10.4 DX fastenings to concrete (DX-Kwik)	351
10.5 Fastener design in the USA and Canada	352

Summary of Approvals - Direct Fastening

Approvals → Nails	353
Nails → Approvals	356

Alphabetical List of DX and GX Fasteners

362

Part 1:**Fastener selection guide**

Fastener selection guide

Selecting the right fastener

There are six fastener selection charts corresponding to six trade groups:

- Steel metal (e.g. siding and decking, cladding, grating)
- Petrochemical and industrial (e.g. installations, off-shore)
- Interior finishing (e.g. drywall, suspended ceilings)
- General construction (e.g. concrete forming, insulation)
- HVAC, plumbing and electrical
- Wood framing

To find a DX- or GX fastener for an application, enter the appropriate trade group chart with the application:

Detailed technical information for the selected fastener family is found on its product information sheet.

For some applications, two or more fastener families are listed as suitable. The final selection is influenced by technical data found on the product sheets.

Regional differences in building methods, materials, trade preferences, available tools, etc. also influence fastener selection. Therefore, designers and specifiers are advised to consult the current Hilti catalogue and make use of the local Hilti technical advisory service.

Corrosion

Corrosion has a major influence on the suitability of a fastener and therefore also on fastener selection. In order to provide a basis for judging the suitability of fasteners, it is useful to categorise applications in three classes:

- Safety relevant, permanent applications: (e.g. profiled metal sheet fastenings in roofs and walls)
- Non-safety relevant, permanent fastenings (e.g. metal track fastenings for drywall)
- Non-safety relevant, temporary fastenings (e.g. fastenings of wooden sills, kickers, etc. in concrete forming).

For **non-safety-relevant applications**, zinc-plated fasteners made of normal carbon steel can be used without restriction.

For **safety-relevant, permanent fastenings** the restrictions described below apply:

- In any case there is a restriction to the use of galvanized carbon steel fasteners if they are exposed to weather or if they are inside and subject to repeated wetting as from condensation. The galvanization (typically in a range from 5 to 20 microns of Zn) provides corrosion protection during transport and construction, during which exposure to weather can never be completely prevented. If the fastenings are exposed to repeated wetting or weather during their service life, the use of galvanized carbon steel fasteners is prohibited and stainless steel fasteners must be used. This safety measure must be observed without exception because the corrosion of galvanized steel fasteners leads not just to material loss but also to hydrogen embrittlement. Hydrogen embrittlement can easily result in fracture of the fastener at very low load.
- Referring to the above-mentioned example of profiled metal sheet fastening for roofs and walls, the use of galvanized steel fasteners is allowable only where wetting of the fastener is not to be expected. This applies in general to inside skins of two skin, insulated roofs and walls enclosing dry and closed rooms. This is the classic application area for X-ENP 19 galvanized fasteners.

Contact corrosion is taken into consideration by observing common rules concerning acceptable material combinations. Parts made of less noble metals are subject to increased corrosion if they are in electrochemical contact with a larger part made of a more noble metal, provided of course that an electrolyte is present. Fasteners that are used in wet areas must be at least as noble or better, nobler than the fastened part. The effect of contact corrosion is shown in the table below. This information is especially applicable to stainless steel X-CR fasteners because only the X-CR is suitable for safety-relevant, permanent application in outdoor areas or areas otherwise exposed to corrosion.

Fastened part	Powder- and gas-actuated fastener:	
	Zinc-plated carbon steel	X-CR stainless steel
Construction steel (uncoated)	○	○
Galvanized steel sheet	○	○
Aluminum alloy	●	○
Stainless steel sheet	●	○

- Negligible or no corrosion of fastener
- Heavy corrosion of fastener

The accelerated corrosion of a fastener due to contact corrosion can take place only in the presence of an electrolyte (moisture from precipitation or condensation). Without this electrolyte – e.g. in dry inside rooms – zinc-plated fasteners can be used in connection with more noble metals.

Design concepts

The recommended working loads (N_{rec} and V_{rec}) are suitable for use in typical working load designs. If a partial safety factor design method is to be used, the N_{rec} and V_{rec} values are conservative when used as N_{Rd} and V_{Rd} . Exact values for N_{Rd} and V_{Rd} can be determined by using the safety factors where given and/or by reviewing test data. Design loads (characteristic strength, design resistance and working loads) for the **X-HVB** shear connector are listed and ordered as per design guideline.

Worldwide the designer may encounter two main fastening design concepts:

Working load concept

$$N_S \leq N_{\text{rec}} = \frac{N_{\text{Rk}}}{\gamma_{\text{GLOB}}}$$

where γ_{GLOB} is an overall factor of safety including allowance for:

- errors in estimation of load
- deviations in material and workmanship

and N_S is, in general a characteristic acting load.

$$N_S = N_{\text{Sk}}$$

Partial factors of safety

$$N_{\text{Sk}} \times \gamma_{\text{F}} = N_{\text{Sd}} \leq \frac{N_{\text{Rk}}}{\gamma_{\text{M}}} = N_{\text{Rd}}$$

where:

γ_{F} is a partial factor of safety to allow for errors in estimation on the acting load.

γ_{M} is a partial factor of safety to allow for deviations in material and workmanship.

Structural analysis of the fastened part (e.g. roof deck panel or pipe hung from a number of fastenings) leads to calculation of the load acting on a single fastening, which is then compared to the recommended load (or design value of the resistance) for the fastener. In spite of this single point design concept, it is necessary to ensure that there is sufficient redundancy that the failure of a single fastening will not lead to collapse of the entire system. The old saying “one bolt is no bolt” applies also to DX and GX fastening.

Nomenclature / symbols

Following is a table of symbols and nomenclature used in the technical data.

Fastener test data and performance	
N and V	Tensile and shear forces in a general sense
F	Combined force (resulting from N and V) in a general sense
N_s and V_s	Tensile and shear forces acting on a fastening in a design calculation
F_s	Combined force (resulting from N_s and V_s) in a design calculation
N_u and V_u	Ultimate tensile and shear forces that cause failure of the fastening; statistically, the reading for one specimen
N_{u,m} and V_{u,m}	Average ultimate tensile and shear forces that cause failure of the fastening, statistically, the average for a sample of several specimens
S	The standard deviation of the sample
N_{test,k} and V_{test,k}	Characteristic tensile and shear resistance of test data, statistically, the 5 % fractile.
N_{Rk} and V_{Rk}	Characteristic tensile and shear resistance of the fastening used for fastening design; statistically, the 5 % fractile. For example the characteristic strength of a fastening whose ultimate strength can be described by a standard Gauss type distribution is calculated by: N_{Rk} = N_{u,m} - k × S where k is a function of the sample size, n and the desired confidence interval.
N_{Rd} and V_{Rd}	Tensile and shear design force on the fastener shank $N_{Rd} = \frac{N_{Rk}}{\gamma_M}$ and $V_{Rd} = \frac{V_{Rk}}{\gamma_M}$ where γ_M is a partial safety factor for the resistance of the fastening
N_{rec} and V_{rec}	Recommended tensile and shear force on the fastener shank $N_{rec} = \frac{N_{Rk}}{\gamma_{GLOB}}$ and $V_{rec} = \frac{V_{Rk}}{\gamma_{GLOB}}$ where γ_{GLOB} is an overall factor of safety
M_{rec}	Recommended working moment on the fastener shank $M_{rec} = \frac{M_{Rk}}{\gamma_{GLOB}}$ where M_{Rk} is the characteristic moment resistance of the fastener shank and γ_{GLOB} is an overall factor of safety. Unless otherwise stated on the product data sheets, the M_{rec} values in this manual include a safety factor of "2" for static loading.

Fastening details

h_{ET}	Penetration of the fastener point below the surface of the base material
h_{NVS}	Nail head standoff above the surface fastened into (with nails, this is the surface of the fastened material, with threaded studs, the surface of the base material).
t_{II}	Thickness of the base material
t_I	Thickness of the fastened material
Σt_I	Total thickness of the fastened material (where more than one layer is fastened)

Characteristics of steel and other metals

f_y and f_u	Yield strength and ultimate tensile strength of metals (in N/mm ² or MPa)
-----------------	--

Characteristics of concrete and masonry

f_c	Compressive strength of cylinder (150 mm diameter, 300 mm height)
f_{cc}	Compressive strength of cube (150 mm edge length)
$f_{c,100} / f_{c,200}$	Compressive strength of 100 mm diameter cylinder / cube with 200 mm edge length

In some cases building material grades are used to describe the suitable range of application. Examples of European concrete grades are C20/25, C30/35, C50/55.

Approvals, technical assessments and design guidelines are given on the product information sheets as abbreviations of the names of the issuing institutes or agencies. Following is a list of abbreviations:

Abbreviation	Name of institute or agency / description	Country
FM	Factory Mutual (insurers' technical service)	USA
UL	Underwriters Laboratories (insurers' technical service)	USA
ICC	International Code Council	USA
SDI	Steel Deck Institute (technical trade association)	USA
CSTB	Centre Scientifique et Technique du Bâtiment (approval agency)	France
DIBt	Deutsche Institute für Bautechnik (approval agency)	Germany
SOCOTEC	SOCOTEC (insurers' technical service)	France
ÖNORM	Österreichische Norm / Austrian National Standard	Austria
SCI	Steel Construction Institute	Great Britain

ABS	American Bureau of Shipping (international classification society for ship and marine structures)
LR	Lloyd's Register (international classification society for ship and marine structures)
GL	Germanischer Lloyd (international classification society for ship and marine structures)
DNV	Det Norske Veritas (international classification society for the marine and energy industry)

Nail designation

	X-C	32	P8 S23 T
Application:			Washer type Ø (in mm):
X-ENP	Siding and Decking Nails		P Plastic washer e.g. P8 = plastic washer Ø 8
X-ENP2K			S Steel washer e.g. S36 = steel washer Ø 36
X-EDNK22	Diaphragm Decking Nails		D Two washers
X-EDN19			L Two domed washers
NPH	Siding and Decking Nails to Concrete		TH Top Hat
X-U	Universal Nails		THQ Top Hat and high shear washer
X-C	Nails for Concrete and Sand lime-Masonry		MX Collated for DX tool/ composite fasteners for GX tool
X-S	Drywall Fasteners to Steel		MXR Collated for DX 860-ENP
X-EGN	Gas Nails		T For tunneling applications
X-GHP			
X-GN			
DS	Heavy Duty Nails for Concrete and Steel		
EDS	Heavy Duty Nails for Fastening Steel to Steel		
X-CR	Stainless Steel Nails for Concrete, Sand lime Masonry and Steel. And Steel only.		
X-CT	Nails for Forming or other Temporary uses		
DNH	DX-Kwik Nails for Concrete		
X-DKH	(pre-drilled)		
			Dimensions:
			Length in mm (For details, please refer to product data)

Examples:

X-U 52 P8

X-U 52 MX

Threaded stud designation

X-M6H		10-37	FP8		
Application:			Washer type and Ø (in mm):		
X-M6H	DX-Kwik Threaded Studs for Concrete (pre-drilled)	10-37	P	Plastic washer e.g. P8 = plastic washer Ø 8	
X-M8H			S	Steel washer e.g. S8 = steel washer Ø 8	
X-M6			D	Two washers	
X-W6			F	Plastic guidance sleeve	
X-F7			SN12-R	Stainless steel washer for sealing purposes	
X-M8					
M10					
W10					
X-EM6H			Threaded Studs for Steel		
X-EW6H					
X-EF7H					
X-EM8H					
X-EM10H					
X-EW10H					
X-BT	Stainless Steel Threaded Studs				
X-CRM		Stainless Steel Threaded Studs for Concrete and Steel			
			Dimensions:		
			Thread Length and Shank Length in mm		

where M, W, F refer to the thread type:

M	Metric
W	Whitworth
F	French

Examples:

X-BT W10-24-6 SN12-R

X-BT M10-24-6 SN12-R

Wood nail designation

GX - WF 51x2.8 (R) (D) 34 (HDG)

Technology:

GX | Gas driven

Profile:

R | Profiled
() | Non Profiled

Application:

WF | Wood Framing

Head shape:

D | D-Head Shape
() | Round Head Shape

Dimensions

Length and Nail Diameter in mm

Collation:

34 | 34° Collation
() | Round Head Shape

Designation of corrosion protection on the box/label

Suffix	Type of protection	Service Class (EN 1995-1-1)
“Bright”	no coating	1
“Galv”	12 µm zinc	1, 2
“HDG”	55 µm hot dip galvanized	1, 2, 3
“Stainless”	A2 or A4	1, 2, 3

Tips for users (“Trouble Shooting”)

DX fastenings on concrete

B

Fault

Fastener properly fixed

Cause

- Proper*) length of fastener
- Proper cartridge
- Proper power setting

Possible remedial measures

Fastener penetrates too deep

- Fastener too short*)
- Too much driving power

- Use longer fastener
- Reduce power setting
- Use lighter cartridge

Fastener does not penetrate deep enough

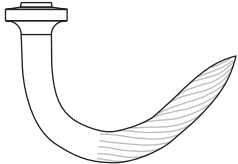

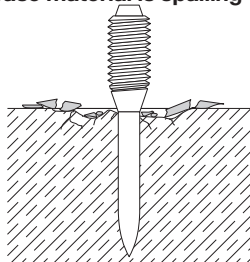

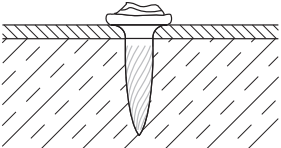

- Fastener too long*)
- Too little driving power

- Use shorter fastener
- Increase power setting
- Use heavier cartridge

*) **Rule of thumb:** The higher the compressive strength of concrete, the shorter the fastener
Proper length (mm): $L_s = 22 + t_1$ (compare, “Fastening Technology Manual” Part Product section)

DX fastenings on concrete

Fault	Cause	Possible remedial measures
<p>Nail is bending</p> 	<ul style="list-style-type: none"> ■ Hard and/or large aggregate in concrete ■ Rebar close to surface of concrete ■ Hard surface (steel) 	<ul style="list-style-type: none"> ■ Use shorter nail ■ Use DX-Kwik (predrill) ■ Use co-acting principle/fastener guide ■ Use stepped shank nail X-U 15 ■ Change cartridge
<p>Base material is spalling</p> 	<ul style="list-style-type: none"> ■ High strength concrete ■ Hard and/or large aggregate in concrete ■ Old concrete 	<ul style="list-style-type: none"> ■ Stud application: Use spall stop X-460-F8SS / - F10SS ■ Nail application: Use shorter nail Use DX-Kwik (predrill) Use X-U 15 (for high-strength precast concrete)
<p>Damaged nail head</p> 	<ul style="list-style-type: none"> ■ Too much driving power ■ Wrong piston used ■ Damaged piston) 	<ul style="list-style-type: none"> ■ Reduce power setting ■ Use lighter cartridge ■ Check nail-piston-combination ■ Change piston

B

Wrong pistons can cause all the above faults: match pistons to nails!

Fastener	Piston	Piston head
X-U, X-C	Use piston X-460-P8	

DX fastenings on steel

B

Fault

Nail does not penetrate surface

Cause

- Too little driving power
- Application limit exceeded (very hard surface)
- Unsuitable system

Possible remedial measures

- Try higher power setting or heavier cartridge
- Short nail application: Try X-U 15
- Long nail application: Try X-U
- Use co-acting principle/fastener guide
- Switch to heavy system like DX 76 PTR

Nail does not hold in base material

- Excess driving energy in thin steel base material (3 to mm steel)

- Try different power setting or different cartridge
- Try X-ENP2K or X-EDNK22 THQ 12 for fastening sheet metal

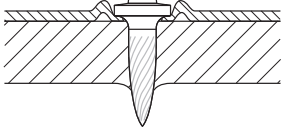

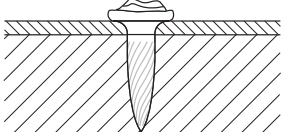

Nail is breaking

- Too little driving power
- Application limit exceeded (very hard surface)

- Try higher power setting or heavier cartridge
- Use shorter nail
- Use X-ENP19
- Use stronger nail (X-...-H)
- Use stepped shank nail: X-U 15

DX fastenings on steel

Fault	Cause	Possible remedial measures
<p>Nail head penetrates through material fastened (metal sheet)</p> 	<ul style="list-style-type: none"> ■ Too much driving power 	<ul style="list-style-type: none"> ■ Reduce power setting ■ Use lighter cartridge ■ Use nail with Top Hat ■ Use nail with washer e.g. X-U ...S12
<p>Damaged nail head</p> 	<ul style="list-style-type: none"> ■ Too much driving power ■ Wrong piston used ■ Worn-out piston 	<ul style="list-style-type: none"> ■ Reduce power setting ■ Use lighter cartridge ■ Check nail-piston-combination ■ Change piston

B

Wrong pistons can cause all the above faults: match pistons to nails!

Fastener	Piston	Piston head
X-U	Use piston X-460-P8

Approvals

ETA-04/0101 (Hilti-DX-DoP001), UL R13203, FM 3021719, ICC ESR-2197, ESR-2776 (USA), MLIT (Japan), ABS, LR 97/00077

Applications

Examples

Roof decking

Floor decking

Wall liners

The intended use only comprises fastenings which are not directly exposed to external weather conditions or moist atmospheres. For out-door applications, that can be ensured by using SDK 2 sealing caps. During construction exposure to external atmosphere must not exceed 6 months. Fastening of aluminum sheeting is generally recommended only for indoor conditions.

Load data

Characteristic loads – steel sheeting

Sheeting thickness t_f [mm]	Trapezoidal profile (symmetric loading)		Liner trays ¹⁾ (asymmetric loading)	
	Char. resistance according to ETA-04/0101		Char. resistance keeping to ETA-04/0101	
nominal	Shear V_{Rk} [kN]	Tension N_{Rk} [kN]	Shear V_{Rk} [kN]	Tension N_{Rk} [kN]
0.75	4.70	6.30	3.30	4.40
0.88	5.40	7.20	3.80	5.00
1.00	6.00	8.00	4.20	5.60
1.13	7.00	8.40	4.90	5.90
1.25	8.00	8.80	5.60	6.20
1.50	8.60	8.80	6.00	6.20
1.75	8.60	8.80	6.00	6.20
2.00	8.60	8.80	6.00	6.20
2.50	8.60	8.80	6.00	6.20

- N_{Rk} and V_{Rk} are valid for steel sheet with minimum tensile strength ≥ 360 N/mm² (\geq S280 EN 10346).
 - For intermediate sheet thicknesses, use recommended load for next smaller thickness or linear interpolation.
- 1) Required load reduction is taken into account in accordance with EN 1993-1-3: 2006, section 8.3 (7) and fig. 8.2. See also construction rules under spacings and edge distances.

Recommended loads – steel sheeting

Sheeting thickness t_f [mm]	Trapezoidal profile (symmetric loading)		Liner trays ¹⁾ (asymmetric loading)	
	Recommended loads		Recommended loads	
nominal	Shear V_{rec} [kN]	Tension N_{rec} [kN]	Shear V_{rec} [kN]	Tension N_{rec} [kN]
0.75	2.50	3.35	1.75	2.35
0.88	2.90	3.85	2.00	2,70
1.00	3.20	4.25	2.25	3.00
1.13	3.75	4.50	2.65	3.15
1.25	4.25	4.70	3.00	3.30
1.50	4.60	4.70	3.20	3.30
1.75	4.60	4.70	3.20	3.30
2.00	4.60	4.70	3.20	3.30
2.50	4.60	4.70	3.20	3.30

- N_{rec} and V_{rec} are valid for steel sheet with minimum tensile strength ≥ 360 N/mm² (\geq S280 EN 10346).
 - For intermediate sheet thicknesses, use recommended load for next smaller thickness or linear interpolation.
 - Recommended loads N_{rec} and V_{rec} are appropriate for Eurocode 1 wind loading design with a partial safety factor $\gamma_F = 1.5$ for wind load and a partial resistance factor $\gamma_M = 1.25$ for the fastening.
- 1) Required load reduction is taken into account in accordance with EN 1993-1-3: 2006, section 8.3 (7) and fig. 8.2. See also construction rules under spacings and edge distances.

Recommended loads – aluminum sheeting¹⁾ with $f_u \geq 210 \text{ N/mm}^2$

Trapezoidal profile (symmetric loading)

Thickness t_f [mm]	Shear V_{rec} [kN]	Tension N_{rec} [kN]
0.60	0.75	0.35
0.70	0.90	0.50
0.80	1.00	0.65
0.90	1.20	0.80
1.00	1.30	0.95
1.20	1.55	1.30
1.50	1.85	1.45
2.00	2.55	1.90

1) Only recommended for indoor applications. Constraint forces and corrosion aspects have to be considered.

- For intermediate sheet thicknesses, use recommended load for next smaller thickness.
- Recommended loads N_{rec} and V_{rec} are appropriate for Eurocode 1 wind loading design with a partial safety factor of $\gamma_F = 1.5$ for wind load and a partial resistance factor $\gamma_M = 1.25$ for the fastening.

Recommended loads – other applications

V_{rec} [kN]	N_{rec} [kN]
4.6	2.4

- Fastened parts: clips, brackets, etc.; thick steel parts ($t_{l,max} = 2.5 \text{ mm}$).
- Redundancy (multiple fastening) must be provided.
- The possibility of prying effects has to be considered
- Failure of the fastened part is not considered in these values of N_{rec} , V_{rec} .
- Valid for predominantly static loading
- Global factor of safety is ≥ 2 based on 5% fractile value

Design

Depending on the verification concept, the corresponding design criteria are given as following.

Working load concept	Partial safety concept
Tensile loads $N_{Sk} \leq N_{rec}$	$N_{Sd} \leq N_{Rd}$
Shear loads $V_{Sk} \leq V_{rec}$	$V_{Sd} \leq V_{Rd}$

N-V Interaction

For combined tensile and shear forces on the fastener, a linear function has to be used.

$$\left(\frac{V_{Sk}}{V_{rec}}\right) + \left(\frac{N_{Sk}}{N_{rec}}\right) \leq 1$$

with:

V_{Sk} , N_{Sk} unfactored characteristic load acting on the fastening (= working load)
 V_{rec} , N_{rec} recommended (allowable) load with $\gamma_{GLOB} = 1.875$

$$\left(\frac{V_{Sd}}{V_{Rd}}\right) + \left(\frac{N_{Sd}}{N_{Rd}}\right) \leq 1$$

with:

V_{Sd} , N_{Sd} Design load with $\gamma_F = 1.5$
 V_{Rd} , N_{Rd} Design resistance of the fastening with $\gamma_M = 1.25$
 $V_{Rd} = V_{Rk} / 1.25$
 $N_{Rd} = \alpha_{cycl} N_{Rk} / 1.25$
 $\alpha_{cycl} = 1.0$ according to ETA-04/0101

Application requirements

Thickness of base material

Steel thickness t_{II}

Thickness of fastened material

$\Sigma t_i, \text{tot} \leq 4.0 \text{ mm}$

Sheet thicknesses and overlap types

(a)
single

(b)
side lap

(c)
end overlap

(d)
side lap and end overlap

Nominal sheeting thickness t_i [mm]

0.63–1.00

> 1.00–1.25

> 1.25–2.50

Allowable overlap types

a, b, c, d

a, c

a

With the above recommended sheet thickness and overlap types, it is not necessary to take into account the effect of constraints due to temperature for steel grades up to S320 (EN 10346). For steel grade S350 (EN 10346) it shall be considered for design. Sheets of grade S350 on base material $t_{II} \geq 8 \text{ mm}$ have been verified by Hilti, forces of constraint can be neglected.

Spacing and edge distances (mm)

Steel base material

Trapezoidal profiles

Centre fastenings in ribs

Clearance to end of sheet

Double fastenings (asymmetric)

Note:
Reduce tensile resistance per fastener to $0.7 N_{Rk}$ or $0.7 N_{rec}$.

Liner trays

Clearance to side of sheet

Clearance to side of sheet

Clearance to end of sheet

Fastener spacing along sheet

When driving the fastener, the fastening tool needs to be positioned perpendicular to the surface.
If $c > 75$ mm, it is recommended to drive an additional fastener at the other side of the tray. This additional fastener is indicated with (1) in the graph above.

Corrosion information

The intended use only comprises fastenings which are not directly exposed to external weather conditions or moist atmospheres. For outdoor applications that can be ensured by using **SDK 2** sealing caps. During construction exposure to external atmosphere must not exceed 6 Month. Fastening of Aluminum sheeting is generally recommended only for indoor conditions.

Application limit

X-ENP-19 with DX 76, DX 76 PTR and DX 860-ENP

Fastener selection and system recommendation

Fasteners			Tools	Fastener guide
	Designation	Item no.	Designation	Designation
Single nail:	X-ENP-19 L15	283506	DX 76 PTR DX 76 F15	X-76-F15-PTR
Collated nails:	X-ENP-19 L15 MX, white magazine strip	283507	DX 76 PTR DX 76 MX	
	X-ENP-19 L15 MXR, grey magazine strip	283508	DX 860-ENP	
Piston:	X-76-P-ENP-PTR		DX 76 PTR	
	X-76-P-ENP		DX 76 DX 860-ENP	

Cartridge selection and tool energy setting

DX 76, DX 860-ENP

Steel thickness t_f [mm]	>20	Red 4 or Black 2	Black 4
	15	Red 3 or Black 1	Black 3
	10	Blue 4 or Red 2	Red 4 or Black 2
	6	Blue 3	Red 3
		S 235	S 355

DX 76 PTR

Steel thickness t_f [mm]	>20		
	15	Red 4 or Black 2	Black 4
	10	Blue 4 or Red 2	Red 4
	6	Blue 3 or Red 1	Red 3
		S 235	S 355 S 275

Fine adjustment by installation tests on site.

Note for S275:

Start with recommendation for S355. In case of too much energy: reduction of tool energy setting or change of cartridge colour till correct nail head stand-offs h_{NVS} are achieved.

Fastening quality assurance

Fastening inspection

$h_{NVS} = 8.2-9.8 \text{ mm}$ for $t_{i,tot} \leq 4 \text{ mm}$

In order to allow the steel sheeting to be in direct contact with the steel supporting structure in the area of connections the X-ENP-19 fastener should be installed $\geq 30\text{mm}$ away from the edges of insulation / isolation tapes that are $\leq 3\text{mm}$ thick.

$h_{NVS} = 8.2-9.8 \text{ mm}$

$h_{NVS} > 9.8 \text{ mm}$
(washers are not compressed)

$h_{NVS} < 8.2 \text{ mm}$
(washers are strongly damaged by the tool piston)

Visible inspection:
Properly driven fastener.
Piston mark clearly visible on the washer.

SDK2, PDK2 Sealing Caps for Cladding Fastening

Product data

Dimensions

SDK2 sealing cap

PDK2 sealing cap

General information

Compatible DX fasteners

X-ENP-19 L15 Base material thickness $t_{II} \geq 6$ mm

Fastening tool

SW/SDK2 setting tool **SDK2**

SW/PDK2 setting tool **PDK2**

Applications

Examples

Roof and wall cladding on single skin buildings

SDK2, stainless steel sealing cap for roof and wall cladding

Stainless steel cap not affected by atmospheric corrosion

Space under the cap isolated from the atmosphere

Neoprene washer insulates against contact corrosion and seals the space under the cap-off from the atmosphere

Pressure on the washer seals the gap between the sheet and the base steel

PDK2, plastic sealing cap for wall cladding

Corrosion protection

Fastening quality assurance

Fastening inspection

For detailed information on X-ENP-19 L15 please see the according product pages.

X-ENP-19 L15

Maximum thickness of single layer (type a):
 $t_{l, \max} = 1.5 \text{ mm}$
 Total thickness of end overlap (type c):
 $\Sigma t_{l, \text{tot}} \leq 2.5 \text{ mm}$

$h_{NVS} = 8.2\text{--}9.8 \text{ mm}$

Note:

It has to be ensured, that the fastened sheet is properly compressed to the base material and no gap remains at fastening point location.

Installation

Position the DX tool so that nail inclination is limited to max. 10° from perpendicular to surface

Centre fastening in valley.
 38 mm min. valley width

Minimum roof slope 6°

These are abbreviated instructions which may vary by application.
ALWAYS review/follow the instructions accompanying the product.

(Hilti-DX-DoPo003),
LR 97/00077

Note: technical data presented in these approvals and design guidelines reflect specific local conditions and may differ from those published in this handbook.

Applications

Examples

Roof and floor decking

Roof and floor decking

Wall liners

Load data

Characteristic loads

Overlap Sheeting thickness t_l [mm]	$3 \text{ mm} \leq t_{ll} < 4 \text{ mm}$			$4 \text{ mm} \leq t_{ll} \leq 6 \text{ mm}$		
	V_{Rk} [kN]	N_{Rk} [kN]	Types of conn.	V_{Rk} [kN]	N_{Rk} [kN]	Types of conn.
0.75	4.70	6.00	a, c	4.70	6.30	a, b, c, d
0.88	5.40	6.00	a, c	5.40	7.20	a, (b)*, c, d,
1.00	6.00	6.00	a, c	6.00	8.00	a, (b)*, c, d
1.13	–	–	–	7.00	8.40	a, c
1.25	–	–	–	8.00	8.80	a, c
1.50	–	–	–	8.60	8.80	a

* Fastening type (b) covered for $5 \text{ mm} \leq t_{ll} < 6 \text{ mm}$, if N_{Rk} is reduced to 6.6 kN

Fastening type (b) fully covered for $t_{ll} = 6 \text{ mm}$

For a, b, c, d please refer to **Application requirements, Sheet thicknesses and overlap types**

Design

Design shear and tension resistance V_{Rd} and N_{Rd}

$$V_{Rd} = V_{Rk} / \gamma_M \quad N_{Rd} = \alpha_{cycl} V_{Rk} / \gamma_M \text{ with } \alpha_{cycl} = 1.0 \text{ for all sheeting thickness } t_l$$

α_{cycl} considers the effect of repeated wind loads

$\gamma_M = 1.25$ in the absence of national regulations

Characteristic tension resistances n_{Rk} [kN/m] and shear resistances v_{Rk} [kN/m] per unit length, taking the effect of thermal constraints into account

N_{Rk} and V_{Rk} characteristic shear and tension resistance

w ... width of the panel sheet

The same characteristic resistances can also be applied along supports at end-overlaps, if connection type “d” is not covered in the load table.

Application requirements

Thickness of base material

$t_{II} = 4.0-8.0$ mm for general shapes

Fastening to cold-formed C- and Z-sections with a thickness from 2.9 to 4.0 mm

Fastening to U-shape concrete inlays with a nominal thickness t_{II} of 3 mm.

$t_{II} = 3.0 \pm 0.3$ mm

Grade: \geq S320 GD according to EN 10346

Sheet thicknesses and overlap types

Type (a)

single

Type (b)

side lap

Type (c)

end overlap

Type (d)

side lap and end overlap

Edge distances (mm)

Rolled I or wide flange shapes

Angles

* For $t_{II} = 3$ to 4 mm, restrictions on application. See approval or contact Hilti.

** Maximum recommended $b_x \leq 8 \times t_{II}$ however, jobsite verification advisable.

Trapezoidal profiles

Centre fastenings in ribs

Clearance to end of sheet

Double fastenings

Note:
Reduce tensile resistance per fastener to $0.7 N_{rec}$.

Corrosion information

The intended use only comprises fastenings which are not directly exposed to external weather conditions or moist atmospheres. For further detailed information on corrosion see corresponding chapter in **Direct Fastening Principles and Technique** section.

Applications

Examples

Roof decking (diaphragm design)

Floor decking (diaphragm design)

Load data

Design data for use in the U.S.A.

Diaphragm strength

Approvals provide load tables or calculation procedures for determination of the allowable strength (in lbs/ft or kN/m) of a steel deck diaphragm. The allowable diaphragm strength depends on the type, strength and thickness of the decking, the span of the decking, the type and pattern of the deck to frame fasteners (X-HSN24, X-EDNK22 or X-EDN19) and the type and spacing of the sidelap connectors (e.g. Hilti sidelap connectors S-SLC 01 and S-SLC 02).

For more details it is referred to the technical literature of Hilti North America (“Steel Deck Fastening Systems” – 2013 Supplement to Hilti North America Product Technical Guide) and the “Decking Design Center” offered on the website www.us.hilti.com as well as the respective approvals.

Recommended shear bearing loads V_{rec}

Sheeting thickness t_f		X-HSN24, X-EDNK22 and X-EDN19	
[Gauge]	[mm]	V_{rec} [lbs]	[kN]
22	0.76	500	2.20
20	0.91	600	2.64
18	1.21	785	3.45
16	1.52	975	4.29

- Valid for steel sheet with a minimum tensile strength of 45 ksi (310 N/mm²). Values refer to failure controlled by the single sheet metal attached.
- For intermediate sheet thicknesses, linear interpolation is allowed.
- Recommended loads include safety factor 3.0 applied to mean shear resistance Q_f . An equation for Q_f is published in the SDI (Steel Deck Institute) Diaphragm Design Manual, 3rd edition.

Recommended tension load N_{rec}

Sheeting thickness t_f		X-HSN24, X-EDNK22		X-EDN19	
[Gauge]	[mm]	N_{rec} [lbs]	[kN]	N_{rec} [lbs]	[kN]
22	0.76	355	1.56	340	1.52
20	0.91	435	1.95	340	1.52
18	1.21	435	1.95	340	1.52
16	1.52	435	1.95	340	1.52

- Valid for steel sheet with minimum tensile strength of 45 ksi (310 N/mm²). Values are either controlled by pullover of sheet or by minimum value of fastener pullout of base metal.
- Values require fastener point penetration for X-EDNK22 and X-EDN19, of 1/2" (12.7 mm). Higher recommended values be applicable for X-HSN24 (see Hilti North America “Steel Deck Fastening Systems”)
- Recommended loads include a safety factor 3.0 applied to mean pullover resistance or a safety factor 5.0 applied to the mean value of pullout resistance.

Design data for use in Europe

Currently, the X-HSN24, X-EDNK22 and the X-EDN19 fasteners are only used in North America. Therefore, no design data is published evaluated in strict compliance with the provisions for European Technical Approvals.

For European markets, the fastener X-ENP2K-20 L15 in connection with the fastening tool DX 76 PTR is recommended for sheet metal fastenings to thin base materials (3 to 6 mm).

Application limits and requirements

Fastening tool DX 860-HSN

Fastener	Base material properties		Ultimate tensile strength	
	Thickness [inch]	[mm]	[ksi]	[N/mm ²]
X-EDNK 22	1/8" to 1/4"	3.2 to 6.35	58 to 91	400–630
X-EDN 19	3/16" to 5/16"	4.8 to 8.0	58 to 91	400–630
	5/16" to 3/8"	8.0 to 9.5	58 to 68	400–470

- Comment on fastening tool DX 460-SM: This fastening tool is recommended for base material thickness from 3/16" to 3/8" (4.8 to 8.0 mm). The same strength limits apply as with the DX 860-HSN.
- X-HSN24 covers full range of the fasteners X-EDNK22 and X-EDN19.

Thickness of fastened material, fastener patterns, spacings and edge distance

(a) single **(b)** side lap **(c)** end overlap **(d)** side lap and end overlap

As part of a steel deck diaphragm, all four fastening types (a), (b), (c) and (d) are executed with the X-EDNK22 and the X-EDN19. The sheet metal thickness typically varies between 22 Gauge (0.76 mm) and 16 Gauge (1.52 mm).

Dependent on the base material thickness and the frame fastener pattern, restrictions on the use of thicker decking might apply. For corresponding details of these provisions, it is referred to the quoted technical literature published by Hilti North America. This literature also contains details with respect to fastener patterns, spacings and edge distance adequately addressing the specifics of the diaphragm components used in the North American market.

Corrosion information

The intended use only comprises fastenings which are not directly exposed to external weather conditions or moist atmospheres. For further detailed information on corrosion see relevant chapter in **Direct Fastening Principles and Technique** section.

Fastener selection and system recommendation

Fasteners	Designation	Item no.	Tool

Nominal sheeting thickness t_f [mm]

Allowable overlap types

0.63–1.13

a, b, c, d

> 1.13–2.50

a

- With the above recommended sheet thickness and overlap types, the effects of temperature induced forces of constraint during construction can be neglected.
- These recommendations are valid for sheets up to S350GD.
- With other sheets or overlaps or when unusually large forces of constraint are expected, analyse the structural system to ensure that the shear force acting on the nail does not exceed V_{rec} .

Spacing and edge distances (mm)

Trapezoidal profiles to girders or purlins

Liner trays to columns

Corrosion information

The intended use only comprises fastenings which are not directly exposed to external weather conditions or moist atmospheres. For further detailed information on corrosion see relevant chapter in **Direct Fastening Principles and Technique** section.

Application limits

Types of concrete

- Precast and cast-in-place pre-stressed concrete
- Precast and cast-in-place reinforced concrete

Concrete design strength

- Minimum C20/25 ($f_c = 20 \text{ N/mm}^2$, $f_{cc} = 25 \text{ N/mm}^2$)
- Maximum C45/55 ($f_c = 45 \text{ N/mm}^2$, $f_{cc} = 55 \text{ N/mm}^2$)
- The **NPH/DX-Kwik** system has been successfully used in concrete having an in-place cube strength of 70 N/mm^2

Minimum strength/age at time of fastening

- C20/25 concrete must be 28 days old
- C45/55 concrete must be 15 days old

Minimum dimensions of concrete member

- Minimum width = 180 mm
- Minimum thickness = 160 mm

Approvals and design guidelines

- SOCOTEC (France)
- DIBt (Germany)
- MLIT / BCJ (Japan),
- Rom. Ministry AT 016-01/214-2010 (Roma),
- TZÚS (Czech)

Note: technical data presented in these approvals and design guidelines reflect specific local conditions and may differ from those published in this handbook. If the fastening is subject to an approval process or where a design guideline must be used, technical data in the approval or design guideline has precedence over data presented here. Approval copies are available from your Hilti technical advisory service.

Applications

Examples

- Shear connectors for building constructions:
- composite beam action
 - end anchorage of composite decking
 - floor diaphragm
 - resist lateral buckling

Design data

Solid slabs

Nominal	Characteristic shear resistance P_{Rk} [kN] ¹⁾	Design shear resistance P_{Rd} [kN] ²⁾	Allowable horizontal shear q [kN] ³⁾	Allowable resistance (working load) R_D [kN] ⁴⁾
X-HVB 50	23	18	N.A	13
X-HVB 80	28	23	14	16
X-HVB 95	35	28	17.5	22
X-HVB 110	35	28	17.5	22
X-HVB 125	35	28	17.5	22
X-HVB 140	35	28	17.5	22

¹⁾ As defined in EN 1994-1-1 (Nominal strength in AISC-LRFD; unfactored shear resistance in CISC.

²⁾ As defined in EN 1994-1-1

³⁾ Allowable shear in AISC-ASD

⁴⁾ Allowable shear for working load design

Reduction factors for profile metal decks

Ribs transverse to beams

Note: $k_t \leq 1.0$

$$k_t = \frac{K}{\sqrt{N_r}} \cdot \frac{b_0}{h_{ap}} \cdot \frac{h_{sc} - h_{ap}}{h_{ap}}$$

EN 1994-1-1 designs:

$K = 0.70$

$N_r = \text{HVBs / rib} (\leq 2 \text{ in the calculation even if 3 are placed in a rib})$

AISC, CISC, BS 5950, other design codes:

$K = 0.85$

$N_r = \text{HVBs / rib} (1, 2 \text{ or } 3)$

Ribs parallel to beams

Note: $k_p \leq 1.0$

for $\frac{b_0}{h_{ap}} \geq 1.8 \Rightarrow k_p = 1.0$

for $\frac{b_0}{h_{ap}} < 1.8 \Rightarrow k_p = 0.6 \times \frac{b_0}{h_{ap}} \times \frac{h_{sc} - h_{ap}}{h_{ap}}$

Engineering advice

Connector placement along the beam

The HVB is a flexible connector and may be uniformly distributed between critical section. These critical sections, where large changes in shear flow occur, may be supporting points, points of application of point loads or areas with extreme values of bending moments.

Partial shear connection

Strength:

The minimum connection depends on the design code used:

- a) In **EN 1994-1-1** design, N/N_f , must be at least 0.4. This is increased depending on span length and decking geometry.
- b) In **AISC**, N/N_f must be at least 0.25.
- c) In **CISC**, N/N_f must be at least 0.50.

Deflection control only:

If the shear connection is needed for deflection control only, there is no minimum degree of connection. However, minimum allowable connector spacing applies and steel beam must have enough strength to carry the self-weight and all imposed loads.

Application requirements

Thickness of base material

Minimum thickness of steel base material $t_{II} = 8 \text{ mm}$

Thickness of fastened material

Maximum thickness of decking $t_I = 1.25 \text{ mm}$

C

Connector positioning, spacing and edge distances

General positioning

Position the HVBs so that the shear force is transferred symmetrically to the beam. The HVB orientation parallel to the axis of the beam is preferred.

Positioning on metal decks - ribs transverse to beam

1) One, two or three HVB's per rib

2a) Position in the rib : 1 HVB per rib – leg centred in the rib or 40 mm clearance

2b) With 2 or 3 HVBs per rib – legs centred in the rib or alternated about the centre

3) Spacing along the ribs

- basic minimum spacing, $a \geq 50$ mm
- $a \geq 100$ mm for:
 $b_o/m < 0.7$ and $b_o/h_{ap} < 1.8$
- SDI 3" composite decking (USA)

m = rib spacing

Positioning on solid slabs and metal decks – ribs parallel to beam

- With 1 connector per row, alternate direction of connectors from X-HVB to X-HVB.
- With 2 or 3 connectors per row, alternate direction of connectors inside of each row and from row to row.

Clearance to metal decking

Split decking if necessary for spacing / clearance

Corrosion information

The intended use only comprises fastenings which are not directly exposed to external weather conditions or moist atmospheres.

Application limits

Application limits are valid only if correct cartridge and power setting are used!

Application limits X-ENP-21 HVB

Cartridge preselection and power setting

In thermo-mechanically rolled construction steel, e.g. S 355M per EN 10025-4 the application limit is reduced by 50 N/mm²

Fine adjustment by setting tests on site

D

Applications

System formwork

Wall-tie to steel and concrete

Mechanical and electrical fixtures

Drywall track to concrete and steel

Conventional formwork

Tagging lables

Tacking of metal decks

Sill plates / 2x4 wood to concrete and steel

The intended use for safety relevant and permanent applications only comprises fastenings which are not directly exposed to external weather conditions or moist atmospheres.

Fastening to Concrete

Recommended loads

N_{rec} [kN]	V_{rec} [kN]	h_{ET} [mm]
0.4	0.4	≥ 27
0.3	0.3	≥ 22
0.2	0.2	≥ 18
0.1	0.1	≥ 14

Design conditions:

- For safety relevant fastenings sufficient redundancy of the entire system is required:
Minimum 5 fastenings per fastened unit.
- All visible failures must be replaced.
- Valid for concrete with strength of $f_{cc} \leq 45 \text{ N/mm}^2$.
- Valid for predominantly static loading.
- Failure of the fastened material is not considered in recommended loads
- To limit penetration of nail and to increase pull-over load, use nails with washers.

Fastening to Concrete

Application requirements

Thickness of base material

Concrete:

$h_{min} = 80 \text{ mm}$

Thickness of fastened material

Wood:

$t_f = 15\text{--}57 \text{ mm}$

Edge distance

Edge distance: $c \geq 70 \text{ mm}$

Fastener selection and system recommendation

Fastening to concrete

Required nail shank length: $L_S = h_{ET} + t_f$ [mm]

Recommendation: $h_{ET} = 22 \text{ mm}$

In case flush fastenings are required:

$L_S = h_{ET} + t_f - 5$ [mm]

Cartridge recommendation

Tool energy adjustment by setting tests on site

Fastening to concrete: **6.8/11M yellow cartridge** on green/ fresh and standard concrete
6.8/11M red cartridge on precast, old and hard concrete

Fastening to Steel

Recommended loads

Fastening of steel sheets and other steel parts with X-U 16 and X-U 19

Recommended loads t_f [mm]	X-U_P8/MX N_{rec} [kN]	X-U_S12 N_{rec} [kN]	V_{rec} [kN]
0.75	1.0	1.4	1.2
1.00	1.2	1.8	1.8
1.25	1.5	2.2	2.6
≥ 2.00	2.0	2.2	2.6

Tacking of steel sheets with X-U 15

according to ECCS-recommendation N73, "Good Construction Practice for Composite Slabs

Recommended loads

t_f [mm]	N_{rec} [kN]	V_{rec} [kN]
0.75–1.25	0.6	0.8

Design conditions:

- Recommended working loads valid for steel sheet with minimum tensile strength $\geq 360 \text{ N/mm}^2$.
- For intermediate sheet thicknesses, use recommended load for next smaller thickness.
- In case of a design based on the characteristic resistance, recommended values have to be multiplied by two: $\Rightarrow N_{RK} = N_{rec} \cdot 2.0$ $V_{RK} = V_{rec} \cdot 2.0$
- For X-U 16 S12: base material thickness $t_{f,min} = 8 \text{ mm}$ for $t_f \geq 1.5 \text{ mm}$ and $t_{f,min} = 6 \text{ mm}$ for $t_f \leq 1.25 \text{ mm}$
- Other fastened parts: clips, brackets, etc.
- Redundancy (multiple fastening) must be provided.
- Valid for predominantly static loading

Forces of constraint

When fastening large pieces of steel, the possibility of shear loadings from forces of constraint should be considered. Avoid exceeding V_{rec} for the fastener shank!

Deflection due to primary loading

Temperature effect

Fastening to Steel

Fastenings of wood to steel

$N_{rec} = 0.3 \text{ kN}$

$V_{rec} = 0.6 \text{ kN}$

Design conditions:

- For safety-relevant fastenings sufficient redundancy of the entire system is required.
- In case soft material is fastened, its strength determines the loads.
- To limit penetration of nail and to increase pull-over load, use nails with washers.
- Observance of edge distance and fastener spacing in compliance with recognized standards EN 1995 (see approval).
- With respect to details of fastening wood, chipboard or OSB members to steel base material, it is referred to the German approval DIBt Z-14.4-517.

Application requirements

Thickness of base material

Steel:

$t_{II} \geq 6.0 \text{ mm}$ (fastening steel to steel)

$t_{II} \geq 4.0 \text{ mm}$ (fastening wood to steel)

Thickness of fastened material

Steel:

$t_I \leq 3 \text{ mm}$ (fastened material not pre-drilled)

$3 \text{ mm} < t_I \leq 6 \text{ mm}$ (fastened material pre-drilled)

Wood:

$t_I = 15\text{--}57 \text{ mm}$

Condition for thick fastened steel parts ($3 \text{ mm} < t_I \leq 6 \text{ mm}$)

If a gap between the fastened part and the base material is unacceptable, the fastened part needs to be prepared with drilled holes.

Edge distance and spacing

Rolled shapes:

Edge distance: $c \geq 15 \text{ mm}$

Spacing: $a = 20 \text{ mm}$

Fastening to Steel

Application limits

Fastening of steel sheets and steel parts to steel

Fastening of wood and soft material to steel

X-U 16 P8, X-U 15 P8TH: For steel sheeting
with $0.75 \text{ mm} \leq t_1 \leq 1.25 \text{ mm}$ sheets

For X-U 22 P8 to X-U 62 P8

Fastener selection and system recommendation

Required nail shank length: $L_S = h_{ET} + t_1$ [mm]

Fastening steel to steel

Recommendation: $h_{ET} = 12 \pm 2 \text{ mm}$

Fastening wood to steel

$h_{ET} \geq 8 \text{ mm}$

Cartridge recommendation

Tool energy adjustment by setting tests on site

Fastening wood to steel: **6.8/11M green or yellow cartridge**

on steel thickness $t_{II} < 6 \text{ mm}$

6.8/11M yellow, red or black cartridge

on steel thickness $t_{II} \geq 6 \text{ mm}$

X-C __ P8S36

General information

Material specifications

Carbon steel shank: HRC 53
HRC 58 *)

Zinc coating: 5–20 μm

*) X-C 82, 97 and 117 P8 (d_{nom} = 3.7 mm)

Recommended fastening tools

See **X-C fastener program** in the next pages and **Tools and equipment** chapter for more details.

X-C __ P8S23T (for tunneling applications)

D

Applications

Examples

Conventional Formwork

System Formwork

Drywall track to concrete

Load data

Recommended loads

Fastening wood to concrete:

N_{rec} [kN]	V_{rec} [kN]	h_{ET} [mm]
0.4	0.4	≥ 27
0.3	0.3	≥ 22
0.2	0.2	≥ 18
0.1	0.1	≥ 14

Fastenings to sandlime masonry:

$N_{rec} = V_{rec} = 0.4$ kN for $h_{ET} \geq 27$ mm

Design conditions:

- For safety relevant fastenings sufficient redundancy of the entire system is required: minimum 5 fastenings per fastened unit.
- All visible failures must be replaced.
- Valid for concrete with strength of $f_{cc} < 30$ N/mm².
- Valid for predominantly static loading.
- Failure of the fastened material is not considered in recommended loads.
- To limit penetration of nail in soft material and to increase pullover load, use nails with washers.

Application requirements

Thickness of base and fastened material

Concrete

$h_{min} = 80$ mm

$t_1 \leq 50.0$ mm

Edge distances [mm]

$c \geq 70$ mm

Corrosion information

The intended use for safety relevant and permanent applications only comprises fastenings which are not directly exposed to external weather conditions or moist atmospheres.

Fastener selection and system recommendation

Fastener selection

Required nail shank length:

$$L_S = h_{ET} + t_f \text{ [mm]}$$

Recommendation:

Concrete $h_{ET} = 22 \text{ mm}$

Sandlime masonry $h_{ET} = 27 \text{ mm}$

In case flush fastenings are required:
 $L_S = h_{ET} + t_f - 5 \text{ [mm]}$

Note:

Technical data presented in these approvals and design guidelines reflect specific local conditions and may differ from those published in this handbook.

D

Applications

Examples

Wood to steel and concrete

Plastic and rubber to steel

Metal parts to concrete

Soft material to steel and concrete

Load data

Recommended loads

Fastening wood to concrete, sandlime masonry or steel

Fastening wood to concrete, sandlime masonry:

$$N_{rec} = V_{rec} = 0.4 \text{ kN}$$

Fastening wood to steel:

$$N_{rec} = V_{rec} = 0.6 \text{ kN}$$

Design conditions:

- For safety-relevant fastenings sufficient redundancy of the entire system is required: minimum 5 fastenings per fastened unit with normal weight concrete base material.
- All visible failures must be replaced.
- Valid for concrete and sandlime masonry with strength of $f_{cc} < 40 \text{ N/mm}^2$.
- Fastened material: wood, minimum thickness = 24 mm
plywood, minimum thickness = 16 mm

Soft material:

- Working loads depend on strength and thickness of material fastened. Do not use working loads in excess of those for wood.
- Depth of penetration and other conditions same as for fastening wood.
- Use R23 or R36 ($\varnothing 4.5 \text{ mm}$ hole) washer to control penetration and to increase pull-over strength. Separately available from Hilti.

Metal profiles to concrete:

$$N_{rec} = V_{rec} = 0.4 \text{ kN}$$

- Minimum 5 fastenings per fastened unit (normal weight concrete)
- Increase to 600 N possible if 8 or more fastenings in each fastened unit.
- All visible failures must be replaced
- $t_1 = 1\text{--}4 \text{ mm}$

Application requirements

Thickness of base material

Concrete

$h_{min} = 100 \text{ mm}$ ($d_{nom} \geq 4.5 \text{ mm}$)

Steel

$t_{II} \geq 6 \text{ mm}$

Thickness of fastened material

$t_I \leq 50.0 \text{ mm}$

Spacing and edge distances (mm)

Edge distance: concrete

Edge distance: steel

Spacing

$a = 20 \text{ mm}$

Corrosion information

The intended use for safety-relevant and permanent applications only comprises fastenings which are not directly exposed to external weather conditions or moist atmospheres. For further detailed information on corrosion see relevant chapter in **Direct Fastening Principles and Technique** section.

Approvals

ICC (USA)

ABS & LR

Note:

Technical data presented in these approvals and design guidelines reflect specific local conditions and may differ from those published in this handbook.

D

Applications

Example

Metal clips

Angle bracket

Mounting bracket

Load data

Recommended loads (predominantly static)

Steel sheet fastening

t_f [mm]	EDS_P10	
	N_{rec} [kN]	V_{rec} [kN]
0.75	1.1	1.5
1.00	1.3	2.3
1.25	1.7	3.2
≥ 2.00	2.4	4.0

- Recommended loads valid for steel sheet with minimum tensile strength ≥ 360 N/mm².
- For intermediate sheet thicknesses, use recommended load for next smaller thickness.
- N_{rec} and V_{rec} include an overall safety factor of 3.0 applied to the characteristic test data.
Static test: $N_{rec} = N_{test,k} / 3.0$, $V_{rec} = V_{test,k} / 3.0$

Forces of constraint

D

When fastening large pieces of steel, the possibility of shear loadings from forces of constraint should be considered. Avoid exceeding V_{rec} for the fastener shank!

Deflection due to primary loading

Temperature effect

Application requirements

Thickness of base material

	t_{II} (mm)
EDS	≥ 6

Thickness of fastened material

$t_I \leq 3$ mm

Steel fastened material ≤ 3 mm thick, usually deforms with the displaced base material to allow a tight fit between fastened steel and base material without pre-drilling.

Because conditions may vary, trial fastenings are recommended

$t_I > 3$ mm

Without pre-drilling: steel fastened material > 3 mm thick is too stiff to deform entirely with the displaced base material. The gap, which increases with increasing t_I , can result in bending moments being applied to the nail shank.

To prevent imposition of a moment on the shank of fastener, use three fasteners in a group.

With pre-drilling:

If a gap between the fastened part and the base material is unacceptable, the fastened part can be prepared with drilled holes.

Spacing and edge distances (mm)

Base material

Fastened material

Corrosion information

The intended use only comprises fastenings which are not directly exposed to external weather conditions or moist atmospheres. For further detailed information on corrosion see relevant chapter in **Direct Fastening Principles and Technique** section.

D

Application limits

① EDS with DX76 and DX 76 PTR

- Limit line valid for steel, $t_1 \leq 3$ mm
- For steel $t_1 > 3$ mm and without pre-drilling, either make trial fastenings or adjust t_{II} to $t_{II} + t_1$ before using the chart.

					2.0	1.6	1.7	1.9	1.7

- Recommended working loads valid for fastened materials as shown above.
- For intermediate sheet thicknesses, use recommended load for next smaller thickness.
- For stainless steel sheet, use same loads as for carbon steel sheet.
- Recommended loads include an overall safety factor applied to the characteristic strength.
Static test: $N_{rec} = N_{test,k} / 3.0$ $V_{rec} = V_{test,k} / 3.0$
- These recommended loads are appropriate for Eurocode 1 (or similar) wind loading designs.

Other applications*

X-CR P8 / X-CR 14 D12 / X-CR S12

N_{rec} [kN]	V_{rec} [kN]	M_{rec} [Nm]
1.6	2.0	3.8

* Fastened parts: thicker steel components (clips, brackets, etc.)

- Failure of fastened material is not considered in N_{rec} and V_{rec} .
- Loads valid for predominantly static loading.

Forces of constraint

When fastening large pieces of steel or aluminium, the possibility of shear loadings from forces of constraint should be considered in the fastening design. Either allow for movement or avoid exceeding V_{rec} !

Deflection due to primary loading

Temperature effect

Application requirements

Thickness of base material

Using **DX 450** tool: $t_{II} \geq 5.0 \text{ mm}$ ¹⁾

Using **DX 460** tool: $t_{II} \geq 6.0 \text{ mm}$

¹⁾ $t_{II} \geq 4 \text{ mm}$ possible for specific types of hollow sections

Thickness of fastened material

$t_I \leq 12.0 \text{ mm}$ (details see fastener selection)

Spacing and edge distances (mm)

Rolled shapes

Cold formed shapes

Fastened material

** max. allowable $b_x \leq 8 \times t_{II}$ (however, jobsite trails advisable)

Corrosion information

For fastenings exposed to weather or other corrosive conditions. Not for use in highly corrosive surroundings like swimming pools or highway tunnels.

For further detailed information on corrosion see relevant chapter in **Direct Fastening Principles and Technique** section.

Application limits

DX 450, DX 460

- ① **X-CR16** ($t_I \leq 3 \text{ mm}$) with DX 450 tool
- ② **X-CR14** ($t_I \leq 2 \text{ mm}$) with DX 450 tool
- ③ **X-CR14** ($t_I \leq 1 \text{ mm}$) with DX 450 tool
- ④ **X-CR14** ($t_I \leq 1 \text{ mm}$) with DX 460 tool

DX 450: Steel thickness $t_{II} \geq 5 \text{ mm}$

DX 460: Steel thickness $t_{II} \geq 6 \text{ mm}$

ICC (USA): X-CR
 with $d_{nom} = 3.7 \text{ mm}$
 all types

Applications

Examples

Exposure to weather or otherwise corrosive conditions

Noble or corrosive fastened material

Load data

DX Standard: Recommended loads

Fastening wood to concrete, sandlime masonry or steel

N_{rec}

V_{rec}

Fastening wood to concrete, sandlime masonry:

$$N_{rec} = V_{rec} = 0.4 \text{ kN}$$

Fastening wood to steel:

$$N_{rec} = V_{rec} = 0.6 \text{ kN}$$

Design conditions:

- For safety relevant fastenings sufficient redundancy of the entire system is required: minimum 5 fastenings per fastened unit with normal weight concrete base material.
- All visible failures must be replaced.
- Valid for concrete and sandlime masonry with strength of $f_{cc} < 40 \text{ N/mm}^2$.
- Valid for predominantly static loading.

Soft material:

- Working loads depend on strength and thickness of material fastened. Do not use working loads in excess of those for wood.
- Depth penetration and other conditions same as for fastening wood
- Use R23 or R36 ($\varnothing 4.5 \text{ mm}$ hole) washer to control penetration and to increase pull-over strength. Separately available from Hilti.

DX-Kwik (with pre-drilling): Recommended loads

	$N_{rec,1}$ [kN]	$N_{rec,2}$ [kN]	V_{rec} [kN]	M_{rec} [Nm]
X-CR 39/44	2.0	0.6	2.0	5.5
X-CR 48	3.0	0.9	3.0	5.5

Conditions:

- $N_{rec,1}$: concrete in compressive zone.
- $N_{rec,2}$: concrete in tension zone.
- Static or cyclic (5000 load applications) loading.
- $f_{cc} \geq 25 \text{ N/mm}^2$. For higher concrete strengths, higher loadings may be possible if supported by testing.
- A sufficient redundancy has to be ensured, that the failure of a single fastening will not lead to collapse of the entire system.
- Recommended loads are based on failure of the fastener anchorage in the concrete. Thickness and quality of the fastened material may lower the loadings.
- Observance of all pre-drilling requirements, fastened thickness limits, and recommended details.

Application requirements

Thickness of base material

Concrete

$h_{min} = 80 \text{ mm}$ ($d_{nom} = 3.7 \text{ mm}$)

$h_{min} = 90 \text{ mm}$ ($d_{nom} \geq 4.0 \text{ mm}$)

Steel

$t_{II} \geq 5 \text{ mm}$ for fastening of wood

Thickness of fastened material

$t_I \leq 25.0 \text{ mm}$ (detailed information see fastener selection)

Spacing and edge distances (mm)

Approvals

IBMB 3041/8171 X-M8H, X-DKH, X-M6H
SOCOTEC (France): DNH, X-M8H

Note:

Technical data presented in these approvals and design guidelines reflect specific local conditions and may differ from those published in this handbook.

Applications

Examples

Base plates, rails for piping

Radiator brackets

Floor stands, metal fixtures to concrete

Suspended ceilings

Load data

Recommended loads

	$N_{rec,1}$ [kN]	$N_{rec,2}$ [kN]	$V_{rec,1}$ [kN]	$M_{rec,1}$ [Nm]
X-M6H, DNH 37	2.0	0.6	2.0	5.5
X-M8H, X-DKH 48	3.0	0.9	3.0	10.0

Conditions

- $N_{rec,1}$: concrete in compressive zone.
- $N_{rec,2}$: concrete in tension zone.
- Predominantly static loading.
- Concrete C20/25–C50/60.
- A sufficient redundancy has to be ensured, that the failure of a single fastening will not lead to collapse of the entire system.
- Recommended loads are based on failure of the fastener anchorage in the concrete. Thickness and quality of the fastened material may lower the loadings.
 - Observance of all pre-drilling requirements, fastened thickness limits, and recommended details.
 - The recommended loads in the table refer to the resistance of the individual fastening and may not be the same as the loads F_N and F_V acting on the fastened part.

Note: If relevant, prying forces need to be considered in design, see example. Moment acting on fastener shank only in case of a gap between base and fastened material.

Arrangements to prevent moment on shank:

Coupler tight against concrete

Non-symmetric arrangement

- Moment on fastened part
- Prying effect must be considered in determining loads acting on fastener

Resultant forces on nail

Miscellaneous attachments

Load data

Recommended loads

Fastener designation	Shank $d_s \times L_s$ [mm]	N_{rec} [kN]	V_{rec} [kN]	M_{rec} [Nm]
X-EM6H, X-EW6H, X-EF7H	3.7 x 8.5	1.6	1.6	5.0
X-EM8H, X-EM10H	4.5 x 12.0	2.4	2.4	9.0
X-EW10H-30-14	5.2 x 15.0	3.0	3.0	14.0

Conditions

- Redundancy (multiple fastening) must be provided.
 - Global factor of safety for static pull-out > 3 (based on 5% fractile value).
 - Predominantly static loading.
 - Strength of fastened material must be considered.
 - Observance of all application limitations and recommendations.
 - The recommended loads in the table refer to the resistance of the individual fastening and may not be the same as the loads F_N and F_V acting on the fastened part.
- Note: If relevant, prying forces need to be considered in design, see example.
Moment acting on fastener shank only in case of a gap between base and fastened material.

Arrangement to prevent moment on shank:
Coupler tight against steel

Application requirements

Thickness of base material

Minimum steel thickness:

	t_{II}
X-EM6H/EW6H, X-EF7H	$\geq 4 \text{ mm}$
X-EM8H/EW8H, X-EM10H/EW10H	$\geq 6 \text{ mm}$

Thickness of fastened material

$$t_1 \leq L_g - t_{\text{washer}} - t_{\text{nut}} \approx 1.5\text{--}33.0 \text{ mm}$$

Spacing and edge distances

Edge distance and spacing: $c = s \geq 15 \text{ mm}$

Corrosion information

The intended use only comprises fastenings which are not directly exposed to external weather conditions or moist atmospheres. For further detailed information on corrosion see relevant chapter in **Direct Fastening Principles and Technique** section.

Application limits

① Shank:

CR 500 (CrNiMo alloy) equivalent to A4 / S31803 (1.4462) AISI grade 316 material
N 08926 (1.4529) ¹ Available on request

② Threaded sleeve: S 31600

(X2CrNiMo 17132)

③ SN12-R washers: S 31635

(X5CrNiMo 17-12-2+2H)

④ Sealing washers: Elastomer, black *

* Resistant to UV, salt water, water, ozone, oils, etc.

¹⁾ For High Corrosion Resistance HCR material inquire at Hilti

Designation according to Unified Numbering System (UNS)

Recommended fastening tools

DX 351-BT / BTG

See **X-BT fastener program** in the next pages and **Tools and equipment** chapter for more details.

Approvals

ICC ESR-2347 (USA), ABS, LR, UL, DNV, BV 23498/A1, GL 12272-10HH, Russian Maritime Register

Applications

Examples

Threaded stud applications especially for:

- High strength steel
- Coated steel structures
- Through penetration of base steel is not allowed

Grating with **X-FCM-R**

Base plates

Installation rails

Junction box, etc.

Earthing / Bonding

Load data

Recommended loads – Steel

Steel grade: Europe, USA	S235, A36	S355, Grade 50 and stronger steel
Tension, N_{rec} [kN/lb]	1.8 / 405	2.3 / 517
Shear, V_{rec} [kN/lb]	2.6 / 584	3.4 / 764
Moment, M_{rec} [Nm/lbft]	8.2 / 6	8.2 / 6
Torque, T_{rec} [Nm/lbft]	8 / 5.9	8 / 5.9

Example:

Recommended loads – cast iron *

Tension, N_{rec} [kN/lb]	0.5 / 115
Shear, V_{rec} [kN/lb]	0.75 / 170
Moment, M_{rec} [Nm/lbft]	8.2 / 6

Conditions for recommended loads:

- Global factor of safety for static pull-out > 3 (based on 5% fractile value)
 - Minimum edge distance = 6 mm [1/4"].
 - Effect of base metal vibration and stress considered.
 - Redundancy (multiple fastening) must be provided.
 - The recommended loads in the table refer to the resistance of the individual fastening and may not be the same as the loads F_N and F_V acting on the fastened part.
- Note: If relevant, prying forces need to be considered in design, see example. Moment acting on fastener shank only in case of a gap between base and fastened material.

*Requirements of spheroidal graphite cast iron base material

Subject	Requirements
Cast iron	Spheroidal graphite cast iron according to EN 1563
Strength class	EN-GJS-400 to EN-GJS-600 according to EN 1563
Chemical analysis and amount of carbon	3.3–4.0 mass percentage
Microstructure	Form IV to VI (spherical) according to EN ISO 945-1:2010
Material thickness	Minimum size 7 according to Figure 4 of EN ISO 945-1:2010 $t_{II} \geq 20$ mm

Design resistance – Steel

Steel grade:		S235	S355
Tension	N_{Rd} [kN]	2.9	3.7
Shear	V_{Rd} [kN]	4.16	5.4
Moment	M_{Rd} [kN]	18.4	18.4

Design resistance – cast iron *

Tension	N_{RD} [kN]	0.8
Shear	V_{RD} [kN]	1.2
Moment	M_{RD} [kN]	13.1

Recommended interaction formula for combined loading

Combined loading situation	Interaction formula
V-N (shear and tension)	$\frac{V}{V_{rec}} + \frac{N}{N_{rec}} \leq 1.2$ with $\frac{V}{V_{rec}} \leq 1.0$ and $\frac{N}{N_{rec}} \leq 1.0$
V-M (shear and bending)	$\frac{V}{V_{rec}} + \frac{M}{M_{rec}} \leq 1.2$ with $\frac{V}{V_{rec}} \leq 1.0$ and $\frac{M}{M_{rec}} \leq 1.0$
N-M (tension and bending)	$\frac{N}{N_{rec}} + \frac{M}{M_{rec}} \leq 1.0$
V-N-M (shear, tension and bending)	$\frac{V}{V_{rec}} + \frac{N}{N_{rec}} + \frac{M}{M_{rec}} \leq 1.0$

Cyclic loading:

- Anchorage of **X-BT-R** threaded stud in steel base material is not affected by cyclic loading.
- Fatigue strength is governed by fracture of the shank. Inquire at Hilti for test data if high cycle loading has to be considered in the design.

X-BT for fastenings of earthing and bonding device

Protective earthing circuits (According to EN 60439-1 and EN 60204-1)

Single point connection

Fasteners

X-BT M10-24-6 SN12-R,
X-BT W10-24-6 SN12-R,
X-BT M6-24-6 SN12-R,

Maximum connected cable size
 $\leq 10 \text{ mm}^2$ **Copper**
AWG 8

Double point connection

Fasteners

X-BT M10-24-6 SN12-R,
X-BT W10-24-6 SN12-R,
X-BT M6-24-6 SN12-R,
X-BT W6-24-6 SN12-R

Maximum connected cable size
 $\leq 16 \text{ mm}^2$ **Copper**
AWG 6

External lightning protection systems (According to EN 50164-1)

Fasteners

X-BT M10-24-6 SN12-R,
X-BT W10-24-6 SN12-R,
X-BT M6-24-6 SN12-R,
X-BT W6-24-6 SN12-R

Test class = **N**
 $I_{\text{max}} = 50 \text{ kA}$
 Time = $t_d \leq 2 \text{ ms}$

Test class = **H**
 $I_{\text{max}} = 100 \text{ kA}$
 Time = $t_d \leq 2 \text{ ms}$

Application requirements

Thickness of base material

Thickness of fastened material

X-BT M8: $2.0 \leq t_1 \leq 7.0 \text{ mm}$
X-BT M10 / X-BT W10: $2.0 \leq t_1 \leq 15.0 \text{ mm}$
X-BT M6 / X-BT W6: $1.0 \leq t_1 \leq 14.0 \text{ mm}$

Note:

For X-BT with SN 12R sealing washer $t_1 \geq 2.0 \text{ mm}$

For X-BT M6 / W6 with SN 12R sealing washer $t_1 \geq 1.0 \text{ mm}$

Spacing and edge distances

Edge distance: ≥ 6 mm

Spacing: ≥ 15 mm

Corrosion information

The corrosion resistance of Hilti CR500 and S31803 stainless steel material is equivalent to AISI 316 (A4) steel grade.

Studs made of N 08926 (HCR) material with higher corrosion resistance, e.g. for use in road tunnels or swimming pools, are available on special order.

Application limit

- $t_{||} \geq 8$ mm [$5/16$ "] \rightarrow No through penetration
- No limits with regards to steel strength

Fastener selection and system recommendation

Fastener program

Designation	Item no.	Tool Designation

Cartridge selection and tool energy setting

6.8/11 M high precision brown cartridge

Fine adjustment by installation tests on site

Fastening quality assurance

Fastening inspection

X-BT M8
 $h_{NVS} = 15.7-16.8 \text{ mm}$

**X-BT M10 / X-BT W10 and
 X-BT M6 / X-BT W6**
 $h_{NVS} = 25.7-26.8 \text{ mm}$

Installation

X-BT with washer

Fastened material hole \varnothing
 $\geq 13 \text{ mm}$

X-BT M6 / X-BT W6

Fastened material with
 pre-drilled hole diameter
 $< 7 \text{ mm}$

Fastened material with
 pre-drilled hole diameter
 $\geq 7 \text{ mm}$

Pre-drill with **TX-BT 4/7** step shank drill bit

Pre-drill until the shoulder grinds a shiny ring (to ensure proper drilling depth)

Before fastener installation:

the drilled hole must be clear of liquids and debris. The area around the drilled hole must be free from liquids and debris.

Tighten using a screwdriver with torque clutch

Tightening torque:
T_{rec} ≤ 8 Nm (5.9 ft-lb)!

Hilti screwdriver:	Torque setting:
SF 121-A	11
SF 150-A	9
SF 180-A	8
SF 144-A	9
SF 22A	9

X-BT for fastenings of earthing and bonding device

Hold the lower nut with a spanner whilst tightening the second nut.

The tightening torque can be in a range of about 20 Nm.

F

These are abbreviated instructions which may vary by application. **ALWAYS** review/follow the instructions accompanying the product.

X-CR M8-15-12 P8	17.0 – 20.0
X-CR M8-9-12 FP10	12.0 – 15.0
X-CR M8-15-12 FP10	17.0 – 20.0

Installation

Fastening to concrete

DX-Kwik (pre-drilling)

X-CR M8- -42 P8

Pre-drill with drill bit TE-C-5/23B (Item-no. 28557) or TE-C-5/23 (Item no. 00061787)

Tightening torque
 $T_{rec} = 10 \text{ Nm}$

Fastening to steel

Tightening torque
X-CR M8 $T_{rec} = 8.5 \text{ Nm}$

These are abbreviated instructions which may vary by application.
ALWAYS review/follow the instructions accompanying the product.

Load data

Recommended tensile loads N_{rec} [kN]

Grating opening type

	Rectangular		Square	
	Bar spacing [mm]		Bar spacing [mm]	
	18	30	18	30
X-FCM	0.8**	0.8**	2.4*	0.8**
X-FCM-M	0.8**	0.8**	1.8*	0.8**
X-FCM-R	1.4**	1.0**	1.8*	1.0**

Grating opening type

	Rectangular		Square	
	Bar spacing [mm]		Bar spacing [mm]	
	30	57	30	60
X-FCM-M_L	0.8**	0.8**	1.8*	0.8**

* Loading is limited by recommended load for threaded stud.

** Loading is limited by elastic limit of the **X-FCM** disk. Exceeding recommended loads can result in plastic deformation of disk.

Notes:

X-FCM, **X-FCM-M**, **X-FCM-R**, **X-FCM-M_L** resist shear by friction and are not suitable for explicit shear load designs, e.g. diaphragms. Depending on surface characteristics, shear loads of up to about 0.3 kN will not result in permanent deformation. Therefore small unexpected shear loads can generally be accommodated without damage.

Characteristic tensile loads N_{Rk} :

Type	Grating – bar spacing	X-FCM-R with		X-CRM
		X-BT S235 / A36 steel	> S355 / Grade 50 steel	
	Rectangle 18 mm	4.2 kN / 945 lb*	4.2 kN / 945 lb*	4.2 kN / 945 lb*
	Rectangle 30 mm	3.0 kN / 675 lb*	3.0 kN / 675 lb*	3.0 kN / 675 lb*
	Square 18 mm	5.4 kN / 1215 lb	6.9 kN / 1550 lb	5.4 kN / 1215 lb
	Square 30 mm	3.0 kN / 675 lb*	3.0 kN / 675 lb*	3.0 kN / 675 lb*

* Loading is limited by elastic limit of the **X-FCM** disc.

Load displacement behaviour – examples:

Tensile load

Shear load

Application requirements

Thickness of base material

X-BT

$t_{II} \geq 8 \text{ mm}$

X-CRM and X-EM8H

$t_{II} \geq 6 \text{ mm}$

Thickness of fastened material

Grating height: 25–50 mm with standard X-FCM. For other dimensions special X-FCM are available on demand.

Spacing and edge distances

X-CRM, X-EM8H

Edge distances: $c \geq 15 \text{ mm}$

Spacing: $s \geq 15 \text{ mm}$

X-BT

Edge distance: $c \geq 6 \text{ mm}$

Spacing: $s \geq 15 \text{ mm}$

Corrosion information

The intended use of the **X-EM8H** carbon steel fasteners only comprises fastenings which are not directly exposed to external weather conditions or moist atmospheres. For outdoor applications **X-BT** or **X-CRM** stainless steel fasteners have to be used, see fastener selection.

Application limits

DX 76, DX 76 PTR

- ① **X-CRM8-15-12 FP10** /
DX 76, DX 76 PTR (impact)
- ② **X-CRM8-15-12 FP10** /
DX 76, DX 76 PTR (co-acting)
- ③ **X-EM8H-15-12 FP10** /
DX 76, DX 76 PTR (impact)
- ④ **X-EM8H-15-12 P8** /
DX 76, DX 76 PTR (impact)

DX 460

- ① **X-CRM8-15-12 P8** / DX 460 (impact)
- ② **X-CRM8-15-12 P8** / DX 460 (co-acting)
- ③ **X-EM8H-15-12 P8** / DX 460 (impact)

X-BT: No application limits → using in high strength steel
 No through penetration → $t_{II} \geq 8 \text{ mm}$ [^{9/16"}]

Fastener selection and system recommendation

Fastener program

Application areas

Indoors, dry and non corrosive environment

Indoors, mildly corrosive environment, or for limited lifetime use

Marine, offshore, petrochemical, caloric (coal, oil) power plants, etc.

Comment: European Technical Approvals for the fasteners **XI-FV** (ETA-03/0004, DOP no. Hilti-DX-DOP-002) and **SX-FV** (ETA-03/0005) for use in ETICS are available. For more information please contact Hilti.

Note: technical data presented in these approvals and design guidelines reflect specific local conditions and may differ from those published in this handbook.

Applications

Composite thermal insulation

Insulation behind curtain walls

Moisture barriers / drainage plates

Fastener program

Fastener selection

Select Fastener Length $L = t_i$

In general:

The fastener length L must be equal to the thickness t_i of mineral wool and EPS insulation material, as shown in the drawing above.

Exceptions:

For mineral wool of intermediate thicknesses use next shorter X-IE.

Not for use with PUR, PIR, XPS, Multi layer boards or similar hard material not listed on this page.

Note:

For soft mineral wool use X-IE 9. Or X-IE 6 with HDT 90/ HDT 90 BK.

Designation	Fastener X-PH Ls	Item no.	Insulation thickness t_i [mm]

System recommendation

Tool

DX 460 IE and DX 460 IE XL

Cartridge selection and tool energy setting

Cartridge recommendation:	Steel:	6.8/11M yellow or red cartridge
	Concrete	6.8/11M yellow or red cartridge
	Masonry:	6.8/11M yellow or green cartridge

Tool energy adjustment by setting tests on site.

Application requirements

Thickness of base material

Concrete:	$h_{min} = 80 \text{ mm}$
Steel:	$t_{II} \geq 4 \text{ mm}$

Thickness of fastened material

Insulation thickness: $t_I = 25\text{--}200 \text{ mm}$

Spacing and edge distances

For setting instructions please inquire at the insulation material supplier.

If recommendations from suppliers are not available, please use minimum 3 pcs of X-IE fasteners per insulation material and ≥ 5 pcs of X-IE fasteners per m^2

Application limits

Concrete:	$f_{cc} = 15\text{--}45 \text{ N/mm}^2$	(aggregate size $\leq 32 \text{ mm}$)
Sand-lime masonry:	$f_{cc} = 15\text{--}45 \text{ N/mm}^2$	
Clinker brick work:	$f_{cc} = 28\text{--}45 \text{ N/mm}^2$	
Steel:	$f_u = 360\text{--}540 \text{ N/mm}^2$	($t_{II} = 4\text{--}6 \text{ mm}$)

Load data

Recommended loads

	Insulation thickness t_I [mm]				
	40	50	60-70	75	80-200
X-IE 6	Shear, V_{rec} [N]				
Polystyrol - EPS [30 kg/m ³]	150	250	300	325	350
X-IE 6	Pullover, N_{rec} [N]				
Polystyrol - EPS [30 kg/m ³]	250	290	300	300	300
X-IE 9, HDT 90	Pullover, N_{rec} [N]				
Mineral wool [$\geq 7.5 \text{ kN/m}^2$]*	–	–	135	135	135
Mineral wool [$\geq 15 \text{ kN/m}^2$]*	–	–	250	250	250

*) Tensile Strength σ_{mt} according to DIN EN 1607

When base material properties are questionable, jobsite qualification is necessary

Fastening quality assurance

Installation

1. Insulation material suitability.

2. Load the X-IE on the tool and push the X-IE all the way into the insulation.

3. Fasten the X-IE into the rib of the composite deck only NOT the trough.

Important: This description of the installation process is only for illustration purposes. The installation must always follow the instructions for use provided with the product.

Fastening inspection

	Insulation thickness t_i [mm]													
	40	50	60	70	75	80	90	100	120	140	150	160	180	200
$h_{ET} = 24-29$ mm														
x_{min} [mm]	9	9	19	29	34	39	49	59	79	99	109	119	139	159
x_{max} [mm]	14	14	24	34	39	44	54	64	84	104	114	124	144	164

Check with the gauge immediately after fastening

Adjust the power setting if required

These are abbreviated instructions which may vary by application. **ALWAYS** review/follow the instructions accompanying the product.

X-SW 30, X-SW 60 Soft Washer Fastener

Product data

Dimensions

X-SW 30

X-SW 60

General information

Material specifications

Plate: PE
 Nail: Carbon steel shank: HRC 52.5
 Zinc coating: 5–13 µm

Recommended fastening tools

DX 460, DX 36, DX-E 72, DX 460-MX
 See **X-SW fastener program** in the next pages and **Tools and equipment** chapter for more details.

Applications

Examples

Membranes and drainage plates

Insulation up to 30 mm thick

Nets, fabric and similar

Plastic corrugated sheets

Load data

Recommended loads

 $N_{rec} = 300 \text{ N}$

 $V_{rec} = 300 \text{ N}$

Design conditions:

1. Minimum 5 fastenings per fastened unit.
2. Predominantly static loading.
3. Design loads valid for nail pull-out strength. Fastened material has to be considered separately.
4. Valid for concrete C 30/37.

Application requirements

Thickness of base material

Concrete: $h_{min} = 80 \text{ mm}$

Steel: $t_{II} \geq 4 \text{ mm}$

Thickness of fastened material

Membranes, nets, etc.: $t_1 \leq 25 \text{ mm}$

Insulation: $t_1 \leq 30 \text{ mm}$

Spacing and edge distances

For setting instructions please inquire at the supplier of fastened material.

Fastener selection and system recommendation

Fastening to concrete

Green concrete

Normal concrete

Old concrete

- **X-SW 30** for stronger, less damageable material.
- **X-SW 60** for more easily damaged material (i.e. aluminium foil, nets, paper, etc.)
- Select **C 37**, **C 47** and **C 62** according to base material conditions and fastened thickness

Fastener program

Designation	Item no. Packs of 100/150	Packs of 400/500	L_s [mm]	Tools
				Designation
① X-SW 30-C 37	40643	40614	37	DX 460, DX 36, DX-E 72

③ X-SW 30	371370			DX 460-MX with collated
③ X-SW 60	371371			X-C nails (3.5 mm shank dia.)

Cartridge selection and tool energy setting

Cartridge recommendation: Concrete **6.8/11M yellow or red**

Masonry: **6.8/11M green**

Tool energy adjustment by setting tests on site.

X-FS Form Stop

Product data

Dimensions

General information

Material specifications

Nail: zinc coating: 5–20 µm

Recommended fastening tools

DX 460, DX 36, DX 460-MX

See **X-FS fastener program** in the next pages and **Tools and equipment** chapter for more details.

Applications

Examples

Positioning concrete forms on concrete surfaces. Leave in place, grey polyethylene is non rusting, nearly invisible and non-conductive.

X-FS is suitable and usable for minor forming applications

Load data

Recommended working loads

$V_{rec} = 400 \text{ N}$

(predominantly static, however, vibration from concrete compacting is allowed)

Application requirements

Thickness of base material

Concrete: $h_{min} = 80 \text{ mm}$

Spacing and edge distances

Spacing and edge distances depending on job site requirements.

Corrosion information

For temporary fixations no restrictions exist.

Fastener program

Fastener				Tools
Designation	Item no.	L_s [mm]	Nail shank diameter [mm]	Designation
① X-FS C 52 *	407346	52	3.5	DX 460, DX 36
② X-FS MX **	408022			DX 460-MX

* For unusual applications, **X-FS** available with other nails on special order

** **X-FS** without nail for fastening with collated nails.

Cartridge selection and tool energy setting

Cartridge recommendation:	Steel:	6.8/11M red cartridge
	Concrete:	6.8/11M yellow or red cartridge
	Masonry:	6.8/11M yellow or green cartridge

Tool energy adjustment by setting tests on site.

Approvals

SOCOTEC (France): X-HS/X-CC with X-DKH

Lloyds Register: X-HS

ICC, UL, FM: X-HS W6/10

Note: technical data presented in these approvals and design guidelines reflect specific local conditions and may differ from those published in this handbook.

Applications

Examples

Threaded rod attachments to concrete and steel

Wire attachments to concrete and steel

Load data

Recommended loads

Concrete (DX-Kwik with pre-drilling) or steel

X-HS

Fastener designation	$N_{rec} = V_{rec}$ [kN]	Base material
X-HS __ DKH 48	0.9	Concrete
X-HS __ U19	0.9	Steel
X-CC DKH 48	0.9	Concrete
X-CC U16	0.9	Steel

Conditions:

- Predominantly static loading.
- Concrete C20/25–C50/60
- Strength of fastened material is not limiting.
- Observance of all application limitations and recommendations (especially pre-drilling requirements).

X-CC

G

Concrete (DX Standard without pre-drilling)

Cartridge selection

Cartridge recommendation:

Steel:	6.8/11M red cartridge	$t_{ij} \geq 6 \text{ mm}$
	6.8/11M green cartridge	$t_{ij} < 6 \text{ mm}$
Concrete:	6.8/11M yellow cartridge	on green/fresh and standard concrete
	6.8/11M red cartridge	on precast, old and hard concrete

Tool energy adjustment by setting tests on site.

Fastening quality assurance

Installation

X-HS

1. Attach the threaded rod to the X-HS before fastening

2. For **DKH 48** pre-drill ($\varnothing 5 \times 23$)

3. Load the assembly into the tool

4. Locate the nail, compress the tool, pull the trigger and the fastening is complete

5. Bend the X-HS assembly down to the vertical position

X-CC

1. Assemble the wire with the **X-CC**

2. For **DKH 48** pre-drill ($\varnothing 5 \times 23$)

3. Load the assembly into the tool

4. Locate the nail, compress the tool, pull the trigger and the fastening is complete

5. Adjust the wire as required

Quality assurance

X-HS

$h_{NVS} = 6-10 \text{ mm}$

X-CC

$h_{NVS} = 4-7 \text{ mm}$

NO LIFTING

Do not use for lifting, such as in a crane or pulley situation.

NO MOVEMENT

Hilti hangers are to be used to suspend stationary loads only. Do not use to suspend moving services, or services likely to be subject to movement.

NO JOINING

Hilti hangers must not be used as an in-line joint using a Hilti fastener, or any other joining device. A Hilti hanger assembly must comprise one length of cable and one Hilti fastener only. If a longer length is needed, do not join two assemblies together.

Recommended fastening tools

DX 460-F8, DX 351-F8, GX 120-ME, GX 100-E, DX 460 MX, DX 351 MX

See **X-EKB, X-ECH fastener program** in the next pages and **Tools and equipment chapter** for more details.

Approvals

UL (USA): X-EKB MX, X-ECH / FR_U37

CSTB (France): X-EKB_U 37, X-ECH_U37

Note: technical data presented in these approvals and design guidelines reflect specific local conditions and may differ from those published in this handbook.

Applications

Examples

X-EKB for fastening cables

X-ECH for fastening bunched cables

Load data

Fastener capacity

X-EKB: Securing electrical cables to concrete ceilings and walls

Max. capacity (number of cables in one **X-EKB**) at spacing of 50–100 cm

Designation	Number of wires/cables and wire sizes	
	NYM 3 x 1.5 mm² (∅ 8 mm)	NYM 5 x 1.5 mm² (∅ 10 mm)
X-EKB 4 __	4	3
X-EKB 8 __	8	5
X-EKB 16 __	16	10

X-ECH: Securing electrical cable to ceilings and walls

Designation	No. of nails	Number of cables
X-ECH-S __ and X-ECH/FR-S __		max. 15 × NYM 5×1.5 ² (∅ 10 mm)
X-ECH-M __ and X-ECH/FR-M __		max. 25 × NYM 5×1.5 ² (∅ 10 mm)
X-ECH-L __ and X-ECH/FR-L __		max. 35 × NYM 5×1.5 ² (∅ 10 mm)
X-ECH-15 MX and X-ECH-B	1 or 2	max. 15 × NYM 3×1.5 ² (∅ 10 mm)
X-ECH-30 MX and X-ECH-B	1 or 2	max. 30 × NYM 3×1.5 ² (∅ 10 mm)

Conditions:

- For concrete C12/15 to C45/55 ($f_{cc} = 15$ to 55 N/mm²)
- All visible placing failures have to be replaced
- Damaged X-ECH have to be replaced

Application requirements

Thickness of base material

Concrete

X-U: $h_{min} = 80$ mm

X-GHP, X-GN: $h_{min} = 60$ mm

Steel

$t_{II} \geq 4$ mm

Thickness of fastened material

Fasteners recommended for cable ∅ 8 mm and 10 mm

Spacing and edge distances

X-EKB: approximately 50–100 cm (Adjust as necessary to control cable sag)

X-ECH: approximately 60– 80 cm (Adjust as necessary to limit sagging)

Corrosion information

These zinc-coated fasteners are not suitable for long-term service outdoors or in otherwise corrosive environments.

For further detailed information on corrosion see relevant chapter in **Direct Fastening Principles and Technique** section.

Typical average moisture content of the wood specimens	≤ 12%	≤ 20%	> 20%
Designation on package / label			
Requirements for Nails with $d \leq 4$ mm	No coating	Fe/Zn 12c	Fe/Zn 25c ²
Suitable GX-WF Materials	All	Galvanized, Hot Dip Galvanized, Stainless	Hot Dip Galvanized, Stainless

1 In particularly corrosive environments, thicker Hot Dip Galvanization or Stainless Steel shall be considered

2 For Hot Dip Galvanized nails typically Fe/Zn 25c is substituted by Z350 according to EN 10147

Note: Certain wood treatments and species, like Oak, Douglas-fir or similar, require stainless steel nails due to the acidity of the wood, typically independent of the Service Class.

1 Values are valid for penetration depths of 12d (smooth nails) or 8d (profiled nails) respectively. Reduction may factors apply acc. to EN 1995-1-1, section 8.3.2 for smaller penetration depths or for nails installed into wood near the fibre saturation point. The minimum point side penetration depth is 8d (smooth nails) and 6d (profiled nails) respectively. See also section "Application limits"

2 For D-Head nails, the head pull-through parameter f_{head,k} was determined based on testing and calculation using the larger diameter d_h as shown in the Product Data Section. Therefore this value is also given in this table to calculate the correct head pull-through resistance

3 Values for smooth nails are calculated per EN 1995-1-1 section 8.3.2 (6)

4 Values for f_{ax,k} and f_{head,k} for profiled nails based on Initial Type Testing in accordance with EN 14592

Design data in accordance with EN 1995-1-1 (Eurocode 5), Section 8

Design Conditions for Wood to Wood connections:

- Correct installation according to this document, Hilti's printed installation instructions and applicable regulations
- Appropriate nail was selected for the relevant Service Class
- Connection must consist of at least 2 nails

Shear Capacity:

The shear capacity and combined loading capacity has to be calculated according to EN 1995-1-1 or other applicable regulations. The shear capacity depends on the type of connection, the bearing strength of the wood, the slenderness of the nails and the withdrawal strength of the nails. Minimum point side penetration depths are given in the section “Fastener Selection”. Other geometrical connection parameters shall comply with EN-1995-1-1 (EuroCode 5) or other applicable regulations.

Explanation of the failure modes associated with the design parameters presented on this document

Yield Moment $M_{y,k}$

Pull-out $f_{ax,k}$

Head pull-through $f_{head,k}$

Calculation example

This calculation should illustrate the characteristic capacity of a common nail type in tension. For a full design, the provisions in EN 1995-1-1 shall be followed using the technical data in this document.

Example:

Characteristic withdrawal capacity for a galvanized profiled nail **GX-WF 90 x 3.1 RD 34 Galv**

Input data:

$t = 20 \text{ mm}$; $t_{pen} = 70 \text{ mm}$; $k_p = 350 \text{ kg/m}^3$

⇒ $f_{ax,k} = 6.32 \text{ N/mm}^2$ and $f_{head,k} = 13.91 \text{ N/mm}^2$ (see **Characteristic Pull out and Pull-through Resistance table**)

GX-WF 90 x 3.1 RD 34 Galv

$l_g = 73.2 \text{ mm}$; $l_p = 4.8 \text{ mm}$; $d_n = 3.1 \text{ mm}$; $d_h = 7.2 \text{ mm}$ (see **Galvanized Nails, Service Class 1&2 table**)

⇒ $l_g + l_p = 78 \text{ mm} > t_{pen}$ ⇒ → Embedded part is fully threaded (except tip)

⇒ Only threaded part transfers axial loads: $= t_{pen} - l_p = 70 \text{ mm} - 4.8 \text{ mm} = 65.2 \text{ mm}$

Calculations:

Pull-out capacity: $f_{ax,k} = 6.32 \times 3.1 \times (70-4.8) = 1277 \text{ [N]}$

Head pull-through capacity: $f_{head,k} = 13.91 \times 7.2^2 = 721 \text{ [N]}$

Char. withdrawal capacity:

$F_{ax,Rk} = \min \{ f_{ax,k} \times d_n \times (t_{pen}-l_p); f_{head,k} \times d_h^2 \} = 721 \text{ N}$

⇒ **Head pull-through governs**

Note: Nail Tensile strength doesn't govern for GX-WF nails

Results:

To calculate the **design withdrawal load $F_{ax,Rd}$** , a safety factor γ_M (= 1.3 for connections) and a modification factor k_{mod} for load duration, wood type and moisture, apply per Eurocode 5

⇒ Example: solid timber, Service Class 2, permanent loading ⇒ $\gamma_M = 1.3$; $k_{mod} = 0.6$

⇒ $F_{ax,Rd} = F_{ax,Rk} \times k_{mod} / \gamma_M = 721 \text{ N} \times 0.6 / 1.3 = 333 \text{ N}$ or **34 kg**

Application requirements

Minimum point side penetration depth

(for nails in tension please consider Characteristic Pull out and Pull-through Resistance table, footnote 1):

- 8 x nail diameter d_n for smooth nails
- 6 x nail diameter d_n for profiled nails

Spacing and edge distance:

Geometrical limitations like spacing and edge distance shall be in compliance with EN 1995-1-1 or other applicable regulations

Fastener Selection and system recommendation

The information in this section complies with EN 1995-1-1 (Eurocode 5) and EN 14592. Item numbers shown in the following tables are for nails only and do not include gas cans.

Where do I use profiled or smooth nails?

In accordance with EN 1995-1-1 the following general rules apply. For non-structural applications, like e.g. battens, other local regulations may apply:

- Profiled nails shall be used for permanent or long-term withdrawal loads > 6 months (see table 2.1 of EN 1995-1-1)
- Smooth nails can only be used for short to medium term withdrawal loads < 6 months (e.g. wind) or for shear loads only

Fastening quality assurance

Fastening Inspection

Fastening wood to wood

Pre-drilling requirements

Pre-drilling requirements are described in EN 1995-1-1, section 8.3.1.2.

Part 5:

Direct fastening principles and technique

1. Introduction

1.1 Definitions and general terminology

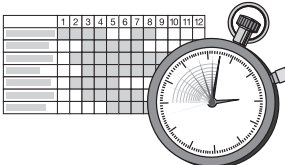

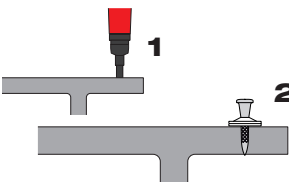

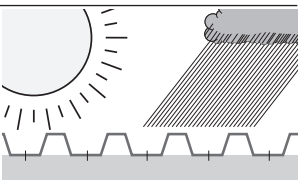

Hilti direct fastening technology is a technique in which specially hardened nails or studs are driven into steel, concrete or masonry by a piston-type tool. Materials suitable for fastening by this method are steel, wood, insulation and some kinds of plastic. Fastener driving power is generated

by a power load (a cartridge containing combustible propellant powder, also known as a “booster”), combustible gas or compressed air. During the driving process, base material is displaced and not removed. In Hilti terminology, **DX** stands for “powder-actuated” and **GX** for “gas-actuated” systems.

1.2 Reasons for using powder- or gas-actuated fastening

The illustrations below show some of the main reasons why many contractors take

advantage of the benefits of powder or gas-actuated fastening.

		
<p>Speed is important.</p>	<p>An easy-to-use, uncomplicated fastening system is required.</p>	<p>A weather-independent fastening system is required.</p>
		
<p>Electric power is not available or electric cables would hinder the work.</p>		

A complete fastening system with assured strength is required.

Drilling is not viable because of noise.

Drilling would be too difficult.

Drilling would cause too much dust.

1.3 Direct fastening applications

Typical applications for powder- or gas-actuated fastening are shown in the illustrations below:

- Fastening thin metal sheets: roof decking wall liners and floor decking
- Fastening thicker steel members: e.g. metal brackets, clips
- Fastening soft materials such as wooden battens or insulation to steel, concrete or masonry
- Threaded studs for suspended ceilings, installing building services, bar gratings or chequer plate floors
- Connections for composite structures: fastening nailed composite shear connectors

Roof decking

Wall liners

Floor decking

Metal brackets, clips and tracks

Fixtures for mechanical and electrical installations

Hangers with threaded connectors

Wooden battens fastened to steel or concrete

Grating fastenings

Shear connectors

Hilti direct fastening systems are specially designed for each application and trade.

Key applications and the corresponding fastening systems are shown below.

Roof and floor decking in steel & metal construction

Gratings in the petrochemical and other industries

X-BT +
X-FCM R

DX 351 BTG

Interior partition walls (drywall) in interior finishing

X-GN

GX 120

Concrete forms in building construction

X-FS

DX 460

**Conduit clips and ties in mechanical and electrical installations**

X-EKS, X-ECT

GX 120-ME

2. The direct fastening system

The fastener, tool and driving energy form a **fastening system** with its own specific characteristics. Examples of Hilti direct

fastening system components are shown below.

Fasteners	Fastening tools	Driving energy
		
Powder-actuated tool		
		
Gas-actuated tool		

2.1 Fasteners

Fasteners can be classified in three general types: nails, threaded studs and composite fasteners.

Nails

Siding and decking nails

General purpose nails

Threaded studs

Blunt-ended fastener
(requires pre-drilling)

Composite fasteners

Multi-part fasteners

X-FCM grating disk with threaded stud

X-HVB shear connectors fastened with **X-ENP-21** HVB nails

X-ENP nail with **SDK 2** sealing cap

The nails used (also known as drive pins) are of a special type equipped with washers to meet the needs of the application and to provide guidance when driven. Threaded studs are essentially nails with a threaded upper section instead of a head. Composite fasteners are an assembly consisting of a nail with an application-specific fastening component such as a clip, plate or disk made of metal or plastic.

Siding and decking nails can be recognized by their washers which are specially designed to hold down the metal sheets and to absorb excess driving energy. Fasteners designed for driving into steel usually have

knurled shanks which increase their pull-out resistance. Fasteners for use on concrete have longer shanks than those for use on steel. Threaded studs may have either a metric (M6, M8 or M10) or Whitworth ($1/4"$, $5/16"$ or $3/8"$) thread.

Nails and threaded studs are commonly zinc-plated for resistance to corrosion during transport, storage and construction. As this degree of protection is inadequate for long-term resistance to corrosion, use of these zinc-plated fasteners is limited to applications where they are not exposed to the weather or a corrosive atmosphere during their service life. The zinc layer on

fasteners driven into steel is, in fact, a disadvantage in that it reduces pull-out resistance. For this reason, the thickness of zinc on the fastener must be optimized to ensure good corrosion protection as well as high holding power. During production, tight control of the galvanizing process is necessary to prevent excess zinc thickness and thereby poor fastening performance.

Fasteners must be 2 to 3 times harder than the material into which they are driven. The tensile strength of structural steel is com-

monly between 400 and 600 MPa. Fasteners for use on steel thus require a strength of approximately 2000 MPa. As Rockwell hardness is much easier to measure than strength, but good correlation exists between hardness and strength, this characteristic is used as a parameter in the specification and manufacturing of the fasteners. In the table below, HRC hardness is given for a range of tensile strengths (DIN 50150).

Tensile strength (MPa)	770	865	965	1810	1920	1995	2070	2180
HRC	20.5	25.5	30	52.5	54	55	56.5	58

2.2 Manufacturing process

Standard hardened steel fasteners

Almost all powder and gas-actuated fasteners used throughout the world are manufactured from carbon steel wire which is subsequently thermally hardened to provide the strength needed for driving into steel and concrete. In nail manufacturing, shank diameter is determined by the wire diameter used. Threaded studs are made from wire corresponding to the required thread diameter. The manufacturing process, which is summarized in the diagram below, consists of cutting the wire to length, shaping the head, knurling, forging or thermo pulling the point, hardening, galvanizing and assembling with washers.

The process of hardening the steel to more than HRC 50 combined with the zinc plating presents a risk of hydrogen embrittlement.

This risk is mitigated by heat-treating the galvanized product at the optimum temperature for the correct time. Galvanized and heat-treated fasteners are subjected to impact bending tests to check the effectiveness of the process. Depending on their intended application, some fasteners are additionally sampled and tested under tension and shear.

Manufacturing Process

Standard zinc-coated fasteners

Stainless steel fasteners

Hilti introduced the first powder-actuated stainless steel fastener in 1994. These fasteners, which are not thermally hardened, are manufactured from special stainless steel wire with an ultimate tensile strength of 1850 MPa. One effect of using steel of such high strength as a raw material is that the forming and forging processes present greater technical difficulties. These fasten-

ers, on the other hand, suffer no risk of hydrogen embrittlement and their strength decreases only very slightly when subjected to high temperatures such as in a fire.

Manufacturing Process

Stainless Steel Fasteners

2.3 Fastener raw material

Hilti standard zinc plated fasteners are made from carbon steel wire with an ultimate tensile strength of 590 to 760 MPa.

Hilti **X-CR / X-CRM / X-BT** stainless steel fasteners are made from high-strength nitrogen alloyed stainless steel wire (Hilti designation CR500).

Nickel and chromium are the components of stainless steel that make it resistant to corrosion. CR500 steel is compared to commonly used stainless steels like AISI 304 and 316 (European A2 and A4) in the graph at the right. Note that CR500 steel contains considerably more nickel and chromium than both 304 and 316.

Another comparison of interest is the difference in ultimate tensile strength, as shown in the graph at the right.

2.4 Powder- and gas-actuated tools

Definitions

In the ANSI A10.3-2006 standard, two basic types of tool are referred to: direct-acting and indirect-acting. The two types are defined by the manner in which the energy is transferred from the hot expanding gases to the fastener.

Direct-acting tool:

The expanding gases act directly on the fastener and accelerate it to a velocity of 400 to 500 m/s (1300 to 1600 fps). This velocity places the tool in the high-velocity class, thereby subjecting it to more stringent rules for usage.

Indirect-acting tool:

The expanding gases act on a captive piston that drives the fastener, which in Hilti indirect-acting tools reaches a velocity of less than 100 m/s (328 fps). Because of the lower velocity, the possibility and extent of injury due to incorrect operation is very much reduced. Rules for usage are less stringent than for high-velocity tools.

ANSI A10.3-2006 classifies powder-actuated tools according to velocity. With increasing velocity, rules for usage become more stringent, for example with regard to equipping the tools with shields. The lowest velocity tool capable of performing the application should be used.

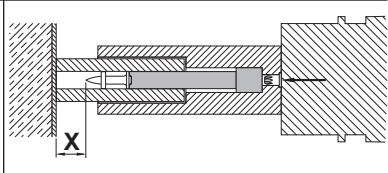

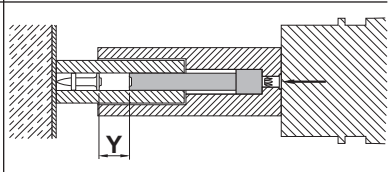

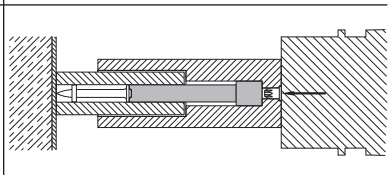

Class of powder-actuated tool	Average test velocity in m/s [fps]	Maximum single test velocity in m/s [fps]
Low-velocity	100 [328]	108 [354]
Medium-velocity	150 [492]	160 [525]
High-velocity	>150 [492]	>160 [525]

Hilti tools

All Hilti tools supplied for construction applications are low-velocity, indirect-acting tools.

Indirect-acting tools operate according to one of three different principles – co-acting, impact or contact operation – which each affect the operating characteristics and the application limit of the system. It should be noted that 100% co-acting operation can be

achieved by pushing the fastener all the way back against the piston with a ramrod or, if the tool is so designed, with a built-in ramrod mechanism. Tools with nail magazines do not achieve 100% co-action because of the need for clearance between the piston end and the collated nail strip. Some single-shot tools allow the operator to make an impact-type tool work as a co-acting tool by using a ramrod.

Operating principle	Characteristics	
Co-acting operation	<ul style="list-style-type: none"> • $X > 0$; $Y = 0$ • Highest application limit • Lowest recoil 	
Impact operation	<ul style="list-style-type: none"> • $X = 0$; $Y > 0$ • Lower application limit • Higher recoil 	
Contact operation	<ul style="list-style-type: none"> • $X = 0$; $Y = 0$ • Lowest application limit • Highest recoil 	

2.5 Cartridges (power loads, boosters)

Cartridges for indirect-acting tools are available in various standard sizes and each size is available in up to 6 power levels. In the United States, the powder in a cartridge, the sensitivity of the primer, and the cartridge dimensions are governed by technical data published by the Powder-Actuated Tool

Manufacturers Institute, Inc. (PATMI). PATMI defines the power level by the velocity measured in a standard test in which a standardized 350 grain [22.7gram] cylindrical slug is fired from a standardized apparatus. The identification and limitations of use are addressed in ANSI A10.3-2006.

PATMI colour codes, power levels and definition of cartridges

Size	Colour code	Power level	Velocity of 350 grain slug		Calculated energy (joules)		
			ft./sec.	[m/sec.]	minimum	average	maximum
6.8 / 11 [Cal. 27 short]	Gray	1	370 ± 45	[113 ± 13.7]	111	144	182
	Brown	2	420 ± 45	[128 ± 13.7]	148	186	228
	Green	3	480 ± 45	[146 ± 13.7]	200	243	291
	Yellow	4	560 ± 45	[171 ± 13.7]	280	331	386
	Red	5	610 ± 45	[186 ± 13.7]	337	392	452
	Purple / black	6	660 ± 45	[201 ± 13.7]	399	459	524
6.8 / 18 [Cal. 27 long]	Green	3	550 ± 45	[168 ± 13.7]	269	319	373
	Yellow	4	630 ± 45	[192 ± 13.7]	361	419	480
	Blue	4.5	725 ± 45	[221 ± 13.7]	488	554	625
	Red	5	770 ± 45	[235 ± 13.7]	554	625	700
	Purple / black	6	870 ± 45	[265 ± 13.7]	718	798	883

The German DIN 7260 standard specifies cartridge dimensions, colour codes and power levels, which are defined in terms of energy delivered when a cartridge is fired in

a standardized apparatus. DIN 7260 specifies a 3.66 gram slug with a somewhat more complex geometry than that of the PATMI slug.

DIN 7260 colour codes, power levels and definition of cartridges

Size	Colour code	Power level	Specified energy (joules)
6.8 / 11	White	weakest	120 ± 50
	Green	weak	200 ± 50
	Yellow	medium	300 ± 50
	Blue	heavy	400 ± 50
	Red	very heavy	450 ± 50
	Black	heaviest	600 ± 50
6.8 / 18	Green	weak	200 ± 50
	Yellow	medium	400 ± 50
	Blue	heavy	500 ± 50
	Red	very heavy	600 ± 100
	Black	heaviest	800 ± 100

In order to achieve interchangeability of the tools and cartridges from various manufacturers, PATMI provides guidelines on cartridge dimensions. Manufacturers optimize the cartridge characteristics for their tools in order to achieve functional reliability and long life.

Interchanging of components is mentioned in 7.10 of ANSI A10.3-2006: “Only

those types of fasteners and power loads recommended by the tool manufacturer for a particular tool, or those providing the same level of safety and performance, shall be used.”

It is the responsibility of the user of powder-actuated products to comply with this requirement.

3. Health and safety

The safety of powder-actuated fastening systems can be examined in terms of three general safety characteristics:

- **Operator safety** refers to safeguarding the operator and bystanders.
- **Fastening safety** is a measure of the adequacy of the in-place fastenings.
- **Functional safety** refers to the operability of the tool, especially the operator safety devices, under construction site conditions.

3.1 Operator safety

Hilti powder-actuated systems incorporate five main design features for maximum operator safety – the DX piston principle, drop-firing safety mechanism, contact pressure safety mechanism, trigger safety mechanism and the unintentional firing safety mechanism.

Hilti DX/GX piston principle

One of the main concerns about the use of explosive powder-filled cartridges to drive fasteners is what happens if the base material is missed by the fastener. The piston principle ensures that the energy from the propellant in the cartridge is transferred to a piston, the accelerated mass of which then drives the fastener. Because the piston is captive within the tool, roughly 95% of the driving energy is absorbed by the tool in the event of the fastener missing the base material. Thus, the velocity of a fastener that misses the base material is far lower than the velocities associated with fasteners from high-velocity tools (tools that do not operate with the piston principle).

Drop-firing safety

The drop firing safety mechanism prevents the tool from firing if dropped unintentionally. This mechanism is so designed that the tool, cocked or uncocked, will not fire when dropped at any angle onto a hard surface.

Trigger safety

This mechanism ensures that pulling the trigger alone cannot cause the cartridge to fire. The trigger in a Hilti DX- or GX-tool is uncoupled from the firing pin mechanism until the tool is fully compressed against the work surface.

Contact pressure safety

A Hilti tool is made ready for firing by compressing it against the work surface. This requires a force of at least 50 N [11.2 pounds]. Tools with large baseplates that can be easily gripped with the hand, for example the DX 76 and the DX 460 SM, GX 120, have an additional surface contact pin that must also be pushed back to allow firing. This is designed to prevent the tool firing when its nosepiece is not in contact with the work surface.

Unintentional firing safety

Hilti DX tools cannot be fired by pulling the trigger and then compressing the tool against the work surface (also known as “bump firing”). These tools can be fired only when they are (1) compressed against the work surface and (2) the trigger is then pulled.

Cartridge (power load or booster)

The propellant powder in the cartridge can only burn if the primer burns first. Burning of the primer is initiated by an impact applied with the correct velocity at the correct location of the cartridge. The propellant and primer are protected from external influences by the metal casing of the cartridge.

Magazine strip

Collated cartridges in strips of 10 (or 40) offer greater safety because the plastic strip helps protect the cartridge cases from impacts and ensures separation between the cartridges.

Packaging

The packaging must contain provisions with respect to tool compatibility.

Promotion of operator safety

Safety of the operator and bystanders is promoted by use of the appropriate safety equipment and by following the instructions in the operator's manual. By supplying the powder-actuated tool in a lifetime kit box with space for eye protectors, operator's manual, etc., retention and use of the safety equipment is much improved.

Tool compatibility information and installation guidelines printed on the cartridge and fastener packaging supplement the operator's manual.

Hilti organizes operator training courses in which general safety measures for powder-actuated tools are covered as well as measures specific to each model of tool used. In some countries, certificates or operator IDs are issued upon completion of training courses to encourage attention to safety by operators and to allow safety officials to enforce training requirement regulations.

3.2 Fastening safety

Fastening safety depends on a correct prediction of the loads and the conditions to which the fastening is subjected and a correct prediction of fastening performance. The necessary conditions for predictable fastening performance are:

1. The fastening system must have been engineered and tested for the application.
2. The quality of the fastening system components used must correspond to the quality of those originally tested.
3. The fastenings must be made as foreseen in the engineering of the system or in the same way as when the system was tested.

Engineering and testing

Sources of information about the engineering and testing of a fastening system are the manufacturer's technical literature, test reports, official approvals and publications in technical journals. If an "or equal" clause is used in the specification, then approval of any alternate fastening system should be made contingent on provision of documentation showing that the proposed fastening system has been engineered and tested for the given application.

Production quality

The need for the materials used on the job-site to correspond to the design of the product and to be of the same quality as those tested is clear. This requires the manufacturer to have a production quality control system, which is necessary for ISO 9001 certification.

Quality of installation

The use of fastening systems for which the manufacturer provides application guidelines and a technical advisory service helps ensure that fasteners will be installed correctly. The concept of controlling the quality of the work must include some feature that can be measured and that feature must indicate the performance of the fastenings.

The primary means of checking the quality of a powder-actuated fastening is by checking the stand-off over the surface of the fastened material. For fasteners that do not allow an accurate visual check of the stand-off, the use of a stand-off template is recommended. In some cases tensile testing of fasteners on jobsites is necessary. Threaded studs and some decking fasteners with suitable head design can be tensile-tested in their final position on a jobsite. Other fasteners like simple flat-headed nails have to be driven through a pull-over test specimen and then tested.

Checking the standoff of an X-EDN 19 roof deck fastening with a plastic template

Pull-out test of an ENP fastening with a Mark V tester and ENP adapter

3.3 Functional safety

Construction professionals demand fastening systems that are dependable under the toughest jobsite conditions. The goal of functional reliability has to be integrated into the development, manufacture, sales and service of a fastening system. The development of a new fastening system must consider the operating conditions and the degree of reliability required. During development, system components and prototypes are tested to determine if they will function reliably. Pilot production lots are tested by contractors on their jobsites to ensure that the design can be produced in a quality that will function. Quality control is integrated in the manufacturing process to ensure that all components are manufactured according to specifications. Salespersons are trained so that they can advise their customers as to the proper system to use for the application. Tool repair and maintenance training help keep the fastening systems functioning.

Lifetime testing of the DX powder-actuated tool with nail magazine

3.4 DX Cartridge safety

Important information about cartridges for powder actuated fastening tools

Only use Hilti cartridges or cartridges of equivalent quality.

The use of cartridges of inferior quality in Hilti tools may lead to build-up of unburned powder, which may explode and cause severe injuries to operators and bystanders.

At a minimum, cartridges must:

1. be confirmed by their supplier to meet the "Combustion residue test" according to EU standard EN 16264,

or

2. bear:

- The CE conformity mark
- The proof mark of fire-arm test house
- The tool designation
- The identification number of the EU notified body
- The number of the type test

For example:

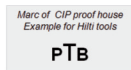

CE conformity mark	Proof mark of fire arm test house	Tool designation	ID proof house	Number of type test
		DX 460	PTB	Sy 812 HR73
		DX 452	PTB	Sy 808 HR63
		DX 351 CT	PTB	Sy 817 HR13
		DX 351	PTB	Sy 809 HR83

3.5 DX Tools safety

Approvals for powder actuated fastening tool:

Hilti Powder Actuated Fastening tools are designed and tested according to "Directive 2006/42/EC" and are CIP approved.

Identifications on the Hilti DX tools:

4. Corrosion

For decades, Hilti is concerned about corrosion of fastening systems and has gained a lot of experience in this area based on laboratory- and field tests. Extensive testing and research are conducted in test facilities of Hilti Corporate Research department, located around the world in different climate zones.

Hilti strives to provide the best possible sup-

port to customers for selecting the right product for safe and reliable fastening solutions.

This chapter gives an overview of corrosion protection solutions for Hilti Direct Fastening elements. More details on corrosion are described in the Hilti corrosion brochure „Corrosion aspects of fastening systems 2010“.

4.1 Corrosion protection of direct fastening systems

The use of the corrosion protection system is dependent on different influencing parameters. Following table shows typical environmental and application conditions affecting the corrosion process.

Humidity	<ul style="list-style-type: none"> • Humidity accelerates corrosion.
Temperature	<ul style="list-style-type: none"> • Higher temperatures promote corrosion.
Salts	<ul style="list-style-type: none"> • Salt accelerates corrosion.
Industrial pollution	<ul style="list-style-type: none"> • SO₂ accelerates corrosion.
Galvanic corrosion	<ul style="list-style-type: none"> • Occurs when fastener is less noble than fixed parts.
Special applications	<ul style="list-style-type: none"> • Include other influencing factors, i.e. indoor swimming pools, road tunnels, chemical industry.

Galvanic zinc coating

A typical corrosion behavior of galvanized zinc coated fasteners is characterized by a rather homogeneous surface reduction. It begins with zinc corrosion (white rust) till the zinc is completely removed. Corrosion of the carbon steel material will then take place (red rust).

Zinc corrosion (white rust)

Start of carbon steel corrosion (red rust)

The amount of material loss due to corrosion can be approximated in laboratory scale experiments. The so-called corrosion rate is generally listed as mm/year or g/m² h (laboratory values). Mean corrosion rates of low alloyed steel and zinc coatings are shown in following table.

Hydrogen embrittlement

A specific corrosion phenomenon of zinc plated DX fastening elements is hydrogen embrittlement, which will transpire if three different conditions are present simultaneously:

- High strength steel (≥ 1000 MPa)
- Presence of hydrogen
- Tensile stresses

Corrosion occurs when zinc plated, high-strength fastening element is used in wet atmosphere. During this corrosion process, hydrogen is formed and diffuses into the material. This leads to a decrease in ductility of the material, leading sudden fastener failure even under very low static load. This phenomenon is unpredictable and uncontrollable.

Failure of a fastener due to hydrogen embrittlement

Duplex coating

Duplex coating is a two layer coating consisting of a sealer layer with a zinc layer below. The sealer prevents the zinc from corrosion, so the duplex coating has got a higher corrosion protection than standard zinc plating.

Stainless steel

There is a wide range of different types of stainless steel, and they each have different corrosion resistance properties. A stainless steel material used in a wrong environment can lead to pitting corrosion and, subsequently, sudden fastener failure. In such a situation, prediction of fastener lifetime is not possible.

Hilti power actuated fasteners are made of CR500 and 1.4462 material, similar to A4 (AISI grade 316) and, for higher corrosion requirements, HCR (1.4529) material. The HCR (High Corrosion Resistance) material can be used in swimming pools and in road tunnels, where A4 material is not sufficient.

Stainless steel with pitting corrosion, e.g. A4 material used in a road tunnel

Suitable stainless steel used, e.g. HCR material used in a road tunnel

4.2 Fastener selection

Following table gives a general guideline of commonly-accepted applications in typical atmospheric environments. Suitability of fastening systems for a specific application can be significantly affected by localized conditions, including but not limited to:

- Elevated temperatures and humidity
- High levels of airborne pollutants
- Direct contact with corrosive products, commonly found in chemically-treated wood, waste water or salt water, concrete additives, cleaning agents, etc.
- Non-atmospheric corrosion like e.g. direct contact to soil, stagnant water
- Cyclical wetting
- Electrical current
- Contact with dissimilar metals
- Physical damage or wear

- ✓ Suitable
- ✗ Not suitable

Environmental conditions		Fastened part	Carbon steel		Stainless steel	
			Galv. zinc coating	Duplex coating	CR500 or 1.4462 (A4, AISI 316)	HCR 1.4529
			Fastener X-ENP X-U X-GHP X-FCM-M X-BT, X-CR X-CRM On demand			
	Dry indoor	steel (zinc coated, painted), aluminum, stainless steel, wood	✓	✓	✓	✓

Remarks:

- The ultimate decision on the required corrosion protection must be made by the customer. Hilti accepts no responsibility regarding the suitability of a product for a specific application, even if informed of the application conditions.
- This table is based on an average service life for typical applications.
- For metallic coating e.g. zinc layer systems the end of life time is the point where red rust is visible over a large percentage of the product and widespread structural deterioration can occur – the initial onset of rust will occur much sooner
- National or international codes, standards or regulations, customer and/or industry specific guidelines must be independently evaluated.
- These guidelines apply to atmospheric corrosion only. Other types of corrosion, such as crevice corrosion or stress corrosion cracking must be independently evaluated.

The typical service life of Hilti GX-WF wood nails in wood to wood connections under various environmental conditions is displayed in the table below.

Service Classes in accordance with EN 1995 (Eurocode 5):		Service Class 1	Service Class 1, 2	Service Class 1, 2, 3				
Type of Corrosion Protection for Hilti GX-WF wood nails (d ≤ 4mm):		No Corrosion Protection	Zinc coated	HDG	A2	A4		
		Dry indoor environments (heated or air conditioned spaces) without condensation, office buildings, schools	20 to 50 years	>50 years	>100 years	✓	✓	
		Indoor environments with temporary condensation, (unheated spaces without pollutants). Storage halls	10 to 30 years	10 to 50 years	60 to >100 years	✓	✓	
		Outdoor, covered, rural or urban environment with low pollution, high distance (> 10 km) from the sea	✗	10 to 50 years	40 to 100 years	✓	✓

		Close distance to streets treated with deicing salts, e.g. fasteners for bridge railings (< 10m distance from streets)	✗	✗	✗	✗	✓	
	Special applications	Special applications Street tunnels with deicing salt, indoor swimming pools, special applications in the chemical industry (exceptions possible)	Consult experts for exceptions					

✓ Suitable

✗ Not suitable

Remarks:

- The use of certain wood species including, but not limited to, Oak, Douglas-fir or Western Red Cedar, require the use of stainless steel nails, independent of Service Class and environmental conditions.
- The use of certain wood treatments including, but not limited to, fire retardants or preservatives can change the chemical composition of the wood and may require the use of stainless steel nails, independent of Service Class and environmental conditions.
- The evaluation of corrosive environmental conditions depends on many factors and lies within the responsibility of the customer. The planned service life of the buildings or structures can to be considered according to local or national building regulations and Eurocode (EN 1990)
- The table does not contain recommendations and Hilti does not assume liability for fastener selection based on its content.
- For the typical service life, it is assumed that the nails are selected, designed, installed and otherwise treated in accordance with Hilti's published literature.
- Local building regulations and trade rules may differ from the table above. The local jurisdiction always needs to be followed.
- Wood to steel connections may require a minimum corrosion protection, independent of the environmental conditions.

5. Steel base material

5.1 Anchoring mechanisms

The following four mechanisms cause a DX- / GX-fastener to hold when driven into steel:

- clamping
- keying
- fusing (welding)
- soldering

These mechanisms have been identified and studied by analyzing pull-out test data and by microscopic examination of fastening cross-sections.

Clamping

As a fastener is driven, the steel is displaced radially and towards both the entry and opposite surfaces. This results in residual pressure on the surface of the nail, which leads to friction or clamping. Clamping is the primary anchoring mechanism of through-penetrating fasteners. This is indicated by the fact that when through-penetrating fasteners are extracted, the pull-out force decreases only slowly over several millimeters of displacement.

Keying

The keying mechanism is possible when the fastener is knurled, that is, it has fine grooves along the shank in which zinc and particles of base steel accumulate during the driving process. Microscopic examination of cross sections has shown that the grooves are not completely filled. Keying is an especially important anchoring mechanism for fasteners that do not penetrate right through the base material.

Fusing (welding)

Complete fusing of the fastener with the base steel is indicated by portions of base material clinging to the extracted fastener as well as by the decarbonized zone. Fusing or welding is observed mostly at the point of a fastener where the temperature during driving can be expected to be the highest.

For fasteners that do not through-penetrate, this is an important anchoring mechanism. It can be relied upon only if the fastener point is manufactured without cracks and with an appropriate geometry. The thermo pulling process is ideal for achieving an optimized geometry. Control of

all steps in the production process is necessary to avoid cracks in the point.

Soldering

In the zone further from the point, there is a prominent zinc layer separating the fastener from the base steel. This zinc, soldered to the base steel, also makes a contribution to the pull-out resistance of the fastener.

Blunt-tipped fastener X-BT

The X-BT fastener with a shank diameter of 4.5 mm is driven in a pre-drilled 4.0 mm diameter hole. This leads to displacement of the base material. Part of the base steel is punched down into the pre-drilled hole, generating high temperatures and causing friction welding. Due to elasticity of the base steel, additional clamping effects are also superposed. Displaced base material can be clearly seen in the photograph. Base material adhering to the fastener shank indicates a welding effect.

5.2 Factors influencing pull-out resistance

Powder-actuated fastening systems must be designed and manufactured to ensure that pull-out resistance will be adequate for the applications intended. Through understanding of the anchoring mechanisms, experience and testing, factors that influence pull-out strength have been identified. Some of these factors are:

- Depth of penetration in the base material
- Surface characteristics of the fastener
- Coatings on the steel base material
- Driving velocity
- Diameter of the fastener shank

Knowledge of the influencing factors is vital to the design of fastening systems and is useful for operators in understanding the various application guidelines and restrictions that apply to a fastening system. Some of the influencing factors are discussed in the following section.

Depth of penetration in the base material

The depth of penetration of fasteners in steel is taken as the distance that the point travels below the surface of the base steel, independent of the steel thickness. In other words the depth of penetration h_{ET} can be greater than, equal to or less than the steel thickness.

Resistance to pull-out increases with increasing depth of penetration. This is also true for through-penetrating fasteners where h_{ET} is greater than the steel thickness.

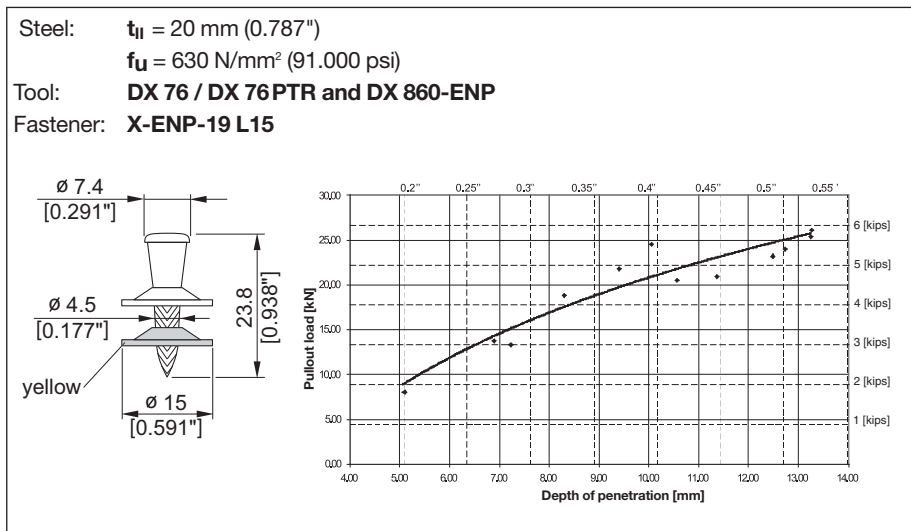

The design of a powder-actuated fastener has to take into account the depth penetration necessary to achieve the pull-out resistance required for the application. Application guidelines published for any fastener include the required nail head stand off h_{NVS} , which corresponds to the penetration depth.

Guide values for the depth of penetration of specific fastener types are as follows:

- Galvanized fastener with knurled shank: $h_{ET} = 12$ to 18 mm (shank diameter 4.5 mm)
- $h_{ET} = 10$ to 14 mm (shank diameter 3.7 mm)
- Galvanized fastener with knurled tip: $h_{ET} = 9$ to 13 mm (shank diameter 4.5 mm)
- Galvanized fastener with smooth shank: $h_{ET} = 15$ to 25 mm
- Stainless steel fastener with smooth shank: $h_{ET} = 9$ to 14 mm
- Blunt-ended fasteners: $h_{ET} = 4$ to 5 mm

The effect of penetration depth on pull-out strength can be demonstrated in experiments in which the driving energy is varied so as to produce varying penetration. The results of a test of this kind are summarized below. The application recommendations for fasteners are based on tests like these and they clearly show the importance of carrying out the fastening work in accordance with the recommendations of the manufacturer.

Knurling on the fastener shank

Fasteners for use in steel base material usually have knurling on the shank so as to improve the resistance to pull-out. The effect of the knurling was shown in a test with fasteners that had knurled and unknurled shanks, but were otherwise the same.

The benefit of knurling is clearly seen from the test results. With virtually the same penetration (actually 106 %), the smooth-shank fastener had only 68 % of the pull-out strength of the knurled-shank type. Even with the penetration increased to 137 %, the pull-out strength was still only 81 % of that of the knurled-shank fastener. In this test, the steel thickness of 10 mm (0.394") allowed through penetration of the steel. If the steel is too thick for through penetration, the beneficial effect of knurling becomes even more pronounced.

Zinc coating on the fastener shank

Zinc on a fastener shank appears to act as a lubricant that reduces its resistance to penetration into steel. Reduced pull-out strength results because the lower resistance means less heat is generated, thus reducing the welding effect between the shank and the base steel. This was shown in an experiment with fasteners that were identical except for the thickness of zinc coating.

Steel base material: $t_{II} = 20 \text{ mm}$ [0.787"],
 $f_u = 440 \text{ MPa}$ [63,817 psi]

Zinc thickness in mm	Average penetration		Average ultimate pull-out load		Variation CV %
	h_{ET} mm / [in.]	%	$N_{u,m}$ kN / [kip]	%	
ca. 10	12.12 [0.477]	100	8.53 [1.918]	67	25.6
2-5	11.86 [0.470]	98	12.82 [2.882]	100	9.3

Although driving the fastener through sheet metal, as is the case when fastening siding and decking, reduces the negative effect of zinc coating on pull-out strength, the reason for tightly controlling the galvanization process is clear.

Surface of the steel base material

Corrosion protection of structural steel is often achieved by hot-dip galvanizing. Tests have shown that if the fastener penetrates right through the steel, the galvanizing has no significant effect on pull-out strength. In the case of fasteners that do not through-penetrate, pull-out strength is reduced by about 25%. The summary of results from one test is shown below to illustrate these effects.

Average ultimate pull-out loads

Ultimate tensile strength of steel :
Surface of the steel :

$f_u = 430 \text{ MPa [62,366 psi]}$
1. Rough with some slag and rust (reference)
2. Sandblasted
3. Pickled + hot-dip galvanized (min. 60 μm zinc)

Several important observations can be made based on these results:

- Pull-out loads in 6 mm (1/4") steel base material are much less affected by the surface condition of the steel than they are in 20 mm (3/4") steel. The reason is that the main anchoring mechanism of through-penetration fastenings is clamping, which is not affected by the surface condition of the steel.
- Hot-dip galvanizing appears to reduce the pull-out strength of non-through-penetrating fastenings by nearly 30%. Note, however, that even with hot-dip galvanizing, the pull-out strength was still 12.5 kN (2.8 kips).
- The negative effect of hot-dip galvanizing is explained by the tendency of zinc on the fastener to act as a lubricant that reduces heat generation during driving. This in turn reduces the tendency of the fastener point to fuse to the base steel. Zinc from the coating on the base steel apparently becomes attached to the fastener as it enters the base steel.

For applications where tensile strength of the fastening is critical and the steel has a heavy coating, the fastening system can be qualified by carrying out pull-out tests on site. If pull-out strength is not adequate, depth of penetration can be increased to improve the situation.

Tensile stress in the steel

The integrity of a powder-actuated fastening is dependent on a relatively smooth pin remaining anchored in structural steel. A large amount of test data, technical assessments, approvals and practical experience with powder actuated fastenings is available to support use of powder-actuated fastening. Performance of fasteners anchored in the steel under tension was investigated by driving fasteners into unstressed steel plates and extracting them with the plates stressed in tension. The steel plates measured $6 \times 80 \times 455 \text{ mm}$ [$0.236" \times 3.15" \times 17.9"$] and possessed two different yield stresses - 328.6 MPa [47.7 ksi] and 411.7 MPa [59.7 ksi].

By expressing the steel stress in terms of % of actual yield, it was possible to combine the data for both steel grades and obtain a reasonable curve fit.

Of significance to the designer is the expected decrease in pull-out strength of the fastener at a typical maximum allowable design stress of 60 to 70 % of yield. At this stress, the pull-out strength reduction is less than 15%. The absolute value in the experiment was still greater than 2 tons.

Compressive stress in the steel

Compressive stress in the base steel has no influence on the pull-out strength of the fastener. This was demonstrated by placing fasteners in unstressed 15 mm [0.59"] thick steel plates having a yield strength of 259.3 MPa [37.6 ksi] and extracting them while the plates were compressed in a testing machine.

The minimal variation in pull-out load is simply random variation experienced in testing.

5.3 Suitability of the steel for fastening

There are three main factors determining the suitability of a construction grade steel member for DX fastening:

- Steel thickness
- Ultimate tensile strength
- Flexibility of the base steel member

5.4 Application limit diagrams

The application limit of a fastening system is a term applied to a combination of the maximum thickness t_{fl} and ultimate tensile strength f_u of steel in which fastenings can be made. There are two general types of application limit diagrams:

- Short fasteners (e.g. siding and decking nails and threaded studs)
- Long fasteners (e.g. nails used to fasten wood to steel)

The application limit line for a **short fastener** is a plot of steel thickness versus ultimate tensile strength. In situations represented by steel thickness / ultimate tensile strength combinations above and to the right of the line, some of the fasteners may shear off during driving. The failure surface will be roughly at a 45° angle to the shank length.

The application limit lines for **long nails** used to fasten **wood to steel** are plots of nail shank length L_s versus steel thickness t_{fl} . Each line is valid only for one ultimate tensile strength of steel f_u . Attempts at working to the right of the limit line result in buckled nail shanks.

5.5 Thin steel base material

In the context of powder-actuated fastening, steel is considered thin when flange deformation during driving dominates fastener design. When the steel flange is thinner than about 6 mm [0.25"], flange deformation makes use of fasteners with a 4.5 mm [0.177"] shank diameter more difficult and switching to a 3.7 mm [0.145"] shank fastener leads to better results. Use of fasteners with tapered shanks and energy-absorbing washers improves performance and reliability.

A fastener can penetrate into steel only when the steel (flange) develops a resistance greater than the force required for penetration. This implies the use of energy in excess of that required for penetrating into the steel. In fact, if the driving energy remains constant, fasteners placed closest to the web will be driven deepest. All siding and decking fasteners should have a mechanism to clamp the sheets down tightly over the entire range of allowable standoffs. This is especially critical for fasteners used for fastening to thin steel.

Obviously, under shear loading, failure of the base material is more likely with thin steel than with thick steel. When approving fastening systems for a project, it is important to consider whether the system has actually been tested with thin base steel or not.

Hilti's general recommendation for thin base steel fasteners is to place the fastenings within $b_x = 8 \times t_{fl}$ of the web.

5.6 Types of load and modes of failure

5.6.1 Shear loads

The shear loads acting on siding and decking fasteners come from:

- Diaphragm action of the fastened sheets
- Forces of constraint (for example due to temperature changes)
- Self-weight of siding material

Testing

Shear testing of siding and decking fastenings is done using specimens made up of a strip of sheet metal fastened to a steel plate. Suitable, non-slip fixtures have to be used at either end. In some cases specimens are bent up at the sides to hinder eccentricity.

Failure of the fastened material

The load-deformation curves of shear tests with powder-actuated fasteners show a nearly ideal behavior. After an initial elastic phase during which the clamping force of the washers against the sheet metal is overcome, the sheet metal reaches its yield stress in an area where the fastener bears against it. Then the fastener shank cuts through the sheet metal until the end of the sheet is reached. The large area under the load-deformation curve represents energy absorbed, and this is what makes the fastening method ideal for diaphragms.

Failure of the base steel

If the thickness of the fastened sheet metal is large compared to the base steel thickness, bearing failure of the base material is a possible mode of failure.

Pull-out from the base steel

The unavoidable eccentricity in the shear test specimen leads to a tensile load component on the fastener. Thick fastened material and thin base material is also involved in this mode of failure. This failure mode is generally not governing for base material thickness of $t_{II} > 6$ mm.

Fracture of the fastener

About 20 kN (4.5 kips) of force is required to shear the Ø 4.5 mm (0.177") shank of an **X-ENP-19 L15** fastener. With about 2.5 mm (12 gauge) thick steel sheet as fastened material, a force of this magnitude could be possible. The force needed to break a Ø 3.7 mm (0.145") shank of an **X-EDNK22 THQ12** fastener is about 13 kN (2.9 kips). This force can be generated with 1.5 mm (16 gauge) sheet steel. In practice, this failure mode is likely only where expansion joints are not provided to relieve forces of constraint from temperature differences.

5.6.2 Tensile loads

The most common source of tensile loading on siding and decking fasteners comes from wind suction acting on the roof or wall cladding. In diaphragms, fasteners can be subject to tensile loads in situations where the combination of geometry and thickness of decking fastened leads to prying. In designs with very stiff decking and wide beams or unbalanced spans, prying can also be caused by concentrated loads.

Testing

Tensile testing of siding and decking fastenings is carried out using specimens made up of a trapezoidal-shaped piece of sheet metal fastened to a steel plate. Suitable, vice-like fixtures are used to grip the specimen. This is often referred to as a pull-over test because the common failure mode is the sheet pulling over the washers or the head of the fastener. If the sheet thickness fastened is increased so that pull-over does not govern, pull-out will be the failure mode.

Some fasteners like the Hilti X-ENP have a head that can be gripped and pulled out by a suitable fixture. With these fasteners, a pull-out test can still be done even if pull-over is the original mode of failure. This fastener type has the further advantage of allowing in-place fasteners on a jobsite to be tested.

Pull-over test specimen

Pull-over test specimen with 3 extra layers to simulate end lap – side lap

Test setup

Sheet pull-over

In this failure mode, the sheet tears and is lifted up over the fastener head and washers. Depending on the sheet thickness and tensile strength, the washers may be bent up.

Washer pull-over

Another possible failure mode is that of the washers being pulled up over the head of the nail. Obviously, this happens when the sheet is somewhat stronger and /or thicker than when sheet pull-over occurs. This failure mode is also heavily dependent on fastener design.

Pull-over test specimen at test start

Sheet pull-over

Washer pull-over

Pull-out from the base steel

As sheet thickness and number of layers is increased, this failure mode becomes more likely. For a properly driven **X-ENP-19 L15** pull-out from the base steel is not a likely mode of failure. The head and washer design of the **HSN24** or **X-EDNK22 THQ12** fasteners can allow this failure mode, especially with multiple layers of sheets.

Fracture of the fastener

A force of more than 30 kN [6.7 kips] is required to break the Ø 4.5 mm [0.177"] shank of an **X-ENP-19 L15** fastener and, even if sheet or washer pull-over does not govern, pull-out strengths of this magnitude are not very common. This mode of failure will therefore hardly ever occur with these heavy-duty fasteners. The Ø 3.7 mm [0.145"] shank of an **X-HSN 24** or **X-EDNK22 THQ12** fastener may break at about 20 kN [4.5 kips] tension. Since these smaller fasteners will pull out at a force of 8 to 15 kN [1.8–3.3 kips], fractures due to tensile loads are rare. If fractured fasteners of this type are found on a jobsite, the most likely cause is that the application limit has been exceeded (the base steel is too hard and/or too thick for the pin).

Cyclic loading

Siding and decking nails used in wall and roof construction are subject to cyclic loading from wind suction. Cyclic load testing is carried out to determine characteristic resistance and allowable (recommended) loads. The approval requirements of the European Technical Approval ETA prepared by DIBt (Deutsches Institut für Bautechnik) govern the design-relevant number of load repetitions (5,000) and the necessary safety factors. Notes in this regard are found on the corresponding product data sheets.

If the fastener will be subjected to a large number of load repetitions and fatigue, we recommend carrying out a design check according to the requirements of Eurocode 3 (or similar code). Eurocode 3 gives the characteristic fatigue resistance and safety concept for steel

construction. To carry out the check according to Eurocode 3 it is necessary to have a statistical analysis of test data obtained under the application conditions. Except for siding and decking fasteners, the applicable product data sheets limit the validity of recommended loads to predominantly static loading. If a design analysis has to be carried out for true fatigue loading, test data can be obtained from Hilti. Examples of such data are shown below.

X-EM8-15-14

(standard zinc-plated fastener)

The X-EM8-15-14 has a shank diameter of 4.5 mm and a hardness of HRC 55.5 ($f_u = 2,000$ MPa). The ΔF -N diagram shows the load range ΔF for a lower load of 0.05 kN. The individual test results are displayed as points and the curves show average and characteristic (95% survival probability) values. The failure mode was shank fracture or fracture in the M8 threading.

The recommended load for predominantly static loading is 2.4 kN. Comparing this value to the ΔF -N diagram will lead to the conclusion that X-EM8-15-14 fastenings designed for 2.4 kN static loading will survive a large number of load repetitions. The fastenings can be said to be robust, even when the actual loading turns out to be in part cyclic.

In older product information and data sheets, this basic suitability of DX fasteners for cyclic loading was emphasized by defining the recommended loads as cyclic recommended loads. At the time that this product information was assembled, a true safety concept for a strict check of DX fastenings subject to fatigue loading was not available. With Eurocode 3, this is today available. If a fatigue design analysis is carried out, it is important – as with static design – that adequate redundancy be provided.

Failure of the sheet

In cyclic load tests, failure of the steel sheet itself is common.

5.7 Effect of fasteners on structural steel

Driving powder- or gas-actuated fasteners into a steel member does not remove steel from the cross-section, but rather displaces steel within the cross-section. It is therefore not surprising that tests like those described in following sections show that both drilled holes and screws, either self-drilling or self-tapping, reduce the strength of a cross-section more than powder-actuated fasteners.

The results of the tests can also be used to show that it is conservative to consider a powder-actuated fastener as a hole. This allows the effect of fasteners in a steel member subject to static loading to be taken into consideration.

Fatigue seldom needs to be considered in building design because the load changes are usually minor in frequency and magnitude. Full design wind and earthquake loading is so infrequent that consideration of fatigue is not required. However, fatigue may have to be considered in the design of crane runways, machinery supports, etc. The S-N curves resulting from fatigue tests of steel specimens with fasteners installed are also presented.

5.7.1 Effect on the stress-strain behaviour of structural steel

The effect that powder-actuated fasteners (PAF's) have on the stress-strain behaviour of structural steel was investigated in a systematic test programme using tensile test specimens containing PAF's, self-drilling screws and drilled holes. A control test was carried out using specimens without any holes or fasteners.

Series A:

- ASTM 607, grade 50
- Cross-section 3.42 x 74 mm
[0.135 x 2.913"]
- X-EDNK22 powder-actuated fasteners, shank diameter 3.7 mm [0.145"]
- Drilled holes, diameter 3.7 mm [0.145"]
- Self-drilling screws, shank diameter 5.5 mm [0.216"]

Series B:

- S235 and S355 steel
- Cross-section 6 x 45 mm [0.236 x 1.772"]
- Powder-actuated fasteners, shank diameter 4.5 mm [0.177"]
- Drilled holes, diameter 4.5 mm [0.177"]

The figures below show representative stress-strain curves for the tests (the plotted stress is based on the gross cross-section). Note that the line for the powder-actuated fasteners follows the control test line more closely than the lines for drilled holes or self-drilling screws.

LOAD_DEFORMATION_SERIES_A

LOAD_DEFORMATION_SERIES_B

The test results were evaluated in terms of utilization as a measure of ultimate strength. Utilization is the ultimate load of a sample expressed as a percent of the ultimate load of the control test.

Graphs of the utilization versus cross-section reductions show that:

- The utilization for PAFs is clearly better than that of drilled holes or self-drilling screws.
- The hole left by a removed PAF has the same effect as when the PAF is left in place.
- Increasing the number of PAFs across a section from one to two or more has a proportionally smaller effect on utilization than placement of the first fastener.

More detailed information on the test program and findings is published in the paper **Powder-actuated fasteners in steel construction** (and the referenced literature), published in the STAHLBAU-Kalender 2011 (Publisher Ernst & Sohn, 2011, ISBN 978-3-433-02955-8). English Reprints of the paper can be distributed per request.

5.7.2 Effect on the fatigue strength of structural steel

During the late 1970s and early 1980s, a fatigue testing program consisting of 58 tests with over 1,100 specimens was carried out at the University of Darmstadt in Germany. The reason for the research at that time was to support the use of powder-actuated fasteners for attaching noise-dampening cladding to railway bridges in Germany.

Parameters investigated in those tests are shown in following table:

Steel grade	Steel thicknesses	Stress ratio R	Imperfections
S 235 (St 37) / A36	6, 10, 15, 20, 26.5, 40, 50 mm	0.8, 0.5, 0.14, -1.0, -3.0	Fastener: - installed and pulled out, - inclined installation and pulled out - inclined installation
S 355 (St 52) / grade 50	[0.236, 0.394, 0.591, 1.043, 1.575, 1.969"]		

Loading conditions

The terminology and notation is shown in the illustration below.

Fasteners tested

The primary fastener used in the tests was the Hilti ENP3-21 L15, the forerunner of the ENP2-21 L15. The difference is in the head shape, which has no effect on interaction with the base steel. Tests were also performed with the ENP2-21 L15, ENP3-21 D12 and the EM8-11-14 threaded stud, all of which have 4.5 mm diameter knurled shanks.

The results of the tests were evaluated by Niessner and Prof. T. Seeger from the University of Darmstadt in accordance with the provisions of Eurocode 3. An example plot of one test series is given at the right. The graph allows for a comparison with European fatigue categories 90 ($m = 3$) and 100 ($m = 5$) as well as American categories according to AWS-provisions.

Conclusions

- The effect of driving a Hilti powder-actuated fastener on the fatigue strength is well known and predictable.
- The constructional detail “Effect of powder-actuated fasteners on base material” (unalloyed carbon steel) was evaluated by Niessner and Seeger from the University of Darmstadt in compliance with Eurocode 3.
- The EC 3 detail category 90 with $m = 3$ or the detail category 100 with $m = 5$ is alternatively applicable.
- Wrong fastener installations as popped out or inclined fasteners are covered. Piston marks in the base material due to wrong use of the tool without a fastener or notches due to fasteners failed during the installation have to be removed by appropriate measures.

More detailed information on the evaluation of the test data and the test program is published in the paper "Fatigue strength of structural steel with powder-actuated fasteners according to Eurocode 3" by Niessner M. and Seeger T. (Stahlbau 68, 1999, issue 11, pp. 941-948).

6. Concrete base material

6.1 Anchoring mechanisms

The following three mechanisms cause a DX-/GX-fastener to hold in concrete:

- Bonding / sintering
- Keying
- Clamping

These mechanisms have been identified and studied by analyzing pull-out test data and by microscopic examination of pulled-out fasteners and the concrete to fastener interface.

Bonding / sintering

When driving a fastener into concrete, the concrete is compacted. The intense heat generated during driving causes concrete to be **sintered** onto the fastener. The strength of this sintered bond is actually greater than that of the **clamping** effect due to reactive forces of the concrete on the fastener.

The existence of the sintered bond is demonstrated by examining pulled-out fasteners. The fastener surface, especially in the region of the point, is rough due to sintered-on concrete, which can only be removed by using a grinding tool.

When performing pull-out tests, the most common failure mode is breakage of the sintered bond between the concrete and the fastener, especially at and near the point.

Keying

The sintered material forms ridges on the fastener surface. These ridges result in a micro-interlocking of the fastener and the concrete.

This anchoring mechanism is studied by examining pulled-out fasteners under a microscope. As in the case of sintering, keying is primarily active in the region of the fastener point.

Mechanically cleaned point of a pulled-out DX fastener

Clamping

The compressibility of concrete limits the buildup of compressive stress around the driven fastener. This in turn limits the effectiveness of clamping as an anchoring mechanism.

The tendency of stressed concrete to relax further reduces the compressive stress and hence the clamping effect. For these reasons, clamping of the fastener shank contributes only insignificantly to the total pull-out strength.

Concrete failure

Concrete cone failure is occasionally observed when using a testing device with widely spaced supports. The fact that the concrete failed indicates that the fastener bond to the concrete was stronger than the concrete.

6.2 Factors influencing resistance to pull-out

Factors that can affect the pull-out strength of fastenings to concrete include:

- Depth of penetration into the concrete
- Concrete parameter (compressive strength, grain structure, direction of concrete placement)
- Distance to concrete edge and fastener spacing

Depth of penetration h_{ET}

Fasteners that are driven deeper typically have a higher resistance to pull-out. This relation is best shown by placing groups of fasteners with different driving energy and comparing the results for each group with the others. The result of such a test is shown in the graph at the right. Note that fastener driving failures were not considered in calculation of the average ultimate load, $N_{u,m}$.

The value of increasing the depth of penetration in order to increase pull-out strength is limited by the increasing fastener driving failure rate. Provided that the penetration depth is the same, fastenings in concrete with a higher compressive strength hold better than fastenings in lower strength con-

crete. The ability to exploit this characteristic is also limited by increased fastener driving failure rate with higher strength concrete. As could be expected, the depth of penetration at which the failure rate is at a minimum decreases with increasing concrete strength.

Pull-out strength and fastener driving failure rate both increase with increasing penetration depth. The optimum depth of penetration is taken as the depth at which the yield in terms of pull-out strength begins to decrease. This is within a range of 18–32 mm depending on the grade and age of the concrete as well as the strength of the fastener.

$$\text{yield} = N_{u,m} \cdot \left(\frac{100 - p}{100} \right)$$

Concrete parameters

The concrete parameters (such as the type and size of concrete aggregates, type of cement and the location on top or bottom surface of a concrete floor) do affect the fastener driving failure rate, sometimes significantly.

Fastener driving failures are caused by the fastener hitting a hard aggregate, such as granite, located close to the concrete surface. A hard aggregate can deflect the fastener and in a severe case, the fastener may bend excessively, leading to con-

crete fracture in a cone shape and no hold being obtained by the fastener.

In case of slight fastener bending, concrete spalling may occur at the surface. However, because pull-out strength is obtained mostly in the area of the fastener point, concrete spalling does not affect the permissible load of the DX-/GX-fastening.

Softer aggregates such as limestone, sandstone or marble may be completely penetrated when hit by the fastener.

Overhead fastening is usually associated with a higher rate of fastener driving failure than floor fastening. This is due to the distribution of the aggregates within the concrete. Large aggregates tend to accumulate at the bottom of a floor slab. At the top, there is a greater concentration of small aggregates and fines.

There are several possible ways of reducing the failure rate when powder-actuated fasteners are used for fastening to concrete. There are two basic ideas: one is to

reduce concrete tensile stresses near the surface and the other is to delay the effect of these stresses.

Pre-drilling the concrete (DX-Kwik)

By pre-drilling a very small hole (5mm diameter, 18 or 23 mm deep), the stresses are relocated to greater depth in the concrete. Fasteners placed with DX-Kwik are surrounded by a stress “bulb” located deep in the concrete. With this method, virtually no fastener driving failures occur.

Spall stop fastener guide

A spall stop is a heavy steel fastener guide. Its weight and inertia counteract the stresses at the surface for a very short time. This allows redistribution of the stresses to other parts of the concrete.

Changing from a long to a short fastener reduces the magnitude of the stresses and thus the rate of fastener driving failure.

Edge distance and fastener spacing

If fasteners are placed too close to the concrete edge, pull-out load capacity will be reduced. Minimum edge distances are therefore published with a view to reducing the effect edges have on pull-out strength. The corresponding data has been obtained from tests and analysis and is given in part 2 of this manual.

Additional provision is made for fastener spacing when positioned in pairs or where fasteners are placed in rows along a concrete edge.

These edge distances and spacing also have the purpose of helping to prevent concrete spalling and/or cracking due to fastening. However, spalling has generally only an insignificant influence on pull-out strength.

6.3 Effect of time on pull-out resistance

The effect of age on pull-out strength has been investigated in comprehensive tests. The main concern is, in fact, the effect of concrete relaxation in the area around the driven fastener.

This graph provides an overview of tests performed with DX-Kwik fasteners. Since standard DX fastenings have the same anchoring mechanism, this statement is also valid for standard DX fastenings. The test results indicate very strongly that relaxation of the concrete has no detrimental effect on the pull-out resistance of DX fastenings. The test data also shows that sintering and keying are the dominant anchorage mechanisms because they do not rely on friction between the fastener and the concrete.

6.4 Effect on concrete components

Fastenings in the compression zone of the structure have no effect on concrete compressive resistance as long as detailed provisions on edge distance and spacing are complied with.

Fastenings in the **tensile zone** are subject to the following provisions:

- a. **Installations on plain load-bearing components such as concrete walls or ceilings are generally possible without restrictions** as the load-bearing behaviour of these components is only negligibly affected by the fasteners. The predominant condition is static loading. This statement is based on experimental investigations carried out at the Technical University of Braunschweig, Germany.
- b. Fastenings in reinforced concrete beams: it has to be ensured that the main rein-

forcement steel will not be hit or penetrated by the DX fasteners. This measure of precaution is mainly founded on the reduction of the ultimate strain of the steel reinforcement. Exceptions are possible when the structural engineer responsible for design is consulted.

- c. Fastenings in pre-stressed concrete members:

it has to be ensured that the pre-stressing steel reinforcement or cables will not be hit or penetrated by the DX fasteners.

If the concrete is too thin, concrete will spall off on the rear surface. The minimum thickness of concrete depends on the shank diameter of the fastener used.

Fastener shank diameter d_{nom} (mm)	Minimum concrete thickness h_{min} (mm)
3.0	60
3.5 / 3.7	80
4.5	100
5.2	100

7. Masonry base material

7.1 General suitability

Direct fastening technology can also be used on masonry. The joints between bricks or blocks and the covering plaster layer on virtually all types of masonry (exception for

lightweight aerated concrete blocks) provide an excellent substrate for light-duty and secondary fastenings.

Suitability table: DX fastening on masonry

Masonry material	Unplastered masonry		Plastered masonry Fastening in plaster (thickness ≥ 20 mm)
	Fastenings in mortar joints* (joint width ≥ 10 mm)	Fastenings in masonry blocks or bricks	
Clay brick

*) Joints must be completely filled with mortar

The above table is based on laboratory and field experience. Because of the wide variety of types and forms of masonry in use worldwide, users are advised to carry out tests on site or on masonry of the type and form on which the fastenings are to be made.

8. Temperature effects on the fastening

8.1 Effect of low temperatures on fasteners

Steel tends to become more brittle with decreasing temperature. Increased development of natural resources in Arctic regions has led to the introduction of steels that are less susceptible to brittle failure at subzero temperatures. Most siding and decking fasteners are used to fasten the liner sheets of an insulated structure and are not exposed to extremely low tempera-

tures during service. Examples of situations where the fastenings are exposed to extremely low temperatures during their service life are:

- Fastenings securing cladding in single-skin construction
- Construction sites left unfinished over a winter
- Liner sheets in a cold-storage warehouse

Low temperature embrittlement

The susceptibility of fasteners to become brittle at low temperatures can be shown by conducting impact bending tests over a chosen temperature range. The ability of

Hilti drive pins to remain ductile over a temperature range from +20°C to -60°C is shown clearly by the fact that the impact energy required remains nearly constant throughout this temperature range.

Impact bending test - DSH57 (4.5 mm diameter, HRC 58 ± 1)

Temperature		Impact energy (foot-pounds)			Impact energy (Joules)		
°F	°C	minimum	maximum	mean	minimum	maximum	mean

Impact bending test - X-CR (3.7 mm diameter)

Temperature		Impact energy (foot-pounds)			Impact energy (Joules)		
°F	°C	minimum	maximum	mean	minimum	maximum	mean
68	20	11.5	14.8	13.2	15.6	20.0	17.9
32	0	12.9	16.3	15.1	17.5	22.1	20.4
- 4	-20	13.1	15.8	14.7	17.8	21.4	19.9
-40	-40	14.2	15.8	14.8	19.2	21.4	20.1
-76	-60	12.3	15.0	13.7	16.7	20.3	18.6

Tests conducted according to DIN EN 10045 parts 1-4

Distance between supports = 22 mm

The symbol ">" indicates no breakage of the specimens. In the other cases, about 50% of the specimens suffered breakage.

8.2 Effect of low temperatures on fastenings to steel

Effect of low temperatures on pull-out strength

Tests show that very low temperatures tend to increase pull-out strength with both standard zinc-plated fasteners and with the stainless steel. The results of two tests are summarized below. The fasteners were driven at

room temperature and tested at -40°C to -70°C. A control sample was tested at 20°C. Explanations for the greater strength at low temperatures include increase in the strength of the zinc that is displaced into the knurling as well as increased strength of the fusing at the point of the fastener.

Base steel : $h = 20 \text{ mm}$
 $f_u = 450 \text{ MPa}$
 Fastened material : none
 Tool : DX 750 G
 Fastener : X-CRM8-15-12 FP10

Two facts stand out from this testing:

- Pull-out strength increased as temperature decreased
- Pull-out from the base steel was the only mode of failure observed. There were no fractures!

8.3 Fire rating of fastenings to steel

Standard zinc-plated, thermally hardened steel fasteners

When subjected to high temperatures as in a fire, both powder-actuated fasteners and

structural steel lose strength. Data for standard zinc-plated, thermally hardened fasteners and structural steel are plotted in the graph below.

Up to about 300°C [572°F], the strength loss for DX fasteners is roughly proportional to the yield strength loss of structural steel. At 600°C [1112°F], DX fasteners have about 12% of their 20°C [68°F] strength left and structural steel about 26%. Since DX fasteners obtain their high strength through a thermal hardening process, the loss in strength at elevated temperatures is proportionally greater than for structural steel.

The relevance of different strength losses has to be evaluated in the context of the proportion of the material strengths that are actually exploited in a design. In a design calculation, it is conceivable that some steel will actually reach yield stress.

The material strengths of an X-ENP-19 L15

fastener is 30 kN [6.74 kips] in tension and 18.6 kN [4.18 kips] in shear respectively. The recommended working load in tension and shear for an X-ENP-19 L15 16 gauge (1.5 mm) fastening is 4.7 kN [1.057 kips] in tension and 4.6 kN [1.034 kips] in shear, respectively. Thus, the exploitation of the X-ENP-19 L15 strength at about 600°C is only 16 to 25% compared to about 74% for structural steel.

In a fire, powder-actuated fastenings will not be the governing factor. If the fire protection requirements permit the use of structural steel, then powder-actuated fastening can also be used without negative impact on fire protection.

CR500 stainless steel fasteners

Hilti X-CR/X-CRM fasteners are much more resistant to loss of strength at high temperatures than standard fasteners. The effect of temperature on ultimate shear stress of X-CR/X-CRM/X-BT fasteners was determined in single lap joint shear tests by the

Swiss Federal Laboratory for Materials Testing and Research (EMPA). The results are plotted in the diagram below. This test was done by shearing 4.5 mm diameter fasteners that were inserted in steel plates with 4.6 mm diameter drilled holes.

In Japan, similar tests were carried out by JTICM (Japan). These tests were done by driving a 4.5 mm diameter X-CR nail through a 6 mm steel plate into a second 6 mm thick steel plate and shearing the two plates. From the graph it is apparent that the results are nearly the same.

At 600°C, the CR500 material has 64% of its 20°C shear strength left. By comparison, standard fasteners have only 12% and structural steel only about 26%. The excellent fire resistance of the CR500 material alone justifies its use for some applications.

8.4 Fire rating of fastenings to concrete

Concrete is weakened and damaged by fire but not as quickly as steel. In ISO-standard fire tests conducted with DX-Kwik fastenings at the Braunschweig Technical University in Germany the only failure mode was fracture of the nails.

The actual test data are shown in the table below:

X-DKH 48 P8S15 DX-Kwik fastener, 4.0 shank

Tested in crack width ΔW (mm)	Tensile load, F (N)	Fire resistance/ time to failure (minutes)	Failure mode
0.2	250	103	Nail fracture
0.2	250	107	Nail fracture
0.2	350	73	Nail fracture
0.2	350	91	Nail fracture
0.2	500	56	Washer pullover
0.2	500	92	Nail fracture
0.2	500	93	Nail fracture

The stress in the fasteners at failure was calculated and plotted so that a plot of stress versus time resulted.

The characteristic failure stress curve from the previous graph can be used to calculate the failure load for various shank diameters with exposure to fire of different lengths of time. The calculated failure loads for 3.7, 4.0 and 4.5 mm shank diameter fasteners after 60, 90 and 120 minutes exposure to fire are shown in the table below.

Failure loads for various shank diameters and fire exposure times

Shank diameter (mm)	Fire exposure time and failure stress		
	60 minutes	90 minutes	120 minutes
	32.1 MPa	22.3 MPa	19.1 MPa
3.7	340 N	240 N	200 N
4.0	400 N	280 N	240 N
4.5	510 N	350 N	300 N

This table can be used to determine recommended loads for the ISO fire resistance required.

9. Design concepts

The recommended working loads N_{rec} and V_{rec} are suitable for use in typical working load designs. If a partial factor of safety design method is to be used, the N_{rec} and V_{rec} values are conservative when used as N_{Rd} and V_{Rd} . Alternatively, the design resistance may be calculated from the recommended loads by multiplying by the factor 1.4, which considers the uncertainties from the load on the fasteners. Exact values

for N_{Rd} and V_{Rd} can be determined by using the safety factors where given and or reviewing test data. Based on cyclic tests it can be stated that DX fastenings can be said to be robust, even when the actual loading turns out to be in part cyclic. Design loads (characteristic strength, design resistance and working loads) for the **X-HVB** shear connector are listed and specified per design guideline.

The designer may encounter two main fastening design concepts:

Working load concept

$$N_S \leq N_{rec} = \frac{N_{Rk}}{\gamma_{GLOB}}$$

where γ_{GLOB} is an overall factor of safety including allowance for:

- errors in estimation of load
- deviations in material and workmanship

and N_S is in general a characteristic acting load.

$$N_S \approx N_{Sk}$$

Partial factors of safety

$$N_{Sk} \times \gamma_F = N_{Sd} \leq \frac{N_{Rk}}{\gamma_M} = N_{Rd}$$

where:

γ_F is a partial factor of safety to allow for errors in estimation on the acting load and

γ_M is a partial factor of safety to allow for deviations in material and workmanship.

The characteristic strength is defined as 5 % fractile:

$$N_{Rk} = N_{u,m} - k \times s$$

The k factor is a function of the sample size and the accuracy required. The characteristic strength of fastenings to concrete is determined based on a 90% probability while fastenings to steel are based on a 75% probability.

Structural analysis of the fastened part (e.g. roof deck panel or pipe hung from a number of fastenings) leads to calculation of the load acting on a single fastening, which is then compared to the recommended load (or

design value of the resistance) for the fastener. In spite of this single-point design concept, it is necessary to ensure adequate redundancy so that failure of a single fastening will not lead to collapse of the entire system. The old saying “one bolt is no bolt” can also be applied to DX fastening.

For standard DX fastenings on concrete, a **probability-based design** concept based on multiple fastening is applied in order to allow for fastener driving failures and the large scatter in holding power observed. This concept applies to tensile as well as shear loading and is described in following chapter.

10. Determination of technical data for fastening design

The determination of technical data is based on the following tests:

- Application limits
- Tensile tests to determine pull-out and pull-over strength
- Shear tests to determine bearing capacity of the attached material and the base material.

These tests are described in more detail in the sections “Steel and other metal base material” and “Concrete base material”.

10.1 Fastenings to steel

Failure loads in tension and in shear are normally distributed and the variation coefficient is <20%. The test data for each test condition are evaluated for the average and characteristic values. The characteristic value is based on the 5% fractile for a 75% probability.

The application range of the fastener is determined by application limit test where fasteners are set on steel plates of thickness ranging from the minimum recommended thickness $t_{II,min}$ to full steel (≥ 20 mm) and varied plate strength.

The application limit is reached when 1 shear off failure with 30 fasteners tested occurs, or if a detrimental effect on the load values (resistance) occurs, or if a detrimental effect on the load values (resistance) occurs.

Due to the small scatter in failure loads fastenings in steel can thus be designed as single points, although good engineering practice should be kept in mind. System redundancy must be always ensured.

10.2 Profile sheet fastenings

In addition to general fastenings to steel, specific data applies to profile sheet fastenings:

Cyclic loading

Profile sheet fastenings are subjected to repeated loading to simulate wind effects. Cyclic pull-through tests are additional optional tests where the failure load at 5,000 cycles is determined.

The design value of the pull-through resistance for repeated wind loads is the design value of the static pull-through resistance multiplied by a reduction factor of α_{cycl} .

- If cyclic tests are carried out:

$$\alpha_{cycl} = 1.5 (N_{Rk,cycl} / N_{Rk,sta}) \leq 1$$

(The factor 1.5 takes the different safety levels for fatigue and predominately static design into account)

- If no cyclic tests are carried out:

$$\alpha_{cycl} = 0.5$$

Sheet bearing capacity

Profile sheet fastenings may be subjected to shear stresses from building movements or thermal dilatation of the sheets. Tests are undertaken to prove the suitability of the fastenings to support the deformations imposed.

For this, shear tests are carried out using a substrate of the minimum and maximum thickness and 2 layers of profile sheet of the thickness specified.

The fastening is considered suitable if an elongation of 2 mm is achieved without the sheet coming loose or showing an excessive reduction in pull-out load capacity. In this case, no consideration of forces of constraint is required since sufficient ductility is provided by the fastening due to hole elongation.

Standardization

The pull-over strength of profiled sheet fastenings is given with reference to core sheet thickness. Ultimate load data is standardized to the minimum sheet thickness and strength as specified by the relevant sheet standard. The correction applied is as follows:

$$F_{u'} = F_u \times \frac{t_{min}}{t_{act}} \times \frac{f_{u,min}}{f_{u,act}}$$

10.3 Fastenings to concrete (standard DX / GX)

The failure loads in tension and shear show a large scatter with a variation coefficient of up to 60%. For specific applications, fastener driving failures may be detected and the fasteners replaced (e.g. threaded studs). For others, however, detection may not be possible (e.g. when fastening wooden battens) and this must be taken into consideration.

The design resistance is therefore determined for:

- failure loads without considering fastener driving failures
- failure loads considering a 20% rate of fastener driving failure

Evaluation of technical data and design according to the single point design approach based on fractiles and a safety factor is not feasible for such systems. The characteristic value would become zero at a variation coefficient of about 50%.

The evaluation of the data and the determination of the design resistance is therefore based on a multiple fastening, i.e. a redundant design, in which the failure probability not of a single, but of a number of fasteners supporting a structure is calculated. By this system, load may be transferred between the fasteners, if slip or failure or more of one of the fasteners occurs.

Test data

The test data for the fastener is consolidated to form a master pullout load distribution.

Static system

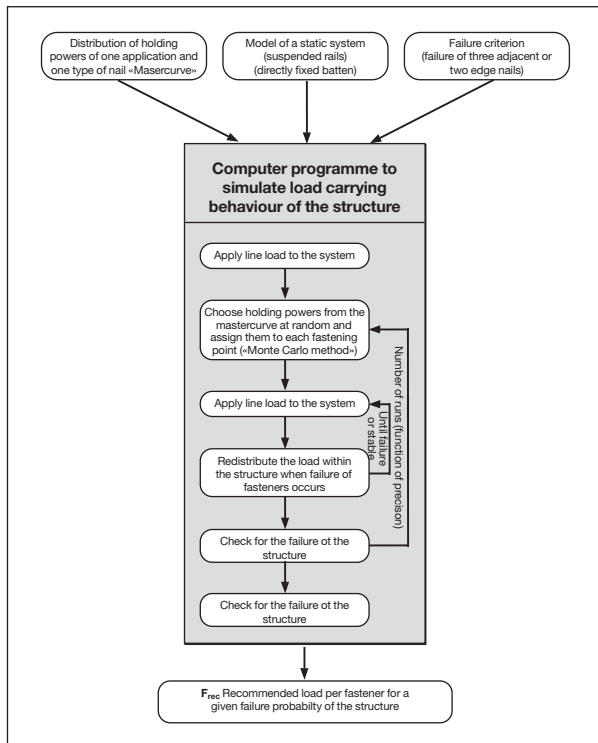

Two static systems are examined

- A suspended beam allowing unrestrained flexure of the beam
- A beam directly attached to the surface, which shows restrained flexure

Calculation method

The calculation method used is the Monte Carlo method, by which holding values taken stochastically from the master distribution are attributed to the individual fasteners of the system and the system is checked to determine whether the imposed line load can be supported. By performing a large number of such simulations, statistical information on the failure probability of a system under a given line load is obtained.

Design parameters

The design is based on the following parameters:

- Failure probability: 1×10^{-6}
- Number of fasteners: 5
- Line load uniformly distributed
- Failure criterion: 2 edge or 3 central fastenings

The result is expressed in **recommended load per fastening**.

Effect on a fastening design

The overall condition for a fastening design in practice is that redundancy of the complete system has to be ensured. The effect of the Monte Carlo approach on a design is illustrated with two examples below.

Example:

Fastening of a plumbing with five ceiling hangers.

1. Due to the stiffness (EI) of the plumbing a redistribution of the dead load (g) to the remaining hangers is given in case of two neighbouring hangers failing.
 - Fixing of each hanger with one nail is sufficient.

2. The plumbing is not stiff enough to redistribute the dead load to the neighbouring hangers in case of one fastener failing.
 - Each hanger has to be fastened with five nails.

10.4 DX fastenings to concrete (DX-Kwik)

Failure loads in tension and shear are log-normally distributed and the variation coefficient is <20%. The test data is evaluated to yield the 5% fractile based on a 90% probability. The recommended working loads are obtained by applying a global safety factor of 3 for tension and shear.

The determination of technical data for cracked concrete (tensile zone) is based on tensile tests. Shear tests in cracked and uncracked concrete give similar results and are therefore not performed.

Failure loads in cracked concrete show a higher variation coefficient. Test data is also evaluated to yield the 5% fractile. The recommended load for the tensile zone is taken as the smaller of the following values:

- $N_{rec} = N_{Rk} / \gamma_{GLOB}$ $\gamma_{GLOB} = 3.0$ for 0.2 mm crack width
- $N_{rec} = N_{Rk} / \gamma_{GLOB}$ $\gamma_{GLOB} = 1.5$ for 0.4 mm crack width.

The application range of the fastener is determined by application limit test where fastenings are made on concrete of varying strength and age according to the application conditions specified (pre-drilling and setting). The attachment height is kept at the lower end of the range specified. The application limit is reached, if the failure rate exceeds 3% or the pull-out values strongly deviate from a lognormal distribution. The sample size is 30 per condition.

10.5 Fastener design in the USA and Canada

Testing of powder-actuated fasteners is carried out according to the ICC-ES AC 70 acceptance criteria and ASTM E 1190 standard test method. The test procedure covers tensile and shear testing in steel, concrete and masonry.

The determination of the allowable (recommended) load is shown below. The recommended working load is derived from the test data by taking the average failure load or the calculated characteristic load divided by a global safety factor.

Three different options have to be distinguished:

COV ≥ 15%		COV < 15%
based on characteristic load N = 30 tests	based on lowest ultimate load N = 10 tests	based on mean ultimate load N = 10 tests
$F_{rec} = \frac{F_{u,m} - 2s}{\nu} = F_{u,m} \frac{1 - 2COV}{\nu}$	$F_{rec} = \frac{\min F_u}{\nu}$	$F_{rec} = \frac{F_{u,m}}{\nu}$

with a safety factor of $\nu = 3.5$	with a safety factor of $\nu = 5$
-------------------------------------	-----------------------------------

where:

- F_{rec} = allowable (recommended) load
- COV = $s/F_{u,m}$ = coefficient of variation in a test series
- s = standard deviation in a test series
- $F_{u,m}$ = average ultimate load in test series
