandostatin LAR and Pegvisomant. Since then, the macroadenoma remains stable and IGF-1, PRL, and thyroid function are normal. In the follow-up thyroid ultrasonography (US) performed in 2017, several nodules in the left lobe thyroid suspected of papillary carcinoma were described and fine-needle aspiration (FNA) of the larger nodule was compatible with papillary thyroid carcinoma (PTC). In June 2017, total thyroidectomy was performed and the histopathological report confirmed the presence of a bilateral multifocal papillary carcinoma with extension to the extrathyroidal tissue adjacent to the left thyroid lobe, associated with nodular hyperplasia and chronic lymphocytic thyroiditis. Radioactive iodine ablation was performed 1 month later and the total body scan performed after treatment did not show evidence of metastasis. Serum thyroglobulin remains undetectable.
Discussion
Several studies report a high frequency of PTC in acromegalic patients, especially in those with prolonged periods of uncontrolled acromegaly, although the controversy remains regarding its BRAF mutation dependence. Previous data suggest relative aggressiveness of these tumours but the outcome seems good after surgery and I-131 therapy. In this patient, the sustained exposure to an overactive GH/IGF axis may have played a dominant role in the development of PTC. Acromegalic patients should be routinely screened by thyroid US and undergo FNA according to current criteria.

Effects of octreotide on hallmarks of autophagy and on parameters related to cell viability and metabolic activity in rat pituitary tumor cells

Giovanni Tulipano[1] & Andrea Giustina[2,3]
[1]Unit of Pharmacology, Department of Molecular and Translational Medicine, University of Brescia, Brescia, Italy; [2]Division of Endocrinology, San Raffaele Vita-Salute University, Milano, Italy; [3]IRCCS San Raffaele Hospital, Milano, Italy.

We investigated the direct effects of the somatostatin analog octreotide on hallmarks of autophagy and of cell viability and metabolic activity in rat pituitary tumor cells (GH1 and GH3 cells). The Western blot analysis of cell lysates suggested that octreotide (100 nM) treatment could induce changes in hallmarks related to autophagy activation (increased LC3-I protein lipidation) and to enhanced autophagic flux (SQSTM1/p62 protein downregulation) in pituitary tumor cells in different experimental conditions which included incubation in

Hank's balanced salt solution (HBSS), in Ham's F10 medium without serum and in the same medium supplemented with serum. Actually, these effects of octreotide were observed after short treatments (up to 4-h long) whereas they were not seen after 20-h long treatment. The primary antibodies were from Cell Signalling. In the same experimental conditions, we analyzed the MTT reduction activity as an index of cell metabolic activity and cell viability. Our results did not suggest any decrease in redox activity of the cells following to their treatment with octreotide in all the experimental conditions tested. On the other hand, in GH3 cells incubated in HBSS for short time (2-h), the addition of octreotide to HBSS tended to enhance the MTT reduction activity (112% ± 6% vs vehicle, $N=4$) and to increase the ATP levels in cell lysates (112% ± 8% vs vehicle, $N=4$), as measured by ATPlite kit (PerkinElmer). Finally, an increase of the pyruvate dehydrogenase (PDH) complex activity (PDH Enzyme Activity Microplate Assay Kit, Abcam) in lysates from GH3 cells treated with octreotide for 2-h, was observed compared to control cells (111% ± 4% vs vehicle, $N=3$). Actually, this effect was not related to any change in the phosphorylation of the regulatory subunit E1alpha (ser-293 in PDHE1-alpha), as assessed by Western blot (primary antibody from Abcam). In conclusion, we provided evidence that octreotide can affect autophagy in pituitary tumor cells. The observed effects of octreotide were not related to decreased cell viability and metabolic activity. Finally, the induction of autophagy was either short-lived or overshadowed by other factors in the long term and this limit does not help clarifying their real impact on the pharmacological activity of somatostatin analogs.

Effects of body mass index and estimated glomerular filtration rate on pituitary function in patients with non-functioning pituitary tumor

Yasufumi Seki & Atsuhiro Ichihara
Department of Endocrinology and Hypertension, Tokyo Women's Medical University, Tokyo, Japan.

Introduction
Hypothalamus or pituitary disorders frequently cause hypopituitarism. Diagnosing deficits of anterior pituitary hormones is important to manage metabolic impairments induced by hypopituitarism. Provocative tests including TRH, LHRH, CRH and GHRP-2 to diagnose hypopituitarism are recommended in Japan, however, the cut-off values in those tests are not adjusted for age, body mass index (BMI) or estimated glomerular filtration rate (eGFR). We retrospectively evaluated effects of age, obesity and renal function on the results of pituitary function tests in patients with hypothalamus or pituitary disorders.
Methods
In this retrospective study, patients with non-functioning pituitary tumor without history of pituitary surgery who admitted and received GHRP-2 test from 2013 until 2016. We evaluated an effect of age, BMI and eGFR on their pituitary functions. To evaluate pituitary function, TRH, LHRH and CRH combination test and GHRP-2 test were performed.
Results
We identified 116 patients who received GHRP-2 test, of which 90 (78%) were non-functioning pituitary adenoma and 17 (15%) were Rathke's cyst. Of the patients, 111 (96%) received TRH and LHRH test, and 112 (97%) received CRH test in addition to GHRP-2 test. Logarithm of peak serum GH level after GHRP-2 was significantly correlated with BMI ($r=-0.37$, $P<0.001$). Serum IGF-1 level was significantly correlated with age ($r=-0.518$, $P<0.001$) and eGFR ($r=0.19$, $P=0.037$). In multiple regression analysis, age was the only independent variable predicting serum IGF-1 level. Not serum free T4 but free T3 level was significantly correlated with age ($r=-0.20$, $P=0.031$) and eGFR ($r=0.33$, $P<0.001$). In multiple regression analysis, eGFR was the only independent variable predicting serum free T3 level. Serum TSH level was significantly correlated with age ($r=0.19$, $P=0.041$) and eGFR ($r=-0.21$, $P=0.024$). In multiple regression analysis, eGFR was the only independent variable predicting serum TSH level. In only men, serum LH level significantly correlated with eGFR ($r=-0.34$, $P=0.009$). Plasma ACTH and cortisol levels and their peak levels after CRH were not significantly correlated with age, BMI or eGFR, respectively.
Conclusion
When we diagnose hypopituitarism, we have to recognize that thyroid and gonadal functions might be altered by renal insufficiency and GH response to GHRP-2 might be altered by obesity.

Salivary carcinoma of the pituitary gland: an exceptional localization never described

Lahoussaine Abainou, Hamza Eljadi, Sanae Elhadri & Hicham Baizri
Department of Endocrinology, Diabetology and Metabolic Diseases, Military Hospital Avicenna, Marrakesh, Morocco.

Introduction
Epithelial-myoepithelial carcinoma is a rare, we report the case of a patient admitted for pituitary macroadenoma whose anatomopathological study was in favor of an epithelial-myoepithelial carcinoma at the level of the pituitary gland knowing that this is the first case described in Literature.
Clinical case
A 50-year-old man, admitted in July 2018 for pituitary macroadenoma with severe headache and blurry vision associated with polydipsia syndrome and asthenia. Magnetic resonance imaging showed a pituitary macroadenoma with compression of the optic chiasm. A tumor biopsy was performed whose pathological study showed a morphological and immunohistochemical profile of a secondary localization of epithelial-myoepithelial carcinoma probably developed on embryonic salivary parenchymal rests or secondary to primitive salivary tumor. The clinical examination as well as the MRI of the salivary glands is normal and thus we retain the diagnosis of salivary gland carcinoma developed on embryonic rests. The occurrence of these salivary gland rests in the pituitary gland is explained by direct transfer of intact seromucinous glands from the oral cavity, derivation from Rathke pouch remnants, or induction of pituitary epithelium by salivary gland mesenchyme. After discussing the case at the Multidisciplinary Care Teams, we decided to treat the patient by radiosurgery. Our observation is an exceptional case that is never described in the literature.

MRI follow-up is not useful in patients with GH-secreting pituitary adenomas primarily treated and responsive to long-acting somatostatin analogs (SMSa)

Naïa Grandgeorge[1], Giovanni Barchetti[2], Solange Grunenwald[1], Fabrice Bonneville[2] & Philippe Caron[1]
[1]Department of Endocrinology and Metabolic Diseases, CHU Larrey, Toulouse, France; [2]Department of Neuroradiology, CHU Purpan, Toulouse, France.

Introduction
Primary SMSa treatment can be associated with hormonal remission and tumor shrinkage in patients with GH-secreting pituitary adenomas. In the 2014 Endocrine Society guideline for Acromegaly, there is no specific mention of MRI follow-up during long-term SMSa treatment. The aim of this study was to evaluate any change of GH-secreting adenoma size during primary SMSa treatment and whether regular MRI follow-up was necessary in acromegalic patients treated with first generation long-acting SMSa.
Patients and Methods
In this retrospective and monocentric study we included patients with GH/IGF-1 hypersecretion and GH-secreting pituitary adenomas with normal visual field, primarily treated with first generation long-acting SMSa between 1995 and 2015, and regularly followed (clinical evaluation, GH/IGF-1 levels, pituitary MRI) during at least 3 years. To assess meaningful adenoma change during SMSa therapy, maximal height of the adenoma under the optic chiasm, on coronal T2-weighted MRI, was manually measured by the same radiologist blinded to clinical history, at baseline and at last pituitary MRI of each patient.
Results
We included 83 patients (32 men and 51 women, mean age at diagnosis 50 ± 12 years) with mean GH = 19.3 ± 25.6 ng/ml, IGF-1 = 284 ± 110% ULN and pituitary adenoma height = 12.9 ± 4.7 mm. Patients were primarily treated with long-acting lanreotide Autogel ($n=67$) or octreotide LAR ($n=16$), and mean follow-up was 8.9 ± 4.9 years in 36 controlled patients (GH < 2.5 ng/ml, normalized IGF-1 for age and sex) and 2.0 ± 1.6 years in 47 partially responders (decrease of IGF-1 > 10%) to SMSa alone, before association with dopamine agonists/pegvisomant or pituitary surgery. During primary SMSa treatment, no increase of pituitary adenoma height was observed. Pituitary adenoma height decreased significantly in controlled patients (diagnosis: 11.9 ± 4.8 mm, SMSa: 9.6 ± 3.3 mm, $P < 0.001$), and in partially responders (diagnosis: 13.6 ± 4.5 mm, SMSa: 11.5 ± 4.5 mm, $P < 0.001$). Controlled patients were older ($P < 0.05$), had lower mean GH ($P < 0.05$) or IGF-1 ($P = 0.05$) concentrations, and smaller pituitary adenoma ($P < 0.05$) at diagnosis.

Conclusion
During long-term treatment with first generation SMSa, no increase of GH-secreting adenoma size was observed. Primary SMSa treatment was associated with a significantly decrease of adenoma height in controlled and in partially responder patients. Therefore MRI follow-up does not seem useful in acromegalic patients responsive to SMSa treatment.

Study of relationship between levels of kisspeptin and neurokinin B and markers of calcium-phosphate metabolism and water-electrolyte balance in patients with neuroendocrine disorders

Ekaterina Pigarova, Svetlana Vorotnikova, Artem Zhukov, Larisa Dzeranova, Alexandra Petrushkina & Larisa Nikankina
Endocrinology Research Centre, Moscow, Russian Federation.

Objective
To study the effect of neurohormones kisspeptin and neurokinin B on the indices of calcium-phosphate and electrolyte metabolism in patients with neuroendocrine pathology.
Material and Methods
Eighty-two female patients were included in this pilot study divided into 2 groups: 'Cushing's disease' group ($n=51$) and 'Acromegaly' group ($n=31$). Median age was 33 years [27; 38] in 'Cushing's disease' group and 39 years [32; 45] in 'Acromegaly' group. Kisspeptin levels were measured using an ELISA test-system 'Kisspeptin-54 S-1308' (Peninsula Laboratories International, Inc., USA) on a Luminometer Photometer LMA01 (Beckman Coulter, Czech Republic). Extraction of peptide from plasma was performed according to the manufacturer's protocol. Measurement of the level of neurokinin B was carried out by the ELISA method on Cobas 6000 Module e601 analyzer (Roche, Switzerland), set 'Neurokinin B S-1271' (Peninsula Laboratories International, Inc., USA).
Results
The median serum levels of kisspeptin in the 'Cushing's disease' and 'Acromegaly' groups were 10.8 [3.0; 13.5] and 7.9 [0.14; 11.7] ng/ml, neurokinin B – 0.11 [0.08; 0.13] and 0.07 [0.06; 0.1] ng/ml, sodium - 142 [140; 143] and 140 [139; 141] mmol/l, potassium – 4.4 [4.2; 4.8] and 4.6 [4.2; 5.0] mmol/l, chlorides - 106 [105; 108] and 107 [105; 109] mmol/l, total calcium – 2.39 [2.28; 2.46] and 2.38 [2.31; 2.45] mmol/l, phosphate – 1.14 [1.07; 1.26] and 1.34 [1.24; 1.53] mmol/l respectively. We observed statistically significant difference in kisspeptin, sodium and phosphate levels between groups ($P<0.05$). In the correlation analysis, no significant dependencies were obtained between neuropeptides and sodium, potassium and chloride blood levels. Negative correlation was observed between kisspeptin and neurokinin B in 'Cushing's disease' group ($r=-0.55$, $P<0.05$), between kisspeptin and serum phosphate in 'Acromegaly' group ($r=-0.45$, $P<0.05$).
Conclusion
In a pilot study assessing the impact of new neuroendocrine hormones, there is no correlation between kisspeptin, neurokinin B and sodium, potassium, chloride levels, which negates their significant role in the control of water and electrolyte parameters of blood. Relationship between the studied neuroendocrine hormones and calcium-phosphate metabolism is not clearly understood and may be the subject of further research.

Spontaneous pregnancy obtained in persistent Cushing Disease treated with Cabergoline: Report of two cases

Almudena Vicente, Enrique Castro, Andrea Cruz, Ana Castro, Sastre Julia & López José
Deparment of Endocrinology. Hospital Virgen de la Salud, Toledo, Spain.

Introduction
Pregnancy is rare in patients with Cushing Disease (CD) owing to ovulatory dysfunction. When surgery is not curative, medical treatment is usually considered. Ketoconazole and mitotane, commonly used medical therapies, have questionable teratogenicity and are not often options in pregnancy. Cabergoline was found to be effective in reducing hypercortisolism in Cushing's disease. Observational studies suggested that low dose cabergoline treatment at the time of conception and during early pregnancy is not likely to induce an increase in the risk of miscarriage or of fetal malformation.
Aim
To describe two patients who achieved pregnancy after treated with low-dose cabergoline (CAB) for persistent CD.
Case description 1
We report a 33-year-old woman diagnosed with CD at the age of 23. She underwent trans-sphenoidal resection of pituitary ACTH-secreting microadenoma on January 2005. 18 months after surgery, CD persisted and she underwent Gamma Knife radiosurgery (GKRS). Following GKRS, her cortisol levels remained elevated despite no evidence of visible tumour on pituitary MRI. Adjuvant medical therapy was commenced with low ketoconazole doses with successful control of hypercortisolism for the subsequent 9 years. As she was keen for pregnancy, medical treatment was changed to CAB 0.5 mg twice weekly from July 2015, to avoid the potential teratogenic side effects of ketoconazole. The patient subsequently conceived spontaneously in October 2015.
Case description 2
We report a 30-year-old woman diagnosed with CD at the age of 28, with no visible adenoma on magnetic resonance imaging (MRI). Bilateral inferior petrosal sinus sampling (BIPPS) was done and showed a higher IPS/periphery ACTH ratio on the left side as compared to right. A left hemi-hypophysectomy was performed on February 2018, based on BIPSS findings. Surgery was not curative. As she expressed desire to become pregnant, medical treatment with CAB was started on April 2018, with a gradual dose titration up to 3 mg per week. Clinical improvement was observed and the patient conceived spontaneously in September 2018.
Conclusion
These cases reports demonstrates that cabergoline may be an effective and safe therapeutic option for the treatment of persistent CD in women who want pregnancy.

Genetic study of AHR exonic part and GNAS intronic part mutations in some of Iraqi acromegalic patients

Abbas Mahdi Rahmah
National Diabetes Center, Baghdad, Iraq.

Acromegaly is a rare syndrome categorized by extreme excretion of growth hormone via a pituitary adenoma, happening everywhere in the world also in Iraqi population. Practically all conditions of acromegaly are produced by a benign tumor in the pituitary that creates much growth hormone. In additions, some tumors in the body may yield an element known as growth hormone releasing hormone which lead the pituitary to oversecrion of growth hormone. So this research proposed to observe the frequency of guanine nucleotide binding protein, alpha stimulating (GNAS), and aryl hydrocarbon receptor (AHR) genes mutations. Consequently, this cross sectional biochemical and molecular genetic study was achieved from December 2016 to September 2017, enrolled seventy patients (36 males, and 34 females) with somatotrophic pituitary adenoma continuously attended to the National diabetic center in Baghdad. Their ages were between 20 to 70 years old. Polymerase chain reaction (PCR) was used for the detection of gsp and AHR mutations as a cause of acromegaly, by using specific primers for amplification of partially intronic and exonic 7 of gsp gene on chromosome no.20 and exon 10 of AHR gene on chromosome no.7. Sequencing was applied for PCR products of AHR and gsp genes, six different alterations in AHR gene and two different mutations in GNAS gene have been recognized. Two were recognized in 6/70 (9%) patients which are codon 705 with substitution thymine by adenine (T/A), and codon 410 with substitution of adenine by thymine (A/T) for 817bp fragment. In addition another four recognized alteration were established in (22/70) (31%) which are codon 193 with substitution of cytocine by adenine(C/A), codon 344 with substitution of thymine by adenine(T/A), codon 459 with substitution of guanine by cytocine(G/C), and codon 518 with substitution of adenine by cytocine(A/C) and this for 706bp fragment of AHR exon 10.Two mutations in GNAS gene were recognized in 5/70 (7%) which their codon 91 with substitution cytocine by guanine(C/G), and codon 128 with substitution guanine by adenine(G/A). We concluded the novelties SNP were identified in Iraqi acromegalic patient. Genetic variationspossiblyencouraging functional irregularities of the aryl hydrocarbon receptor (AHR) pathway and guanine nucleotide binding protein, alpha stimulating (GNAS) are connected with a more severe acromegaly increased pituitary tumor mass, and somatostatin analog resistance in patients living in HR areas.

Primary infundibulohypophysitis in a young man with DI and Hypogonadism

Iuliana Ilie[1], Madalina Musat[1,2], Dan Hortopan[1], Carmen Iordachescu[1], Dan Mitrea[3], Andreea Banica[1] & Luciana Oprea[1]
[1]C.I. Parhon National Institute of Endocrinology, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [3]Neuroaxis-Neurology Clinic, Bucharest, Romania.

Primary hypophysitis is a rare inflammatory condition which is mostly encountered in women. It represents 0.2–0.8% of pituitary pathologies and its annual incidence is estimated at 1 case per 9 million inhabitants. We present the case of a 28-year-old male, smoker, with sudden onset decreased libido, polyuria and polydipsia. At presentation he had an epicranial lipoma with and no other suggestive clinical signs. Biochemistry revealed hypernatremia 146 nmol/L, low testosterone level 0.5 ng/mL, low normal FSH and LH, normal prolactin level, normal adrenal and thyroid function. The dehydration test was positive for central diabetes insipidus (test stopped after 4 hours due to high plasma osmolality- 307 mOsm/l while urinary osmolality was lower than 300 mOsm/l and increased to 756 mOsm/l after Desmopressin). Diagnosis of central diabetes insipidus and hypogonadotropic hypogonadism has been made. Pituitary MRI showed thickening of the pituitary stalk close to the chiasm, a homogenous enlarged pituitary gland with loss of posterior bright spot. Serum alpha-fetoprotein and β-HCG were negative both in blood and CSF and scrotal ultrasound was normal excluding germinoma; normal blood angiotensin-converting enzyme, negative tuberculin purified protein derivative test and normal chest CT excluded sarcoidosis, tuberculosis and lung cancer. Also CSFflow cytometry, serum IGG4, c-ANCA, HIV serology were normal. The patient was treated with Desmopressin and Testosterone undecanoate and reevaluated at 3 and 6 months - pituitary IRM showed regression of the pituitary stalk mass, with persistence of DI and hypogonadism. The etiological spectrum of pituitary stalk (PS) lesions is broad, presenting a diagnostic challenge. We will discuss the differential diagnosis and management of this unusual case of primary infundibulohypophysitis. Pituitary stalk biopsy in this case was considered deleterious and not absolutely necessary as repeated MRI at 3 months showed a reduction of the stalk lesion. In cases of suspected lymphocytic hypophysitis, it is reasonable to try a course of high-dose glucocorticoids before proceeding to PS biopsy. However a positive response to glucocorticoids is not specific for hypophysitis, as a temporary relief can be observed also in lymphoma and germinomas. Similarly, in the absence of mass effect symptoms, like in our case it is reasonable to observe a PS lesion ensuring close hormonal and radiological follow-up as spontaneous resolution of PS has been observed.

Conclusion

Primary hypophysitis occurring in a young man is a rare condition with poorly understood pathogenesis and lack of specific markers, thus represents a diagnostic challenge.

A case of 'micromegaly': need for revision of oral glucose tolerance test (OGTT) cut-offs with modern growth hormone assays in acromegaly

Katharina Schilbach, Sylvère Störmann, Martin Bidlingmaier & Jochen Schopohl
Medizinische Klinik und Poliklinik IV, Klinikum der Universität München, Munich, Germany.

The OGTT is the gold standard for confirmation or exclusion of acromegaly in treatment-naïve patients as well as after surgery. According to former guidelines, acromegaly is ruled out if the growth hormone (GH) nadir lies below 1.0 µg/l and 0.4 µg/l pre- and postoperatively, respectively. We present the case of a 40-year-old man who presented to the outpatient clinic in 2014 for endocrinological evaluation after an elevated IGF-I concentration had occasionally been detected within the scope of a clinical study. GH and IGF-I were measured using a modern, monoclonal antibody based assay adhering to recent guidelines (IDS iSYS). At that time, a GH nadir of 0.3 µg/l formally ruled out acromegaly. However, due to the clinical presentation and comorbidities (typical physiognomy, sleep apnea, arterial hypertension, impaired glucose tolerance, hypogonadotropic hypogonadism, and obesity) the patient was scheduled for follow-up consultations. IGF-I was persistently elevated (IGF-I SDS between 3.1 and 5), but GH nadir remained below 0.4 µg/l in two repeated OGTTs (0.36 and 0.24 µg/l in 2015 and 2016, respectively). In 2015, MRI revealed a pituitary microadenoma (9×4 mm) but the patient refused surgery. Tumour size was unchanged in annual follow-up MRIs. In November 2018, over 4 years of initial observation of elevated IGF-I, the patient finally agreed to transsphenoidal tumour resection. Neuropathological examination confirmed GH-secreting pituitary adenoma. Postoperatively, IGF-I concentration fell within the gender- and age-specific reference range (SDS 2, 10 weeks after surgery), and GH was suppressible to <0.05 µg/l after oral glucose load. The case also supports our recent observation in a larger cohort of healthy subjects: Using the same modern GH assay, GH nadir concentration fall below 0.4 µg/l in lean (BMI <25 kg/m^2) and below 0.2 µg/l in obese (BMI >25 kg/m^2) subjects. In the present case the BMI was >38 kg/m^2 at all times. This case suggests that mild or early acromegaly might be missed when the commonly used cut-off of 0.4 µg/l is applied for all patients, particularly if modern, highly sensitive and specific GH assays are used.

What patients with acromegaly have to say about their diagnostic pathway: A qualitative study

Jordan Sibeoni[1,2], Emilie Manolios[2,3], Laurence Verneuil[2], Philippe Chanson[4,5] & Anne Revah-Levy[1,2]
[1]Service Universitaire de Psychiatrie de l'Adolescent. Centre Hospitalier, Argenteuil, France; [2]ECSTRA Team, UMR-1153, Inserm, Paris Diderot University, Sorbonne Paris Cité, Paris, France; [3]Service de Psychologie et Psychiatrie de Liaison et d'Urgences, Hôpital Européen Georges Pompidou AP-HP, Hôpitaux Universitaires Paris Ouest, Paris, France; [4]Service d'Endocrinologie et des mladies de la Reproduction, Centre de référence des Maladies rares de l'Hypophyse, Hôpital de Bicêtre, Le Kremlin Bicêtre, France; [5]UMR S1185, Faculté de Médecine Paris-Sud, Université Paris-Sud, Le Kremlin-Bicêtre, France.

Background

Acromegaly is a rare disease with a long and complex diagnostic pathway leading to a substantial diagnostic delay associated with an increased risk of comorbidities and psychosocial deterioration. Qualitative methods are the gold standard to explore patients' perspectives, focusing on how individuals understand and report what they are experiencing. To the best of our knowledge, no qualitative study has yet examined the diagnostic pathway of subjects with acromegaly. This study aimed to fill this gap.

Methods

Face-to-face unstructured interviews were conducted by experienced qualitative researchers in a third referral Endocrinology center. Participants, purposively selected until data saturation was reached, were patients with acromegaly with various disease durations, types of treatment, or associated comorbidities. The data were examined by thematic analysis.

Results

Twenty patients with acromegaly, 11 women and 9 men, were included. The duration of misdiagnosis and uncertainty resulting in diagnostic delay ranged between 3 and 16 years (mean, 8 years). Our analysis shows four themes; (i) *what happened for patients before the diagnosis,* with the early symptoms the patients perceived, but also the terror they felt not to recognize themselves and the lack of understanding, (ii) *what happened after,* with the tragic ending of the diagnostic assessment and how they look at the damage retrospectively; (iii) *the style or type of doctor involved*, the ones they met before the right diagnosis, at diagnosis and after and (iv) *participants' suggestions for limiting diagnostic delay,* with two suggestions, one concerning directly doctor training and the other involving how society, patients, and others look at people with acromegaly, as well as the need to look more attentively at oneself and at others

Conclusion

Our findings underline the direct associations between diagnostic delay and the doctor-patient encounter, and the truly catastrophic experience of this disease, both before and after the diagnosis. Limiting diagnostic delay requires an active involvement and awareness of any doctor, especially primary care providers. We suggest several practical implications such as the intervention of patient-experts in medical schools or a statement that all physicians can use to address the catastrophic dimension of their patients' experiences and to support them in this process.

IgG4-releated hypophysitis: A case report

Fatih Kilicli[1], Hatice Sebile Dokmetas[1], Gunes Cavusoglu[2], Meric Dokmetas[2], Kubra Karaipek[2], Bugra Erol[2] & Aysenur Cila[3]
[1]İstanbul Medipol University, Department of Endocrinology, İstanbul, Turkey; [2]İstanbul Medipol University, Department of Internal Medicine, İstanbul, Turkey; [3]İstanbul Medipol University, Department of Radiology, İstanbul, Turkey.

Introduction
IgG4-dependent disease is a newly defined fibroinflammatory disease. This disease has been shown to affect almost all organs in the body, especially the pancreas, salivary gland, orbital tissue, lymph node, lung and kidney. IgG4 hypophysitis is a rare and inflammatory process that mimics pituitary tumors. The diagnosis of IgG4 releated hypophysitis can be done in many ways. The definitive diagnosis is biopsy; however, it is not necessary in most cases. If the other organs are diagnosed with IgG4-releated disease with biopsy, the appearance of pituitary mass is also diagnostic.
Case
A 28-year-old woman was admitted to our clinic with blurred vision and double vision during her pregnancy. Our patient was receiving replacement therapy due to total hypophyseal insufficiency. In June 2018, pituitary biopsy was performed and the pathology report was revealed as IgG4 pituitary. In November 2018, outward shifting started in the right eye. The patient presented with a Gamma-knife recommendation. TSH: 0.026 (N: 0.27–4.2 IU/ml), freee T4: 0.836 (N: 0.93–1.7 ng/dl), FSH: 1.24 (N: 3.5–12.5 mIU/ml), LH 0.4 (2.5–11.2 IU/ml), E2 (3 pg/ml), Prolactin: 0.466 (N: 4.79–23.3 ng/ml), IgG4: 340 (N: 80–140 mg/dl). Pituitary MRI revealed bilateral cavernous sinus, optic chiasm and infundibulum infiltration, and T2 hypointense hypophysitis. The patient was diagnosed with IgG4-releated hypophysitis and pulse steroid treatment was started, but because there was no clinical and radiological improvement, rituximab1000 mg was given twice daily for 15 days.
Conclusion
There is still no consensus about the treatment of IgG4-releated hypophysitis, and in patients with steroid resistance, rituximab therapy may be required.

Trunk fat increase is prevented both in patients undergoing long-lasting continuous r-hGH therapy and in those who discontinued r-hGH compared to untreated patients: results from baseline data of the MAGHD study

Maria Laura Monzani, Elisa Magnani, Chiara Diazzi, Simone Pederzoli, Laura Volpi & Vincenzo Rochira
Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy.

Background
Adult growth hormone (GH) deficiency (AGHD) is related with alterations in body composition, increased abdominal and visceral adiposity, adverse change in lipid and carbohydrate metabolism, and reduction of bone mineral density (BMD).
Aim
To compare baseline outcomes concerning body composition and biochemical/hormonal data among adult patients with AGHD referring to a single endocrinological center and grouped according to their history of r-hGH therapy.
Methods
The Management of Adult Growth Hormone Deficiency Study(MAGHD) is a prospective, single-center trial aiming to improve AGHD management through a smartphone app (MAGHD App: Manage AGHD) and a wearable device integrated with a software framework able to merge several kind of patients' daily data with clinical data collected in institutional databases. Up-to-now, a total of 74 subjects (26 Female, 48 Male, mean age: 56.6 + 14.8 years) with AGHD, fulfilling the inclusion criteria, were enrolled in the study. According to r-hGH therapy, they were divided in 3 groups: patients on long-term r-hGH therapy (Group1, $n = 33$), patients previously treated with r-hGH, who had stopped the therapy at any time (Group2, $n = 18$), patients never treated (Group 3, $n = 23$). Each patient has completed the baseline visit, including biochemical and hormonal measurements and data on BMD and body composition obtained by DXA. The nonparametric Kruskal-Wallis test was used for comparison among 3 groups and data are expressed as median. Only baseline data are here shown.
Results
Mean duration of AGHD disease was 121.2 + 105.8 months; it was lower in Group 3 compared to both Group1 and 2 ($P < 0.05$). Waist circumference (Group 1 95 cm; Group 2 96.5 cm; Group 3 109 cm), total fat mass (Group 1 25016g; Group 2 26491g; Group 3 33887g) and trunk fat mass (Group 1 11743g; Group 2 12598g; Group 3 16761g) were significantly higher in Group 3 compared to both Group 2 and 1 ($P < 0.05$), while total fat mass and trunk fat mass did not differ significantly among Group 1 and 2. Serum insulin and total body fat (%) were significantly higher in Group 3 than Group1 ($P < 0.05$). IGF-1 and IGFBP3 were significantly higher in Group 1 compared to both Group 2 and 3 ($P < 0.0001$). BMD, circulating lipids, and fasting glucose did not differ among the 3 groups.
Conclusions
r-hGH therapy seems to confer a long-lasting beneficial effect on body fat, especially trunk fat even after its discontinuation in AGHD patients, but not on metabolic parameters.
Acknowledgment
This clinical study is conducted thanks to the competitive assignment of an Independent Grant for Learning & Change ('IGCL') Dissemination & Implementation ('D&I') by Pfizer Inc.

Hyperglycemia and pasireotide lar in acromegaly: a study with continuous glucose monitoring

Lucia Russo, Sara Mazzocut, Francesca Dassie, Matteo Parolin, Chiara Martini, Eugenio De Carlo, Francesco Fallo, Roberto Mioni, Roberto Vettor, Alberto Maran & Pietro Maffei
DIMED, Università di Padova, Padova, Italy.

Background
Pasireotide LAR is a multireceptor targeted somatostatin analogue that has been shown to obtain a better biochemical control of acromegaly. However, pasireotide LAR could induce hyperglycemia in acromegalic patients with higher baseline glucose values. The devices that can track interstitial glucose levels such as continuous glucose monitoring (CGM) could be a useful for studying the impact of SSA on patients' glucose status.
Aim
We aimed to study the glucose metabolism with CGM in a group of acromegalic patients during first generation SSA treatment before pasireotide LAR start.
Methods
We studied 10 patients with uncontrolled acromegaly (Male 5; median age 58y) in therapy with first generation SSA eligible for the treatment with pasireotide. At pasireotide start (T0) we performed a CGM of 9 days to investigate the glycemic variability (J whole, GRADE, MAGE, CONGA). We also collected endocrinological and metabolic data (GH, IGF 1, fasting plasma glucose -FPG-, HbA1c) at T0 and after at least 3 months of therapy (T1).
Results
Analysis of the data, revealed a significant decrease in GH (T0 2.06 vs T1 1.02 ug/L, P 0.01) and in IGF1 (T0 275.5 vs T1 193.5 ug/L, $p = $NS) after treatment with pasireotide, with a median treatment duration of 9 months. There was also a significant increase in FPG and HbA1c (FPG T0 97 vs T1 124 mg/dL, P 0.01; HbA1c T0 41.5 vs T1 44.5 mmol/mol, P 0.01) At T0, 5 patients (50%) had glycemic alterations: 2 patients had diabetes mellitus (DM) in therapy with metformin and 3 patients had an impaired fasting glucose (IFG). At T1, 5 patients (50%) received antidiabetic medications and among this 60% started antidiabetic treatment after T0. Patients with FPG > 100 mg/dl at T0 showed higher glucose variability for most important CGM-based variability indexes (FPG < 100 vs FPG > 100: J whole 17.3 vs 25,2 $P < 0.03$, GRADE 2 vs 4 $P < 0.03$, MAGE 54.7 vs 96.1 $P < 0.01$, CONGA1h 12.8 vs 28.3 $P < 0,03$).One patient discontinued the drug due to severe hyperglycemia (> 500 mg/dl). At T1 there were no significant correlations between HbA1c/FPG and glycemic indexes.
Conclusions
We confirm the efficacy of pasireotide and the effect on glucose metabolism. For the first time in literature we found higher glycemic variability indexes in acromegalic patients with known alterations of glucose metabolism. Further studies are needed to determine the role of CGM in acromegalic patients on pasireotide treatment.

Radiation therapy in patients with pituitary somatotropinomas

Saodat Issaeva, Zamira Khalimova, Adliya Khalikova, Shokhsanam Safarova & Mijgona Safarova
Republican Specialized Scientific and Practical Medical Center of Endocrinology, Tashkent, Uzbekistan.

Purpose
To assess the effect of radiation therapy (RT) in patients with acromegaly, depending on the age of the patients and the activity of the formation.
Materials and methods
The object of the study was 50 patients (36 women and 14 men) with acromegaly who received gamma-therapy in a total dose of 45-60 Gr. The age of patients ranged from 29 to 77 years. By age, the patients were divided into 3 groups: 1st age group-29–44years old-23patients (46%), 2nd group-45–59years old-16 patients (32%), 3rd group-60-79years old-11patients (22%). All patients underwent hormonal (GH, IGF-I) studies in the dynamics of treatment.
Results
The hormone levels of GH and IGF-1 remain high in group I in 22% of patients, and in group III in 9%. Remissions reached 64% in the III group. The highest levels of GH were in the age range from 45 to 59 years old and amounted to 77.5 ± 9.68 mMe/l, and from 26 to 44 years old was 68.1 ± 6.84 mMe/l. After RT, this indicator in both age groups was almost equally depressed, but not to the norm. At the same time, in the Igroup, a decrease in the level of GH is observed in 10 patients, and in the II age group in 9patients it was 9.99 ± 6.2 mMe/l. As the results of the study showed, the use of RT leads to a significant decrease in the level of GH and IGF-1 in all age periods and a particularly significant decrease was observed in age group III.
Conclusions
Thus, the analysis of the results of studying the relationship between the age of patients and the activity of the process at different periods of observation after RT showed that in all age periods, RT is a fairly effective method of treatment and gives positive results in most cases.

Anterior pituitary insufficiency in clinically non-functioning pituitary microadenoma

Karina Arcano[1], Vanesa Triviño[2], Paula García-Sancho[3], Juan José Diez[4], Fernando Cordido[2], Carles Villabona[3] & Pedro Iglesias[4]
[1]Hospital Universitario Rey Juan Carlos, Madrid, Spain; [2]Hospital Universitario A Coruña, A Coruña, Spain; [3]Hospital Universitario De Bellvitge, Barcelona, Spain; [4]Hospital Universitario Puerta De Hierro, Madrid, Spain.

Background
Systematic exploration for anterior pituitary deficiency in patients harboring pituitary microadenomas is not well defined. So far, little is known on the involvement of pituitary function in clinically non-functioning pituitary microadenomas (CNFPM).
Objective
To evaluate the prevalence of anterior pituitary insufficiency, defined as at least one hormonal deficiency, in patients diagnosed of CNFPM.
Patients and methods
A multicenter retrospective study in patients diagnosed of CNFPM was performed. In every patient, clinical parameters (age at a diagnosis, sex, and main complaint at presentation) and endocrine dysfunction (the presence of hypopituitarism, number of axes involved, and hyperprolactinemia) were recorded.
Results
Of a total of 162 patients with CNFP adenomas, 31 patients (19.1%; mean age 43.6 ± 15.65 yr (range, 14–83); 21 women (67.7%)) with microadenomas (median size 5 mm (IQR, 4–7 mm) were evaluated. In most patients ($n=23$, 74.2%), the finding of the pituitary microadenoma was incidental. In the remaining, the main complain at presentation was galactorrhea ($n=3$), erectile dysfunction ($n=2$), infertility ($n=1$), amenorrhea ($n=1$) and menstrual disorders ($n=1$). Anterior pituitary insufficiency was seen only in 2 patients (6.5%), both of them with only one hormonal deficiency. The first one was a 51-year-old woman who complained of facial pain. Pituitary MRI showed a 5 mm pituitary microadenoma and hormonal evaluation was compatible with ACTH deficiency (low/normal ACTH (13 pg/ml) with low cortisol (3.8 µg/dl)). The second one was a 28-year-old man studied for infertility. Investigations showed hypogonadotropic hypogonadism (low FSH (0.2 mU/ml), low LH (0.4 mU/ml) and low total testosterone (20 ng/dl)). Pituitary MRI showed a 4 mm pituitary adenoma. In both patients serum PRL concentrations were into the normal range.
Conclusion
In our series, the percentage of pituitary hormone deficiencies associated with CNFPM was very low (6.5%). Although the relationship between CNFPM and pituitary hormone deficiency might be coincidental, it would seem appropriate and prudent to rule out pituitary hormonal insufficiency in these patients.

Neural network for predicting recurrence of the Cushing's disease within three years after neurosurgical treatment

Elena Nadezhdina, Olga Rebrova & Andrey Grigoriev
Endocrinology Research Center, Moscow, Russian Federation.

Introduction
The reccurence rate after successful neurosurgery for patients with Cushing's disease (CD) varies between 10% and 65%. It is shown earlier that some features are associated with the probability of recurrence, yet no rules were elaborated how to analyse the set of variables.
Materials and methods
The retrospective study was based on 219 cases of CD (32 men, 187 women) with a disease duration ranged from 4 months to 22 years, who underwent an endoscopic transsphenoidal adenomectomy in 2007-2014 at the age of 38 ± 12. The duration of a postoperative follow-up was 3 years or more. The 3-years remission persisted in 172 patients, the recurrence developed in 47 patients. Univariate and multivariate analyses were performed.
Results
The univariate analysis did not reveal association between the CD recurrence and sex, age, duration of disease, size of adenoma. At the same time, adrenocorticotropic hormone (ACTH) and cortisol levels in the early post-operative period found out to be statistically significant predictors: patients with ACTH levels less than 7 pg/ml had recurrence about 6 times less than patients with higher levels of ACTH, odds ratio (OR) 0.16, 95% CI [0.06; 0.43]; patients with cortisol levels less than 123 nm/l had recurrence about 5 times less than patients with higher levels of this hormone, OR 0.19 [0.09; 0.39]. However, in 58% of cases the levels of these two hormones are dissociated, so it is not possible to use any of them to predict recurrence. This made multivariate analysis reasonable. No effective logit-regression model was developed, but the highly effective neural network (3-layer perceptron) was obtained. The predictors are sex, age, duration of disease, size of the adenoma, levels of ACTH and cortisol in the blood in the early postoperative period. The correct prediction on randomly generated samples was 94.2% on the training sample ($n=155$), 84.4%, on the control sample ($n=32$), and 87.5% on the test sample ($n=32$). The model has sensitivity 74%, specificity 97%, positive predictive value 85%, negative predictive value 93%.
Conclusion
The developed ANN is an effective tool for predicting recurrence and it will allow to perform personalized approach to the management of patients who underwent neurosurgery, eg. vary frequency of dynamic examinations, prescribing and correcting drug therapy, etc.

Hyperglycemia in patients with acromegaly treated with pasireotide LAR

Seung Hee Yu & Ki Young Lee
Gachon University Gil Medical Center, Incheon, Republic of Korea.

Pasireotide long-acting release (LAR) is a multireceptor-targeted somatostatin receptor ligand approved for treatment of patients with acromegaly. In some clinical reports, pasireotide LAR has been shown to regulate biochemical outcomes more than other somatostatin receptor ligands. However, hyperglycemia was frequently observed in pasireotide LAR treated patients with acromegaly. Three patients were treated with pasireotide LAR to regulated biochemical parameters of acromegaly. They had an elevated levels of insulin-like growth factor 1 (IGF1) and growth hormone (GH) after surgery of pituitary tumor and medication treatment of octreotide LAR. All three had consistently high level of IGF1 and GH for several years. After 3 months of pasireotide LAR treatment, IGF1 level tended to decrease compared to the previous clinical

outcomes. In first case, IGF1 and GH before pasireotide LAR were 369.41 ng/ml and 6.28 ng/ml. After 3 months of pasireotide LAR, IGF1 and GH were decreased to 187.56 ng/ml and 3.41 ng/ml. In second and third cases, levels of those were 409.98 ng/ml, 341.7 ng/ml and 4.48 ng/ml, 5.14 ng/ml to 167.07 ng/ml, 178.18 ng/ml and 2.27 ng/m, 1.00 ng/ml. But levels of fasting plasma glucose (FPG) and glycated hemoglobin (HbA1c) increased. FPG and HbA1c were elevated 2-fold from baseline in 2 patients with diabetes mellitus (DM) treated oral hypoglycemic agents (OHAs); FPG 183 mg/mL to 312 mg/mL and HbA1c 6.2% to 11.9% in first case. Another, FPG 110 mg/mL to 265 mg/mL and HbA1c 6.3% to 12.6%. The patient with previously normal glucose tolerance was newly diagnosed DM; FPG 85 mg/mL to 461 mg/mL and HbA1c 6.0% to 12.6%. These clinical cases suggest that the effect and safety of the pasireotide LAR should be considered in patients with acromegaly. Especially, pasireotide LAR-induced hyperglycemia should be carefully observed and treatment of hyperglycemia should be started at an appropriate time.

Novel insight into ACTH-secreting pituitary tumors biological behavior: somatostatin receptor type 5 (SST5) modulation by ubiquitin specific peptidase 8 (USP8)

Erika Peverelli[1], Donatella Treppiedi[1], Elena Giardino[1], Rosa Catalano[1,2], Federica Mangili[1], Pietro Vercesi[1], Marco Locatelli[3], Anna Spada[1], Maura Arosio[1] & Giovanna Mantovani[1]
[1]Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico; Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy; [2]PhD Program in Endocrinological Sciences, Sapienza University of Rome, Rome, Italy; [3]Neurosurgery Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy.

Cushing's Disease (CD) is a rare condition characterized by an overproduction of ACTH by an ACTH-secreting pituitary tumor, resulting in excess of cortisol release by the adrenal glands. Pasireotide is the pituitary-targeted drug approved to treat adult patients. Its mechanism of action seems to rely on the preferential binding to the highly expressed somatostatin receptor in corticotroph tumors, SST5. Recently, somatic mutations in the deubiquitinase *USP8* gene have been reported in 40% of patients affected by CD, resulting in epidermal growth factor receptor (EGFR) signaling hyperactivation and ACTH secretion. Although mutated tumors were found to express significantly higher levels of SSTR5, the interplay between USP8 and SST5 has never been explored so far. The aim of this study is to investigate whether modulation of USP8 activity could affect SST5 physiology. First, by immunoprecipitation experiments we found an enhanced SST5 ubiquitination in murine corticotroph tumor AtT-20/D16v-F2 cells incubated with the chemical inhibitor of USP8, RA-9, compared to basal (2.1 ± 0.4-fold increase vs basal, $P < 0.05$). On the contrary, pasireotide did not significantly modify the ubiquitination status of the receptor. Interestingly, a significant SST5 protein expression levels increase was only observed in cells pre-treated with RA-9 and exposed to 10 nM pasireotide for 72 h ($+36\% \pm 12.1$, % vs basal, $P < 0.01$), this effect being reverted by cycloheximide treatment ($-49.3\% \pm 23$, % vs basal, $P < 0.05$). Accordingly, cells transfection of the catalytically active USP8-C40, followed by pasireotide incubation, resulted in a reduction of SST5 expression level ($-38.7\% \pm 18.4\%$ vs basal, $P < 0.05$). In AtT-20/D16v-F2 cells, similar inhibitory actions on p-ERK1/2 were triggered by pasireotide, RA-9 and by their co-incubation ($-72.1\% \pm 16.1$, $-60.2\% \pm 16.7$, and $-66.4\% \pm 14.6$,% $P < 0.05$ vs basal), whereas RA-9 was able to reduce p-ERK1/2 levels ($-48.5 \pm 9.2\%$ vs basal, $P < 0.05$) in human tumoral corticotroph primary cultures regardless *in vitro* responsiveness to pasireotide. Altogether, our data demonstrate that the expression of agonist-activated SST5 is negatively modulated by USP8 in AtT-20/D16v-F2 and that RA-9 is effective in reducing ERK phosphorylation in mouse and human ACTH-secreting pituitary tumor cells.

Rare lesions of sellar, parasellar and suprasellar pathologies

Melda Apaydin[1] & Güzide Gonca Oruk[2]
[1]Izmir Katip Celebi University Ataturk Training and Research Hospital, Radiology, Izmir-Turkey, Turkey; [2]Izmir Katip Celebi University Ataturk Training and Research Hospital, Endocrinology and Metabolism, Izmir-Turkey, Turkey.

Differential diagnoses of sellar, parasellar and suprasellar pathologies other than tumors such as common adenoma, rathke cleft cysts and meningioma and craniopharyngiomas were presented. This retrospective study was performed including 25 patients who were operated or treated medically in between 2008 and 2019. The patients were analyzed with preoperative/postoperative magnetic resonance imaging (MRI), endocrinological and neuro-ophthalmologic examination results. Pre and post contrast sagittal T1WI, pre and post contrast dynamic coronal T1WI, coronal T2WI were obtained for MRI. Some patients were imaged several times to reach final diagnosis and treatment control. The diagnosis revealed metastatic tumors ($n = 3$), colloid/epidermal/dermoid cysts ($n = 3$), pilocytic astrocytomas ($n = 5$), and one case each of hemangioblastoma, lymphoma, chordoid glioma, meckel cave schwannoma, chordoma, aneurysm, fibrous dysplasia, germ cell tumour. 3 hypophysitis, (lymphocytic/tuberculous granuloma/xanthomatous), 2 developmental chordomatous lesions (fossa navicularis, notochordal remnants), 2 hamartoma. Metastatic tumors demonstrated main growth within destructive remodelling of the dorsum sellae. Big lesions (> 20 mm) showed a significantly worse outcome regarding hormonal and visual deficits. Developmental lesions (developmental chordomatous lesions (fossa navicularis, notochordal remnants), hamartoma were stabile. While some of the lesions were operated some were followed by MRI.

Conclusion

The correlation of the radiological findings with the specific clinical features maybe helpful for the differential diagnosis of rare lesions of the sellar, parasellar and suprasellar pathologies. Interdisciplinary diagnostic and therapeutic procedure for these lesions are very important to control the specific disease.

Baseline characteristics of adult patients with growth hormone deficiency (GHD) enrolled in NordiNet® International Outcome Study (IOS): are there variations between countries?

Matthias M Weber[1], Alberto Pietropoli[2] & Charlotte Höybye[3]
[1]University Hospital, Universitätsmedizin Mainz, der Johannes Gutenberg-Universität, Mainz, Germany; [2]Novo Nordisk Healthcare AG, Zürich, Switzerland; [3]Department of Endocrinology and Department of Molecular Medicine and Surgery, Karolinska University Hospital and Karolinska Institute, Stockholm, Sweden.

Czech Republic background

NordiNet® IOS (NCT00960128), a non-interventional study (2006–2016), assessed the effectiveness and safety of real-life treatment with Norditropin. From 23 countries, 2,321 adults with GHD were included; 971, GH-naïve at baseline, were included in the effectiveness analysis set (EAS). Baseline characteristics in the six largest contributing countries were evaluated.

Methods

Patient information was entered at routine clinic visits by participating physicians. EAS baseline data are presented (Table 1).

Results

Proportionally more females than males were enrolled in France and Czech Republic versus other countries. Patients were older in Sweden, Germany and UK; males were older than females except in France and Czech Republic. Mean baseline IGF-I SDS was below 0 across all countries. Mean GH peak was lower in males than in females and varied across countries. Mean BMI (kg/m^2) was >25 across all countries. Average baseline GH dose was lowest in Sweden, highest in UK (females) and lowest in Sweden, highest in France (males).

Table 1

	Germany	Sweden	Denmark	France	UK	Czech Republic

β-arrestin 2 expression is required for dopamine receptor type 2 (DRD2) inhibitory effects on Akt phosphorylation and cell proliferation in PRL-secreting and non functioning pituitary tumors

Federica Mangili[1], Elena Giardino[1], Donatella Treppiedi[1], Rosa Catalano[1,2], Marco Locatelli[3], Andrea G Lania[4], Anna Spada[1], Maura Arosio[1], Giovanna Mantovani[1] & Erika Peverelli[1]
[1]Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico; Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy; [2]PhD Program in Endocrinological Science, Sapienza University of Rome, Rome, Italy; [3]Neurosurgery Unit, IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [4]Endocrine Unit, IRCCS Humanitas Clinical Institute, Humanitas University, Rozzano, Italy.

Dopamine receptor type 2 (DRD2) agonists (DAs) are the first-choice treatment for PRL-secreting pituitary tumors due to their efficacy in reducing tumor size and hormonal secretion. However, DAs are poorly effective in non-functioning pituitary tumors (NFPTs), despite most of them express DRD2. No correlation between DAs clinical responsiveness and DRD2 expression was found, suggesting post-receptor alterations underlying resistance. DRD2 signaling pathways that control cell proliferation are mostly unknown. In particular, no data are available in pituitary tumor cells about DRD2 effects on Akt activation, a survival and proliferative pathway over-activated in pituitary tumors. In other cell models, a β-arrestin 2-mediated Akt inhibition by DRD2 has been shown. The aim of this study was to investigate the effects of DRD2 activation on Akt phosphorylation (p-Akt) and cell proliferation in human primary cultured NFPT cells and in rat tumoral lactotroph cells MMQ, and to test the involvement of β-arrestin 2. Firstly, Akt inhibitor GSK2110183 reduced cell proliferation in both MMQ ($-88.2\pm3.6\%$, $P<0.001$ vs bas) and NFPTs ($-41.4\pm10.9\%$, $P<0.01$ vs basal). DRD2 specific agonist BIM53097 inhibited p-Akt in MMQ ($-24\pm7\%$, $P<0.001$ vs basal) and in a subset (30%, $n=23$) of NFPTs ($-25\pm7\%$, $P<0.001$ vs basal) (subgroup 1), whereas increased p-Akt ($+1.9\pm1.2$ fold vs basal) in the remaining tumors (subgroup 2). Western blot analysis revealed a striking correlation between DRD2 ability to inhibit Akt and β-arrestin 2 expression, since it was expressed only in MMQ and NFPTs subgroup 1, but not subgroup 2. The mechanism by which DRD2 dephosphorylates Akt is G protein-independent, as demonstrated by pertussis toxin treatment in MMQ and NFPTs, and β-arrestin 2 mediated, since β-arrestin 2 silencing prevented DRD2 effects on p-Akt in MMQ. Accordingly, β-arrestin 2 transfection in subgroup 2 NFPTs conferred to DRD2 agonist the ability to inhibit both p-Akt ($-23\pm8\%$, $P<0.05$ vs bas) and cell proliferation ($-32.1\pm23.8\%$, $P<0.05$ vs bas). In conclusion, these data demonstrate that β-arrestin 2 is required for DRD2 inhibitory effects on Akt phosphorylation and cell proliferation in MMQ cells and NFPTs, paving the way for a potential role of β-arrestin 2 as a biomarker predicting NFPTs responsiveness to treatment with DAs.

Somatostatin receptor type 2 trafficking through the cytoskeleton: role of scaffolding proteins Filamin A and β-arrestin 2

Donatella Treppiedi[1], Elena Giardino[1], Rosa Catalano[1,2], Federica Mangili[1], Marco Locatelli[3], Anna Spada[1], Maura Arosio[1], Giovanna Mantovani[1] & Erika Peverelli[1]
[1]Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico; Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy; [2]PhD Program in Endocrinological Sciences, Sapienza University of Rome, Rome, Italy; [3]Neurosurgery Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy.

The high expression of somatostatin receptor 2 (SST2) in growth hormone (GH)-secreting tumors represents the rationale for the clinical use of somatostatin analogs (SSAs) in acromegaly. However, about one third of patients displays resistance to SSAs and, to date, the responsible molecular mechanisms are still under investigation. Recently, the cytoskeletal protein Filamin A (FLNA) and the scaffolding proteins β-arrestins have emerged as key modulators of the responsiveness of GH-secreting pituitary tumors to SSAs, by regulating SSTR2 signaling and desensitization, respectively. The aim of this study is to further explore FLNA involvement in SST2 intracellular trafficking in somatotroph cells, since alterations in this system might affect the amount of available receptor at the plasma membrane and lead to unresponsive tumor features. By biotinylation assay we first found that FLNA silencing strongly reduces octreotide-mediated SST2 internalization in rat GH-secreting pituitary tumor cell line, GH3 cells, ($26.9\pm2.7\%$ vs $4\pm1.7\%$ SST2 internalization, control vs FLNA SiRNA cells, respectively, $P<0.001$) and in one human GH-secreting primary culture tested (93.2% vs 31.6% SST2 internalization, control vs FLNA SiRNA cells, respectively). Then, co-immunoprecipitation and immunofluorescence experiments performed in GH3 cells showed that FLNA knock down does not prevent the recruitment of β-arrestin2 to cell surface ligand-activated SST2, but rather impairs receptor localization into cytosolic vesicles positive for the early endocytic marker Rab5 (Pearson's coefficient mean 0.29 ± 0.07 vs 0.16 ± 0.03 of SST2-Rab5 colocalization in control vs FLNA SiRNA, $P<0.01$). Furthermore, after octreotide removal, SST2 recycling fate was affected by the loss of FLNA. Conversely to control cells, SST2 failed to accumulate into intracellular recycling vesicles linked to the early recycling marker Rab4, as resulted by Rab4-SST2 colocalizaition analysis (Pearson's coefficient mean 0.24 ± 0.05 vs 0.16 ± 0.04 of SST2-Rab4 colocalization in control vs FLNA SiRNA, $P<0.05$) and could not reach the plasma membrane in wash out experiments. Altogether these data unveil a crucial role of FLNA in the regulation of octreotide-induced SST2 trafficking in GH-secreting cells, suggesting the possibility of targeting FLNA-SST2 complexes for the treatment of pharmacologically resistant GH-secreting pituitary tumors.

Pituitary neuroendocrine tumors (PitNETs) are mostly benign lesions originating from the anterior pituitary and represent 10–15% of all the intracranial neoplasms. PitNETs can be classified in non-secretory, clinically non-functioning pituitary adenomas (NFPAs), and secretory, comprising prolactin (PRL), growth hormone (GH) and adrenocoticotropic hormone (ACTH) PitNETs. Surgical resection is the first line treatment for PitNETs, whereas chemotherapy and radiotherapy are preferred for resistant or metastatic tumors. GH-releasing hormone (GHRH), apart from promoting pituitary GH secretion, exerts many extrapituitary functions, including stimulation of cell proliferation and survival. GHRH, GHRH receptor (GHRH-R) and splice variant 1 (SV1) of GHRH-R, are expressed in different cancer cell types, where they promote cell growth and tumor progression. Conversely, it has been shown that GHRH antagonists inhibit the growth of different tumors *in vitro* and *in vivo*; moreover, previous reports showed that first generation GHRH antagonists reduce the secretion of GH in tumoral rat GH-secreting (GH3) cells. However, to date the role of GHRH antagonists in PitNETs remains largely unknown. Thus, the aim of this study was to evaluate the effects of the novel GHRH antagonists, MIA-602 and MIA-690, on survival, apoptosis and hormone secretion using tumoral murine ACTH-secreting cells (AtT-20/D16v-F2) and tumoral rat PRL- and GH-secreting cells transfected with human GHRH-R (GH3-hGHRHR). Our results show that MIA-602 and MIA-690 dose-dependently reduced cell survival and promoted apoptosis in tumoral ACTH-secreting cells; moreover, we observed an increase in expression of the proapoptotic protein BAX and the tumor suppressor protein P53, paralleled by a reduction of the antiapoptotic protein Bcl-2. MIA-602 and MIA-690 also reduced colony formation and expression of c-Myc oncoprotein, indicating inhibitory activity on migration and proliferation. Furthermore, the combination of MIA-

602 or MIA-690 with Temozolomide (TMZ), the main chemotherapy agent for PitNETs, produced a synergistic effect on inhibition of cell survival in AtT-20 cells. Importantly, ACTH secretion was also attenuated when these cells were treated with the antagonists. Finally, our preliminary results showed that GHRH antagonists reduced cell survival and promoted apoptosis in GH3-hGHRHR. Overall, these results demonstrate GHRH antagonists reduce aggressiveness features in PitNETs, suggesting the putative utility of these drugs as novel therapeutic tool for the treatment of these pathologies.

Somatostatin receptor type 5 modulation by Filamin A in ACTH-secreting pituitary tumors

Donatella Treppiedi[1], Elena Giardino[1], Rosa Catalano[1,2], Federica Mangili[1], Marco Locatelli[3], Anna Spada[1], Maura Arosio[1], Giovanna Mantovani[1] & Erika Peverelli[1]
[1]Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico; Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy; [2]PhD Program in Endocrinological Science, Sapienza University of Rome, Rome, Italy; [3]Neurosurgery Unit, IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy.

Cushing's disease (CD) is a rare disorder of chronic hypercortisolism due to an adrenocorticotropic hormone (ACTH)-secreting pituitary tumor. Pasireotide, a multireceptor-targeted somatostatin (SST) analog with high binding affinity for the predominant SST receptor in human corticotroph tumors, SST5, has been recently approved to treat adult patients for whom surgery failed or does not represent a suitable option. However, to date, the molecular predictors of antisecretory and antiproliferative favorable responses to the medical therapy with pasireotide, are unclear. The cytoskeletal protein FLNA plays a crucial role in GH-secreting pituitary tumor responsiveness to somatostatin analogs by regulating the physiology of SST2. Aim of the present study was to investigate a possible involvement of FLNA in the modulation of SST5 expression, signaling and pasireotide-mediated downregulation. First, by co-immunoprecipitation experiments, we demonstrated that FLNA binds to SST5 in mouse tumor corticotroph AtT-20/D16v-F2 cells. FLNA genetic silencing led to statistically significant strong decrease of receptor expression in basal condition ($-45.3\pm$ 33.5% and -27 ± 12%, % of basal negative control, $P<0.05$, in AtT-20/D16v-F2 and primary tumoral corticotroph cells). Moreover, downregulation of SST5 was observed in negative control cells incubated with 10nM pasireotide for 72h (-46 ± 25.7%, $P<0.01$, % of basal), whereas no further reduction of SST5 was detected in FLNA silenced cells. Regarding SST5 signaling, FLNA expression knock down caused an impairment of SST5 inhibitory action on ERK 1/2 phosphorylation (-48 ± 25%, $P<0.05$, in negative control cells vs $-22\pm$ 30.3%, $P=$ ns, in FLNA silenced cells). Furthermore, by Western blot, FLNA and SST5 protein expression levels correlates in 8 human ACTH-secreting pituitary tumors tested ($r=0.762$, $P=0.037$). Interestingly, a trend of higher FLNA protein expression levels were observed in the group of primary tumor cultures that responded to pasiretoide (with reduction of p-ERK1/2 levels) compared to the not responding group ($P=0.071$). In conclusion, our study demonstrated that FLNA is implied in SST5 expression modulation and SST5 signal transduction mechanisms. Additional experiments are needed to unveil a possible role of FLNA in the inhibitory effect of SST5 on ACTH secretion.

The PATRO adults study of Omnitrope® for the treatment of adult patients with growth hormone deficiency: latest safety results

Paolo Beck-Peccoz[1], Charlotte Höybye[2], Robert D Murray[3], Suat Simsek[4], Markus Zabransky[5], Hichem Zouater[5] & Günter Stalla[6]
[1]Fondazione Istituto di Ricovero e Cura a Carattere Scientifico Cà Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Karolinska University Hospital, Solna, Sweden; [3]St James's University Hospital, Leeds, UK; [4]Medisch Centrum Alkmaar, Alkmaar, Netherlands; [5]Sandoz International GmbH, Holzkirchen, Germany; [6]Medicover Neuroendokrinologie und Medizinische Klink und Poliklinik IV der Ludwig-Maximilians-Universität, München, Germany.

Introduction
PATRO Adults is an ongoing, longitudinal, noninterventional study assessing the long-term safety and efficacy of Omnitrope® (Sandoz; recombinant human growth hormone [rhGH]), among adults with severe growth hormone deficiency (GHD) treated in routine clinical practice in European countries. Omnitrope® was approved by the European Medicines Agency (EMA) in 2006, representing the first biosimilar approved by the EMA. We report the latest safety data from PATRO Adults, focusing on diabetes risk.
Methods
Adult patients receiving treatment with Omnitrope® and providing informed consent were eligible for inclusion, regardless of prior treatment with another rhGH. This interim analysis was performed using data available as of 30th November 2018.
Results
At the interim analysis timepoint, 1324 patients had been enrolled since 2007, including 1106 (83.5%) with adulthood-onset and 206 (15.6%) with childhood-onset GHD. In total, 665 (50.2%) patients had previously received another rhGH. Mean age at baseline was 49.2 years (standard deviation [SD]: 15.4), with mean BMI of 29.5 kg/m^2 (S.D.: 6.4). Overall, 4287 adverse events (AEs) were reported by 934 (70.5%) patients; 812 of these events (among 400 [30.2%] patients) were serious AEs (SAEs). One hundred and sixty-nine AEs in 102 (7.7%) patients were suspected to be treatment-related, with musculoskeletal/connective tissue disorders (36 patients), general disorders/administration site conditions (27 patients), and nervous system disorders (24 patients) most commonly reported. Twenty-eight SAEs (among 21 patients [1.6%]) were suspected to be treatment-related, resulting in treatment discontinuation in 7 patients. Overall, 349 (26.4%) patients have discontinued the study, 83 (6.3%) due to AEs (31 [2.3%] due to treatment-related AEs). Twenty-eight cases of diabetes have been reported as AEs (24 in combined GHD patients; 27 in adulthood-onset GHD); 14 cases were SAEs, of which 3 were suspected to be treatment-related. These three cases included: diabetes in a 29-year-old male with childhood-onset combined GHD, following ~11 years' GH therapy, in whom Omnitrope® treatment was not changed; diabetes mellitus aggravation in a 45-year-old male with adulthood-onset combined GHD, following 4–6 months' GH therapy, in whom treatment was discontinued; and worsening of diabetes in a 72-year-old male with adulthood-onset combined GHD, following 19 years' GH therapy, in whom treatment was interrupted.
Conclusions
This interim analysis indicates that Omnitrope® is well tolerated in routine clinical practice, including among those previously receiving GH. The ongoing PATRO Adults study will provide further insights into the overall safety and diabetogenic potential of long-term GH.

Diabetes insipidus and diabetes mellitus type 2 diagnosed at the same time in a male with langerhans cell histiocytosis

Carlos Antich Barceló, Guillermo Serra Soler, Mercedes Noval Font, Elena Mena Ribas, Santiago Tofé Povidano, Iñaki Argüelles Jiménez, Honorato García Fernández & Vicente Pereg Macazaga
Hospital Son Espases, Palma de Mallorca, Spain.

Introduction
Langerhans cell histiocytosis (LCH) is a rare systemic disease. Diabetes insipidus is the most frequent endocrine alteration and occurs mostly after diagnosis. Others are hypogonadism, growth hormone deficiency (GHD) and alterations in glucose metabolism.
Clinical case
A 61-year-old smoker, diagnosed with LCH 9 years ago with pulmonary and hepatic involvement, without treatment, who consulted for asthenia, unquantifiable polyuria, polydipsia and 3 kg of weight loss over a period of 2 weeks. The physical examination showed blood pressure of 128/81 mmHg and dry mucus membranes. The blood test showed hypernatremia, hyperchloraemia, hyperglycemia and elevated glycosylated hemoglobin (HbA1c). It was oriented as type 2 diabetes mellitus (DM2) and treatment with metformin was initiated. The patient did not show improvement and because of the persistence of the same symptoms he went to the emergency department. The blood test showed hypernatremia with high osmolality, hyperglycemia, hypercalcemia and elevated HbA1c. The 24-hour urine test was 10 litres and had decreased osmolality and density. Given these findings, Diabetes insipidus was also diagnosed with DM2. A pituitary magnetic resonance was requested that revealed thickening of the pituitary stalk and absence of posterior pituitary bright spot in the T1 sequence. Treatment was started with sublingual desmopressin with normalization of serum sodium and diuresis. The pituitary hormones were normal, except for an elevation of cortisol and ACTH and a decreased vasopressin. Cortisol after 1 mg dexamethasone suppression test was normal. Positron emission tomography (PET) showed hypermetabolism only in the pituitary gland. The patient was discharged with sublingual desmopressin 60 mcg every 8 hours and metformin 850 mg every 12 hours.

Conclusions
- We have to consider the endocrinological alterations in patients diagnosed with LCH and their referral to Endocrinology consultations
- The importance of quantifying polyuria and assessing the coexistence of two types of diabetes in these patients, as in our case

Assessment of endocrine function before and after transsphenoidal surgery for Cushing s disease

Galina Kolesnicova, Svetlana Arapova, Evgenia Marova & Andrey Grigoriev
Endocrinology Research Center, Moscow, Russian Federation.

It is known that disoaders of the hypothalamic-pituitary-adrenal system and excess glucocorticoids in Cushing's disease (CD) can significantly affect various organs and systems, in particular, the secretion of pituitary hormones. However, in the literature there is practically no work on the assessment of the state of tropic hormones and hormones of the peripheral glands in the early postoperative period after transsphenoidal adenomectomy. The aim of this study was to assess the effect of transsphenoidal adenomectomy on the state of pituitary function before and in the early postoperative period in patients with Cushing's disease. The our study included 434 patients with active stage of Cushing's disease {374 women (age 38.0 (23–55) years) and 60 men (age 32 (19–51) years}. The duration of the observation from 2001 to 2017. The state of pituitary function was analyzed in patients with CD before and directly in the early postoperative period (average follow-up period from 4 to 14 days) on the basis of hormonal parameters in peripheral blood in the morning (GH, prolactin, TTH, fr T_4, LH, FSH, estradiol, testosterone). The content of ACTH and cortisol in the blood was determined two times a day: in the morning and in the evening, and the average daily content of these hormones was calculated. In addition, to confirm the diagnosis of CD, a study of free cortisol levels in saliva (in the evening) and daily urine was conducted. It was shown that the number of patients with simultaneous reduction of all tropic hormones was minimal – only 22 (4.7%). Different combinations of hormone reduction were found in other patients. The most common decrease in blood levels of prolactin (66.2%) and TSH (53.0%). The most rare decrease in gonadotropins: LH-36.7% and FSH – (21.2%). This mosaic in the lower level of tropic hormones, which may be explained by the fact that often the cells of the pituitary tumors have a mixed activity, and most often in conjunction with an ACTH produce prolactin. Thus, the rehabilitation of patients with CD after transnasal adenomectomy is a complex multicomponent process characterized by a complex approach to therapy and requires regular monitoring of all the tropic functions of the pituitary gland.

Diverticular perforation of colon: a dangerous complication in Cushing's disease

Güzide Gonca Örük[1], Dilek Karakuş[2], Gökce Eglenoglu[3], Barış Önder Pamuk[2] & Melda Apaydin[4]
[1]Katip Celebi University Ataturk Training and Research Hospital, Endocrinology and Metabolism, Izmir, Turkey; [2]Katip Celebi University Ataturk Training and Research Hospital, Endocrinology and Metabolism, Izmir, Turkey; [3]Katip Celebi University Ataturk Training and Research Hospital, Internal Medicine, Izmir, Turkey; [4]Katip Celebi University Ataturk Training and Research Hospital, Radiology, Izmir, Turkey.

Exposure to supraphysiologic doses of exogenous glucocorticoids is associated with gastrointestinal (GI) complications such as peptic ulcer disease, gastrointestinal hemorrhage, duodenal ulcer, and colonic diverticular perforation (DP). Patients receiving high dose glucocorticoids, for rheumatological or autoimmune disease are at increased risk for lower gastrointestinal tract abscesses and perforation. However, little is known about GI complications in endogenous hypercortisolism caused by Cushing syndrome (CS). Here we present a case with Cushing Disease (CD) who developed sudden diverticular perforation (DP) that necessitated surgical intervention. 29 years old female patient was first admitted to outpatient clinic with symptoms of weight gain, edema, weakness, easy bruising, wide purplish stria, hirsutism and skin atrophy. There was history of refractory hypertension, diabetes mellitus,heart failure, asthma bronchiale and menstrual irregularity. She was married and had two children. On presentation the patient had a blood pressure of 190/95 mmHg and a potassium level of 2.6 meq/L. Her physical exam was significant for a moon and plethoric face, dorsocervical fat pad, abdominal obesity and skin thinning with several large areas of ecchymosis. Biochemical evaluation confirmed severe hypercortisolism: Cortisole: 25.13 µg/dl, 1 mg dexamethason suppression test (DST): 24.9 µg/dl, 2 day 2 mg DST: 19 µg/dl, ACTH- 210 pg/ml, 24-hour urinary free cortisol (UFC) 690 mg, diurnal rhythm was disturbed midnight 0300 h cortisole: 20 µg/dl. MRI of the pituitary showed an area of 5 mm in the left lobe of the pituitary that had decreased uptake of contrast on early dynamic screening. Transphenoidal hypophysectomy was performed and ACTH secreting adenoma (Kİ67: <%1) was found on pathological examination. While she was being followed with symptoms due to diabetes insipidus and hypokalemia, 15 days following surgery, the patient also developed symptoms of abdominal pain and vomiting. Laparotomy revealed an intra-abdominal abscess and extensive colonic diverticulitis with evidence of perforation at the ascending colon. Right hemicolectomy with colostomy was performed and pathological specimen revealed diverticular disease complicated with supurative inflammation, diverticulitis, multiple intraabdominal abscesses. This case illustrates the potential for fulminant diverticular disease complications in patients with Cushing's disease. Multiple elements contribute to the increased risk of diverticular perforation in association with hypercortisolism. Surgeons and endocrinologists should be aware of this potentially fatal complication when caring for patients with Cushing's disease. When treating such patients, this risk should be eliminated through management of malnutrition, uremia, hypokalemia, constipation, early detection and aggressive management of diverticulitis and DP.

A retrospective study of 275 cases of pituitary intervention in south great plain region of Hungary

Krisztina Kupai [1], Béla Fülöp[2], László Tiszlavicz[3] & Zsuzsanna Valkusz[1]
[1]First Department of Medicine, University of Szeged, Szeged, Hungary; [2]Department of Neurosurgery, University of Szeged, Szeged, Hungary; [3]Department of Pathology, University of Szeged, Szeged, Hungary.

Objective
Tumors of the pituitary gland and sellar region, called pitiutary adenoma (PA) represent approximatly 10% of all central nervous system tumors. The characteristics of these tumors may vary from population to population.
Aim
The aim of this retrospective study was to investigate and understand the clinicopathological characteristics, the invasiveness, tumor features and clinical symptoms of PA in adult patients at south great plain region of Hungary.
Design and methods
Totally, 275 patients were retrospectively reviewed from 2007 to 2017. At 171 cases the pathological diagnosis was pituitary adenoma. Patients were periodically followed up at the Department of Neurosurgery and 1st Department of Medicine, University of Szeged, Clinical Center. Data of general information, clinical symptoms, invasive behaviors, surgery approaches, adenoma type by immunhistochemistry and adenoma relapses were collected and analyzed. All patients underwent transsphenoidal approach: total of 83 (48.53%) males and 87 females (50.87%) were diagnosed as pituitary adenoma with the mean age of 52.1 and 53.7 years, respectively. The main clinical manifestations were visual defects, headache and hormonal abnormalities such as increased growth hormone (GH), prolactin (PRL) and adrenocorticotropic hormone (ACTH), respectively. Among the patients with firm adenomas 21.63% had hypopituitarism.
Results
Based on the WHO 201 classification of pituitary adenomas, the types of adenoma in the investigated region were the following: 53% non-functioning null cell adenoma. Among the hormonally active adenomas 22% was somatotroph, 9-9% lactotroph and plurihormonal and 7% corticotroph. Interestingly, the adenoma recurrence was observed not in null cell adenomas; 41.6% relapse was detected in ACTH producing type.
Conclusion
Detailed clinical, hormonal and pathological evaluation is essential for better understanding the nature of adenoma growth and its progression. This study is the first at this region which overview the PA from endocrinological, neurosurgical and pathological aspects together. Specialized care and teamwork of endocrinologists, neurosurgeons, pathologists are equally important during treatment planning.

DOI: 10.1530/endoabs.63.P272

Differences of efficiency of treatment of isolated growth hormone deficiency and panhypopituitarism in children in real clinical practice

Ekaterina Rudkova & Ivan Grisuk
Belarusian State Medical University, Minsk, Belarus.

Introduction
Deficiency of growth hormone (GH) in children is manifested by pronounced stunting (below −2 sigmal abnormalities (SD)), different changes in body composition. Frequency of occurrence varies from 1:4000 to 1:10000 newborns.
Objective
To assess the effectiveness of treatment by comparing the dynamics of growth of those with isolated growth hormone deficiency (IGHD) and of those with panhypopituitarism (PHP).
Materials and methods
Medical History of 47 patients aged from 3 to 18 years diagnosed with IGHD and PHP in 2006–2018 have been analyzed in the Republican Center for Pediatric Endocrinology. Microsoft Excel, SPSS have been used for statistical data analysis.
Findings
Among 47 patients participating in the study (66% girls, 34% boys) eighty-three per cent (83%) is with IGHD and seventeen per cent (17%) with PHP. It was revealed that before treatment, 36 patients had a significantly short stature (from –6 to –2.01 SDS); SDS of 11 patients (2 of them with PHP) was from −1.9 to −1. At the time of diagnosis, the mean height SDS was −2.4 in children with IGHD, after completion of treatment, SDS was −1,4; height SDS was −2.7 before treatment and −0.8 after completion of treatment in children with PHP. The largest values of STH maximum level according to stimulation tests was 6.8 ± 5.2 ng/ml in group with IGHD and 2.56 ± 1.65 ng/ml in group with PHP ($P < 0.05$). IGF-1 was below normal range in 76.6%, after treatment it was below normal range in 46.68% of patients; the IGF-1 level in the group with PHP was lower compared to the IGHD group ($P < 0.05$) and were observed in 87.5%. After treatment completion, IGF-1 remained below reference values in 87.5% of patients with PHP. A lagging of the bone age from the passport in the IGHD group before treatment was 2 years 5 months ±1 year 3 months, after treatment it was 2 years 5 months ±2 years; in the group with PHP it was 2 years 11 months ±1 year 4 months before treatment and 3 year 7 months ±4 year 7 months after treatment ($P < 0.05$). The average dynamics of growth during the entire period of treatment in patients with IGHD is 6.9 ± 1.62 cm/year, while in patients with PHP it is 7.9 ± 4.3 cm/year ($P < 0.05$).
Conclusion
Comparative analysis of the effectiveness of growth hormone treatment showed a significant dynamics of growth, more obvious in patients with panhypopituitarism.

Functioning gonadotroph adenoma in a 46 years old male

Mihai Lucian Pavel[1], Anca Elena Sirbu[1,2] & Simona Fica[1,2]
[1]Elias University Emergency Hospital, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania.

Introduction
Functioning gonadotroph adenomas (FGA) are adenomas secreting and expressing biologically active gonadotropins and causing distinct clinical manifestations. The vast majority of the immunohistochemically confirmed gonadotroph adenomas are hormonally silent (presenting only with mass effects), clinically FGA's being very rare; whereas their exact prevalence is not known.
Case study
A 46 years old male patient presents to our clinic after being diagnosed with pituitary macroadenoma on MRI scan. The scan was made for elucidating the cause of cluster type of headache, symptom that appeared 4 years prior to the investigation. The contrast MRI scan showed a 37/34/24 mm expansive mass located intra-, supra-, and infrasellar, going in the sphenoidal sinus. General examination revealed symptoms like headache and increased libido, while the signs showed right facial muscle spasm and macro-orchidism (approx. 45 ml). Blood test showed polyglobulia (RBC = $6.70*10^6$/µl, Hb = 17.9 g/dl, Hct = 55.6%) and increased levels of FSH (145.4 mIU/ml), LH (23.2 mIU/ml), Testosterone (>1500 ng/dl), Estradiol (152.8 pg/ml). We recommended surgical intervention for the macroadenoma. Histopathology slides made by hematoxylin and eosin staining revealed a proliferation of cuboidal-columnar and oval cell with a fine chromatin nucleus, eosinophilic cytoplasm, arranged in a trabecular, papillary and perivascular pattern, with the reticulin network disorganized at tumoral level. Immunohistochemical testing found positive result for chromogranin A, FSH and LH with a Ki 67 of 4%. The patient presented 3 months after surgery for postoperative evaluation. On the follow up contrast MRI scan no tumoral rest was detected, the head ache was gone but the facial muscle spasm remained. The patient accused a lack of libido and a decrease in testicular size (in present approx. 30 ml). The CBC returned to normal, the FSH dropped to 1.6 mIU/ml, LH to 1.12 mIU/ml, Testosterone to 23.05 ng/dl and Estradiol to 5 pg/ml. After a Diphereline 0.1 mg (triptorelin) stimulation test FSH and LH levels remained the same at 4- and 24-hour testing. We started testosterone replacement therapy.
Conclusion
This is a rare case of functioning gonadotroph adenoma treated surgically. The 46 years old patient is now suffering gonadotropin insufficiency for which he receives testosterone replacement therapy.

Acromegaly: ominous cause of hirsutism

Manel Jemel[1,2], Mahdi Khalthoum[1], Hajer Kandara[1,2], Meriem Stambouli[1], Sonia Nagi[2,3], Leila Mansouri[1] & Ines Kammoun[1,2]
[1]National Institute of Nutrition and Food Technology Department of Endocrinology, Tunis, Tunisia; [2]Manar University Tunis, Tunis, Tunisia; [3]National Institute of Neurology and Food Department of Neuroradiology, Tunis, Tunisia.

Hirsutism though common in women of reproductive age, is classically associated with polycystic ovarian syndrome (PCOS). It is rarely seen as a prominent feature of acromegaly because of its lack of specificity and occurrence. We report a case of 28-year-old female with 3 year duration of aligoamenorrhea and hirsutism. She was followed by a gynecologist who retains the diagnosis of polycystic ovary syndrome (PCOS). After 5 years the patient complaints of increased hand finger and shoes size. She was referred to endocrine department for suspicion of Acromegaly. Clinical examination revealed acromegaloidism features with mandibular prognathism and moderate macroglossia wic. Biological investigation were significant for elevated insulin-like growth factor 1 (IGF-1) level (774 ng/ml normal: 98–290 ng/ml) and a growth hormone level not suppressed by a glucose challenge test. MRI brain revealed a pituitary macroadenoma (10.7× 14 mm). The patient underwent an uncomplicated trans-sphenoidal resection of a pituitary macroadenoma. Immunohistochemistry demonstrated a GH tumor. The patient subsequently had normalization of growth hormone dynamics and regular menstrual cycles. Our case highlights the importance of a lookout for subtle features of acromegaly in patients with hirsuitism and going for hormonal investigation to make the diagnosis of acromegaly at an earlier stage of the disease.

Pituitary apoplexy: clinical features, management and outcomes

Meriem Riahi[1], Manel Jemel[2,3], Hajer Kandara[1,3], Wafa Mimita[1], Leila Mansouri[1] & Ines Kammoun[1,3]
[1]National Institute of Nutrition and Food Technology Department of Endocrinology, Monastir, Tunisia; [2]National Institute of Nutrition and Food Technology Department of Endocrinology, Tunis, Tunisia; [3]El Manar University Tunis, Tunis, Tunisia.

Background
Pituitary apoplexy is a rare clinical syndrome due to abrupt hemorrhaging and/or infarction of the pituitary gland, generally within a pituitary adenoma. The outcome of acute apoplexy is variable and difficult to predict. This explains why the optimal management of acute pituitary apoplexy remains controversial. The aim of our study was to investigate the clinical, hormonal and radiological characteristics of pituitary apoplexy and to determine treatment outcomes.
Methods
We performed a retrospective study of pituitary apoplexy managed at the department of endocrinology, National Institute of Nutrition over a 23-year.
Results
A series of 33 patients with a clinical diagnosis of pituitary apoplexy was reviewed. It included 16 men and 17 women aged between 21 to 73 years (mean age: 42 years). A pituitary adenoma was unknown at the time of apoplexy in twenty-eight patients. Pituitary apoplexy occurred in macroadenoma in all the cases. It was observed most frequently in non functioning adenoma,

A precipitating factor was identified in ten cases. Tumor syndrome with headache of sudden was the main complaint: 81.9%, associated with decreased of visual acuity in 57.7% of cases, visual-field impairment with bitemporal hemianopsia in 18.2%. Corticotropic deficiency which is the life threatening complication was noted in 11 patients. Thyrotropic deficiency was the most common endocrine deficiency in our work (36.4%). The diagnosis of pituitary apoplexy has been confirmed by cerebral computed tomography in 6 cases and magnetic resonance imaging in 27 cases. Surgery was indicated in 61% of cases and 39% of patients received conservative medical treatment. The outcomes in terms of visual disturbances were a resolution in 86% after conservative treatment, against 100% improvement after surgery. After conservative treatment, 39% of patients normalized their pituitary function versus 65% in the group that received surgical treatment, but one patient developed diabetes insipidus and 4 patients maintained hypopituitarism with a permanent corticotropic deficiency. Three patients had tumor recurrence after surgery.

Conclusion

Pituitary apoplexy can be difficult to diagnose. It is usually related to a pituitary unknown macroadenoma. A high index of clinical suspicion is essential to diagnose this condition as prompt management may be life and vision saving. It is always used to be treated surgically; nowadays conservative management can be used in selected patients.

Gross total versus incomplete resection of craniopharyngioma in adults

Cristina Capatina[1,2], Anda Dumitrascu[2], Andra Caragheorgheopo[2], Vasilie Ciubotaru[3] & Catalina Poiana[1,2]
[1]Carol Davila UMPh, Bucharest, Romania; [2]CI. Parhon National Institute of Endocrinology, Bucharest, Romania; [3]Bagdasar Arseni Emergency Hospital, Neurosurgery Department, Bucharest, Romania.

Background

Craniopharyngioma is a rare epithelial tumor of the central nervous system, affecting both children and adults and associated with significant morbidity.

Objective

To study the postsurgical evolution of craniopharyngioma in adults after total or incomplete surgical resection.

Material and methods

We performed a retrospective review of craniopharyngioma patients evaluated in the National Institute of Endocrinology in Bucharest between 1998 and 2018.

Results

A total of 60 patients (39.62 ± 15.6 years-old) diagnosed with craniopharyngioma were included. All underwent initial surgery (68.3% transcranial, 31.7% transsphenoidal approach). Gross total resection (GTR) was achieved in 21 cases (35%), in all the others maximal resection was attempted (non-GTR). Surgery led to anosmia (in 2 cases), CSF leak (3 cases), subdural hematoma (2 cases). After surgery 13 cases (21.66%) had cognitive impairment (2 with GTR, 11 with non-GTR), 14 (23.3%) had hypothalamic syndrome (diurnal sleepiness, appetite and memory dysfunction- present in 1 case with GTR, 13 with non-GTR), 27 cases (45%) reported lethargy (7 GTR, 20 non-GTR), 24 (40%) complained of headaches (6 GTR, 18 nonGTR). All these complications were significantly more frequent in cases with incomplete tumor resection compared to those with GTR: $P = 0.000$; 0.000; 0.036 and 0.009, respectively.

Conclusions

Craniopharyngioma is a tumor associated with very significant morbidity. GTR should only be attempted when a low risk of neurologic injury is considered; for the rest of the cases limited tumor resection followed by irradiation of the remnant might be the safest approach.

When a rare syndrome keeps behaving in rarer manners over and over again!

Sarah Craus[1], Miriam Giordano Imbroll[1] & Mark Gruppetta[1,2]
[1]Mater Dei Hospital, Msida, Malta; [2]University of Malta, Msida, Malta.

Pituitary apoplexy arises when haemorrhage and/or infarction occurs within a pituitary tumour. In Malta, the estimated standardised incidence rate (SIR) of apoplexy is 0.15/100,000/yr. ACTH secreting pituitary adenomas have a SIR of 0.17/100,000/year.

Case Report

A 46 year-old gentleman with a history of poorly controlled diabetes mellitus was referred following the diagnosis of a pituitary adenoma. He had presented with a 1.5 year history of left third cranial neuropathy with complete ptosis. Magnetic resonance imaging (MRI) showed a 3.2×1.5 cm lesion extending into the suprasellar cistern, abutting the optic chiasm and extending into the cavernous sinuses, more pronounced on the left side. Biochemical assessment revealed cortisol of 483 nmol/l, prolactin 31 mIU/l, Testosterone 3.5 nmol/l, LH 1.9 U/l, FSH 4.5 U/l, TSH 2.34 micIU/l and T4 12.27 pmol/l. The patient had an inadequately suppressed cortisol level (149 mmol/l) on a 48-hour low dose dexamethasone suppression test and a high ACTH (102 pg/ml) in keeping with ACTH-dependent Cushing's syndrome. The patient was referred for infra-petrosal sinus sampling, which confirmed an ACTH secreting pituitary macroadenoma. The patient could not undergo surgery at the time in view of an infected diabetic foot ulcer. He was initiated on Metyrapone in an effort to control his hypercortisolaemia. The patient presented two months later with severe headache and new onset visual disturbances. He developed a right III and VI cranial nerve (CN) palsies. Ophthalmological assessment revealed a reduction in visual acuity. Areas of hyperintensity in the pituitary adenoma were noted on unenhanced T1 MRI scan and there was lack of enhancement on a contrast scan, in keeping with apoplexy. Urgent debulking was carried out through a trans-sphenoidal approach. Clinical symptoms and visual disturbances showed improvement post-operatively; the right 3rd and 6th CN palsies improved but he had a persistent right temporal visual field defect. Histology confirmed pituitary apoplexy due to tumour infarction of a functional (ACTH secreting) pituitary macroadenoma.

Conclusion

Presentation of Cushing's Disease can be very varied and the work up is extensive and elaborate with a number of different steps. Cushing's syndrome is associated with multiple comorbidities including increased risk of cardiovascular events, neurological consequences osteoporosis and poor quality of life. Hence, it is imperative that an early diagnosis is made as early as possible so that the condition is appropriately treated. Although apoplexy is rare, this complication needs to be kept in mind as an inherent risk when managing patients with pituitary adenomas.

Ipilumumab induced hypophysitis

Sarah Craus[1], Miriam Giordano Imbroll[1] & Mark Gruppetta[1,2]
[1]Mater Dei Hospital, Msida, Malta; [2]University of Malta, Msida, Malta.

Introduction

Immunotherapy has advanced significantly over the past years. Immune-related adverse events (IRAEs) are various and include endocrinological complications such as Ipilimumab-induced hypophysitis (IIH). The incidence of this cytotoxic T-lymphocyte antigen 4 antibody ranges from 0 to 17%. Patients usually present with symptoms secondary to hormonal insufficiencies.

Case report

A 73 year-old lady, known case of metastatic melanoma on immunotherapy presented with a 1 week history of pre-syncopal episodes and nausea. She gave a few week history of non-vertiginous dizziness, lethargy and headache. The patient had received her third course of ipilimumab few days prior to presentation. Cortisol level during admission was 23 nmol/l, from a previously normal level of 993 nmol/l few weeks prior. The patient had low T4 and TSH levels (0.080 mIU/ml and 6.7 pmol/l respectively) together with low FSH (2.4 U/l), LH (0.6 U/l) and prolactin levels (59 mIU/l) in keeping with panhypopituitarism. The patient was started on glucocorticoids and thyroxine with rapid improvement of her symptoms.

Imaging

MRI brain at presentation showed a $1.5 \times 1.4 \times 1.2$ cm sellar lesion involving the pituitary gland with mild suprasellar extension. The lesion demonstrated low T1 and mildly hyperintense T2 signal intensity and enhanced avidly following contrast administration, with a central non-enhancing component. The infundibulum was thickened. Repeat MRI after 3 months revealed complete resolution of the sellar and infundibular changes with normalization of the gland confirming the initial hypothesis of hypophysitis.

Discussion

Literature suggests that a high index of suspicion for hypophysitis needs to be kept in mind in patients receiving immunotherapy. It is advised that patients undergo 6 monthly assessment of pituitary function and MR scans should be compared to previous imaging if available to assess for a change in pituitary size. In hypophysitis, the degree of pituitary enlargement should reduce after treatment as was in our case. If this is not observed, alternative diagnoses such as pituitary metastasis should be considered. It is debatable whether patients with IIH should

be administered higher dosages of glucocorticoids in contrast to physiological replacement, since there are concerns that treatment with high dosages of glucocorticoids may affect the antitumor efficacy of Ipilimumab. In our patient, a physiological replacement dose was sufficient for her to improve clinically and have complete resolution of symptoms after 3 months.
Conclusion
Development of IIH can precipitate acute adrenal failure or crisis. Early diagnosis and management are vital to prevent complications including increased morbidity and mortality rates.

Acute lethargy, the main symptom of macroprolactinoma

Esther Delgado Garcia, Emilia Gomez Hoyos, Ana Ortolá Buigues, Susana Garcia Calvo, Cristina Serrano, Rebeca Jimenez Sahagun, Juan Jose Lopez Gómez, Beatriz Torres Torres, Gonzalo Diaz Soto & Daniel De Luis Roman
Endocrinology Department of University Hospital of Valladolid, Valladolid, Spain.

Introduction
The most common pituitary adenoma is a prolactinoma.The most relevant clinical manifestations are amenorrhoea galactorrhoea infertility *gonadal and sexual dysfunction*. Macroprolactinoma are more often in men because they had more difficulty for asking the sintomatology. Initial treatment of macroadenoma wasinitiated with a dopamine agonist with control of PRL concentration and size of tumor
Clinical case
A 52-year-old manpresented at the emergency roomby acute lethargy. He has acongenital blindness, deafness and chronic depression with history of suicide attempt in three times. He had only taken lorazepam. He didn't complain ofdecreased libido, impotence, or infertility.On examination, he had blilater-alasymptomatic ginecomastia. There were no other stigmata of endocrine dysfunction. Pituitary MRI found a pituitary macroadenoma ($27 \times 17 \times 15$ mm) and laboratory evaluations showedhyperprolactinemia(PRL 1998 ng/ml) and central hypogonadism, adrenal insufficiency. The patient was prescribed the dopamine agonist cabergoline (0.5 mg twice a week) hydroaltesone 30 mg. After 4 months of treatment, PRL level decreased to 47.17 ng/ml, normalitation of testosterone and tumor size wasn't suffer any change. After a year of treatment PRL concentration was normal (8.20 ng/ml) and tumor size has been reduced by one third ($10 \times 6 \times 5$ mm)
Conclusion
Our clinical case is an atypical manifestation of pituitary adenoma. The treatment with dopamine agonist allowed restore only gonadal funtion and control size of tumor.

Pituitary apoplexy: which treatment?

Youssef Lazreg, Amine Ezzerrouqi & Hanane Latrech
Department of Endocrinology- Diabetology, Mohammed VI University Hospital, Mohammed I University, oujda, Morocco.

Introduction
Pituitary apoplexy (PA) is a syndrome caused by acute hemorrhage or infarction of the pituitary gland, generally within a pituitary adenoma. Early diagnosis of PA and a multidisciplinary approach are essential for the timely treatment of pan-hypopituitarism and prevention of severe neurologic complications.
Observation
We report the cases of two men aged 46 and 53 years old with pituitary apoplexy. Apoplexy occurred in one patient with pre-existing pituitary macroadenoma and as a presenting form in the second case. Unilateral ptosis with severe visual acuity loss was the main clinical symptom in one patient and without visual acuity loss in the second one. Hypothalamic-pituitary MRI showed a macro-adenoma with hemorrhagic remodelling in one case and heterogeneous intrasellar processes in T1- and T2-weighted images. Necroticohaemorrhagic areas were observed in the second patient. Surgical treatment was proposed for both patients, after a multidisciplinary meeting. Only one patient underwent transsphenoidal surgery while conservative treatment was the therapeutic option chosen by the second one. The hormonal evaluation revealed an anterior pituitary insufficiency in both cases leading to an appropriate hydrocortisone and levothyroxin substitution.
Conclusion
The treatment of pituitary apoplexy remains controversial. Therefore, its management inside a pituitary referral center should be the rule. But the main issue remains about choosing the best therapeutic option: either surgery or conservative treatment.

Cushing disease: Clinical presentation

Paloma Moreno-Moreno, Concepción Muñoz-Jiménez, Ana Barrera-Martín & María Ángeles Gálvez-Moreno
Hospital Universitario Reina Sofía, Córdoba, Spain.

Objective
Cushing's disease (CD) accounts for approximately 80% of cases of Cushing's syndrome. Its clinic is nonspecific and its diagnosis difficult. The objective of this study is to review the most frequent clinical signs of this disease in our environment and compare it with that described in the literature.
Patients and methods
Retrospective descriptive study of patients with CD. We included all patients diagnosed with CD (2005–2017) treated with transsphenoidal surgery, and whose tumor sample was analyzed in the Department of Cell Biology, Physiology and Immunology of the University From Córdoba. Variables analyzed: age, sex, body mass index (BMI), reason for consultation, clinical presentation and time to diagnosis. The data obtained were compared with those described in the literature. Statistical analysis (SPSS v.18.0 for Windows): t-student for comparison of means and McNemar for comparison of proportions.
Results
Thirty-seven patients with CD. Age 45.03 ± 13.13 years. Women: 94.6% %. Cyclic EC: 10.8%. Time to diagnosis: 40.96 ± 31.91 months. Most frequent reason for consultation: suspected cushing syndrome (24.3%), obesity and overweight (24.3%) and type 2 diabetes (DM-2). BMI: 32.91 ± 7.06 kg/m^2. Clinical presentation: central obesity 90.9%, asthenia 93.1% ($P=0.001$), menstrual disorders 46.2% ($P=0.000$), face of a full moon 93.5%, cutaneous atrophy 85%, cervical lipomatosis 89.3%, muscular atrophy 84.6%, fragile capillary 56.3%, hirsutism 83.3%, raclavicular fat 87.5%, stretch marks 57.1%, acne 63.6% and edema 46.2%. Comorbidities: arterial hypertension 62.2%, osteoporosis 50% (8.3% atypical fracture), dyslipidemia 37.8%, DM-2 43.2% ($P=0.02$), depression 34.6%, infections 8.3% ($P=0.03$), gastric ulcus 14% and stroke 2.7%.
Conclusions
CD is more frequent in women, predominating in the fourth decade. Clinic present in our series is very similar to that described in the literature. Only significant differences were seen with the published series on the appearance of menstrual disorders, diabetes mellitus and infections, which is higher in the literature. The presence of asthenia is greater in our series.

The Importance of AGR2 Expression in Pituitary Adenoma Tissue Specimens on Tumor Aggressivity

Sema Ciftci Dogansen[1], Omur Gunaldi[2], Ayla Solmaz Avcikurt[3], Baris Colluoglu[2], Ilhan Yilmaz[2], Meral Mert[1] & Osman Tanriverdi[2]
[1]Division of Endocrinology and Metabolism, Department of Internal Medicine, Bakırkoy Dr. Sadi Konuk Training and Research Hospital, Istanbul, Turkey; [2]Department of Neurosurgery, Bakırkoy Prof. Dr. Mazhar Osman Training and Research Hospital, Istanbul, Turkey; [3]Department of Biology, Faculty of Science and Literature, Balikesir University, Balikesir, Turkey.

Purpose
Tumor-associated protein called as anterior gradient 2 (AGR2), which is defined particularly in breast and lung carcinomas, is involved in a variety of cellular functions such as cell migration, differentiation and proliferation. Since the role of AGR2 expression in pituitary adenomas is not well known yet, it was aimed to compare AGR2 expression in normal pituitary tissue and pituitary adenoma specimens in the study.
Material and Method
We included 44 patients' pituitary adenoma specimens (20 female/24 male) who underwent pituitary surgery at the neurosurgery clinic between 2015 and 2017 years and 10 patients' normal pituitary tissues (5 female/5 male) operated for any reason were included as control group. Examples were stored frozen at $-80°C$

until the study. After RNA isolation from adenomas or pituitary tissue specimens, AGR2 gene expression was evaluated by Livak method using real-time PCR method. The results were calculated as multiples of '1' by making calculations according to the control group, and AGR2 expression >1 was considered to be significantly higher than the control group. Those with AGR2 expression <1 and >1 were compared with possible related parameters. Invasiveness of adenomas is described to Hardy classification and Knosp scale.
Results
The mean age at diagnosis was 47 ± 15 (range 20–71) years, the mean maximum tumor diameter was 28 ± 16 (range 4–75) cm. The distribution of adenomas with AGR2 expression >1; 80% (4 of 5) in ACTH secreting adenomas, 93% (13 of 14) in GH secreting adenomas, 77% (2 of 3) in PRL secreting adenomas, 71% (10 of 14) in LH / FSH secreting adenomas, 0% (0 of 1) TSH was in secreting adenomas and 71% (5 of 7) in nonsecretory adenomas ($P>0.05$). The maximum tumor size was larger ($P=0.043$), and the tumors were more invasive ($P=0.01$), the tumors had higher Ki-67 labelling index ($P=0.05$) and in AGR2<1 group when compared with AGR >1. In addition, there was a negative correlation between AGR2 expression levels and Ki-67 labelling index ($r=-0.328$, $P=0.029$).
Conclusion
The results revealed that pituitary adenomas with weak AGR2 expression present with more aggressive behaviour. However, more adenoma tissue specimens are needed to evaluate the relation with hormonal secretion pattern and effects on clinical long term course.

Introduction
A growth hormone-secreting pituitary adenoma (GH-PA) increases the risk of complications and death. It's management is determined by MRI data and decrease of insulin-like growth factor-1 (IGF-1) during the octreotide suppression test (OST). Currently, there is evidence that MRI-T2-hypointensive somatotropinoma and high expression of somatostatin receptors type 2 (SSTR2) according to immunohistochemical analysis (IHC) predict high efficacy of somatostatin analogues (SSA).
Objective
To study the relationship of the MR-structure, MR-signal intensity, the SSTR1-5, p53 and Ki-67 expression with the sensitivity of GH-PA to octreotide to assess their predictive value.
