AIR

Data in Table 2.12 has been recalculated and the results presented in an attached spreadsheet which is located on the first page of the Table. ND data which were averaged as zero are averaged at 50% of the detection level. Data that are between the detection level and the quantitation level are used at full emission rate. This procedure follows the procedures for Emission Factors development.

1.0 INTRODUCTION

The U.S. Environmental Protection Agency (EPA) Emission Standards Division (ESD) is investigating iron and steel foundries to identify and quantify hazardous air pollutants (HAPs) emitted from cupolas; electric arc furnaces; and pouring, cooling and shakedown operations of sand mold casting processes. ESD had requested that EPA's Emissions, Monitoring and Analysis Division (EMAD) conduct the required testing. EMAD had issued a work assignment to Pacific Environmental Services, Inc. (PES) to plan and conduct the air emissions test program to gather emissions data as specified in the ESD test request. The planning and testing phase of the program was conducted through EPA Contract No. 68D20162, Work Assignment No. 4-14. This test report was completed under EPA Contract No. 68D70069, Work Assignment No. 2-08.

The EPA's ESD is investigating two types of control devices (baghouses and scrubbers) as potential Maximum Achievable Control Technology (MACT) floor technology for cupolas. Two facilities were selected by ESD as host facilities for the testing program. One uses a baghouse for control of cupola emissions, and the other uses a wet scrubber for the control of cupola emissions. The Waupaca Foundry, located in Tell City, Indiana, uses a baghouse and was the subject of this test program. Results of tests on a wet scrubber at the second facility were presented under a separate report.

Testing at the Waupaca Foundry was conducted by two EMAD contractors to address the following ESD requirements: 1) characterize HAP emissions from cupolas that are controlled by baghouses; 2) characterize uncontrolled HAP emissions from pouring, cooling, and shakeout (PCS) processes; 3) determine baghouse performance in controlling HAP emissions from cupolas; and 4) identify surrogates for estimating HAP emissions from the subject foundry processes. PES conducted testing for requirements (1) and (3). Data gathering for requirements (2) and (4) was conducted by the other contractor and is not a part of this document.

The Waupaca Foundry was selected by the ESD as the host facility for this project. This facility is a large job shop foundry that conducts melting and casting operations. EPA deemed this facility to be representative of a large segment of the sand casting foundry industry. It operates a relatively large cupola (50 standard tons per hour melting capacity) that is controlled by a negative pressure baghouse. Ducts were available to measure emissions from pouring, cooling, and shakeout sections of the casting lines. The new facility recently began production and the modern design of the cupola baghouse was expected to be as effective as any used in this type of application. Tests were conducted at the cupola baghouse inlet and outlet. The sampling locations at the Waupaca Foundry are shown in Figure 1.1 PES performed particulate matter (PM) and metal HAPs testing at the cupola baghouse inlet

and outlet and organic HAPs testing at the cupola baghouse outlet. The organic HAPs consisted of polychlorinated dibenzo-*p*-dioxins and polychlorinated dibenzofurans (PCDDs/PCDFs) and semi-volatile organic hazardous air pollutants (SVOHAPs).

PES used three subcontractors for this effort: Deeco, Inc. (DEECO); Triangle Laboratories, Inc. (TLI), and Atlantic Technical Services, Inc. (ATS). DEECO provided on-site sampling support for the determination of PM and metal HAPs; TLI provided analytical support for the analysis of HAPs; and ATS provided support for preparation of the site-specific test plan (SSTP), quality assurance project plan (QAPP), and report documentation..

The field testing program organization and major lines of communication are presented in Figure 1.2. The PES Project Manager communicated directly with the EPA Work Assignment Manager and coordinated all of the on-site testing activities.

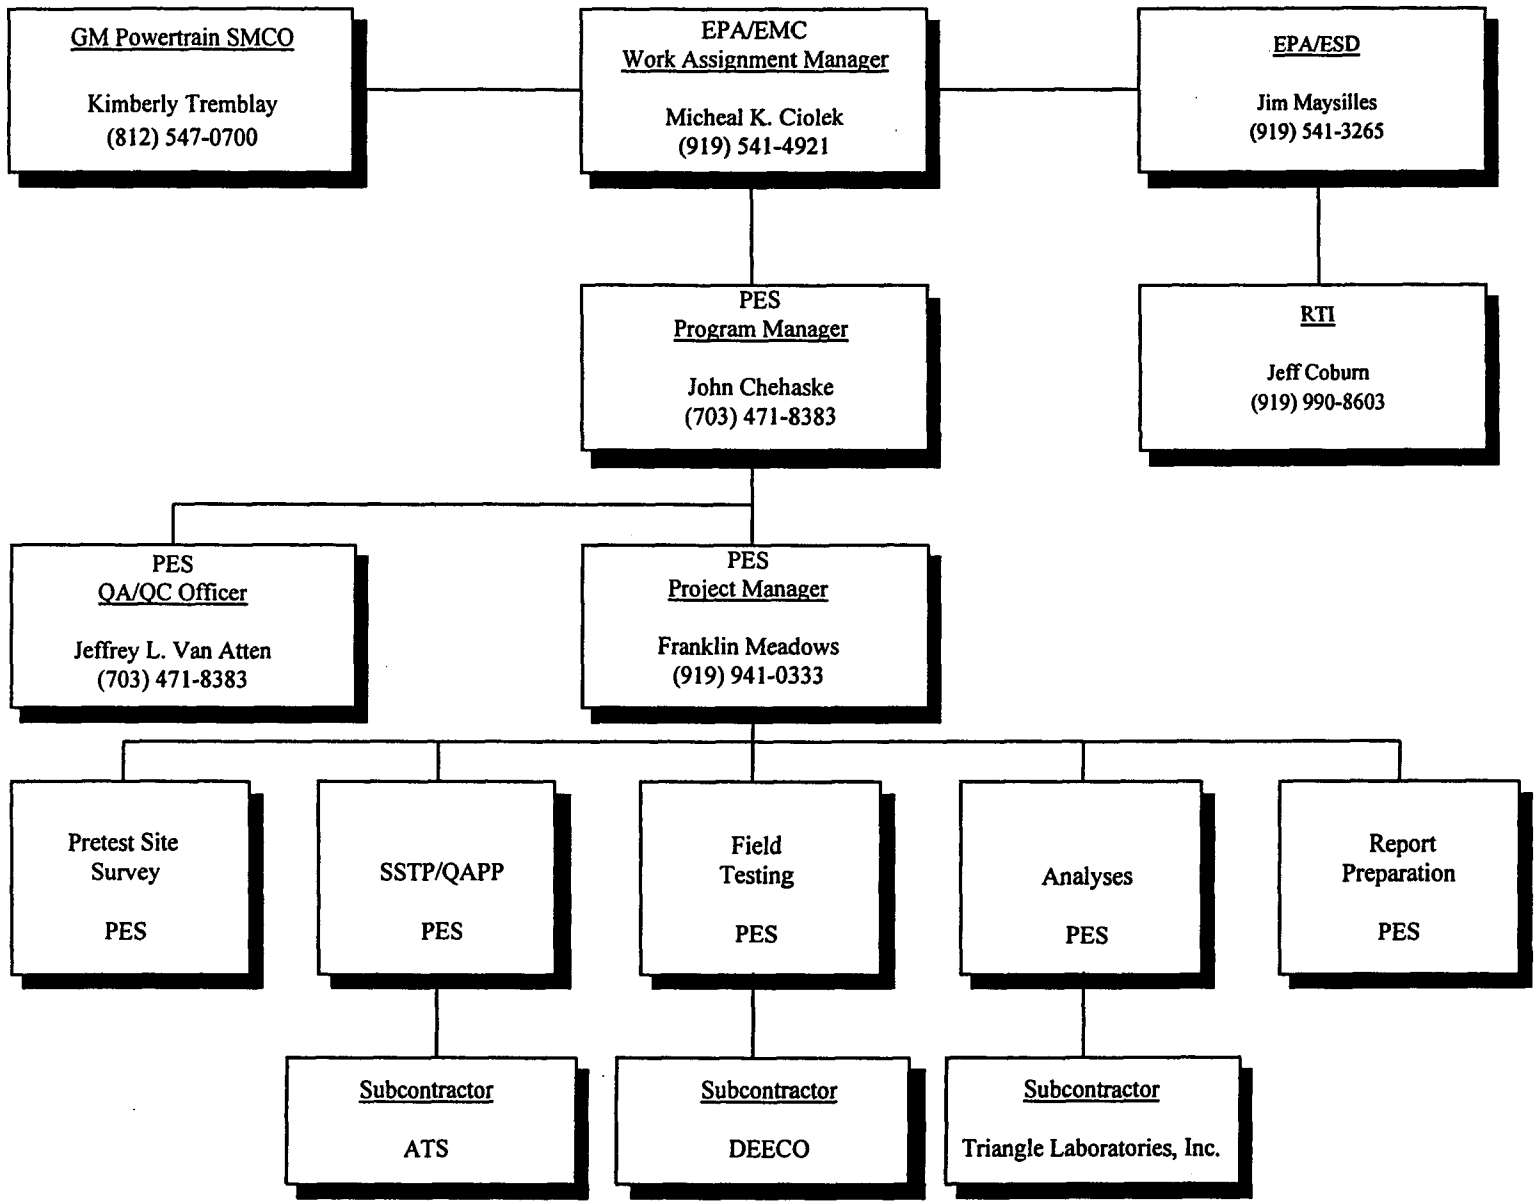

Figure 1.2 Key Personnel and Responsibility for Testing Program at the Waupaca Foundry - Tell City, Indiana

2.0 SUMMARY OF RESULTS

This section provides test results summaries obtained from the Waupaca Foundry testing. Included are results of the tests conducted for particulate matter/metals at the cupola baghouse inlet and outlet, and SVOHAPs and PCDDs/PCDFs testing at the cupola baghouse outlet. Although we have included averages, there were differences in production rates and operating conditions.

2.1 EMISSIONS TEST LOG

Sampling at the cupola baghouse was conducted on September 9 and 10, 1997. Table 2.1 summarizes the emissions test log. Presented are the run numbers, test dates, pollutants, run times, and downtime for filter and port changes.

2.2 PARTICULATE MATTER AND METALS

2.2.1 Baghouse Inlet

Table 2.2 summarizes the particulate matter and metals emissions sampling and flue gas parameters at the baghouse inlet. The total sampling time for each test run was 240 minutes. The average sample volume was 105.362 dry standard cubic feet (dscf) or 2.984 dry standard cubic meters (dscm). The average flue gas temperature was 293°F. The flue gas contained 11.6 percent (%) carbon dioxide (CO_2), 9.7% oxygen (O_2), and 2.6% moisture. The average flue gas volumetric flow rate was 52,700 actual cubic feet per minute (acfm) or 34,500 dry standard cubic feet per minute (dscfm) or 976 dry standard cubic meters per minute (dscmm).

Table 2.3 summarizes the flue gas particulate matter concentrations and emission rates at the cupola baghouse inlet. The average concentration was 1.04 grains per dry standard cubic foot (gr/dscf) or 2.39 grams per dry standard cubic meter (g/dscm). The concentrations are also shown adjusted to 7% O_2. The average mass emission rate was 323 pounds per hour (lb/hr) or 146 kilograms per hour (kg/hr).

Table 2.4 summarizes the flue gas metals concentrations and emission rates. The blank correction procedures of EPA Method 29 were used to correct the samples for the back half reagent blank only, because the analytical results for the front half reagent blank were considered inappropriate for blank correction.. All of the target metals were found to be present in all three samples. Average concentrations ranged from 2.89 micrograms per dry standard cubic meter (µg/dscm) for beryllium to 247,458 µg/dscm for zinc.

2.2.2 Baghouse Outlet

Table 2.5 summarizes the particulate matter and trace metals emissions sampling and exhaust gas parameters at the baghouse outlet. The total sampling time for each test run was 240 minutes. The average sample volume was 120.781 dscf or 3.420 dscm. The average exhaust gas temperature was 246°F. The exhaust gas contained 9.6 % CO_2, 11.6% O_2, and 3.6 % moisture. The average exhaust gas volumetric flow rate was 60,900 acfm or 43,400 dscfm or 1,230 dscmm.

Table 2.6 summarizes the exhaust gas particulate matter concentrations and emission rates at the baghouse outlet. The average concentration was 0.00124 gr/dscf or 0.00283 g/dscm. The concentrations are also shown adjusted to 7% O_2. The average mass emission rate was 0.393 lb/hr or 0.178 kg/hr. The results presented for run O-M29-2 use a negative filter catch weight. Both the filter and acetone rinse fractions were low and at the limit of detection. There are no known reasons for the negative result. If a zero had been used, the mass emission rate for the run would be 0.0897 lb/hr.

Table 2.7 summarizes the exhaust gas metals concentrations and emission rates. The blank correction procedures of EPA Method 29 were used to correct the samples for the back half reagent blank only, because the analytical results for the front half reagent blank were considered inappropriate for blank correction. All of the target metals, except beryllium, cobalt, and thallium, were found to be present in all three samples. Metals that were not detected in a sample have "ND" in place of any emissions calculations and were not included in the total metals sum. Average concentrations ranged from 0.244 µg/dscm for silver to 115 µg/dscm for zinc.

2.2.3 Baghouse Performance

Table 2.8 summarizes the performance of the baghouse in controlling PM and total HAP metals emissions. The removal efficiencies for PM and total HAP metals are based on the inlet and outlet mass emission rates. The average removal efficiency for PM and total HAP metals was 99.79% and 99.88%, respectively.

2.3 DIOXINS AND FURANS

Table 2.9 summarizes the PCDDs/PCDFs emissions sampling and exhaust gas parameters at the baghouse outlet. The total sampling time for each run was 240 minutes. The average sample volume was 145.249 dscf or 4.113 dscm. The average exhaust gas temperature was 247°F. The flue gas contained 9.6% CO_2, 11.6% O_2, and 2.8% moisture. The average exhaust gas volumetric flow rate was 62,600 acfm or 44,800 dscfm or 1,270 dscmm.

The EPA Method 23 sample extracts were first analyzed using a DB-5 capillary column to determine the concentration of each isomer of PCDDs and PCDFs (tetra- through octa-). Tetra-chlorinated dibenzofurans were detected in this analysis; therefore,

[b] Dry standard cubic feet at 68° F (20° C) and 1 atm.

[c] Dry standard cubic meters at 68° F (20° C) and 1 atm.

[d] Actual cubic feet per minute at exhaust gas conditions.

[e] Dry standard cubic meters per minute at 68° F (20° C) and 1 atm.

another aliquot of the sample was analyzed using a DB-225 capillary column to measure the 2,3,7,8 tetra-chloro dibenzofuran isomer (2378 TCDF).

Some PCDDs/PCDFs catch weights were reported as estimated maximum possible values or EMPCs. Catch weights, concentrations, and emission rates based on EMPC values were noted by enclosing them in brackets ({}). EMPC values were included in the three-run averages and total PCDDs/PCDFs calculations. Averages or totals that were based on EMPC values were also enclosed in brackets to indicate the values were estimated. The PCDDs/PCDFs test results are presented in actual concentrations and mass emission rates, concentrations adjusted to 7% O_2, and concentrations adjusted to 7% O_2 in 2378 TCDF toxic equivalents.

Table 2.10 presents the PCDDs/PCDFs stack gas concentrations and emission rates. The average concentration of total PCDDs was estimated to be {12.3} ng/dscm. The average concentration of total PCDFs was estimated to be {111} ng/dscm. The average concentration of total PCDDs/PCDFs was estimated to be {123} ng/dscm. These values corresponded to average estimated emission rates of {992}, {8,764}, and {9,756} µg/hr, respectively.

Table 2.11 presents the PCDDs/PCDFs concentrations adjusted to 7% O_2. The average measured stack gas O_2 concentration was 11.6%. The average adjusted concentration of total PCDDs was estimated to be {17.7} ng/dscm @ 7% O_2. The average adjusted concentration of total PCDFs was estimated to be {162} ng/dscm @ 7% O_2. The average adjusted concentration of total PCDDs/PCDFs was {179} ng/dscm @ 7% O_2. The concentrations, adjusted to 7% O_2, were also adjusted by each congeners respective Toxic Equivalency Factor (TEF). The TEFs used were the international TEF values. The average concentration for total PCDDs/PCDFs, adjusted for the 2378 TCDD TEFs, was estimated to be {3.65} ng/dscm @ 7% O_2.

2.4 SEMIVOLATILE ORGANIC HAZARDOUS AIR POLLUTANTS

The semivolatile organic hazardous air pollutants (SVOHAPs) were collected using a SW-846 Method 0010 Modified Method 5 (MM5) sampling train. The MM5 sampling train collects organic-laden particulate materials and semi-volatile organics species. This method speciates and quantitates low concentrations of these semi-volatile organics with boiling points above about 100°C.

Table 2.12 summarizes the SVOHAPs emissions sampling and exhaust gas parameters at the cupola baghouse outlet. The total sampling time for each run was 240 minutes. The average sample volume was 142.003 dscf or 4.021 dscm. The average exhaust gas temperature was 249°F. The exhaust gas contained 9.6% CO_2, 11.6% O_2, and 2.9% moisture. The average exhaust gas volumetric flow rate was 60,900 acfm or 43,400 dscfm or 1,230 dscmm.

[c] Dry standard cubic meters at 68° F (20° C) and 1 atm.

[d] Actual cubic feet per minute at exhaust gas conditions.

[e] Dry standard cubic meters per minute at 68° F (20° C) and 1 atm.

The results of the semivolatile organic emissions are shown in Table 2.13. Analysis was performed for 70 target compounds. Of these 70 target compounds, 50 were not detected. In cases where a compound was not detected, the emission rate, and concentration, was replaced with a "ND". If a compound was not detected in one of the three runs, a zero was used in the three-run average for that compound and was not summed in any SVOHAPs totals.

Analysis for the SVOHAPs was performed using SW-846 Method 8270. The lower quantitation limit for SW-846 Method 8270 for all but four compounds was 10 μg/sample. The four compounds, 2,4-dinitrophenol, 4-nitrophenol, 4,6-dinitro-2-methylphenol and pentachlorophenol, had quantitation limits of 25 μg/sample. Some samples had reported values below the quantitation limit but above the detection limit. This was the case for 19 of the 20 detected target compounds. Like the PCDDs/PCDFs, these values were reported as estimates and all values and calculated results were enclosed by brackets ({}) to indicate that the compound was detected but was below the quantitation limit. These estimated values were used in the three-run averages and the resulting averages were also enclosed in brackets to indicate the values were estimated.

Five compounds were detected in the run samples that were also detected in the laboratory blank (sample ID SBLK 091497). Naphthalene, phenol, acetophenone, di-n-butylphthalate, and bis(2-ethylhexyl)phthalate were detected in the laboratory blank, but at amounts below the quantitation limit. TLI's case narrative advises that target analytes in the laboratory blanks should not be considered as truly present in the native samples unless found at five times the amount found in the blank. In the case of di-n-butylphthalate, all three run samples had estimated amounts that were less than five times the blank and therefore should not be considered truly present in the native samples. In the case of acetophenone, only the first and third run's samples had estimated amount slightly higher than five times the estimated lab blank value. In the case of bis(2-ethylhexyl)phthalate and phenol, all three run samples had estimated catches that were more than five times the estimated lab blank value. In the case of naphthalene, the first and third run samples estimated catches were 12.9 and 13.4 times, respectively, that of the estimated blank value, while the second run's estimated catch was only three times the estimated blank value. The TLI's case narrative also advises that "in the event that the amount of a target analyte found in the samples is twenty times the amount found in the associated blank, the contribution from the blank can be considered negligible." The estimated amounts of phenol in all samples and the estimated amount of bis(2-ethylhexyl) phthalate in the third run's sample were all greater than 20 times the estimated blank value. Refer to Table 6.16 in section 6.0 for a complete listing of all the detected or estimated SW-846 Method 0010 field, method, and laboratory blanks compared to the average sample catch weights.

A Spreadsheet file with results which follow the procedures for developing emission factors is attached. ND data are averaged using 50% of the detection limit. Test runs which have all ND runs are flagged as BDL and test runs with one or two ND runs are flagged as DLL. Data above the detection limit are used at the indicated emission rate.

3.0 PROCESS AND CONTROL EQUIPMENT OPERATION

3.1 INTRODUCTION

The Waupaca foundry in Tell City, Indiana, is a completely new grey iron foundry that started operation in February 1997. The foundry casts a diverse group of products, including brake drums, shoes, rotors, calipers, and other parts. The plant operates one large cupola that melts at a rate of about 60 tons/hr (tph), and operates four pouring lines. This section of the test report provides a description of the cupola operation for iron melting, and the casting operation, including pouring, cooling, and shake out.

3.2 PROCESS DESCRIPTION

3.2.1 Iron Melting in Cupolas

The Waupaca foundry in Tell City operates a large, water-cooled cupola that melts at a rate of approximately 60 tph, with a blast rate of 10,000 to 15,000 standard cubic feet per minute (scfm), which makes it a large cupola by U.S. industry standards. Figure 3.1 is a simplified schematic of the cupola gas handling system and emission control equipment.

The cupola is charged with metal scrap, re-melt, coke, and limestone at the top of the cupola, using one of two automated skip buckets. The level of metal within the cupola is monitored, and the charge material in the skip bucket is dumped into the cupola when the level of charge falls below a set level. The seal from the charge material and a draft on the cupola prevent gases from escaping. If, for any reason, the charge material cannot be added to the cupola within five minutes of the level falling below the set point, the cupola will automatically go "off blast" until the appropriate charge level in the cupola can be achieved.

The blast air is preheated to about 1,000°F in the blast air recuperator and is introduced into the bottom of the cupola through eight tuyeres. The blast is also enriched with oxygen under certain melting conditions. The off gas from the cupola is removed at 250-300°F. The off-take duct is lined with refractory material and leads to a coarse grain separator where heavy particles are removed. The separator is cooled with non-contact water.

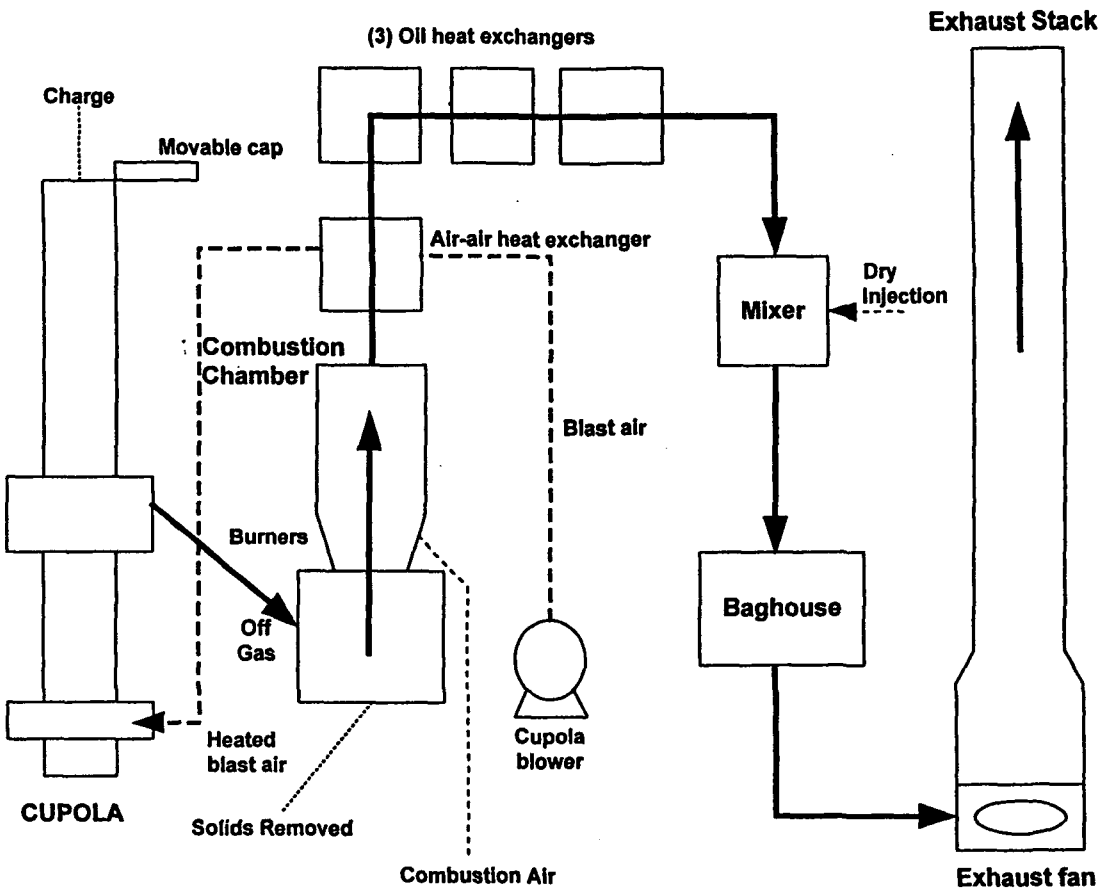

Figure 3.1. Simplified Schematic of Cupola Gas Handling System

After removal of the heavy particles, the gas enters a large combustion chamber where combustion air is introduced and the carbon monoxide (CO) is burned. Two burners are used when necessary to maintain the combustion temperature. The gas leaves the combustion chamber at approximately 1650°F, and enters a dropout chamber where additional heavy particles are removed. The hot gas then passes through an air-to-air heat exchanger (blast air recuperator), followed by a series of three oil heat exchangers that are used to cool the air. These oil heat exchangers are not currently used for heat recovery. (Modifications may be made in the future to recover and use the heat, such as for heating the building.)

The gas from the heat exchangers is injected with a dry mixture (mostly calcium carbonate and magnesium oxide) in a venturi mixer that increases the gas velocity and suspends the injected particles. Dry injection is used to improve pollutant removal in the baghouse. During the source test, the dry powder injection was turned off to afford better characterization of uncontrolled emissions and baghouse efficiency for hazardous air pollutant (HAP) constituents. The gas is then sent to a 10 module, negative pressure baghouse that uses a high temperature fabric designed to withstand temperatures of up to 320°F. The temperature of the gas at this point is typically 280 to 290°F. A fan pulls the gas through the system and discharges the cleaned gases through a stack.

The pressure drop across the baghouse is monitored, and when the pressure drop increases to six inches of water, individual bag house compartments are cycled off-line, the bags are cleaned with a pulses of air, then the compartments are brought back on-line. The baghouse uses plenum pulsing. During testing, each compartment was off line for approximately eight minutes for cleaning, with cleaning pulses occurring approximately every 30 seconds during this interval.

The plant routinely monitors several parameters associated with the cupola, including blast air and oxygen rate, and afterburner air addition rates, as well as temperature at various points in the process. The combined air flow rate through the recuperator and the baghouse system is not directly monitored, but can be estimated from the blast air, oxygen and afterburner air addition rates. During testing, the combined flow rate of offgas was also measured by the test crew at the final stack sampling location. The plant also records the amount of each type of material added to the cupola by the automatic skip buckets for each charge load. The composition of a typical charge is given in Table 3.1 and contains approximately four tons of iron. The iron includes remelt from the foundry, steel scrap, and pig iron.

3.2.2 Pouring, Cooling and Shakeout

The plant has four lines for pouring, cooling, and shakeout. Silica sand, bentonite, and seacoal constitute the molding sand, which is recycled about 50 times prior to disposal in a monofill. Resins and a catalyst are used to produce warmbox cores. Some of the company's cast products use cores, and others do not. During the source test, cores were not being used on any of the lines. The lines are all similar except that Line 4, which is designed to handle larger molds, has an automatic pouring station and the other lines do not. Line 4 is typically used for casting the larger size parts.

TABLE 3.1

TYPICAL CUPOLA CHARGE MATERIALS

Material	Typical range (lbs/charge)[a]
Remelt from foundry[b]	3,500 to 4,500
Steel scrap[b]	3,200 to 4,000
Pig iron[b]	600 to 1,400
Silicon bricks	70 to 105
Blend bricks (Si, Mn, Cr)	260 to 300
Silicon carbide	210 to 250
Coke	500 to 900
Limestone	280 to 300

[a] Typical range observed during the test days.
[b] Remelt, steel scrap, and gray iron bricks are the sources of iron and total 8,700 lbs (4.35 tons) per charge.

Pouring emissions are not captured at any of the four pouring stations. Cooling emissions are captured by hoods that cover the entire cooling line prior to shakeout. The shakeout operation is totally enclosed and evacuated to capture the emissions. After shakeout, the parts are transferred to a casting cooling house where they are placed on a metal "tree." The parts then proceed to a "spinner house" and are shot blasted to remove residual sand. The spinner house is also evacuated to the duct that removes emissions from shakeout. The captured emissions from shakeout and cooling are sent to a baghouse for gas cleaning. There are three baghouse systems; each system predominantly receives emissions vented from a single line, but a few of the vents from a given line are routed to another line's baghouse system. Consequently, controlled emissions represent contributions from multiple lines and multiple processes.

The ductwork for the cooling lines are interconnected with either other cooling lines or shakeout enclosure ductwork. Therefore, it is impossible to get a representative sample for cooling emissions that could be attributed to an entire cooling line. The least amount of interconnection was on Line 4, so it was selected for emissions testing. The first third of the cooling section of Line 4 was ducted to a single vent that had a long, straight vertical section before connecting with other ductwork. Ports were installed in this straight section of the vent, so that the uncontrolled emissions from the first third (approximately 20-25 minutes) of the cooling line could be measured. The shakeout enclosure ductwork has a short vertical rise, then elbows to a horizontal section where it is tied to the vent from the spinner housing and the last hood from the cooling line. Ports were installed in the short vertical duct from the

shakeout enclosure approximately one foot above the roof of the enclosure prior to the point where the ducts from the spinner house and the end of the cooling line join the shakeout enclosure duct. This point represents uncontrolled emissions from the shakeout operations.

3.3 SUMMARY OF PROCESS OPERATING DATA COLLECTED DURING SOURCE TEST

3.3.1 Process Operating Data for Cupola Melting Operations

Testing of the melting operations was conducted over a three-day period. Single test runs were performed on September 8th and 9th, and two runs were performed on September 10th. During testing, process information was collected from the operating room's computer control panel. Process information collected included cupola charging data, process chemistry, gas flow rates, temperatures, baghouse pressure drop, and cupola stack opacity.

Table 3.2 and Figure 3.2 present metal charging rates for the cupola during the three days of testing. Table 3.2 and Figure 3.2 show that the average metal production rate for September 8th was higher than on the 9th or 10th. Table 3.2 and Figure 3.2 also show that hourly production rates varied significantly within a given day.

Table 3.3 presents average gas flow rates and temperatures for several locations in the cupola flue gas system on September 8th, 9th, and 10th. As can be seen from Table 3.3, the average blast rate was lowest on September 9th, and the cupola typically operated with oxygen addition on that day. On September 8th and 10th, the average blast rate was higher, and oxygen addition was not used. The average baghouse pressure drop was lower on September 9th than on September 8th or 10th, (2.8 inches of water versus 4.4 inches of water), and the average opacity was higher on September 9th than September 10th (5.7% versus 2.8%).

Continuous records of blast air flow rates are presented in Figure 3.3. Blast air rates were significantly reduced (i.e., the cupola was placed "on relief") for varying lengths of time on September 9th and 10th. The specific times when the cupola was on relief are listed in Table 3.4

Table 3.5 presents average process iron chemistry values (from cupola) for September 9th and 10th. Although process chemistry values were not recorded on September 8th, average trace metal impurity levels were typical on all three days.

3.3.2 Process Operating Data for Pouring, Cooling and Shakeout Operations

Emissions from cooling (first third section) and shakeout were measured on September 5, 1997. Line 4 employs an automated molding machine. Testing was conducted only when the entire mold line was filled with recently poured molds. During the day of the source test of the cooling and shakeout operations, Line 4 was used to cast brake drums. Each mold produced two brake drums, and used 189 pounds of poured metal. For the test day,

[a] The process chemistry values reported here are considered typical; the process chemistry values were not specifically recorded on September 8, but were also considered typical.

249 molds per operating hour were produced. Each mold contains 1393 lbs of green sand (lake sand, sea coal, and bentonite), so the molds had a sand to metal ratio of 7.35:1.

The properties of the molding sand measured during the test day are given in Table 3.6. A bonding agent was added to the sand in the amount of 38.1 pounds of bond per ton of sand mulled. The bonding agent is a dry mixture of coal, brittle asphalt, cellulose, bentonite, starch, and cereal. The material safety data sheet for the product indicates no volatile components, and no hazardous ingredients other than coal dust and crystalline quartz.

Volatile content (%, at 900°F)	4.0

4.0 SAMPLING LOCATIONS

Isokinetic source sampling was conducted at the inlet and outlet of the cupola baghouse at the Waupaca Foundry. Descriptions of the sampling locations are presented below, as well as schematic diagrams.

4.1 CUPOLA BAGHOUSE INLET

The cupola baghouse inlet measurement site was located in a 55⅜-inch inside diameter (ID) round, horizontal duct 50 feet (10.8 duct diameters) downstream of the nearest flow disturbance (45° bend) and 23 feet 9½ inches (5.2 duct diameters) upstream of the nearest flow disturbance (90° elbow). According to EPA Method 1 criteria this site required a minimum of 12 sample traverse points, six along each of two perpendicular diameters. Figure 4.1 shows a simplified schematic of the baghouse inlet measurement site. Figure 4.2 shows the sample traverse point locations. A check for the presence of non-parallel flow was conducted as specified in Section 2.4 of EPA Method 1. The check confirmed the average yaw angle for the horizontal port was 13.8 degrees, which is less than the Method 1 requirement of 20 degrees.

4.2 CUPOLA BAGHOUSE OUTLET

The baghouse outlet sampling location was located in a 92-inch ID round vertical stack 25 feet (3.3 stack diameters) downstream of the nearest flow disturbance (expansion joint) and 89 feet (11.6 stack diameters) upstream of the stack exit. According to EPA Method 1, this location required 24 sample traverse points, 12 along each of two perpendicular diameters. Six points were sampled, at each of four sample ports, located at 90°. Figure 4.3 shows a simplified schematic of the baghouse outlet measurement site. Figure 4.4 shows the sample traverse point locations.

PES checked for the presence of non-parallel flow in all four sampling ports during a preliminary site visit and just prior to sampling. The average of the 24 sampling points yaw angles was found to be 15.3 degrees, requiring no modifications for isokinetic sampling.

5.0 SAMPLING AND ANALYTICAL PROCEDURES

Table 5.1 summarizes the sources, test parameters, test methods, number of tests, and net run times. Simultaneous, isokinetic, sampling was conducted at the cupola baghouse inlet and outlet for PM/metals. Simultaneous with the PM/metals testing, additional isokinetic sampling was conducted at the cupola baghouse outlet for PCDDs/PCDFs and SVOHAPs. Brief descriptions of the methods used follow:

5.1 LOCATION OF MEASUREMENT SITES AND SAMPLE/VELOCITY TRAVERSE POINTS

EPA Method 1, "Sample and Velocity Traverses for Stationary Sources," was used to select the measurement sites and to establish velocity and sample traverse point locations. The location of measurement sites and traverse points are discussed in Section 4.0.

5.2 DETERMINATION OF STACK GAS VOLUMETRIC FLOW RATE

EPA Method 2, "Determination of Stack Gas Velocity and Volumetric Flow Rate (Type S Pitot Tube)," was used to determine stack gas volumetric flow rate at the cupola baghouse inlet and outlet. A Type S pitot tube, constructed according to Method 2 criteria and having an assigned coefficient of 0.84 and connected to an inclined-vertical manometer was used to measure velocity pressure. A calibrated Type K thermocouple attached directly to the pitot tube was used to measure stack gas temperature. The average stack gas velocity was calculated from the average square roots of the velocity pressure, average stack gas temperature, stack gas molecular weight, and absolute stack pressure. The volumetric flow rate is the product of velocity and the stack cross-sectional area.

5.3 DETERMINATION OF DRY MOLECULAR WEIGHT AND EMISSION CORRECTION FACTORS

EPA Method 3B, "Gas Analysis for the Determination of Emission Rate Correction Factor or Excess Air," was used to measure carbon dioxide and oxygen content of the stack gases. Gas samples were extracted from the stack or duct simultaneous with the EPA Method 23 sample trains using the multi-point, integrated bag sampling technique. The bag contents were analyzed on-site within four hours after sample collection using an Orsat® analyzer to

TABLE 5.1

SOURCES, TEST PARAMETERS, AND TEST METHODS SUMMARY
THE WAUPACA FOUNDRY - TELL CITY, INDIANA

Source	Parameter	Test Methods	No. of Tests	Net Run Time, Minutes
Cupola Baghouse Inlet	Flow Rate	EPA 1 & 2	3	240
	O_2/CO_2	EPA 3B	3	240
	Moisture	EPA 4	3	240
	PM/Metals	EPA 29	3	240
Cupola Baghouse Outlet	Flow Rate	EPA 1 & 2	3	240
	O_2/CO_2	EPA 3B	3	240
	Moisture	EPA 4	3	240
	PM/Metals	EPA 29	3	240
	PCDDs/PCDFs	EPA 23	3	240
	SVOHAPs	SW-846 0010	3	240

determine percent concentrations of carbon dioxide and oxygen. The Orsat® analyzer had 0.1 percent subdivisions.

5.4 DETERMINATION OF STACK GAS MOISTURE CONTENT

EPA Method 4, "Determination of Moisture Content in Stack Gases," was used to determine stack gas moisture content. The quantity of condensed water was determined gravimetrically and then compared to the total volume of gas sampled to determine the volume percent moisture content. The Method 4 procedure was conducted in conjunction the EPA Methods 23 and 29 and SW-846 Method 0010 sampling runs. Condensed moisture was determined by the difference in pre-test and post-test weights of the impingers, reagents, and silica gel. Condensed moisture in the XAD® adsorbent trap from the SW-846 Method 0010 and EPA Method 23 sample trains was also determined gravimetrically and the results included in the moisture content calculations.

5.5 DETERMINATION OF PARTICULATE MATTER AND METALS

EPA Method 29, "Determination of Metals Emissions From Stationary Sources," was used to determine filterable particulate matter and metals at the cupola baghouse inlet and outlet. The target metals included: antimony (Sb), arsenic (As), barium (Ba), beryllium (Be), cadmium (Cd), chromium (Cr), cobalt (Co), lead (Pb), manganese (Mn), mercury (Hg), nickel (Ni), phosphorus (P), selenium (Se), silver (Ag), thallium (Tl), and zinc (Zn). Multi-point integrated samples were extracted isokinetically from the 12 traverse points at the inlet and 24 traverse points at the outlet as shown in Figures 4.2 and 4.4, respectively. At each traverse point, sampling was performed for 10 minutes at the inlet and five minutes at the outlet for a total run time of 240 minutes per test. At each location, readings were taken every five minutes. The samples were extracted through a glass nozzle, a heated glass-lined probe, a heated quartz fiber filter, two impingers containing an acidic hydrogen peroxide solution (H_2O_2/HNO_3), an empty impinger, and two impingers containing acidic potassium permanganate ($KMnO_4$). A schematic of the EPA Method 29 sampling train is shown in Figure 5.1. The inlet sampling train was modified to allow for vertical sampling. A heated Teflon® jumper was used between the probe exit and the heated filter. The nozzle was attached to the probe using Teflon® or Teflon® coated unions and Teflon® or graphite ferrules.

The sample recovery scheme for metals is shown in Figure 5.2. Note that the optional empty first impinger was not used.

The filter and acetone rinses of the probe and front half of the filter housing were analyzed gravimetrically in the PES laboratory to determine filterable particulate matter. Upon completion of the particulate matter analyses, the particulate fractions and aqueous fractions were submitted to TLI for metals analyses. The sample preparation and analysis scheme is shown in Figure 5.3. Metals other than Hg were analyzed by graphite furnace

Figure 5.3 Sample Preparation and Analysis Scheme for EPA Method 29.

atomic absorption spectroscopy (GFAAS) or inductively coupled argon plasma (ICP) emission spectroscopy. Hg was analyzed by cold vapor atomic absorption spectroscopy (CVAAS).

5.6 DETERMINATION OF DIOXINS AND FURANS

EPA Method 23, "Determination of Polychlorinated Dibenzo-*p*-Dioxins and Polychlorinated Dibenzofurans from Stationary Sources" was used to determine PCDDs/PCDFs at the cupola baghouse outlet. The proposed rules amending EPA Method 23, as published in the Federal Register, Volume 60, No. 104, May 31, 1995, were incorporated. The proposed changes correct existing errors in the method, eliminate the methylene chloride rinse, and clarify the quality assurance requirements of the method. Samples were extracted through a glass nozzle, a heated glass-lined probe, a pre-cleaned and heated glass fiber filter, a water cooled condenser coil and an adsorbent trap containing approximately 40 grams of XAD®-2 adsorbent resin. A schematic of the EPA Method 23 sampling train (which is the identical to the SW-846 Method 0010 train) is shown in Figure 5.4. Multi-point integrated samples were extracted isokinetically from the 24 traverse points shown in Figure 4.4. At each traverse point, sampling was performed for 10 minutes, with pertinent readings taken every five minutes, for a net run time of 240 minutes per test. TLI prepared the filters and adsorbent traps, and performed the required analyses.

5.7 DETERMINATION OF SEMIVOLATILE ORGANIC HAZARDOUS AIR POLLUTANTS (SVOHAPs)

Method SW-846 0010, "Modified Method 5 Sampling Train (MM5)," was used to collect SVOHAPs at the cupola baghouse outlet. Multi-point, integrated samples were extracted isokinetically from the 24 traverse points shown in Figure 4.4. At each traverse point, sampling was performed for 10 minutes for a total run time of 240 minutes per test. Readings were taken every five minutes. The SW-846 Method 0010 samples were extracted through a glass nozzle, a heated glass-lined probe, a precleaned and heated glass fiber filter, a water-cooled condenser coil and a adsorbent trap containing approximately 40 grams of XAD®-2 adsorbent resin. A schematic of the SW-846 Method 0010 sampling train is shown in Figure 5.4.

The SW-846 Method 0010 samples were extracted following the procedure of Method 3542, dated January, 1995. The extracts were analyzed in accordance with the guidelines of Method 8270A by High Resolution Gas Chromatography/Low Resolution Mass Spectrometry. The three sample fractions for each test run, i.e., front half extract, the back half extract (XAD®-2 and back half rinse), and the condensate extract were combined for one analysis, per test run. The samples were analyzed for the SW-846 Method 8270 polynuclear aromatic hydrocarbon (PAH) and Clean Air Act (CCA) semivolatile compounds.

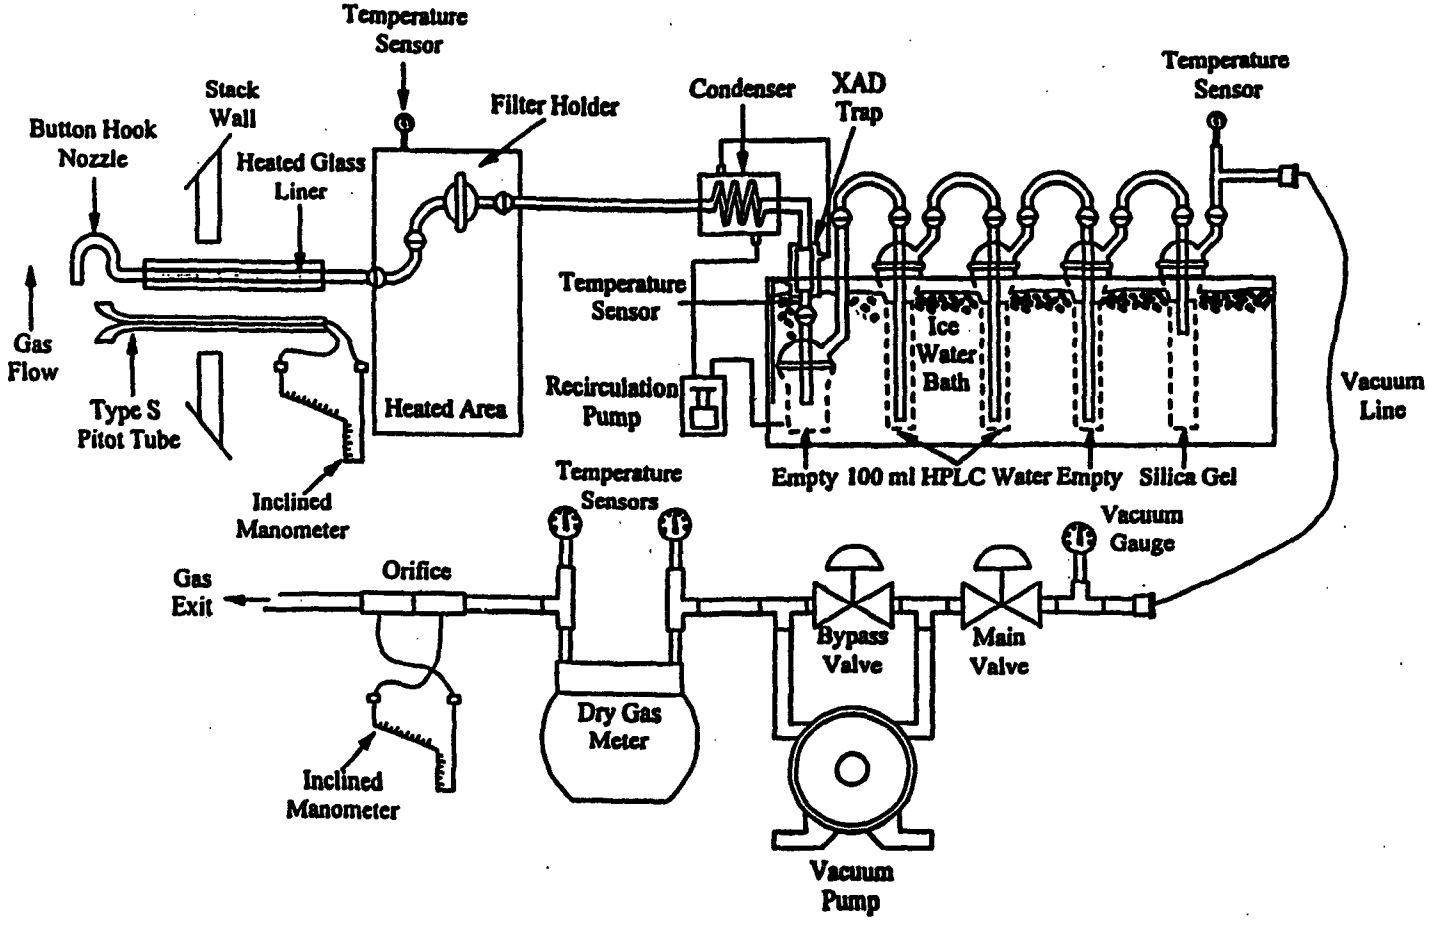

Figure 5.4 Sampling Train Schematic for EPA Method 23 and SW-846 Method 0010.

6.0 QUALITY ASSURANCE/QUALITY CONTROL PROCEDURES AND RESULTS

This section describes the specific QA/QC procedures employed by PES in performing this series of tests. The procedures contained in the "Quality Assurance Handbook for Air Pollution Measurement Systems, Volume III, Stationary Source Specific Methods," EPA/600/R-94/038c, and in the reference test methods served as the basis for performance for all testing and related work activities in this project.

6.1 CALIBRATION OF APPARATUS

The preparation and calibration of source sampling equipment is essential in maintaining data quality. Brief descriptions of the calibration procedures used by PES follow.

6.1.1 Barometers

PES used aneroid barometers which are calibrated against a station pressure value reported by a nearby National Weather Service Station corrected for elevation.

6.1.2 Temperature Sensors

Bimetallic dial thermometers and Type K thermocouples were calibrated using the procedure described in Section 3.4.2 of the Quality Assurance Handbook, Volume III, 1994. Each temperature sensor was calibrated over the expected range of use against an ASTM 3C or 3F thermometer. Table 6.1 summarizes the type of calibrations performed, the acceptable levels of variance, and the results. Digital thermometers were calibrated using a thermocouple simulator having a range of 0-2400°F.

6.1.3 Pitot Tubes

Type S pitot tubes constructed to EPA Method 2 specifications were used. Pitot tubes meeting these specifications are assigned to a baseline coefficient to 0.84 and need not be calibrated. The dimensional criteria and results for each pitot tube used are summarized in Table 6.2.

TABLE 6.1

	Assigned Coefficient	0.84	0.84	0.84	0.84

6.1.4 Differential Pressure Gauges

PES used Dwyer inclined/vertical manometers to measure differential pressures. The differential pressures measurements included velocity pressure, static pressure, and meter orifice pressure. Manometers are selected with sufficient sensitivity to accurately measure pressures over the entire range of expected values. Manometers are primary standards and require no calibration.

6.1.5 Dry Gas Meters and Orifices

The SW-846 Method 0010 and EPA Method 23 and 29 dry gas meters and orifices were calibrated in accordance with Sections 5.3.1 and 5.3.2 of EPA Method 5. This procedure involves direct comparison of the dry gas meter to a reference dry test meter. The reference dry test meter is calibrated annually using a wet test meter. Before its initial use in the field, the metering system was calibrated over the entire range of operation as specified in EPA Method 5. After field use, the metering system was calibrated at a single intermediate setting based on the previous field test. Acceptable tolerances for the initial and final dry gas meter factors and orifice calibration factors are ± 0.05 and ± 0.20 from average, respectively. The results for the gas meter and orifice used in this test program are summarized in Table 6.3.

6.2 ON-SITE MEASUREMENTS

The on-site QA/QC activities include:

6.2.1 Measurement Sites

Prior to sampling, the stack and inlet duct were checked dimensionally to determine measurement site locations, location of velocity and sample test ports, inside stack/duct dimensions, and sample traverse point locations. Inside stack/duct dimensions were checked through both traverse axis to ensure uniformity of the stack/duct inside diameter. The inside stack/duct dimensions, wall thickness, and sample port depths were measured to the nearest 1/16 inch.

6.2.2 Velocity Measurements

All velocity measurement apparatus were assembled, leveled, zeroed, and leak-checked prior to use and at the end of each determination. The static pressure was determined at a single point near the center of the stack or duct cross-section.

6.2.3 Flue Gas Composition

Integrated, multi-point, flue gas samples were collected in Tedlar® gas bags from the baghouse inlet and outlet. Prior to use the bags were leak checked and purged with nitrogen to ensure cleanliness. Prior to and after completion of each sampling run the entire sampling

TABLE 6.3

SUMMARY OF DRY GAS METER AND ORIFICE CALIBRATION DATA

Meter No.	Gamma				Orifice Coefficient		
	Pre-test	Post-test	% Diff.	EPA Criteria	Average	Range	EPA Criteria
M5-3	1.028	1.060	3.1	± 5%	1.591	1.555-1.621	1.591 ± 0.20
M5-4	1.021	1.049	2.7	± 5%	1.662	1.653-1.674	1.662 ± 0.20
RMB-13	1.010	0.994	-1.6	± 5%	1.884	1.875-1.894	1.884 ± 0.20
MB-13	0.947	0.945	0.2	± 5%	1.762	1.760-1.765	1.762 ± 0.20

system was leak checked from the tip of the probe. The bag samples were analyzed on-site using an Orsat® analyzer within four hours after sample collection, in accordance with EPA Method 3B. Prior to use the Orsat® analyzer was assembled and replenished with fresh reagents and leak checked using the manufacturer's procedures.

6.2.4 Moisture

The SW-846 Method 0010 and EPA Methods 23 and 29 sampling trains were used to determine the flue gas moisture content. During sampling, the exit gas of the last impinger was maintained below 68 °F to ensure complete condensation of flue gas water vapor. The total moisture was determined gravimetrically using an electronic platform balance with 0.1 gram sensitivity. The XAD® adsorbent modules from the EPA Method 23 and SW-846 Method 0010 sampling trains were also weighed and their weights included in the moisture catch.

6.2.5 Method 23, Method 0010 and Method 29

The field sampling QA/QC for EPA Methods 23 and 29 and SW-846 Method 0010 were similar. Table 6.4 summarizes the critical measurements made and the EPA's acceptability criteria. All pre- and post-test sample train leaks met the acceptance criteria. The isokinetic sampling rates deviated by no more than 6.5% thereby meeting each method criteria of 90-110%.

EPA Methods 23 and 29 and SW-846 Method 0010 field blanks were collected near each of the sampling locations to check for any sample contamination at the sites. Sample trains were assembled and pre- and post-test leak checks were conducted. The sample trains were recovered in the same manner as the actual sample runs. Each field blank train was subjected to a minimum of one leak check in the laboratory and three to five at the sampling site, depending on the location.

An acetone blank and quartz fiber filter were taken as control samples for the particulate analysis and subsequent analysis for the target metals. Blanks were taken of the metals absorbing and recovery reagents.

6.3 LABORATORY ANALYSES

6.3.1 Particulate Matter

Particulate matter analysis consisted of front half acetone sample rinses and quartz fiber filters. Prior to the field testing program, the filters were tared in the PES (or DEECO) laboratory, stored in petri dishes, and sealed with Teflon® tape. Several beakers were also cleaned and tared for subsequent use in evaporating the acetone rinses. Upon receipt in the PES laboratory, the acetone rinses were placed in the tared beakers and evaporated to dryness at room temperature. The filters and beakers were desiccated and weighed to a constant

weight. All weighings were within the method requirements of 0.5 milligrams between two consecutive weighings taken at least six hours apart.

6.3.2 EPA Method 29

TLI analyzed the EPA Method 29 samples consisting of five stack gas samples, three blank samples and reagent blanks to determine concentrations of antimony (Sb), arsenic (As), barium (Ba), beryllium (Be), cadmium (Cd), chromium (Cr), cobalt (Co), lead (Pb), manganese (Mn), mercury (Hg), nickel (Ni), phosphorus (P), selenium (Se), silver (Ag), thallium (Tl), and zinc (Zn). All metals, except Hg and some Tl concentrations, were determined by inductively coupled plasma emission spectroscopy (ICP). Thallium concentrations for the back half samples and some front half samples (refer to the TLI case narrative for an exact listing of the samples) were determined using graphite furnace atomic absorption (GFAA). Specific TLI QA/QC activities for GFAA and ICP analyses consisted of: laboratory control spikes, post-digestion matrix spikes of one sample set, duplicate analysis of one sample set, serial dilution and analysis of one sample set, analysis of a method blank, and analysis of field and reagent blanks. Mercury was analyzed by cold vapor atomic absorption spectroscopy (CVAAS). Specific TLI QA/QC activities for CVAAS analyses consisted of analysis of a method blank and analysis of field and reagent blanks. The results of these QA/QC activities are summarized in Tables 6.5 through 6.14. Complete QA/QC data are contained in the TLI analytical report in Appendix C.

6.3.3 EPA Method 23 PCDDs/PCDFs

Prior to the field testing program, TLI prepared PES' XAD®-2 adsorbent traps and precleaned the glass fiber filters. TLI's laboratory QA/QC program consisted of adding isotopically labeled standards to each sample at various stages of the project to determine recovery efficiencies. The following types of standards were used:

Internal Standards were spiked in the TLI laboratory after the field sampling program and prior to sample extraction. Recovery efficiencies for these compounds were used in quantifying the actual PCDDs/PCDFs isomers measured in the samples.

Surrogate Standards were spiked in the TLI laboratory on the XAD®-2 resin prior to the field sampling program. Recovery efficiencies for these surrogate compounds provided a measure of the sample collection efficiency and an indication of any analytical matrix effects.

Alternate Standards were spiked in the TLI laboratory after the field sampling program and prior to sample extraction. Recovery of these compounds indicated the extraction efficiencies.

Recovery Standards were added in the laboratory after extraction just prior to GC/MS analysis.

Table 6.15 summarizes the recovery efficiencies for the various standards and the respective quality control limits. In general, the recovery efficiencies for the XAD® blank, field blank, and samples were all within the method QC limits. Refer to TLI's case narrative for their discussion of any quality control anomalies.

6.3.4 SW-846 Method 0010

TLI analyzed the SW-846 Method 0010 samples following the procedures of SW-846 Method 8270A Rev. 1 (7/92). Field blanks and laboratory blanks were used to check for contamination. The blanks were processed in the same way the field samples were processed. The results of the field and laboratory blanks are presented in Table 6.16. Also shown are the average catch weights for the compounds presented. The significance of the blank values was discussed in Section 2.

A five point initial calibration was performed using internal standards and instrument response factors developed for the target analytes. Method 8720A procedures require the percent standard deviations of the initial calibrations to be within 50% for most analytes and 30% for some analytes. All internal standards were within the Method 8270A quality control criteria. The XAD®-2 resins were spiked with surrogate standards prior to the field sampling. The percent recoveries for the surrogate standards are presented in Table 6.17. Refer to TLI's case narrative for their explanation of the high terphenyl-d_{14} recoveries.

Acetone rinse volume (V_{aw}) 150 ml

Acetone blank residue concentration (C_a) 0.0 mg/g

$W_a = C_a V_{aw} \rho_a$ = (0.0) (150) (.7852) = 0.0 mg

Date and time of wt 9/22/97 1600 Gross wt 104264.4 mg

Date and time of wt 9/22/97 0740 Gross wt 104264.2 mg

Average gross wt 104264.3 mg

Tare wt 104256.1 mg

Less acetone blank wt (W_a) 0.0 mg

Weight of particulate in acetone rinse (m_a) 8.2 mg

Filter(s) container number O-M29-3 301632

Date and time of wt 9/16/97 1335 Gross wt 447.6 mg

Date and time of wt 9/17/97 1015 Gross wt 447.8 mg

Average gross wt 447.7 mg

Tare wt 446.5 mg

Weight of particulate on filter(s) (m_f) 1.2 mg

Weight of particulate in acetone rinse 8.2 mg

Total weight of particulate (m_n) 9.4 mg

Note: In no case should a blank residue >0.01 mg/g or 0.001% of the weight of acetone used be subtracted from the sample weight.

Appendix B.2

Analytical Data - Metals

TRIANGLE LABS

CASE NARRATIVE

Analysis of Samples for the Presence of Trace Metals

Method 29 April 1996 Rev.

Client:	Pacific Environmental Services
TLI Project Number:	43231
Date:	November 6, 1997

Rev. 25-Sep-96

Triangle Laboratories, Inc.
801 Capitola Drive
Durham, NC 27713-4411
919-544-5729
P.O. Box 13485
Research Triangle Park, NC 27709-3485
Fax # 919-544-5491

Overview

Five train samples, three blank train samples and a DI water sample were analyzed for silver (Ag), arsenic (As), barium (Ba), beryllium (Be), cadmium (Cd), cobalt (Co), chromium (Cr), manganese (Mn), nickel (Ni), phosphorus (P), lead (Pb), antimony (Sb), selenium (Se), thallium (Tl), zinc (Zn), and mercury (Hg). For all analyses, the samples and associated QC samples were prepared and analyzed following the guidelines of Method 29 April 1996 Rev. Results reported relate only to the items tested.

QC Remarks

The release of this set of data by Triangle Laboratories, Inc. was authorized by the Quality Control Chemist who has reviewed each sample data package individually following a series of inspections/reviews. When applicable, general deviations from acceptable QC requirements are identified below and comments are made on the effects of these deviations upon the validity and reliability of the results. Specific QC issues associated with this particular project are:

Sample Receipt:

Eight train samples (without the filters) were received at 5 ^{0}C on September 12, 1997 in good condition under project# 43231. (The acetone rinse samples were temporarily put on hold and then reentered into the system on September 23, 1997) The components for the reagent blanks were not received with the samples. The containers for inlet (FHAce and FHAR) and outlet (FHAce and FHAR) blank were not marked "BLK" like the remaining blank containers.

One reagent blank sample (except the KMnO4 sample) was received without coolant on September 15, 1997 in good condition under project# 43243. The KMnO4 sample arrived broken and the sample had leaked out, therefore, an analysis could not be performed for this sample. The sample also arrived without a client chain-of-custody. The Acetone rinse for the reagent blank was cancelled per the client's request.

Eight filter and acetone rinse samples and one reagent blank filter were received without coolant on September 23, 1997 under project# 43350. All components that were received on September 12, 15, and 23, 1997 were processed under project 43231. The components for the inlet and outlet reagent blanks were combined on order to make one complete reagent blank train sample. Only eight samples were reported in this data package.

Sample Preparation:

Laboratory documentation of the sample preparation is included in the data package.

Instrumentation:

Silver (Ag), arsenic (As), barium (Ba), beryllium (Be), cadmium (Cd), cobalt (Co), chromium (Cr), manganese (Mn), nickel (Ni), phosphorus (P), lead (Pb), antimony (Sb), selenium (Se), and zinc (Zn) concentrations were determined by Inductively Coupled Plasma Emission Spectroscopy (ICP). Thallium (Tl) concentrations for the front half samples I-M29-1 FH, I-M29-FIELD BLANK FH, O-M29-1 FH, O-M29-3 FH, I-M29-3 FH, and I-M29-2 FH were determined by Inductively Coupled Plasma Emission Spectroscopy (ICP).

Thallium (Tl) concentrations for the back half samples and front half samples (except samples I-M29-1 FH, I-M29-FIELD BLANK FH, O-M29-1 FH, O-M29-3 FH, I-M29-3 FH, and I-M29-2 FH) concentrations were analyzed by Graphite Furnace Atomic Absorption (GFAA). Due to instrument failure, all samples could not be analyzed by GFAA.

Mercury (Hg) concentrations were determined by Cold Vapor Atomic Absorption (CVAA).

The linear range for the instrument TJA 61E Trace Analyzer was based on four standards and a blank, which established a correlation coefficient value greater than or equal to 0.995. A calibration curve, based on a blank and one standard, is established for each analytical run, followed by a check high standard and an initial calibration verification (ICV). The check high standard does not deviate from the calibration curve by more than 5%. In addition, continuing calibration verifications (CCVs) are performed throughout the analytical run.

A Reporting Detection Limit (RDL) is used instead of an Instrument Detection Limit (IDL). The spectrometer and atomic absorption instruments can achieve low detection limits between 0.2-8 ppb levels for many analytes. Triangle Labs is using RDL values of 1-10 times the IDL as detection limits for reporting purposes.

Data Review:

All analytes found in the method blank (MB) prepared on September 25-26, 1997 are detected at a level equal to or less than the respective Reporting Detection Limits (RDLs) except for Zn. All analytes found in the method blank (MB) prepared on October 02-03, 1997 are detected at a level equal to or less than the respective Reporting Detection Limits (RDLs) except for Mn. The following guidelines may be used to assess analyte concentrations relative to the method blank: 1. Analyte quantitations should be considered valid if the level of blank contamination is less than five percent of the level detected in the field sample, 2. Analyte quantitations should be considered estimated if the

analyte level in the sample is five to twenty times the level of the analyte in the blank, or 3. Analytes whose level in a sample is the same as or less than five times the level detected in the associated blank should be considered present likely due to laboratory contamination and not native to the sample. Please note that the concentrations for samples prepared on September 25-26, 1997 should be considered biased high for Zn. Also note that the concentrations for samples prepared on October 02-03, 1997 should e considered biased high for Mn.

The client Ids did not match the Ids on the sample labels. The sample labels were used to identify the samples.

A sampling date was not supplied by the client for the reagent blank received on September 15, 1997, therefore, the sampling to analysis holding times cannot be determined. The sample was analyzed within 23 days of sample receipt at Triangle Laboratories. Due to laboratory problems, samples I-M29-FHAR,BLK-5% 10% BH and O-M29-FHAR,BLK-5% 10% BH were not analyzed within the 28 day sampling to analysis holding time for Hg. All samples were analyzed within the six month sampling to analysis holding time for all other requested analytes.

Due to a confusion in the laboratory, the sample preparation procedure deviated from the method. The filter and acetone rinse samples (except I/O REAGENT BLANK FH) were not prepared simultaneously with the HNO3 rinse samples on September 25-26, 1997. The filter and acetone rinse samples were prepared on October 02-03, 1997. The samples were analyzed separately and the concentrations from each analysis were added together in order to obtain a composited concentration for the front half samples. Only the elements with concentrations greater than the RDL were added together. If one concentration was below the RDL and one concentration was above the RDL, the concentration above the RDL was used in the calculations. If both concentration for each analysis from both preps were below the RDL, the concentration from the first analysis was used in the calculations. The results for the QC samples were not combined, however, the individual results for the QC samples were included in the data package.

A duplicate analysis is not reported for elements analyzed by GFAA. The GFAA instrument analyzes two separate aliquots of the sample and averages the values for a final result. These two analyses agree within a RPD of 20% or a second run is done for that sample. The ICP instrument analyzes one continuous aliquot three times and averages the values for a final result. The ICP does not take two separate aliquots, therefore a DA is performed.

The post-digestion spike (PDS) for Tl for the sample I-M29-1 FH (prepared on October 02-03, 1997) demonstrated a percent recovery outside the QC criteria of 85-125 percent, which indicates significant matrix effects specific to this analyte in the native sample matrix. The Method of Standard Additions (MSA) was performed on all of the samples prepared on October 02-03-1997. The MSA results are reported if the correlation coefficient value is at least 0.995. Only samples I-M29-FHAR,BLK BH (prepared on September 25-26, 1997), O-M29-2 FH and O-M29-FIELD BLANK FH had passing correlation coefficients. The remaining samples that were analyzed by GFAA demonstrated significant matrix interferences during analysis and the results reported are considered underestimated.

Due to instrument failure, all of the samples could not be analyzed by MSA for a second time. The initial results for all of the samples (except for the samples that had passing MSAs and for samples I-M29-1 FH, I-M29-2 FH, and I-M29-3 FH) were taken from the initial GFAA analysis. The samples I-M29-1 FH, I-M29-2 FH, and I-M29-3 FH were reanalyzed by ICP and the Tl concentrations were taken from the reanalysis data.

The post-digestion spike (PDS) for P and Tl for samples I-M29-1 FH and I-M29-1 BH demonstrated percent recoveries outside the QC criteria, which may indicate significant matrix effects specific to these analytes in the native sample matrix. Please note that these samples should be considered biased low for these elements due to matrix interferences.

The post-digestion spike (PDS) for Ag for the sample I-M29-2 FH demonstrated a percent recovery slightly outside the QC criteria, but does not indicate any significant matrix effects specific to this analyte in the native sample matrix.

The pre-digestion spike (MS) and the pre-digestion spike duplicate (MSD) for Hg for the sample I-M29-3-5% 10% BH demonstrated percent recoveries outside the QC criteria, which may indicate significant matrix effects specific to this analyte in the native sample matrix. Please note that this sample should be considered biased low for Hg due to matrix interferences.

The recoveries for the post-digestion spike (PDS) are not reported for Mn, Pb, and Zn for sample I-M29-1 FH and I-M29-2 FH . The spike concentrations added were insignificant in comparison to the levels of these analytes present in the native sample.

The recoveries for the pre-digestion spike (MS) and the pre-digestion spike duplicate (MSD) are not reported for Hg for samples I-M29-2-5% 10% BH and O-M29-1-5% 10% BH. The spike concentrations added were insignificant in comparison to the levels of this analyte present in the native sample.

QC requirements:

The duplicate analyses for analytes analyzed by GFAA cannot be considered valid qualifiers if the concentrations of the analytes in the original and/or duplicate sample are not at least five times the respective RDL. The RPDs for these analyses are indicated by "<RDL" in the Analyte Summary Reports.

The duplicate analyses for analytes analyzed by ICP cannot be considered valid qualifiers if the concentrations of the analytes in the original and/or duplicate sample are not at least ten times the respective RDLs. The RPDs for these analyses are indicated by or "<RDL" in the Analyte Summary Reports.

For duplicate analyses which are valid qualifiers, the quality control RPD is ± 20.0 percent. If RPDs are outside this range, interferences are suspected.

The serial dilution analyses for analytes analyzed by GFAA cannot be considered valid qualifiers if the concentrations of the analytes in the serial dilution sample are not at least five times the respective RDLs. The serial dilution RPDs for these analyses are indicated by "<RDL" in the Analyte Summary Reports.

The serial dilution analyses for analytes analyzed by ICP cannot be considered valid qualifiers if the concentrations of the analytes in the serial dilution sample are less than ten times the respective RDLs. The serial dilution RPDs for these analyses are indicated by "<RDL" in the Analyte Summary Reports.

For serial dilution analyses which are valid qualifiers, the quality control RPD is ± 10.0 percent. If RPDs are outside this range, interferences are suspected.

The quality control range for percent recoveries of laboratory control spiked samples is 80-120.

The quality control range for percent recoveries of spiked samples is 75-125. If recoveries are outside this range, a matrix effect is suspected.

If the analyte concentrations analyzed by GFAA in the native samples are less than five times the respective RDLs, or if valid serial dilution analyses demonstrate RPDs outside the ten percent quality control range, the percent recoveries of post-digestion spiked samples is 75-125. If recoveries are outside this range, all matrix-related samples are analyzed by the Method of Standard Additions (MSA). The MSA analysis for each sample is reported only if the correlation coefficient value is at least 0.995.

By our interpretation, the analytical data in this project are valid based on the guidelines of Method 29 April 1996 Rev. Any specific QC concerns or problems have been discussed in the QC REMARKS section with emphasis on their effect on the data. Should Pacific Environmental Services have any questions or comments regarding this data package, please feel free to contact Project Scientist, Amy J. Boehm, at (919) 544-5729 ext.268.

LIST OF CERTIFICATIONS AND ACCREDITATIONS

ENVIRONMENTAL

American Association for Laboratory Accreditation. Accredidation pending. Certificate Number 0226-01. Accreditation for technical competence in Environmental Testing.(Including Waste Water, Sol/Haz Waste, Pulp/Paper, and Air Matrices) Parameters are AOX/TOX, and Dioxin/Furan. Method 1613 for Drinking Water.

State of Alabama, Department of Environmental Management. Expires December 31, 1997. Laboratory I.D. # 40950. Dioxin in drinking water.

State of Alaska, Department of Environmental Conservation. Expires December 21, 1997. Certificate number OS-00397. Dioxin in drinking water.

State of Arizona, Department of Health Services. Expires May 26, 1998. Certificate #AZ0423. Drinking Water for Dioxin, Dioxin in WW and S/H Waste.

State of Arkansas, Department of Pollution Control and Ecology. Expires February 18, 1998. Pulp/paper, soil, water, and Hazardous Waste for Dioxin/Furan; AOX/TOX.

State of California, Department of Health Services. Expires August 31, 1999. Certificate #1922. Selected Metals in Waste Water; Volatiles, Semi-volatiles, and Dioxin/furan in WW and Sol/Haz Waste. Dioxin in drinking water.

State of Connecticut, Department of Health Services. Recertification pending. Registration # PH-0117. Dioxin in drinking water.

Delaware Health and Social Services. Expires December 31, 1997. Certificate #NC 140. Dioxin in drinking water.

Florida Department of Health and Rehabilitative Services. Expires June 30, 1998.Dioxin in DW. Drinking Water ID HRS# 87424. Metals, Extractable Organics (GC/MS), Pesticides/PCB's (GC) and Volatiles (GC/MS) in Environmental Samples. Environmental water ID HRS# E87411.

Hawaii Department of Health. Expires March 1, 1998. Dioxin in drinking water. "Accepted" status for regulatory purposes .

Triangle Laboratories, Inc.

Idaho Department of Health and Welfare. Expires November 30, 1997. Dioxin in drinking water.

State of Kansas, Department of Health and Environment. Expires January 31, 1998. Environmental Analyses/Non potable Water and Solid and Hazardous Waste. Method 1613 for drinking water. ID #'s - Drinking water and/or pollution control - E-215. Solid or Hazardous Waste - E-1209.

Commonwealth of Kentucky, Department for Environmental Protection. Expires December 31, 1997. ID#90060. Dioxin in drinking water.

Maryland Department of Health and Mental Hygiene. Expires September 30, 1998. Certification #235. Drinking water by Method 1613A.

State of Michigan, Department of Public Health. Expires June 3, 1998. Drinking water by Method 1613.

Mississippi State Department of Health. No expiration date.. Dioxin in drinking water.

Montana Department of Health and Environmental Services. Expires December 31, 1997. Dioxin in drinking water.

State of New Jersey, Department of Environmental Protection and Energy. Extended by state. Temporary certificate until December 31, 1997. ID #67851. BNAs and Volatiles. Dioxin in drinking water.

State of New Mexico, Environment Department. Recertification pending. Dioxin in drinking water.

New York State Department of Health. Expires April 1, 1998. ID #11026. Environmental Analyses of non-potable Water, Solid and Hazardous Waste. Method 1613 in DW.

State of North Carolina, Department of Environment Health and Natural Resources Expires August 31, 1999. Certificate # 37751. Dioxin in drinking water.

State of North Carolina, Department of Environment, Health, and Natural Resources, Division of Environmental Management. Expires December 31, 1997. Certificate # 485. Metals, pesticides & PCBs, semi-volatiles and volatiles; TCLP.

North Dakota State Department of Health and Consolidated Laboratories. Expires December 31, 1997. Certificate # R-076. Effective October 4, 1993. Dioxin in drinking water.

Oklahoma Department of Environmental Quality. Expires August 31, 1998. Laboratory #9612. Dioxin by 1613A, 8290 and 8280.

State of South Carolina, Department of Health and Environmental Control. Expires April 1, 1998. Certificate number #99040001 (drinking water). Expires August 31, 1999. Certificate number #99040002 (other parameters). Dioxin/Furans, BNA, Volatiles, and PCBs/pesticides under Clean Water Act, 2,3,7,8-TCDD for Drinking Water, and Organic extractables for Solid and Hazardous Waste.

State of Tennessee. Department of Environment and Conservation. Expires February 5, 1999. *ID #02992. Method 1613 Drinking water only.*

U.S. Department of Agriculture Soil Permit. Expires September 30, 2001. Permit No. S-3790. Under the authority of the Federal Plant Pest Act, permission is granted to receive foreign soil samples for use in laboratory analysis.

U.S. Army Corps of Engineers. Expires November 30, 1997. Validated to perform methods 8280 & 8290 for Lockbourne Landfill Site Investigation, Defense Distribution Depot Projects, and assorted projects for the USACE North Pacific Division Laboratory.

U.S. EPA Region V. Expires November 14, 1999. Dioxin in drinking water.

U.S. EPA Region VIII, for the State of Wyoming. Expires November 13, 1997. Dioxin in drinking water.

State of Utah, Department of Health. Expires December 31, 1997. Certificate Number E-166. Certification for the following parameters: Semi-Volatiles and Volatiles under RCRA; Volatiles under Clean Water Act; Dioxin/furans by Method 8280; Drinking water for Dioxin by Method 1613; Metals including Mercury and Microwave Digestion.

Commonwealth of Virginia, Department of General Services, Division of Consolidated Laboratory Services. Expires June 30, 1998. ID # 00341. Dioxin in drinking water.

State of Washington, Department of Ecology. Expires September 11, 1998. Lab Accreditation Number C067. Scope of Accreditation applies to water analyses for Polychlorinated Dibenzo-p-dioxins and Polychlorinated Dibenzofurans, BNA Extr (Semivolatile) Organics and Purgeable (Volatile) Organics.

State of Washington, Department of Health. Expires April 30, 1998. Dioxin in drinking water. Lab I.D. 129

State of West Virginia, Department of Health. Expires December 31, 1997. Certificate No. 9923(C). Dioxin in drinking water.

State of Wisconsin, Department of Natural Resources. Expires August 31, 1998. Laboratory ID Number 999869530. Certification for the following categories of Organics: Purgeable, Base/Neutral, Acid, PCBs, and Dioxin. Expires November 14, 1999. Laboratory ID 999869530. Dioxin in drinking water.

PHARMACEUTICAL

Drug Enforcement Agency (DEA). Expires November 30, 1997. Registration number RT01195835. Controlled substance registration for schedules 1,2,3,3N,4,5.

N.C. Department of Human Resources. Expires October 31, 1998. Registration number NC-PT 0000 0031. North Carolina controlled substances registration. Application submitted for renewal.

Food & Drug Administration (FDA) Registration. Expires June 1998. ID #'s 001500 1053481. Annual registration of drug establishment. Annual registration of drug establishment.

OTHER

Clinical Laboratory Improvement Amendments (CLIA) Registration. Expires May 30, 1999. ID # 34D0705123. Department of Health & Human Services, Health Care Financing Administration.

U.S. EPA Large Quantity Hazardous Waste Generator. No expiration date. EPA ID #NCD982156879. Permit indicates that the laboratory is a large generator of hazardous waste.

North Carolina Radioactive Materials License. Expires April 30 1998. License No. 032-0954-1. License authorizes the licensee to receive, acquire, own, possess, transfer, import and use such radioactive materials as designated.

North Carolina General License for Radiation Protection. No. expiration date. License No. 032-875-OG. The general license applies only to radioactive material contained in devices which have been manufactured and labeled in accordance with specific requirements.

ABBREVIATIONS

BH = Back Half
CCB = Continuing Calibration Blank
CCV = Continuing Calibration Verification
CHECK HS = Check High Standard
D = DUP = Analytical Duplicate (Prepared Duplicate)
DA = Duplicate Analysis
FH = Front Half
FV = Final Digestate Volume
ICB = Initial Calibration Blank
ICV = Initial Calibration Verification
ICSAB = Interference Check Solution (Solution AB)
    I = Initial
    F = Final
    Solution AB contains common interferents in addition to the analyte of interest.
IDL = Instrument Detection Limit
L = Serial Dilution
LCS = Laboratory Control Spike Sample
MB = Method Blank
MPV = Mercury Preparation Volume
MS = Pre-digestion Spike
MSD = Pre-digestion Spike Duplicate
N/A = Not Applicable
N/Av = Not Available
N/V = Not Valid
PDS = Post-digestion Spike
%REC = Percent Recovery
RDL = Reporting Detection Limit
RPD = Relative Percent Difference
T = Analytical Triplicate (Prepared Triplicate; for Hg analysis by Method 7471 only)
TV = Total Sample Volume
< = Analyte concentration in the sample is less than the respective RDL

STANDARD CONCENTRATIONS
for the TJA 61E TRACE ANALYZER

Note: Use this reference page to review the raw data from the TJA 61E Trace Analyzer.

This page includes the standard concentrations for the check high standard, initial calibration verification (ICV), continuing calibration verification (CCV), and the interference check solution (ICSAB). In addition the reporting detection limit (RDL) and wavelength are reported for each analyte.

Revision Date: 15-Jul-96

CALCULATIONS FOR AIR SAMPLES

RESULTS FOR TRACE METALS (except mercury):

$$\text{RESULT in } \mu g \text{ (Front Half)} = \frac{\mu g/L * FV\ (mL) * DF}{1000\ mL/L}$$

$$\text{RESULT in } \mu g \text{ (Back Half \& Impingers)} = \frac{\mu g/L * TV\ (mL) * FV\ (mL) * DF}{mL\ used * 1000\ mL/L}$$

FV = final volume in mL
TV = total volume in mL
DF = Dilution Factor

The RESULTS for combined Front Half & Back Half samples use the same calculation as the Back Half & impinger samples.

RESULTS FOR MERCURY (Hg):

RESULT in µg (Front Half) = µg/L * (mL FV/mL aliquot) * MPV * DF

RESULT in µg (Back Half & Impingers) = µg/L * (mL TV/mL aliquot) * MPV * DF

MPV = mercury preparation volume = 0.1 L

%REC (Percent Recovery) for MS/MSD Hg spikes:

$$\%REC = \frac{\text{spike sample results - original sample results}}{\text{true spike sample results}} * 100$$

NOTE: Original sample results less than the RDL are not used in calulations.

%REC (Percent Recovery) for PDS:

$$\%REC = \frac{\text{Spike sample µg/L conc. - original sample µg/L conc.}}{\text{spike conc. (µg/L)}} * 100$$

%REC (Percent Recovery) for LCS/LCSD:

$$\%REC = \frac{\text{Spike sample µg/L conc.}}{\text{spike conc. (µg/L)}} * 100$$

RPDs:

$$RPD = \frac{|\ \text{Result 2 - Result 1}\ |}{(\text{Result 2} + \text{Result 1})/2} * 100$$

Reanalyzed w/ larger dilutions.

→ Failed slightly low for Be. This will have to be accepted. Since the failure was due to sample matrix effects on introduction system of ICP DKH 10/8/97.

15. SUPPLEMENTARY NOTES		

16. ABSTRACT

The United States Environmental Protection Agency (EPA) is investigating iron and steel foundries to identify and quantify hazardous air pollutants (HAPs) emitted from cupolas; electric arc furnaces; and pouring, cooling and shakedown operations of sand mold casting processes. The Waupaca Foundry in Tell City, Indiana was selected by the EPA as the host facility at which to 1) characterize HAP emissions from cupolas that are controlled by baghouses, and 2) assess baghouse performance in controlling HAP emissions from cupolas. The Waupaca Foundry was selected because EPA deemed this facility to be representative of a large segment of the sand casting foundry industry. Waupaca Foundry operates a large cupola (50 standard tons per hour melting capacity) that is controlled by a negative pressure baghouse. The new facility recently began production and the modern design of the cupola baghouse was expected to be as effective as any used in this type of application.

This report presents the results of a manual emissions testing program to characterize emissions from a cupola and assess the performance of the baghouse in controlling HAP emissions. Testing was conducted at the cupola baghouse inlet and outlet to determine air emissions of particulate matter (PM) and metal HAPs; and at the cupola baghouse outlet to determine organic HAPs consisting of dibenzo-*p*-dioxins and polychlorinated dibenzodurans (PCDDs/PCDFs), and semi-volatile organic hazardous air pollutnats (SVOHAPs). The data may be used by the EPA as potential Maximum Achievable Control Technology (MACT) floor technology for cupolas.

During the testing program, Research Triangle Institute (RTI), another EPA contractor, monitored and recorded process and emission control system operating parameters, and prepared Section 3.0, Process and Control Equipment operation, of this report.

This volume (Volume I) is comprised of 569 pages and consists of the report text, and Appendices: A (Raw field Data), and B (Analytical Data - Particulate Matter and Metals).
