Verification Problems

Response of Secondary Systems

Primary Systems:

Building that receives the motion directly from the ground

Secondary Systems:

Piping systems and equipments that are attached to the building

Conventional Analysis Method

Building Design Spectrum

Compatible Time History

Building Model

Floor Time History

Floor Response Spectrum

Problems

1. Evaluation of the compatible time history is not unique. (Several time histories can be developed that are "compatible.")
2. The method does not account for mass-interaction between secondary and primary systems - response is overestimated.

Multiply Supported Secondary System (Piping Systems)

- 1. Floor spectra are enveloped - overestimation of response.**
- 2. For relative displacements between the supports - worst case analysis is performed - overestimation of response.**

Overall, calculated piping stresses may be an order of magnitude too high.

New Methods

- 1. Coupled Response Spectrum Analysis**
- 2. Floor Response Spectrum Analysis -
approximating the coupled analysis**

These new methods are rational, rigorous and elegant.

In the overall scheme of things, the new methods do not significantly increase the cost of analysis.

New methods give significantly reduced seismic stresses. They are useful for:

- 1. Requalification of existing systems for higher than the original design seismic forces.**
- 2. Reduction of piping supports (snubbers).**
- 3. Margin evaluation.**

Free Vibration Equation

$$[M]\{\ddot{U}\} + [C]\{\dot{U}\} + [K]\{U\} = \{0\}$$

$$\{U\} = [\Phi]\{X\}, \quad \{X\}^T = [\{X_p\}^T \{X_s\}^T]$$

$$[\Phi] = \begin{bmatrix} \phi_p & 0 \\ 0 & \phi_s \end{bmatrix} \quad \begin{aligned} \{X_p\}^T &= [X_{p1} \ X_{p2} \ \dots] \\ \{X_s\}^T &= [X_{s1} \ X_{s2} \ \dots] \end{aligned}$$

$$[\phi_p] = [\phi_{p1} \ \phi_{p2} \ \dots]$$

$$[\phi_s] = [\phi_{s1} \ \phi_{s2} \ \dots]$$

$$r_{i\alpha}^{1/2} = [\gamma_{c\alpha}] \{ \phi_{ci} \}$$

SDOF Secondary System

$$[\gamma_{c\alpha}] = \sqrt{m_s}$$

SDOF Primary System

$$\{ \phi_{ci} \} = \frac{1}{\sqrt{m_p}}$$

$$r_{i\alpha}^{1/2} = \sqrt{\frac{m_s}{m_p}}$$

The definitions of $[\bar{K}]$ and $[\bar{C}]$ are as accurate as they can be.

For moderately light secondary systems, these expressions can be used to obtain **approximate but accurate** eigenvalues and eigenvectors.

Eigenvalue Problem

$$[K^*]\{X\} = \{0\}$$

$$[K^*] = \lambda^2[1] + \lambda[\bar{C}] + [\bar{K}]$$

λ = coupled complex eigenvalue

**High Frequency Mode Effect
on Coupled Analysis**

Equation of motion of the coupled system

$$[M] \{\ddot{U}\} + [C] \{\dot{U}\} + [K] \{U\} = -[M] \{U_b\} \ddot{u}_g$$

$$\{U\} = \begin{Bmatrix} \{U_p\} \\ \{U_s\} \end{Bmatrix}$$

$\{U_p\}$, $\{U_s\}$ are the primary and secondary system displacements, respectively, relative to the base of the primary system.

Secondary system displacement vector relative to the primary systems connecting DOF

$$\{\bar{U}_s\} = \{U_s\} - [U_{sc}] \{U_c\}$$

$[U_{sc}]$ contains one secondary system displacement vector for each connecting DOF.

Each such vector represents the displacement vector when the corresponding connecting DOF undergoes a unit displacement.

Transformation

$$\{U\} = \begin{Bmatrix} \{U_p\} \\ \{U_s\} \end{Bmatrix} = \begin{bmatrix} [I] & [0] \\ [U_{sp}] & [I] \end{bmatrix} \begin{Bmatrix} \{\bar{U}_p\} \\ \{\bar{U}_s\} \end{Bmatrix}$$

$$\{U_p\} \equiv \{\bar{U}_p\}$$

$[U_{sp}]$ is obtained from the matrix $[U_{sc}]$ by adding zeros for the non-connecting DOF of the primary system.

$$[\bar{M}] \{\ddot{\bar{U}}\} + [\bar{C}] \{\dot{\bar{U}}\} + [\bar{K}] \{\bar{U}\} = -[\bar{M}] \{\bar{U}_b\} \ddot{u}_g$$

Primary system residual mode vector

$$[K_p] \{U_o\} = -[M_p] \{U_{bo}\} \ddot{u}_g^* \text{ Scaled Out}$$

$$\{U_{bo}\} = \{U_{bp}\} - \sum_{i=1}^{np} \{\phi_{pi}\} \gamma_{pi}$$

Normalize $\{U_o\}$ to get $\{\phi_o\}$ such that

$$\{\phi_o\}^T [M_p] \{\phi_o\} = 1$$

Define a fictitious frequency

$$\omega_o^2 = \{\phi_o\}^T [K_p] \{\phi_o\}$$

Treat $\{\phi_o\}$ as an extra uncoupled primary system mode just like any other mode.

Evaluation of Secondary System Residual Mode Vectors

$$[M_s] \{\ddot{U}_s\} + [C_s] \{\dot{U}_s\} + [K_s] \{U_s\} = - [M_s] [U_{sc}] \{\ddot{U}_c^t\}$$

$\{\ddot{U}_c^t\}$ = Total acceleration at the primary system connecting DOF.

$$[M_s] \{\ddot{U}_s\} + [C_s] \{\dot{U}_s\} + [K_s] \{U_s\} = - \sum_{\alpha} [M_s] \{\phi_{s\alpha}\} \sum_c \gamma_{c\alpha} \ddot{u}_c^t$$

$\gamma_{c\alpha}$ = Participation factor for the secondary system mode α at connecting DOF c , an element of $[\Gamma_c]$

$$[\Gamma_c] = [\Phi_s] [M_s] [U_{sc}]$$

$$[K_s] \{\bar{U}_{so}\} = - [M_s] \sum_c \{U_{sco}\} \ddot{\psi}_c \quad \text{Scaled Out}$$

$$\{U_{sco}\} = \{U_{sc}\} - \sum_{\alpha=1}^{ns} \{\phi_{s\alpha}\} \gamma_{c\alpha}$$

Calculate nc values of $\{U_{sco}\}$ vectors

$$[K_s] \{\bar{U}_{so}\} = - [M_s] \{U_{sco}\}$$

Normalize each $\{\bar{U}_{so}\}$ to give $\{\phi_R\}$ such that

$$\{\phi_R\}^T [M_s] \{\phi_R\} = 1$$

Each of the nc $\{\phi_R\}$ vectors is orthogonal to the given ns modal vectors $\{\phi_{s\alpha}\}$.

However, the $\{\phi_R\}$ vectors themselves are not orthogonal to each other.

Coupled eigenvalue problem

$$[M] \{\ddot{U}\} + [C] \{\dot{U}\} + [K] \{U\} = -[M] \{U_b\} \ddot{u}_g$$

$$\begin{aligned} \{U\} &= \begin{Bmatrix} \{U_p\} \\ \{U_s\} \end{Bmatrix} = [\Phi] \{X\} \\ &= \begin{bmatrix} [\Phi_p] & [0] & [0] \\ [0] & [\Phi_s] & [\Phi_R] \end{bmatrix} \begin{Bmatrix} \{X_p\} \\ \{X_s\} \\ \{X_R\} \end{Bmatrix} \end{aligned}$$

$$[\tilde{M}] \{\ddot{X}\} + [\tilde{C}] \{\dot{X}\} + [\tilde{K}] \{X\} = -[\Phi]^T [M] \{U_b\} \ddot{u}_g$$

Primary System

$$m_p = 1.0 \text{ Kip-s}^2/\text{in}$$

$$K_p = 3000 \text{ Kips/in}$$

Secondary System

$$m_s = 0.1 \text{ Kip-s}^2/\text{in}$$

$$K_s = 1000 \text{ Kips/in}$$

Research on Coupled Seismic Response of Secondary Systems

Ajaya Kumar Gupta¹
Hussein Ahmad Megahed²

Abstract

Coupled seismic analysis of primary-secondary systems may reduce response of a secondary system by one or more orders of magnitude over that calculated from a conventional uncoupled secondary system analysis. When individually classically damped primary and secondary systems are coupled, the combined system becomes nonclassically damped if the modal damping values of the two systems are different. Various topics related to such systems have been studied to further the state of the art, and thereby improve the accuracy of the analysis. Two methods of analyzing nonclassically damped systems, an "original" and a new canonical, are shown to be mathematically identical. The former is preferred because it represents response in terms of physical quantities, relative displacements and velocities. The response spectrum method for nonclassically damped systems requires the conventional relative displacement-based response spectrum and a new relative velocity-based spectrum. For combination of modal responses, three sets of correlation coefficients are needed. Evaluation of the response of a single-degree-of-freedom (SDOF) system is studied to be able to evaluate the response spectra and correlation coefficients. It is shown that the commonly used time-domain analysis gives incorrect relative velocity values for high frequency SDOF systems. An alternative frequency-domain approach is proposed. New expressions for correlation coefficients showing better agreement with the numerical values than the existing expressions are developed. Impact of damping values on rigid response coefficients is studied and is incorporated in new equations. Empirical values for the key frequencies that define the rigid response coefficients are derived. To account for uncalculated high frequency modes of the uncoupled primary and secondary systems, a residual mode method is developed.

Introduction

Various topics related to analyzing nonclassically damped coupled primary-secondary systems have been investigated to further the state of the art, and thereby improve the accuracy of the analysis. Coupled response of a secondary system may be one or more orders of magnitude less than that calculated from the conventional uncoupled analysis. Dynamic analysis of multi-degree-of-freedom (MDOF) systems is often performed by the modal superposition-time history method, or the equivalent response spectrum method. Mode shapes

¹Professor and Director, Research Program on Nuclear Power Plant Structures, Equipment and Piping, Department of Civil Engineering, North Carolina State University, Raleigh, NC 27695-7908.

²Assistant Professor, Department of Civil Engineering, Cairo University, Cairo, Egypt. Former graduate student, Department of Civil Engineering, North Carolina State University, Raleigh, NC 27695-7908.

and frequencies of the undamped system are calculated. It is assumed that when the equation of motion (including the damping term) is transformed using the mode shapes and normal coordinates, a set of uncoupled equations in terms of the normal coordinates are obtained. These equations are similar to the equations of motions of single-degree-of-freedom (SDOF) systems, thus greatly simplifying the solution process. In the above process, the off-diagonal terms in the modally transformed damping matrix are assumed to be zero. The systems, in which this assumption is valid, are called classically damped. MDOF systems in which the off-diagonal terms in the transformed damping matrix cannot be ignored are called nonclassically damped. A coupled primary-secondary system is an example of such a system. A detailed state of the art of analyzing nonclassically damped coupled systems is presented by Gupta (1992). A summary of recent research performed by us (Megahed and Gupta, 1992) at North Carolina State University to further the state of the art is presented here.

Methods of Analysis

The equation of motion of an N-DOF coupled nonclassically damped system is given by:

$$M\ddot{U} + C\dot{U} + KU = -MU_b\ddot{u}_g \quad (1)$$

where M , C and K denote mass, damping and stiffness matrices, respectively; U is the relative displacement vector; U_b is a displacement vector obtained by statistically displacing the support by unity in the direction of the input motion; u_g is the ground displacement; and the super dot ($\dot{}$) represents a derivative with respect to the time variable. In the Foss approach (Foss, 1958), Equation (1) is cast into a $2N$ -dimensional matrix equation, and a complex eigenvalue problem is solved. There are N -pairs of complex eigenvalues and eigenvectors. Each pair consists of eigenvalues and eigenvectors that are conjugates of each other. The complex eigenvalue pairs give the values of modal frequencies ω_i (rad/sec) and damping ratios ζ_i , in which (here and elsewhere in the paper) the subscript denotes the mode number. Each complex eigenvector pair gives two real vectors ψ_i^d and ψ_i^v of the rank $N \times 1$. The modal superposition equation of the nonclassically damped system is given by:

$$U = \sum_{i=1}^N U_i = \sum_{i=1}^N U_i^d - U_i^v = \sum_{i=1}^N \psi_i^d x_i - \psi_i^v x_i \quad (2)$$

in which x_i is the relative displacement of an equivalent SDOF system and can be calculated from:

$$\ddot{x}_i + 2\omega_i\zeta_i\dot{x}_i + \omega_i^2 x_i = -\ddot{u}_g \quad (3)$$

A new "canonical" method was recently proposed by Yang, Sarkani and Long (1987). They define *sine* and *cosine* responses of a SDOF system, denoted here by s_i and c_i , respectively. The modal superposition equation is written in terms of these responses and new modal vectors ψ_i^s and ψ_i^c as:

$$U_c = \sum_{i=1}^N U_i^s + U_i^c = \sum_{i=1}^N \psi_i^s s_i + \psi_i^c c_i \quad (4)$$

We have shown that:

$$\begin{aligned} \psi_i^s &= -\frac{1}{\omega_{Di}} (\psi_i^d + \zeta_i \omega_i \psi_i^v), \quad \psi_i^c = \psi_i^v \\ s_i &= -\omega_i x_i, \quad c_i = \dot{x}_i - \zeta_i \omega_i x_i \end{aligned} \quad (5)$$

in which ω_{Di} is the damped frequency of the i th mode. Equations (4) and (5) give a vector U_c that is identical to the vector U of Equation (2). In the time domain, therefore, the new canonical method would give responses that are identical to those given by the "original" method. The corresponding response spectrum methods should give comparable results. The original method deals with physically meaningful quantities, relative displacement (x_i) and velocity (\dot{x}), and the *sine* and *cosine* responses (s_i and c_i) used in the canonical method are physically not as meaningful. Therefore, we propose to continue to use the original method.

In the response spectrum method of nonclassically damped systems, two response spectra need to be defined (Gupta, 1992; Gupta and Jaw, 1986).

$$S_A^d = \max |x(t)|, \quad S_V^v = \max |\dot{x}(t)| \quad (6)$$

Both the spectra can be defined in alternate units.

$$\begin{aligned} S_A^d &= \omega S_V^d = \omega^2 S_D^d, \\ S_A^v &= \omega S_V^v = \omega^2 S_D^v \end{aligned} \quad (7)$$

in which the small letter superscripts d and v denote the source of the spectral value (relative displacement and velocity, respectively), and the capital letter subscripts A , V and D denote the units, acceleration, velocity, and displacement, respectively.

The maximum value of a response R in mode i obtained from the relative displacement spectra is denoted by R_i^d and that from the relative velocity spectra by R_i^v . Since these maximum values do not occur at the same time, the following modal combination equation is used:

$$R^2 = \sum_i \sum_j (\epsilon_{ij}^d R_i^d R_j^d + \epsilon_{ij}^v R_i^v R_j^v - 2\mu_{ij} R_i^d R_j^v) \quad (8)$$

in which ϵ_{ij}^d , ϵ_{ij}^v , and μ_{ij} are appropriate correlation coefficients.

In the analysis of classically damped systems, only relative displacement-based design spectra are needed and defined. Analysis of a system as nonclassically damped is uncommon, and therefore, relative velocity-based design spectra are not readily available. A method for estimating a velocity spectrum from the corresponding displacement spectrum is proposed by Gupta and Jaw (1986) that will be further investigated here. Analytical values of the correlation coefficients ϵ_{ij}^d , ϵ_{ij}^v , and μ_{ij} based on the assumption that the ground motion is a white noise are available in literature. Empirical studies based on real earthquake ground motions are also available in literature for ϵ_{ij}^d . No such studies have been performed, however, for ϵ_{ij}^v and μ_{ij} . It is proposed to empirically investigate all three coefficients in the present work. In all these numerical investigations on the response spectra and the correlation coefficients, we need to evaluate the response of SDOF systems subjected to earthquake motions in all frequency ranges. Problems with the calculations of the responses were investigated and are summarized (along with the solutions to the problems) in the next section.

Response of an SDOF System

Response of an SDOF system subjected to earthquake ground motions is usually calculated in time domain using an "exact" Nigam and Jennings method (1969). The processed earthquake data has nonzero initial values of the acceleration, velocity and displacement. That is due to the instrument triggering threshold and the process of data filtering. When these nonzero initial conditions are not explicitly accounted for, the calculated response becomes erroneous for the low-frequency SDOF oscillators. This problem has been long recognized and can be solved by introducing a fictitious, prefixed pulse proposed by Pecknold and Riddell (1978). The ground motion is defined in terms of acceleration values at discrete time intervals. In the response evaluation it is assumed that the ground acceleration varies linearly between the data points. The assumption of linear acceleration variation between the data points introduces a practically limitless frequency content in the ground motion that is well beyond the Nyquist frequency, f_c (Hz) = $1/2 \Delta t$, the upper frequency limit of the accurate representation, in which Δt is the record interval in seconds. The spurious high frequency content of the motion does not significantly affect the calculation of the relative displacement values that have been calculated in the past for the classically damped systems. The same is, however, not true of the relative velocity calculations. For illustration, let us consider a 100 Hz oscillator with 2% damping subjected to the El Centro earthquake (SOOE, 1940). The earthquake record is digitized at 0.02 intervals, and is capable of representing a maximum frequency of 25 Hz. It is not expected to generate a significant 100 Hz response in the oscillator. Figure 1 shows a 0.5 second segment of the relative velocity history of the oscillator, that clearly shows a major 100 Hz content (for any 0.1 second duration in the figure, we can count approximately 10 sinusoidal

waves). We were unable to develop a suitable time-domain technique to suppress this spurious response.

Figure 1 0.5 Second Segment of Relative Velocity History of an SDOF System, 100 Hz, Damping Ratio = 0.02, El Centro (SOOE, 1940)

To calculate the response of the oscillator accurately in all frequency ranges, therefore, we proceeded to perform a frequency-domain analysis. The method consists of obtaining the Fourier transform of both the input motion and the unit impulse function over an appropriate range of frequencies, multiplying the two transforms, and performing an inverse Fourier transform on the product resulting in the response time history. The nonzero initial conditions are handled the same way as in the time-domain analysis. When the unit impulse function is also discretized in the time domain (the input motion is already discretized), two new problems appear in the solution. The Fourier analysis implicitly introduces periodicity in the input and output, the period being equal to the length of the record being processed. This results in an "end effect," due to nonzero output at the end of any "period" interfering with the outputs of the subsequent periods. The error is cumulative from period to period and can give very erroneous results. The problem is solved by adding enough zeroes at the end of both the earthquake and the unit impulse data, assuring a zero output at the end of the period, thus avoiding the end effect. Another problem is "aliasing" that occurs in the high frequency range. When the oscillator frequency is beyond the earthquake record's Nyquist frequency,

the true high frequency content of the unit impulse function cannot be accurately represented. The mathematical process interprets the unit impulse function records in terms of the lower "alias" frequencies within the Nyquist frequency, thus giving incorrect response values.

To avoid the aliasing problem, we used an alternate procedure in which the unit impulse function is not discretized to evaluate its Fourier transform. Instead, we use the analytical form of the Fourier transform of the unit impulse function, thus avoiding the aliasing problem. To overcome end effect problems in this case, a correction proposed by Veletsos et al (Veletsos and Ventura, 1985) is used. Figure 2 shows the velocity response of the 100 Hz oscillator (the same as the one used before) from the frequency-domain analysis along with that from the time-domain analysis. The frequency-domain analysis has clearly eliminated the spurious 100 Hz output.

Figure 2 Comparison of 0.5 Second Segment of Relative Velocity History of an SDOF System from Time and Frequency Domain Analyses, 100 Hz, Damping Ratio = 0.02, El Centro (SOOE, 1940)

Correlation Coefficients

The correlation coefficients ϵ_{ij}^d , ϵ_{ij}^v , and μ_{ij} are used in Equation (8) to obtain the combined response R from the corresponding maximum modal responses R_i^d and R_j^v . These coefficients depend upon the closeness of the modal frequencies, except in the high frequency range, where the correlations ϵ_{ij}^d and ϵ_{ij}^v become practically equal to unity irrespective of the (lack of the) closeness of modal frequencies.

Rosenblueth and Elorduy (1969) have proposed an expression for ϵ_{ij}^d (called the Rosenblueth equation) assuming earthquake motion to be a finite segment of white noise, and Igusa, Der Kiureghian and Sackman (1984) have given expressions for ϵ_{ij}^d , ϵ_{ij}^v , and μ_{ij} (called the Der Kiureghian equation) for white noise input of infinite duration. Both sets of equations are applicable only when the high frequency effects are not present. We found that Rosenblueth and Der Kiureghian equations gave values of ϵ_{ij}^d that were numerically very close when the finite segment length (duration) of the earthquake is assumed to be infinity and the two modal damping values are identical. When a practical earthquake duration, 10 - 20 seconds, is substituted in the Rosenblueth equation, it gives correlation values that are too high. Also, the Rosenblueth equation gives ϵ_{ij}^d values that do not agree with the numerical results when the two modal damping values are significantly different. A modified Rosenblueth equation, given below, can be developed by setting the earthquake duration to infinity and by incorporating an expression to account for different modal damping values based on the Der Kiureghian equation:

$$\epsilon_{ij}^d = b_{ij}, \quad b_{ij} = a_{ij} \left[1 + \left(\frac{\omega_i - \omega_j}{\zeta_i \omega_i + \zeta_j \omega_j} \right)^2 \right]^{-1}, \quad a_{ij} = \frac{2 \sqrt{\zeta_i \zeta_j}}{\zeta_i + \zeta_j} \quad (9)$$

According to Igusa and Der Kiureghian, $\epsilon_{ij}^v = \epsilon_{ij}^d$, and:

$$\mu_{ij} = \frac{2}{\zeta_i + \zeta_j} \frac{\omega_i - \omega_j}{\omega_i + \omega_j} b_{ij} \quad (10)$$

Equations (9) and (10) are in reasonable agreement with the average numerical data from twelve earthquakes for low modal damping values. Further modification of the equations is needed for the modal damping values that are on the order of 10%. We propose to modify the above equations as follows:

$$\begin{aligned} \epsilon_{ij}^d &= \frac{a_{ij}}{a_{ij} - c_{ij}^d} (b_{ij} - c_{ij}^d), & \epsilon_{ij}^v &= \frac{a_{ij}}{a_{ij} - c_{ij}^v} (b_{ij} - c_{ij}^v), \\ \mu_{ij} &= \frac{1}{c_{ij}^\mu} \left(\frac{\omega_i - \omega_j}{\zeta_i \omega_i + \zeta_j \omega_j} \right) b_{ij}, \\ c_{ij}^d &= 2.5 \left(\frac{\zeta_i + \zeta_j}{\omega_i + \omega_j} \right) \leq \frac{\zeta_i + \zeta_j}{2}, & c_{ij}^v &= 0.005 + 0.7 \frac{\zeta_i + \zeta_j}{2}, \\ c_{ij}^\mu &= 0.35 + 0.65 \frac{\omega_j}{\omega_i}, & \omega_j &\geq \omega_i \\ &= 0.35 + 0.65 \frac{\omega_i}{\omega_j}, & \omega_i &\geq \omega_j; & 1 \leq c_{ij}^\mu \leq 3 \end{aligned} \quad (11)$$

Figure 3 shows one set of comparisons between the average numerically obtained correlation coefficients and those predicted by Equation (11).

High Frequency Effect - Rigid Response Coefficients

To account for the high frequency effect on correlation, modal responses, R_i^d and R_i^v , can be decomposed into two parts each: the rigid parts, R_i^{dr} and R_i^{vr} , and the damped periodic parts, R_i^{dp} and R_i^{vp} . The following relationships have been proposed by Gupta et al (Gupta, 1992; Gupta and Chen, 1984):

$$\begin{aligned} R_i^{dr} &= \alpha_i^d R_i^d, & R_i^{dp} &= \sqrt{1 - (\alpha_i^d)^2} R_i^d \\ R_i^{vr} &= \alpha_i^v R_i^v, & R_i^{vp} &= \sqrt{1 - (\alpha_i^v)^2} R_i^v \end{aligned} \quad (12)$$

in which α_i^d and α_i^v are rigid response coefficients, both of which are assumed to vary between 0 and 1. The rigid parts from various modes are combined algebraically, and the damped periodic parts are combined in accordance with Equation (8).

$$\begin{aligned} R^{dr} &= \sum_i R_i^{dr}, & R^{vr} &= \sum_i R_i^{vr} \\ (R^p)^2 &= \sum_i \sum_j (\epsilon_{ij}^d R_i^{dp} R_j^{dp} + \epsilon_{ij}^v R_i^{vp} R_j^{vp} - 2\mu_{ij} R_i^{dp} R_j^{vp}) \end{aligned} \quad (13)$$

Finally, the two rigid parts (R_i^{dr} and R_i^{vr}) and the combined damped periodic part (R^p) are assumed to be statistically independent. Therefore,

$$R^2 = (R^{dr})^2 + (R^{vr})^2 + (R^p)^2 \quad (14)$$

Equations (12) through (14) give:

$$R^2 = \sum_i \sum_j (\bar{\epsilon}_{ij}^d R_i^d R_j^d + \bar{\epsilon}_{ij}^v R_i^v R_j^v - 2\bar{\mu}_{ij} R_i^d R_j^v) \quad (15)$$

in which the modified correlation coefficients are defined as follows:

$$\begin{aligned} \bar{\epsilon}_{ij}^d &= \sqrt{[1 - (\alpha_i^d)^2][1 - (\alpha_j^d)^2]} \epsilon_{ij}^d + \alpha_i^d \alpha_j^d \\ \bar{\epsilon}_{ij}^v &= \sqrt{[1 - (\alpha_i^v)^2][1 - (\alpha_j^v)^2]} \epsilon_{ij}^v + \alpha_i^v \alpha_j^v \\ \bar{\mu}_{ij} &= \sqrt{[1 - (\alpha_i^d)^2][1 - (\alpha_j^v)^2]} \mu_{ij} \end{aligned} \quad (16)$$

Note, in the high frequency range, $\alpha_i^d, \alpha_j^d, \alpha_i^v, \alpha_j^v = 1$, and $\bar{\epsilon}_{ij}^d, \bar{\epsilon}_{ij}^v = 1$; and in the low frequency range $\alpha_i^d, \alpha_j^d, \alpha_i^v, \alpha_j^v = 0$, and $\bar{\epsilon}_{ij}^d = \epsilon_{ij}^d, \bar{\epsilon}_{ij}^v = \epsilon_{ij}^v, \bar{\mu}_{ij} = \mu_{ij}$.

Gupta and Chen (1984) originally proposed an approximate equation for α_i^d that can be represented by a straight line on a semi-log chart. Such an equation did not account for the effect of damping on the coefficient. We have modified the original equation for α_i^d and proposed a similar equation for α_i^v . The two sets of modified equations are given below:

$$\begin{aligned}\alpha_i^d &= \alpha_{oi}^d + \alpha_{oi}^d (1 - \alpha_{oi}^d) \Delta\alpha_i^d, \\ \alpha_i^v &= \alpha_{oi}^v + \alpha_{oi}^v (1 - \alpha_{oi}^v) \Delta\alpha_i^v, \\ \alpha_{oi}^d &= \frac{\ln(f_i/f_1^d)}{\ln(f_2^d/f_1^d)}, f_1^d \leq f_i \leq f_2^d \\ \alpha_{oi}^v &= \frac{\ln(f_i/f_1^v)}{\ln(f_2^v/f_1^v)}, f_1^v \leq f_i \leq f_2^v\end{aligned}\quad (17)$$

in which f_i is the modal frequency, and $f_1^d, f_2^d, f_1^v, f_2^v$ are key frequencies (all in Hz) yet to be defined. The expressions for α_{oi}^d and α_{oi}^v define the coefficients without taking into account the effect of damping that is introduced in Equation (17) by including $\Delta\alpha_i^d$ and $\Delta\alpha_i^v$. The key frequencies, $f_1^d, f_2^d, f_1^v, f_2^v$ were studied by performing numerical analysis on twelve earthquake ground motions. Empirical expressions of these frequencies, and $\Delta\alpha_i^d$ and $\Delta\alpha_i^v$ based on the averages of the twelve earthquakes are given below:

$$\begin{aligned}f_1^d &= 0.86f_{AV}^{dd}, f_2^d = 0.84f_r^d, \\ f_1^v &= 1.86f_{AV}^{dd}, f_2^d = 1.20f_r^d, \\ f_{AV}^{dd} &= \frac{S_{Amax}^d}{2\pi S_{Vmax}^d} \\ \Delta\alpha_i^d &= 2.1 + 0.6\zeta_i, \\ \Delta\alpha_i^v &= 1.2 + 0.5\zeta_i\end{aligned}\quad (18)$$

in which f_r^d is the rigid or the ZPA frequency defined as the lowest frequency at which the (relative displacement-based) spectral acceleration becomes almost equal to the zero period

acceleration (ASCE, 1986). We found that the definition is not very precise since it can lead to the use of different f_r^d values by different engineers for the same earthquake motion. Therefore, we propose to add the requirement that the spectral acceleration become practically independent of the damping values at the rigid frequency. Figure 4 shows a comparison of the numerically calculated α_i^d and α_i^y values with those predicted by Equations (14) and (15) for three damping values. Figure 5 shows a comparison of numerically calculated correlation coefficients with those calculated using Equation (16) in the high frequency range.

Velocity Response Spectrum

As was discussed earlier, two types of response spectra are needed in the analysis of nonclassically damped systems: the relative displacement spectrum, S^d , and the relative velocity spectrum, S^v . Conventionally, most structures and equipments are assumed to be classically damped for which only the relative displacement spectrum is needed. Therefore, as a rule, only relative displacement-based design spectra are available. To analyze nonclassically damped systems, we need to be able to estimate a relative velocity spectrum from a relative displacement spectrum. A method proposed by Gupta and Jaw (1986) is investigated here.

In the intermediate frequency range, it can be shown that the relative displacement and velocity-based spectra are almost equal when represented in the same units. In the low and high frequency ranges, the following relationships hold:

$$f_L = \frac{S_A^v}{2\pi S_A^d} = \frac{\dot{u}_{g\max}}{2\pi\omega\ddot{u}_{g\max}}, \quad f_H = \frac{S_A^v}{2\pi S_A^d} = \frac{\ddot{u}_{g\max}}{2\pi\omega\dot{u}_{g\max}} \quad (19)$$

If the key frequencies (Hz) f_L and f_H are known, the relative velocity-based spectrum can be calculated from a relative displacement spectrum in the low and high frequency ranges using Equation (19). Gupta and Jaw had given empirical values of these frequencies based on twelve earthquake ground motions. They used time-domain analysis that does not give accurate relative velocity values in the high frequency ranges. Therefore, we repeated their work with our frequency-domain analysis. The new relationships for f_L and f_H are:

$$f_L = f_{VD}^{dd}, \quad f_{VD}^{dd} = \frac{S_{V\max}^d}{2\pi S_{D\max}^d}$$

$$f_H = 2.68f_{AV}^{dd} = 0.22f_r^d,$$

$$f_{AV}^{dd} = \frac{S_{A\max}^d}{2\pi S_{V\max}^d} \quad (20)$$

There is a small transition zone between the intermediate and the high frequency ranges, the relative velocity spectrum for which can be evaluated using the procedure presented in the references (Gupta, 1992; Megahed and Gupta, 1992; Gupta and Jaw, 1986). Figure 6 shows a comparison between the estimated and the directly calculated velocity spectrum for the El Centro earthquake (1940, SOOE), which is one of the twelve given in the original report (Megahed and Gupta, 1992). In the estimation of the velocity spectrum in Figure 6, actual values of f_L and f_H for the earthquake were used.

Figure 6 Comparison of Estimated and Actual Velocity Spectra, Damping Ratio = 0.05, El Centro (SOOE, 1940)

Secondary Systems with High Frequency Modes

In recent years, several modal synthesis methods have been developed to perform coupled analysis of primary and secondary systems. In these methods, it is assumed that all uncoupled modal properties of the primary and secondary systems are known, which is not practical for systems with large degrees of freedom. Typically, several (often, much less than all) modes each of both the primary and the secondary systems are calculated. It is well known that in certain complex problems, the effect of higher uncalculated modes can be quite significant. In the analysis of (uncoupled) single systems, this effect is represented in terms of a residual response vector obtained through a pseudo-static analysis of the system subjected to the missing mass inertia forces. We have developed a method in which we use this type of residual response vector as a fictitious mode, called the residual mode, to represent the response of all the uncalculated higher modes both for primary and secondary systems.

In the existing coupled analysis methods, both the primary and secondary degree of freedom are represented relative to the fixed base of the primary system. Thus, the secondary system degrees of freedom include a rigid body motion component that the residual mode vector cannot model - since, by definition, it represents a deformed shape. Therefore, we reformulated the coupled problem such that the secondary system degrees of freedom are defined relative to the primary system degrees of freedom at which the secondary system is connected to the primary system.

The new formulation, that at the present is applicable to only singly connected primary-secondary systems, has been implemented in a new version of the CREST program

originally developed by Gupta and Jaw (1985). The modified program was used to analyze five primary-secondary coupled systems of the type shown in Figure 7. The five coupled systems have identical primary systems, and have secondary systems with identical story masses and with five different story stiffnesses. The frequencies (Hz) of the uncoupled primary system modes are: 8.139, 23.944, 38.358, 50.542, 59.789 and 65.561. Uncoupled secondary system frequencies (Hz) are: Case 1, 8.155, 22.849, 33.018; Case 2, 12.495, 35.009, 50.589; Case 3, 13.690, 38.358, 55.429; Case 4, 23.398, 65.562, 94.758; Case 5, 38.328, 107.392, 155.186. The uncoupled primary system modal damping is 2%, and all the uncoupled secondary systems have 7% modal damping. The frequencies and damping ratios for the five coupled system are given in Table 1. All the coupled systems were subjected to the El Centro earthquake (1940, SOOE). The coupled analysis was performed two ways: considering all the uncoupled modes, and considering only the uncoupled modes up to the rigid frequency and accounting for the remaining modes with the residual mode vector. The two sets of nodal displacements and spring forces given in Table 2 are practically the same.

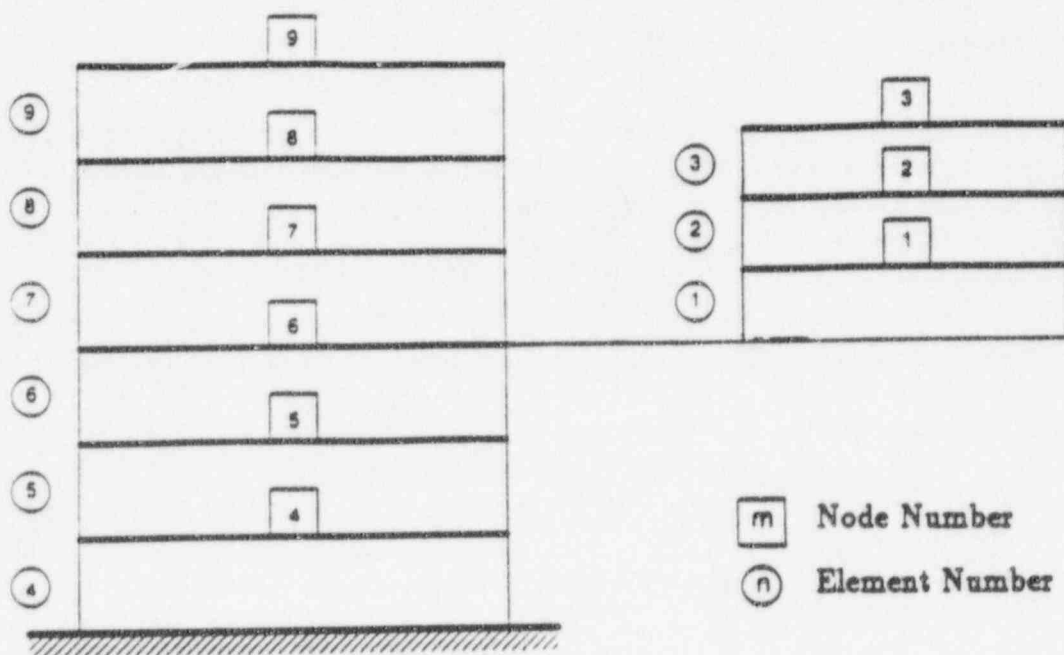

Figure 7 Example Coupled System

Summary and Conclusions

The conventional uncoupled analysis of secondary system gives resonance values that may be one or more orders of magnitude higher than the actual coupled resonance. In recent years, several efficient methods have been developed that treat the primary and secondary systems as a single coupled multi-degree-of-freedom (MDOF) system. It is shown that the original method of analysis in which the modal responses are represented in terms of the relative displacements and velocities of the equivalent SDOF oscillators is mathematically identical to a newly proposed canonical method in which the *sine* and *cosine* responses are used. Since the relative displacements and velocities are physical quantities, it is proposed to continue to use the original method of analysis. The corresponding response spectrum method requires definition of relative displacement-based response spectrum, which is also used in the conventionally performed analysis of the classically damped systems and is commonly available, and of a new relative velocity-based spectrum. The modal responses are calculated in terms of these two spectral values. Combination of modal responses requires definition of correlation coefficients ϵ_{ij}^d , ϵ_{ij}^v , and μ_{ij} . Investigations related to the new relative velocity spectrum and the correlation coefficients are reported in the paper.

To numerically evaluate the spectrum and the correlation coefficients for a given earthquake, we need to calculate the response of SDOF systems subjected to ground motion. It is shown that the time-domain analysis introduces spurious inputs in the calculation of the relative velocity of an SDOF system having frequencies beyond the Nyquist frequency of the earthquake record. An appropriate frequency-domain analysis eliminates the problem.

The Rosenblueth equation for ϵ_{ij}^d is first modified to be in better agreement with the Der Kiureghian equation by eliminating the earthquake duration term and by including a term to account for different modal damping values, thus obtaining a better agreement with the average numerical values from the twelve actual earthquakes. These equations are further modified to improve agreement between the equation and numerical values, especially for systems with relatively higher damping values, in the order of 10%. New equations are also proposed for ϵ_{ij}^v and μ_{ij} .

The high frequency effects in modal combination are incorporated using the rigid response coefficients α_i^d and α_i^v . A previously proposed equation for α_i^d , that gives a straight line variation with respect to the modal frequency f_i on a semi-log chart and is independent of the modal damping value, has been modified to include a damping dependent term introducing a parabolic representation of the coefficient. A similar equation is proposed for α_i^v . Empirical equations are obtained for the key frequencies f_1^d , f_2^d , f_1^v and f_2^v that are needed in the evaluation of the rigid response coefficients.

In the present seismic analysis practice, only relative displacement-based design spectra are given. For the analysis of the nonclassically damped systems, therefore, one needs to estimate the relative velocity spectrum from a given relative displacement spectrum. An existing method of making such estimations that is based on two key frequencies f_L and f_H is reviewed. The method gives estimates of the relative velocity spectra that are in good

agreement with the actual spectra, provided that the key frequency, f_H , is recalculated based on the new frequency-domain analysis.

Finally, results of the coupled analysis from a new formulation are presented. It is shown that the effect of uncalculated uncoupled primary and secondary system modes having frequencies beyond the rigid frequency can be accounted for by introducing residual mode vectors both for primary and secondary systems.

INTERPOLATED SPECTRAL ACCELERATIONS FOR CORRESPONDING FREQUENCIES & DAMPING RATIOS

Table with 4 columns: FREQUENCY (HZ), DAMPING RATIO (I), SPECTRAL ACCELERATIONS (SAD), and SAV. It lists numerical values for various frequency and damping ratios.

DISPLACEMENT RESPONSE UD (FROM SD)

INTERPOLATED SPECTRAL ACCELERATIONS FOR CORRESPONDING FREQUENCIES & DAMPING RATIOS

Table with columns: FREQUENCY (Hz), DAMPING RATIO (%), SPECTRAL ACCELERATIONS (SAU), and SAV. Rows include data for nodes 0 through 9.

DISPLACEMENT RESPONSE UD (FROM SD)

Table of displacement response UD for nodes 1 through 10. Each node section lists frequency, damping ratio, and acceleration values.
