NEW JERSEY DEPARTMENT OF ENVIRONMENTAL PROTECTION AND ENERGY

The mission of the New Jersey Department of Environmental Protection and Energy is to conserve, protect, enhance, restore and manage our environment for present and future generations. We strive to prevent pollution; ensure the efficient use of safe, environmentally sound and reliable energy resources; provide opportunities for recreation and enjoyment of natural and historical resources; and promote a healthy and sustainable ecosystem.

HYDROGEOLOGIC FRAMEWORK OF THE MIDDLE AND LOWER ROCKAWAY RIVER BASIN, MORRIS COUNTY, NEW JERSEY

Abstract

The valley-fill deposits of the Rockaway River basin between Wharton and Montville in Morris County, New Jersey, were investigated using geologic mapping, records of wells and borings, and seismic techniques. The valley fill includes unconfined and semiconfined aquifers. The unconfined aquifers consist of late Wisconsinan glaciolacustrine sand and gravel. The semiconfined aquifers consist of late Wisconsinan glaciolacustrine sand and gravel and pre-late Wisconsinan glaciolacustrine and glaciofluvial sand and gravel. They occur in the deepest parts of buried bedrock valleys, and are as much as 60 feet thick. The unconfined aquifers are generally less than 50 feet thick. The confining units are as much as 150 feet thick and consist of glaciolacustrine silt, fine sand, clay, and, in places, glacial till.

The study confirmed the presence of a buried bedrock gap, first suggested by Davis and Wood (1889), that connects the upper Rockaway and Passaic buried valley systems. The Troy Hills buried valley was mapped from the Rockaway Valley through this gap to the Passaic buried valley system of Nichols (1968).

Introduction

The Rockaway River basin between Wharton and Montville, together with small areas of the Whipppany and Passaic basins included within the study area, encompasses approximately 120 square miles (fig. 1). Included are the Boroughs of Mountain Lakes, Rockaway, and Wharton, parts of the Borough of Morris Plains, the Townships of Rockaway, Randolph, Denville, Roxbury, Boonton, Hanover, East Hanover, Jefferson, Mine Hill, Montville and Parsippany-Troy Hills, and the Towns of Boonton, Dover, and Victory Gardens (figs. 2, 3). Within this area, buried valley aquifers are the principal

source of potable water. They supplied approximately 19.5 million gallons per day (MGD) in 1987 (table 1). Within Morris County as a whole, a 17-percent increase in water consumption is projected by the year 2000 (Havens and Emerson, 1980). A large part of this increase is expected to come from high-capacity wells in valley-fill aquifers.

The study was undertaken as part of an effort to determine the effects that increased withdrawals would have on water levels in aquifers, water supply from ex-

isting wells, and condition of streams and lakes. It defined the hydrogeologic framework for a three-dimensional ground-water flow model of the valley-fill aquifer system developed by the United States Geological Survey (Schaefer and others, 1993; Gordon, in press). The framework of buried bedrock valleys and valley-fill aquifers was shown with a bedrock topography map (pl. 1), a surficial materials map (pl. 2), and geologic sections (pl. 3). These were based on geologic mapping, records of wells and borings, and seismic refraction.

Acknowledgements

This study was funded by a grant from the U.S. Environmental Protection Agency, Underground Injection Control Program, and by the New Jersey Water Bond Issue of 1981.

The authors are grateful to Frank Boyarski, former superintendent of the Parsippany-Troy Hills Water Department, Carl Danser of the Mountain Lakes Water Department, Steve Koval of the Boonton Township Water Department, and Joe Lowell of the Denville Water Department for their assistance and cooperation in obtaining information for this study. We also thank A.D. Randall and P.T. Harte of the U.S. Geological Survey - Water Resources Division, and I.G. Grossman and D.P. Harper of the New Jersey Geological Survey for their expert review of the report. The authors acknowledge Wayne Hutchinson, Evelyn Hall and Jeff Kearns of the New Jersey Geological for assisting in the collection and processing of the data contained in this study.

Geologic setting

The Rockaway River basin lies within two geologic provinces. North and west of the 200- to 400-foot-high

Highlands escarpment, extending from Montville through Boonton to Fox Hill, is the New Jersey Highlands (fig. 2). To the south and east, below the escarpment, is the Newark Basin. The Highlands escarpment coincides with the Ramapo Fault, a major fault which separates Precambrian granite and gneiss of the Highlands to the northwest from Jurassic sedimentary and igneous rocks of the Newark Basin to the southeast. The escarpment is an erosional feature created by the contrast between resistant Precambrian granite and gneiss and less resistant Jurassic sedimentary rock.

Preglacial drainage routes generally coincide with present drainage (Stanford, 1989a,b). In the only major exception, the preglacial Rockaway River flowed northwest-southeast through a valley from Denville across the Highlands escarpment to Troy Hills (fig. 3). This valley subsequently was filled with as much as 400 feet of glacial sediment and the Rockaway River now flows northeast from Denville to Boonton Township, then southeast through a gap near Boonton (fig. 3). From Boonton, the present-day river flows southeastward, following a partially filled tributary of the preglacial Rockaway, to the Passaic River at Pine Brook. In another, smaller change due to glaciation, the preglacial course of the Rockaway was blocked with glacial deposits at Dover and the river now is incised into a bedrock spur about 2,000 feet to the south of the preglacial valley.

Deposits record at least two glaciations (Stanford, 1989a,b). A pre-late Wisconsinan glaciation, of probable Illinoian age, extended south of the Rockaway Valley (fig. 3). The late Wisconsinan glaciation extended to a well preserved terminal moraine which follows the Highlands escarpment from Littleton to Denville, then

traverses the Rockaway Valley westward to Wharton (fig. 3). Deposits of the earlier glaciation occur south of and in places beneath the terminal moraine. They include till as much as 40 feet thick and sand and gravel as much as 50 feet thick. These are overlain by thick late Wisconsinan till and glaciolacustrine deposits in the major valleys and do not occur at the land surface north of the terminal moraine.

Late Wisconsinan deposits are primarily lacustrine. Of the several glacial lakes in the study area (fig. 3), glacial Lake Passaic (Kummel, 1895) was the largest and occupied the entire area east of the Highlands escarpment. Valley-fill sediments within the Lake Passaic basin include interbedded till and glaciolacustrine silt, clay, sand, and gravel. The silt and clay are as much as 120 feet thick. The till and sand and gravel are as much as 80 feet thick.

Smaller glacial lakes occupied the Rockaway River valley and its tributaries. Valley-fill sediments within

the basins of these lakes generally consist of a three-part sequence in which as much as 50 feet of glaciolacustrine sand and gravel is overlain by as much as 150 feet of silt, fine sand, and clay. This is in turn overlain by as much as 50 feet of glaciofluvial sand and gravel. Till is interbedded with these sediments in and near the terminal moraine.

Previous hydrogeologic investigations

Gill and Vecchioli (1965) provided general information on ground water in both bedrock and buried valley aquifers for Morris County. Nichols (1968) showed bedrock topography in the eastern part of the study area. Geonics (1979a) used seismic techniques to determine the thickness of valley-fill sediments in the Rockaway River valley in Denville, Mountain Lakes, Boonton, and Boonton Township. Borings by Geonics (1979a) demonstrated the existence of a semi-confined sand and gravel aquifer in the valley between Denville and Boonton Townships. Geonics (1979b) delineated valley-fill sediments in Montville Township.

Techniques of Investigation

Geologic data

Approximately 750 records of water wells, monitor wells and test borings (table 2) from files at the New Jersey Bureau of Water Allocation and the New Jersey Department of Transportation were used to construct the bedrock topography map (pl. 2) and geologic sections (pl. 3). The locations of public-supply wells were checked in the field; the locations of other wells and borings were obtained from State well permits, site plans, engineering reports, tax maps, drillers' reports, and, in some cases, site visits.

Surficial geologic data were from Kummel (New Jersey Geological Survey, unpublished maps), Salisbury (1895), Darton and others (1908), Bayley and others (1914), Sims (1958), and Stanford (1989a,b; unpublished maps). Interpretations by Geonics (1979a) and Nichols (1968) and subsurface data from Geraghty and Miller (1968) were taken into account in contouring bedrock elevation.

Seismic refraction

Fifty two seismic refraction traverses were taken, following the field procedures described by Haeni (1988), to determine the thickness and composition of the valley-fill sediments. The degree of urbanization and the anticipated depth to bedrock were the limiting factors for seismic profile length and geophone spacing. Both single-channel and 12-channel refraction data

were collected. Initially, a single-channel seismograph was used and the slope-intercept method (Dobrin, 1976) was used to determine depths to the different layers. Later, a 12-channel, signal-enhancement seismograph was used. The 12-channel instrument proved to have superior resolution and filtering capabilities. Multiple-shotpoint data collected with the 12-channel instrument were reduced using two computer programs: HRASSD (Hoffman and Waldner, 1985) to pick the time breaks and layer numbers for individual shotpoints, then FSIP1 (Scott, 1977) to calculate average apparent velocity (speed of a seismic impulse) for layers and assemble multi-shotpoint refraction lines into depth profiles. Generally, multiple shotpoint data are more reliable because depth determinations are based on repeatedly sampling.

Most of the lines were best modeled as 3-layer cases (table 3). In some cases 4 distinct layers could be detected (see pl. 3, RV-4).

The velocity of layer 1 ranged from 650 to 2,000 feet per second (ft/sec). Such relatively low velocities are typical of unsaturated, unconsolidated sediments, and layer 1 was interpreted as being valley fill above the water table.

Layer 2 velocities ranged from 3,480 to 7,400 ft/sec and, in most cases, were interpreted as showing saturated, unconsolidated sediments. Where velocities were

below 4,500 ft/sec, however, layer 2 was interpreted as partially saturated, fine-grained sediment. Within the study area, velocities of 6,900 to 7,400 ft/sec may indicate either sedimentary bedrock (shale or conglomerate), or saturated sediment. Interpretation of seismic data with velocities in this range was based in part on type of bedrock known to underlie the site.

Layer 3 velocities indicated either unweathered sedimentary rock (8,870 to 12,000 ft/sec), or crystalline bedrock or basalt (11,000 to 22,000 ft/sec). In the absence of velocities appropriate for the type of bedrock known to underlie a site, bedrock was assumed to be deeper than the maximum calculated depth for refraction of seismic energy.

Discussion

The Rockaway buried valley (fig. 4, pl. 1) is the upstream extension of the Passaic buried valley system of Nichols (1968) and the downstream extension of a buried valley system mapped in the upper Rockaway basin by Canace and others (1983). The deepest part of the principal buried valley declines in elevation from approximately 400 feet above sea level near Washington Pond in Wharton Borough to less than 60 feet above sea level under Troy Meadows. The segment between Arrowhead Lake and Troy Meadows, where the buried valley intersects the Millburn buried valley of Nichols (1968; modified by Ghatge and Hall, 1989) is referred to here as the Troy Hills buried valley. The Montville buried valley extends northward from the Troy Meadows area into Montville Township. The northern ends of the Cedar Knolls and Parsippany buried valleys (Hoffman and Stone, 1991) are also within the study area.

Because the area is near the limit of glaciation, bedrock topography is interpreted as being inherited predominantly from stream erosion, rather than as the result of glacial scour. Although the glaciers did scour closed depressions within the Passaic buried valley area (Nichols, 1968), closed depressions were noted in the study area only beneath Picatinny Arsenal and in the southeast corner, where all topography below roughly the 60-foot bedrock elevation contour (pl. 2) is glacially scoured. Both areas are north of the terminal moraine in north-south tributary valleys underlain by easily eroded sedimentary bedrock. The main Rockaway buried valley, in contrast, was less subject to erosion because of its east-west orientation, perpendicular to ice flow, and

because it lies along the terminal moraine, where deposition was predominant over erosion.

Ground-water resources

Productive valley-fill aquifers in the Rockaway basin consist of sand and gravel deposits of glaciofluvial and glaciolacustrine origin (table 2). Both unconfined and semiconfined aquifers are present.

Within the glacial Lake Passaic basin, semiconfined aquifers of sand and gravel as much as 80 feet thick are overlain by as much as 120 feet of silt, clay, fine sand, and till. Unconfined aquifers exist where silt and clay are absent, but they are not extensive or thick.

Upstream, within the Highlands, the valley fill of the Rockaway valley and its tributaries generally consists of an unconfined aquifer, a leaky confining layer, and a semiconfined aquifer. The unconfined aquifer consists of sand and gravel as much as 50 feet thick. The underlying leaky confining layer is as much as 150 feet thick and consists of silt, fine sand, clay, and locally till. The semiconfined sand and gravel aquifer ranges in thickness from 30 to 80 feet, but it can be less than 30 feet thick and is absent in places.

The Troy Hills buried valley, connecting the buried valleys in the Passaic basin with those in the Highlands, contains a semiconfined aquifer continuous along its length. Piezometric levels in this aquifer indicate that ground-water underflow is occurring between the Rockaway and Passaic basins through the buried gap at Mountain Lakes (Schaefer and others, 1993).

NOTES: 1) Numbers beginning with UN lack NJDEPE permit numbers. UN numbers were assigned sequentially as records were processed

2) Total depth of borehole.

3) From log or approximated from casing length.

4) Bottom of casing for bedrock wells; top of screen for wells in valley fill.

5) Bottom of well for bedrock wells; bottom of screen for wells in valley fill.

6) Below top of casing.

7) To water (pumping test) or end of drill stem (air-lift test).

8) Gallons per minute per foot of drawdown.

9) PC = Precambrian gneiss, related rock; Qsd = Pleistocene glacial sediment (unit not specified); JTrb = Brunswick Group (Jurassic in study area); Jbs = Jurassic basalt; Sgp = Silurian Green Pond Conglomerate; Cl = Cambrian Leithsville Formation.

Table 3. - Seismic refraction data and interpretation

[Location of lines shown on plate 1; elevation (feet above sea level) interpolated from U.S.G.S. 7.5-minute quadrangle maps; > means indicates that depth to bedrock based on the slope-intercept method is beyond the reach of the farthest geophone.]

Base from U.S. Geological Survey
Boonton, 1954, photorevision as of 1970
Caldwell, 1954, photorevision as of 1970
Dover, 1954, photorevision as of 1981
Mendham, 1954, photorevision as of 1970
Morristown, 1954, photorevision as of 1981
Pompton Plains, 1954, photorevision as of 1981

Slashes indicate that materials on left overlie materials on right. For example, **t/g** = silt, fine sand, and clay overlie till, which in turn overlies gravel and sand.
Commas indicate that associated materials are interbedded or occur alternately. For example, **t,g** = silt, fine sand and clay are interbedded with till or occur alternately with till.

Where slashes and commas occur together, slashes separate groups of interbedded or alternating materials. For example, **t,g/t,g** = till overlying interbedded or alternating silt, fine sand, clay and gravel and sand, which in turn overlies interbedded or alternating till and gravel and sand.

s - sand and pebbly sand
t - till; generally less than 20 feet thick, over bedrock
tt - thick till; generally more than 20 feet thick, over bedrock. May include sand and gravel.
g - gravel and sand

Plate 2. Surficial materials map showing location of geologic sections.

CONTOUR INTERVAL 20 FEET

NATIONAL GEODETIC VERTICAL DATUM OF 1929

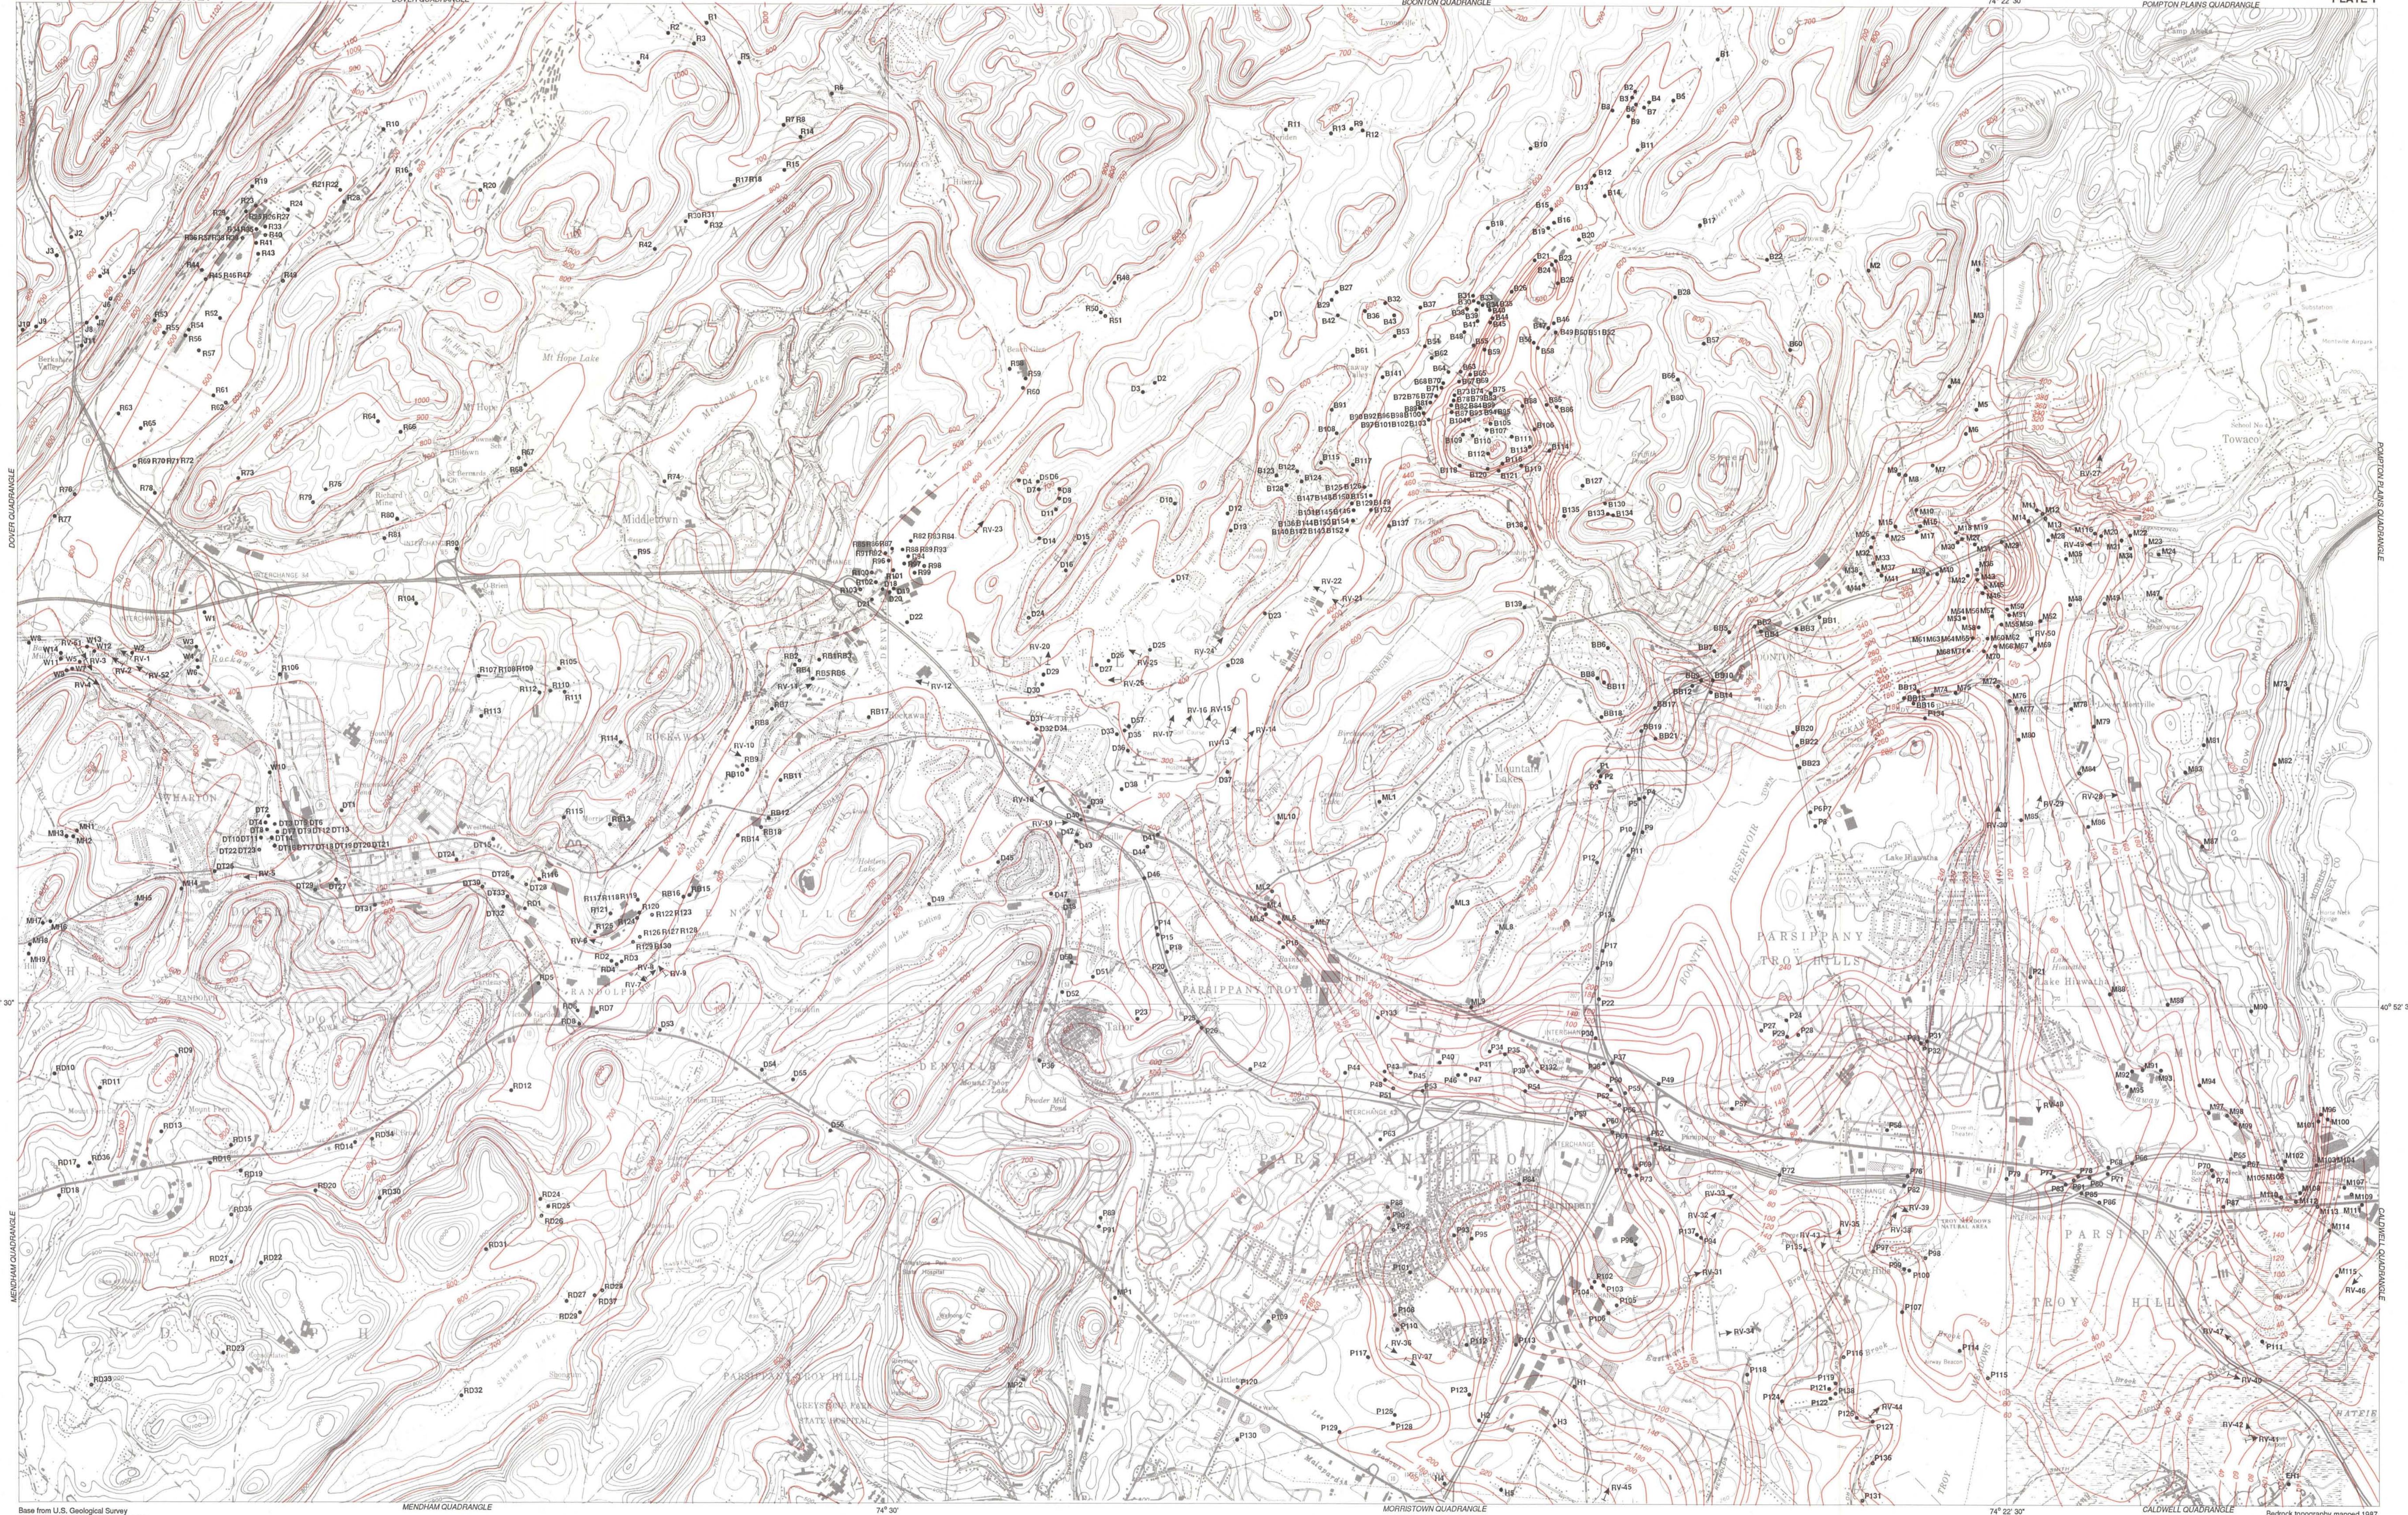

Plate 1. Bedrock topography map showing location of wells, borings and geophysical lines.

EXPLANATION

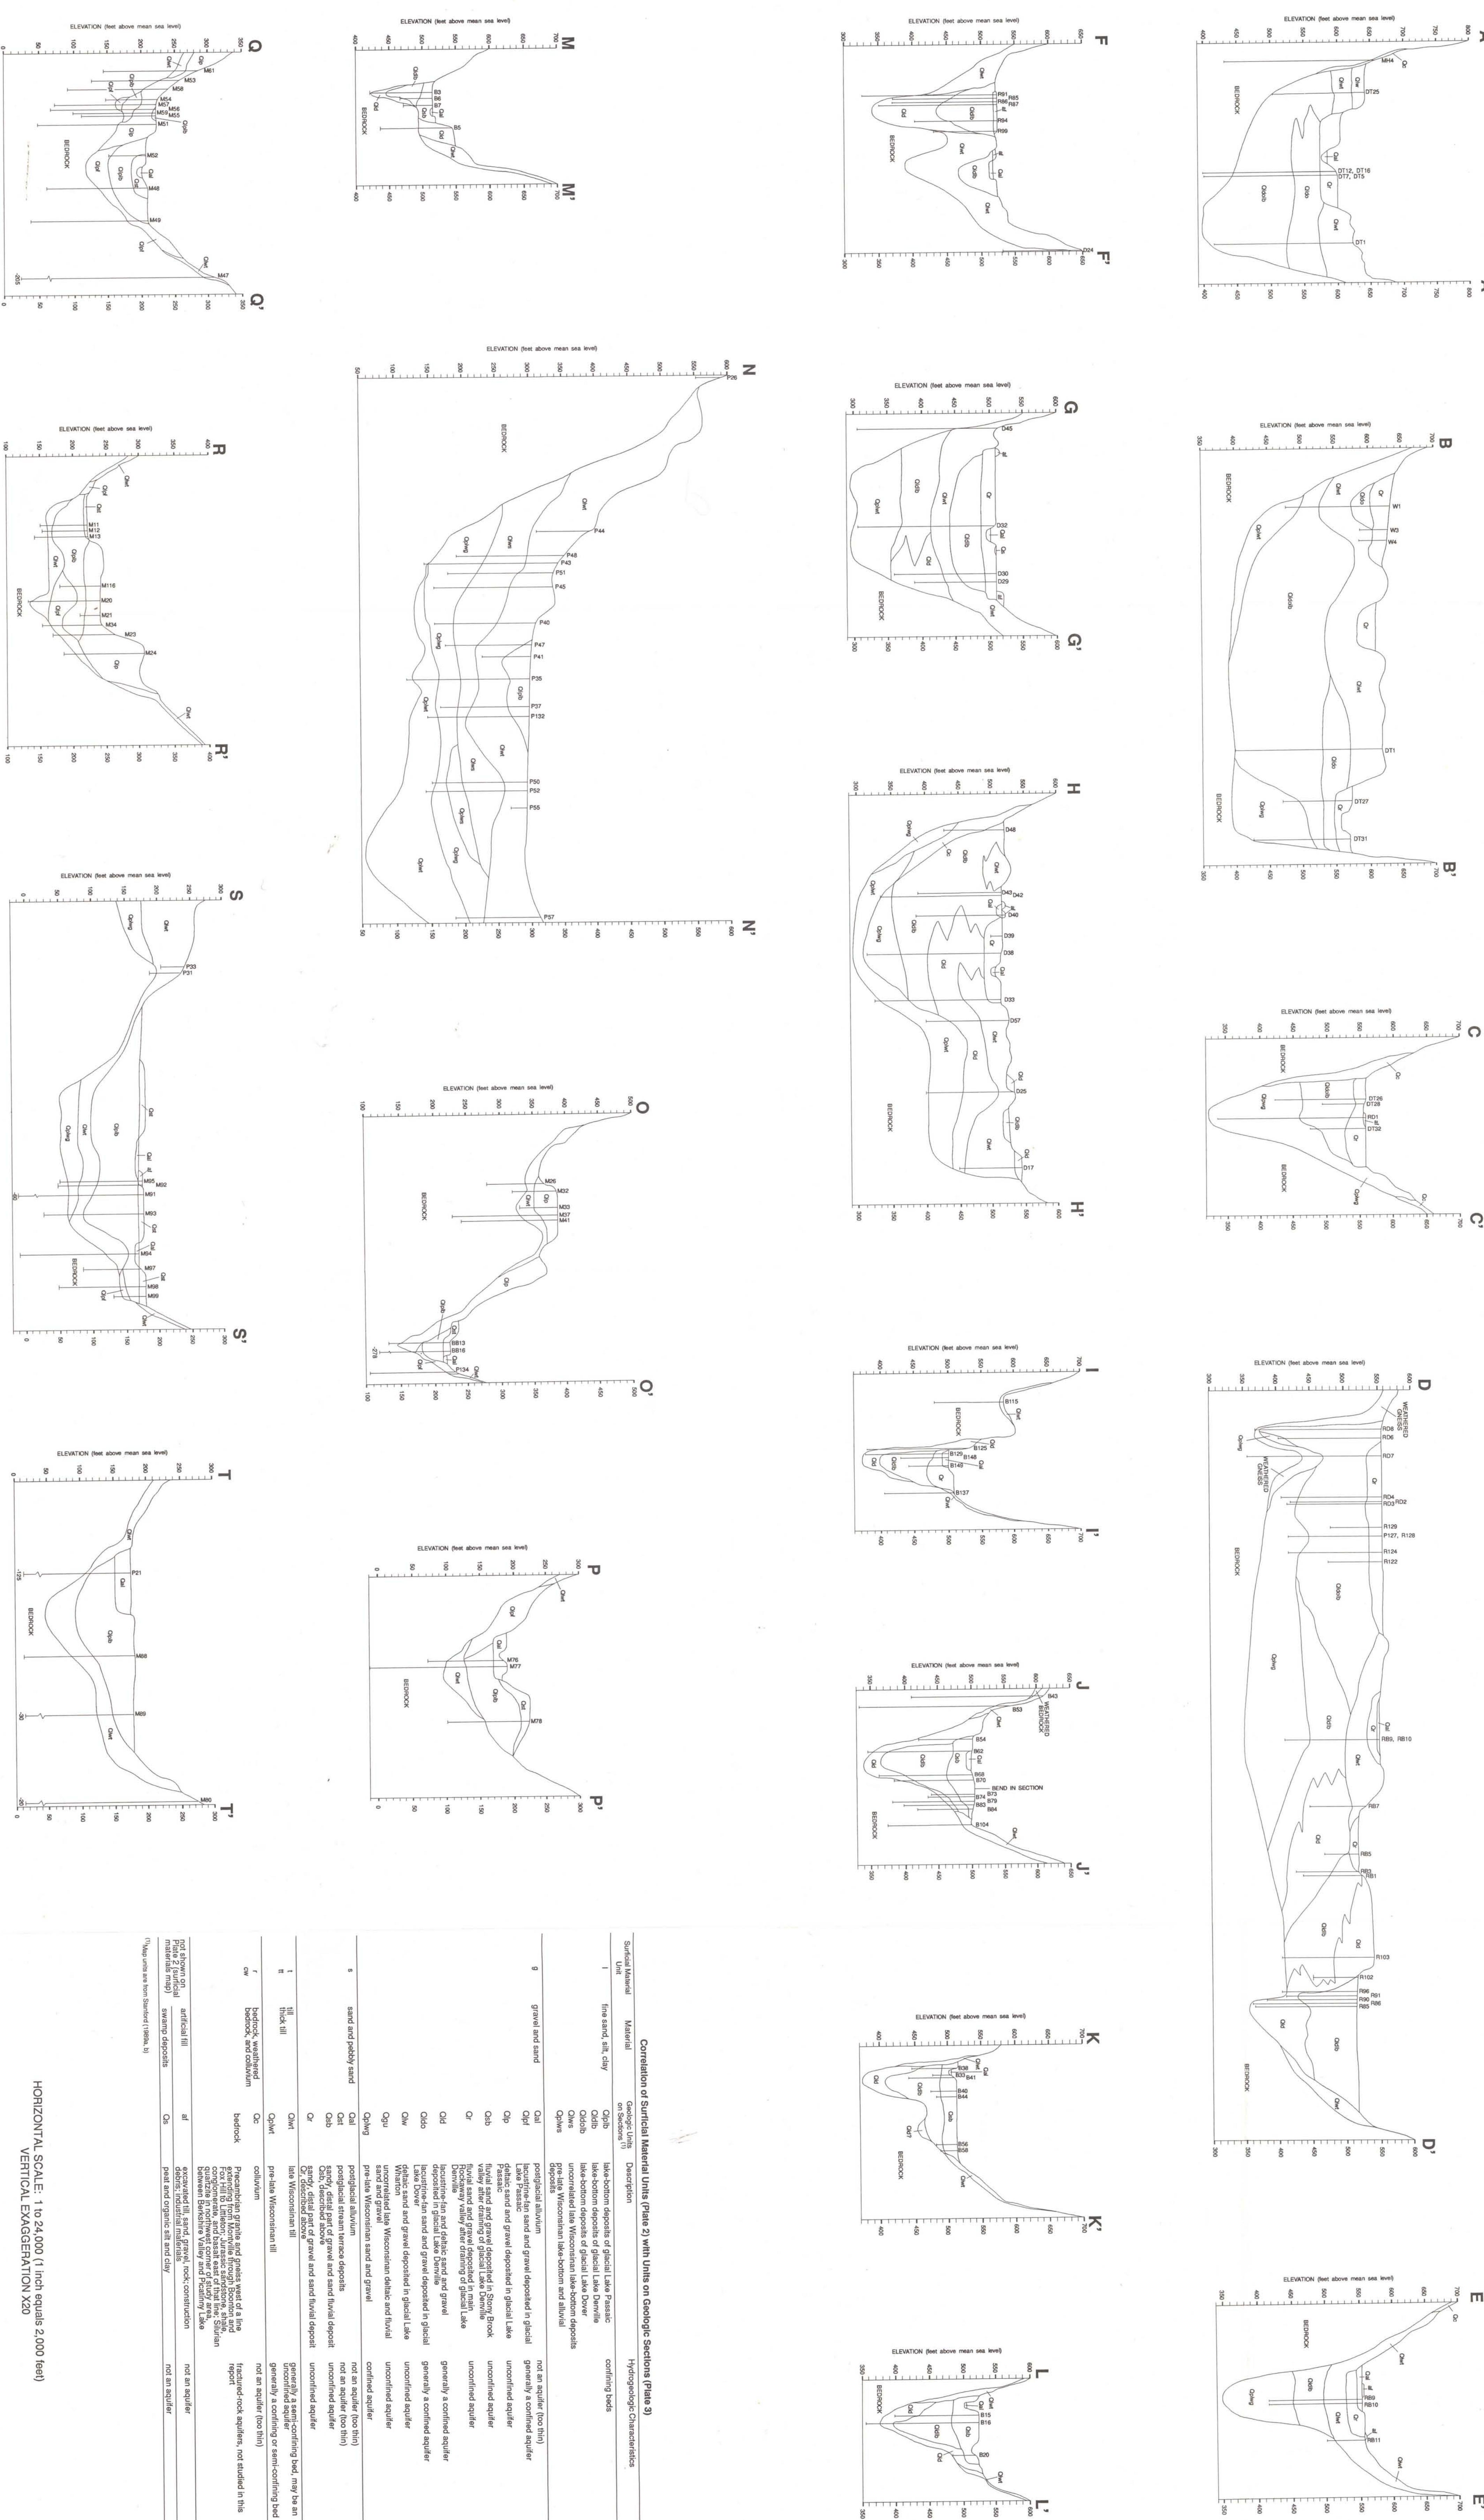

- Contour interval 100 feet; supplementary interval 20 feet in places
- Well or boring- refer to Table 2
- Seismic refraction line- arrow indicates direction of forward traverse; refer to Table 3
